Servetus, according to Motheim's account, conceived that the genuine doctrine of Christ had been entirely lost, even before the council of Nice; and he was moreover of opinion, that it had never been delivered with a sufficient degree of precision in any period of the church. To these extravagant assertions he added another still more so, even that he himself had received a commission from above to reveal anew this divine doctrine, and to explain it to mankind. His notions with respect to the Supreme Being, and a Trinity of persons in the godhead, were very obscure and chimerical, and amounted in general to the following propositions: that the Deity, before the creation of the world, had produced within himself two personal representations or manners of existence, which were to be the medium of intercourse between him and mortals, and by whom, consequent ly, he was to reveal his will, and to display his mercy and beneficence to the children of men: that these two representations were the Word and the Holy Ghost: that the former was united to the man Christ, who was born of the Virgin Mary, by an omnipotent act of the Divine Will; and that, on this account, Christ might be properly called God: that the Holy Spirit directed the course, and animated the whole system of nature, and more especially produced in the minds of men wise counsels, virtuous propensitys, and divine feelings; and, finally, that these two representations were to cease after the destruction of this terrestrial globe, and to be absorbed into the subsistence of the Deity, from whence they had been formed.

Servetus, however, did not always explain his system in the same manner, nor avoid inconsistencies, contradictions, and ambiguities; so that it is extremely difficult to learn his true sentiments. His system of morality agreed in many circumstances with that of the Anabaptists, whom he also imitated in cenuring with the utmost severity the custom of infant-baptism. Eccl. Hist. vol. iv. 1768.

SERVETUS, Michael, in Biography, was born at Villa-

nueva, in Arragon, in 1509. His father was a notary-

public, and he himself was sent to the academy of Toulouf, where he studied the law during the space of three years. About this period his attention was turned to the study of the sacred scriptures, to which he was probably excited by the reformers of that day. He soon discovered many

errors and abuses in the church of Rome, in the tenets of which he had been brought up, and laid then the foundation of his opinions concerning the doctrine of the Trinity. It is known, that at this period, many learned men in Italy and other parts, among whom were some dignitaries of
of the church, condemned in private the reigning superstitions, to which, however, they readily conformed in public. Whether Servetus was instructed by any of these, or whether his own opinions were the result of independent thought, cannot be ascertained: it is certain, that he did not think it prudent to divulge them in France, and therefore retired to Germany, where a much greater liberty of conscience was allowed and afforded, and where several princes secretly favoured the bold attacks on the popedom. He went through Lyons and Geneva to Switzerland, and fixed his residence at Basel in the year 1530. Here he was on a footing of friendly intimacy with Colompanus, with whom he often conversed about various religious topics, but to whose peculiar opinions he would not yield, in the smallest degree, any notions which he had previously adopted. The unbending disposition with regard to matters of small moment, alienated many persons from Servetus who had formed a high opinion of his talents and integrity. While he was at Basel, he put into the hands of a bookseller a manuscript, "De Trinitatis Erroribus," which was printed in the year 1531. Servetus now went to Strasbourg, in which city he became acquainted with two reformers, viz., Capito and Bucer. Here he searched for opportunities to communicate his religious tenets to his new acquaintances, and here he learned that his work had excited a considerable sensation among people of all classes. He was aware that he had, in many respects, treated the subject too imperfectly; and had made use of expressions that were liable to give offence; he accordingly, in the following year, endeavoured to soften the unfavourable impression, and to avert a form that seemed threatening to fall upon him, by publishing a work entitled "Dialogorum de Trinitate Libri duo," in which he explained and defended his opinions. The consequences of this second piece was, that many were exasperated against the author, while a few adopted his doctrines and spread them abroad. Colompanus requested his friend Bucer to inform Luther, that Servetus's book had been published without their knowledge, in order that it might not be supposed they had given any countenance to the propagation of the offensive tenets. And Melanchthon, in speaking at this time of Servetus, says, "He wants neither acuteness nor cunning in disputing, but I cannot allow him energy. He has, moreover, as it appears to me, confused imaginations, neither is he able sufficiently to explain his thoughts with precision. He unquestionably speaks like a madman about justification; about the Trinity, you know that I have been always apprehensive that similar things sooner or later would break out. Good God! what tragedies will this quixotic enthusiasm among forgeries?"

The circumstances of Servetus being low, he engaged for some time with the Frellons, eminent booksellers at Lyons, as corrector of the press. From Lyons he went to Paris, where he studied physic under the celebrated Sylvius, Fermerius, and other professors; and, as we shall have occasion to remark hereafter, he carried into that science the same penetrating spirit and love of improvement which distinguished him in theology. He graduated at Paris, and being invested with this honour, he delivered public lectures in geography and some branches of mathematics, while he followed the profession of a physician. At Paris he quarrelled with the faculty, and wrote an "Apology," which was suppressed by the parliament. After quitting that capital he practised physic at Charleville, near Lyons, whence, at the invitation of the archbishop of Vienna, he removed to that city, and had apartments near the palace. He had, previously to this, viz. in 1542, superintended the printing of a Latin Bible at Lyons, to which he added marginal notes, under the name of Villamont.

During this time, Servetus was in constant correspondence with Calvin, with whom he discussed various points of controversy, and to whom he opened himself freely and without reserve concerning his particular notions, and consulted him respecting his writings. Calvin afterwards made a base use of this confidence, by actually producing his letters and manuscripts as matter of accusation against him on his trial. It must not, however, be concealed, that Calvin does not appear to have encouraged Servetus to this exposition of his sentiments, for he frequently sent him in reply angry and severe letters. In 1553, Servetus published his matured theological system under the title of "Christianismi Restitutio." Conscious of the danger to the author of such a work in a Catholic country he concealed his name, but Calvin took care that the magistrates of Geneva should be informed of it. He was in consequence thrown into prison, and his death would have added an example to the numberless cruelties of Roman Catholic persecutions, had he not made his escape. His effigy and his books were condemned to the flames. Servetus, purposing to go to Naples to practice in his profession, imprudently went through Geneva. Calvin, who was acquainted with the plans of the traveller, and who was on the watch to entrap him, gave information to the magistrates the moment he arrived within the gates of the city. He was accordingly seized, thrown into prison, and a charge of blasphemy and heresy was preferred against him by Calvin's own servant. In order to ensure conviction and condemnation, no less than thirty-eight articles of accusation were brought against him, for which not only his last work, but all his other writings were ransacked. As a proof of the malice and unfairness with which he was treated, it is mentioned that one of the charges was extracted from his preface to an edition of Ptolemy's Geography, published twenty years before, in which he had ascertained that Judea had been falsely extolled for its beauty and fertility, since modern travellers had found it to be sterile and unfruitful. That no doubt might be left whence the prosecution came, one of the main articles against the prisoner was, that in the preface of Mr. Calvin, minister of the word of God in the church of Geneva, he had defamed the doctrine preached in it, uttering all imaginable injurious and blasphemous words against it.

Servetus, in the first examination, repelled with firmness every accusation, though he avowed that he published in Germany his book "De Trinitatis Erroribus" in France his "Restitutio Christianismi," together with Ptolemaeus, and the edition of Pagnini's Bible. At the second examination, he acknowledged, when urged to confess the truth, some of the articles brought against him in regard to his publications, denied others, and hesitated to explain himself more plainly upon others. But when he was again questioned, "why he had slandered Calvin, and lacerated the Christian doctrine?" he protested that Calvin had been the aggressor, and that if he had recriminated it was done in self-defence; which plea was deemed by his judges as an aggravation of his offence.

The magistrates of Geneva were, however, sensible that many eyes were upon them in this extraordinary proceeding, with respect to one who was no subject of their, nor a refident in their city, nor could he be accused of having committed any offence in their territory, and within their jurisdiction. He was, in truth, kidnapped in his palage. Moreover,
Moreover, it could not but appear strange, that men should be associates in perdition, with those very people who would infamously burn them as heretics, should they fall into their hands. They therefore thought it advisable to consult the magistrates of the Protestant cantons of Switzerland, to whom they sent Servetus's book, with Calvin's reply. The Helenist divines, to whom the matter was referred, unanimously declared for his punishment; they said that Servetus's errors ought to be detected, and that great care ought to be taken that the infection spread no further, and that the man ought to be restrained; but they, none of them, made a word respecting capital punishment, nor do they alude to the kind of coercion that should be chosen. Their meaning was, however, readily inferred from their own practice: for the capital punishments of heretics had not been abolished in Switzerland; they had been frequently practised at Zurich against the Baptists.

Servetus was for a time kept ignorant of all the proceedings against him; at length he discovered the intentions of his enemies, and drew up, and casued to be presented, two petitions to his judges; in the first he endeavoured to extenuate himself; in the second he complained that a fair trial had not been allowed him. As he refused to retract his opinions, he was, notwithstanding his pleas, condemned to the flames as an obstinate heretic, which cruel sentence was carried into execution on the 27th of October 1553, when he was in the forty-fourth year of his age. His sufferings were particularly severe, and the fire was so managed, that the unfortunate man lingered in excruciating pain more than two hours.

That this bloody persecution was disapproved by many at the time, is rendered very probable by the apology for the Genevan magistrates, published by Calvin, in which he undertook to prove that it was lawful to punish heretics with death. The mild and otherwise moderate and benevolent Melanchthon functioned the deed by a congratulatory letter addressed to the magistrates of Geneva. The conduct of Calvin in this business, as instigated not only by bigotry, but personal hatred, has impressed an indelible stain on his memory; and the only plausible excuse now offered for it arises from the provocation given by Servetus, "whole excessive arrogance," according to Mosheim, "was accompanied with a malignant and contumacious spirit, and an invincible obstinacy of temper."

The theological sylllem of Servetus is described as singular in the highest degree. The greatest part of it was a necessary consequence of his peculiar notions concerning the universe, the nature of God, and the nature of things, which were equally strange and chimerical. See the article Servetists.

Servetus is numbered among those anatomists who made the nearest approach to the doctrine of the circulation of the blood. The passage cited to this effect is contained in his latest and fatal work, "De Reititutione Christianiim."

It clearly states the circulation of the blood through the lungs. He pursued, in his medical studies, anatomical researches with the greatest ardour.

Servetus was a man of great erudition and unfeigned piety; his mind was floured with a variety of knowledge, and he brooded very high, in the elevation of his contemporaries, for his talents and for his discoveries in the profession of medicine. Whatever might have been his errors as a theologian, it is certain he never preached them to the vulgar, but communicated them freely to Calvin, Cæcolampadius, Capito, Bucerius, and other reformers, with an eagerness to discover truth which has never been surpassed.

The atrocious murder committed on him will not ad-
Personal service is a disgraceful sort of tenure, under which lands were formerly held, and in which the tenant did various sorts of work for the lord, and provided with a variety of different articles. It is a custom which has long been abolished in this part of the kingdom, as being highly injudicious and improper: but which, Mr. Donaldson remarks, is not wholly discarded in Scotland. "In the north of Scotland," says he, "the rents are to a certain extent paid in personal services; the tenants being bound to plow and harrow a certain proportion of the proprietor's farm; to reap, carry home, thresh, dress, and mill a certain quantity of his crop at their own charges; and that they are also bound to pay poultry, eggs, cheese, sheep, swine, fish, linen, yarn, &c." It might, continues he, have been unavoidably necessary, from the want of a circulating medium in the early periods of the history of this country, to oblige the tenants to pay their rents in personal services, and in the various articles of produce which their farms afforded; but it must be considered a singular circumstance in the history of Great Britain, that in the end of the eighteenth century, and at a period when the introduction of improvements in agriculture is the chief topic of conversation, there should exist proprietors, who are so loth to every sentiment regarding what is due to the community of which they are members, to the people whom Providence has placed under their protection, and to the improvement of their native country, as to perfilt in demanding from their tenants a species of rent, which no farmer, who is entitled to the name, would submit to pay, nor any proprietor, who regarded the good of his country, or his own interest, think of requiring. These disgraceful services should of course be done away with in every situation, as being incompatible with all sorts of improvements in husbandry, or the introduction of spirited agriculture into any part.

This sort of service is not only hostile to all kinds of farming improvements, but highly distressing and ruinous to tenants at particular seasons, as during the feed-time, the harvest, and the time of getting in the hay, by being often under the necessity of neglecting their own operations and businesses, in order to perform the various works of their lords, or superiors. The sooner these services are wholly abolished in every part of the kingdom, the better it will be for the interests of agriculture.

**SERVICE, Reel,** is either *urbane* or *rustic,* which two kinds differ, not in the place, but the thing. The first is that due from a building or house, in whatever place situate, whether in city or in country, as keeping a drain, a viata, or the like.

**SERVICES, Rustic,** are those due for grounds, where there is no building; such is the right of passage through ways, &c.

**SERVICE, Mixt,** is that due from the person, by reason of the thing, as an ufruit, &c.

Our ancient law-books tell us of lands held of the king, by the tenant's letting a fart before the king on New Year's Day; others, by furnishing the king with horses, whenever be travelled that way; others, by bringing the king a mels of pottage at his coronation-feast, &c.

There are also *natural services.* For instance, if a man cannot gather the produce of his lands, without passing through his neighbour's grounds, the neighbour is obliged to allow a passage, as a natural service.

**SERVICE, Forensic or Extrinsic, Servitium forensicum, &c.** was a service which did not belong to the chief lord, but to the king.

It was called *forensic* and *extrinsic,* because done *foris,* out of doors; and *extra servitium.* We meet with several grants, in the Monasticon, of all liberties, with the appurtenances, *libus forensi servitio.*

**SERVICE, Intrinseque, Servitium intrinsecum,** that due to the chief lord alone, from his vaillals within his manor.

**SERVICE, Frank, Servitium liberum,** a service done by the feudal tenants, who were called *liberi homines,* and distinct from vaillals, &c. It was likewise by the nature of things, not bound to any base services, as to plow the lord's lands, &c. but only to find a man and horse to attend the lord into the army or court.

**SERVICE, Bajx.** See *VILLENAGE.*

**SERVICE, Bord.** See *BORDAGE.*

**SERVICE, Foreign, Honorary, Knights, Rent.** See the adjectives.

**SERVICE, Heris.** See *HERITAGE.*

**SERVICE, Ovoly of.** See *OVETY.*

**SERVICE, Suit of.** See *SUIT.*

**SERVICE, Choral, in Church History,** denotes that part of religious worship which consists in chanting and singing. The advocates for the high antiquity of singing, as a part of church music, urge the authority of St. Paul in its favour: Ephes. chap. v. ver. 9. and Coloss. chap. iii. ver. 16. On the authority of which passages it is asserted, that songs and hymns were, from the establishment of the church, sung in the assemblies of the faithful; and it appears, from undoubted testimony, that singing, which was practised as a sacred rite among the Egyptians and Hebrews, at a very early period, and which likewise constituted a considerable part of the religious ceremonies of the Greeks and Romans, made a part of the religious worship of Christians, not only before churches were built, and their religion established by law, but from the first profession of Christianity. However, it is not from whence others have dated the introduction of music into the service of the church, is that period, during which Leontius governed the church of Antioch, *i.e.* between the year of Christ 347 and 356. See *APOTHEAN.*

From Antioch the practice soon spread through the other churches of the East; and in a few ages after its first introduction into the divine service, it not only received the sanction of public authority, but those were forbid to join in it who were ignorant of music. A canon to this purpose was made by the council of Laodicea, which was held about the year 372; and Zonaras informs us, that thefe canonical fingers were reckoned a part of the clergy. Singing was introduced into the western churches by St. Ambrose, about the year 374, who was the instigator of the Ambrosian chant, established at Milan about the year 386; and Eufebius (ib. ii. cap. 17.) tells us, that a regular choir, and method of singing the service, were first established, and hymns used in the church at Antioch, during the reign of Constance; and that St. Ambrose, who had long reigned there, had his melodies thence. This was, about two hundred and thirty years afterwards, amended by pope Gregory the Great, who established the Gregorian chant; a plain, unisonous kind of melody, which he thought consistent with the gravity and dignity of the service to which it was to be applied. This prevails in the Roman church even at this day: it is known in Italy by the name of canto fermo: in France, by that of plainchant; and in Germany, and most other countries, by that of the canto Gregorianum. Although no satisfactory account has been given of the specific difference between the Ambrosian and Gregorian chants, yet all writers on this subject agree in saying, that St. Ambrose only used the four authentic modes, and that the four plagals were afterwards added.
added by St. Gregory. Each of these had the same final, or keynote, as its relative authentic; from which there is no other difference than that the melodies in the four authentic, or principal modes, are generally confined within the compass of the eight notes above the keynote, and those in the four plagal, or relative modes, within the compass of the eight notes below the fifth of the key.

Each of the four different methods of singing was taken from the reformed modes of Ptolemy; but Dr. Burrow observes, that it is difficult to discover any connection between them, except in their names; for their number, upon examination, is not the same; those of Ptolemy being seven, the ecclesiastical eight; and, indeed, the Greek names given to the ecclesiastical modes do not agree with those of Ptolemy in the single instance of key, but with those of higher antiquity. From the time of Gregory to that of Guido, there was no other distinction of keys than that of authentic and plagal; nor were any semitones used but those from E to F, B to C, and occasionally A to B.

With respect to the music of the primitive church, it may be observed, that though it consisted in the singing of psalms and hymns, yet it was performed in many different ways; sometimes the psalms were sung by one person alone, whilst the rest attended in silence; sometimes they were sung by the whole assembly; sometimes alternately, the congregation being divided into separate choirs; and sometimes by one person, who repeated the first part of the verse, the rest joining in the close of it.

Of the four different methods of singing now recited, the second and third were properly distinguished by the names of *symphonia* and *antiphony*; and the latter was sometimes called *responsaria*, in which women were allowed to join. St. Ignatius, who, according to Socrates ( hb. vi. cap. 8.), convented with the apostles, is generally supposed to have been the first who suggested to the primitive Christians in the East the method of singing hymns and psalms alternately, or in dialogue; and the custom soon prevailed in every place where Christianity was established; though Theodoret, in his History (hb. ii. c. 24.), tells us, that this manner of singing was first practiced at Antioch. It likewise appears, that almost from the time when music was first introduced into the service of the church, it was of two kinds, and confined in a gentle inflection of the voice, which they termed plain long, and a more elaborate and artificial kind of music, adapted to the hymns and psalmody contained in its ritual; and this distinction has been maintained even to the present day.

Although we find a very early distinction made between the manner of singing the hymns and chanting the psalms, it is, however, the opinion of the learned Martini, that the music of the first five or six ages of the church consisted chiefly in a plain and simple chant of unisons and octaves, of which many fragments are still remaining in the canto fermo of the Romish Missals. For with respect to music in parts, as it does not appear in these early ages, that either the Greeks or Romans were in practice of harmony or counterpoint, which has been generally ascribed to Guido, a monk of Arezzo, in Tuscany, about the year 1029; though others have traced the origin of it to the eighth century, it is in vain to seek it in the church. The choral music, which had its rise in the church of Antioch, and from there spread through Greece, Italy, France, Spain, and Germany, was brought into Britain by the singers who accompanied Audian to the monks, when he came over, in the year 596, charged with a commission to convert the inhabitants of this country to Christianity. Bede tells us, that when Audian and the companions of his mission, had their first audience of King Ethelbert, in the isle of Thanet, they approached him in procession, singing hymns; and that afterwards, when they entered the city of Canterbury, they sung a litany, and at the end of it, Allelujah. But although this was the first time the Anglo-Saxons had heard the Gregorian chant, yet Bede likewisel tells us, that our British ancestors had been instructed in the rites and ceremonies of the Gallican church by St. Germanus, and heard him sing Alleluia many years before the arrival of St. Aulian. In 660, John, precentor of St. Peter's in Rome, was sent over by pope Agatho to instruct the monks of Weremouth in the art of singing; and he was prevailed upon to open schools for teaching music in other places of Northumberland. Benedict Biscop, the precentor of Bede, Adrian the monk, and many others, contributed to disseminate the knowledge of the Roman chant. At length the successors of St. Gregory, and of St. Aulian his missionary, having established a school for ecclesiastical music at Canterbury, the rest of the isle was furnished with matters from that seminary. The choral service was first introduced into the cathedral church of Canterbury, and, till the arrival of Theodore, and his settlement in that see, the practice of it seems to have been confined to the churches of Kent; but after that, it spread over the whole kingdom; and we meet with records of very ample endowments for the support of this part of public worship. This mode of religious worship prevailed in all the European churches till the time of the Reformation: the first deviation from it is that which followed the reform of the church by Luther, who being himself a lover of music, formed a liturgy, which was to be chanted in plain service, contained in a work, entitled, "Psalmodia, lib. c. 38," printed at Norimberg in 1531, and at Wittenberg in 1524. But Calvin, in his establishment of a church at Geneva, reduced the whole of divine service to prayer, preaching, and singing; the latter of which he restrained. He excluded the offices of the antiphon, hymn, and motet, of the Romish service, with that artificial and elaborate music to which they were sung; and adopted only that plain melodic psalmody, which is now in general use among the reformed churches, and in the parochial churches of our own country. For this purpose he made use of Marot's version of the Psalms, and employed a musician to set them to easy tunes only of one part. In 1553, he divided the Psalms into partes or small portions, and appointed them to be sung in churches. Soon after they were bound up with the Geneva catechism, from which time the Catholics, who had been accustomed to sing them, were forbid the use of them, under a severe penalty. Soon after the reformation commenced in England, complaints were made by many of the dignified clergy, and others, of the intricacy and difficulty of the church music of those times: in consequence of which it was once proposed, that organs and curious singing should be removed from our churches.
Latimer, in his diocese of Worcester, went still further, and issued injunctions to the prior and convent of St. Mary, forbidding in their service all manner of singing. In the reign of Edward VI. a commission was granted to eight bishops, eight divines, eight civilians, and eight common lawyers, to compile a body of such ecclesiastical laws as should in future be observed throughout the realm. The result of this compilation was a work, first published by Fox the Martyrologist, in 1571, and afterwards in 1640, under the title of "Reformatio Legum Ecclesiasticarum." Thence thirty-two commissioners, instead of reproducing church music, merely condemned figurative and operatic music, or that kind of singing which abounded with fughes, repulsive passages, and a commixture of various and intricate proportions; which, whether extemporary or written, is by musicians termed defective. However, notwithstanding the objections against choral music, and the practice of some of the reformed churches, the compilers of the English liturgy, in 1548, and the king himself, determined to retain musical service. Accordingly the statutes 2 & 3 Edw. VI. cap. i. though it contains no formal obligation on the clergy, or others, to use or join in either vocal or instrumental music in the common prayer, does clearly recognize the practice of singing; and in less than two years after the compiling of king Edward's liturgy, a formula was composed, which continues, with scarcely any variation, to be the rule for choral service even at this day. The author of this work was John Marbecke, or Marbeke; and it was printed by Richard Grafton, in 1550, under the title of the Book of Common Prayer, noted. Queen Mary laboured to re-establish the Romish choral service; but the accession of Elizabeth was followed by the act of uniformity; in consequence of which, and of the queen's injunctions, the Book of Common Prayer, noted by Marbecke, was considered as the general formula of choral service. In 1566, another musical service, with some additions and improvements, was printed by John Day; and in 1565, another collection of Offices, with musical notes. Many objections were urged by Cartwright, and other Puritans, against the form and manner of cathedral service, to which Hooker replied, in his Ecclesiastical Polity. In 1664, the statutes of Edward VI. and Elizabeth, for uniformity in the common prayer, were repealed; and the directory for public worship, which allows only of the singing of psalms, established. But upon the restoration of Charles II. choral service was again revived, and has since uniformly continued. The Quakers objected to singing as a part of public worship, and accordingly it is never practised in their meetings. To this respectable body we here make an apology for a jeu d'esprit of our learned coadjutor, Dr. B., who compiled part of the article Liturgy, which escaped him, notwithstanding his well-known liberality and candour, and which was undoubtedly unfeasibly introduced, in an account of their public worship. Religious scruples, though in some respects unfounded and unwarrantable, when seriously avowed, are not fit subjects of ridicule. See on this subject Hawkins's Hist. of Music, vol. ii. p. 404. vol. iii. p. 254. vol. iv. p. 58—468, &c. vol. iv. p. 44—347. Burney's Hist. Mus. vol. ii. ch. i. passim.

SERVICES of the Church. (See CATHEDRAL SERVICES.) These have been collected, and splendidly and accurately published in score, by doctors Green, Boyce, and Arnold. These valuable publications appeared in the following order, and are reputable monuments of the abilities of our old masters in the ecclesiastical style of composition, equal, at least, to contemporary productions by the greatest contrapuntists on the continent.

CATHEDRAL MUSIC: being a collection in score of the most valuable and useful compositions for the service by the several English masters of the last 200 years, the whole selected and carefully revised by Dr. William Boyce, organist and composer to the royal chapels, and master of his majesty's band of musicians. Vol. i. 1760.

The second volume was published in 1768, and the third in 1773. These were both dedicated to his majesty.

In 1780, Dr. Samuel Arnold, organist and composer to his majesty's royal chapels, published, in the same splendid manner, a fifth volume, in continuation of this collection of services and full and verse anthems of old masters; and in 1790 a second and third volume, all dedicated to the king.

There is likewise, in the British Museum, Bibl. Harl. 7337, Plut. VI. B. a collection of English church music, in five vols. 4to, all transferred for and dedicated to the right hon. Edward lord Harley, by Dr. Thomas Tudway, musician professor of Cambridge. In these volumes, among some compositions of no great merit, there are many valuable productions by Tye, Tallis, Bird, Morley, Gibbons, Child, Blow, Purcell and Crofts, that have never yet been published.

SERVICE, Cathedral. See CATHEDRAL SERVICES.

SERVICE, Trees, in Botany. A corruption of the Latin SORBUS; see that article, as well as PYRIUS and MESPILUS.

SERVICE, Wild. See CRATAEGUS.

SERVIENTES VIRGATORES. See VIRGATORES.

SERVIERE, in Geography, a town of France, in the department of the Lozere; 15 miles N.W. of Mende.

SERVIERES, a town of France, in the department of the Correze, and chief place of a canton, in the district of Tulle; 13 miles S.E. of Tulle. The place contains 1,115, and the canton 8,567 inhabitants, on a territory of 265,000 square miles, in 10 communes.

SERVILLE, in Hebrew Grammar, the denomination of a class of letters used in contradistinction to radical. The latter constitute roots (which see), and the former constitute derivatives, or branches from these roots, and are employed in all the different flexions. Of all the twenty-two letters of the alphabet, any of which may be radicals, there are properly only eleven letters that can claim this title, because they never can be ferviles. The ferviles are the other eleven letters, by means of which the whole bulk of flexions, derivation, numbers, genders, persons, and tenses, is accomplished. But even these letters are somewhat limited in their servile power. For only two of them, ו and י can be inflected or ingrained between radical letters; the others must be either prefixed or suffixed to the root. The eleven fervice letters are the following: ג ד ד ש ד פ ש פ ד פ ש פ ש פ ד פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ ש פ Sh...

SERVIN, Louis, in Biography, a celebrated lawyer in France, who flourished at the sixteenth and beginning of the seventeenth centuries, was descended of a good family in the Vendomois. He cultivated polite literature with success while he was young, and at an early period became the correspondent of several eminent men of letters in different parts of Europe. In 1580 he was appointed advocate-general to the parliament of Paris, being then, according to Vendome, "a young man of great learning, and much attached to the interests of his majesty Henry III." He distinguished himself in that station by his zealous support of the liberties of the Gallican church, and his opposition to the pretensions of the court of Rome. His printed pleadings were honoured with the censure of the Sorbonne, and with a virulent attack by a Jefuit of Provenç. The title of his work was "Actions notables et Plaidoyers." In
1590 he published a work in favour of Henry IV., who had succeeded to the crown, entitled "Vindiciae temporis Libertatem Ecclesiæ Galliarum, et Defensione Regni Status Gallo-Francorum sub Henrici IV. Rege." In 1598, being joined in a commission for the reformation of the universitiy of Paris, he delivered "a remonstrance" on the subject, which was printed. To him also is attributed a work in favour of the republic of Venice in the affairs of the Interdict. In the reign of Lewis XIII., at a bed of justice held in 1620, he made strong and animadversions in favour of the right of parliament to register royal edicts. On another similar occasion, for the purpose of compelling the registry of some financial edicts, as he was firmly but respectfully making fresh remonstrances to his majesty, he suddenly fell and expired at the king's feet, a memorable death, and such, lays his biographer, as may in a measure entitle him to be enrolled among the martyrs to liberty. The private character of this excellent magistrate was worthy his high public reputation, and few men of his time stood in more general reputation.

SERVING, encircling a rope with line or spun-yarn, &c. to preserve it from the wet getting to it; also to preserve it being chafed. Rigg, Plate 1. fig. 48.

Serving the Rigg. See Mallet.

Serving-Maltii, a cylindrical piece of wood with a handle in the middle. It is used for serving rope, and has a groove along the surface, opposite to the handle, which fits the convexity of the rope to be served. Rigg, Plate 1. fig. 40, a short board with scores in it, is used for laying on small service.

SERVISTAN, in Geography, a town of Persia, in the province of Farahian; 25 miles S.E. of Shiraz.

SERVIT, an order of religious, so denominated from their riving a peculiar attachment to the service of the Virgin.

The order was founded by seven Florentine merchants, who, about the year 1233, began to live in community on mount Senor, two leagues from Florence. In 1239, they received from the bishop the rule of St. Augustine, with a black habit, in lieu of a grey one, which they had worn before. In 1251, Bonifacio Montali, one of the seven, from being simple prior of mount Senor, was named general.

This order was approved of by the council of Lateran, and again by cardinal Raynerius, legate of pope Innocent IV., who put it under the protection of the holy see. The succeeding popes have granted it a great many favours. It is become famous in Italy, by the history of the council of Trent, of F. Paolo, a Venetian, who was a religious Servite. M. Hermant gives this order the name of the Annunziate, doubtless from this mistake, that in some cities of Italy they are called religious of the Annunziate, because in those cities their church is dedicated under that name. F. Archang. Giani derives the name Servites, ferrarit of the holy Virgin, from hence; that when they appeared for the first time in the black habit given them by the bishop, the sucking children, as they lay, cried out, Behold the servants of the Virgin. There are also many of this order.

SERVITIA, Per Ques. See per Ques.

SERVITIUS AEQUITANDUS, a writ judicial that lies for a man disbarred for services to one, when he owes and performs them to another, for the acquittal of such services.

SERVITIUS CONSULTANDUS. See CONSULTUNDIUS.

SERVITOR, in the university of Oxford, a scholar or student, who attends and waits on another for his maintenance there.

Survivors of Bills, denote such servants of the king's of the marshal of the king's household, as were least afraid with bills or writs, to summon men to that court. They are now commonly called rip florin.

SERTUDE, the condition of a servit, or rather slave. Under the declaration of the Roman empire, a new kind of servitude was introduced, different from that of the ancient Romans: it consisted in leaving the lands of subjugated nations to the free owners, upon condition of certain rents, and servile offices, to be paid in acknowledgment. Hence the names of servi confini, september, and adhuc fidelis; some of which were taxable at the reasonable discretion of the lord; others at a certain rate agreed on; and others were incorruptible, who, having no legitimate children, could not make a will to above the value of five-pence, the lord being heir of all the rest; and others were prohibited marrying, or going to live out of the lordship. Most of which services still subsist in one province or other of France; though they are all abolished in England. Such, however, was the original of our tenures, &c. See Slaves.

SERVIUS, MAECEN-HONORATUS, in Biography, a grammarian and critic, who flourished in the reigns of Arcadius and Honorius, is principally known by his Commentaries on Virgil, which, however, are considered rather as a collection of ancient remarks and criticisms on that poet than as made by himself. They contain many valuable notices of the geography and arts of antiquity. The Commentaries of Servius were first printed separately at Venice in 1471, and have frequently been reprinted since. In 1532 they were annexed to Stephanius's Virgil, but they are most correctly given in Burman's edition in 1756. A tract on profody by this author, entitled "Centilometrum," is printed in the collections of the ancient grammarians.

Servius is mentioned with respect and honour by Macrobius, who makes him one of the speakers in his Saturnalia.

Gen. Dog.

SERVIUS, Sulpicius REIS, an eminent Roman jurit and statesman, was descended from the illustrious patrician family of Sulpicius. He was contemporary with Cicero, and born probably about a century before the birth of Christ. He cultivated polite literature from a very early period, especially philosophy and poetry, and wrote some pieces in the latter class, which were marked with the licentiousness of the time. He bore arms in the Marish war, but finding himself better pleased with the arts of peace, he appeared a pleader at the bar in the 25th year of his age. The professions of advocate and lawyer were then so distinct, that the former were accustomed to consult jurists upon all difficult points. Servius having once applied for that purpose to Quintus Mucus, a very eminent lawyer, the latter perceiving that Servius did not comprehend his explanations, asked him if it were not a shame that he, a patrician and pleader, should be ignorant of the law upon which he was frequently called to speak. This reproach is laid to have had such an effect upon him, that Servius quitted the bar, and gave all his attention to legal studies; and such was his success, that Cicero said of him, "If all, in every age, who in this city have acquired a knowledge of the law, were brought together, they would not be so well compared with Servius Sulpicius," and he further adds, that "he was not less the oracle of justice than of the law: he always referred to principles of equity and obvious interpretation what he deduced from the civil code, and was lea defers of finding grounds for actions than of settling disputes." There was a great intimacy formed between these two personages, and there are several letters extant from Cicero to Sulpicius, and two from Sulpicius to Cicero, of which
SERVUS TULLIUS, the sixth king of Rome, was the son of Ocrisius, a native of Coreum, who was made a captive when the Romans took that place. Tarquin the Elder presented Ocrisius to his queen Tanaquil, and having a son born while she was in a state of servitude, he was named SERVUS. It is not at all known who the father of this king was, and it was probably not till after his elevation to the regal dignity that he was represented as having been a person of rank who was killed in the defence of his country. Young Servius was brought up in the palace, and became a great favourite of the king and queen. He distinguished himself both in a civil and military capacity; was raised to the patrician order; had an important command in the army given him; and was at length united in marriage to Tullia, the king's daughter. On the affabination of Tarquin, Servius took possession of the throne, which event is dated in the year 577 B.C. As the sons of Ancus Martius, who were the authors of the conspiracy against Tarquin, had a strong party among the patricians, Servius pursued the policy of attaching the people to his interest, by paying off their debts, and making several regulations in their favour; and having added to his reputation by a defeat of the revolted Etruscans, he strengthened his title to the crown by procuring a legal election from the curia. He then applied himself to the improvement of the public police, and several of the most useful institutions of the Roman state took their origin in his reign. Servius enlarged the city by taking two more hills into its limits; he added a fourth tribe to the three old ones: he divided the whole Roman territory into tribes, with a pagus, or fortified post to each, and instituted a cenus, by which all the Roman citizens were distributed into six classes, according to their property. He also gave to the freedmen the privileges of citizens; and finding the duties of the regal office under the augmented population too numerous, he committed to the senate the determination of ordinary causes, referring to himself only the cognizable crimes against the state. Aware that he was still looked upon by the nobles as an intruder on the throne, he endeavoured to add consequence to his family by marrying his two daughters to the grandson of the late king. He now created a closer connection between the Romans and their allies, the Latins and Sabines, by the erection of a temple of Diana at Rome, at their common expense, in which they were to join in annual sacrifices, and in the amicable decision of all disputes among them. Servius, in many respects, was fortunate as a man and a monarch; but his greatest calamity was in his youngest daughter, who was continually urging her husband Aruns to criminal attempts against her father, but he nobly rejecting her infamous solicitations, she attacked herself to the other brother, her father's husband, Tarquin, a prince of a character and disposition very similar to her own. They got rid of their partners by poison, and then, having formed an inexcusable union, they boldly and openly declared Servius an usurper, and Tarquin laid claim to the throne before the senate. The patricians generally came over to his interest; but the great mass of the people were determined to support their king, who, whatever might have been his defects, had shewn himself worthy of the crown which his infamous relations wished to tear from his head. Tarquin, however, continued to intrigue with his party, and at length took the daring step of assuming the royal robes and insignias, and feated himself on the throne at the temple in which the senate assembled. He there pronounced a violent invective against the perfon and government of Servius, who arrived while he was speaking, and approached to pull down his fon-in-law from the throne; but Tarquin feized the venerable monarch by the waist, and threw him down the steps of the temple. He rofe with difficulty, and was moving away by the help of some by-standers, when his unnatural daughter Tullia arrived, who, having faluted her husband as king, fuggested to him the necelcity of dispatching her own father. Tarquin lent perfons to perpetrate the foul deed, and Tullia feared her cruelty and impety by driving her chariot over the dead body. Servius was murdered in his 74th year, after a reign of forty-four years, during which he had done enough to merit the title and character of one of the best kings of Rome.

SERULA, in Ornithology, the name of a web-footed seabird, a kind of mergus, very common about Venice, and called by Mr. Ray mergus cirratus fusCUS, the brown-crested, or leffer-toothed diver, and supposed to be the anas longirostra, or long-beaked duck of Gesner. This is the red-breasted merganfer of Pennant.

It is very nearly of the size of the duck; its head and throat are of a fine changeable black and green; on the first there is a long pendent crest of the same colour; the upper part of the neck and of the breast, and the whole belly, white; the lower part of the breast ferruginous, spotted with black; the upper part of the back black; near the setting on of the wings some white feathers, edged and tipped with black; the exterior capular black; the interior white; lower part of the back, the coverts of the tail, and feathers on the sides, under the wings, and over the thighs, grey, marked with waving lines of black; covers on the ridges of the wings dusky, succeeded by a broad bar of white; the quill-feathers dusky, the tail is short and brown, and the legs orange-coloured; the head and upper part of the neck of the female are of a deep rust colour; the crest short, the throat white, and distinguished by some other varieties of colour from the male. These birds breed in the northern parts of Great Britain. Pennant.

SERUM. See Blood.

SERUS. Alum-safum, Alum-sahuy, a form of medicine prescribed in the late London Pharmacopeia, made of a pint of milk boiled to whey with a quarter of an ounce of alum.

SERVONG, in Geography, a town on the N. coast of Sumatra. N. lat. 5° 3'. W. long. 96° 18'.
1. S. orientale. Common Sefamum or Oily-grain. Linn. Sp. Pl. 883. Wild. n. 1. Att. n. 1. (Sefamum seu Sampiemen; Alpin. Egypt. 98. i. 100. S. iive Sefamum; Ger. Em. 1332.)—Leaves ovate-oblong, undivided; the lower ones somewhat serrated.—Native of the East Indies. Vol. XXXII.

A tender annual, occasionally raised to the status of a sub-shrubs, in the leaves of Egypt and the Indies, and in the buds of its flowers. The seeds are used as a narcotic. The plant is much used in Egypt and the Indies, as a narcotic. The leaves of the common Sefamum are used as a narcotic, and the plant is much used in Egypt and the Indies. The seeds are used as a narcotic, and the plant is much used in Egypt and the Indies.

3. S. indicum. Indian Sefamum. Linn. Sp. Pl. 552. Wild. n. 3. Rumph. Ambon. v. 5. 204. f. 1. Spec. Bot. 2, 100, f. 4.—Lower leaves terete, or three-lobed, lower undivided. Stem erect.—Native of the East Indies, Mauritius, &c. Differs from the first species principally in the division of its lower leaves. The flowers are whiter, compared by Rumphius to those of Huesana. Both callix and corolla are externally hairy, as in S. orientale. There is a variety with black, and another with brown or greyish, seeds. Both are used in Amboyna, but the latter is preferred.

4. S. laetivium. Jagged Sefamum. Wild. n. 4.—"All the leaves deeply three-lobed, jagged. Stem profusely, bifid."—Gathered by Klein, in the East Indies, near Hydrabad.—The stem is branched, the extremities of its branches only ascended. Leaves opposite, on short stalks, rough on both sides; the stems are blunted, deeply toothed. Flowers axillary, solitary, on very short stalks. Cappule obtuse at each end, tipped with the broad permanent style. Wildflowers.

Both this and the preceding may possibly be mere varieties of the first species. S. luteum appears to be distinct.

5. S. profusum. Dwarf Hoary Sefamum. Retz. Obs. f. 28. (Euphrasus affinis pulla planta, periparuo ligundo oblongo quadrato bivalvis; Phil. Am phil. 85. t. 373. f. 2.)—Leaves roundish, toothed, hairy; hoary breast. Stem profusely, villous. —Nature of the U. S. plant, near Madras; very rare elsewhere. Kerrias, Rinder. Root woody, thick and strong, evidently perenn. Stems several, woody at the base, about a span long, much branched, leafy, villous, spreading flat on the ground in every direction. Leaves opposite, toothed, small, from one quarter to three quarters of an inch long, obtuse or abruptly, toothed, or wedge-shaped; the base of the upper surface hairy; lower white and grey; the upper two, beyond the flowers, often alternate. Flowers axillary, solitary, toothed, one to two; as long as the leaves, very hairy. Corolla externally hairy and hairy; internally villous, beautifully flavous and dotted with black red. Cappule ovate, quadrangular, hard woody, hairy, scarcely more than half
half the length of the corolla. *Seeds* numerous, oblong, angular, black.

Linnaeus has erroneously referred the above synonym of *Platen* to his *Tantina asiatica*, a very different plant. Hence Willdenow was led to omit the present species of *Sesamum*, as very uncertain. *S. javanicum*, Born. Ind. 133.

*Sesamum* is also a name given by some authors to the mygamura, or gold of pleasure.

*Sesban*, a barbarous and inadmissible generic name, even when altered by Mr. Pursh into *Sesbania*, in his Flora of North America, v. 2. 460, 485. This name is given by Poiret in Lamark's Dictionary, v. 7. 146, to a genus selected by him out of *Aeschynomene*, see that article; and consisting of the Linnean *A. grandiflora*, *Eccinum*, and *Sesban*, with several others more recently discovered. These plants are mostly referred by Willdenow to *Coronilla*, with which they do not ill accord. They certainly cannot remain with the original species of *Aeschynomene*, which fearfully differ from *Sesbania*, see that article.

*SESEL*, Poiret in Lam. Dict. v. 7. 130, the Amboyna name of a tree, which, according to Corripphus, affiumes a very different appearance on the coast to what is usual in the adjacent plains; the leaves, always strongly three-ribbed and entire, lanceolate in the latter situation, being roundish-ovate, and much shortened in the former. He speaks of this plant as allied to *Metabularia*, the wood being to hard as to spoil the tools used in cutting it down. Nothing is known of the fruitification, except that the *flowers* form small whitish heads, subequently brown, and the *fruit* seems a globose yellow berry, or drupa. See Rumph. Amb. v. 3. 64. t. 36. 37.

Gen. Ch. General Umbel rigid; partial very short, of many rays, globose. General involucrem of very few leaves, or none; partial of several pointed leaves, about the length of the partial umbel. *Perianth* scarcely discernible. Cor. *Unifloral* uniform; flowers all fertile; partial nearly flat, of five petals, whose inflexed points render them heart-shaped. Stam. Filaments five, awl-shaped; anthers simple. Pil. Germen inferior; styles two, dilat. stigma obtuse. Peris. Fruit ovate, small, oblong; separable into two parts. Seeds two, ovate, convex and inflated at the outer side, flat on the inner.

Eff. Ch. Umbels globose, rather rigid. Flowers regular, all fertile. General involurem of one or two leaves; partial of several. Fruit ovate, inflated.

Obf. *S. Hippomorathrum* offers a remarkable exception to the above generic character, having a partial involurem of one leaf, orbicular and toothed, like the wheel of a clock. That of *S. gymniferum* is nearly similar.

1. *S. filiformum*. Thread-leaved Meadow-faxifrage. Thunb. Prodr. 51. Willd. n. 1.—Leaves linear-threaded, stem zigzag, erect. Perianth awl-shaped.—Gathered at the Cape of Good Hope, from which we have an authentic specimen. The *flom* is a foot high, slightly branched, round, furrowed, smooth. *Leaves* two or three, one of which only remains perfect, an inch long, undivided, very narrow, acute, ribbed, smooth, somewhat channelled. Umbel terminal, of four rigid flat-topped, with a general involurem of as many unequal, lanceolate, ribbed, smooth leaves, the longest but half the length of the rays. Partial umbels level-topped rather than globose, of ten or more short, flat, angular rays, and several lanceolate partial involurem leaves, of the same length. The half-rice fruit is oblong, about as long as the *flom* which support it, furrowed, crowned with a very evident *calyx*, of five awl-shaped, sharp, permanent, somewhat fimbrous, teeth, finally recurved at the points. We have been the more particular in our description, as there is no figure of this plant extant, and yet botanists would recognize it for a *Sofelii*.

2. *S. pinnatifolium*. Nodding Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 2.—Stem declining, and umbels drooping, before flowering. Leaves pinnate; leaflets doubly pinnatiradiate, with alternate, flat, linear, deciduous segments.—Native of the fourth of Europe. Cultivated by Linneaus at Uplal. Perennial. Stem a foot high, slightly leafy, round, finely striated, smooth, decumbent at first, but finely erect as the *flowers* come to perfection, and bearing about three rather large umbels, which in a young late droop, like those of *Pinimella Soffixifrage*. Radical leaves *flaked*, a span long, smooth, of a light glaucous green; their segments spreading, acute, entire, veiny, very uniform. *Flowers* white. Partial involurem of one or two, almost capillary, leaves. *Seeds* a quarter of an inch long, nearly oval, with five elevated ribs, three of which are central, two marginal, and dark intermediate furrows.

3. *S. montanum*. Mountain Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 3. *Ait. n. 1. (S. multicaule; Jacq. Hort. IND. v. 2. 59. t. 129. Carvifolia; Vaill. Paris. t. 5. f. 2.)—Foot-talks under the branches oblong, entire, with a membranous edge. Stem-leaves with linear very narrow segments. Seeds downy.—Native of hillocks in Italy and France. Cultivated at Oxford in the middle of the 17th century. A hardy plant, flowering in summer. *Root* perennial, tapering, crowned with the fibres of decayed foot-talks. *Stems* erect, from one to three feet high, round, striated, smooth, branched, leafy. *Leaves* doubly pinnate, three-clasped; their segments of the upper ones longest, narrow, and most glaucous; their foot-talks sheathing, clove, striated, with more or less of a membranous border, entire at the summit. *Umbels* smaller than in the preceding; erect, white, of many rays, sometimes accompanied by a general involucral leaf. *Seeds* obvate, one-fourth the length of the former, ribbed, minutely downy.

5. *S. glaucomum*. Glaucous Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 5. *Ait. n. 2. Jacq. AnnuL. t. 144.—Foot-talks under the branches oblong, entire, with a membranous edge. Branches spreading. *Leaflets* linear, channelled, smooth, glaucous, longer than their foot-talks. *Seeds* ovate, downy. *Umbels* lax.—Native of France. To define the difference between this plant and *S. montanum* is very difficult. The *glaucum* has longer leaflets, and the primary divisions of its radical leaves seem to be always flattened, not fitting clove to the mid-rib. The *branches* are more divaricated,
eated, and umbels more lax. Seeds rather shorter. In Jacq.'s figures these plants appear very different, but the *gymnium* of most authors is merely *monatum*. Jacquin does not notice the hairy seeds.

6. S. arvatum. Bearded-leaved Meadow-faxifrage. *Linn.* Sp. Pl. 273. Wild. n. 10. *S. melandrioides*.—Footstalks under the branches lax, entire, somewhat membranous. Leaves repeatedly compound; leaflets lanceolate, bristle-pointed. Flowers ovate.—Native of the Pyrenean mountains. Cultivated by Miller at Chelsea. A hardy perennial, flowering in June and July. Miller says the *root* is biennial. *Leaves* doubly pinnate; lobes very narrow, and finely divided. *Stems* branching, a foot and half high, furnished with flaking winged leaves, and terminated by pretty large umbels of *white flowers*. A specimen sent by Gouan for S. annuum, which it certainly is not, seems to be the plant under consideration. The segments of its leaves have callous tips. The leaves of the *partial involucrum* are ovate, with broad white membranous edges, their points extending beyond the flowers.

7. S. annuum. Caraway-leaved Meadow-faxifrage. *Linn.* Sp. Pl. 273. Wild. n. 7. Jacq. Auct. t. 55. (S. carvifolium; Villars Dauph. v. 2, p. 586, from the author. S. co- luratum; Ehrh. Herb. n. 115. Beitr. v. 5, 179. Pimpinella tenuefolia; Rivin. Pentap. Irr. t. 83. f. 1. Foeniculum vulgare annuum, tragoselinum odor, umbellata alba; Vail. Paf. 54. t. 9. f. 4.)—Footstalks of the upper leaves lax, membranous, margined. Stem and branches erect. Leaves doubly pinnate, cut; their primary divisions fimbriate. Seeds smooth.—Native of France, Germany, and Switzerland. *Root* tapering, woody, crowned with fibres of decayed leaves, and having all the appearance of being perennial. *Stem* twelve or eighteen inches high, erect, stiff, some- what zigzag, round, fluted, leafy, often purplish; its branches very little spreading. *Leaves* filiform, varying greatly in the length of the leaflets and their divisions, green rather than glaucous; occasionally purplish; their segments linear-oblong, narrow, keeled. Umbels white or purplish, of many general as well as partial rays, all more or less downy. *Partial involucrum* of many lanceolate membranous-edged leaves, whose taper points reach beyond the flowers. *Seeds* elliptic-oblong, very convex, with three dorsal ribs, deltoid of pubescence in every part. We have this species from M. Du Croze Haller's t. 762, to which it seems well enough to ascribe, but if so, Gouan mistakes Haller's plant.

9. S. Ammodites. Milfoil Meadow-faxifrage. *Linn.* Sp. Pl. 373. Wildl. n. 9. Ait. n. 4. Jacq. Hort. Vind. v. 1, t. 20. t. 52. (Ammodiae; Bauh. Pin. 150. Ammi; Matth. Valgr. v. 2, 170. A. Matthioli; Dalech. Hift. 695.)—Leaflets of the radical leaves imbricated; those of the upper ones almost capillary. Stem spreading. Rays of the umbel capillary, very unequal. Seeds smooth.—Native of Greece, Portugal, Italy, Sicily, and the south of France. A slender annual plant, about a foot high, its *stem* generally branched from the very bottom. Lower leaves on long slender flanks, pinnate, their leaflets in many narrow-lanceolate, channelled segments, lying over each other; upper usually twice ternate, with much longer, and very slender, undivided leaflets; their footstalks short, sheathing, furrowed, and membranous. Umbels terminal, very delicate and lax, of about seven or eight extremely unequal capillary rays; the partial ones of more numerous, but like-
high, nearly upright, rigid, round, smooth, rufous, somewhat branched above, bearing several oblong, sheathing, membranous-edged footstalks, with only very short or abortive leaves. The proper leaves are radical, pretty numerous, flanked, two or three inches long, doubly pinate and cut, linear, glaucous and smooth like the rest of the herbage. Umbels terminal, foliary, small and close, rigid, minutely downy, with several principal rays, and sometimes a sheath-like leaf at the base; the partial ones of many white, nearly fleshy, flowers, chiefly remarkable for the simple, cup-like, partial involucrum, whose membranous downy edge is variously jagged and toothed. Dillenius rightly observes, in the letter to Haller, quoted under our last species, that this singular part is not shown in the figure of Clausius and Gerarde. It indicates an affinity to our gummiferum, which obliges us to place these two species together, next to tortuosum, with which they accord greatly as to habit.

13. S. Turbitii. Turbitii Meadow-faxifrage. Linn. Sp. Pl. 374. Ameon. Acad. v. 4. 310. Willd. n. 11. (S. que folus face, Thapféa, five Turbitii, gallorum; Bauh. Hift. v. 3. p. 2. 45. Boich. Lugd. Bat. v. 1. 50. Thapféa Dioec.; Lob. Ic. 779. T. telufolia; Ger. Em. 1030.)—Leaves repeatedly three-cleft, divaricated, awl-shaped. General involucrum of one to two awl-shaped leaves; partial of many short, pointed, membranous ones. Seeds villous, the length of the permanent styles. —Native of Spain, and the south of France. The root is perennial, thick, discharging a milky juice, which, according to John Bauhin, to whom it was pointed out by his preceptor Rondelet, pos sesses a valuable purgative quality. Stem erect, branched, round, smooth, not so clumpy as in Bauhin's figure. Leaves chiefly opposite, with broad sheathing footstalks, spreading, repeatedly subdivided into divaricated, slender, awl-shaped segments, crossing each other, and much resembling fennel. Umbels terminal, large, of many slender, downy, spreading, general as well as partial, rays. General involucrum of very few and short, tapering, scarcely membranous-edged leaves; those of the partial ones more membranous, lanceolate, fringed, half the length of the flower-stalks, quite distinct at their base. Petals white. Fruit ovate, covered with fine hoary dense bristly hairs, and crowned with the long spreading styles, very tumid at their base. Stigmas obtuse, but hardly capitately.

14. S. pyrenaeum. Pyrenean Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 13. Ait. n. 7. (Selimum pyreneæ; Gouan IIuftr. n. 1. t. 5. Carvi album; Bauh. Prodr. 84. Lachenal Act. Helif. v. 7. 332. t. 12.)—Leaves doubly pinnate, with many linear, acute, decurrent, flat segments. Partial involucrum fetaeous, equal to the flowers. Seeds smooth, nearly orbicular, with three close central ribs. —Native of the Pyrenees. Miller appears to have cultivated it in 1731. The root is perennial, the size of the finger. Stem a foot high, erect, arrowed, smooth, scarcely branched, moit leafy at the lower part. Footstalks long, dilated and sheathing at the base. Leaves three or four inches in length, light green, smooth, their leaflets uniform, with linear, alternate, pointed, decurrent, veiny segments. Umbels of six or eight unequal rays, without any general involucrum; the partial ones convex, dense, many-flowered, with a partial involucrum of many smooth, slender leaves, almost capillary, distinct at the bottom. Petals yellowish, with a purple tinge externally. Seeds with a broad, flat, even margin, their centre marked with three close prominent ribs.

15. S. faxifragum. Slender Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 14. (Pimpinella faxifraga tenuifolia; Bauh. Prodr. 84.)—Stem thread-angled, divaricated. Leaves doubly ternate, linear. Umbels of about fix rays. —Plentiful about the lake of Geneva, according to C. Bauhin, who describes the with an oblong root. Stem a foot high, green, smooth, friated, bent, divided from the base, and subdivided into slender branches. Leaves in slender, afterwards almost capillary, segments. Leaves of a minute, white, in a small umbel. It is not possible to determine this from the description, nor have we seen an authentic specimen. Linnaeus faw this species in Burser's herbarium only. His account agrees with the above, only adding that the partial involucral leaves are brittle-shaped.

16. S. elatum. Tall Meadow-faxifrage. Linn. Sp. Pl. 375. Mant. 357. Willd. n. 15. Ait. n. 8. Gouan IIuftr. 16. t. 8.—Stem much branched, round, rigid, very smooth. Leaves twice ternate, with linear, fleshy, dilatant leaflets. Fruit smooth, ovate, with dilatant obtuse ribs. Partial involucrum awl-shaped, shorter than the flowers. —Native of Italy and the south of France. Specimens are in the Linnaean collection from Arduins and Gouan, as well as the garden plant alluded to in the letter of Linnaeus, cited by Gouan. These, as well as Gouan's figure, prove the present species to vary greatly in luxuriance. The stem is from eighteen inches to five feet high, much branched from top to bottom, very smooth, pale at the joints, leafy, the upper part greatly divaricated. Lower leaves twice ternate; upper quite simple; all linear, very narrow, fleshy, smooth; each leaf, or leaflet, from one to two inches long. Footstalks linear, channelled, sheathing, close, with an evident, though narrow, membranous edge. Umbels numerous, terminal, of from two to three to ten rays, smooth, without an involucrum; partial ones of many sheathless unequal rays, their involucral leaves slender, but membranous, rarely equal to the flowers. Petals white. Seeds ovate, gibbous, smooth, by no means tuberculated, though Gouan describes them dotted; each is marked with three slightly prominent ribs, but not bordered. The synonym of Maegard quoted in Sp. Pl. was afterwards referred to Linnaeus to his Pimpinella glauca.

17. S. trichorum. Yellow Meadow-faxifrage. Pursh v. 1. 197.—"Leaves triply ternate; leaflets linear, elongated. Umbels hemispherical. Partial involucrum of many linear leaves, as long as the flowers."—About the waters of Columbia river, where it was found by governor Lewis, flowering in April and May. The spindly-shaped perennial root is one of the grateful vegetables of the Indians, who use it baked or roasted. Flowers deep yellow. Pursh.

18. S. junceum. Rushy Meadow-faxifrage. Sm. Prodr. Fl. Græc. Sibth. n. 698.—Stem much branched, divaricated. Footstalks of the item-leaves very short, and spreading. Umbels solitary, simple, of few flowers. —Found in the Greek herbarium collected by Dr. Sibthorp, but without any name, or mention of the place where it was gathered. The root appears to be perennial. Herb a sparsely high, rigid, smooth, rather glaucous. Radical leaves twice ternate, with keeled three-pointed leaflets; those of the item very small, and as if abortive. Umbels small, white.

19. S. caespitosum. Tufted Meadow-faxifrage. Sm. Prodr. Fl. Græc. Sibth. n. 699.—Stem simple, nearly naked. Radical leaves tufted, flat, pinnate, cut; the terminal leaflet three-cleft, decurrent. —Gathered by Dr. Sibthorp, and his companion Borone, on the summit of the Bithynian Olympus. The root is thick, perennial, dividing at the crown into many heads. Stems from four to eight inches high, simple, scarcely ever divided, erect, straight, stiff and smooth, bearing a solitary leaf only. Radical leaves forming a dense tuft, smooth, rigid, of various sizes. The footstalk of the item-leaf has a membranous edge. General umbel of.
The common hart-wort is possessed of the same sort of virtues with the other two, but its heat is more warm and aerid than that of either of them. It is esteemed a very efficacious remedy in obstructions of the menes, and Schroder tells us, that it has the credit of being an antidote to the poison of hemlock.

The feed of the French hart-wort, or jepsh Ruffens, has been esteemed of great virtue in diseases of the head and nerves, in convolutions and epilepsy, and in weaknesses of the sight. It is also given in elecatures, intended against all disorders of the breast and lungs. They are given in suppositories of urine, and of therectum, and in all kinds of flatulencies; and are, among the German phlœtisans, a common ingredient in medicines, intended to promote expectoration.

The feed of the French hart-wort, or jepsh Ruffens, has been esteemed of great virtue in diseases of the head and nerves, in convulsions and epilepsy, and in weaknesses of the sight. It is also given in electuaries, intended against all disorders of the breast and lungs. They are given in suppositories of urine, and of the rectum, and in all kinds of flatulencies; and are, among the German phlebitans, a common ingredient in medicines, intended to promote expectoration.

See SERMENTAINE.

SERIPTANUS. See SANKAPRADEGA.

SEEMELEQUIAN, in Geography, a river of the New territory, in the United States of America, which runs into the Illinois.

SESEN, or SDOI, a town of the principality of Wellenbuttle; 12 miles S.W. of戈fight.

SESERINUS, in Ethnology, a name given by Rondetius, and some other authors, to a broad and short sea-fish, seeming the same with the lampyra of Italian fishermen; and described by authors in general, and by this very author in another place, under the name of Hosterus.

SESHA, in Hindoo Mythology. Images of Naga, or Selna, in brahs, are said to be instated in cates of ill-health, with appropriate ceremonies, according to the author of the Hindu Pashithon, they are very common in India, where the idea of the medicinal virtues of snakes appears to be of very old date. A Hindu, attacked by a fever, or other disease, makes an image of Naga in brahs, clay, or wax, and perforates appropriate ceremonies in furtherance of his recovery. Such ceremonies are particularly efficacious when the moon is in the nakshathras, or allerims, called Sarpa, or the serpent. We have observed that the snake, in all mythological language, is an emblem of immortality; its scaly figure, when its tail is inerled in its mouth, an astrological mysticism common to Asia and Europe; and the annual renewal of its skin and vigour allude symbols of continued youth, of duration, and eternity; and its supposed medicinal virtues, or life-preserving qualities, may also have contributed to the fabled honours of the serpent tribe. In the mythological machinery of India, Egypt, and Greece, these coincidences are numerous. Some learned writers attribute this universality of serpent-forms to the early and all-pervading prevalence of fire, its first shape on earth. For the seed of a plant that is stowed hereafter in Kalka and Haranaka. With the Haranaka, Haras is named, and all of them. A multiplicity of names, called 'serpent of the form of serpents, or that are consecrated in the Pashita and Ganges Paranvitha.' Cn the towns, rivers, men, women, trees, and mountains, the Hindus used in their poetical oracles. Ngnner, the god of the wrath of Pashita and Naga, and after one of the common names of Selna, as all a town is Metre, Nagmungan, properly Nagmungala. See MAHAGAN,

One of the tables commonly alluded to in Hindoo writings, is Vishnupopesh Sela, and it is a favourite subject with painters. In a beautiful ode, by the fr. J. J., addressed to Lakithuna, the Mag is a master of her lectures, (see LAHJEMH) her union with Vishnupopesh introduced. On this occasion the bride rode from the church on a horse, like our Venus, and choosing Vishnupopesh for her husband, the subject of this article formed a nuptial couch for her reception: it is poetically described.

"... Love bade the banqgovm ile,..."

The operation of churning the ocean, alluded to above, is described under the article KURMAVATAR of this work, and a poetical allusion to the reflecting gems or mirrors on the head of Sela, will be found under SHITAKOSHTI.

SESHNAGA, a name of a wisp play mythological serpent among the Hindus, otherwise called Sela; which see.

SESHTI-MATRIYA, a name of Kartikya, the mythological commander of the celestial armies in Hindoo fable. The name means having for masters. Shanmatriva has the same meaning, and is another of his names, and Shanmura. Shanmuka is another, and means with six faces or mouths. For the origin of these appellations, and for some particulars of the hero to distinguish, see KARTIKYA, and SKANDA, another of his names.

SESA, in Geography, a river of Italy, which rises in the Alps, on the borders of the Valais, and runs into the Po, a little below Catal.

SESA, one of the six departments of France, into which Piedmont was divided, when it was united to the French republic, Aug. 26, 1802; it is composed of Vercell and materials, in lat. 45° 25', E. of Dure, and contains 140 square leagues, and 204,445 inhabitants; it was divided into three circles, viz. Vercell, composed of 70,551 inhabitants; Santra, with 36,014; and Bene, having 89,459 inhabitants. The climate of the department is doubtful; the emenues and hillys are favorable for the culture of the vine; and the cultivated plains yield abundance of grain, fruits, and vegetables.

Sesa, a town on the N.W. coast of Timor, S. lat. 8° 34', E. long. 125° 26'.

SESKAR, a small island in the N. part of the Gulf of Bothnia, N. lat. 65° 38', E. long. 23° 39'-Al, a small island in the gulf of Finland, N. lat. 59° 57', E. long. 25° 14'.

SÉSÉLIA,
SESLERIA, in Botany, received that appellation from Scopoli, who in the first edition of his excellent Flora Carolinica, 1745, he could never forget the delightful garden, so rich in scarce plants, which he often used to visit, while at Venice, in the year 1745. It was formed in the island of St. Helen, by Dr. Leonard Seler, whole great diligence in observing and cultivating plants justly entitled him, in Scopoli's opinion, to this botanical commemoration. A letter from his, describing a supposed new genus, under the name of Vitaliana, is subjoined to Donati's Storia Naturale del Adriatico, but Linnæus reduced the plant to Primula.—Scop. Carn. ed. t. 189. Sm. Fl. Brit. 93. Prodr. Fl. Græc. Sibth. v. t. 52. Ait. Hort. Kew. v. t. 153. Jull. 31. Lamarck Dict. v. 7. 138. Illstr. t. 42. —Clas and order, Triandra Digynia. Nat. Ord. Gramina.

Gen. Ch. Cal. Glume of two, nearly equal, ovato-lanceolate, concave, pointed valves, containing about three flowers. Cor. of two unequal, erect, parallel, acute, valves; the inner folded, two-ribbed, cloven; outer rather the longest, entire or some-leafed. Stam. Filaments three, capillary, longer than the flower; anthers pendulous, obtuse, cloven at the end. Pyl. Gernmen superior, ovate; styles two, various in length, capillary, more or less combined; stigmas oblong, cylindrical, feathery. Peric. none, except the corolla, which embraces the seed, but is not attached to it. Seed solitary, ovate, smooth.

Eff. Ch. Calyx of two valves, containing about three florets. Corolla of two valves; the inner cloven; the outer variably pointed. Styles united at their base.

2. S. albus. White Moor-grass. Sm. Fl. Græc. Sibth. v. t. 56. t. 72. v. 2. (Carex dubia; Sibth. MSS.)—Spikes ovate-oblong, imbricated, Bractæae alternate. Outer petals lanceolate, acute, undivided. — Discovered by Dr. Sibthorp, who wrote about the village of Belgrad, near Constaninople. The general aspect of this grass, so like some of our common species of Carex, with compound androgynous spikes, easily led its learned discoverer to refer it to that genus. He was, at the same time, too accurate to overlook the differences of its generic character; though not sufficiently acquainted with Seleria, to perceive its agreement herewith. This species is somewhat larger in every part than the foregoing, and has a creeping root, sheathed with the wrinkled bals of old leaves. The fruits are twelve or eighteen inches high, and the foliage nearly as tall. Spike of a greenish-white, rather shining, scarcely branched. Spikelets two or three together, falked. Calyx three or four-flowered, membranous, taper-pointed; the middle faplets falked. Petals membranous, whitish, with green roughish keels; the outer one lanceolate, pointed, undivided; inner cloven a little way down into two sharp-pointed lobes, each of which has its own folded rib or keel. Stamens white, considerably longer than the flowers; anthers pale yellow, drooping. Styles smooth, united throughout, the length of the corolla; stigmas divaricated, awl-shaped, clothed with short pubescence. This Seligeria serves greatly to confirm the genus, and to indicate its true effential character.

3. S. pharocephala. Round-headed Moor-gras. Arduin. Spec. 2. 20. t. 7. Poiret in Lam. Dict. n. 2. Lamarck Illstr. t. 47. f. 2. (Cynogorphus pharocephalas; Jacq. Mifc. v. 2. 71. Ic. Rar. t. 20. Wild. Sp. Pl. v. 1. 414. C. microcephalus; Hoffm. Germ. 49.)—Spike capitata, globofæ, bracteated at the base. Outer petals with three teeth; the middle tooth awned. — Of the loftiest alps of Carinthia, Austria, the Tyrol, &c. A very much more slender plant than either of the former. The root is fibrous. Stem four or five inches high, somewhat quadrangular, bearing one leaf only, at the lower part, which is flat, short and broad, with a long fhorted fiolet, and a more elongated filipula than that of the other species. Radical leaves larger and narrower, folded, numerous. Spike almost globular, the size of a common currant, subtended by two or three opposite, broad, concave, notched, membranous, coloured brachias, not half its own length. Spikelets imbricated every way, of a blue-hus-purple, nearly kefts. Each calyx contains two or three florets. The petals are divided as in S. cerulea, but the middle segment of the outer one is lengthened out into an awn, of a dark hue, twice or thrice as long as the reat. Wullen, who communicated this species, and its description, to Jacquin, observed what he fupposed a variety, with white flowers, in rather larger spikes, four or five florets in each calyx, and a shorter central awn to the corolla. This seems to be represented in Jacquin's plate, and Hoffmann, after Henk and Hopp, has made it a distinct species, by the name of Cynogrophus pharocephalas, calling our's microcephalus. We do not fife sufficiently permanent characters to authorize this. Haller makes another Seligeria, at his n. 1447, which is Poa dityclus, Jacq. Mifc. v. 2. 74. Ic. Rar. t. 19. Wild. Sp. Pl. v. 1. 400. Allioni has given it the barbarous appellation of F. jeflérioides. This plant is unquestionably a true Poa, see that article.

SEOSTRIS, in Biography, king of Egypt, of whom the accounts are so much mixed with fable, and so obscured by antiquity, that it has been found extremely difficult to form a confluent and probable story. Historians are even divided as to the identity of the name Selotritis with that of some other refembling names in the Egyptian history, and several hold him to be the fame with the Sefas or Shellac of the Hebrew scriptures. The following is regarded as the most probable account of this monarch. He is generally placed by chronologists in the 15th century B.C., and is by some thought to have been the son of Amenophis. Educated in many exercises with a number of companions, he is said to have been fent, by his father, at an early age, upon an expedition into Arabia; and after subduing that country, into Africa. While engaged in the conquest of the latter, his father died; and his successes having inflamed his ambition, he resolved to grasp at universal empire. Before his
his departure from Egypt, he ingratiated himself with the people by many acts of kindness, and made a division of the country into thirty-six departments, to each of which he assigned a governor. Then having constituted his brother Armas regent, he marched with a numerous army into Ethiopia, which he reduced tributary, penetrating near to the limits of Hildahmish. As he now perceived that he could not carry on his great designs without a navy, he fitted out two fleets, notwithstanding the aversion of the Egyptians to maritime occupations, one in the Mediterranean and the other in the Red sea. By means of the former he reduced the countries of Phoenicia, Cyprus, and several of the Cyclades, and with the latter he failed into the Indian gulf, and made himself master of its coasts. Then, purging his conquests by land, he is represented as having overrun all Asia, and even as having crossed the Ganges. On his return, he invaded the country of the Scythians and Thracians, in which, however, he lost a great part of his army. It is commonly thought that he left an Egyptian colony at Colchis, but Thrace was his fatherland progres wellward. On his arrival at Pelusium, after an abecence of nine years, laden with spoil, and attended with a vast number of captives, he was received by his brother Armas with pretended joy and submission, though he had formed a plot against him. For this traitorous attempt he expelled Armas from Egypt, and then, disbanning his army, he sat down to the improvement of his country. He erected magnificent temples in all the cities of Egypt, in the building of which none but his captives were employed. He raised obelisks, with inscriptions recording his conquests and revenues. He built a wall of great length, on the eastern boundary of Egypt, to protect it from the incursions of the Arabs, and he dug a number of canals, branching from the Nile in all directions, for the purpose both of commerce and navigation. He is said, in the height of his pride, to have harried tributary kings to his chariot, till one of them, pointing out to him the rotation of the wheels, by which each part was succesively at top and bottom, brought him to reflection. Becoming blind in his advanced years, he finished his course by a voluntary death.

It may be observed that sir Isaac Newton has endeavoured to prove that Seoforio is the Ofris of the Egyptians, and the Bacchus of the Greeks, as well as the Sebac of scripture. Univer. Hift.

SESI, a particle often used by old masters and theorists, in Myci, in the composition of words to express different kinds of measure. They called sesqui-measures those which contain notes equal to one-third more than their usual value; that is, when equal to three notes of less value, instead of two. This happened in what was called perfect time, before the use of points or dots, when the breve was equal to three semibreves, the semibreve to three minims, &c.

In Italian treatises by old theorists, sesqui is much used to express a kind of ratio, particularly in different species of triads; that is, when the greater term contains the less once, and some small quantity more; as 3 : 2, when the first term contains the second, and unity over, which is the half of 2. So that if the part remaining be just half the less term, as 4 : 3, the ratio is called sesqui terza, or tertia; if a fourth, or 5 : 4, the ratio is sesqui quarta, and so on to infinity; still adding to sesqui the ordinal number of the less term.

SESQUIALTER is a stop in the organ, implying a whole and a half. In large organs this stop has usually five ranks of pipes, each note having one found in unison with the diapason, one with the principal, one with the twelfth, and one with the fifteenth.

SESQUI-ALTERATE, the greater perfect, which is a triple where the breve is three measures, or femibreves, and that without having any point or dot annexed to it.

SESQUI-ALTERATE, greater imperfect, which is where the breve, when pointed, contains three measures, and without any point, two.

SESQUI-ALTERATE, lesser perfect, which is where the semibreve contains three measures, and that without any point.

SESQUI-ALTERATE, lesser imperfect, a triple, where the semibreve, with a point, contains three measures, and two without.

According to Buontempi, one may likewise call the triples 3, 4, sesqui-altarates.

SESQUI-ALTERATE, in Geometry and Arithmetick, is a ratio, between two lines, two numbers, or the like, where one of them contains the other once, with the addition of a half.

Thus 6 and 9 are in a sesqui-alterate ratio; since 9 contains 6 once, and 3, which is the half of six, over; and 20 and 30 are in the same; as 30 contains 20, and half 20 or 10.

SESQUIDUPPLICATE, in Myci, a concord, resulting from the founds of two flingos, whose vibrations, in equal times, are to each other in the ratio of 3 to 4. See Ditone and Trientail.

SESQUIDUPLICATE RATIO, is when of two terms, the greater contains the less twice, and half the terms remains; as 15 and 6; 50 and 20.

SESQUI-OCTAVE, is a kind of triple, marked C, called by the Italians nonupla di creme, where there are 9 quavers in every measure or bar, in lieu of 8.

SESQUIDUPLICATE, an aspect, or position of the planets, when at the distance of four ligus and a half, or 135 degrees, from each other.

SESQUI-QUARTA, DUPLA, is a kind of triple, marked C, called by the Italians nonupla di feminimin, where there are 9 crotchets in each measure, instead of 4; that is, three crotchets to each time.

SESQUIQUINTILE, an aspect of the planets, when 108 degrees distant from each other.

SESQUIQUINTAL PROPORTION. When any number or quantity contains another once and one-third, they are sesquiquintal proportions.

SESSA, in Biography, an Indian philosopher and mathematician, and the inventor of the game of chefs, which he communicated to his soverign Scheram, who was so pleased with it, that he ordered him to demand what he pleased as a reward for his ingenuity. Sessa asked only for a single grain of wheat to be laid on the first square, two on the second, four on the third, and so on in progression through the sixty-four squares. The king, offended that he should demand so mean a gift, directed that he should have just what he asked, and no more; but upon coming practically to the sixtieth, it was, in a very short time, found that all the grains in the kingdom would not supply the demand. Scheram, aľmoxified at the fact, crowned Sessa with very high honours, He lived about the eleventh century.

SESSA, in Geography, a town of Naples, in Principato Citra; 13 miles S.W. of Caugiano.

SESSA. See ZEFESE.

SESSA, in Botany, a Peruvian genus of plants, dedicated by the authors of the splendid flora Peruviana, to the honour of a Spanish botanist, named Martin Zelleso, to whom the care of the botanic garden at Mexico was entrusted. —Poiret in Lamarc 'Dict. v. 7. 139. "Ruiz and Pavon, Fl. Peruv. v. 7. 9."—Clacs and order, Pentandria Monogyna. Nat. Ord. Liridae. Linn. Solanace, Jull.

Gen.
Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five angles, each angle terminating in an oval tooth, permanent. Cor. of one petal, funnel-shaped; tube as long again as the calyx; throat globose; limb plaited, in five deep, straight, oval segments, revolute at their margin. Stam. Filaments five, inserted towards the middle of the tube, curved and downy at their base, as long as the tube; anthers oval, of two cells. Pij. German superior, small, oblong; style terminal, thread-shaped, the length of the stamina; stigma of two unequal lobes. Peric. Capsule cylindrical, slightly curved, as long again as the calyx, of one cell, and two cloven valves. Seeds numerous, imbricated, oblong, compressed, each encompassed with a membranous border.

1. S. stipula. "Fl. Peru v. 2. 9. t. 115. f. B."—"Leaves lanceolate, or heart-shaped. Clusters panicled."—Native of cool situations, on the mountains of Peru, flowering in June and July. A feedit shrub, five or six feet high, having the apect of a Cæstrum. The branches are straignt, leafy, alternate. Leaves alternate, falked, mostly lanceolate, heart-shaped at the base; others, especially the upper ones, narrower, oval, oblong, entire, pointed, from three to five inches long, and one or two broad, smooth above, white and downy beneath. Stipulas at the base of the footstalks, equal to them in length, opposite, large, oval, obtuse, fellite, a little heart-shaped at the bottom, deflexed at the sides, deciduous. Panicula terminal, composed of straight, downy clusters, with corystome falks, of yellow downy flowers, accompanied by small, awl-shaped, deciduous bracteas.

2. S. dependens. "Fl. Peru v. 2. 9. t. 116."—"Leaves oblong, heart-shaped. Clusters very long, pendulous."—Native of the banks of rivers in Peru, flowering in November, December, and January. A tree, twenty-five or thirty feet high, agreeing in many respects with the foregoing, but the leaves are very powdery at the back, and the clusters very long, fimple, and pendulous, slightly zigzag. The flowers are usually placed three together, in alternate fellite tufts. Calyx powder, Corolla with a black tube, and yellowish limb, externally downy. Capsule black.

Both species are esteemed emollient anodyne. Poir. 

SESI, in Geography, a town of Bengal; 5 miles N.W. of Dofea. N. lat 23° 4'. E. long. 84° 58'.

SESENREUTH, a town of Germany, in the princi- pality of Cumbach; 10 miles N. of Bayreuth.

SESSERY, a town of Hindooflan, in Oude; 15 miles S. of Lucknow.

SESSILE, in Botany, a term applied to any part of the herbage or flowers of a plant, that is not elevated on any kind of stalk; from the Latin sessilis, sitting close. Many plants bear flores sessiles, fellite flowers, on the branches; very few at the root, like Crocus, Colchicum, and Apolytis. It is not unusual for the fructification, though sessile at the flowering period, to become falked as the fruit advances toward maturity. The german is fo usually sessile, as feldom to require to be fo defcribed, it being sufficient to notice a falked ferman, whenever fuch occurs, as affording moftly an im- portant generic character. For folia fessilis, fellite leaves, fee LEAF.

SESSILE Roots, such tuberous roots as adhere to the bafe of the flalk. See Root.

SESSION, Sessio, denotes each sitting, or assembly, of a council.
to advise it himself, or to advise with the whole lords upon it. And it was of the parties think themselves wronged by the sentence of the ordinary, they may complain to the lords, and get their answer upon a bill.

An appeal lies from the court to the house of lords.

The lords of session were first appointed by James I. of Scotland, who selected, among the estates of parliament, a certain number of persons, and distinguished them by this appellation. They were empowered to hold courts for determining civil cases three times a year, and forty days at a time, in whatever place he pleased to name. James IV. on pretence of remedying the irregularities arising from the short terms of the court of sessions, appointed other judges, called lords of daily council. The session was an ordinary court, and met seldom; the daily council was fixed, and sat constantly at Edinburgh; and though not composed of members of parliament, the same powers which the lords of session enjoyed, were vested in it. At half, James V. erected the new court that still subsists, and which he called the college of justice, the judges or senator of which were called lords of council and session. Robertson's Hist. of Scotland, 1776, i. vol. i. p. 40.

Sessions, Kirk. See Kirk.

SESSLACH, in Geography, a town in the duchy of Wurzburg; 50 miles N.E. of Wurzburg.

SESSA, a town of Bengal; 21 miles S. of Dacca.

SESTO, a town of the Ligurian republic; 5 miles N.W. of Brugnetto.

SESTA, half the interval and consonant of the sixth, in Music. See Hexachord, and Hexachordon.

SESTERCE, Sestertiis, a silver coin, in use among the ancient Romans, called also simply nummus, and sometimes nummum septertia.

The sesterce was the fourth part of the denarius, and originally contained two asses and a half.

The sesterce was at first denoted by IIIC; the two I's signifying two librae, and the S half. But the librae, afterwards converting the two I's into an H, expressed the sesterce by HS.

The word sesterce was first introduced by way of abbreviation for semisemisemisemisemisemifemisertium, which signifies two, and a half of a third, or, literally, only half a third; for in expressing a third, it was understood that there were two before. Hence sesterce came to be the great estimate of Roman money.

Some authors make two kinds of sestertii: the less, called sestertii, in the masculine gender; and the great one, called sestertium, in the neuter: the first, that which we have already dervived; the latter containing a thousand of the other. Others will have any such distinction of great and little sestertii unknown to the Romans, sestertius, say they, was an adjective, and signified as sestertius, or two asses and a half; and when used pluraliter, as in quingenarius sestertium, or sestertii, it was only by way of abbreviation, and there was always understood centena, millia, &c.

This matter has been accurately stated by Mr. Raper, in the following manner. The substantive to which sestertius referred is either as, or pondus; and sestertius is to two asses and a half; sestertium pondus, two ponders and a half, or two hundred and fifty denarii. When the denarius padded for ten asses, the sesterce of two asses and a half was a quarter of it; and the Romans continued to keep their accounts in these sestertii long after the denarius padded for six times a denarius; till, growing rich, they found it more convenient to reckon by quarters of the denarius, which they called nummi, and used the words nummus and sestertius indifferently, as synonymous terms, and sometimes both together, as sestertius nummus; in which case, the word sestertius having lost its original significance, was used as a substantivum; for sestertius nummus was the supposed value of a denarius and a half, but a single denomination of four asses. They called any sum under two thousand sestertii to many sestertii in the masculine gender; two thousand sestertii they called desso or dina sestertii in the neuter; so many quarters making five hundred denarii, which was twice the sestertium; and they said dena, vicena, &c. sestertius, till the sum amounted to a thousand sestertii, which was a million of sestertii. But, to avoid ambiguity, they did not use the neuter sestertium in the singular number, when the whole sum amounted to no more than a thousand sestertii, or one sestertium. They called a million of sestertii, decies nummum, or decies sestertium, for decies centena millia nummorum, or sestertiorum (in the masculine gender), omitting centena millia, for the sake of brevity. They likewise called the same sum decies sestertium (in the neuter gender) for decies centia sestertiorum, omitting centia for the same reason; or simply decies, omitting centia millia sestertiorum, or centes sestertiorum; and with the numeral adverbs, decies, vicies, centies, millies, and the like, either centia millia, or centes, was always understood. There were their most usual forms of expression; though for bina, dena, vicena sestertias, they frequently said bina, dena, vicena nummorum. If the consular denarius contained sixty four grains of fine silver, it was worth somewhat more than eight pence farthing and a half shilling; and the iso, of sixteen to the denarius, a little more than a halfpenny. To reduce the ancient sestertii of two asses and a half, when the denarius padded for sixteen, to pounds shillings, multiply the given number by 1543; and cut off the figures on the right hand for decimals. To reduce nummi sestertii, or quarters of the denarius, to pounds shillings; if the given sum be consular money, multiply it by 8727; and cut off the figures on the right hand for decimals; but for imperial money, diminish the paid product by one-eighth of itself. Phil. Trans. vol. I. part ii. art. 48. See Denarius and Drachm.

To be qualified for a Roman knight, an estate of four hundred thousand sestertii was required; and for a senator, of eight hundred thousand.

Authors also mention a copper sesterce, worth about one-third of a penny English.

Sestertii, Sestertius, was also used, in Antiquity, for a thing containing two wholes and a half of another; as at was taken for any whole, or integer.

SESTINI, in History, engaged as a prima buffa in the comic opera, arrived in England from Lisbon in 1755; and her first performance was in Aucocin's comic opera, entitled "La Marchesa Giardiniera." Her face was beautiful, her figure elegant, and her action graceful. Her voice, though by nature not perfectly clear and sweetly toned, had been well directed in her studies, and she sung with considerable agility, as well as taste and expression.

She was married to a young man of family at Lisbon, by which imprudent step he had totally lost all parental favour, and even support; so that, instead of being an auspicious match for herself, she had him and a large family to maintain by her talents; which not being of the first class, were soon disregarded by the public. And after languishing some years unemployed, she went with her helpless husband and family to Italy, where, it is to be feared, they suffered all the melancholy mortifications of extreme indigence.

SESTO, Cesare, known by the name of Cesare Milanese, was a native of Milan, and flourished about the year 1500. He is one of those painters by whom probably were executed some of the many pictures attributed to Leonardo da Vinci; and in the Ambrosian library was a head by him often attributed to Leonardo. In some of his works he also

imitated
imitated Raphael, to whom he was known. He died at Milan in 1524.

Sesto, in Geography, a town of Italy, in the Milanese; 28 miles W.N.W. of Milan.—Alfo, a town of Italy, in Friuli; 5 miles N. of Concordia.

SESTOLA, a town of Italy, in the department of the Pararo; 17 miles S. of Modena.

SESTOS, a fortress of European Turkey, in the province of Romania, opposite to Abydos; 24 miles S.S.W. of Gallipoli. N. lat. 40° 6'. E. long. 26° 25'. Abydos (which see) and Sefos were two towns, opposite one another at the most narrow part of the Hellepont: they were famous for the love-adventures of Leander, who lived at Abydos, and Hero, a priestess of Venus, at Seftos. Leander swam across the Hellepont to visit his mistress, guided by a torch, which he lighted on the top of a tower; but, in a tempestuous night, Leander, having too imprudently committed himself to the waves, could not reach the other shore, and was unfortunately swallowed up by the agitated waves. Hero, in true despair, threw herself into the sea, in order to share the fate of her lover. Propocapis places Seftos in the cove the nearest to Abydos; and he adds, that the emperor Julianian caused a citadel to be built near that city: the remains of this citadel are still to be seen on the east-fore. On the declivity of the hill, the walls of the ancient city may very easily be traced. Four miles from Seftos, on ascending the渠道, is another harbour, near which is seen only a single habitation of derelicts, occupied by three or four Mussulman monks.

Sestos, a river which rises in the mountains of Sierra Leone, traverses the Grain Coast, and runs into the Atlantic, N. lat. 5° 30'.

SESTRE, Grand, or Great Paris, a town of Africa, on the Grain Coast, being one of the largest commercial towns of the country. N. lat. 4° 10'. W. long. 8° 20'.

SESTRE, Petit, or Little Paris, a town of Africa, on the Grain Coast, near Grand Sefite.

SESTRE-KRO, or Settra-Kroo, a town of Africa, being the chief town of the Kroo country, which extends along the Grain Coast, between Cape Mount and Cape Palmas, from 5° 34′ to 5° 7′ N. lat. The chief town is in long. 7° 48′. This district, though small, is extremely populous, and the natives are of a migratory disposition. Above 800 are employed as labourers at Sierra Leone; and they are to be found at every factory and town along the coast for a space of 350 miles. They are employed as factors or intermediate merchants, boatmen and sailors; and while the slave trade was carried on upon this coast, they had their share of its occupations. After the age of forty, they return and settle at home. Their country produces grain, particularly rice, pepper, and cattle; but their staple article is their own labour, with which they purchase goods, and return to their homes with the produce. Wars are rare among these people; they never fell one another, nor kill their captives; nor do they punish any offence by slavery, though witchcraft among them is a capital offence, and the only one that is invariably so among them. One of the most singular parts of the character of the Kroomees, is their extreme love for their own country, and their confident belief in its vast superiority over all others. Every action of their lives bears a reference to it. With regard to their talents and acquirements, they are sufficiently acute and observant, where the occasion calls their minds into action. They have not the use of letters, nor will they permit their children to learn; their language in conversation is very bad; and as they live by daily labour, which is paid for in European goods, they have no occasion for manufactures of their own, and of course no opportunity for displacing their talents. They make their own canoes, some implements of agriculture, and a few musical instruments.

SESTRI di Levante, a town of the Ligurian republic; 12 miles W. of Brugnetto.

SESTRI di Ponente, a town of the Ligurian republic; 4 miles W. of Genoa.

SESTUPLA, in Majic. See SEXTUPLA.

SESVAH, or Ramour, in Geography, a town of Hindoo land, in Bahar; 22 miles E.S.E. of Bettinah.

Gen. Ch. Cal. Periath inferior, of one leaf, bell-shaped, deeply cloven into five, ovate, acute, withering segments, coloured on the inside. Cor. none. Stam. Filaments numerous, sub-lilaped, shorter than the calyx and inferted at its base; anthers roundish. Petals German inferior, oblong, at the bottom of the calyx, triangular at the upper part; styles mould three, capillary, erect, the length of the flaments; filaments simple. Peric. Capule ovate, of three cells, burrowing all round. Seeds rounded, flatshaped, with a beak at the margin.

1. S. Portulacolstrum. Purflane-leaved Sewsvium. Linn. Sp. Pl. 684.Jacq. Amer. 95. (Portulaca alozoides maritima procumbens, flore purpureo; Sloane Jam. v. 1. 204. Crithimus indicus; Rump. Amboin. v. 6. 165. t. 72. f. 1.)—Stem round. Leaves opposite, oblong. Flower-flake solitary, much shorter than the leaves.—Native of the West Indies, in maritime situations; flowering in July and August.—Root perennial. Stems succulent, four or five inches long, round, thick, diffus, branched, at first procumbent, then erect. Leaves on short stalks, feathery, bright green; their stalks feathery, with membranous edges. Flowers solitary, axillary, green on the outside, white and blood-red or purple on the inside, inodorous. Seeds black.—The whole plant is very succulent, and abundant with a neutral-alcalieent salt, which is easily extracted, and would probably serve as a subtitute for Kail.

SET, a term used for a pole or shaft, used to shove boats along a canal, &c.

Set is also a term signifying to let, as land.

Set, in Agriculture and Gardening, a term used in Ireland to signify a fort of ridge. It also signifies a cutting of any fort of feathery root, flax, or tree of the fruit kind. Likewife any fort of young plant from the feed-bed to be planted out.

SET-off, in Law, is an a€, by which the defendant acknowledges
SET

knowledges the justice of the plaintiff's demand on the one hand; but, on the other, sets up a demand of his own, to counterbalance that of the plaintiff, either in the whole, or in part; as, if the plaintiff sues for ten pounds due on a note of hand, the defendant may set-off nine pounds due to himself for merchandise sold to the plaintiff; and, in case he pleads such set-off, must pay the remaining balance into court. This answer very nearly to the *compensatio*, or hagglmage, of the civil law, and depends upon the statutes 2 Geo. 11. cap. 22. and 8 Geo. 11. cap. 24.

SETCHOU, or Setchen, a town of Africa, alyently called Sinthi, and capital of a part of Mauritania, which made a stout resistance against the Saracens. There is scarcely any fragment left, either of the ancient walls, pillars, or columns of the Romans; the few remaining structures being obviously the work of the later inhabitants. The fountains, which continue to flow very plentifully near the centre of the city, are equally delightful and convenient; and without doubt gave occasion formerly for many ingenious and useful contrivances in the distribution of the water; 50 miles S.W. of Concastante. N. lat. 35° 58'. E. long. 5° 36'.

SETECUT, or SETHERA, a town of Africa, on the Grain Coast.

SETHIAH, SETHIANS, SETHIAN, or Sethianus; an Eclectic History, a branch of the ancient Gnostics; thus called, because of their pretending to deduce their origin from Seth, son of Adam, whom they called Jesus and Christ; from an opinion, that Seth and Jesus were the same person, who came down from heaven at two several times.

As the Sethians had the same philosophy with the other Gnostics, they had numerous other names in their system. They pretended to have several books of the ancient patriarchs; particularly, seven of their great master Seth; besides one of Abraham, which was full of manifest futilities, which yet they called Apocalypsis, or Revolution. The book called the "Little Genesis," anciently very common in the churches of the East, was borrowed from them. From this book they learned the name of Seth's wife, who, they say, was called Horei. Some imagine, they borrowed a great many of their fictions from the Hellenist Jews.

SETHRON. in Geography, a town of Egypt, on the S. coast of the lake Mentach ; 16 miles W. of Tmhe.

SETHON, in Geography, a mountain in the E. part of the Tyroles. SETULANA, a town of Hindoostan, in the circom of Siroy; 35 miles N.W. of Siroy.

SETELLE, a town of Turkish Armenia; 30 miles S.W. of Akalzikey.

SETELLE, a river of Hindoostan, which rises in the mountains of Thibet, and runs into the Indus, near Veh, anciently called Hesmarus.

SETON, a river of Spain, which runs into the Gallego, in the province of Aragon.

SETON, Setuxum, denotes, in Surgery, a sheen of silk or thread, introduced through a part of the flesh by means of a needle, and left there to keep up a continual discharge of matter, and a degree of counter-irritation, with a view of relieving or curing a variety of diseases. In a few cases, fetons are employed on another principle. When sinuses and fistulae have lost all disposition to heal, in consequence of a want of action in the parts affected, a feton, passed through the track of the diseaee, will sometimes excite a salutary kind of inflammation, which brings on the healing process. Great judgment, however, is necessary in the application of a feton for this purpose; for, unless the fistula be prevented from healing merely by the caufe above specified, namely, a want of action in the parts, no success can be expected to attend the practice, and the patient will be put to much unnecessary pain and inconvenience.

A feton is also sometimes employed as a means of discharging X x 2 charging
charging the contents of large chronic abscesses. It is thought by some practitioners that this method has the advantage of letting the matter escape very gradually, a circumstance, by which the dangerous effects, often arising from emptying the abscesses all at once, are in a great measure avoided. Many surgeons even suppose that fevers hinder the external air from getting into the cavity of the abscesses, and, as prejudice and exaggeration have filled their minds with fictitious apprehensions upon this subject, they are perhaps more attached to the practice than any recommendations which it really possesses would justify.

Formerly, fevers were frequently used for accomplishing the radical cure of the hydrocele. The celebrated Mr. Pott was an advocate for this method, which he certainly brought to great perfection. It is scarcely necessary for us to remark here, that the fevers excited the requisite degree of inflammation in the cavity of the tunica vaginalis tectis, and the adhesion of its opposite surfaces to each other. See HYDROCELE.

The common mode of making a fever is with a flat broad flat needle, which is somewhat curved towards the point, and furnished with cutting edges. This form enables the surgeon to bring the needle out of the part again without any difficulty. The incisions are pinched up into a fold, of which the operator raises one end with the fore-finger and thumb of his left hand, while an ailant raises the other. The needle, armed with the filk or thread dipped in sweet oil, is then to be pushed through the skin thus lifted up. It is only necessary to draw the end of the filk or thread a little way out of the fecond aperture: the needle may now be removed. The next object is to fix the ends of the filk, which is usuallly done with adhesive plaster. The wounds are then to be covered with plasters, and a retentive bandage. The oil prevents the skin from adhering to the feff, and facilitates its paffage through the wound; for, as soon as suppuration has taken place, that part of the filk which is in the wound is to be drawn out and cut off. The fame method is to be repeated every day, and the fame plan of dreffing continued. When the skin of filk is exhausted, a new one, oiled in the above manner, is to be introduced by means of an eye-probe.

Settons, unless kept exceedingly clean, and drest with much tenderness, sometimes excite a great deal of irritation, and prove very troublesome to the patient. The thread is also apt, with the leaff neglect, to cut its way out, and leave an ugly sore.

When a fever is made in a cafe of large chronic abscesses, a puncture is first made in the upper part of the tumour; an eye-probe, armed with a feck of filk, is introduced downward; and the end of the instrument being felt against the inside of the lower part of the swelling, an incision is made upon it, so that the end of the filk can then be drawn out.

The manner of making a fever for the cure of hydroceles has been described in a former volume. See HYDROCELE.

The like operation is frequently practiced on hordes, &c. and called, by the farriers, rowelling.

SETOSCH, in Geography, a town of Bohemia, in the circle of Chrudim: 8 miles S.S.W. of Chrudim.

SETRA-JETA, the name, in Hindoo romance, of the father of one of the favourite wives of the popular deity Krishna. Her name was Satyavama; and she is sometimes said to have been an incarnation of Lakshmi, consort of the god Vishnu. See those articles.

SETS, in Agriculture and Gardening, a term applied to the cuttings or planted parts of potatoes, hops, liquorice, lavender, &c. It has lately been found to be of material consequence for the fets which produce the plants, in some cafes, to have a large sufficiency for their early nourishment and support, as in theofe of the potato; as though the small parts, called eyes or buds, will grow and produce crops, they are far from being equit thumbs when the fets of a large size. In short, the result of various experiments has shown that crops of this fort prove, ceteris paribus, abundant or otherwife, nearly in proportion to the fize of the fets. Therefore, as there is no material faving produced by the ufe of small fets or cuttings of this root, while the difference in the quantity of produce is from one hundred to one hundred and fifty fiftles the acre, the practice of employing fuch small fets in planting should be discontinued in all situations; and for the very fame reafon that heavy well-fed corn, when otherwise in good condition, should, in all cafes and circumstances, be preferred to that which is light. See POTATO and Seed.

SETSE, in Botany, the name of a Chienefe tree, called alo chifta, and much efteemed by the people of that country for its beauty, and for the goodnefs of its fruit. In the provinces of Canton and Honan there are whole plains covered with thefe trees, many of which grow to the fize of our walnut-tree. The fruit ripens every where in the Ealt, where the tree grows, but it is of a much more delicious flavour in fome places than in others. The leaves are of the colour and fhape of thefe of our walnut-tree, only that they are more round at the ends. The fruit is fometimes round, fometimes pointed at one end, fometimes oval, fometimes flat, and not unfrequently composfed of two pieces, as it were, and resembing two apples, cut and joined together. The rind is always green, never changing yellow or red, and the fruit keeps its freshness all the winter. They are about the fize of the orange, and the skin is very tender and thin, and the fruit has a mixed taste of the sharp and the luscious. It is very wholesome and good.

SETTE'S, in Geography, a town of Africa, and capital of a country the fame name, fubjet to Loango, on the river Sette: 160 miles north of Loango.—Alfo, a country of Africa, south of cape Lopez Gonfalvo, watered by a river of the fame name. This country is gouverned by a mani, who is fubjet to the king of Loango.—Alfo, a river of Africa, which runs into the Atlantic, S. lat. 2° 15'.

SETTEE, in Sea Language, a veftel, very common in the Mediterranean, with one deck, and a very long and sharp prow. They carry, fome two mafts, fome three, without top-masts. They have generally two mafts, and are rigged and navigated like xebecs or galleys, with fetteis flats instead of lateen falls. The leaff of them are of fixty tons burden. They ferve to transport cannon, and provisions for ships of war, and the like. These veffels are peculiar to the Medi-terrannen fea, and are ufually navigated by Italians, Greeks, or Mahometans.

SETTEFRAtri, in Geography, a town of Naples, in Abruzzo Ultra, 10 miles N. E. of Teramo.

SETTENIL, a town of Spain, in the province of Grenada; 8 miles N. of Ronda.

SETTER, among Farmers. To fetter, is to cut the dew-hairs of an ox, or cow, and into the wound to put the root of the helleborafter; by which an iffe is made, for ill humours to vent themfelves.

SETTER-Wort, in Botany. See HELLEBORE.

SETTIA, in Geography, a province of the ifland of Candia, occupying the whole eastern part of the ifland; it is the moft extensive, but the leaff peopled, and the leaff productive,
producing, though in a great measure susceptible of culture, and though most of its lands are very fertile. But distance from the capital, want of harbours, and the incen- dative injustice of the ages, and almost every other circum- stance, contribute to render the inhabitants of this part of the island more indolent than the others. Contented with gathering corn and fruit for their subsistence, oil for paying their taxes, and procuring for themselves a few clothes, and the utensils necessary for their family, they are not eager to seize from the earth a surplus of productions, which would render them more subject to the oppression and foliation of the ages. The town is situated on a flat shore, with a cape not much advanced, and three hills placed at upwards of a league's distance, protect it feebly from the N. and N.E. winds. When the Venetians were masters of the island, it was tolerably well fortified, and sufficiently peopled. They constructed a mole, in order to shelter the vessels which came thither to load with the productions of the province, or which brought those that were necessary to supply the wants of the inhabitants. At this day none but small boats may be seen at Settia. The popula ction has diminished considerably, and the fortifications are in the greatest disorder. It is the fee of a Greek bishop; 44 miles E.E. of Candia. N. lat. 35° 3'. E. long. 16° 3'.

SETTIAVERAM, a town of Hindostan, in the cir- car of Ciaccole; 30 miles S.W. of Coimicotta.

SETTIMA, ItaL., in Music, the interval of the seventh; which fee.

SETTIMANA Santa, ItaL, passion-week, during which holy time, the sacred music of the highest class used to be performed in the most perfect and impressive manner in the pontifical chapel. See Miniserka and Allegro.

SETTIMO, in Geography, a town of France, in the department of the Po; 8 miles N. of Turin. — Alfio, a town of Italy, in the department of the Tefino; 5 miles N.E. of Pavia.

SETTING, in Astronomy, the withdrawing of a star or planet; or its sinking below the horizon.

Astronomers and poets make three different kinds of setting of the stars: coelical, aeronical, and helical.

To find the times of the setting of the sun and stars, see Globe.

Setting, in Seamanhip. To set the land, or the sun, by the compass, is to observe how the land bears on any point of the compass, or on what point of the compass the sun is; likewise the act of observing the situation of any distant object by the compass, in order to discover the angle which it makes with the nearest meridian: as at seven pole meridian, we set the tower of Arabia near the port of Alexandria, and it bore S.E. distant four leagues by elimation. (See Bearing.) Also, when two ships fail in sight of one another, to mark on what point the chafed bears, is termed setting the chase by the compass.

Setting also denotes the direction of the wind, current, or sea, but particularly the two latter; as, the tide, which sets to the south, is opposed to a swelling sea, setting to the north-west.

Setting, when applied to the sails, is the loosening and expanding them, so as to give the ship motion, or to acce- lerate her velocity, when she is already moving, and perhaps give a new direction to her motion. It is used in contra- distinction to taking-in the sails, as loosening or heaving-out is opposed to furling or flowing them.

Setting, in the language of Sportsmen, a term used to express a manner of attacking partridges, in order to the taking of them by means of a dog peculiarly trained to that purpose. The setting dog generally used is a large land-spaniel, taught by nature to hunt partridges more than any other game, and in his unsought state running over the fields in search of them, with an alacrity that is truly wonderful; yet by art this creature is taught under such excellent command, that he will, in the midst of his highest career, attend to the least hint from his master, and stand still to look in his face, and take his orders by the slightest signals; and when he is, to near his game, that it is almost in his mouth, he will stand still, or he soon on his heels till his master arrive, and he receives his directions.

The setting-dog being taken to the haunt of the partridges is to be call off, and sent to range; but he must be made to keep near the sportsman, and not to run wildly on, but to beat all the ground regularly. On being reproved for ranging too widely and too fast, he will keep close the whole day, and at times look up in his master's face, to know if he does right or wrong. If in the dog's ranging he drop of a sudden, the sportsman is to make up to him, and as there is certainly game before him, he must be ordered to advance; if he refuses this and book back and shake his tail, it is a signal that they are close before him, and the sportsman is then to take a circumference, and look with a careless eye before the dog's nose to see where they are, and how they lie; then going up, and faking down one end of the net, he is to command the dog to lie still, and to draw the net gently over the birds; then making in with a noise, he is to spring them, and they will be en- tangled and taken as they rise. It is a rule with fair sports- men, when they take a covey in this manner, always to let the cock and hen go.

Setting, among Cock-Masters, is the placing a cock that has fought so that he cannot stand, beak to beak against the other cock, and if he does not strike, the battle is won.

Setting-down, in Falconry, is when a hawk is put into mew.

Setting-dog, one trained up to find out and discover for the sportsman whereabout fowls are. See Spaniel and Dog.

Setting-up, in Ship-Building, is raising a ship by shores and wedges from her blocks, the act of extending the shores, flats, and back-flats, to secure the masts, by the application of tackles, &c.

Setting, or Setting-is, the act of making the planks, &c. lay or set cleve to the timbers, by driving wedges between the plank, &c. and wrench-flatt. Hence "set, or set away," means to exert more strength. The power or engine used for this purpose is simple, and called a fet, and is composed of two ring-bolts, and a wrench-flatt, cleats and lashing, or flares.

Setting, in Agriculture and Gardening, the business of putting lots of different kinds into the ground, as those of the potato, hop, madder, liquorice, lavender, and many other kinds.

Setting out Plants, the practice of thinning and reducing them; in the former, to their proper distances, in order to stand for crops, as in the turnip, cabbage, and many other sorts of plants; and, in the latter, the business of putting them into the ground as crops; it being practiced for a great many different sorts of plants that are raised on feed- beds, as all the cabbage kind, lettuces, endives, beets, and many other plants of a similar nature. It is usually performed as soon as the plants have acquired a proper state of growth in the feed-beds, and mostly when the weather is cloudy and rather moist, as it can then be done to the greatest
greatest advantage, in so far as the plants are concerned. They are commonly put out in this way to the proper distances for growing as crops, and the work is for the most part done by means of a line and dibble. See THINNING out CROPS, and TRANSPLANTING.

Setting of Wheat, is a method of cultivating wheat, which was probably first suggested by planting grains in a garden from mere curiosity, and first attempted on a larger scale by a farmer near Norwich, about the year 1768. His example was followed by some of his neighbours, and particularly by one of the largest occupiers of land in the county of Norfolk, who set fifty-seven acres in one year. His success, from the visible superiority in his crop both in quantity and quality, was so great, that the following autumn he set three hundred acres, and afterwards continued the practice. The method of setting was generally introduced, in consequence of this experiment, among the intelligent farmers, in a very large district of land. And it has been observed, in recommendation of it, that, although the set crops appear very thin during the autumn and winter, the plants tiller and spread prodigiously in the spring. The ears are indubitably larger, without any dwarfish or small corn; the grain is of a larger fathom, and specifically heavier per buchel than when town. It furnishes employment for aged persons and children, at a season when they have little else to do; it favours to the farmer fix pecks of seed-wheat in every acre; the expense is already reduced to about five shillings an acre; and a drill-plough has been invented, by which one man may let an acre a day.

The lands on which this method particularly succeeds, are either after a clover stubble, or those on which trefoil and grås-feed were sown the spring before the fall, and on which cattle have occasionally pastrised during the summer. These grounds, after the usual manuring, are once turned over by the plough in an extended fall or turf, at ten inches wide; along which a man, who is called a dibbler, with two setting-irons, somewhat bigger than ram-rods, but considerably bigger at the lower end, and pointed at the extremity, leaps backwards along the turf, and makes the holes about four inches afunder every way, and an inch deep. Into these holes, the droppers (women and children) drop two grains, which are quite sufficient. After this, a gate, bushed with thorns, is drawn by one horse over the land, and closes up the holes. By this mode, three pecks of grain are sufficient for an acre; and being immediately buried, it is equally removed from vermin, or the power of frost. The regularity of its rising affords the best opportunity of keeping clear from weeds, by weeding or hand-hoeing.

Setting, a term used in sheep management, which signifies the picking, checking, and selecting those which are the best formed, and most perfect for the purposes of breeding, forming the flock, and keeping as stock; the others, or the refuse ill-formed sheep, being sold off, or lent to be fattened in the proper pastures. The practice is extremely useful and necessary, where good stock of this kind is aimed at, as it cannot be well obtained without it. See SHEEP, and SORTING SHEEP-STOCK.

Setting Lamb-Stock, a term made use of to signify the practice of culling and removing those lambs, which are any way improper for being kept as stock. It is an excellent custom in sheep-management, which should be as seldom as possible neglected.

Setting of Farms, the business of letting them to tenants of different kinds. Much care and attention are necessary in the management of this business. See LETTING FARMS.

Setting of Bricks. See BRICKS.

Setting-Pin, the name of a dibble or setting-tool.

Setting-Stick, the flick used in setting out plants or cuttings as field crops, and in putting in and planting out those used for garden culture.

SETTLE, in Geography, a market-town in the parish of Giggleswick, wdd division of the wapentake of Staincliffe and Ewecroft, West Riding of Yorkshire, is situated at the distance of 58 miles W. by N. from York, and 323 miles N.W. by N. from London. The position of this town, though singular, is pleasant, standing close to the base of an almost perpendicular limestone rock, about 350 feet high; from the summit of which is a fine prospect on a commanding vale, bounded on all sides by craggy mountains. This vale, which is watered by the river Ribble, and hence has acquired the appellation of Ribblefdale, is not surpassed by any in England in richness of verdure. As the prevalence of fogs and rains prevents the ripening of corn, it is almost wholly appropriated to pasturage; and fitch is its fertility, that the greater part of it rents as high as six pounds an acre. According to the parliamentary returns of 1811, Settle township contains 274 houses, and 1153 inhabitants, who are chiefly engaged in the cotton manufacture, and in the pursuits of husbandry. Like most of the other towns and villages in this district, it is principally built of stone, brick being used only for the chimneys. The market day here is Friday, weekly; and the fairs are on Tuesday before Palm Sunday, Thursday before Good Friday, and every alternate Friday till Whit Sunday, 26th April, 2d June, 1st August, 1st Tuesday after 27th October, and every other Monday throughout the year. These fairs are generally well attended, and are noted for large supplies of cattle.

About a mile to the N.W. of Settle is the village of Giggleswick, which gives name to the parish, and where the church is accordingly situated. This village is remarkable for an excellent free grammar-school, founded in the reign of Edward VI., and supported by rich endowments in land. At present the salary of the master is 50l. per annum, that of the usher 20l., and that of the writing-master 15l. per annum. The school is situated in a good house, garden, and every convenience for a comfortable dwelling. Near Giggleswick is a spring, which exhibits the singular phenomenon of a constant influx and reflux of its waters at irregular periods, sometimes thrice or oftener in an hour. No satisfactory explanation of this singularity has yet been offered to public notice.

At the distance of several miles further to the N.W. from Settle, on the road to Kendle in Westmoreland, stands Ingleton, a large village, the vicinity of which presents many objects worthy the attention of the admirers of romantic scenery. Among these are Thornton-Scar, Yorond Cave, and Weathercote Cave, and the mountains of Ingleborough, Pennignant, and Wharfnnde. Thornton-Scar is a tremendous chasm, above 300 feet in depth, which extends a considerable way into the mountains, and is so narrow towards the bottom, that the sides in some places approach within a few feet of each other. Yorond Cave is situated under a mountain, called Greg-roof. It is entered through a rude arched opening, resembling the gateway of an ancient caille, and extends about 170 feet in length, 40 in breadth, and 48 in height. On one side are several recesses, and the roof and walls exhibit a variety of petrifications. Weathercote Cave displays, in every still more romantic and sublimine nature, a form, and divided into two by a grotesque arch of lime-stone rock; the total length about 200, and the breadth about 90 feet. At the fourth
fourth end is an entrance down into a small cave, which communicates with the larger one by a subterranean passageway, "where the abundant resultant fosse, fluming from a large aperture in the rock, an immense cataract, falling above 20 yards in an unbroken sheet, with a noise that drowns the ear. The water disappears as it falls from the rocks and pebbles, and runs about a mile under ground. The whole cave is filled with the spray that arises from the cataract, and sometimes a small vivid rainbow appears, which, for colour, size, and situation, is scarcely any where else to be equalled."

"That the most sublime features of this romantic district are the mountains of Ingleborough, Penningant, and Wharnside. The summit of Ingleborough is level and horizontal, and, from its great elevation, commands extensive prospects on all sides. To the east, the picturesque country of Craven presents 9 confluent affluent of hills, gradually diminishing in height till they vanish in the horizon. Penningant, at the distance of four miles, appears to be almost within a leap; as do also the rocks of Settle and Pendlehill. The northern and north western prospect exhibits a mass of mountains. Wharnside is within the distance of six miles, and Snowdon and Coflmer are clearly visible in the back ground. Towards the west the flat country of Lancashire lies as a map, and the prospect extends far into the Irith sea. the nearest point of which is 24 miles from Ingleborough. Beauties of England and Wales, vol. xi. by John Bigland, 8vo. 1816."

SETZINI, in Geography, a town of Poland, in the palatinate of Sandomirr: near it are some silver mines, and some lapiz-lazuli; 16 miles W. of Malpocez.

SEV, a river of Russia, which runs into the Dufna, near Trubchevsk, in the government of Orlov.

SEU, a river of Malaece, which runs into the Chineke sea, N. lat. 6° 45'. E. long. 10° 19'.

SEVAJEE, in Biography, a distinguished person in the history of Hindoostan, the founder of the modern Mahatta empire, was the son of Shawjee, who, from an humble situation, had raised himself by his talents to be guardian to a minor of the house of Nizam Shah. On a Mogul invasion of the country, being clothed pursu by the troops of his father-in-law, Jadoor Row, with whom he was in enmity, Shawjee escaped with an infant son, and left his pregnant wife to fall into the hands of her father. She was kindly received, and was delivered of her second son, Sevajee, the subject of this article, in the month of May 1626, and finally separated from her husband.

Sevajee, at the age of 17, placed himself at the head of a body of bandits, who pillaged all the neighbouring districts, which so affected the person who had been entrained with the care of his education, that he put an end to his life. Upon this, Sevajee took possession of the property accumulated from his father's estate, and increased the number of his followers, so as to become a most formidable free-booter. His exploits soon rendered him dangerous to the government of Vitiapour, which sent a powerful army against him, and brought him to submission. Sevajee asked pardon for his offences, and, by the humility of his deportment, threw the general, sent against him, off his guard, till he found an opportunity to stab him to the heart with a concealed dagger: in consequence of which the army disperled. Shawjee, the father of this desperate young man, was now high in office at Vitiapour, and though he pretended entirely to have renounced his son, a correspondence between them was suspected, and a plan was formed for seizing his person, and putting him to death. He was, however, saved by the intercession of a patron, and at length released to office. But he was resolved to have ample revenge for the affront, and caused Sevajee to murder the chief who had feized him, and his whole family. After this Shawjee paid a visit to his son at Poona in great state, and manifested much affection and respect for him.

Sevajee now proceeded in a career of successful predatory war, and in 1664 pillaged the rich city of Surat. Having, in 1672, laid the king of Golconda under a heavy contribution, he afterwards entered into an alliance with a potentate against the Mogul and the king of Vitiapour, the object of which was the expulsion of all the Mahometan powers from the Deccan; and marching with a great army, in 1677, towards Golconda, he took possession of many fortresses,
fortresses, and pillaged the whole country. His half-brother, Eccojce, was now king of Tanjore; and the different branches of the family were possessed of a large portion of the south of India.

The principal dominions of Sevaje were in the tract called Concan, extending from the south of Surat to the south of Goa, which rendered him completely master of the western Gatts; from which he was, at all times, able to inflame and ravage the plain country, while it was impof- sible to force him from his fastnesses; hence he was denounced by Aurungzebe the mountain rat. Sevaje continued this course of action till his death in 1680, when he was succeeded in his conquests by his son Sambajee.

SEVANI, in Geography, a town of Persia. Armenia, on a lake; 40 miles E. of Erivan.

SEVASTOPOL, a sea-port town of Russia, in the province of Tauris, on the coast of the Black sea, with an excellent harbour for men of war; 80 miles S. of Perektop, N. lat. 44° 45'. E. long. 33° 24'.

SEUOBELSROD, a town of Germany, in the principality of Culmbach; 6 miles N. of Culmbach.

SEUBITZ, a town of Germany, in the principality of Culmbach; 8 miles S.E. of Bayreuth.

SEUCKENDORF, a town of Germany, in the margin-gravate of Anspach; 4 miles E. of Langenzenn.

SEUDRE, a river of France, which runs into the sea, opposite the island of Oleron, N. lat. 45° 49'. W. long. 1° 5'.

SEVE, a town of France, in the department of the Seine and Oise, celebrated for its manufacture of china; 15 miles S.W. of Paris.

SEVEKTON, or SEVEKOTE, a town of France, in the department of the Lys; 10 miles S.W. of Bruges.

SEVEN, a river of Yorkshire, which runs into the Derwent.

SEVEN AYES, rocks in the Caribbean sea, near the S.E. coast of the island of Blanca.

SEVEN BROTHERS, a cluster of small islands near the north coast of Hifpaniola. N. lat. 19° 53'. W. long. 72° 35'.

SEVEN CAPES. See SEBSA REAS.

SEVEN HEADS, a promontory of the county of Cork, Ireland, west of Courtmasherry bay, and 6 miles W.S.W. of the old head of Kinfale. N. lat. 51° 34'. W. long. 8° 41'.

SEVEN, a cluster of small islands in the East Indian sea. S. lat. 5° 9'. E. long. 105° 21'.

SEVEN ISLANDS, a cluster of islands in the north coast of Sumatra, lying off Padang.

SEVEN ISLANDS, a cluster of small islands in the English Channel, near the coast of France. N. lat. 48° 54'. W. long. 3° 23'.

SEVEN ISLANDS, a republic so named, lately formed by the union of the islands of Zanzé, Cephalonia, Corfu, Cé- rigo, Curzola, St. Maura or Leucadia, and Teskii, constituted about the year 1799, acknowledged by the Ottoman Porte, and by the French and Great Britain, at the peace of Amiens, 1802.

SEVEN ISLANDS, small islands of Virginia, in James river. N. lat. 39° 40'. W. long. 75° 32'.

SEVEN ISLANDS, a cluster of small islands near the coast of Canada, in the gulf of St. Lawrence. N. lat. 50° 10'. W. long. 66° 5'.

SEVEN ISLANDS' BAY, a bay of Canada, on the north side of the river St. Lawrence. N. lat. 50° 5'. W. long. 66° 25'.

SEVEN PAGODAS, a town of Hindoostan, in the Carnatic; 30 miles S. of Madras.

SEVEN ROCKS' POINT, a cape in the English Channel, on the coast of Dorsetshire; 3 miles S.W. of Lyme Regis.

SEVENAER, or ZEVENAER, a town of Germany, in the ducy of Cleves; 10 miles N. of Cleves.

SEVENBERGEN, a town of Dutch Brabant; 8 miles N.W. of Breda.

SEVENNES, or SEVENSEN, mountains of France, crowning the department of the Lozere, particularly mem- orable as being the strong hold of the Protestants in the 17th century, and beginning of the 18th.

SEVENOAKS, or SEVENOKE, a market-town, in a parish of the same name, hundred of Codheath, lathe of Sutton at Home, and county of Kent, England, is situated on high ground at the distance of 16 miles W. by N. from Maidstone, and 33 miles S.E. from London. In the Textus Roffensis the name is written Seuanancca, and is said to have been suggested by the circumstance of a cluster of seven large oaks growing on the site of the town, at the time of its foundation. The principal building here is the church, which forms a conspicuous object for several miles round the country. It formerly contained a chantry chapel, founded by Sir Henry Gawdy, who was buried within it. The only monument of note is that of William Lambarde, the celebrated Kentish antiquary, whose family had a seat in this parish. Here are an almshouse and free-school, originally built and endowed by Sir William de Sevonceke, in the beginning of the 15th century. They were subse- quently incorporated under the title of the free grammar-school of queen Elizabeth, and now provides a revenue of nearly 1000l. a-year. The school-house was rebuilt in 1727, at which time the alm-shouse was substantially re- paired. The former has fix exhibitions to either university, and the latter affords an asylum to thirty-two elderly trades-people, who have a weekly allowance in money. This town consists chiefly of two wide streets, in one of which stands the ancient market-house, where the alshouses were frequently held during the reign of queen Elizabeth, and where the petty fellions for the lathe of Sutton at Home are still held. Many of the houses are large and respectable mansions, inhabited by independent families. The market- day here is Saturday, weekly; and there are two annual fairs on the 10th of July and the 22d of October. Seven- oaks town and parih constitute a liberty, governed by a warden or baliiff and four jjaffiliants, who are not, however, empowered to hold any court of record for pleas. Ac- cording to the parliamentary returns of 1811, this liberty contains 638 houses and 3444 inhabitants, of whom about 1500 reside in the town. History and Topographical Survey of Kent, by Edward Hallett, 8vo. 1797, vol. iii. Beauties of England and Wales, vol. viii. by E. W. Bray- ley, 8vo. 1805.

SEVENTH, SEPTIMA, in Mefo, an interval, called by the Greeks heptachordon; of which there are four kinds.

The first, the defective or diminished seventh, consisting of three tones, and three greater semitones, as from H sharp to F flat: its ratio is 128 to 75. The second, called by Zarzini, and the Italians, semiditona con diapente, or settino minor, is composed dionotically of few degrees; and fixes intervals, of which are tones, and the rel. greater semitones, as from de to re; and chromatically of ten semitones, of which are greater, and four les: it takes its form from the ratio quadripartitae quintas, 9 to 5. The third, called by the Italians il ditono con diapente, or set- tima
...is composed diatomically, like the former, of seven degrees, and six intervals, five of which are full tones, and a single one a greater, or diminished, tone; so that only one greater tone is wanting of the octave; as from 3 to \( 7 \) flat, and chromatically of eleven tones, six of which are greater, and five lesser. It takes its origin from the ratio of 15 to 8.

The fourth is the redundant seventh, composed of five tones, a greater tone and a lesser, as from \( 3 \) flat to \( 7 \) flat: so that it only wants a comma of an octave; that is, so much as it wants to render its second femitone a greater. Hence many confound it with the octave itself; maintaining, with good reason, that only the three first sevenths can be of any use.

In thorough bass the seventh, whether double, simple, major, or minor, is marked by a figure of 7; but if it be accidentally flat, or minor, thus, 6, or 7. If sharp, major, thus, \( 2 \) and 7. Again, if it be naturally minor, it be marked with a flat, it must be diminished.

See FUNDAMENTAL.

SEVERAC-le-Châtel, in Geography, a town of France, in the department of Aveyron, and chief place of a canton, in the district of Milhaux; 21 miles E. of Rodès. The place contains 2,113, and the canton 6,651 inhabitants, on a territory of 212 square kilometres, in 7 communes. N. lat. 46° 19'. E. long. 3° 9'.

SEVERAL, in Agriculture, the same as beole. See DOLE.

SEVERAL Tail, or Inheritance, in Law. See Inheritance.

SEVERANCE, Tenancy, Tenurial separatis, a plea, or exception taken to a writ that is laid against two persons as joint tenants, who are severats.

SEVERALTY, Eftates in. He holds lands or tenements in severalty, or is sole tenant of them, is he who holds them in his own right only, without any other person being connected with him in point of interest, during his estate therein.

SEVERALTY Land, in Agriculture, such as is in an open field state, and divided amongst many. It is a bad situation or tenure of land, and ought to be done away as soon as possible.

SEVERANCE, in Law, the suing or severing two or more that join, or are joined, in the same writ or action.

As if two join in a writ, de libertate probanda, and the one be afterwards nonsuit; here severance is permitted, so as, notwithstanding the nonsuit of the one, the other may severally proceed. There is also severance of the tenants in feque; when one, two, or more deferts appear upon the writ, and the other. And severance in debt, where two executors are named plaintiffs, and the one refuses to prosecute. We also meet with severance of summars, severance in attaints, &c.

An estate in joint tenancy may be severed and destroyed by destroying any of its unities. 1. That of time, which respects only the original commencement of the joint estate, cannot indeed (being now past) be affected by any subsequent transfusion. But, 2. The joint-tenant's estate may be destroyed, without any alienation, by merely dissimulating their possession. 3. The jointure may be destroyed, by destroying the unity of title. And 4. By destroying the unity of interest. Blacklt. Comm. book ii.

SEVERANCE of Corn. The cutting and carrying it from the ground; and sometimes the setting out the tyrthen from the tail of the corn, is called severance.

SEVERIA, or SEVERIZ, in Geography, a town of Austrian Poland, in Galitz, capital of a duchy held by the duke of Tetschen to the bishops of Cracow; 4 miles N.W. of Cracow.

SEVERIA, a town of European Turkey, in the Mores; 14 miles N.E. of Mitana.

SEVILLIANS, SEVILLIANS, in Ecclesiastical History. There were two sects of heretics called: the first, those who are as old as the beginning of the third century, were an impure branch of the Gnostics; thus called from their chief, Severus.

The second, by some called Severites, were a sect of Monophysites, or Eutychians; their leader, Severus, was preferred to the see of Antioch in 513, where he did his utmost to fet aside the council of Chalcedon.

SEVERIUS, in Geography, a town of Asiatic Turkey, in the government of Darbikir; 50 miles W. of Darbekir.

SEVERIN, or Sevrini, a town of Walachia, in the Danube, founded by the emperor Severus; 12 miles E. of Orlova.

SEVERINUS, pope, in Biography, a Roman, was elected soon after the death of Honorius, in 638, but was not consecrated till May 640, when the papal see had been vacant nearly two years. This delay was owing to the refusal of the emperor to confirm the election till the clergy of Rome had promised that their bishop should sign the declaration of faith relative to the one will of Christ, drawn up by Sergius, the patriarch of Constantinople, and published by Heraclius. During the vacancy of the see, the Lateran palace was plundered of all its treasures by the exarch of Ravenna. At length the confirmation of the election of Severinus arrived, but he enjoyed his elevation only about two months, which afforded opportunity for no remarkable act, except that he refused to receive the declaration, and even published a decree condemning it.

SEVERINUS, Marcus Aurelius, a distinguished physician, was born at Tarfa, in Calabria, in the year 1580. His early inclination led him to the study of the law; but he subsequently abandoned that pursuit for the profession of medicine, and received the degree of doctor in the university of Naples. He became ultimately one of the most celebrated professors of that school, and taught anatomy and surgery with such reputation, as to attract a crowd of students to the university. His method of treating surgical subjects in his writings was highly commended by Bartholin. He was, however, a harsh practitioner, and censured the inferences of his contemporaries, for neglecting the cautery and the knife, as employed by the ancients, and himself carried the use of the actual cautery to a great extent. He died at Naples, on the 15th of July, 1656, at the age of seventy-five. He was a man of bold and original mind, but often what attached to paradox; and was the author of several publications, of which we have the following catalogue.

1. "Hispaniam Irivans, Obserúatique medicae evivserati\n
nimiis;" 1629.

2. "De recondita aulfeclium natura Libri\n
octo;" 1630, which passed through many editions. "Vipera Pythii, id est, de Viperis natura, venena, et medicina;" 1632.

3. "Zootoca Demercica, id est, Anatomie generalis\n
naturae animalium officina, Lib. v;" 1645, containing\n
the refult of his dissection of a great many animals. "De efficacioribus Medicinae, Libri in," 1646. In this work he extols the advantages of fire and steel in the cure of diseases. "De\n
5. "Lapider fungiferœ, de Lapide fungimappa, Epitole duæ;" 1649.

At the time of his death, Severini was preparing for publication some papers, which he meant to illustrate by engravings; they were published together, and entitled, "Antiperipatias, hoc est, adversus Arifoteles de respirazione plica Diatriba." "Commentarius in Theophrastum de piscibus in focco viventibus." "Phoca anatomice spectatus;" 1661. A sort of extract or abridgment of his writings on surgery was also published in 1661, with the title of "Synopses Chirurgiae Libri vi." See Elac Dict. Hist.

SEVERN, in Geography, the second most important river in England, is foppoed by some antiquaries to derive its name from the British word fabris, fandy, or muddy; but others, with greater probability, consider it as a corruption of the Saxon term seforns, which signifies flowing. This river has its source from a large bog on the top of P.infalmon-hill, in Montgomeryshire, North Wales, whence it enters down with a swift current, and being joined by many leffer torrents, it presently appears considerable; and passing by Llanydros and Newtown, becomes navigable near Welsh-Pool, where the river Vernew joins it with a stream little inferior to its own. From thence proceeding gently to Shrewsbury, which it almost surrouns, it flows on through a rich vale, with many extensive windings, to Benhall Edge; by the way receiving into it the river Tern, which waters all the north of Shropshire. Here the Severn begins to be rapid, being pent up from thence, to Bridgenorth and Bewdley, by high woody banks and rocky cliffs, which afford a variety of beautiful prospects. Afterward it again glides pleasantly on through the fertile plains of Worcestershire, visiting in its course the city of Worcester itself, near which it receives the waters of the Teme. At Tewkebury it forms a junction with the Avon, and thereafter pursues its course to Gloucester, about fifty miles below which city the name of Severn is lost in that of the Bristol channel.

The Severn is a river of great importance, being navigated by vessels of large burthen for more than 160 miles from its mouth, without the assistance of any lock. Upwards of 100,000 tons of coal are annually shipped by the colliers about Madeley and Broseley, for the cities and towns situated on its banks, and thence conveyed into the adjacent counties. Great quantities of grain, pig and bar iron, iron manufactures, and earthen-ware, as also wool, hops, cider and provisions, are likewise sent to Bristol and other places, whence various kinds of goods are brought in return. This traffic is carried on with vessels of two forts, the larger ones being called trows, and the leffer ones barges, or frigates. In May 1597, the number of these vessels navigating from Welsh-Pool, in Montgomeryshire, to Bristol, amounted to 376; but in consequence of the addition of the inland canals from the Trent, the Mersey, and the Thames, into the Stroud navigation, it may be fairly calculated that more than double that number are now employed. This river is peculiarly remarkable for its tide, which rolls in with a head of three or four feet high, foaming and roaring in its course, as if enraged by the opposition it meets with from the strong descending current of fresh water, which seems to contend with it for the superiority. They clash in such a manner as to dash the waters to a considerable height. This conflict is called the hygres, or eagers, as Rudder supposes, from the French eau-guerre, i.e. water-war. Drayton, in his Poly-Albion, describes it in these words.

With whose tumultuous waves,
Shut up in narrow bounds, the Hygry wildly raves,
And frights the flaggard flocks, the neighbouring shore to fly.

As far as from the main it comes with hideous cry,
And on the angry front the hideous foam doth bring.
The billows' gatf the banks when fiercely it doth fling,
Hurles up the flamy oaze, and makes the fealy brood
Leap madding to the land, affrighted from the flood;
O'turns the toiling barge, whose stcreman doth not launch,
And thirls the furrowine beam to her ieful panache.

Rudder, in his "History of Gloucestershire," remarks that the bailiwick of the Severn is vested in the crown; that John Arnold obtained a lease of it in 1669 for 31 years, at 10l. a year, and that the bailiff in 1779 was a Mr. Edward Baylis. From the rapid and boisterous character of this river, its waters are extremely muddy, a circumstance which renders it unfavorable as an abode for fish. It is, however, well furnished with salmon in some of the calmer spots, and is particularly famous for lampreys. For an account of the local circumstances of this river, and the feenery on its banks, see the articles MONTGOMERYSHIRE, SHROPSHIRE, WORCESTERSHIRE, and Gloucestershire, also Welsh-Pool, Shrewsbury, and Worcester. Skrine's History of Rivers, 8vo. Atkyns's Ancient and present State of Gloucestershire, folio, 1768. Rudder's New History of Gloucestershire, fol. 1779. Fulbrooke's Abstracts of Records and Manuscripts respecting the County of Gloucester, 4to. 1807. Naft's History of Worcestshire, fol. 1782. Alfo Tours in Wales by Pennant, Bingley, Hutton, Skrine, Warner, and Wyndham.

SEVERN, a river of America, in Maryland, which runs into the Cheapeak, a little below Annapolis.—Alfo, a river of North America, which runs into Hudfon's bay, with a settlement at its mouth, called "Severn Houfe." N. lat. 50°. W. long. 88°.—Alfo, a river of North America, which runs from lake Simecoe to lake Huron.—Alfo, a river of Virginia, which runs into the Cheapeak bay, N. lat. 37° 23'. W. long. 76° 27'.

SEVERNDROOG, a fea-port town and forfets of Hindooyan, in Concan, taken by the English in 1759; 68 miles S. of Bombay. N. lat. 17° 55'. E. long. 72° 52'.

SEVERUS, Lucius-Septimus, in Biography, a Roman emperor, was born at Leptis, in Africa, in the year 140 of the Christian era. His father, Septimus Geta, was of a Roman equestrian family, and his two paternal uncles were raifed to the confular dignity. Severus was liberally educated, and made a proficiency in rhetorical studies. He came to Rome in the reign of Marcus Aurelius, by whom he was raifed to the offices of advocate of the treasury, and senator. His youth was licentious; he however paid with credit through the offices of quaefitor, tribune of the people, and prætor, in confinement of his active and regular performance of his public duties. After his quaefitorship, he went into Africa, as lieutenant of the proconsul, where he shewed his fent of the dignity of office, and the importance of frieth discipline, by ceaining an old acquaintance of ordinary rank to be fervouring for greeting him familiarly, as he was walking, preceded by lectors. After he had completed the prætorian year, he was fent to Spain with the command of a legion. He paffed some time in retirement at Athens, at the beginning of the reign of Commodus; after this, however, he was raifed.
SEVERUS.

raised to the highest honours, being successively appointed governor of the district of Lyons, and, in 192, commander of the legions posted on the banks of the Danube.

At the death of Commodus, Severus acquiesced in the elevation of Pertinax to the throne; but when, after the murder of that prince, the empire was purchased by Didius Julianus, he procured himfelf to be declared emperor by his Pannonian legions, in the year 193. Suspecting that nothing was so essential to his success as gravity, after preparing his troops, he immediately commenced his march, which he performed on foot, at the head of a fecond body of guards, sharing with the main body all the hardships of his rapid advance. He entered Italy without meeting with any reftistance. Julianus being incapable of any confident and effective measures. On his approach to Rome, his competitor was defeated and put to death, and Severus received the decree of his election to the empire. His firft act of power was to inflict a just punishment on thofe of the pretorian guards who were immediately concerned in the murder of Pertinax, which was the only blood that his elevation hitherto called. Though he spared the lives of the refl of that mutinous and diffolute body, he determined to difband them, and with this view he summoned them on a plain near the city, ordering them to come without arms. He now reproached them for their want of discipline, stripped them of their ornaments, and ordered them, on pain of infall death, to deprefl the distance of one hundred miles from the capital. Severus was not fcorne on his throne, having to contend with two formidable rivals, Pefcennius Niger, governor of Syria, and Clodius Albinus, commander in Britain. Niger being the more powerful, Severus made the firit attack upon him; and in the mean time, to secure himself againft the attacks of Albinus, he flattered his vanity, conferring upon him the title of Cæfar; and in a letter conceived in terms of apparent refpecf and friendship, he requef{tcd him to partake with himfelf the toils of government, which age and infirmity rendered him unable to undergo without an associate. In this manner he difarmed the unsuspecting foldier. Severus now marched out to encounter Niger, whom he defeated in several battles, of which the lafl was at Ifius, in Cilicia. Severus was now freed from further conflft on the death of his rival, who was slain in his flight to the Euphrates, but he ufed his victory with great rigour; he banifhed and afterwards put to death the fons of Niger, feverally fined all the towns which had taken his part, and executed all the fenvors who had been officers in his army. Taking Byzantium after a long fiegfe, he difmantled and reduced it to the condition of a village, confifling all the property of the inhabitants. He remained in Asia fome time after the victory over Niger, and made an expedition into Mefopotamia, where he obliged the Parthians to raise the fiegfe of Nifbis, and gained other advantages over the Barbarians on the fronfeis.

Severus was now too great to think of sharing his power with a partner: he accordingly deprifed Albinus of the prerogatives attaching to the title of Cæfar, while Albinus laid claim to the rank of Augustus. An open rupture ensued, and each prepared to decide the contest. They met at Lyons, each at the head of 150,000 men, equal in valour and discipline. Severus was the conqueror, and his rival defoyed himfelf. This event took place in 197. Severus being now undisputed master of the empire, indulged without reftraint his disposition to cruelty. After putting to death the family of Albinus, and all the prisoners of rank taken in the battle, together with many citizens in the towns of Gaul, which had favoured his rival, he extended his severity to the Roman senate, which had displayed an inclination towards the caufe of Albinus. By way of in/file to that body, he conferred divine honours on the tyrant Commodus, whose memory they had declared to be deteftable and infamous; and when he returned to Rome, he made a reproachful and menacing speech to the assembled senate, followed by the execution, without trial, of twenty-nine, or, as another account lays, of forty-one of the most distinguished men. In a letter of his own accord he pronounced guilty of favouring the enemy. Confident of having thus made himself odious to the superior classes, he endeavoured, by all the means in his power, to gratify himself with the people at large by public exhibitions, and by exemptions from certain duties; and it has been affirmed that, notwithstanding his tyranny, peace and prosperity were generally prevalent throughout the empire during the reign of this emperor. Severus fludiously cultivated the affection of the foldiers, by the augmentation of their pay, and by privileges and indulgences which he granted them, and which have been considered as materially tending to introduce that relaxation of military discipline which in the end put a period to the Roman empire.

He supplied the place of the pretorian guards, whom he had disbanded, by a more numerous body, selected from the legions, and confiding, in great part, of the natives of barbarous nations; and he conferred unusual authority on their commander Plautianus. To his reign is chiefly attributed the introduction of those maxims of imperial prerogative which entirely put an end to all ideas of a republic, and placed the government upon the footing of an absolute and unlimited monarchy. The indolence of the capital did not suit the disposition of Severus. Learning that, while he was engaged with Albinus, the Parthians had made an irruption into Mefopotamia, and threatened Nifbis, he hastened into the East, and not only relieved that city, but took Seleucia and Ctesiphon. He then marched towards Armenia, the king of which country fued for peace, and obtained it. Some fucceflive incursions into Arabia concluded his eafthern expedition, from which he returned in the year 203, after an abfence of five or fix years. He celebrated his victories by many splendid fpefeacles; and in the fame year he married his fon Caracalla, whom he had fome years before created Augustus, to the daughter of Plautianus; his fecd, Geta, had been elevated to the rank of Cæfar, and both thefe princes had received their honours at a very early age. This union, which feemed likely to exalt the favourite minister Plautianus to the summit of fortune, was the caufe of his deftruction, for Caracalla, who had acquired a great afcendancy over his father, scorned his bride, and hated her father, and procuring an accusation againft him of having formed a conspiracy to take away the emperor's life, he caused him to be killed in the presence of Severus. His death drew after it that of many of his relations and adherents, and the cruelty of the emperor increased with his years. The reciprocal hatred between his two fons, and the ferocious character of the eldef, were fources of the utmost difquietude to him in the midst of his external prosperity. He, in vain employed every argument to reconcile them, and at length he placed them on a perfect equality, by raising Geta, as well as his brother, to the rank of Augustus. It was chiefly with a view of removing these princes from the licentiousnefs of the capital, and keeping them under his own eye, that in the year 208 he undertook an expedition to the northern part of Britain, the uncivilized tribes of which had made incursions into the Roman provinces. He took his fon with him, and at the head of a powerful army proceeded beyond the walls of Adrian and Antoninus, and penetrated to the northern extremity of the

Y 2
illand. He was harassed by the natives, who did not dare to meet him in the field, and he suffered much from the severity of the climate. At length the Caledonians purchased peace by surrendering all the country south of the Clyde and Forth, which he secured by raising a rampart between those filthy. The attacks against his life by his son Caracalla, joined to age and a declining state of health, so reduced him, that he died at York in the year 209, in the 60th year of his age. In his last moments he recommended concord to his sons, and his sons he recommended to the protection of the army. Gibbon speaks of Severus ending a glorious and successful reign, but other historians have doubted whether Severus ought to be reckoned among the good or the bad emperors; for while his perversity towards his competitors, his cruelty to vanquished enemies, and the general severity of his administration, justify a very unfavourable view of his moral character, it is not denied that he professed in a high degree the virtues of industry and vigour, the love of order, attention to correct abuses, strict and impartial administration of justice, and simple and frugal habits of life. He was a good judge of the characters of men, and the empire was in general well administered and prosperous during his reign.

He is supposed to have been favourable, in the early part of his reign, to Christians, but the rapid increase of their number seems to have alarmed him, and he is reckoned the author of the fifth persecution, which took place in the tenth year of his reign, and which lasted with more or less violence, according to Dodwell, two years, and according to Balfour, six years and upwards. See Lardner's Works, vol. viii. ed. 1790. ch. 23.

SEVERUS, CORNELIUS, a Roman poet, who lived in the reign of Augustus, was author of a poem entitled "Ætna," which has sometimes been attributed to Virgil. He is reported by Quintilian to have given a relation in verse of the Sicilian war, and some lines of his on the death of Cicero are quoted by Secundus the orator. It is to him that Ovid is supposed to have addressed one of his Pontic elegies, in which he is termed "Vates magnumorum maxime regum." An elegant edition of the remains of this writer, was published with notes at Amsterdam in 1709, by Le Clerc: and they are printed in Mattei's "Corpus Postumum."

SEVERUS, SANCTUS, a Christian rhetorician and poet, was a native of Aquitaine, and flourished in the fourth century. He wrote an eclogue, which is still extant, where, in a dialogue between a Pagan and a Christian, he treats of the mortality of cattle. It was first printed in the "Poemata Vetera" of Pithæus, and has been several times republished. Gronovius gave an edition of it, with a preface, under the title "Severi Sancti five Endecasyllaborum Rhetorici de moribus Bonum Carmen, ab Elia Vinetio et Petro Pethæo fervaturum, cum notis John Weitzii et Wolffang. Lug. Bat. 1715." Another edition was published by D. Richter, with a preface, in 1747. SEVESE, in Geography, a town of Italy, in the Milanese; 8 miles N.N.W. of Milan.

SEVIAMALLY, a town of Hindooftan, in the Carnatic; 19 miles W. of Trichinopoly.

SEVIER, a county of Tennessie, Hamilton district, containing 3419 inhabitants, of whom 162 are slaves.

SEVIERVILLE, a poll-town and capital of the above county; 555 miles from Washington.

SEVIGNAC, a town of France, in the department of the Lower Pyrenees; 9 miles N. of Morlaus.

SEVIGNE; MARIE RABUTIN, Marquise de, in Biography, a distinguished lady, was born in 1626. Her father, baron of Chantal and Bourbilly, died while she was very young, leaving her heirs of the house of Buffy Rabutin. Her rank, and the graces of her person and conversation, procured her many admirers, and in 1644 she married the marquis de Sevigne, who in 1651 was killed in a duel. She from this time devoted herself to her children, and to the cultivation of her own mind. She had an extraordinary affection for her daughter, who, in 1669, married the count de Grignan, and accompanied him to his government of Provence, and this separation gave rise to the greater part of the letters which have gained her such a high reputation, though she had many other correspondents. Many of M. de Sevigne's letters are of a domestic nature, but others are enriched with court anecdotes, remarks on men and books, and topics of the period in which they were written, which render them very amusing; and in point of style, they are models of epistolary writing, which, perhaps, have never been surpassed. In her letters to her daughter, the reader sometimes is hurt with the excess of flattery on her talents and beauty, which latter quality appears to have been a principal source of her maternal tenderness, and the preference of it the great object of her anxiety. This lady died in 1696, at the age of 70. Though endowed with much penetration, and, to a certain degree, with a cultivated understanding, she did not rise high above the level of her age and sex in taste and principles. She was attached to rank and splendour, loved admiration, and was apt to be taken with frivolous accomplishments in preference to solid worth. She had a deep taste of religion, but wished to conciliate it with the polite world, the manners and maxims of which, according to the rigid tenets of the Catholics, were entirely at variance with it. She has been centred for want of taste in her infidelity, to the poetical merit of Racine, but this has been imputed to her prepossessions in favour of Corneille. The best editions of her letters are that in 8 vols. 1775; and that in 10 vols. 1801.

SEVIGNY, in Geography, a town of France, in the department of the Ardennes; 12 miles N.W. of Rethel.

SEVIL, in the Marque. The devil of the branches of a bridge is a nail turned round like a ring, with a large head, made fast in the lower part of the branch, called gargouille. See Banquet.

SEUIL, in Geography, a town of France, in the department of the Ardennes, on the Aisne; 12 miles S.E. of Rethel.

SEVILLE, a province of Spain, commonly called the kingdom of Seville, is now exclusively, but improperly, denominated Andalusia, and occupies the western part of ancient Baetica. Its figure is irregular, 58 leagues long from E. to W., and 27 broad from N. to S.; a point of it bending towards the Straits of Gibraltar, 14 leagues from N. to S. and 9 from E. to W. It is bounded to the E. by Cordova; to the E. and S.E. by Granada; to the S. by the Atlantic and the Straits of Gibraltar; to the W. by the kingdom of Algarve, &c.; and to the N. by Extremadura. There are two sea-ports in this province, the one in the Mediterranean at Algeciras, the other on the Atlantic at Cadiz: the latter is spacious and beautiful, the best known, and the most frequented in Spain; its bay is eight leagues round. The principal towns of the kingdom of Seville are its own capital, Seville, an archiepiscopal see; Cadiz, an archiepiscopal see, fortified, and a sea-port; Santa-Maria, a sea-port; Xeres, Ecija, and Oliva, inland towns. Its rivers are, the Saltes, Guadiana, Tinto, Odiel, Chanca, Verde, Barbate, Guadalet, Guadaluquivir, Xenil, Guadianar, Guadayra, Las Freguas, Candon, and San-Pedro. See Seville.
SEVILLE.

Seville, in Spanish Sevilla, and in Latin Hespàlia, the capital of the above kingdom, is a large bulky city, one of the first in Spain, and so ancient, that it is mentioned by Strabo, Pomponius Mela, Pliny, and Ptolemy, as being ancient even in their time. Fabre ascribes its origin to Hercules, Bacchus, to the Hebrews, to the Chaldeans, and to the Phœnicians; but its real founder is unknown. From the Romans it obtained the privilege of a Roman colony, and it was called "Julia Romula," or Little Rome. This town has often changed its sovereignty and its form of government. It was formerly subject to the Gothic kings, who made it their place of residence; and in 582 it took part in the rebellion of Ermengedon, son of king Leudwigid. In 711, it opened its gates to the Moors; and in 1027 it supported the rebellion of the Moor, who was its governor, in favour of the king of Cordova, whom it proclaimed king of Seville. Retired to the empire of the sovereigns of Cordova, it again raised the standard of rebellion in 1144, and chose itself a king, whose descendants united Cordova to their new dominions. Aben-abu, the last of those kings, being assassinated at Almeria, and Ferdinand II., king of Castile and Leon, having seized upon Cordova and Jaen in 1236, it threw off all authority, formed itself into a republic, and was governed by its own laws. In its turn, however, it experienced the power of a conqueror Ferdinand II., assembled his forces before Seville in 1247, and compelled it, after a year's rebellion, to surrender in the 23rd of Nov., 1248. From the period of this memorable siege Seville has always made a part of the dominions of the kings of Castile.

Seville is situated on a beautiful and extensive plain, on the banks of the Guadalquivir. Its shape is circular, and its circumference, as it was left by the Romans, is surrounded by a wall more than a league in circuit, flanked by 176 towers; the number of gates is 12, that of Triana being of Doric architecture, and ornamented with columns and statues. Over one of the gates is the following inscription:

"Conditid Alecides, renovavit Julius Urbem, Reipublice Christifio Fernando Tertius, Heros."

The town is badly planned, the streets being narrow, crooked, and ill-paved; the houses, however, are tolerably well built, and, including those of the suburbs, amount to 11,820 in number. The number of inhabitants is stated by Mr. Townend at 80,268, contained in 30 parishes, 84 convents, and 24 hospitalls. Laborde estimates the present population, since the decline of its commerce, at 65,000. Many of the houses have large courts, surrounded by galleries or columns, with fountains in the middle. In summer the families live in the galleries, or courts, where they spread tents. In Seville there are many squares, the bowl of which are La Lonja, or the Exchange; the Hotel de Ville; the Arsenal, at the entrance of the harbour, with the Custom-houses and the India-house, in which the gold and silver brought from the Indies are deposited; here are also several fine suburbs, and a handsome promenade, called Alameda, having three walks planted with trees, and ornamented with fountains and fountains. This city is the fee of an archbishop; and of the public ecclesiastical edifices, the first that demands attention is the cathedral, chiefly admired for its tower, constructed by Guerrer the Moor; originally, A.D. 1568, 250 feet high, and afterwards raised 100 feet. It is so easy of ascent, and at the same time so spacious, that two horsemen may ride up abreast; and on the top is the Giralda, or brazen image, which, with its palm-branch, weighs near 14 tons, and yet turns with the slightest variation of the wind.

The dimensions of the cathedral are 490 feet, by 273; and the height is 126 feet. It was built A.D. 1492. It receives light by four-square windows with painted glass, the work of Arnau of Flanders, each of which cost 1000 ducats.

The treasures of this church are inestimable: one altar is wholly silver, with all its ornaments, as are the images, large as life, of B. Issidore and S. Leander, and a ciborium or tabernacle for the host more than four yards high, adorned with forty-eight columns; yet these are truing in value, when compared with the gold and precious stones deposited by the piety and zeal of Catholics, during the period in which all the wealth of a newly-discovered world flowed into this city. The profusion of gold, of silver, and of gems, would be more thriving, were not the attention occupied and lost in admiration of innumerable pictures, the works of those Spanish masters who flourished immediately after the revival of the art in Seville. Every chapel prefers some monuments of their superior skill. Of these, the most conspicuous are of Luis de Vargas, and of Fr. Zurbaran, but chiefly of Murillo. By the last is a Nativity in the chapel of the Conception, and, near the baptismal font, S. Anthony of Padua, with the Baptism of Christ. In the principal facroty, are his much admired pictures of S. Isidore with his brother S. Leander; and in another facroty his Holy Family, and an Ecce Homo, by Morales. The chapter-house is wholly devoted to Murillo, and the chapel of S. Peter is given up to Zurbaran. The works of Luis de Vargas are dispersed in various places; but his famous picture called de la Gamba, is in a chapel near the gate of S. Christopher, and merits particular attention.

To the cathedral belongs a library of 20,000 volumes, collected by Hernando, son of Christopher Colon, the first discoverer of America, a man of taste, and much admired in his day for learning. It is to be lamented, that modern publications have not been added to complete what was so well begun by him.

The construction of the organ is peculiar; it contains 5300 pipes, with 110 stops, being, as it is said, 50 more than those of the famous one at Haerlem, yet so ample are the bellows, that when stretched they supply the full organ fifteen minutes. The mode of filling them with air is singular; for instead of working with his hands, a man walks backwards and forwards along an inclined plane of about fifteen feet in length, which is balanced in the middle on its axis; under each end is a pair of bellows of about six feet by three and a half. These communicate with five other pair united by a bar; and the latter are so contrived, that when they are in danger of being overthrown, a valve is lifted up, and gives them relief. Passing ten times along the inclined plane fills all these bellows.

In the cathedral are eighty-two altars, at which are said daily five hundred masses. The annual consumption is fifteen hundred arrobas of wine, eight hundred of oil, and of wax about one thousand.

The wealth belonging to this chapter may be estimated by the numbers that are supported by it.

The archbishop, with a revenue of three hundred thousand ducats; or, in sterling, nearly thirty-three thousand pounds a-year.

Eleven dignitaries, who wear the mitre on high festivals, amply, but not equally, provided for.

Forty canons, of forty thousand reals, or about four hundred pounds each per annum.

Twenty
SEVILLE.

Twenty prebendaries, with an income of thirty thousand reals each.

Twenty-one minor canons, at twenty thousand reals each.

Besides these, they have twenty chanters, called Veinteneiros, with three assistants, called Sochantres, two headles, one master of the ceremonies, with a deputy, three attendants to call the roll and mark the absentees, thirty-six boys for singing and for the service of the altar, with their rector, vice-rector, and music-masters; nineteen chaplains, four curates, four confessors, twenty-three musicians, and four supernumeraries; in all, two hundred and thirty-five.

Many of the convents are remarkable for the beauty of their architecture; but, in Seville, the eye covets only pictures, and amidst the profusion of these, it overlooks works, which in other situations would rivet the attention, and everywhere fixes on the pencil of Murillo. His most famous performances are in the Hospital de la Caridad, and, suited to the institution, express some acts of charity; such as the Miracle of the Loaves and Fishes; the mowing of the Rock in Horeb; the Pool of Bethesda; the Reception of the returning Prodigal; Abraham addressing the three Angels, and presenting them to enter his habitation; the Deliverance of Peter from the Prison; and Charity, in the person of Elizabeth, washing the wounds and curing the diseased of the poor. Besides these, in the same hospital, is the Annunciation of the blessed Virgin; and two little pictures, the one of the infant Jesus, the other of John.

The church of the Capuchins is richly furnished with his works; and although in these the composition is more simple than in the former, yet they may be considered as some of the best of his productions. Eleven of his pictures are to be seen in a chapel called de la Vera Cruz, belonging to the Franciscans. These do much credit to his pencil; and not inferior to them, are many preferred in other convents; such as, an Ecce Homo, and the blessed Virgin, with the infant Jesus, in the church of the Carmelites; the Flight into Egypt, in that of La Merced Calzada; a rich variety of subjects in S. Maria de la Blanca; and S. Augustin writing, with S. Thomas of Villanueva, stripping himself to clothe the poor, in the convent of the Augustin friars, near the gate of Carmona. In the opinion of Mr. Townfend, the most materially of all his works is in the refectory of an hospital designed for the reception of superannuated priests. It represents an angel holding a baluster to the infant Jesus, who, standing on his mother’s lap, takes bread from it to feed three venerable priests. No representation ever approached nearer to real life, nor is it possible to give more expression, than glows upon that canvas. In the parochial church of Santa Cruz are two pictures in a superior style, a Stabat Mater Dolorosa, which excels in grace and softness; and the famous Decent from the Cross, of Pedro de Campana, which Murillo was accustomed daily to admire, and opposite to which, by his own directions, he was buried.

This great painter was born A.D. 1618, and died in 1682.

His name stands high in Europe; but to form an adequate idea of his excellence, every convent should be visited, where he deposited the monuments of his superior skill.

In exactness of imitation he was equalled; in claro obscurum, and in reflected lights, he was surpassed by Velazquez; but not one of all the Spanish artists went beyond him in tendernefs and softnefs.

Of the convents, that which is upon the most extensive scale belongs to the Franciscans. It contains fifteen cloisters, many of which are elegant and spacious, with apartments for two hundred monks; but at present they have only one hundred and forty in their community. Thefe, like all their order, are fed by charity, and are much favoured by the people. Their annual expenditure is more than four hundred thousand reals, or in sterling about four thousand pounds, amounting to twenty-eight pounds eleven shillings and five-pence for each. But then out of this must be deducted the expense of wine, oil, and wax, with the alms distributed daily to the poor, which altogether is considerable.

Among all the hospitals, Mr. Townfend was most pleased with that of La Sangre, designed for the reception of female patients. The front is elegant, and the sculpture is much to be admired, more especially the three figures of Faith, Hope, and Charity. The wards are spacious, and the whole is remarkable for neatnesss.

Our limits will not allow our introducing particular descriptions of other public buildings; such as the Torre del Oro, the Plaza de Toros, the Aqueduc with its four hundred and ten arches, and especially the Exchange. The latter, planned by Herrera (A.D. 1598), and worthy of its great architect, is a quadrangle of two hundred feet, with a corridor or spacious gallery round it, adorned with Ionic columns, and supported by an equal number of Doric.

The university was founded in the year 1502, and soon rose into consideration. The name of Aries Montanus, who lies buried at the convent of S. Jago, is alone sufficient to give celebrity to this seminary. His translation of the holy scriptures will be valued by the learned, as long as the scriptures themselves shall be the objects of veneration to mankind. The number of under-graduates here is about five hundred.

We meet at Seville with the favourite institutions of count Campomanes, his academy for the three noble arts of painting, sculpture, and architecture, and his economic society of the friends of their country. Both these have been attended with success, and have given affiance not only to the arts, but to agriculture, to manufactures, and to commerce. About two hundred pupils attend the former.

The alcazar, or royal palace, built by the Moors, is very spacious. The principal article of manufacture in Seville is snuff; and it furnishes also cigars to a very considerable amount. The filk manufacture was also formerly very flourishing in this place; so that in the year 1248 it employed 16,000 looms, and 150,000 persons; and such was then the population of the city, that the Moors who left it, when it was surrendered to the Christians, were 400,000, besides multitudes who died during a sixteen months’ siege, and many who remained after their fellow-citizens were gone. But in consequence of the accumulation of taxes and other circumstances, the number of looms has been very much diminished; so that A.D. 1740, the looms for wide filks amounted to 462, and for other purposes to 1856.

The country round the city to a considerable distance lies so low, that it is frequently overflowed, and upon some occasions the water has been eight feet high, even in their habitations. The soil is rich, and being at the same time very deep, its fertility is inexhaustible. The produce is corn, leguminous plants, hemp, flax, lemons, oranges and liquorice. The quantity of this exported from Spain is said to be annually not less than four thousand quintals, or nearly two hundred tons, a considerable part of which was made from the silage. The exportation of wine is very considerable; and the cultivation of it is carried on in every part of the country.
SEV

is supposed to be purchased by the porter-brewers in London.

In consequence of vapours and misfurnace, occasioned by flagrant water, and by frequent floods, the inhabitants of Seville and its neighbourhood are subject to tertians, to putrid fevers, and to hysterical disorders. The predisposition to such diseases may be likewise fought for in the quantity of cucumbers and melons consumed by them all the year, in consequence of which they are likewise afflicted with worms, accompanied with epilepsies, especially in the more youthful subjects. Other diseases arise from heat, whenever they have the Sodano wind, that is, whenever the wind blows from Africa, they become liable to pleurisies, and also a very pernicious irritability of nerves. N. lat. 37° 12'. W. long. 6° 8'.

SEVILLA del Oro. See MACAS.

SEVILLA Plantation, a place on the N. coast of Jamaica, W. of Mammee bay, where are the ruins of an ancient town, called “Sevilia Nueva,” founded by Esquivel on the spot where Columbus resided after his shipwreck in the year 1503.

SEVILLETa, a town of New Mexico; 100 miles S. of Santa Fé.

SEVIN, Francis, in Biography, a man of letters, born in the diocese of Sens, was educated at Paris, where he pursued, with great ardour, the study of the learned languages, in company with the abbe Fourmont the elder. He became an associate of the Academy of Belles Lettres in Paris in 1714. He was sent in 1728, by the king's command, with the abbe Fourmont the younger, to Constanti- nople, in search of MSS., of which he brought back a great number, and was, in 1737, prefected with the place of keeper of MSS. in the king's library. His letters, descriptive of this journey, were published in 1801, in one vol. 8vo. These contain several interesting details concerning Turkey, Egypt, &c. Sevin died in 1741. Several of his papers are published in the “Memoires de l'Acad. des Incriptions.”

SEVION, in Geography, a river of North Wales, which runs into the Clyde; 3 miles N.W. of St. Asaph.

SEVIR, among the Romans, an officer who, according to Pitsicus, commanded a whole wing of horse; though others pretend him only the commander of a troop, turmis, a division answering to our regiments.

SEVIRI were also magistrates in the colonies, so called, from their being first in number.

SEURAH, in Geography, a town of Hindooottan, in Bundealand; 18 miles N. of Callinger.

SEVRE, or Sevres Nantos, a river of France, which rises about eight miles W. of Parthenay, passes by Mortagne, Tiffauges, Clisson, &c. and runs into the Loire, opposite to Nantes.

SEVRE Nantos, a river of France, which rises near St. Maixent, passes by Niort, Marance, &c. and runs into the sea; 7 miles W. of Marance.

SEVRES, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Verfailles. The place contains 2643, and the canton 3485 inhabitants, on a territory of 50,000, in eight communes.

SEVRES, TWO, one of the nine departments of the western region of France, formerly Lower Poitou, between Vendée and Vienne, in N. lat. 46° 50', containing 6337 square kilometres, or 2442 square leagues, and 242,068 inhabitants. This department comprehends 4 districts, 30 cantons, and 305 communes. The districts or circles are, Thouars, including 435,443; Parthenay, 53,020; Niort, 84,923; and Melle, 61,167 inhabitants. Its capital is Niort. According to Hallenfritz, the extent is 32 French leagues in length, and 12 in breadth; the number of circles is 6, and of cantons 50, and the population is 259,122. The contributions in the 11th year of the French era amounted to 2,556,115 francs; and the expenses for administration, justice, and public instruction, to 233,694 francs 60 cents. The soil of this department, in general, is fertile, yielding grain, wine, fruits, and pastures. The S.W. district is marly.

SEVRI, a river of Natalia, which runs into the Sakaria, near Sevrishar.

SEVRHISAR, a town of Asiatic Turkey, in Natalia, at the confluence of the Sevri and Sakaria; 60 miles W. of Auburn. N. lat. 36° 53'; E. long. 31° 12'.

SEURRE, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Beaune; 21 miles S. of Dijon. The place contains 2777, and the canton 11,546 inhabitants, on a territory of 280 square kilometres, in 23 communes. N. lat. 46° 58'; E. long. 5° 12'.

SEVSK, a town of Russia, in the government of Orel, on the Sev; 56 miles S.W. of Orel. N. lat. 52° 15'; E. long. 34° 44'.

SEUTZACH, a town of Switzerland, in the canton of Zurich; 17 miles N.N.E. of Zurich.

SEVYNEY, a river of South Wales, which runs into the Clethy, in Pembrokehire.

SEW, in Sea Language, the situation of a ship when the water firr leaves her resting on the ground, or blocks in a dock. Thus, if a ship runs on the side of ebb, or by the reflux of the tide she rests on her blocks; and if it be required to know she has faved, or how much she has faved, the mark the water-line has made on her bottom when afloat is examined, and as much as is the difference above the surface of the water and this mark, so much she is said to have faved.

Sew is also a term applied to a cow, signifying to go dry.

SEWAD, or Sowad, in Geography, a province of Cundahar, situated on the W. side of the Indus, which separates it from Puckholl; 40 codes long and 15 broad. The climate is pleasant, as well as healthy, is very mountainous, and abounds with palls and strong situations; so that their inhabitants have not only held themselves generally independent of the Mogul emperors, but have occasionally made very furious inroads into their territories. The country of the Afflaceni, or Ailacani, answers to Sewad; Ahsenagur being the ancient name of Sewad; or rather Sewad was one of the subdivisions of Ahsenagur. At present Sewad includes the three provinces of Sewad proper, Bijore, and Bener.

SEWAD, the easternmost and largest of the four rivers that unite successively with the river Cabul, before it falls into the Indus; the other three being that which passes by the town of Bijore, the Penjakour river, separating Bijore on the W. from Sewad on the E., and the Chendoul river, which is a branch of the Bijore river.

SEWALICK, or Sewu-Luck, a chain of mountains forming the northern boundary of Hindooottan, and separating the country of Lahore from Thibet.

SEWAN, or Alligunc, a town of Hindooottan, in Bahar; 32 miles N.W. of Chuprah. N. lat. 26° 11'; E. long 84° 32'.

SEWARD, Thomas, in Biography, an English divine of the church of England, was born in 1708. He became rector of Evesham, in Derbyshire, and prebendary of Litchfield, where he died in 1790. He was a man of taste and learning,
ing, and of considerable talents for poetry and polite literature. He published an edition of Beaumont and Fletcher’s works, and was author of a treatise on the “Conformity between Popery and Paganism.” Some of his poems are in Doddley’s collection.

SEWARD, Anna, daughter of the preceding, a poetess of distinguished elegance, was born about the year 1745.

Her infant mind was nourished by her father with the vivid and sublime imagery of Milton, and her early education amidst the wild and alpine scenery of the Peak, enhanced the enthusiasm of feeling to which she was naturally disposed. In her seventh year, her father being appointed canon residuary of Litchfield, she removed with the family to that city, which thenceforth became her residence during the whole of her life. The fruit of her father’s instructions appeared in some early efforts at poetical composition, which, however, met with discouragement from her mother; and Mr. Seward was afterwards induced to withdraw the countenance he had given to her literary pursuits; so that several years of her youth elapsed with only illogical and interrupted attempts to cultivate an art of which she had so strongly imbibed the rudiments. As she advanced in life, she of course followed more freely the bent of her genius, and in 1768 she published an “Elegy on Captain Cook,” a performance of great merit, as well from the harmony of its verification, as the beautiful and appropriate imagery with which it abounds, and the force and delicacy of its sentiments. The contrast between the different moods on this event, queen Obera, and the wife of the great navigator, is peculiarly striking. In the following year she gave the world a “Monody on Major Andre.” With this lamented young officer she was intimately acquainted; she accordingly wrote with peculiar pathos on the occasion, and expressed a glowing, and we scruple not to say, a just indignation against the actors in that tragedy; the laws of what are called civilized war do not and ought not to suppress the feelings of humanity. Miss Seward made herself known as a writer on many other topics: in 1790 she published “Llangollen Vale,” with other poems; and in 1804 she gave the public “Memoirs of the Life of Dr. Darwin.” This is a defunct performance, but it contains much entertaining matter, enriched with some judicious criticism on Dr. Darwin’s poetic character. Miss Seward died in March 1809. A collection of her letters has been published since her decease, in six vols. 12mo. Athenæum. Monthly Mag.

SEWARD, William, was the son of a brewer in London, and born in 1797. He received his education at the Charter House, which he completed at Oxford; this place he left without taking a degree. Having a fortunate health, he devoted his life to literary and antiquarian researches. He is known as an author by five volumes of “Anecdotes of Distinguished Persons,” extracted from curious books, to which he added a supplement, in two volumes, under the title of “Biographiana.” Europ. Mag.

SEWARD, in Geography, a town of Hindoostan; in the circar of Seward, 22 miles E. of Seward. 

SEWEE, a country of Asia, between Persia and Hindoostan, on the W. side of the Indus. 

SEWEE, or Bull’s Harbour, a bay of the Atlantic, on the coast of South Carolina. N. lat. 32° 58’. 

SEWEESTAN, a country of Hindoostan, between Sewee and the Indus, about 110 miles long and 90 broad. 

SEWEL, among Sportsmen, denotes any thing that is set or hung up, to keep a deer out of any place. 

SEWEL, Coroado, a name given by the natives of Ceylon to a species of cinnamon, which, when chewed, is of a mucilaginous nature, like the cajafa: this dries well, and is very firm and hard, and has the appearance of a very fine cinnamon; but it has very little taffe, and a disagreeable smell. The natives take advantage of the handsome appearance of this kind of cinnamon, and are very apt to mix it with the good kind, to the great detriment of the buyer. Phil. Trans. N° 489.

SEWER, formed from the French eaufer, eaufer, gentleman, or officer, in the House, an officer who comes in before the mess of a king, or nobleman, to place and range it on the table. Of these officers there are four in the king’s household, and eight, called feveurs of the great chamber. 

SEWERS, in Building, are shores, conduits, or conveyances, for the fuillage and fifth of a house. 

SEWERS, Clerk of the. See Clerk. 

SEWERS, Commission of. See Commission. 

SEWIN, in Ethnology. See Grey. 

SEWL, in Agriculture, provincially a plough. It is sometimes written sulc. See Plough.

SEWNADY, in Geography, a town of Hindoostan, in the circular of Ruttunpour; 35 miles N. of Ruttunpour. 

SEWNY, a town of Hindoostan, in Goodwoodah; 60 miles N. E. of Nagpore. 

SEX, SEXUS, something in the body, which distinguishes male from female. See Generation. 

The number of seconds, of the two sexes, are exceedingly well balanced; so that every man may have his wife, and every woman her husband. 

Hermaphrodites have the apparent marks of both sexes. It is expressly forbidden by the law of Moses, to disguise the sex. 

SEXAGENERY, SEXAGENARIUS, something relating to the number fixty: more particularly a person arrived at the age of sixty years. 

Seme caufitis difpensare with sexageners for not falling: the Papian law prohibits fexagenarii from marriage; because at that age the blood and humours are frozen. 

SEXAGENARY Arithmetic. See Sexagesimal. 

SEXAGENARY Tables, are tables of proportional parts, shewing the product of two sexageners that are to be multiplied; or the quotient of two to be divided. 

SEXAGESIMA, the second Sunday before Lent, or the next to Shrove Sunday; so called, as being about the fixtieth day before Easter. 

Sexagesima is that which follows Septuagesima, and precedes Quinquagesima. 

SEXAGESIMAL, or Sexagenary Arithmetic, a method of computation, proceeding by fixties. 

Such is that used in the division of a degree into fixty minutes; of the minute, into fixty seconds; of the second, into fixty thirds, &c. See Arithmetic. 

SEXAGESIMALS, or Sexagesimal Fractions, are fractions, whose denominators proceed in a sexagesimal ratio; that is, a prime, or the first minute = 1/60; a second = 1/60²; a third = 1/60³. 

Anciently there were no other than sexagesimal used in astronomical operations, and they are still retained in many cases; though decimal arithmetic is now much used in astronomical calculations. 

In these fractions, which some alfo call afinity fractions, the denominator being always 60, or a multiple of it, is usually omitted, and the numerator only written down: thus, 4², 59', 32°, 50', 16°, is to be read, 4 degrees, 59 minutes, 32 seconds of a degree, or 60th parts of a minute, 50 thirds, 16 fourths, &c. 

SEXANGLE, in Geometry, a figure having fix sides, and consequently fix angles. 

SEXDRAGA,
SEX

SEXDRAGA, in Geography, a town of Sweden, in Weil Godland; 48 miles E. of Gotterborg.

SEXES of Plants, in Vegetable Physiology. See Fernation, and Propagation.

SEX T, in Geography, a town of France, in the department of Mont Blanc; 2 miles S. E. of St. Maurice.

SIXTH PART, Lat. a sixth vocal part in the motetti and madrigals of old masters.

The Romans divided their as, which was a pound of brass, into twelve ounces: the ounce was called unius, from one; and two ounces sextuns, as being the sixth part of a pound. See As.

Sextans was also a measure which contained two ounces of liquor, or two cyath. Hence,

"Sextentes, Calister, duos infundi Palerni."

Sextants, the Sextant, in Astronomy, a constellation of the southern hemisphere, made by Hevelius out of uniform stars. In Hevelius's catalogue it contains 11, but in the British catalogue 41 stars. See Constellation.

Sextant, in Mathematics, denotes the sixth part of a circle, or an arc comprehending sixty degrees.

Sextant is more particularly used for an astronomical instrument, made like a quadrant; excepting that its limb only comprehends sixty degrees.

The use and application of the sextant is the same with that of the quadrant.

In the observatories of Greenwich and Pekin, there are very large and fine sextants.

Sextarius, an ancient Roman measure, containing two cotyle, or two hemina. See Cotyla.

Sectery-Lands, are lands given to a church, &c. for maintenance of the sexton.

Sextile, Sextiles, the position or aspect of two planets, when at sixty degrees distance; or at the distance of two figures from one another. It is marked thus (•). See Aspect.

Sextillis, in Chronology. See August.

Sexton, a church-officer, thus called by corruption of the Latin sacerdos, or Saxon seofen, which denotes the name. His office is to take care of the vessels, vestments, &c. belonging to the church; and to attend the minster, churchwarden, &c. at church. He is appointed by the minister or others, and receives his salary according to the custom of each parish.

Sixtons, as well as parish clerks, are regarded by the common law as persons who have freedom in their offices; and, therefore, though they may be punished, yet they cannot be deprived, by ecclesiastical censures.

The office of sexton in the pope's chapel, is appropriated to the order of the hermits of St. Augustine. He is generally a bishop, though sometimes the pope only gives a bishopric, in particular, to him on whom he confers the pall. He takes the title of prefex of the pope's sacerdos, and has the keeping the vessels of gold and silver, the relics, &c.

When the pope fays mass, the sexton always tafes the bread and wine first. If it be in private he fays mass, his obnifs, of two wafers, gives him one to eat; and, if in public, the cardinal, who affifts the pope in quality of dean, of three wafers, gives him two to eat. When the pope is desperately fick, he adminifers to him the sacrament of extreme unction, &c. and enters the conclave, in quality of first conclavift.

Sexton's River, in Geography, a river of America, in Vermont, which runs into the Connecticut, N. lat. 43°, W. long. 72° 25'. Vol. XXXII.

SEXTULA, a word used by some pharmacutic writers to express the sixth part of an ounce, that is, four scruples, or one dram and one scruple.

SEXTULIA, Ital. Sestuple, Fr. and Eng. in Measure, implies a compound time of triplets mixed with binary time. Sextuple time is never properly used but in the second, confiding of six even erotchets, or quavers, expressed by ″; albeit triplets are out of the question. All other combinations of compound measure, or, as formerly called, time, are at present the following: 8, 8, 8, 8, 8, 8, all which measures consist of triplets.

Old authors mention five different species of sextuple time: as,

Sextuple of the Semibreve, by the French called triple of 6 for 1, as being denoted by those two numbers; or because here are required six semibreves to a measure, in lieu of one, viz. three rising, and three falling.

Sextuple of the Minim, called by the French triple of 6 for 2, as being denoted by ″; which shew, that six minim are here required to a measure, instead of two.

Sextuple of the Grotchet, called by the French triple of 6 for 4, because denoted by C 5, or ″; which shew, that there must be six erotchets to a measure, in lieu of four.

Sextuple of the Chrona, by the French called triple of 6 for 8, as being denoted by ″; which shew, that six quavers here make the measure, or semibreve, instead of eight.

Sextuple of the Semichrona, or triple of 6 for 16, to called, because denoted by ″; which shew, that six quavers are here required to a measure, instead of sixteen.

Sextus, Sixth, in the Canon Law, denotes a collection of decreals, made by pope Boniface VIII. usually thus called from the title, which is "Liber Sextus;" as if it were a sixth book added to the five books of decreals, collected by Gregory IX.

The Sextus is a collection of papal constitutions, published after the collections of Gregory IX, containing those of the same Gregory, Innocent IV., Alexander IV., Urban IV., Clement IV., Gregory X., Nicholas III., and Boniface VIII., by whose order the compilation was made. The persons employed in making of it were Will. de Mandegot, archbishop of Ambrun; and Bereuger, bishop of Bezierc; and Richard of Sienna. See CANON LAW.

Sextus, in Biography, an ancient philosopher of the flo-ecial sect, was a native of Chersonia, and the nephew of Plutarch. He is celebrated as the preceptor of the emperors Lucius Verus and Marcus Aurelius.

Sextus, Empircus, in Medical History, a Roman physician, of the empiric sect, who followed Herac-we and others in the adoption of that typhem which Serapion and Philinus begun. He is said to have been the pupil of Herodetus, the physician, and the preceptor of Saturninus. There are two works extant, with the name of Sextus attached to them; but Le Clerc believes, that they are not both the production of this physician, who only composed that which is entitled "Sixti Placiti;" and that the other work, which contains six books, treating of the doctrines of Pyrrhonism, and ten books relative to all the sciences, was the production of another Sextus, of Chersonia, who was of the Platonic school, a nephew of Plutarch, and preceptor of the emperor Marcus Aurelius. See Le Clerc, Hist. de la Méd. p. n. chap. 8.

Sextus Oculi, in Anatomy, a name given by Fallopis to one of the muscles of the eye, called by Albinus, and others, the obliquus oculi inferior, and by fome, the obliquus oculi brevis.

Sextus Thracicus, a name given by Fallopis, and others, to
to a muscle, now generally known by the name of the tri-
angularis femini.

SEXUAL SYSTEM, in Botany, denotes that sytem,
which is founded on a discovery, that there is in vegetables,
as well as in animals, a distinction of the sexes; or that plants
propagate themselves by means of male and female organs,
either growing upon the fruit tree, or upon different trees
of the same species. This system is flaggelated and confirmed
by the analogy observable between the eggs of animals and
the fruits of plants, both serving equally to the same end,
viz. that of propagating a similar race; and by the remarks
which have been made, that when the seed of the female plant
is not impregnated with the profligate powder of the male, it
bears no fruit; inasmuch that as often as the communication
between the sexual parts of plants has been interrupted, which
is the cause of their fecundity, they have always proved barren.
The authors of this system, after exactly anatomizing all the
parts of the plant, affign to each a name, founded on its use
and analogy to the parts of an animal. Thus, as to the
male organs, the filaments are the spermatic vessels, the an-
tere the tealticles, and the duct of the antherze correspond
to the sperm and seminal animalcles; and as to the female,
the stigma is the external part of the female organ, which
receives the dust; the style anfwers to the vagina; the germ
to the ovary; and the pericarpium, or fecundated ovary,
to the womb. See Vegetation.

The sexual system was not wholly unknown to the an-
cients, though their knowledge of it was very imperfect.
Accordingly we find in the account given by Herodotus
(lib. i.) of the country about Babylon, where palm-trees
abounded, that it was a custom with the natives, in their
culture of these plants, to affift the operations of nature, by
gathering the flowers of the male trees, and carrying them
to the female. By this means they fecured the ripening of
the fruit; which might else, on account of unfavourable
seasons, or the want of a proper intermixture of the trees of
each sex, have been precocious, or at least not to have been
expected in equal quantities. The ancients had also similar
notions concerning the fig. Theophrastus (Hift. Plant.
lib. iii. cap. 9.) observes, that the characteristic and universal
difference among trees is that of their gender, whether male
or female. And Arittote (De Plantis, lib. i. cap. 2.) says,
that we ought not to fancy, that the intermingling of sexes
in plants is the fame as among animals. However, there
seems to have been a difference of opinion among the an-
cients as to the manner in which plants should be allowed
to have a difference of sex. Some apprehended that the two
sexes existed separately; and others thought that they were
united in the same individual. Empedocles thought, that
plants were androgynous or hermaphroditical, or that they
were a composition of both sexes. Aristotle expresses his
doubt upon this head. Empedocles (vide Arif. de Generat.
Anim. lib. i. c. 23.) called plants oviparous; for the need or
egg, according to his account, is the fruit of the generative
faculty, one part of which serves to form the plant, and
the other to nourish the germ and root; and in animals of
different sexes, we fee that nature, when they would pro-
create, impels them to unite, and like plants to become one;
that from this combination of two, there may spring up
another animal.

As to the manner in which fruits were impregnated, the
ancients were not ignorant that it was by means of the pro-
fligate dust contained in the flower of the male; and they
remarked, that the fruits of trees never come to maturity till
they had been cherifhed with that dust. Upon this subject
Aristotle says (De Plant, lib. i. cap. 6.) that if one shakes
the dust of a branch of the male palm-tree over the female,
her fruits will quickly ripen; and that when the wind flieis
this dust of the male upon the female, her fruits ripened apce,
just as if a branch of the male had been flupended over
her. And Theophrastus (Hift. Plant. lib. ii. cap. 9.) ob-
serves, that they bring the male to the female palm, in order
to make her produce fruit. The manner in which they pro-
ceed, says he, is this: when the male is in flower, they
select a branch abounding with that downy dust which re-
fides in the flower, and shake this over the fruit of the fe-
male. This operation prevents the fruit from becoming
abortive, and brings it to perfect maturity. Pliny also
inform us (Nat. Hift. tom. i. lib. xii. c. 7.) that naturalists
admit the distinction of sexes only in trees, but in herbs,
and in all plants. Yet this is no where more observable,
be adds, than in palms, the females of which never pro-
pagate, but when they are fecundated by the dust of the
male. He calls the female palms, deprived of male altfance,
bare-widows. He compares the conjunction of these
plants to that of animals; and says, that to generate fruit,
the female needs only the afperation of the dust or down
of the flowers of the male.

Zuluzanifki seems to have been the first among the mo-
derns who clearly distinguished from one another the male,
the female, and the hermaphroditical plants. About a
hundred years after him, sir Thomas Millington, and Dr.
Grew, communicated to the Royal Society their observa-
tions on the impregnating dust of the ifamna. Grew's Anfamy
of Plants, published in 1682.

Camerarius, towards the end of the last century, observed,
that upon plucking off the ifamna of some male plants,
the buds that ought to have produced fruit came not to
maturity. Malpighi, Geoffroy, and Vaillant, have also
carefully considered the fecundating dust; the latter of whom
seems to have been the first eye-witness of this secret of
nature, the admirable operation that piles in the flowers of
plants, between the organs of different sexes. Many authors
afterwards applied themselves to improve this ifynam;
the principal of whom were Morland, Logan, Van Royen,
Bradley, Ludvig, Blair, Wolfius, &c. But Linneus had
the honour of applying this ifynam to practice, by reducing
all trees and plants to particular classes, distinguished by the
number of their ifamna, or male organs. See Dutens' Inquiry
into the Origin of the Difcoveries attributed to the Moderns,
1769, chap. vii. Phil. Tranf. vol. xlvi. art. 25.

The sexual hypothesif, on its first appearance, was re-
ceived with all that caution which becomes an enlightened
age; and nature was traced experimentally through all her
variations, before it was universally affented to. Taurne-
fort refused to give it a place in his ifynam; and Pontedera,
though he had carefully examined it, treated it as chimerical.
The learned Dr. Alfton, professor of botany in the university
of Edinburgh, violently oppofed it; but the proofs which
Linneaus has given amongst the aphorifms of his "Fundamenta
Botanica," and farther illustrated in his "Philofophia Botan-
ica," are fo clear, that the mind does not heflate a moment in
pronouncing animal and vegetable conception to be the fame;
but with this difference, that in animals fruition is voluntary,
but in vegetables neccifary and mechanical. The impregna-
tion of the female palm by the farina of the male, related by
Mylius, in his letter to Dr. Watfon (Phil. Tranf. vol. xlvii.
art. 25.) eflablishes the fact attested by the ancients con-
cerning the palm-tree; and as the fruitification in other
vegetables, though it may differ in particular circumstances,
has nevertheless a general conformity to that of the palm-tree,
with refpect to the parts fupposed to be the organs of gen-
eration, which are discoverable either on the fame or in a
separate flower, we may, from this fingle experiment, deduce
an
argued an analogy by analogy for the confirmation of the whole

theoretical hypothesis. Indeed, a very striking proof of the

analogies between plants and animals — be drawn from ob-

servations made in their native states, at which early age

and then they are nourished and protected in a similar man-

ner. Those who desire further reflection, may see the

several demonstrations collected, and portedly connected, in

the "Spandauer Praktikum," of J. Gudewitz Waldstein,

published in the "Annalen der Akademie," at Leyden in

1759. See Botany, Classication, I. in Nature,

Plan, a., &c.

SEY.

SEXUALIS,

Botanical Authors See Bot-

Dany, I. Classification, and Sexual Synonymy.

SEXUX, in Physiog., the weight of its ounce, or half a pound Troy.

SEYBO, or SEYVO in Geography, a settlement in the

Joat in the line of Hпус. lat. 70 miles N.E. of St. Donsbore.

SEYDORSFORD, a town of Prussia, in the province of

Oberland; 6 miles N. of Luckbit.

SEYCHELLES, an island in the Indian ocean, N.E. of

Madagascar; high and mountainous, and estimated at 72 miles

in circumference. The soil appears to be rich and good; and

the island is covered with trees, many of which were left

for masts and yards for ships, as they are large and straight.

among the trees are great quantities of rose-wood, and coco-

anut trees. Wild goats, land-tortoises, and Gemina-lion,

are found in plenty; and in the harbour abundance of good

fish. The harbour is well sheltered from the south-wind.

When the winds are from the north and west-north, it is

rather an open road, but the ground forms to hold well.

The tide rises about six feet, and lets about S.S.W. High

water full and change, thirty minutes past five. S. lat.

4° 34'. E. long. 55° 35'.

SEYDA, or SEDAL, a town of Saxony; 10 miles E.

of Wittemberg. N. lat. 51° 55'. E. long. 12° 59'.

SEYDE. See SAIDE.

SEYDEWITZ, a river of Saxony, which runs into the

Elbe, near Pirna, to the margravate of Meissen.

SEYER. See Pulo Seyer.

SEYER OR, an island of Denmark, in the Cattegat,

about eight miles long, and hardly one broad; about five

miles from the coast of Zealand. N. lat. 55° 53'. E. long.

11° 11'.

SEYFFERSDORF, a town of Silesia, in the prin-

cipality of Grotkau; 3 miles N.E. of Grotkau.

SEYFORTESVOLT, a town of Prussia, in the

province of Ermeland; 9 miles S. of Heilberg.

SEYGAR, in the Materia Medica, a name used by some

authors for the natmeg.

SEYGERWALD in Geography, a town of Prussia, in the

province of Oberland; 4 miles N.E. of Saffeld.

SEYLONE, a town of Hindoostan, in Oude, rested on

a river which runs into the Gouty; 15 miles S.E. of

Bareilly.

SEYMAN, an island in the Red sea. N. lat. 15° 26'.

E. long. 57° 20'.

SEYMOUR, EDWARD, in Biography, brother of lady

Jane Seymour, wife of Henry VIII. (see his article), and

e uncle to Edward VI., was created viscount Beauchamp, earl

of Hertford, and duke of Somerset. On the accession of

his nephew to the throne he became his guardian, and pro-

tector of the kingdom. Not thinking that the vote of the

executors of Henry VIII. was a sufficient foundation for

the high authority which he partly ascribed to the influence

which his relationship to the king gave him, he procured a

patent from Edward, by which he overfet the meaning and

intent of the late king's will. In this patent he named him-

self protector, with full regal power, and appointed himself

entirely at the pleasure of one whom he thought he could trust.

The protector became the warm friend of the reformers,

and endeavored to make the means of preserving the

object he had at heart. He appointed a general visitation

to be made throughout England, the visitor consisting of a

certain number of the clergy and laity, and they had

done different sects among them. The chief part of

their instructions was, besides correcting the moral

vices and irregularities of the clergy, to abolish, but with a very

severe hand, ancient superstitions, and to bring discipline

and worship somewhat nearer the practice of the ancient

churches. Somerset made war upon Scotland, and upon his

return in Nov. 1547, he called a parliament, and being elated

with the successes which he obtained over the Scots, he pro-

cured from the young prince a patent, appointing him to sit

on the throne, upon a half at the right hand of the king,

and to enjoy the same honours and privileges that had

usually been possessed by any prince of the blood, or uncle of

the kings of England. In this patent the king employed

his dispensing power, by setting aside the statute of pre-

cedency enacted during the reign of his father. If, however,

the protector gave offence by affuming too much state, he

served high praise on account of the laws which were

passed during this session, by which the rigour of former

statutes was much mitigated, and some security given to those

principles of freedom which seem to make a part of the con-

stitution. All laws were repealed which extended the crime

to treason beyond the statute of the twenty-fifth of Edward III.;

all crimes enacted during the late reign extending the crime

of felony. All the former laws against hereby, together with

the statute of the four articles, None, in future, were to be

accused for words, but within a month after they were spoken.

"By these repeals," says Hume, "fervor of the most rigorous

laws that were ever passed in England were annulled, and

some, both of civil and religious liberty, began to appear

to the people."

About this time, many violent differences subsided

between the protector and his brother, Thomas Seymour, admiral of

England. The ambition of the latter was insatiable: he was

besides arrogant, affuming, and intractable; and though

enfeemed of superior capacity to the protector, he did not

possess the same degree of confidence and regard of the people.

By his flattery and address, he had so far inflamed himself

into the favour of the queen-dowager, that the married him

almost immediately upon the demise of the king. The credit

of this alliance supported the ambition of the admiral, and
gave great offence to the duchesses of Somerset, who, uneasy

that the younger brother's wife should have the precedence,

employed all the credit the had with her husband, first to

create, and then to widen the breach between the two

brothers. Matters, at length, were carried so far, that the

admiral was attained of high treason, and executed by a

warrant, which was signed by the hand of his brother, whose

own disgrace was as at great dilanee.

After the duke of Somerset had obtained the patent,

inviting him, as it were, with full regal authority, he thought

every one was in duty bound to yield to his sentiments.

Besides his general hauteur, he gave great offence to the higher

ranks of society, by the attention with which he evidently

courted the applause of the people at large. For the relief

of the people who had erected a court of requests in his own

house, and he interposed with the judges in their behalf, a

circumstance that could not but be deemed illegal. Though

the protector had thus courted the people, to the displeasure

and disgust of the nobles, whom Hume represents as "the

sured.
fureft support of monarchical authority," the interest which he had formed with them was in no degree answerable to his expectations. The Catholic party, who retained influence with the lower ranks, as might be expected, were his declared enemies, and took advantage of every opportunity to decry his conduct. The attender and execution of his brother bore an odious aspect: the introduction of foreign troops into the kingdom was represented in invidious colours: the great estate which he had suddenly acquired at the expense of the church, and of the crown, rendered him obnoxious; and the palace which he was building in the Strand served, by its magnificence, and still more by other circumstances attending it, to expose him to the cenfure of the public. The parish church of St. Mary, with three bishops' houses, were pulled down, in order to furnish ground and materials for this structure. Not content even with this, which, at that period, was regarded as great sacrilege, an attempt was made to demolish St. Margaret's church, Westminster, and to employ the flones for the same purpose, but the parishioners rofe in a tumult, and chafed away the protector's trade-men. He then laid his hands on a chapel in St. Paul's church-yard, with a cloifter and charnel-house belonging to it, and these edifices, together with the church called the St. John of Jerufalem, were made ufe of to raife his palace. All these impiuities were remarked by Somerset's enemies, who refolved, when an opportunity offered, to take advantage of them to his ruin. A conspiracy was foon formed againft him, and he resigned his office, hoping that with this confeffion his foes might be fatisfied, but he was mistaken, they determined to profe him even to the scaffold. He was committed to the Tower, with fome of his adherents, and articles of inducement were exhibited againft him, of which the chief was his ufurpation of the government, and his taking into his own hands the whole administration of affairs. The clause of his patent, which invested him with absolute power, unlimitted by any law, was never objeeted to him, because, fays Mr. Hume, "according to the sentiments of thofe times, that power was, in fome degree, involved in the very idea of regal authority." Somerset was prevailed upon to confeff on his knees, before the council, all the articles laid to his charge, and he imputed thofe misdeemors to his own rheafins and indefcretion, not to any malignity of intention. He even fubfcribed a paper which contained a full confeffion of his guilt; he was accordingly fined two fhousand pounds a-year in land, and deprived of all his offices, and here the matter for the prefeft ended; the fine was remitted, and he recovered his liberty. After this, he was re-admitted into the council, and foon obtained a confiderable portion of popularity, which rendered him an object of jealousy to the duke of Northumberland, who planned his dilfutation. Under pretence of an intended inflammation, he had him feized, with his friends, and committed to the Tower. He was now brought to trial before a jury of twenty-feven peers, none of whom were his avowed enemies, and was of course found guilty, and condemned to death. Care was taken to propofe the young king againft his uncle, and let he fhould relent, no access was allowed to the duke of Somerset's friends, and the prince was, by a continued feries of occupations and anfumements, kept from refleétion. The prisoner was executed on Tower-hill, much to the regret of the great body of people, who entertained the hopes of pardon to the laft. A vast multitude of thofe friendly to him were the witnefles of his death. Many of them dipped their handkerchiefs in his blood, which they preferred as a precious relic; and fome of them, when Northumberland, his great enemy and one of his jurors, met with a like doom, upbraided him with this act of his cruelty, and displayed to him thofe symbols of his crime. "Somerfet, indeed," fays Hume, "though many actions of his life wereexceptionable, feems in general to have merited a better fate, and the faults which he committed were owing to weaknesses, not to any bad intention. His virtues were better calculated for private than for public life; and by his want of penetration and firmness, he was ill-fitted to extricate himself from thofe cabals and violations to which that age was fo much addicted."

Somerfet left three daughters, Anne, Margaret, and Jane, who were distinguished for their poetical talents. They composèd Latin dittics on the death of Margaret de Valois, queen of France, which were tranflated into the French, Greek, and Itahan languages, and printed in Paris in 1551. Anne, the eldeft of thofe ladies, married firft the earl of Warwick, the fon of the duke of Northumberland, already mentioned, and afterwards fir Edward Hunton. The other two died single. Jane was maid of honour to queen Elizabeth.

SEYMOUR, Arabella, better known in history by the name of the lady Arabella, was daughter of Charles Stuart, earl of Lennox, youngest brother of Henry Darley, husband to Mary queen of Scots. Her mother was daughter of fir William Cavendish of Chatsworth, in Derbyshire. Her affinity to the crown was the caufe of her misfortunes. SeveraJ projects were formed for placing her on the English throne, fo that he was kept under confinement in the reign of queen Elizabeth. At the beginning of that of James, a conspiracy, or rather a project of a conspiracy, was formed to raife her to the crown. She was firft couin to the king, being the daughter of a younger brother, which flew how rath the project was, supposing it to have been real; because James did not ascend the throne of England by the right of his father but that of his mother, consequently Arabella, though of the Stuart family, stood in a very remote degree of relation to the late queen Mary, had no claim to the crown of England, and the more so, as James had three children. The authors of this conspiracy were lords Grey, Cobham, fir Walter Raleigh, and others, who were tried, convicted, and condemned, but none were executed at the time, except a brother of lord Cobham, and two priests. The others were remanded to the Tower. (See Raleigh.) Arabella died in the year 1615, in prison, to which place she had been committed some time before, for having contracted marriage, without the knowledge of the crown, with William Seymour, grandson to the earl of Hertford. Hume. Acta Regia.

SEYMOUR'S Canal, in Geography, an inlet on the S.E. coast of Admiralty Island, extending from Point Hugh, about 28 miles N.N.W. of the entrance between Point Hugh and Point Gambier.

SEYMS, among Farriers. See SEAMS.

SEYNE, in Geography, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Digne; 15 miles N. of Digne. The place contains 2557, and the canton 5227 inhabitants, on a territory of 3073 square kilometres, in 8 communes.

SEYNEY, a town of Lithuania; 38 miles N.N.W. of Grodno.

SEYPUR, a town of Hindoostan, in Oude; 40 miles N.E. of Fyzabad.

SEYSSÉL, Claude de, in Biography, an historical and political writer, who flourished in the beginning of the sixteenth century, was brought up to the law, which he practised with great applause at Turin. He obtained the places of master of requests and counsellor under Lewis XII. of France. He attended in the name of that prince at the council
council of Lateran, and was promoted to the bishopric of Marseille in 1512, and to the archbishopric of Turin in 1517. He died in 1520, leaving behind him a great number of works, on theological, juridical, and historical subjects. He also translated into the French language Deuben's Eclesiasticall History, Thevenudes, Appian, Duadurus, Xenophon, Justin, and Strabo. He is said to have been the first who alleged the Salic law as influencing the succession to the crown of France. His "Grand Monarque de France," published in 1519, and translated by Sklidan into the Latin language, maintains that the French constitution is a mixed monarchy, and that the king is dependent on the parliament. In his "Histoire de Louis XII. Pere du Peuple," he is the perpetual panegyrist of that prince, but gives some curious facts respecting the reign of Louis XI., whose vices are exposed by way of contrast.

SEYSEL, in Geography, a town of France, in the department of the Am., and chief place of 3 canton, in the diocese of Belley, seated on the Rhone, which here becomes navigable, and divides it into two parts; 13 miles N. of Belley. The place contains 2,246, and the canton 6,902 inhabitants, on a territory of 1,292 square kilometres, in 5 communes.

SEZANE, or Cézane, a town of France, in the department of the Po, on the Dora; 7 miles E. of Briançon.

SEZANNES, a town of France, in the department of the Marne, and chief place of a canton, in the district of Épernay; 45 miles W. of Vité le Français. The place contains 4,149, and the canton 12,203 inhabitants, on a territory of 500 square kilometres, in 27 communes. N. lat. 48° 34'. E. long. 4° 48'.

SEZANIK, a town of Hungary; 4 miles W. of Kapdorff.

SEZENEA, a town of Ruffia, in the province of Vatka; 16 miles N.E. of Glazov.

SEZULFE, a town of Portugal, in the province of Tras los Montes; 7 miles N.E. of Miranda.

SEZZA, a town of the Campagna di Roma; 35 miles S.E. of Rome.—Alfo, a town of Naples, in Lavora, the see of a bishop, suffragan of Capua; 29 miles N.W. of Naples. N. lat. 41° 16'. E. long. 13° 34'.

SFACCIA, a town of European Turkey, in Albania; 8 miles N. of Dulejino.

SFACHIA. See SPACHIA.

SFALASSA, a river of Naples, which runs into the sea; 4 miles E. of Cape Sciagho.

SFASACA, a town of Japan, on the S.W. coast of Nippon; 18 miles E. of Amanguehi.

SFAX, or El Stacke, a town of Africa, in the kingdom of Tunis, surrounded with walls. The trade of the inhabitants in oil and cloth is considerable; 45 miles S.E. of Cairoon. N. lat. 34° 49'. E. long. 10° 56'.

SFORZA, GIACOMUZZO, in Biography, named also Attendolo, founder of the illustrious house of Sforza, was born in 1369 at Cottignola, in Romagna. He is said to have been originally a peasant, and, according to a traditionary report, being one day at work, he was solicited to enlist for a soldier, when throwing his spade on the tree, he said he would enter if the spade did not fall down again, which proving to be the case, he immediately engaged in that military life which rendered him famous. He first served under general Alberico de Barbiano, and had for his comrade in arms the celebrated Braccio. Thence, in the early part of their career, were as intimate as brothers, but as they advanced in the profession, jealously intervened, and they became at length such determined enemies, that when one engaged in the service of a prince or state, it was a sufficient motive for the other to engage on the opposite side. Sforza was soon distinguished for his bravery, and for a disposition to seize by force whatever booty fell in his way. Braccio and he perfectly agreed in selling their services as dearly as possible, and in considering war as a trade which was to be kept up for their benefit. From the command of 100 men he rose to that of 7,000; he obtained the office of podestà in the latter, and by the end of John XXIII. he was created count of Cognola, as his honour that was given by way of payment of a sum of money due to him. He commanded in the kingdom of Naples against Alphonso of Aragon, and was made constable of the kingdom. In marching to the relief of Aquila, he was drowned in the passage of the river Aterno or Pisarsa, in the year 1424. He is represented to have been rebuilt in body, and when elevated to his highest rank, that he preferred the peacock's disfigurement of luxury, and frankness of manners.

SFORZA, FRANCESCO, first duke of Milan of that family, natural son of the preceding, was born in 1401. In 1421 he was vicerey to Louis, duke of Anjou, whom he had adopted by queen Joan II. of Naples, and in 1424 he defeated the troops of Braccio; but his father, as we have seen, being drowned, he could make no advantage of his successes. Although an illegitimate son, Joan conferred upon him all his father's estates, and he served successively against the Aragonese commanders. He afterwards entered into the service of the duke of Milan, and defeated a fleet of the Venetians in the Po, in 1431. After the death of the queen, in 1435, he attached himself to her heir, René, duke of Anjou, and made himself master of several places in the Marche of Ancona. He even feigned some of the pope's professions, which brought on him an excommunication from Eugenius IV., whom he had formerly served. He had long wished to marry Bianca, the natural daughter of Philip-Maria Visconti, duke of Milan, and being in the Venetian service against that prince, he gained such advantages as induced Philip, who had often deceived him, to enter into a treaty in 1441, by which prince he made peace with the Venetians, and gave his daughter to Sforza, with Cremona and its territory for her portion.

The father and fon-in-law did not long continue united, and Sforza commanded, as general, the troops of the pope, Venetians, and Florentines, in a war against Philip. He was, however, at length, induced to go over to the party of the duke of Milan, who, in 1447, died without legitimate issue. Sforza was now ambitious of succeeding him, and took a commission, as general of the troops of Milan, against the Venetians. But he soon made a treaty with the latter, and then led an allied army to the gates of Milan, to which he laid siege. The ditto of the city occasioned a popular commotion, the leaders of which proposed the electing of Sforza for their duke. The majority concurred in the proposal, and in February 1450 he was received with great acclamations in that quality. Sforza remained in possession of the dukedom, and in 1464 made himself master of Genoa, Lewis XI. of France having made over to him all the right of France to that city. Sforza died in 1466, and transmitted the sovereignty to his son. He had three himself a brave and skilful commander; but with several traits of grandeur in his character, he was not a man of principles, and was ready to change sides as suited his interest. Mod. Univ. Hist.

SFORZA, CATHERINE, an heroine of the same family, the natural daughter of Galeazzo Sforza, duke of Milan, who was affianced in 1476. She married Jerome Rarío, lord of Forli and of Imola, which was her own dowry; but she was left a widow at the age of twenty-two, with several children. In 1500 Forli was besieged by the duke of Valentinois, son of pope Alexander VI. but the defended
the fortress with the greatest bravery, though the besiegers threatened to put her children to death, who were in their hands. At length the place was taken, and Catherine sent prisoner to Rome; but she soon recovered her liberty, and was married to John de Medicis, to whose family the rendered very eminent services.

Sforza, Isabella, an ingenious lady of the same family in the sixteenth century. Her letters were printed at Venice in 1549, by Hortensio Lando.

Sfrondatti, Francis, a senator of Milan, and counsellor of state to the emperor Charles V. On the death of his wife he entered into orders, and was elevated to the cardinalship. He died in 1550, aged 56. A poem of his, on the "Rape of Helen," was printed at Venice in 1559. His son Nicholas became pope by the name of Gregory XIV; there was another cardinal of this name and family, who wrote several works against the liberties of the Gallican church. He died in 1696.

Sfuggito, Ital. in Music, to shun, avoid, go out at the common way: as antente sfruggita, a disappointed eadence. This happens when the base feems preparing for a full close, instead of falling a 5th or rising a 4th. It riles only one tone or femitone, or falls a 3d; or in other words, when all the parts avoid their natural and expected conclusion.

Sfumberg, in Geography, a town of Bohemia, in the circle of Chrudim; 5 miles S.S.E. of Chrudim.

Sigigata, Sigzgata, or Stora, a town of Africa, in the country of Algiers, ancienly called Ruseda; situated near the coast of the Mediterranean. A few citlerns are the only remains of its ancient splendour; 30 miles W. of Bona. N. lat. 36° 48'. E. long. 6° 40'.

Sigigatchee, or Shigigatchee Jeung, a town of Thibet, situated in a narrow valley, on a ridge of rock, so as to command the road near the river Painom-tcheni; 130 miles W.S.W. of Lafta. N. lat. 29° 51'. E. long. 88° 52'.

Sgraftt, Sgraaffita, in Painting. See Scratchwork.

Shaab al Tadayn, in Geography, a dry shelf in the Red sea, extending from N.E. by E., deriving its name from its supposed resemblance to two arms wide open with their hands, fitted at the end of a great bay, far out to sea. There is a secure harbour on the side towards the land.

Shaal Stone, in Mineralogy. See Tabular spar.

Shab, or Shée, in Geography, a town of Africa, in the county of Nubia; 400 miles S.S.W. of Cairo. N. lat. 23° 35'. E. long. 30° 30'.

Shabadpouër, a town of Hindoostaan, in Oude: 50 miles W. of Kairabad.

Shabala, a name of a wonderful boon-granting cow, often spoken of in Hindoo romance; but more commonly under the name of Surakhli; which fee.

Shabaleg, in Geography, a mountain of Turkistan; 70 miles N.N.E. of Toncata.

Shabamoushwan Lake, a lake of Canada; 210 miles N.N.W. of Quebec. N. lat. 49° 10'. W. long. 75°.

Shabat, a town of the kingdom of Charafin; 95 miles S.S.E. of Urguenez.

Shabaygan, a river of Canada, which runs into lake Michigan, N. lat. 48° 30'. W. long. 86° 45'.

Shabazpouër, a town of Hindoostaan, in Allhabad; 16 miles S.E. of Cooch.

Shabran, a town of Persia, in the province of Schirvan; 40 miles N.E. of Schamachie.

Shabur, a town of Persia, in the province of Irak; 6 miles S.W. of Calbin.—Also, a town of Egypt, on the west branch of the Nile, thought to be the ancient Andropolis; 50 miles N.N.W. of Cairo. N. lat. 30° 47'. E. long. 31°.

Shack, in Ancient Cylomis, a liberty of winter-pasturage. In the counties of Norfolk and Suffolk, the lord of the manor has shack, i.e. a liberty of feeding his sheep at pleasure, in his tenants' lands, during the six winter months.

In Norfolk, shack also extends to the common for hogs, in all men's grounds, from the end of harvest till feeding-time. Whence to go a shack, is to feed at large.

Shack, in Agriculture, provisionally to find as grain at harvest. See Harvesting Grain.

Shack, or Shack-corn, a provincial term applied to the waite corn left in the fields at harvest; also the stock turned upon the stubble after harvest, and likewise to such grounds as lie open to common fields. Pigs are the flock usually employed in gathering this, and in some parts flock of geese and turkeys. Where pigs are cloven through the summer, they are filled with the shackles and the acorns; but some farmers are lo improvident, as neither to feed their clovers in that advantageous way, nor even keep pigs enough to pick up the waite corn, which is sometimes absolutely suffered to rot in the fields. Young pigs answer well in this use, as they thrive greatly, especially when bred upon the farm.

Shack-Fork, provisionally a wooden fork for shaking straw off the barn-floor, made of forked willow, &c.

Shackleford, in Geography, a post-town of America, in Virginia; 143 miles W.S.W. of Washington.

Shackles, in Ship-Building, the small ring-bolts driven through the ports, or scuttles, and through which the laffings or an iron hook paffes when the ports are barred in. There are also shackles put upon billow-bolts, for confining feamen, &c. who have deferved corporal punishment.

Shacora, in Geography, a town of Egypt, on the coast of the Red sea; 65 miles S. of El Cofer.

Shad, Alausa, in Ichthyology, the name of a sea-fish, called also the mother of herrings, and by some authors elpeus and trutta, by the ancients tricus, or trichias, and the clupeus albo of Linnaeus. See Clupea.

It very much resembles the herring in its general form, but it is flatter and broader, and grows to a cubit long, and four inches broad. The head drops down considerably from the back, which at the beginning is very convex, and rather sharp; the body from thence grows gradually less towards the tail; the under jaw is rather longer than the upper; the teeth very minute; the dorfin fin is placed very near the centre, is small, and the middle rays are the longest; the pectoral and ventral fins are small; the tail very forked; the belly extremely sharp, and strongly serrated; the back is of a dull blue; above the gills begins a line of dark spots, which mark the upper part of the back on each side; the number of these spots is different in different fish, from four to ten.

It is very common in many seas, and in some of our large rivers which lie near the sea. They run up these in great numbers, and are then very fat; they afterwards become lean, and then go down to the sea again. They usually swim in large flocks together.

In Great Britain the Severn affords the flad in higher perfection than any other river; where it first appears in May, but in very warm seasons in April, and continues about
About two months. The fish at its first appearance, especially near Gloucester, is esteemed a very delicate fish, and sells dearer than salmon. The London fishmongers distinguish it from that of the Thames, by the French name of sole.

Whether they spawn in the Severn or Wye is not determined, as their fry has not yet been ascertained. The old fish come from the sea in full force. The fishermen erroneously imagine that the bleak, which appears in multitudes near Gloucester in July and August, are the fry of the shad. Many of these are taken in those months only, but none of the emaciated shads are ever caught in their return. The Thames shad does not frequent that river till the month of July, and is esteemed a very stupid coarse fish. About the same time, the twaite, a variety of the shad, makes its appearance near Gloucester, and is taken in great numbers in the Severn, but held in as great disfavour as the shad of the Thames. The true shad weighs sometimes eight pounds, but their general size is from four to five. The twaite, on the contrary, weighs from half a pound to two pounds, which it never exceeds. The twaite differs from a small shad only in having one or more round black spots on the sides; if only one, it is always near the gill, but commonly there are three or four, placed one under the other.

Pennant.

No fish is to be taken in the Thames or Medway, except from May 10 to June 30. 39 Geo. II. cap. 21.

SHADDOCK, in Botany. See Citrus.

SHADE, in Agriculture, any fort of protection employed for preventing the heat, cold, and rain, from affecting and injuring any kind of stock, whether of the nature of building or plantation, of the woody kind, &c. See Screen-Plantation, and Shelter.

Shade, in Gardening, anything that intervenes to obscure or protect plants from the rays of the sun. It is effected in various ways by the gardener; as by mats, covers, &c.

Shade, provincially a shed for fuel, or house for sheltering live-stock, &c; it also signifies to shed as grain, as used in some places.

Shade Mountain, in Geography, a mountain of Pennsylvania, N.E. of Lewistown.

SHADENDORFF, a town of Austria; 4 miles N.E. of Brugg.

SHADING of Plants, in Gardening, the art of protecting plants of young and tender growths in seed-beds, &c. from the sun. It is necessary work on many occasions, in warm, dry, sunny weather in spring and summer, &c. in protecting various sorts of small young plants from seed-beds, into nursery-beds, pots, &c. as well as small cuttings, slips, above-ground offsets, pipings, &c. as hedges, occasionally in transplanting any kind of more advanced plants, flowers, &c. into beds, or pots, in a hot, dry season; and sometimes to seed-beds of particular sorts of small or curious seeds, in hot sunny days; also to plants in hot-beds, under frames and glasses, both of young and more advanced growths. It is the most commodiously and effectually performed by garden mats in a sort of awning over the beds, to plants in the full ground, or to those in pots placed close together, or sometimes to seed-beds, either in that way, or by being spread on the surface; in the latter method, being occasionally watered over the mats; or sometimes, in hot dry weather, by some loose straw litter, or straw over seed-beds, which by screening the surface from the parching sun, and preferring the moisture in the earth, promotes a more quick, regular, and free germination in the seed; and when the plants are come up, the covering is soon drawn off slightly with a wooden or other rake. To plants under glasses in frames, &c. the occasional shading is effected either by mats spread thinly over the glasses, or sometimes by a little Ile, long litter, shaken lightly over them, just during the fierce heat of the sun. In all cases the shade should not be made too thick, so as to darken the plants too much.

Also in the business of occasional shading, it is in general only to be continued in the warmed time of funny days, generally longer to plants, cuttings, &c. which have not struck root, than those that are in a growing state; and in common with all plants in the full ground, or others designed for placing in the open air, whose occasional shading is necessary. It should be of continued on evenings, mornings, and nights, that they may enjoy the benefit of the full fresh air at these times; as also the tender sorts, striking or advancing in growth under glasses, having occasional shading when the sun is powerful, in the warmer part of the day, should remain unhaded before and after that time, that they may receive the necessary beneficial influence of light and air in a proper degree. But in plants, cuttings, slips, &c. that have had occasional shading till they have struck good root, and begin to advance a little in a renewed growth, the shading should be most discontinued gradually, especially for those in beds, pots, &c. in the open ground or others designed for transplantation, or for placing in pots, in the full air for the summer, according to their kinds; but in some small tender plants of slender growth, the occasional shading may probably be necessary in longer continuation, as till they acquire more strength; and to plants remaining all summer in hot-beds, or under frames and glasses, the continuance of occasional moderate shading in hot sunny days will be proper; but in small young plants, cuttings, &c. potted out or planted as above, and designed for the full ground or open air, not continued under glasses, the having the benefit of occasional shade till well struck is all they require.

The shading of plants which require this kind of management are very numerous; but it is constantly mentioned in their culture where necessary.

SHADMAN, in Geography, a town of Grand Bucharia; 36 miles N.E. of Termed.

SHADOW, Shade, in Optics, a certain space deprived of light, or where the light is weakened by the interposition of some opaque body before the luminary.

The doctrine of shades makes a considerable article in optics, astronomy, and geography; and is the general foundation of dulling.

As nothing is seen but by light, a mere shadow is invisible; when, therefore, we say, we see a shadow, we mean partly, that we see bodies placed in the shadow, and illuminated by light reflected from collateral bodies; and partly, that we see the contours of the light.

If the opaque body, that projects the shadow, be perpendicular to the horizon, and the plane it is projected on be horizontal, the shadow is called a right shadow. Such are the shadows of men, trees, buildings, mountains, &c. If the opaque body be placed parallel to the horizon, the shadow is called a vertical shadow; as the arms of a man stretched out, &c.

Such a shadow is an opaque Body, in a ray of the Projection of.

1. Every opaque body projects a shadow in the same direction with the rays of light; that is, towards the part opposite to the light. Hence, as either the luminary or the body changes place, the shadow likewise changes its place.

2. Every opaque body projects as many shadows, as there are luminaries to enlighten it.

3. As the light of the luminary is more intense, the shadow

4. As the

Illuminated.
SHADOW.

dow is the deeper. Hence, the intensity of the shadow is measured by the degrees of light that space is deprived of. In reality, the shadow itself is not deeper, but it appears so, because the surrounding bodies are more intensely illuminated.

4. If a luminous sphere be equal to an opaque one, which it illumines, the shadow this latter projects will be a cylinder; and, of consequence, will be propagated still equal to itself, at whatever distance it extends; so that, if it be cut in any place, the plane of the section will be a circle equal to a great circle of the opaque sphere.

5. If the luminous sphere be greater than the opaque one, the shadow will be conical. If, therefore, the shadow be cut by a plane parallel to the base, the plane of the section will be a circle; and that so much the less as it is at a greater distance from the base.

6. If the luminous sphere be less than the opaque one, the shadow will be a truncated cone; consequently it grows still wider and wider; and therefore, if cut by a plane parallel to its base, that plane will be a circle so much the greater as it is farther from the base.

7. To find the length of the shadow, or the axis of the shady cone, projected by a lens opaque sphere, illumined by a light of the semidiameters of the two, as G C and I M, (Plate XX, Optics, fig. 1.) and the distances between their centres G M, being given:

Draw F M parallel to C H; then will I M = C F; and therefore F G will be the difference of the semidiameters G C and I M. Consequently, as F G, the difference of the semidiameters, is to G M, the distance of the centres; so is C F, or I M, the diameter of the opaque sphere, to M H, the distance of the vertex of the shady cone, from the centre of the opaque sphere. If then, the ratio of P M to M H be very small, so that M H and P H do not differ very considerably, H M may be taken for the axis of the shadowy cone: otherwise the part P M must be substracted from it, to find which, seek the arc L K, which is the measure of the angle L M K, or M H I, and this angle is one of the angles of the right-angled triangle M H I, the sides of which, M I and M H, are known; for this, substracted from a quadrant, leaves the arc I Q, which is the measure of the angle I M P. Since then, in the triangle M I P, which is right-angled at P, besides the angle I M Q, we have the side I M; the side M P is easily found by plain trigonometry.

E. 2. If the semidiameter of the earth be M I = 1; the semidiameter of the sun will be = 117; and therefore G F = 111; and of consequence M H = 217; since then M P is found by calculation to bear a very small ratio to M H, for the angle M I P = K M L, may be taken equal to the apparent semidiameter of the sun, because of the sun’s great distance, and its considerable magnitude, in proportion to the globe M; and therefore, M P = M I : line of 10° : radius, i.e. = 217 : 1, nearly; and as M H is about 217 times M I, M P may be neglected, and P H may be taken to be 217 semidiameters of the earth. See Eclipse of the Moon.

Hence, as the ratio of the distance of the opaque body, from the luminous body G M, to the length of the shadow M H, is constant; if the distance be diminished, the length of the shadow must be diminished likewise. Consequently, the shadow continually decreases as the opaque body approaches the luminary.

8. To find the length of the shadow projected by an opaque body T S (fig. 2.) ; the altitude of the luminary, e. gr. of the sun above the horizon, viz. the angle S V T, and that of the body, being given. Since, in the rectangled triangle S T V, which is rectangular at T, we have given the angle V, and the side T S; the length of the shadow T V is had by trigonometry.

Thus, suppose the altitude of the sun 37° 45’, and the altitude of a tower 178 feet; T V will be found 230 feet nearly.

9. The length of the shadow T V, and the height of the opaque body T S, being given; to find the altitude of the sun above the horizon.

Since, in the rectangled triangle S T V, rectangular at T, the sides T V and T S are given; the angle V is found thus: as the length of the shadow T V, is to the altitude of the opaque body T S, so is the whole line to the tangent of the sun’s altitude above the horizon. Thus, if T S be 30 feet, and T V 45’, T V S will be found 41° 49’.

10. If the altitude of the luminary, e. gr., the sun above the horizon T V S, be 45’, the length of the shadow T V is equal to the height of the opaque body, the triangle in this case being isosceles.

11. The length of the shadows T Z and T V of the same opaque body T S, in different altitudes of the luminary, are as the co-tangents of these altitudes.

Hence, as the co-tangent of a greater angle is less than that of a lefs angle; as the luminary rises, higher, the shadow decreases; whence it is, that the meridian shadows are longer in winter than in summer.

12. To measure the altitude of any object, e. gr., a tower A B (fig. 3.) by means of its shadow projected on an horizontal plane.

At the extremity of the shadow of the tower C, fix a flick, and measure the length of the shadow A C; fix another flick in the ground of a known altitude D E, and measure the length of the shadow thereof E F. Then as E F is to A C, so is D E to A B. If, therefore, A C be 45 yards, E D 5 yards, and E F 7 yards; A B will be 32½ yards.

13. The right shadow is to the height of the opaque body, as the cofine of the height of the luminary to the finite.

14. The altitude of the luminary being the same in both cases, the opaque body A C (fig. 4.) will be to the vered shadow A D, as the right shadow E B to its opaque body D B. Hence, 1. The opaque body is to its vered shadow, as the cofine of the altitude of the luminary to its finite; consequently the vered shadow A D is to its opaque body A C, as the finite of the altitude of the luminary to its cofine.

2. If D B = A C; then will D B be a mean proportional between E B and A D; that is, the length of the opaque body is a mean proportional between its right shadow and vered shadow, under the same altitude of the luminary.

3. When the angle C is 45°, the finite and cofine are equal; and, therefore, the vered shadow is equal to the length of the opaque body.

15. A right line is to a vered line of the same opaque body, under the same altitude of the luminary, in a duplicate ratio of the cofine to the finite of the altitude of the luminary.

Right and vered shadows are of considerable use in measuring: as by their means we can commodiously enough measure altitudes, both accessible and inaccessible, and that too when the body does not project any shadow. The right shadows we use, when the shadow does not exceed the altitude; and the vered shadows, when the shadow is greater than the altitude. On this footing is made an instrument called the quadrat, or line of shadow; by means of which the ratios of the right and vered shadow of any object, at any altitude, are determined. This instrument is usually
SHADOW.

Let the scheme, N 1. (Plate 1. Shadows, fig. 1.) represent the vanishing plane, and N 2. the plane of the picture.

In the vanishing plane, N 1, draw M 1, the vanishing line, e the point of light or place of the rays. A B the intersection of the original vertical plane, as in the picture in the angle A. Let M 1 be the line, as given in position, to the horizon. Make the angle D A F equal to the inclination of the line to the plane of the horizon. Draw D F perpendicular to A D, and D B perpendicular to A B; produce D B to K; and make K E equal to D F, and join A K, which is the beat of the line on the vertical plane. Draw e parallel to A B, and draw the perpendicular to v, i.e. v, and make the angle 1 v m equal to v, and make the angle 1 m h equal to BAK, and h will be the vanishing point of the beat of the line. Draw v parallel to D A, and v perpendicular to v; make v in the vanishing line, equal to v; make the angle v n equal to the angle D A F, which the original line makes with the plane of the horizon. Draw e perpendicular to v, meeting v in O.

In the plane of the picture N 2, let V L be the vanishing line answering to v, N 2 : in V L make choice of any convenient point, O, for the centre of the picture; make O L equal to O, N 1, and O V equal to v. N 1 : draw I, H and V L perpendicular to V L, then H is the vanishing point of the feet of the line itself.

The points and I will be on the same side of the vanishing line of the horizontal planes.

This problem is the same when the feet and altitude of a ray of the sun are given, and the inclination of a vertical plane to the plane of the picture; to find the vanishing point of a ray of light, and the vanishing point of the beat of the sun's rays.

When the sun is on the same side of the picture with the spectator, the vanishing point of the beat of the rays, and the vanishing point of the rays, will be below the vanishing line V L; but when on the other side of the picture, the vanishing point of the rays and the vanishing point of their beat will be above V L.

The following problem united to finding the vanishing points of the feet of a line, and the vanishing point of the line itself, with the vanishing point of the beat of the sun's rays and the vanishing point of the rays, as relating to the plane given.

Given the inclination of a plane to the plane of the picture, both being perpendicular to the original plane, the feet and inclination of a straight line, and the feet and inclination of the sun's rays, both to the plane of the horizon; to determine the vanishing point of the feet of the sun's rays, the vanishing point of the feet of the line on the vertical plane, as also the vanishing point of the sun's rays and vanishing point of the line itself.

It is evident, that the vanishing point of the beat of the sun's rays, and the vanishing point of the foot of the line, are both in the vanishing plane of the plane, which is a straight line perpendicular to the vanishing line of the horizon; since the original of the beat of a ray, and the original of the feet of the line, are both in the original plane; and if the line be parallel to the original plane, the vanishing point of the feet of the line will be in the intersection of the vanishing line of the vertical plane and that of the horizon.

Join V S, (fig. 2.) and let it meet A B in i; draw i, and a S, cutting each other in c, and c is the shadow of the line required.

For the vanishing point of the line that projects the shadow and the vanishing point of the sun's rays, are in the plane of the sun's rays.
SHADOW.

vanishing line of the plane of shade; and because the plane of shade is supposed to cut the original plane, the intersec-
tion, which is the shadow, will be a line in the original plane, and therefore the vanishing point of the shadow will be in the vanishing line of the original plane; and as it has been shown that it is also in the plane of shade, it will therefore be in the intersection of the plane of shade, and the vanishing line of the plane on which the shadow is thrown.

This problem is general for planes and lines in all situations, but in the following examples the context and distance of the picture are supposed to be given, and the position of the picture is that of being perpendicular to the primary plane or first original plane: the objects themselves are solids, whose edges or planes are supposed to be perpendicular to the plane on which they stand. As oblique positions very seldom occur in practice, we shall suppose the vanishing line of the original plane, on which the object is placed, to be given.

To find the shadow of a prism placed on the primary plane.

Let A B (fig. 3, 4, and 5) be the vanishing line of the plane of the base, and since the picture is supposed to be perpendicular to the primary plane, the vanishing line of the plane of shade, occasioned by the vertical lines which form the concourse of the sides of the object, will be perpendicular to the vanishing line A B. Let S I, therefore, be the vanishing line of a plane of shade, occasioned by any line of concourse, S being the vanishing point of the fun's rays, and I the intersection of the vanishing line of the plane of shade, with that of the plane on which the shadow is to be thrown.

Let g d, h a, m n, be the edges of the solid; join h a and a S, cutting each other in e; and b c is the shadow, occasioned by the edge or line of concourse h a. Draw e B and d S, cutting each other in e; or, if necessary, produce them to cut in e, and e c is shadow, occasioned by the edge a d, parallel to the plane of the original plane; also draw e A and S f, cutting each other in i; or, if necessary, produce them to cut each other in i, then e i will be the shadow of the edge d f. Lastly, draw i j, which will complete the shadow of the prism, as required.

Fig. 3 shows the shadows of the object when the fun is before the picture; fig. 4, shows the shadow when the fun is behind the picture; and fig. 5, when the fun is in the plane of the picture.

To find the shadow of a building with a break. Let V L (fig. 6) be the vanishing line of the horizon, V the vanishing point of the horizontal lines, represented by a c and b d, that form the end of the building, also of e f, g h, which represent the horizontal lines forming the sides of the break. Let the fun be supposed to be in the plane of the picture, or its rays parallel thereto, and let the planes a b d e and e g b f be in shade, and the plane e g b f will throw a shadow upon the plane a b l k, and the plane a b d e upon the horizon. As the fun's rays are parallel to the picture, they will have no vanishing point, but still the rule will hold in this case also. Through the vanishing point L, draw L M perpendicular to V L, then L M is the vanishing line of the plane a b l k, on which the shadow is to be thrown; through V draw V M parallel to the fun's rays, or make the angle L V M equal to the angle which the fun's rays make with the plane of the horizon. Thus M is the vanishing point of the shadow of all lines vanishing in V, upon the plane a b l k: therefore, to find the shadow of the line h g, join M h, and produce it to m; and draw g m parallel to M V, then m will be the shadow of the point g, and h m of h g. Draw m n parallel to g s, and m n will be the shadow of g s; therefore h m n f will be the whole shadow of the plane b g e f, upon the plane a b l k.

To find the shadow of the end a b c d upon the plane of the horizon: draw a o parallel to L V, and be parallel to M V; then a o is the shadow of the vertical line A B; join o V, and draw f p parallel to M V, and o p is the shadow of b d; join p L, and draw r q parallel to M V, and p q will be the shadow of the line d r, not seen: join q o, or draw it parallel to L V, then a o p q r will be the shadow of the building upon the plane of the horizon.

Many examples of shadows might be given, but if the principles here shewn are understood, the artifl will not be at a loss to find the shadow of any right-lined object whatever: for to find the shadow of an object constituted by planes, and consequently terminated by straight lines, is no more than to find the shadow of these lines. If a circle be given, the circumference may be divided by parallel lines into parts, and the shadows of the points of division may be found by finding the shadows of the intercepted lines, and drawing a curve round the extremities.

If we were required to find the shadows upon several planes, first find the shadow in the plane on which the object stands, and observe where the shadow meets the next plane; then having the vanishing line of this second plane, observe where the vanishing line of the plane of shade cuts the vanishing line of this second plane, then the point of interception is the vanishing point of the shadow on the second plane.

The principles shewn under the article Projection, will apply equally to the representation of objects in perspective, particularly where the planes which throw the shadow intersect the plane upon which the shadow is to be thrown; for by continuing the line that throws the shadow, and the inter-
section of the plane to meet each other, you have the point where the shadow terminates; and therefore, if a point be given in the shadow, the direction of the shadow will be known. Thus in the last example, suppose the line a o obtained; and since the point o is the beginning of the shadow of the line b d, produce a e and b d to meet in V; join o V, and draw the ray of the fun d p, then o p is the shadow of b d: produce d r and e s to meet in L, and join p l, draw the ray r p from r, then p r is the shadow of d r, not seen.

To find the vanishing line of a pole upon several planes.

Let A B C D E F G H I K, (Plate II. Shadows, fig. 1.) be the outline of a building, with a lean-to or pent-housethefun's rays, and also of the gable D M Q C of the pent-housethe fun's rays, of all the horizontal lines in the parallel fronts B F G L and D E N M; and as all vertical planes have vertical vanishing lines, V R is the vanishing line of the parallel gables A B L I K and C D M Q; L U is the vanishing line of the fronts B F G L and D E N M; and L G H I is the representation of the roof of the main building, and M N P Q of the pent-housethe sun's rays, or point of the sun's rays, S; draw S L, which will be the vanishing line of the inclined plane L G H I, for S and L are the vanishing points of two lines in that plane: produce M Q to meet V R in T, and draw T L; then T L is the vanishing line of the inclined plane M N P Q of the roof of the pent-housethe sun's rays, of the line that throws the shadow: therefore by drawing O R, or R will be the vanishing line of the plane of shade, which let cut V I, the vanishing line of the horizon, in Y; and L U,
SHADOW.

LUX, the vanishing line of the vertical plane BFG I and D E M N of the walls, in U; VR, the vanishing line of the gables, in R; SL, the vanishing line of the main roof, in Z; and TL, the vanishing line of the pent-houses, in Z'. We are now prepared for drawing the shadow of the pole WX upon the horizontal plane and upon the building.

Produce AB to meet WX in X, then X will be the point where the pole rests upon the ground or horizontal plane; draw XY, cutting DE in M, draw Ua, cutting DM in b; draw AR, cutting MN in V; draw ZJ, cutting PQ in d; draw Ua, cutting G T at I; and draw ZE, cutting the ridge 1 H at j; then X a b c d e f will be the shadow of the pole.

Now, since the shadow first begins at the foot of the pole or line in the plane of the horizon, and since the intersection of the vanishing line of a plane on which the shadow is to be thrown, and the intersection of the vanishing line of the plane of shade, gives the vanishing line of the shadow upon that plane; now Y is the intersection of the vanishing line of the plane of shade with the vanishing line of the horizon; therefore Y is the vanishing point of the shadow of the line WX upon the plane of the horizon. The next plane on which the shadow is thrown is DENM; now LU is the vanishing line of the plane DENM, and U is the point where the vanishing line of the plane of shade cuts L U; therefore U is the vanishing point of the shadow upon the plane DENM. The next plane on which the shadow is projected is the plane CDMQ; now VR is the vanishing line of the plane CDMQ, and it intersects the vanishing line of the plane of shade in R; therefore R is the vanishing point of the shadow upon the plane CDMQ. The next surface on which the shadow is projected is the plane MNPQ, of the roof of the pent-house; now Z is the intersection of the vanishing line of the plane of shade with the vanishing line of the plane MNPQ; therefore Z is the vanishing point of the shadow on the plane MNPQ. The next surface on which the shadow is projected is the plane BFG I of the wall, but U has already been shown to be the vanishing point of the shadow. The plane of the roof is the last surface on which the shadow is projected: now SL is its vanishing line, and it meets the vanishing line of the plane of shade in Z, therefore Z is the vanishing point of the shadow upon the roof.

In carrying the shadow of a line across several planes, it will not be surprising if some little inaccuracy takes place from the obliquity of intersections: it might be a great chance, that when the part of the shadow d I, which falls upon the plane BFG L, is drawn from the vanishing point U, through the point d, that it will meet the pole at I, as it ought to do. To remedy this, begin with the shadow I d, and proceed in the reverse order, until it meets the line WX at X, which it must in principle, and will not be liable to vary much in practice.

The points which direct the shadows upon the several planes might also be found by the methods shown in the article Projection.

The following observations will be useful in the practice of shadows.

When a straight line that throws a shadow is parallel to the picture, it is then represented parallel to the original. In this case it has no vanishing point; or, in other words, the vanishing point of the line may be laid to be at an infinite distance; and, therefore, instead of the vanishing point of the line being joined to the vanishing point of the sun's rays, draw a straight line from the vanishing point of the sun's rays parallel to the projection of the line which throws the shadow, which will be the vanishing line of the plane of shade, and therefore the intersection of the vanishing plane of the plane of shade with the vanishing line of the plane on which the shadow is to be thrown, will give the vanishing point of the shadow on that plane, after the same analogy as lines which are incline to the picture. This case is similar to that of the sun's rays being parallel to the picture: for here also the vanishing plane of the rays is at an infinite distance; but as the plane of shade will be a vanishing line, this will be found by drawing a straight line through the vanishing point of the line that throws the shadow parallel to the sun's rays, as already shown in a former example.

But, if a straight line be drawn from the luminous point to the plane, and its feet upon any plane, also the representation of any point in space, and its representation upon that plane, the shadow of the point will be found by drawing a straight line from the luminous point through the point in space, and by drawing another straight line from the feet of the luminous point through the feet of the point in space; and the intersection of the two lines thus drawn will represent the shadow of the point upon the plane. But when the relation of several planes represented in a picture, the representation of the light with its feet, and the representation of a point in space with its feet, are given, to project the shadow of the point on the other planes, other considerations become necessary.

For this purpose, let ABCD (fig. 2.) be the inside of a room, confining internally of the vertical planes, AH, E I, FK, GC, and of the horizontal planes A E F G B and D H I K C: also, let L be the luminous point, and M its seat in the plane A E F G B. In order to form an idea of the point L, in respect of the other planes, it is necessary to have the intersection of a line drawn through L, in a given position with one of the planes. Thus, if it is known that the straight line LA, parallel to the picture, cuts the plane of the wall BK, in the point a; the position of the point L, to any of the other planes may be easily determinded, as follows.

Through a draw ab parallel to the vanishing line NO, of the plane BK, cutting BG, the intersection of the planes BK and AG, in b; through b draw bM parallel to PQ, the vanishing line of the floor, cutting AE, the intersection of the planes AG and AH, in c: also FE, the intersection of the planes AG and AH, in d. Draw ce parallel to NO, the vanishing line of the plane AH; and df parallel to KS, the vanishing line of the plane EI. Then, because the intersecting and vanishing lines of any plane are parallel to each other, and because a line drawn parallel to the intersecting line is parallel to the picture; therefore the representations of all the lines, ab, bc, or bd, ce, and ef, are all parallel to the picture, and in a plane passing through the luminous point L.

Given the representation of any straight line TU, and the points V and W, where the lines TV and UW, drawn parallel to the picture and to each other, meet the plane AG, whose vanishing line, PQ, is given, to find the vanishing point, X, of the line TU.

Draw WV, cutting PQ, the vanishing line of the plane AG, in Y; and draw XY parallel to TV or UW, meeting the line UT, produced in X, the vanishing point required.

To make this appear, it is evident that the vanishing line of a plane passing through W and V, must also pass through Y; and likewise the vanishing line of a plane passing through UW, must be parallel to it: wherefore XY is the vanishing line of the plane, which passes through UW.

Now
Now let $WY$ cut the plane $AX$ in $Z$; and in this example the vanishing line, $YX$, is parallel to the vanishing line of the plane $EI$: therefore the planes, represented by $EI$ and $XUWY$, intersect each other in a line parallel to the picture; and, therefore, the representation of such an intersection is parallel to $XY$, or to $RS$, the vanishing line of the plane $EI$.

Given the vanishing lines, $AB$, $CD$, $EF$, (fig. 3.) of three planes, $GHIK$, $LMNO$, and $MNQR$, the common intersection, $NO$, of the planes $GHIK$ and $LMNO$; also the intersections, $NI$ and $MN$, of the planes $GHIK$ and $LMNO$, with the plane $MNQR$; the representation, $ab$, of a line in the plane $LMNO$; the point of light, $c$; $cd$, a line parallel to the picture; and $d$, the point where it intersects the plane $MNQR$: to find the shadow of the line on the plane $GHIK$.

First, find the representation of a ray of light parallel to the picture, thus: draw $de$ parallel to $AB$, cutting $MN$ at $e$; draw $ef$ parallel to $EF$: then if $ab$ be not parallel to $ef$, produce $ba$ to $f$, and join $fe$, which is the ray required. Secondly, find the vanishing line of a plane of shade paffing through the line $ab$, and the ray $fe$, thus: produce $e$ to meet $CD$ in $D$, which is the vanishing point of $ab$; through $D$ draw $DF$ parallel to $fe$, and $DF$ will be the vanishing line of the plane required. And, lastly, find the shadow of $AB$ upon the plane $GHIK$, thus: produce $ON$ and $ab$ to meet in $g$; from $F$, through $g$, draw the line $FGi$; and from the point of light, $c$, draw $eh$ and $ca$; then $hi$ will be the shadow of the line, as required.

For $de$ being parallel to $AB$, the vanishing line of the plane $MNQR$, $de$ will be parallel to the picture; and since $ef$ is drawn parallel to $EF$, the vanishing line of the plane $LMNO$, $ef$ will be parallel to the picture; and because $ba$ meets $ef$ in $f$, $fe$ is a ray of light parallel to the picture, meeting the line $ab$; and because $CD$ is the vanishing line of the plane $LMNO$, and $ab$ is in the plane $LMNO$, therefore the vanishing point of $ab$ is in $CD$, and consequently at $D$, where $ab$ produced meets $CD$; and because $D$ is the vanishing point of $ab$, the vanishing line of the plane of shade will pass through $D$ parallel to $fe$: but $F$ is the intersection of the vanishing line of the plane of shade, with the vanishing line $EF$ of the plane $GHIK$, on which the shadow is projected, therefore $F$ is the vanishing point of the shadow on the plane $GHIK$; and because $g$ is the intersection of $ab$ with the plane $GHIK$, the shadow will commence at $g$, and consequently drawing $Fg$ $bi$ gives the direction of the shadow; and lastly, because $c$ is the luminous point, the rays $ca$ and $eh$ will terminate the shadow.

As $D$ would be the vanishing point of all lines parallel to the original of $ab$ in the plane represented by $LMNO$; and as different representations could not meet the line $ef$ in the same point, the ray $ef$ will have different positions, and consequently $DF$, which is drawn parallel thereto; and as the point $D$ is stationary, the point $F$ will be variable.

Given the representation of three rectangular planes, forming a solid angle, the representation of a point of light or candle, and the seat of the light on one of the planes; to find the seat of the light on the other two planes.

Let the three planes be $ABCD$, $ABFG$, $AFED$, (fig. 4.) it is evident that every two adjoining planes have three edges parallel to each other, one common to both, which is their line of concourse; these edges will therefore vanish in a point or be parallel to each other, according as the original planes are oblique or parallel to the picture; let the original planes be obliquely situated; therefore produce the sides $CD$, $BA$, $GF$, of the two adjoining planes $ABCD$, $ABFG$, and they will all meet in $V$, their vanishing point; also produce the sides $DE$, $AF$, $BG$, of the two adjoining planes $DAFE$, $FABG$, and they will meet in $W$, their vanishing point; likewise produce the sides $CB$, $DA$, $EF$, and they will meet in $X$, their vanishing point.

Let $L$ be a luminous point, and $S$ its seat in the plane $ABCD$; draw $SX$, cutting $AB$ in $a$; draw $aW$, and draw $LX$, cutting $aW$ in $S'$; then $S'$ is the foot of the luminous point in the plane $ABGF$: draw $SV$, cutting $AD$ in $b$; draw $bW$, and $LV$, cutting each other in $S''$, then $S''$ is the foot of the luminous point in the plane $ADEF$.

Because the plane $ABCD$ represents a rectangle, and $V$ is the vanishing point of the one side, and $X$ that of the other; all the lines drawn to $X$ will represent right angles with the lines which vanish at $V$, and therefore $S$ and $A$ represent a right angle in the plane $ABCD$. For the same reason, $aS$ represents a right angle in the plane $ABGF$, and since the planes $ABGF$ and $ABCD$ are at right angles, the angle $Sas$ will represent a right angle; and because $aS$ represents a perpendicular to $AB$, $aS'$ and $SL$ will represent parallel lines; and since $LS'$ and $aS$ have the same vanishing point $X$, the original of $LS'$ is parallel to the original of $Sa$; but $Sa$ represents a perpendicular to the plane $ABGF$, therefore $LS'$ also represents a perpendicular to the plane $ABGF$; and because the point $S'$ is in the plane $ABGF$, $S'$ is the foot of the luminous point $L$, in the plane $ABGF$. In the same manner it may be shown that $S''$ is the foot of the luminous point in the plane $ADEF$.

Given the representation $cd$ of a line perpendicular to the original of the plane $ABCD$, and the vanishing point $W$ of the line, and the point $d$, where the line meets the plane $ABCD$, a luminous point $L$, with its seat $S$, also upon the plane $ABCD$; to find the shadow of the line $CD$ upon the said plane.

Draw $Sd$ and $Le$ to meet each other in $e$, then $de$ will be the shadow of the line $cd$, as required. In the same manner, if $fg$ represent a line perpendicular to the plane $ABGF$, and $g$ the point where it meets the plane $ABGF$, $gb$ will be the shadow of the line, by drawing $Lf$ and $Sg$ to meet in $b$.

This method is general for any position of the original planes, with respect to the picture; and this position of the planes, in respect of each other, is that which most frequently occurs in practice.

Let $ABCD$ (fig. 5.) be the inside of a room, shewing five sides, one, $FGH$, being parallel to the picture, and the other four perpendicular to it; $C'$ is the centre of the picture.

Let $L$ be the light of a candle, $S$ its seat upon the floor; then to find the seat of the light on all the other four sides. Through $S$ draw $ab$ parallel to $VL'$, the vanishing line of the horizon, cutting $BF$ at $a$; and $CG$ at $b$; draw $aS'$ and $bS''$ parallel to $YZ$, the vanishing line of the two vertical planes; through $L$, the point of light, draw $S's'S''$, then $S'$ is the foot of the light in the plane $ABFE$, and $S''$ the foot of the light in the plane $CDHG$. Produce $CS$ to meet $BC$ in $e$; draw $ed$ parallel to $ZY$, and join $dC'$; draw $S''S$ parallel to $YZ$; then $S''$ is the foot of the light in the plane $AEHD$; let $CS'$ cut the line $FG$ in $e'$; draw $e'S'$ parallel to $ZY$, cutting $LC'$ in $S''$, then $S''$ will be the foot of the light on the plane $EFGH$. Then to project a prism standing perpendicular to any of these planes, suppose that
that which stands on the floor. From the seat S draw S; meeting C G in a ; draw s r parallel to Z Y, and draw the ray L m. r w will be the shadow of the points ; also draw S b, cutting C G m p, draw p a parallel to Z Y, and draw L m, cutting p a t n; then n is the shadow of the point a; also draw S g, meeting C G in q; draw q r parallel to Z Y, and draw L n, meeting q s t n; then n is the shadow of the point f; join r e and r t, which complete the whole shadow of the prism upon the floor, and on the wall.

The principle of finding the shadows of the prisms on the other sides is the same, and will be obvious to inspection.

The truth of the method has already been shown.

Shadow, in Geography. The inhabitants of the globe are divided, with respect to their shadows, into Alti, Amphitex, Heteroselii, and Perniss.

Shadow, in Painting, denotes a imitation of a real shadow, effected by gradually heightening and darkening the colours of such figures as by their disposition cannot receive any direct rays from the luminary suppos'd to enlighten the piece. The management of the shadows and lights makes what painters call the chiar-oiature: the laws of which see under the article CLAIR-OBSCURE.

Shadows, Genus of Curves by. See Curve.

Shadows, Blue. See Blue-

SHADUAN, in Geography, a small island in the Red Sea. N. lat. 27° 28'. E. long. 33° 58'.

SHADWELL, Thomas, in Biography, a dramatic writer, and poet-laureat to King William III., was descended of an ancient family in Staffordshire, and was born about the year 1640, at Lauton-hall, in Norfolk, a seat belonging to his father, who was bred to the law, but having an ample fortune did not practice, choosing rather to serve his country as a magistrate. He was in the commission for three counties, viz. Middlesex, Norfolk, and Suffolk, and discharged the duties of the office with distinguished ability, and the most perfect integrity. In the civil wars he had been a considerable sufferer for the royal cause, so that having a numerous family, he was reduced to the necessity of selling and spending a considerable part of his estate to support it. In these circumstances he resolv'd to educate his son to his own profession. He was sent for preparatory studies to Caius college, Cambridge, and was afterwards entered at the Temple, but becoming acquainted with some of the wits of that time, he deserted his profession and devoted himself to literature. It is not long before he became eminent in dramatic poetry, and he appeared before the public as the writer of a comedy entitled "The Filled Lovers," or "The Impertinent," which was acted in the duke of York's theatre, and in 1668 it was printed. The success of this piece encouraged the author to proceed, and he from this period rapidly brought out plays, chiefly of the comic kind, till he had reached the number of seventeen. His model was Ben Jonson, whom he imitated in drawing humorous characters, rather from his own conceptions than from nature; and though his name has not been transmitted to posterity with much encomium, and his works have long since disappeared from the stage, yet some of his delineations are said to display much real humour. Lord Rochester has given him a respectable place among his contemporaries; he says,

"None seem to touch upon true comedy,
But hasty Shadwell, and slow Wycherly."

As every one in those days was of necessity a party man, Shadwell ranked himself among the Whigs, and in consequence of this he was set up as a rival to Dryden. Hence there grew a mutual dislike between them, and upon the appearance of Dryden's tragedy, entitled the "Duke of Guise," in 1683, Shadwell was charged with having the principal hand in writing a piece, entitled "Some Reflections on the pretended Parallel in the Play called the Duke of Guise, in a Letter to a Friend," which was printed the same year. Dryden wrote a vindication of the Poet, and a considerable storm was raised both against Shadwell and his friend Hunt, who assisted him in it, and who on the occasion was forced to fly to Holland. Dryden, by way of revenge upon Shadwell, wrote the bitterest satire upon him that ever was penned; this was the celebrated Mac-Flecknow.

In 1688 Shadwell was appointed to succeed his rival Dryden in the laureateship, an honour which he did not enjoy many years. He died suddenly in the year 1692, in the fifty-second year of his age, at Chelsea, and was interred in the church there. Dr. Nicholas Brady preached his funeral sermon, in which he affirms us, "that the subject of his discourse was a man of great honesty and integrity, and had a real love of truth and sincerity; an inviolable fidelity and strictness to his word; an unalterable friendship wherever he professed it; and a much deeper love of religion, than many others have who pretend to it more openly." The titles of Shadwell's plays are given in the Biographia Dramatica. An edition of his works, consisting of those plays and miscellaneous poems, was printed in 1720, in four vol. 8vo. The Earl of Rocheller, in speaking of Shadwell, says, "If he had burnt all he had written, and printed all he spoke, he would have had more wit and humour than any other poet."

Shadwell, in Geography, a parish in the Tower division of the hundred of Ophullon, and county of Middlesex, England, is situated about two miles and a half E. by S. from St. Paul's cathedral. It was formerly called Chadwell, as it was supposed from a spring dedicated to St. Chad, and constituted a hamlet in the parish of Stepney, till separated from it, and made parochial, in 1669. The extent of this parish is very small, being only 410 yards in length, and 760 in breadth, and is wholly covered with houses, except a few acres, called Sun Tavern fields, which are appropriated as rope-walks. That portion of it which abuts a river, and is called Lower Chadwell, is chiefly inhabited by tradesmen, and manufacturers connected with the shipping, such as ship-chandlers, bungo-bakers, Invoice-bakers, mill-makers, sail-makers, anchor-smiths, cooperers, &c. A market which had been formerly held at Shadwell under the authority of a charter of king Charles II., but which was long discontinued, has been revived within the last few years. The church, dedicated to St. Paul, is a modern structure of brick. The living is a rectory in the deanery of the diocese of St. Paul's. In Shakespeare's walk is a meeting-house for Presbyterian dissenters, opened only on Sunday evenings, when sermons are delivered by dissenting ministers of different denominations, for the support of a charity-school, in which 50 boys and 20 girls are clothed and educated. Here are also a Calvinist meeting-house, and a chapel for Wesleyan Methodists, who have a Sunday-school attended by above 150 children. A third charity-school, founded in 1712, and partly endowed by queen Anne, provides clothes and education for 50 boys and girls.

The Shadwell water-works, which were established in 1609, and served a district containing 8000 houses, have been lately discontinued; the premises having been purchased by the East London Water-works' company, by whom this parish and its neighbourhood are now supplied with water. In Sun Tavern fields is a mineral spring, called the Shadwell Spa, which long fulminated a high character for its medicinal qualities,
H and drawn (haft original alfo poles as truth, years.

SHAFEITES, in the History of Mahometanism, the followers of Mohammed Ebn Edris al Shafei, the author of the third orthodox sect, who were formerly spread into Mawara^naih, and other parts eafward, but are now chiefly of Arabia. Al Shafei was born either at Gaza or Alcalon, in Palantine, in the year of the Hegira 150, on the fame day in which, as fame fay, Abu Hanifa, the founder of the Hanefites, the first of the four orthodox fects, died; and was carried to Mecca at two years of age, where he was educated. He died in 204, in Egypt, whither he went about five years before, though Abulfeda fays he lived 58 years. This doctor was very highly efeemed for his excellence in all parts of learning, inomuch that his contemporary, Ebn Henbel, used to fay that he was as the fun to the world, and as health to the body. Al Shafei is faid to have been the first who difcourfed of jurisprudence, and methodized that fience; and accordingly it was wiftly faid of him, that the relations of the traditions of Mahomet were alleept, till Al Shafei came and awoke them. He was a great enemy to the feholatic divines. It is faid of him, that he used to divide the night into three parts; one for study, another for prayer, and the third for fleep. It is alfo related of him, that he never fo much as once swore by God, either to confirm a truth, or to affert a falehood; and that being once afked his opinion, he remained filent for some time; and when the meaning of his filence was demanded, he anfwered, "I am confidering firft whether it be better to fpeak or to hold my tongue." The following faying is alfo recorded of him, "Whoever pretends to love the world and its creator at the fame time is a liar." Sale's Koran, Int.

SHAFERS, in Geography, a town of Pennsylvania; 48 miles N.E. of Eafon.

SHAFT, in Building. The fhaft of a column is the body of it; thus called from its ftraightness; but by ar- chitects more frequently the fhaft. See the dimensions under Column.

SHAFT is alfo used for the fpire of a church-feepe; and for the f ank or tunnel of a chimney.

SHAFT, or Tunnel-Pit, is the well through which the fhaft, excavated from a tunnel, is drawn up to the surface.

SHAFT of a Mine, is the hollow entrance or paffage into a mine, funk or dug to come at the ore.

In the tin-mines, after this is funk about a fathom, they leave a little, long, square place, which is called a pabble.

Shafts are funk fome ten, fome twenty fathoms deep into the earth, more or les. Of thefe shafts, there is the landing or working-fhaft, where they bring up the work or ore to the furface; but if it be worked by a horfe engine or whim, it is called a whim-fhaft; and where the water is drawn out of the mine, it is indifferently named an engine-fhaft, or the rod-fhaft. See Mine and Quarry.

SHAFT, in Agriculture, a name provincially applied to a handle of a tool, as a fpade, fork, &c.

Shafts of Carts and Wagons, the parts or poles be- twen which the thigh-horses draw. The manner in which the fore-horses are attached to these shafts, when there are more than the thigh-horses in the teams, is a matter of great confequence; as the weight or prejudice on them is more or les, according to its nature, and the way in which it is performed. See THILL-HORSES and WAGGON.

SHAFT-Drain, that fort which is efected by carrying a fort of shaft or pit down to the porous ftratum below, and which is in ufe where a superficial defect cannot be had for the collected waters, and an open ftratum lies beneath the fubfioil, ready to receive it. A communication between them becomes here of high advantage, as the colt and at- tendence of raising the water by machinery may thereby be avoided. In cafes of this kind, Mr. Marshall advises the drainer to afeertain the lowest point of the fite to be improved; and there, lays he, sink a shaft down, and into, the receiving ftratum, and fill it up to within a few feet of the surface, with rough foines, the roots of trees, or other open materials; and, on the top of thofe, form a filter, with heath and gravel, or other fubfiances, that will pre- vent earthly matter, or water in a foul flate, from entering the shaft; and to this filter lead the collected waters. And that where the water is collected by the means of covered drains, and where the filter alfo has a covering placed over it, the entire procefs will be free from external injury; and a work of this kind may remain unimpaired for ages. But even if the waters were collected by open drains, and the filter were fuffered to remain in a flate of neglect, until the shaft, in procefs of time, fhould become defective, the re- medy would be efay. Embrace, fays he, a dry feaon to re-open the shaft, and to cleanfe it, and the materials with which it may be filled, from their impurities; and thus refolve it, at a small expence, to its original flate of per- fection. It is further 3lated allfo, that if the fite of im- provement be liable to any other surface-water, than what falls on its own area, fuch water ought to be conducted away from it superficially, by cutting it off at fuch a height as will gain a fufficient fall. And that where the quantity of water, which depends into it subterraneously, (or would defcend, if a free paffage were opened for it,) fhould be found to be too copious to be readily difcharged by a fhaft-drain, in the manner here propofed, proper efforts fhould be used to cut off the fupply, or as much of it as may be, by a perforated trench or otherwife, at a fufficient height to be able to convey it away superficially; and with a fufficient fall, to prevent its entering the area to be im- proved; which will thus have only its own superficial waters to defcharge by the fhaft. He is defirous to clear the way which leads to this valuable improvement, as he is convinced that there are many instances in which it might be applied with great profit. Many of the low, flat-lying, moory vallies of Norfolk, from whole bafes superficial drains would be difficult to make, have for their subtructures, it is probable, he fays, inatable depths of land; and that, in every district of the ifland, fuch objects as are proper for this practice may be found.

SHAFTESBURY, Earl of, in Biography. See Cooper.

SHAFTSBURY, or Shaftesbury, in Geography, a borough and market-town in the hundred of Upwimborne, Shafton division of the county of Dorset, England, is situated at the distance of 28 miles N.N.E. from Dor- chefter, and 101 miles W.S.W. from London. Concern- ing the origin of this town much difference of opinion prevails. While some authors ascribe its foundation to Cicuber, Lud, or Cafliblan, supposed kings of the Brit- tons, many years previous to the birth of Chrift; others limit its antiquity to the reign of Alfred. This last opinion
England, and among its contents are the famous suicides of the abbey, including the monks, and the name of that fact, which it retained till the dissolution.

The abbey was among the number of those who held a whole barony in capite, and was in consequence liable to serve in parliament, though excused on account of her sex. She had writs, however, directed to her, to fend her quota of men into the field, according to the knight's fees. On the translation of the body of Edward the Martyr, bishop, from Wareham, this monastery attained the name of that same, which it retained till the dissolution. Many miracles are said to have been wrought at its shrine, which was visited by an immense concourse of pilgrims, among whom was the illusrious Canute, who died here. After the Conquest, this convent was for some time neglected; but the patronage of succeeding monks soon restored it to celebrity, and conferred upon it such extensive donations in land, that it became proverbial to say, "that if the abbot of Glastonbury should marry the abbess of Shaftesbury, their heir would have more land than the king of England." At the dissolution, the nuns amounted to fifty-four in number, and enjoyed a revenue valued by Speed at £329/11.3d. The last abbess was Elizabeth Zouche, who had an yearly pension assigned to her of £133/6.

Shaftesbury is a very ancient borough by prescription, being mentioned as such in Domesday Book. It was not, however, incorporated by regular charter till the reign of queen Elizabeth, who confirmed all the privileges it enjoyed by charter, and vested the government in a corporation, consisting of a mayor, recorder, twelve aldermen, a bailiff, and common council-men. That charter has since been confirmed by kings James I. and Charles II., with little variation. Henry VIII. made this town the seat of a suffragan bishop, but it did not retain its episcopal dignity above a few years. Shaftesbury has sent two members to parliament since the 27th year of Edward I. They are elected by the inhabitants paying 6d. and 1d. who are estimated at about 400 in number, and are returned by the mayor. Shaftesbury has a weekly market on Saturday, and an annual fair; and according to the parliamentary returns of 1811, contains 515 houses, and a population of 2850 persons.

The town of Shaftesbury is most pleasantly situated, being built on a very hilly eminence, which commands an extensive prospect over the three adjoining counties of Dorset, Somerset, and Wiltshire. From the irregularity and narrowness of most of the streets and the mean character of the buildings, however, it presents but an indifferent appearance. In ancient times it was more flourishing and important than at present; containing besides the abbey church, twelve others, several charities and fraternities, and a hospital of St. John the Baptist. Of its public structures only four churches remain, respectively dedicated to St. Peter, the Holy Trinity, St. James, and St. Ursula. The principal of these is Peter's, which is a building of considerable antiquity, and date from the 12th century; its architectural proportions are correct, but the eastern part of it is defaced by modern alterations. Of the abbey church scarcely a vestige exists, the whole having been destroyed soon after the dissolution, except the high embattled wall supported by buttresses, which formerly enclosed the park, and is still in part that long the site of the chapel of the abbey.

The other principal buildings of Shaftesbury are the town hall, a free-school, two almshouse institutions, and three meeting-houses, for Presbyterians, Methodists, and Quakers.

The manor of Shaftesbury appears from Domesday Book to have been very anciently divided into two manors, one of which belonged to the crown, and the other to the abbey. The abbey manor was surrendered in the 12th year of Henry VIII., whose successor granted it to Thomas Wrothley, earl of Southampton, together with the town, borough, feite, and precincts of the monastery. From him it passed to Sir Thomas Arundel, and afterwards to the earls of Pembroke, by one of whom, Philip, the royalty of the manor, and borough manor, were held to Anthony Ashley Cooper, earl of Shaftesbury, in whose family they still continue.

Well is a town of an eminence called Castle Green, which is supposed to have received that appellation from its having been the scene of an ancient castle, though history is silent respecting any such structure belonging to Shaftesbury. On the brink of this hill is a small mount, surrounded by a hollow valley, which may have belonged to it, but it is commonly regarded as a Roman intrenched. Tradition reports that the old town stood here, and it is certain that it occupied somewhat different ground from the site of the present buildings. The immediate vicinage of Shaftesbury is noted as the birth-place of the Rev. James Granger, author of the celebrated Biographical History of England. The beautiful woodlands, gravel walks, and vale of Painshill, near the town, have been incorporated by the earl of Pembroke, and form a delightful view.

The woods are so extensive that they have been called "the woods of Pembroke" by many; and the country about is rich in ancient antiquities, including the remains of the old town, and the ruins of the abbey.

SHAG ISLAND, an island near the entrance into the river of the same name, and containing 1733 inhabitants.

SHAGGE, or Shag, in Ornithology, a name by which we call a water-bird common on the northern coasts, and called by Mr. Ray cuculus aquaticus minor, or the lesser cormorant, being properly a bird of the cormorant kind, or the pelicanus graculus of Linnaeus.

It is somewhat larger than the common duck, and weighs about four pounds; its beak is straight and slender, and is not flattened, but roundish; it is four inches long, and is hooked at the end; its mouth opens very wide, and its eyes small; the head is adorned with a crest, two eyes long, pointing backward; the whole plumage of the upper part of this bird is of a fine and very shining green; the edges of the feathers are purplish-black; but the lower part of the back, head, and neck, wholly green; the tail dusky, and the legs black. It builds its nest in the common cormorant, swims with the head erect, and is very difficult to be
shot; because, when it sees the flash of a gun, it pops under water, and does not rise but at a considerable distance.

SHAGR, in Geography, a town of Syria, in the pacchali of Aleppo; 40 miles W. of Aleppo. N. lat. 35° 45'. E. long. 36° 25'.

SHAGREEN, or CHAGREEN, derived from the Tartar Shagyr, a kind of grained leather, prepared in Astrakan, chiefly by Tartars and Armenians, and molly used in the covers of cases, books, &c. It is very close and solid, and covered over with little roundish grains, or papilla. It is brought from Constantinople, Tunis, Tripoli, Algiers, and some parts of Poland.

There has been a dispute among authors, what the animal is from which the chagreen is prepared? Rauwolf affires us it is the onger, which, according to him and Bellonius, is a kind of wild ass. Vide Ray, Synop. An. Quad. p. 63.

It is added, that it is only the hard part of the skin which is used for this purpose. Or, it is that part of the skin that grows about the rump: that of horses is laid to be equally good. There are large manufactures of it at Astrakan, and in all Periss. Borel says, it is the skin of a serval; others, of a kind of fish, called by the Turks shagrain, whose skin is covered with grains; and thofe go hard, that they will rap and polish wood.

There is also a sort of chagreen, which was formerly made of the skin of the fquatlina; in English, the monk or angel-fish, but now of that of the greater dog-fish. Vide Wil- lughby fcelth. p. 80.

SHAGREEN, Manner of preparing. The proceeds for making chagreen is as follows: of horse-hides and ass-hides the hinder back-piece, cut off immediately above the tail in nearly a semi-circular form about an arithme and a half upon the crupper, and rather lefs than an arithme along the back, is felected as the only part that is useful, and the rest is thrown away. The back pieces thus cut out are laid in a vat filled with clean water, and left in it several days successively, till they are thoroughly foaked, and the hair comes freely off. Then the hides are taken one by one out of the vat, spread again against a board fettling against the wall, one corner of it reaching over the edge of the board where it is fetten; and in this position the hair is fcrapped off with a blunt fcraper, urak, and with the hair the upper pellicle; and the cleaned skin is laid again in clean water to fofthen. This done, they take it a second time out, fpread one piece after another in the manner before described, ferape now the fheelid with the fame fcraping-iron, and the whole skin cleaned again on the hair-fide with great care, so that nothing now remains of the fotteden skin but the clean finewy web which serves for parchement, confifting of thick fhefculi of mellow fibres, reftembling a hog's bladder fotteden in water. After this preparation they immediately take in hand certain frames, palzzi, compofed of a straight piece and a femi-circular bow, forming therefore nearly the shape of the skin, which is fretched in it with frings as even and uniform as poifible; and during this operation is sprinkled between whites with fair water, that no part of it can dry and occafion an unequal extension. In like manner they finally wet them when the whole floc of skins is fretched, and carry all the thoroughly wetted skins into the worke-room. There the frames are one by one laid flat on the floor, fo that the fheelid of the fretched skins is turned undermoft. The other fide of it is then thick frewed over with the black, very frough, and hard feds of a species of the herb gooffe-foot, or the greater orach (chenopodium album), which the Tartars call alabunda, and which grows in great abundance, and almost to man's height, about the southern Volga in farmyards and gardens; and that these may make a strong imprefion on the skin, a fett is spread over them, and the feds trod in with the feet, by which means they are impreffed deeply into the very yielding fkins. Then, without faking off these feds, the frames are carried again into the open air, and let sponges or rags against a fwall to dry, in fuch manner that the feds covered with the feeds face the wall and cannot be done on by the fun. In this imputation the fretched fkins must dry for several days successively in the sun, till no trace of moifure is perceptible in them, and they may be taken out of the frames. Then, when the impreffed feds are beaten off from the hair-fide, it appears full of little pits and roughneffes, and has got that impreffion which the grain of the shagreen ought to produce when the true polifh has been given to the skin by art, and the lay now to be mentioned has been used previous to the flaining.

The polifh is done on a stretching-bench, or a board on trellefs, furnifhed with a small iron hook, and covered with some thick felts or voilocks of sheep's wool, on which the dried shagreen-skin may lie foft. This is hung in the middle, by a hole which has been occafioned by the string in the ftrechting, to the hook, and faffned at the end by a ftring with a weight or a stone, by means of which the skin is allowed to move to and fro, but cannot easily be flowned out of its proper imputation. This done, the polifhing or fraping is performed by two feveral instruments; the frill is called by the Tartars tokar, being an iron, crooked at one end like a hook and fhardened. With this the face of the shagreen is fraped prefently happily, in order to remove the moft prominent roguouflage, which from the horne hardneffes of the dried skin is no other matter, and in which great care must be taken not to have away too deeply the impreffions of the alabuta-feeds, of which there is imminent danger if the iron be kept too sharp. As the blade of this iron is very narrow, it will make the shagreen rather uneven, and therefore after it, must be ufed the other fperaf, or urak, by which the whole face acquires a perfect equality, and only a flight impreffion remains of the feeds, exaftly as it ought to be. After all these operations the shagreen is laid again in water, partly for rendering it fpufle and partly to make the elevated grain appear; for the feeds having caufed pits in the face of the skin, the interfiles of these pits have loft their prominent subfance by the polifhing or fHAVING, and now the points that were preffed down, have loft nothing of their subfance, springing up above the flaved places, and thus form the grain of the chagreen. To this end the pieces of shagreen are left to foftten twice 24 hours in water, and are floated several times afterwards in a strong and hot ley, which is obtained by boiling an alkalecent faltne earth, fehora, found about Astrakan. From this ley the skins are bundled warm one on another, and thus fuffered to lie some hours, by which they flwell up and are foftened in an extraordinary manner. Again, they are left to lie 24 hours in a moderately strong brine of common falt, by which they are rendered fine and white, and excellently adapted to receive any agreeable colour, which the work- man has left to give them as soon as they are come out of the brine. The colour most commonly communicated to the fine chagreen is the fcarlet, as the moft beautifiil. But the expert chagreen-makers have the art of making alfo black, red, blue, and even white chagreen.

For the green dye, nothing more is necessary than fine copper-filings and fa-t ammoniac. As much of the latter is melted in hot water as the water will admit. With this fa-t ammoniac water the chagreen skins, fiill moift from the brine, are bruised over on the ungrained fheel-fide, and when they are thoroughly wetted, a thick layer of copper-filings
rubbed A Kairabad, them yet peeling boiled ’ when 1 pound B this not whence. The may a I I irfiKr ii... kettle "Ut twciiity-lour In,;; much Fur rarely'«• not blunt but nnnii Geography, worle i:i When then and pastie river rtr<rw^ in iiorrjhlc mrr.tiinrd till Ai
common finely to prelfed then promote fufficient furplus tion, dyers, cleaned, and was entirely renewed, in a broken bottle. But the old cup could not be obtained to such perfection with that preparation. But the flaxen intended to be boiled red must not be brought out of the requisite, bitter leaf into the brine, but must be made white, in the manner above detailed, and afterwards supplied with the brine, in which it may lie for twenty-four hours, or less, from time to time. The dye is made with cow's milk or milk, as the Tatars call it. — The operation is begun by boiling for a full hour about a pound of the dried herbitchag, which grows plentifully on the salt plains about Afshar, and is a sort of kalk, in a kettle large enough to contain about four common vessels of water, by which the water acquires a greenish colour. The herb is then taken out, and about half a pound of grated cotton is put into the kettle, with which the above described must boil another full hour, diligently stirring it on the fire, that the kettle may not boil over. Lastly, to this are added fifteen or twenty grains of the material which the dyers call litter (perhaps orpiment), let the dye boil a little more, and then take the fire from under the kettle. Then the skins taken out of the brine are laid separately in trays, pouring the dye upon them four times, rubbing it in with the hands, that it may be equally spread and imbied, preffing it out every time, which done, they are ready for drying and ornamenting, and fell much dearer than the others.

The bell flaxen is that brought from Constantinople, of a brownish colour; the white is the worst. It is extremely hard; yet, when steeped in water, it becomes very soft and pliable; whence it is of great use among cafe-makers. It takes any colour that is given it, red, green, yellow, or black. It is frequently counterfeited by morocco, formed like flaxen; but this last is distinguished by its peeling off which the first does not.

SHAHUM, in Geography, a river of America, which runs into lake Erie, N. lat. 41° 49'. W. long. 84° 21'.

SHAH, the Persian title corresponding to king, and equivalent to khan. (See Citam.) Nevertheless, the most absolute Persian monarchs, who have never assumed any other title than that of shah, have permitted the governors of provinces in their empire to take that of khan, which is its equivalent, and which they have ever affected. Even in our time, the governors of the provinces of Ghilan, Mazanderan, &c. who have no more authority in Persia, than the pachas in Turkey, take the title of khan, the reason of which it is not easy to assign.

SHAHABAD, in Geography, a town of the kingdom of Candahar; 40 miles S.W. of Cabul. — Alfo, a town of Hindooollan, in the circur of Sirhídd; 42 miles E.S.E. of Sirhund. — Alfo, a town of Hindooollan, in Oude; 45 miles W. of Kairabad. N. lat. 27° 40'. E. long. 80° 20'. —Alfo, a town of Hindooollan, in Oude; 25 miles S.W. of Mahomody.

SHAHAMA, a name given to a colossal statue, cut in a mountain in the neighbourhood of the ancient city of Bamiyan, in the East Indies. This city, (which is described in our article Bamian,) is eight days' journey north-wellerly from Cabul, and is rarely visited by Europeans, though highly deserving of examination. The statue in question is accompanied by another, called Salifala. Native travellers
SHA

differ as to their height: from fifty cubits to eighty ells. Their origin, age, and sex, are also variously related. The few Hindoos who live in the neighbourhood, say, they are the statues of one of their heroes named Bhim, and his consort. Bhim is one of the five famous Pandus. (See Pandu.) The followers of Buddha call them by the names first mentioned. The Mahomedans say, they are of Adam and Eve; and a third statue, half a mile distant, about twenty feet high, they say is of Seth, their son. The author of a celebrated Persian dictionary, entitled "Farhang Jehrangi," says they existed in the time of Noah; but gives them other names. There can be little doubt but these statues, and the wonderful excavations of the city of Bamban, scooped, like Thebes, out of a mountain, were executed by the fame indefatigable race of workmen, who in the more southern parts of India constructed the gigantic statues in the similar caverns at Kenera, on the island of Sajette, near Bombay, in the province of Kanara, and at Karly; all believed to be of Jaina or Budhah origin. See Jaina, Karly, and Kenera.

SHAHBUNDER, in Geography, a town of Hindostan, in the province of Tatta; 45 miles S.S.W. of Tatta.

SHAHDURAS, a town of Hindostan, in the circle of Sirhind; 10 miles N. of Tannafar.

SHAHG, a town of Hindostan, in Myloire; 18 miles S. of Venchatigery.

SHAHJEBHAN, a town of Hindostan, in Bahar; 18 miles N.W. of Bahar.—Allo, a town of Hindostan, in Rohulceund; 45 miles S. of Pillibeat.

SHAHHJEHPOUR, a town of Hindostan, in Malwa; 20 miles N.E. of Oueine. N. lat. 23° 26'. E. long. 76° 18'.—Allo, a town of Hindostan, in Oude; 30 miles S.E. of Fuzabad. N. lat. 26° 26'. E. long. 82° 40'.—Allo, a town of Hindostan, in Mewat; 20 miles W. of Alwar.—Allo, a town of Hindostan, in Bahar; 14 miles S.S.E. of Patna. N. lat. 25° 24'. E. long. 85° 30'.

SHAHIGIAN, a town of Peru, in the province of Khorasan, near Maruz, which since is called Marur Shaghigian. SHAHJOLE, a circar of Bengal, bounded on the north by Raujefhy, on the east by Mahommed, on the south by Jedore, and on the west by Kifhenagur; about 30 miles long, and from 5 to 10 broad.

SHAHISABI, a town of Peru, in the province of Khorasan, on the borders of Bucharia; 80 miles N. of Maruz.

SHALI-SHAK, a town of Peru, in the province of Khorasan, on the borders of Bucharia; 5 miles N. of Maruz.

SHAHPOUR, a town of Hindostan, in Lahore; 30 miles W. of Nagoreote.—Allo, a town of Hindostan, in Lahore; 27 miles E. of Sealcot.

SHAHR and VAN, the ancient Apollonia, a town of the pachal of Bagdad, 27 miles from Bocouba, which is nine furlongs from Bagdad, peopled by about 4000 Turks and Kirds, and is, upon the whole, a handsome little town, watered by two canals drawn from the Dula. At the distance of 18 miles is Kuzil Roobat, not so large as the former, situated in a handy plain, about one mile from the river Dula. Khankan is also a handsome little town, built on that branch of the Dula, which has its source in the mountains of Kurzand, 18 miles from Kuzil Roobat; it occupies both banks of the river, over which is a handsome bridge, and is surrounded by numerous gardens and plantations. Mendeli, about the same size as Solymania, is situated in one of the roads leading to Kermanhaw; and four furlongs on the Bagdad side is a fountain of naphtha. Thirteen leagues from Mendeli, and four from the foot of the mountains, is Bedri, the frontier town, in this quarter of the Turkish empire.

SHAIGI, a town of Nubia, on an island in the Nile; 130 miles E. of Dongola. N. lat. 20° 20'. E. long. 30° 45'.

SHAIGOL, a town of Peru, in the province of Khorasan; 10 miles S.W. of Maruz.

SHAIMA, a town of Peru, in the province of Me- ran, on the sea-coast; 200 miles W.S.W. of Kidge.

SHAIINT, or HOLY, ISLES, three small islands of the Hebrides, or Western isles, are situated in the channel between the iles of Lewis and Skye, in the parish of Lochs and district of Lewis. These isles are well known to mariners, and are remarkable for their fine sheep fatture. One of them, called St. Mary's island, has a small chapel upon it, dedicated to the Virgin, and bears marks of having been formerly better inhabited than at present. Sinclair's Statistical Account of Scotland, vol. xix. 8vo.

SHAINYMALY, a town of Hindostan, in Coimbo- tore; 12 miles S. of Erroad.

SHAIIZAR, a town of Syria, in the pachal of Da- mfeus, on the Orontes; 20 miles N. of Hamah.

SHAK, a town of Peru, in the provence of Schirvan; 20 miles N.W. of Schamachie.

SHAK, in Maha, is a grace, an embellishment of melody, of which the indication is a $,$ or sometimes only $t$, the initial of the Italian term trillo, which implies the same thing. There are two kinds of shakes, the continued, and the transient. The continued shake, upon a long note, must be practiced at first by incipents, flow, and accelerated by degrees. The effect of a shake is a rapid motion of two adjoining notes: as de, be, &c.

In our didactic and elementary articles, we should not wish to confine ourselves to mere dry definitions of terms of art; but, having had some little experience, we would gladly assist students, by pointing out the means of acquiring the practical use of what we describe.

With regard to a vocal shake, we can do young fingers no greater kindness, than in referring them to the 3d chap. of Toff's "Observations on florid Song" as admirably translated by Galliard, and illustrated with the notes of that able and experienced master.

101

Tofî, after informing the student of the importance of the shake to fingers, says, "Let the latter strive to enable his scholar to attain a shake that is equal, distinctly marked, easy, and moderately quick, which are its most beautiful requisites."

This excellent author describes the different kinds of shakes, and their preparation, that are worth cultivating, as well as those that are to be avoided. The free and open shake on the cobbles tone and the fémale, are certainly the principal.

The
The two tones or semitones that constitute the shake, or an or more, should be equally loud and distinct, but above all, perfectly in time with the rates of the vocal scale and particularly in that which the performer uses. The Italians call a bad shake, or no shake at all, but a quivering upon the same note. To give a good shake, most of the members are called upon the end of a round-board. At the first, the shake is reduced to the tone of a mere appoggiatura. See Quakers.

SHAKER-PIGEON, in Ornithology, a kind of pigeons, of which there are two sorts, the broad-tailed, and the narrow-tailed. The first is the finest, and most valued. It has a beautiful long thin neck, which bends like the neck of a swan, leaning towards the back. It has a full breast, a very short back, and a tail consisting of a great number of feathers, seldom less than four and twenty, which it spreads in an elegant manner, like the tail of a turkey-cock, and bends it up so, that it meets the head. It is commonly all white, but sometimes is red, yellow, or blue-pied. The longer the neck of this bird is, the more it is valued.

The second, or narrow-tailed shaker, has a shorter and thicker neck and a longer back. It is esteemed by many a different species, but seems only a mixed breed with some other pigeon. They are called shakers, from a tremulous motion which they have with their necks when courting.

SHAKERS, in Ecclesiastical History, a sect which originated in Lancashire, with some dissenters from the society of Quakers, or Friends, about the year 1747, and which continued for some time unconnected with every denomination of Christians. During this period, their testimony, derived, as they fancied and pretended, from what they saw by vision and revelation from God, was, “that the sect, appearing of Christ was at hand, and that the church was rising in her full and transcendant glory, which would effect the final downfall of Antichrist.” From the shaking of their bodies in religious exercises, they were denominated Shakers and by some persons they were called Shaking Quakers. The sect seems to have made no great progress until the year 1774, when the testimony originally announced was fully opened, according to the special gift and revelation of God through Ann Lee, who was born of obscure parentage; at Manchester, about the year 1736; and who, having joined the society in 1738, became afterwards a distinguished leader among them. Her exercises, both of body and of mind, were singularly trying and severe for about the term of nine years; but she was thus prepared for receiving the testimony of God, against the whole corruption of man, in its root and every branch. Accordingly, her testimony was in the power of God, attended with the word of prophecy, and such energy of the Spirit, as penetrated into the secrets of the heart, and was irresistible, especially in those with whom she was united.

And from the light and power of God which attended her ministry, and the certain power of salvation transmitted to those who received her testimony, she was received and acknowledged as the first Mother, or spiritual parent in the line of the female, and the second heir in the covenant of life, according to the present display of the gospel. Hence among believers, she had been distinguished by no other name or title than that of Mother, from that period to the present day. To such as addressed her with the customary titles used by the world, she would reply, “I am Ann the Word;” signifying that in her dwelt the Word.

In 1774, Ann Lee, with some of her followers, having been thought mad, and falsely persected, settled their temporal affairs in England, and set sail from Liverpool for New York. James Wardley and his wife remaining behind, were removed into an almshouse, and there died. The others, we are told, being without lead or protection, left their power, and fell into the common course and practice of the world!” Ann Lee and the brethren reached New York, after working a sort of miracle, for the ship springing a leak on the voyage, and it is more than hinted, that had it not been for their exertions at the pump, the vessel would have gone down to the bottom of the ocean! She, however, left New York, and fixed her residence up the Hudson river, eight miles from the city of Albany. In this retired spot, her followers greatly multiplied, but she was not without bitter reproaches and manifold persecutions. She and the elders would delight in missionary journeys, being out for two or three years, and returning with wonderful accounts of their success.
After Mother and the elders were released from prison, they again collected together at Water-Vilet, where they were visited by great numbers from distant parts of the state of New York, Massachusetts, Connecticut, New Hampshire, and the district of Maine, who received faith; and through the power and gifts of God, which were abundantly manifested for the destruction of sin, and the salvation of souls, many were filled with joy unspeakable and full of glory, and increased in their understanding of the way and work of God.

Ann Lee died on the eighth day of the ninth month 1784. From the year 1780 to 1787 the credit of this faith revived in America, and the number of its adherents considerably increased.

The creed of the Shakers is very obscurely and mythically expressed. They seem to be believers neither of the Trinity nor of the Satisfaction. They deny also the imputation of Adam’s sin to his posterity, as well as the eternity of future punishment. The tenets on which they most dwell are those of human depravity, and of the miraculous effusion of the Holy Ghost! Their leading practical tenet is the abolition of marriage, or indeed the total separation of the sexes. This circumstance of course attracts great attention, and they pride themselves on their superior purity. The essence of their argument is, that the resurrection spoken of in the New Testament means nothing more than conversion; our Saviour declares that in the resurrection they neither marry nor are given in marriage, therefore, on conversion or the resurrection of the individual, marriage ceases. To speak more plainly, the single must continue single, and the married must separate. Every passage in the gospel and in the epistles is interpreted according to this strange and unnatural hypothesis.

The fyltem of the Shakers is thus pretty plainly described. In the fulness of time, according to the unchangeable purpose of God, that same Spirit and Word of power, which created man at the beginning—which spake by all the prophets—which dwelt in the man Jesus—which was given to the apostles and true witnesses as the Holy Spirit and Word of promise, which groaned in them waiting for the day of redemption—and which was spoken of in the language of prophecy as a woman travelling with child, and parted to be delivered, was revealed in a woman.

And that woman, in whom was manifested that Spirit and Word of power, who was anointed and chosen of God, to reveal the mystery of iniquity, to stand as the first in her order, to accomplish the purpose of God, in the restoration of that which was lost by the transgression of the first woman, and to finish the work of man’s final redemption, was Ann Lee.

As a chosen vessel, appointed by divine Wisdom, she, by her faithful obedience to that same anointing, became the temple of the Holy Ghost, and the second heir with Jesus, her lord and head, in the covenant and promise of eternal life. And by her sufferings and travail for a lost world, and her union and subjection to Christ Jesus, her lord and head, she became the first born of many fathers, and the true mother of all living in the new creation.

Thus the perfection of the revelation of God in this latter day, excels, particularly, in that which respects the most glorious part in the creation of man, namely, the woman. And herein is the most condescending goodness and mercy of God displayed, not only in redeeming that most amiable part of the creation from the curse, and all the forrows of the fall, but also in condescending to the lowest estate of the lost of mankind.

So that by the first and second appearing of Christ, the foundation of God is laid and completed, for the full restoration of both the man and the woman in Christ, according to the order of the new covenant, which God hath established in them for his own glory, and the mutual good and happiness of each other.

And in this covenant, both male and female, as brethren and sisters in the family of Christ, jointly united by the bond of love, find each their correspondent relation to the first cause of their existence, through the joint parentage of their redemption.

Then the man who was called Jesus, and the woman who was called Ann, are verily the two first foundation pillars of the church of Christ—the two anointed ones—the two first heirs of promise, between whom the covenant of eternal life is established—the first father and mother of all the children of regeneration—the two first visible parents in the work of redemption—and the invisible joint parentage in the new creation, for the increase of that seed through which all the families of the earth shall be blessed.

The Shakers record several cales which they pretend to be miraculous, but it is needless to enlarge on a fyltem that is wholly founded in delusion.

SHAKERTOWN, in Geography, a town of Kentucky, in Mercer county, containing 208 inhabitants.

SHAKES, in Ship-Building, a name given to the cracks or rents in a plank, &e., occasioned by the sun or weather.

SHAKING, a disease in sheep, consisting of a weakens in their hind quarters, so that they cannot rise up when they are down. There has not hitherto been found any remedy for this disease. It is probably of the nature of palsy, and to be removed by strong nervous stimulant remedies.

SHAKLES, on board Ship. See Shackles.

SHAKRA, in Geography, a town of Arabia, in the province of Nedsjed; 120 miles N.E. of Faid.

SHAKSPEARE, William, in Biography, an English dramatic poet, is justly esteemed the most eminent and most interesting author of the ancient or modern world. His writings have progressively rifen in popular estimation in proportion as they have been studied and analyzed. Some of his dramas are continually acted on the London and provincial stages; many critics and commentators, both English and foreign, have employed their pens, and exerted their faculties, in dissertations on the merits and defects of his productions. From the most trying and falsidious ordeal of investigation he has risen in glory and greatness; and may, at the present time, be justly pronounced pre-eminent and unrivaled as a dramatic poet.

To Englishmen his writings are singularly estimable; for they have conferred on the country a literary immortality, which nothing less than the dilution of ‘the great globe itself’ can annihilate. Nor is he exclusively endeared and valuable to the man of letters; but all classes of artists, and even many artisans, have derived both fame and emolument through the medium of his works. It has been often remarked, that the prophet is never honored in his own country, or appreciated by his contemporaries. Although this maxim is now more readily considered as figurative, and the age of, and confidence in, prophecy is past, yet it may be fully and strictly applied to the meritorious author. After decease, his whole merits are gradually unfolded; his talents and genius command admiration, and each reader and commentator seem eager to discover new beauties, and to point out hidden excellencies. Among the literary ‘worthies’ of the world, from the days of Homer to Milton, no one has attained equal celebrity with Shakspeare. He now shines as the sun of the intellectual hemisphere, and every other poet seems to derive a reflected light from him, or moves in a less circumscribed orbit. Like divine nature, which was at once his
his guide and goddefi, his writings excite admiration and delight, the more intently they are studied. Prompted by inspiration, and impregnated with profound knowledge, with the keen and acute "poet's eye," he commanded every region of the terrestrial globe, presented the hitherto thoughts of man, gave to "airy nothing a local habitation and a name," and alligned to every passion and sentiment "its true form and feature."

This wonderful
That an invisible instinct should frame him
To poetry unlearned; honours unattaght;
Civility not seen in other; knowledge
That wildly grew in him, yet yielded crops
As though it had been flown: for he could find
"Tongues in trees, books in the running brooks,
Sermons in stones, and good in every thing."

Do not smile at me that I boast him off,
For ye shall find he will outstrip all prais,
And make it halt behind him.

DOYANSTON.

Heaven has him now: let our idolatrous fancy therefore sanctify his relics. Decease to be his equal, lift up your point by his precepts; seek to acquire in your widoms, imitate his gentleness, talents, and honour. Confound the comparative trufiines of our own faculties, let us warm our hearts by his celestial fire, and kindle our souls at his unex-tinguishable flame! If enthusiasm be justifiable on any subject, the writer of the present article hopes to stand excused in giving this tribute to his feelings and expectations. He has to regret, with thousands of others, that the subject of this memoir is only known in his writings, and that his personal history is as obscure as that of Homer or Archimedes. Indeed, before we proceed further, it is necessary to premise, that a singular and unaccountable mystery is attached to Shakspeare's private life; and, by some strange fatality, almost every document concerning him has either been destroyed, or still remains in obscurity. The first published memoir of him was drawn up by Nicholas Rowe, in 1709, nearly 100 years after the decease of the poet; and the materials for this were furnished by Betterton, a player. It should be remembered, that the age in which he lived was not the age of minute inquiry. From Rowe's account, and from other evidence, it is clear that our poet was not ambitious of posthumous fame; that he disregarded the estimation of after ages; that he was unconscious of the high merit of his own writings; and that, though he was much in the public world, and died in comparative affluence, his private life and character were scarcely noticed by the biographer or critic. To the man of taste and refined felicity, he has, however, bequeathed an inexhaustible treasure in his dramatic productions, and as these constitute an essential part of the well-stored library, it is equally essential to record every fact, and investigate every problematic statement, relating to the inimitable author.

He was born at Stratford-upon-Avon, in Warwickshire, on the 23d of April 1564, is well ascertained; and that he was baptized on the 26th of the same month, appears by the parish register. He is there described as the son of John Shakspeare, who, according to Rowe, and most subsequent biographers, was "a considerable dealer in wool," and whose "family were of good figure and fashion." Opposed to this statement is that of John Aubrey, who entered himself as a student in the university of Oxford, 1642, only 26 years after our poet's death, who derived his information from "some of the neighbours" of Shakspeare, and who appears to have made a practice of writing down every fact and tradition that he heard relating to public characters. His account is entitled not only to recital, but to cautious credit.

"Mr. William Shakspeare was born at Stratford-upon-Avon, in the county of Warwick; his father was a butcher; and I have been told by some of the elders, that when he was a boy he excelled his father's trade; but when he killed a calf, he would do it in a high style, and make a speech. There was at that time a mother hankering for him in the town that was held out at all inferior to him for a natural wit, her son, and another, but a dyed young. This Wm., and not naturally to poetry and acting came to London, I believe about 1588, and not an actor at one of the play-houses; and I could exactly tell you. Now B. Jonson was never a dramatist, but an excellent instructor. He grew to be a keen player at dramatic poetry, which at that time was very rare, and his players took it well. He was a strong man, well-read man, very good company, and of a very readiness and pleasant fancy."

"Ten in the hundred the devil allows
But Combes will have twelve, how cares and voices:"
If any one asks who has in this tomb,
'Ho!' quoth the devil, 'tis my John o'Combe.'

"He was wont to goe to his native country once a yeare.
I think I have been told that he left 2 or 300,000, per annum, and there-about to a sister. I have heard sir Wm. Davenant and Mr. Thomas Shadwell (who is counted the best comedian we have now) say, that he had a most prodigious wit, and did admire his natural parts beyond all other dramatic writers. He was wont to say that he never blotted out a line in his life; sayd Ben Jonson 'I wish he had blotted out a thousand.' His comedies will remain wit as long as the English tongue is understood, for that he handles more hominum; now our present writers reflect so much upon particular persons and circumstances, that twenty yeares hence they will not be understood.

"Though, as Ben Jonson sayes of him, that he had but little Latine and little Greek, he understood Latine pretty well, for he had been in his younger yeares a schoolmister in the country."

The latter fact was communicated by Mr. Beelton.

In another memorandum Aubrey states, that
"Mr. William Shakespeare was wont to goe into Warwickshire once a yeare, and did commonly in his journey lie at this house in Oxon," (i.e. the Crown tavern, kept by the father of sir William Davenant,) "where he was exceedingly respected."

Now sir Wm. would sometime, when he was pleasant over a bottle of wine with his most intimate friends,—e.g. Sam. Butler, (author of Hudibras) &c. say, that it pleased him to hear him with the very spirit that Shakespeare, and seemed contented enough to be thought his son."

These anecdotes are now published in "Letters written by eminent Persons in the Seventeenth and Eighteenth Centuries," three vols. N. Y. 1813.

This account is truly curious and interesting; and in spite
spite of the scepticism of Dr. Farmer, in his "Effay on the Learning of Shakspeare," and of some other writers, the impartial reader must admit that it affumees the air of probability, candour, and truth. Aubrey might have erred in some points; particularly in saying, Shakspeare visited London at the age of eighteen, when the registry of his own baptism, and that of his twin-children, shew that he must have remained at home till the age of twenty. Again, it is very probable that he met with a confidant at Grendon, or Long-Crendon, in Buckinghamshire, where character he dramatized, not in "A Midsummer Night's Dream," but in "Much ado about Nothing," or in "Love's Labour's Lost." The extemporaneous epigraph on John o'Combe is represented by Rowe, who gives it different to the above, as having been made during the life-time, and in the presence of the person commemorated, who is also said never to have forgiven the poet. In Aubrey's relation there is nothing improbable, nor unreasonal, in a poet producing such lines fortuitively over his cups, and among convivial friends: it is a smart epigram on an ufnious character.

Instead of leaving 300. per annum to a sister, he bequeathed as much to his daughter, as will be thrown in the lagoon. If there be any lurking prejudice against the profession of a butcher, let it be remembered, that the proud and ostentatious cardinal Wolsey was the son of a butcher; and that the parentage of a Homer, a Milton, and a Shakspeare, cannot be honoured or degraded by their ancestors.

"Honour and fame from no condition rise; Aet well your part, there all the honour lies."

The house in which our poet was born has been occupied by a succession of butchers from time immemorial. Besides, it is not at all improbable that the butcher and the woolf-hapler were united in one person. Admitting this, we shall find Rowe and Aubrey in harmony, and one great difficulty removed.

The early education of Shakspeare, as well as his parentage, is not ascertained; on this topic all the biographers and commentators have supplied us with conjectures and opinions. Chalmers, in his "Apology," is at once ingenuous, intelligent, and learned on this subject. Rowe observes, and most of his followers repeat the fame, that he "was bred for some time at a free school, where it is probable he acquired what Latin he was master of; They proceed to remark, that "on leaving school, he seems to have given entirely into that way of living which his father proposed to him." About the age of eighteen he married Anne Hathaway, daughter of a substantial yeoman, then residing at Shottery, a hamlet at Stratford. In the parish register we find that "Susanna, daughter of William Shakspeare, was baptised May 26, 1555." By the same record we learn that his wife produced him twins in 1584: 5; as on the 2d of February in that year, the names of Judith and Hamnet are entered in the register. It must have been soon after this event that our poet visited the metropolis; but the cause of leaving his native place, as well as his object, connection, and prospects in London, are alike unknown. Rowe relates, and others have adopted the opinion, with some variation as to sentiment and inference, that "falling ill company," he was induced, "more than once," to affift his associates in stealing deer from a park belonging "to sir Thomas Lucy, of Charlecote, near Stratford. For this he was prosecuted by that gentleman so severely," that he was first impelled to write a fatirical ballad on him, and afterwards fly from his home to avoid arrest and imprisonment. This story, however, is not entitled to full credence; for though our young poet might have associated with some idle youths, and have accompanied them to the neighbouring park, either for the sake of catching deer, or for some less difficult and less hazardous enterprise, yet the circumstance seems improbable, and comes in such a questionable shape," that before he be admitted as historical evidence against an amiable man and super-eminent author, it should be supported by "confirmations strong as proofs of holy writ." Without reflection on this circumstance, or crediting another his history, story, of his holding horfes at the door of a theatre for his livelihood, we shall find a rational motive for his visiting London, and retorting to the theatre, by knowing that he had a relative and townswoman already established there, and in some estimation. This was Thomas Green, "a celebrated comedian."

We now come to that era in the life of Shakspeare, when he began to write his immortal dramas, and to develop those powers which have rendered him the delight and wonder of succssive ages. At the time of his becoming, in some degree, a public character, we naturally expected to find many anecdotes recorded of his literary history: but, strange to say, the fame defirition of authentic incidents marks every flage of his life. Even the date at which his first play appeared is unknown; and the greatest uncertainty prevails with respect to the chronological order in which the whole series were written, exhibited, or published. As this subject was justly considered by Malone to be both curious and interesting, he has appropriated to its examination a long and laborious effay. Chalmers, however, in his "Supplemental Apology," and in a recent pamphlet, 1815, endeavours to controvert some of Malone's dates, and assigns them to other eras; as specified in the second column, below. Malone says, the "First Part of King Henry VI." published in 1589, and commonly attributed to Shakspeare, was not written by him, though it might receive some corrections from his pen at a subsequent period, in order to fit it for representation. The "Second Part of King Henry VI." this writer contends, ought therefore to be considered as Shakspeare's first dramatic piece; and he thinks that it might have been composed about the year 1591, but certainly not earlier than 1590. The other dramas are placed in the following order of time by him and by Mr. George Chalmers.

---|---
The Third Part of Henry VI. | 1591 | 1595
A Midsummer Night's Dream | 1592 | 1598
Comedy of Errors | 1593 | 1591
Taming of the Shrew | 1594 | 1598
Love's Labour's Lost | 1594 | 1592
Two Gentlemen of Verona | 1595 | 1595
Romeo and Juliet | 1595 | 1592
Hamlet | 1596 | 1597
King John | 1596 | 1598
King Richard II. | 1597 | 1596
King Richard III. | 1597 | 1595
First Part of Henry IV. | 1597 | 1596
Second Part of Henry IV. | 1598 | 1597
Merchant of Venice | 1598 | 1597
All's Well that ends Well | 1599 | 1599
King Henry V. | 1599 | 1597
Much ado about Nothing | 1600 | 1599
As you Like it | 1600 | 1599
Merry Wives of Windsor | 1601 | 1596
King Henry VIII. | 1601 | 1595
Troilus
SHAKESPEARE.

Besides the above thirty-five plays, Shakspere wrote some poetical pieces, which were at first published separately, e. g., "Venus and Adonis," printed in 1593; "The Rape of Lucrece," 1594; "The Passionate Pilgrim," printed in 1594; "A Lover's Complaint," not dated; and a Collection of Sonnets, printed in 1609. The first and second of these poems were dedicated, as "the first heir of my invention," to Henry Wriothesley, earl of Southampton; who, according to Sir William d'Avenant's statement, presented the poet with the sum of 100l. to make some purchase. If this be a fact, it is honourable to the liberality and good taste of the nobleman, and flews that the "poor Warwickshire lad" met with a munificent patron in an early stage of his literary career. Other circumstances tend to prove that his merits were known, and admired by some illustrious personages. Queen Elizabeth, whose ear was perpetually allayed by foulsome panegyrick, and who encouraged all sorts of silly shows, May-games, and buffoonsery, was not insensible of Shakspere's talents; for the command several of his plays to be acted before her; and having been much delighted with the character of Falstaff, as delineated in the first and second parts of "Henry the Fourth," recommended, or perhaps commanded, the bard to portray the fat knight in love. Hence originated "The Merry Wives of Windsor;" some incidents in which may have pleased the daughter of Henry VIII., although they are jocund repulsive to modern taste and delicacy. King James I. also attended the representation of many of our author's plays. Sir William d'Avenant told Sheffield, duke of Buckingham, that the monarch wrote the poet "an amicable letter" with his own hand; probably to thank him for the compliment contained in the play of Macbeth.

Shakspere, as already hinted, was an actor, as well as author of plays, and performed some of the characters in his own dramas. As late as the year 1603, only 13 years before his death, his name appears among the players of Ben Jonson's tragedy of Sejanus. Thus it is evident that he continued to perform many years; but of his histrionic merits we have no satisfactory evidence. Hence on this point there is much diversity of opinion; some contending that he was an excellent actor, and others that he was only equal to the perfonification of his own character of the ghost in Hamlet. Some paffage in his own writings prove that he was well qualified to appreciate and to describe the essentials of good action. See Hamlet's admirable advice to the players; the scene between Hamlet and his mother; and also the description of a tragedian in "King Richard III.;" Aubrey states that Shakspere visited his native town periodically; but we do not learn when he finally returned home. From a document in the possession of Mr. R. B. Wheler, the historian of Stratford, it appears that he was in London in November, 1614. At that time Mr. Thomas Green, a professional gentleman of that town, and a relative of Shakspere's, visited the metropolis, to which he had set out on purpose, or to settle some business relating to the purchase of an open field, in which our poet was a party concerned. His memorial writes:

"Rec. 12, Nov. 1614, at 4 o'clock Mr. Tom. a man from Mr. Basy & Mr. Alderman, [the bailiff and chief alderman of Stratford upon Avon] dined 12, No. 1614, touching the inclosure business. Dines 17, No. 1614, may Mr. Shakspere coming yesterday to town, I went to see him how he did. He told me that they [the parties willing to mediate] "afford him they went to mediate no further than to deliver both, & to umpire (leaving out pt. of the wrongs in the field) to the gate in Clapton hedg & take in Salisbury's piece; & that they meant in a week to try the land & then to give satisfaction & not before; & he & Mr. Hall [Shakspere's son-in-law, probably present] "say they think yr. [there] will be nothing done at all." It appears that Mr. Green, after his return to Stratford, made the following entry, which is partly illegible, "23 Dec. 1614, 4 Hall, Lives written, one to Mr. Manyngs—another to Mr. Shakspere, with almost all the company's hands to either. I also weave my copy to my own fr. [fellow] Shakspere, the coppies of all our . . . . . . . . the other diversities woulby. by the medilce." Another part of the memorandum states, that the town of Stratford was then "lying in the ashes of defolation."

We find that Shakspere had purchased a house, called "New-place," at Stratford, about three years before his death, where he resided in the style and character of a private gentleman. Here he died on the anniversary of his birth-day, April 23, 1616, and was interred on the second day after his death, in the chancel of Stratford church, where a monument still remains to his memory. It is constructed partly of marble and partly of stone, and consists of a half-length bust of the deceased, with a cushion before him, placed under an ornamental canopy, between two columns of the Corinthian order, supporting an entablature. Attached to the latter is the Shakspere arms and crest, sculptured in bold relief. Beneath the bust are the following lines:

Judicio Pylivm, genio Sacratem, arte Maronem, Terra tegit, popvlvs mæret, olympus habet.

Stay, pellenger, why goest thou by so fast, Read, if thou canst, whom curious death hath platt Within this monument, Shakspere: with whom Quicke naturè dide; whose name doth deck ye tombe Far more than coffe; both all ye hath wrought Leaves living art, but page to erase his wit.

On a flat stone, covering the grave, is this curious inscription:

Good friend for Iesu' sake forbear, To digg the dvtl enclosed heare; Blest be ye man yt spares these bones, And evr'th be ye yt moves my bones.

The common tradition is, that the four last lines were written by Shakspere himself; but this notion has perhaps originated solely from the use of the word "my," in the last line. The imprecation, says Mr. Malone, was probably suggested by an apprehension that our author's remains might share the same fate with those of the rest of his countrymen, and be added to the immense pile of human bones deposited in the charnel-house at Stratford."
heere Judith, and alfo Stratford, one, and but to which an forth, Hart, gentleman to fifty three gilt within Michael pounds above daughter, no Lam
the who but with Cundell, Sufanna, To Nov. Vbera, is of Clavfa; all years appurtenances, the her right in a copyhold tenement and appurtenances, parcel of the manor of Rowington. To the said Judith he also bequeathed 150l more, if she, or any of her issue, were living three years from the date of his will; but in the contrary event, then he directed that 100l of the sum should be paid to his niece, Elizabeth Hall, and the proceeds of the fifty to his fitter, Joan, or Jone Hart, for life, with residue to her children. He further gave to the said Judith a broad silver gilt bowl.

To his fitter Joan, besides the contingent bequest above-mentioned, he gave twenty pounds and all his wearing apparel; also the house in Stratford, in which he was to reside for her natural life, under the yearly rent of twelve pence. To her three sons, William Hart, — Hart, and Michael Hart, he gave five pounds a-piece; to be paid within one year after his decease. To his grand-daughter, Elizabeth Hall, he bequeathed all his plate, the silver bowl above excepted.

To the poor of Stratford he bequeathed ten pounds; to Mr. Thomas Combe, his sword; to Thomas Ruffel five pounds; to Francis Collins, elq. thirteen pounds six shillings and eight-pence; to Hamlet (Hamnet) Sadler twenty-six shillings and eight-pence, to buy a ring; and a like sum, for the same purpose, to William Reynolds, gent., Anthony Nath, gent., John Hemyng, Richard Burbage, and Henry Cundell, his "fellows;" also twenty shillings in gold to his godson, William Walker.

To his daughter, Sufanna Hall, he bequeathed New-place, with its appurtenances; two meffriages or tenements, with their appurtenances, situated in Henley-street; also all his "barns, stables, orchards, gardens, lands, tenements, and hereditaments whatsoever, situate, lying, and being, or to be had, received, perceived, or taken within the towns, hamlets, villages, fields, and grounds of Stratford-upon-Avon, Old Stratford, Bishopton, and Welcombe, or in any of them, in the said county of Warwick; and also all that meffUAGE or tenement, with the appurtenances, wherein one John Robinson dwelteth, situated, lying, and being in the Blackfriars, London, near the Wardrobe; and all my other lands, tenements, and hereditaments whatsoever: to have and to hold all and singular the said premises, with their appurtenances, unto the said Sufanna Hall, for and during the term of her natural life; and after her decease, to the first son of her body lawfully issuing, and to the heirs male of the body of the said first son, lawfully issuing; and for default of such issue, to the second son of her body lawfully issuing, and to the heirs male of the body of the said second son lawfully issuing; and for default of such issue, to the third, fourth, fifth, and seventh sons of her body, and their heirs male: and for default of such issue, the said premises to be and remain to my said niece Hall, and the heirs male of her body lawfully issuing; and for default of such issue, to my daughter Judith, and the heirs male of her body lawfully issuing; and for default of such issue, to the right heirs of me the said William Shakespeare.

To the said Sufanna Hall and her husband, whom he appointed executors of his will, under the direction of Francis Collins and Thomas Ruffel, esqrs. he further bequeathed all the rest of his "goods, chattels, leaves, plate, jewels, and household stuff whatsoever," after the payment of his debts, legacies, and funeral expenses; with the exception of his "second bed with the furniture," which constituted the only bequest he made to his wife, and that by infirnition after the will was written out.

Among the mysteries connected with our poet's private life and actions is one, which has hitherto escaped the in- veteate researches and countless opinions of his biographers and commentators. We have already seen, that his wife bore him three children in less than two years after marriage. In the Stratford register is an entry of "Thomas Greene, alias Shakfpear," in 1589-90, which excites some suspicion respecting the fidelity of our bard's wife; and it may be inferred from his will, that his lady could not have enjoyed much of his affection, to have been put off with only the bequest of a "second bed bed;" besides, we do not hear of any other children by the poet.

The first collection of Shakespeare's plays was published in 1623, with the following title: "Mr. William Shakspere's Comedies, Histories, and Tragedies. Published according to the true original copies. London, printed by Isaac Jaggard and Ed. Blount, 1623, folio." This volume was edited by John Hemyng and Henry Condell, and was dedicated to "the most noble and incomparable pair of brethren," William, earl of Pembroke, and Philip, earl of Montgomery. In the title page is a portrait, said to be a likeness of the author, with the engraver's name, "Martin Droeshout, sculptor, London;" and on the opposite page are these lines by Ben Jonson, addressed to the reader:

"This figure that thou here seest put, It was for gentle Shakespeare cut, Wherein the graver had a firfe With nature to outdo the life: O, could he but have drawne his wit As well in braffe, as he hath hit His face; the print would then surpasse All that was ever writ in braffe. But, since he cannot, Reader, looke Not on his picture, but his Booke." B. I.
The above volume was carefully reprinted, in close imitation of the original, a few years back, by J. Wright, for Vernor and Hood, London. A facsimile edition of Shakspere's plays was also published, in 4to, in 1814, a second in 1817, and a third in 1821, and a fourth in 1831. These several impressions are usually denominated "ceptive editions," because published within the first century after the death of the poet, and before any comments or elucidations were employed to expound the original text. Some of his dramas were published in facsimile, during his own life.

Of these editions, which are distinguished by the title "modern," the earliest was published by Nicholas Rowe, in 1709, in 7 vols. 8vo. This was followed by an edition in 9 vols. 12mo. by the same author, in 1714; and in both were prefixed a biographical memoir of the illustrious bard. In 1725, Pope, who first introduced critical and emendatory notes, published his edition in 6 vols. 4to. with a preface, which Johnson characterizes as valuable alike for composition and judicious of remark. A second edition by the same editor was published in 10 vols. 12mo., with additional notes and corrections, in 1728. The successor of Pope was Theobald, who produced a very elaborate edition in 7 vols. 8vo. in 1733; and a second, with corrections and additions, in 8 vols. 12mo. in 1740. Sir Thomas Hamner next turned his attention to the illustration of Shakspere, and in 1744 gave the world an edition of his plays in 6 vols. 4to. Warburton published his edition in 8 vols. 8vo. in 1747; from which time no critic attempted the task till the year 1765, when Dr. Johnson's first edition made its appearance in 8 vols. 8vo. It was preceded by an able and ingenious preface, in which the character of Shakspere's writings are commented on in a powerful style of eloquence, but with a severity far removed from accuracy and justice. Indeed Johnson did not fully understand the varied merits of his author. In 1766, Steevens published the twenty "Old Plays," in 4 vols. 8vo. This was followed, in 1768, by an edition in 10 vols. crown 8vo. by Mr. Capell. Next came out, in 1771, a second and improved edition in 6 vols. 4to. by Sir Thomas Hamner, which was succeeded by an edition in 10 vols. 8vo. in 1773, by Johnson and Steevens, conjointly. Of this last, a second edition was published in 1778; a third, revised and corrected by Reed, in 1785. In the year following was produced the first volume of the dramatic works of Shakspere, with notes by Joseph Rann, A.M. which work was completed in 6 vols. 8vo. in 1794. In 1784 was published, in 1 vol. royal 8vo, an edition by Stockdale, with a very copious index of palliates, by the Rev. Mr. Aylcough. Bell's edition appeared in 1788, in 20 vols. 18mo.; and in 1790 Malone's was ushered into the world in 10 vols. crown 8vo. In 1793, a fourth edition, "revived and augmented," in 15 vols. 8vo. was produced by Mr. Steevens. A fifth edition, in 21 vols. 8vo. was published in 1823, from the text and with the notes of Johnson, Steevens, and Reed; and a revised edition of 21 vols. with corrections, &c. appeared in 1837.

Many other impressions of our author's plays have been published by different booksellers, in different sizes, and of various degrees of typographic merit. Most of them, however, are unauthenticated reprints: but many have the popular attraction of embellishments. The most splendid of this class was published by Boydell, in 9 vols. folio, embellished with 100 engravings, executed by and from artists of the first eminence. The same work was also printed in 4to. In 1805 was published an edition of Shakspere's plays in 10 vols. 8vo., with a preface by Alexander Chalmers, F.S.A. and a print to each play from a design by Henry Fuseli, esq. R.A. The last edition of this kind has just appeared in 7 vols. 18mo., with 250 engravings on wood, from the beautiful press of Whittingham.

Steevens estimated, at the time he published his notes on Shakspere, that "not less than 25,000 copies of one author's works have been thus defaced; and it may now be confidently said, that nearly 100,000 of them have been printed and sold."

From what has been already stated, it is evident that the writings of Shakspere have progressively acquired considerable publicity; and that they now rank as chief, or in the first rank, of British classics. This high celebrity is to be attributed to various secondary causes, as well as to their own intrinsic merits. To players, critics, biographers, and artists, a large portion of this popularity is to be ascribed: for had the plays been represented by Garrick, Kemble, &c. as originally published by Conolly and Hemyng, or reprinted verbatim from that text, the spectators to the one, and readers of the other, would have been comparatively limited. It is talent only that can properly represent and appreciate talent. The birth and productions of one man of brilliant genius, will stimulate the emulation, and call into action the full powers of a correlative mind. Hence the British theatrical hemisphere has been repeatedly illuminated by the corruptions of Garrick, Helderfon, Pritchard, Kemble, Siddons, Cooke, Young, and Kean, and these performances have derived no small portion of their justly acquired fame from the exquisite and powerful writings of the bard of Avon. While the one may be considered as the creator of thought and inventor of character, the others have performed and given "local habitation" and exultation to the poetical vision. The painter has also been usefully and honourably employed in delineating incidents, and portraying characters from the poet: while the engraver has translated these designs into a new language, and given them extensive circulation and permanent record.

The consummate acting of Garrick tended, in a great degree, not only to revive the fame of Shakspere, but to augment and extend it. The peculiar powers of Betterton, and of his other dramatic predecessors, have not been sufficiently defined to enable us to estimate their real talents; but those of the English Rofcius have been commented on and defcribed by so many able critics, that we are certain they were of the most accomplished kind. He was therefore amply qualified to personify, and give life and effect to the characters of Macbeth, Hamlet, Lear, Richard the Third, Romeo, &c.; and by his exquisite representation of these biftronic personages, the public were additionally delighted and admiration with the amazing genius of the author. Since Garrick's time other actors have judiciously chosen some of Shakspere's characters, as best calculated to show their own talents; and as the most certain touchstone of passion. A Kemble and a Siddons have enwreathed their brows with never-fading laurel by diligently studying and successfully perforating many of our poet's great characters. The former has acquired a well-earned fame in portraying Macbeth, Lear, Coriolanus, Prefce, Cardinal Wolsey, Richard, Hamlet, and Othello; the latter has astonished and gratified many thousand spectators by her horrifying representation of lady Macbeth, her dignified playing of the queen in Henry VIII., and the queen in Hamlet; by her commanding powers in Portia; and in her pathetic eloquence of Daffodona. Cooke displayed the characters of Richard the Third, Iago, and Shylock, with great skill and excellence: and in the present day, Kean has personified these characters, with that of Richard II. and Hamlet, so as to command the approbation of the most acute and intelligent critics.
SHAKESPEARE.

The number, variety, and veracity of commentaries that have been successively published on the text of Shakespeare's plays almost exceed credibility; and a foreigner, or stranger to the subject, would be more than astonished, were the whole brought in one mass before him. It is true, that many of them are unimportant and useless, but it is equally true, that several of his critical annotators have displayed much research, learning, and acuteness; and to such the puffed and poetical antiquaries are much indebted. It was our intention to have given a concise account of these; because the whole constitute the Shaksparian library; and all may be regarded as satellites to the vast and replete poetic planet. The chief editors of his plays have been already noticed, as well as the respective eras of their different writings. Rowe was the first to add any thing to the original text, by prefixing a memoir of the author. This memoir has been reprinted with almost every succeeding edition, and without any alteration or comment, till Malone accompanied it with notes to his edition of 1792. Mr. Alexander Chalmers, in an edition of 1805, has prefixed a "Sketch of the Life of Shakspere," in which he has adopted most of the statements of Rowe, with the additional and corrective remarks of Malone and Steevens.

"The whole, however," he remarks, "is unsatisfactory. Shakspere in his private character, in his friendships, in his amusements, in his closet, in his family, is no where before us."

The plays of Shakspere are divided into three classes, and called in the first edition "comedies, histories, and tragedies." Each is of a distinct character; but in some of them there is a mixture of the three in one. "The Merry Wives of Windsor," "The Comedy of Errors," and "The Taming of the Shrew," are all comedies; the rest have something of both kinds. It is not easy to determine in which way of writing he most excelled. His Falstaff is universally allowed to be a master-piece; the character is always well sustained, though drawn out into three plays; and even the account of his death, given by his landlady, Mrs. Quickly, in the first act of Henry V. is as natural and diverting as any part of his life. "If there be any fault," says the critic, "in the draught he has made of this lewd old fellow, it is, that though he has made him a thief, a liar, and a coward, and, in short, every way vicious, yet he has given him so much wit, as to make him almost too agreeable; and I do not know whether some people have not, in remembrance of the amusements which he had formerly afforded them, been forry to see his friend Hal uly him so curiously when he comes to the crown, in the end of the second part of Henry IV. Among other extravagancies in the "Merry Wives of Windsor," he has made him a deer-stealer, that he might have the opportunity of remembering his Warwickshire protector under the name of Justice Shallow." The whole play is admirable, the humours are various and well opposed; the main design, which is to cure Ford of his unreasonable jealousy, is extremely well conducted.

Another of the characters which has been fixed on as one of Shakspere's fine delineations, is that of Shylock, the Jew, in "The Merchant of Venice," in which there appears such a deadly spirit of revenge, such a savage fierceness, and such a bloody denunciation of cruelty and mischief, as cannot agree either with the style or character of comedy, though usually ranked as such. Taken altogether, it is perhaps one of the most finished of Shakspere's pieces; the tale indeed is improbable in some of its parts; but taking the facts for granted, the story is beautifully written. There is something in the friendship of Antonio and Bassanio very great and generous. The whole fourth act is extremely fine, but there are two passages that are universally known and applauded, the one is in praise of mercy, and the other is on the power of music.

The melancholy of Jaques in the comedy of "As you like it," is as singular and odd, as it is amusing, and if, according to the maxim of Horace,

"Difficile est proprie communia dicere,"

it will be a hard task for any one to go beyond him in the delineation of the several degrees and ages of a man's life. See the article A.

Shakspere's images are indeed every where so lively, that the thing he would represent flounds full before you, and you possest every part of it. Rowe mentions his image of Patience, in the person of a young woman in love, as one of the finest and most uncommon things ever written; it is as follows:

"She never told her love; but let concealment, like a worm i'th' bud, Feed on her damask cheek: she pin'd in thought, And fad like Patience on a monument Smiling at grief."

The style of his comedy is, in general, natural to the characters, and easy in itself; and the wit most commonly sprightly and pleasing, except in those places where he runs into dogdrill rhymes. But the greatness of this author's genius does no where so much appear, as where he gives his imagination the entire loofe, and raises his fancy to a flight above mankind, and beyond the limits of the visible world. Such are his attempts in the Tempest, Midsummer Night's Dream, Macbeth, and Hamlet. Of these, the Tempest is thought by able critics to be the most perfect in its kind of any thing that Shakspere has left behind him. His magic hath something in it very solemn, and very poetical: and that extravagant character of Caliban is extremely well sustained, and sways a wonderful invention in the author, who could strike out such a particular wild image, and it is certainly one of the finest that was ever exhibited to the human imagination. It has been said by able judges, that "Shakspere had not only found out a new character in his Caliban, but had also devised and adapted a new manner of language for that character."

It is the same magic that railes the fairies in the Midsummer Night's Dream, the witches in Macbeth, and the ghost in Hamlet, with thoughts and language so proper to the parts they sustain, and so peculiar to the talent of this writer. "If," says the author whom we have so often quoted, "one undertook to examine the greatest part of his tragedies by those rules which are established by Aristotle, and taken from the model of the Grecian stage, it would be no difficult task to find a great many faults; but as Shakspere lived under a kind of more light of nature, and had never been made acquainted with the regularity of those written precepts, so it would be hard to judge him by a law of which he was ignorant. We are to consider him as a man, that lived in a state of almost universal licence and ignorance; there was no established judge, but every one took the liberty to write according to the dictates of his own fancy. When one considers, that there is not one play before him of a reputation good enough to entitle it to an appearance on the present stage, it cannot but be a matter of great wonder, that he should have advanced dramatic poetry as far as he did.

"It is now a received article of literary faith in England, that notwithstanding the faults and defects with which Shakspere abounds, and which were chiefly those of his age, no dramatist in any country has displayed such intimate
intimate knowledge of the human heart; such extensive acquaintance with nature in its various forms, an imagination so powerful and poetical, and such a copiousness of moral instrument supplied to the mind, as was almost incredible. The amours of nature were dear to him, and he drew them not laboriously, but luckily. When he describes any thing, you more than feel it, you feel it too. He needed not the spectacles of books to read nature; he looked inward, and found her there. I cannot say he is everywhere; where he is, he is seen. He is many times flat and stupid; his comic wit degenerating into cleshes, his serious swarming into bombast. But he is always great, when some great occasion is preferred to him. No man can ever say, he ever had a subject for his wit, and did not then raise himself as high above the rest of the poets.

"Quantum levis follet inter vivarum cuprelii."

Shakspeare, like most men of pre-eminent talents, is said to have been much inflamed by the attacks of envious rivals, notwithstanding that generous and good nature were the peculiar characteristics of his personal deportment. Among those who are said to have treated him with hostility was the celebrated Ben Jonson; but Dr. Farmer departs from the received opinions on this subject, and thinks that, though Jonson was arrogant of his scholarship, and publicly professed a rivalry of Shakspeare, he was in private his friend and associate.

Pope, in his preface, says, that Jonson "loved" Shakspeare "as well as honoured his memory; celebrates the honesty, openmindedness, and frankness of his temper; and only differs in his temper, as he reasonably ought, between the real merit of the author, and the unflattering abuse of the player." Mr. Gilchrist, whose dramatic criticisms are generally profound and acute, has published a pamphlet, to prove that Jonson was never a harsh or an envious rival of Shakspeare; and that the popular opinion on this subject is founded in error. The following story respecting these two great dramatists is related by Rowe, and has been generally credited by subsequent biographers. "Mr. Jonson, who was at that time altogether unknown to the world, had offered one of his plays to the players, in order to have it acted; and the persons into whose hands it was put, after having turned it carelessly and superciliously over, were just upon returning it to him with an ill-natured answer, that it would be of no service to their company, when Shakspeare luckily called his eye upon it, and found something so well in it, as to engage him first to read it through, and afterwards to recommend Mr. Jonson and his writings to the public."

The opposition or rivalry of Shakspeare and Jonson produced, as might naturally be expected, much contention, concerning their relative merits, between their respective friends and admirers; and it is not a little remarkable, that Jonson seems to have maintained a higher place in the estimation of the public in general than our poet, for more than a century after the death of the latter. Within that period Jonson's works are said to have passed through several editions, and to have been read with avidity, while Shakspeare's were comparatively neglected till the time of Rowe. This circumstance is in a great measure to be accounted for on the principle that classical literature and college learning were regarded in these days as the chief criteria of merit. Accordingly Jonson's charge against Shakspeare was the want of that species of knowledge; and upon his own pretensions in it, he was entitled to handle a topic with more vigour. That all classical scholars, however, did not feel Jonson's pretensions, is certain; for among the most intimate adherents of Shakspeare, was one of the most learned men of his age, the ever memorable Dr. Johnson. On one occasion, the latter, after listening to silence to a warm debate between John Suckling and Jonson, is reported to have interposed by observing, "That if Shakspeare had met the authors, he had his wit to rid him of anything from them; and that if he (Jonson) would produce any one topic fairly treated by any one of them, he would undertake to show something on the same subject, at least as well written, by Shakspeare." A trial, it was added, being made, six or seven judges were appointed to decide the dispute, who unanimously voted in favour of the English poet, after a candid examination and comparison of the passages produced by the contending parties.

In September, 1769, was celebrated the Shakspeare Jubilee, at Stratford, under the direction of Garrick.

Shakspeare was fond of music, and not wholly ignorant of the art. He not only frequently introduces music in his plays, but singing in almost all his fourteen comedies; and even in most of his tragedies, where this wonderful and exquisite dramatic art has manifested the same predilection for music as poetry.

In the "Tempest," the use that he has made of it is admirable, as well as the description of its effects. Act i. Sc. 5. Ariel, invisible, playing and singing to Ferdinand, says,
Where should this music be, 'tis th' air or earth?
It founds no more: and sure it waits upon
Some god o' th' isle.

And afterwards:

This is no mortal business, nor no found
That the earth owns: I hear it now above me.

Indeed, the serious part of this most fanciful play is very fortunately calculated for an opera. Shadwell, in the last century, made one of it, in the manner of what were then called operas on our stage. It has been performed of late years more as a musical masque, than opera or play, at Drury-lane, to the music of the late Mr. T. Linley, as it used to be to that of Dr. Arne, and others. The songs in this play, Dr. Wilton, who wrote and published two of them, tells us, in his "Court Ayres, or Ballads," published at Oxford, 1666, that "Full fathom five," and "Where the bee sucks," had been first set by Robert Johnson, a composer contemporary with Shakspeare.

Aét ii. Sc. 1. "Enter Ariel playing solemn music."
We never could understand this indication: no music seems to be heard by the characters on the stage, nor do they take any notice of it through the whole scene. Afterwards, when with music and a song he acquaints Gonzalo of the danger he is in, his million has meaning. "While you here do roaring lie," &c.

Even Caliban talks well about music:

"the isle is full of noises,
Sounds and sweet airs, that give delight and hurt not."

Ariel never appears or is employed without music, which is sweetly defcribed, and introduced with perfect propriety. Prospero calls for medicinal music:

"A solemn air, and the bell comforter
To an unsettled fancy, cure thy brains."

"Midsummer Night's Dream."

Aét i. Sc. 5. "Come now a roundel, and a fairy song."
If, as Dr. Gray says, a roundel is "a dance in a ring," a roundelay was the long and tune to such dance; as ballad, from ballata, Italian; fo roundelay, from rondelet, old French, rondeau, modern.

The ideas and language of fairytale are wonderfully imagined and supported in this play; and the vfe alligned to music happy and fertile.

Aét iv. Sc. 1. "Rural music, song, &c."

Poker and song, narrow-bones and cleavers, salt-box, hurdy-gurdy, &c. are the old national instruments of music on our island.

Queen. "Music, ho! music: such as charmeth sleep."

Still music, meaning such soft and gentle music as tranquillizes, soothes, and lulls to music.

Aét v. Sc. 1. In the lift of sports ready for the nuptial feast of Theseus, is "the battle with the Centaurs; to be sung by an Athenian eunuch to the harp." This seems to imply a more ancient practice of calbration for the voice than can be found in opera annals.

Speaking of Quince, in the clown's prologue, Hippolita says, "indeed, he hath play'd on his prologue, like a child on a recorder; a found, but not in government."

Two songs alluded to in the last scence of this play are lost.

Oberon. "And this ditty after me
Sing and dance it trippingly."

Queen. "First rehearse this song by rote,
To each word a warbling note; Hand in hand, with fairy grace,
Will we sing, and blest this place."

"Two Gentlemen of Verona."

Though this comedy furnishes fewer occasions for music than the two preceding dramas, yet musicians are employed in it as well as musical allusions. As Ben Jonson, in his masque of "Cythian's Revels," speaks of the gamut or syllables of solemnity, ut, re, mi, fa, sol, la, which pianofingers had made well known to his audience; so Shakspeare, in this play, aét i. fc. 3. introduces all the musical terms then in use: as, a tune, a note, a light, a heavy tune, burden, melodious, to reach high, keep in tune, fang out, too sharp, too flat, concord, harsh defect, the mean bose, &c.

Aét iv. Sc. i. there is a laboured description of the powers of poetry and music; Orpheus's lute, concert, spelt as now:

"— to their instruments
Tune a deploring dump?"—
or lament (lamentation), sung by a wretched and forrow ing lover in the dumps.

Sc. 2. A fermata, or notturno, is introduced:

"— now muft I to her window,
And give some evening music to her ear."

Enter Musicians.

"— now, gentle men,
Let's tune, and to it lustily."

Song. "Who is Sylvia? what is she?" &c.

"Measure for Measure."

Though this play has less music in it than the three preceding, yet at the beginning of aét iv. a song, from his own Passionate Pilgrimage: "Take, oh, take those lips away," is sung to Mariana by a boy, who is sent away on the arrival of the duke, in the character of a friar; when apologizing for the seeming levity of listenning to music, he says:

"I cry you mercy, sir, and well could with
You had not found me here so musical."

To which the duke answers:

"'Tis good; though music oft hath such a charm,
To make bad good; and good provoke to harm."

This is a heavy charge, which it would not have been easy for Shakspeare to substantiate, and does not very well agree with what he says in the "Tempest," of the innuovous efficacy of music. "Sounds and sweet airs, that give delight, and hurt not." Music may be applied to licentious poetry; but the poet in it corrupts the music, not the music the poetry. It has often regulated the movements of lascivious dances; but such airs heard, for the first time, without the song or dance, could convey no impure ideas to an innocent imagination; so that Montefquieu's assertion is still in force: that "music is the only one of all the arts, which does not corrupt the mind."

"Merchant of Venice."

Aét i. Sc. 1. A flourith of cornets when the Moorish prince comes in.

Act i. sc. 2. "Let music sound, while he doth make his choice; when, if he love, he makes a swan-like end. Fading in music,  
— he may wax;  
And what is music then? then music is  
As are those dulcet sounds at break of day,  
That creep into the dreaming bridegroom's ear,  
And summon him to marriage,"  

Music within.  
A long while Baffano examines the calf's feet:  
"Tell me where is fancy bred," &c.  
The passages in the fifth act of this interesting play are beautiful, numerous, and celebrated:  
"And bring your music forth into the air," &c.  
"Soft stillness and the night,  
Become the touches of sweet harmony."  

Jefica: "I am never merry when I hear sweet music."  
This is the initial of a well-known, and now proverbial eulogium on moderated sound: "The man that has no music in his soul," &c.  
"As you like it."  

Act ii. sc. 1. A song:  
"Under the green-wood tree," &c.  
Remarks on music by Jacques. Then another song:  
"Blow, blow, thou winter's wind."  
Music. Song: "What shall he have that kill'd the deer."  
Song: "Twas a lover and his lute."  
Still music. Song: "Then is there mirth in heav'n."  
Another song: "Wedding is great Juno's crown."  
"Love's Labour's lost."  

Act iii. Armado. "Warble child; make passionate my tende of hearing."  
This is a most beautiful and comprehensive request: none of the fine arts can subserve, or give rapture, without passion. Hence mediocrity is more intolerable in them than in other inventions. Music without passion is as monotonous as the tolling of a bell. But no song is printed; though the author tells us there is singing. Dr. Johnson says, "Here is apparently a song lost."  

Music as for a masquerade.  
Songs for spring and autumn:  
"When daffodils begin to peere."  
"Winter's Tale."  
Two nonsensical songs, by the rogue Autolycus:  
"When daffodils begin to peere."  

"He's main musical." This Autolycus is the true ancient minstrel, as described in the old Fabliaux. See Gen. Hist. Muf. vol. ii. p. 268.  

Act iv, sc. 4. The clown, as elsewhere, is much addicted to singing. Song, by the clown:  
"When that I was a little boy," &c.  

Serves as an epilogue to this entertaining play.
In "The Taming of the Shrew," no other use is made of music than to introduce minstrels at the wedding, and disguise Hortensio in the character of a man well-versed in music, to facilitate his admission to the presence and courtship of Bianca; an expedient, however, which was unsuccessful.

More fragments of old ballads are here quoted than in any other of Shakespeare's plays; though, as Dr. Warburton said, "he seemed to bear the ballad-makers a very particular grudge, and often ridicules them with exquisite humour."

In "The Comedy of Errors," music has no admission or concern.

"Much ado about Nothing."

Music at the masquerade, act ii. sc. 2. And in Benedick's dainty description of such an all-accomplished woman as could ever incline him to wed, he adds to her qualifications, music: "—of good discourse, an excellent musician, and her hair of what colour it shall please God." Sc. 8.

Act ii. sc. 9. "The song, 'Sigh no more, ladies, sigh no more,' is introduced by several reflections on music, and the affection of fingers. Baltazar, the musician and servant to Don Pedro, was perhaps thus named from the celebrated Baltazarini, called 'De Beaujoyeux,' an Italian performer on the violin, who was in the highest fame and favour at the court of Henry III. of France, 1577. In the last act, sc. 8, the epitaph and song are beautiful, and well calculated for music.

"All's Well that ends Well."

Act i. sc. 5. Flourish of cornets for the king of France's entrance and exit.

Act iii. sc. 8. Aucket afar off. Ibid. A march afar off.

Act v. sc. 3. Sound trumpets.

Historical plays. "King John."

No music but trumpets and the din of war.

"King Richard II."

Act i. sc. 4. Military instruments are admirably described:

"—rous'd up with boist'rous untun'd drums,
And harfth refounding trumpets dreadful Bray."

Ibid. Mowbray, duke of Norfolk, on being ordered into banishment, says:

"My native English, now I must forgo;
And now my tongue's use is to me no more,
Than an unfringed violin, or a harp;
Or, like a cunning instrument can't up,
Or being open, put into his hands
That knows no touch to tune the harmony."

Act ii. sc. 1. "—the tongues of dying men
Inforce attention, like deep harmony:
—more are men's ends mark'd, than their lives before;
The setting fun, and music in the close,
As the last taffe of sweets, is sweetest last—"

Ibid. sc. 3. Speaking of John of Gaunt's death:

"—all is fay'd,
His tongue is now a ftringles instrument."

Act v. sc. 10. Richard, in his prifon, fays:

"—Music do I hear?
Ha, ha! keep time: how fow'r sweet music is,
Where time is broke, and no proportion kept?"

Here he plays on musical terms for several lines.

All instruements played with the bow, in Shakespeare's time, were fretted, except violins.

In "The Taming of the Shrew," act ii. sc. 3, he could not refit the temptation of quibbling on the term fret.

"Frets call you them? quotio she: I'll fume with them."

"—then call'd me rafcal, fidler, And twangling Jack;"

alluding to a famous street musician of the time.

"First Part of Henry IV."

Act i. sc. 2. Falstaff fays he's as melancholy as the "drone of a Lincolnshire bagpipe."

Act ii. sc. 3. "An I have not ballads made on you all, and fong to filthy tunes, let a cup of fack be my poison."

Act iii. sc. 3. "——thy tongue
Makes Welch as sweet as ditties highly penn'd,
Sung by a fair queen in a fummer's bow'r,
With ravifhing defcription to her lute."

"Second Part of Henry IV."

Induction. "——Rumour is a pipe,
Blown by furnifes, j-aloufies, conjectures;
And of fo easy and fo plain a stop,
That the blunt mofter with uncounted heads,
The ffill discordant wavering multitude,
Can play upon it."

We advanced no farther in hunting through the pleafant wilds of Shakespeare; but in digging accidentally, the following passages struck us as worthy of notice.

"Henry V." Act i. sc. 2. There is a manifest allusion to the different parts of music.

"For government, though high, and low, and lower,
Put into parts, doth keep in one confent,
Congreffing in a full and natural clofe,
Like music."

In "Othello," act iv. sc. 13. Defdemona fays:

"My mother had a maid, called Barbara;
She was in love; and he, the lo'v'd, prov'd mad (falle)
And did forfake her; she had a song of willow,
An old thing twas, but it express'd her fortune,
And the died finging it. That fong, to-night,
Will not go from my mind; I've much ado,
Not to go hang my head all o' one fide,
And fing it like poor Barbara."

"King Lear," act i. sc. 7. "O, these episodes portend these divilions! fa, fa, la, mi?"

None of the commentators have hitherto been sufficiently skilful in music to fee the meaning of these fyllables in composition, which imply a feries of founds fo unnatural, that ancient musicians prohibited their use. "Mi contra fa eft diabolus." Shakfpeare, however, fways by the context, that he was well acquainted with the property of the musical intervals contained in the tritonus, or sharp 4th, which confiding of three tones, without the intervention of a femitone, is extremely difficult to fing, and difagreeable when
when fungi, if ni, or fi, is the fat rate of the phrase or passage.

Shakspere's Chief, or High Cliff, in Geography, a lofty cliff on the E. coast of England, in the county of Kent; so called from the beautiful description of it given by that poet in the tragedy of King Lear, 2 miles S. of Dover.

Shaky, or Shaken, a natural defect in timber when it is full of tight cracks, and will not bear the fastingen, or when sawn into planks the caulking.

Shal, in Geography, a district of Peria, in Baluchistan, the country of the Baluchis, which is considered by some as a province distinct from Mekran (the ancient Gedroidea), and which commences at Kohuline (the hilly road), 25 miles N.E. of Bayla, or in N. lat. 30° 25', and extends to Nukshki, 70 miles N.W. of Kelat, or in N. lat. 30°. This country is a confused mass of mountains, through which the road generally leads in water-courses. Flocks of sheep and cattle abound in every part of this country, and it also produces great quantities of wheat. It is divided into the two mountainous provinces of Jhalawan and Sarawan, the low country of Cutch Gandava to the E., and the provinces of Zhurbe and Amund Dijel; and to these may be added the small districts of Shal and Mutlung, lying N. of Kelat. Shalawat is the most southern province of Baluchistan, and Sarawan (which fee) is the most northern province. Cutch Gandava, situated at the bottom of the mountain lying S.E. of Kelat, is about 150 miles long, and 40 or 50 broad. Its soil is rich, black, and loamy, and produces every species of grain, as well as cotton, indigo, madder, &c. Cutch Gandava exports great quantities of grain to the sea-ports of Curacher and Semnawati, whence it is shipped to Muscat, the coast of Mekran, &c. Amund Dijel lies N. of Cutch Gandava: its climate is good, the soil excellent, and the productions abundant; so that the Khan of Kelat derives a large revenue from this small district. Shal and Mutlung are smaller than Amund Dijel, but they are remarkable for their fruits, which are excellent and cheap. The climate is warmer than that of Kelat; the soil is more sandy; but the grain and other products are the same. (See Zhurbe.) The capital of Baluchistan is Kelat, a town surrounded by a mud-wall, and containing 4000 houses, and about 7000 inhabitants, of whom about 500 are Hindoos. The bazaar of Kelat is well supplied, and the town appears opulent, being frequented by merchants, and carrying on a considerable trade. N. lat. 25° 6'. E. long. 67° 57'.

Shalberg, a mountain of Switzerland; 4 miles N. of Sargans.

Shalberis, a cairn of Hindoosan, bounded on the N. by Goragot and Bettoorish, on the E. and S. by Bettoorish, and on the W. by Bettoorish and Dinagpour; about 18 miles from N. to S. and nearly as much from E. to W. The chief town seems to be Carz.é.

Shaldea, a town of Hindoosan, in Bahar; 7 miles S.W. of Rotafurg.

Shale, in Natural History, a variety of chalcedony clay: the first variety is denominated slate clay, the schewer Thon of Werner. (See Clay.) The second variety is bituminous slate, the brand of which of Werner, of a brownish black, or blackish-brown, colour, appearing black coal; it is found in considerable quantities in Saxony; 1 litre, 0 gr. 38; transparency, 0; fracture dull; fragments tabular; barrettes 6; fp. gr. about 2,600; breaks like slate; variegated, though very slowly, with the mineral acids; is feeling rather greasy; placed on burning coal, it bursts with a weak flame and fulphurous smell, the residuum being light-grey; it seems to differ from the former variety, in containing bitumen. Kirwan. See Bitumen. The acid emitted from shale, during its calcination, uniting itself to the argillaceous earth of the shale, forms alum. About a hundred and twenty tons of calcined shale will make one ton of alum. The shale, after being calcined, is steeped in water, by which means the alum, which is burned during the calcination of the shale, is dissolved: this dissolved alum undergoes various operations, before it is formed into the alum of the shops. Watton's Chem. Ell. vol. n., p. 315. See Alum.

This kind of slates forms large strata in Dethbureh; and that which lies near the surface of the earth is of a softer and more flinty texture than that which lies deeper. It is also found in large strata, generally above the coal, in most coal counties of this kingdom. Dr. Short informs us, that the shale washes the lead ore near it, by its strong acid; and that it corrodes and destroys all minerals near it, except iron or coal, of whose vitriol it partakes. See Slate.

Shalg, in Geography, a town of Turkellen; 10 miles S. of Turkellen.

Shallop, Shalloop, or Sloop, is a small light vessel, with only a small main-mast, and fore-mast, and lug-foils, to hale up, and let down, on occasion. Shallop are commonly good faders, and are therefore often used as tenders upon men of war.

The French sloop is a large-decked sloop of burden, used in Holland and Flanders, having one mast, carrying a gaff-sail. On the fore-side of the mast, above the top-sail, is a short spar projecting forwards; to which is bent a long narrow sail, the tack of which is made fast to the item, and the sheet to the side near the shrouds. On the bowsprit are set two or three jibs, and a small mast is often fixed abaft that carries a naze.

Shallot, in Gardening, the common name of a very useful culinary plant. See Allium.

To what has been said under the above head, it may here be necessary to add some improvements, which have since been made, in the culture of these small bulbous roots. As the habits of growth in roots of this nature differ greatly in the different sorts, some requiring to be nearly or quite on the surface of the ground, while others stand in need of being a considerable depth below it, which has not been well attended to in the garden culture of such roots; it may be readily supposed that these have considerable influence and effect on the growth of such root crops. In consequence of finding that crops of this root generally became mouldy and perished, and that they were usually planted, from the directions of garden cultivators, at the depth of two or three inches from the surface; the injury, failure, and destruction of such crops, were naturally ascribed to this cause. A few bulbs or bunches of this root were consequent divided, as far as possible, into single bulbs, &c. and planted upon or rather above the surface of the ground, some very rich soil being placed underneath them, and the mould upon and side near the shrouds. A few boue and causes the mould to be fully planted, until they became firmly rooted. This mould was then removed by means of a hoe, and the use of the watering-pot, and the bulb of course left wholly out of the ground. The growth of the plant had now to perform a resemblance to that of the common onion, as not readily to be distinguished from it, until their irregularity of form, the consequence of the numerous germs within each bulb, became evident. The forms of the bulbs, however, continued constantly different from all those raised in the ordinary method, being much more broad, but of less length. The crop was a great deal better in quality, and at the same time much more

2
more abundant in quantity, it may confequently not be unworthy of the gardener’s attention. See the Transactions of the Horticultural Society of London, vol. ii. p. 97.

SHALLOT CREEK, in Geography, a river of North Carolina, which runs into the Atlantic, N. lat. 33° 53’. W. long. 78° 28’.

SHALLOW. See SHOAL.

SHALTOCH CAIRN, in Geography, a mountain of Scotland, in Ayrshire; 12 miles E. of Girvan.

SHAM, Ed. See DAMASCUS.

SHAMAK PALLAME, in Geography, a town of Hindooftan, in Coimbetore; 15 miles N.E. of Coimbetore.

SHAMARASHUP, a town of Hindooftan, in Coimbetore; 18 miles S.W. of Eroora.

SHAME, or SHAMMAL, in Mining, a term used to epxrefs a fort of nich, or landing place, left at certain di-tances in the adits of mines, and formed by a flage of boards. The method of digging the tin-mines in Devonshire, and some parts of Cornwall, is this; they fpink their way in fuch a breadth as is fufficient for them to fland and work, and at every fatham they leave a fquare place vacant, to which the ore is to be thrown up with fhovels as it is dug. This they do from call to call; that is, as far as a man can conveniently throw up the ore with his fhovel. Thus the ore, as it is dug by the beclmen, is thrown up by the fhovellers, who follow them from fhamble to fhamble, till it comes to the top of the mine. This, however, is but an inconvenient way, and the ufe of fhimals is generally supplied by a widder at the opening of the mine, which manages two buckets, the one of which is fent down empty, while the other is fent up full; and one man employed below to load, and another to empty. Phil. Tranf. No. 62. See Mining.

SHAMBLES, or SHINGLES, in Geography, a bank of sand in the English Channel, near the coaft of Doriftire, about four miles E. by S. from Portland Bill, with 14 feet at low water.

SHAMBRIER, in the Manage, is a long thong of leather, made falt to the end of a cane, in order to animate a horse, and punifh him, if he refufes to obey the rider.

SHAMBYPATAM, in Geography, a town of Hindooftan, in the Carnatic; 36 miles S. of Tanjore.

SHAMDAK, a town of Aflam, on the Burhampoor-ter; 65 miles N.W. of Gerghonge.

SHAME, in Ethics. See Passion.

SHAMERAN, in Geography, a town of Curdiitan; 18 miles S. of Sherezur.

SHAMMY, CHAMMY, or CHAMOIS, a kind of leather, either dressed in oil, or tanned; much efpewed for its softness, pliancy, &c.

It is prepared from the skin of the chamois, or shamais, a kind of rupecapra, or wild goat, called also Jard, inhabiting the mountains of Dauphiny, Savoy, Piedmont, and the Pyrenees. See CHAMOIS.

Besides the softness and warmth of the leather, it has the faculty of bearing foap without damage; which renders it very useful on many accounts.

In France, &c. some wear the skin raw, without any preparation. Shammy leather is used for the purifying of mercury; which is done by passing it through the pores of the skin, which are very close.

The true chamois leather is confidered with common goat, kid, and even with fheep-skins; the practice of which makes a particular profession, called by the French chamo-

fure. The leaf, though the leaf efteemed, is yet so popular, and such vast quantities of it are prepared, especially about Orleans, Marfilles, and Touloufe, that it may not be amifs to give the method of preparation.

Manner of Shamofing, or of preparing Sheep, Goat, or Kid-skins in Oil, in imitation of Shammy. — The skins, being fuffled, drained, and incarved over with quick-flime on the flefhy fide, are folded in two lengthways, the wool outwards, and laid in heaps, and left to ferment eight days; or, if they had been left to dry after faying, then fifteen days.

Then they are washed out, drained, and half fried; laid on a wooden led, or horfe; the wool flrapped off with a round flaff for that purpose, and laid in a warm pit, the lime of which had been used before, and has loft the great part of its force.

After twenty-four hours they are taken out, and left to drain twenty-four more; they are then put in another ftronger pit. This done, they are taken out, drained, and put in again, by turns; which begins to difpofe them to take oil; and this practice they continue for fix weeks in fummer, or three months in winter: at the end of which they are washed out, laid on the wooden led, and the furface of the skin on the wool-fide peeled off, to render them the fouter; then made into parcels, flapped a night in the river, in winter more, stretched fix or seven over one another, on the wooden led, and the knife padded ftrongly on the fleffy, to take off any thing fuperfuous, and render the skin fmoth.

Then they are flapped, as before, in the river, and the fame operation is repeated on the wool-fide; they are then thrown into a tub of water, with bran in it, which is brewed among the skins till the great part fticks to them, and them feparated into fmall tubs, till they fwell, and rise of themselves above the water.

By this means the remains of the lime are cleared out; they are then wrung out, hung up to dry on ropes, and fent to the mill, with the quantity of oil neceffary to fcorum them: the beef oil is that of ftock-fish.

Here they are firft thrown in bundles into the river, for twelve hours, then laid in the mill-trough, and fullled without oil till they be well foftened; then oiled with the hand, one by one, and thus formed into parcels of four fkins each; which are milled and dried on cords a fecind time; then a third; and then oiled again, and dried.

This procefs is repeated as often as neceffity requires; when done, if there be any moifure remaining, they are dried in a flove, and made up into parcels wrapped up in wool; after fome time they are opened to the air, but wrapped up again as before, till fuch time as the oil f eens to have loft all its force, which it ordinarily does in twenty-four hours.

The fkins are then returned from the mill to the chamofier, to be fcored; which is done by putting them in a liquid fum of wood-afhes, working and beating them in it with poles, and leaving them to fleep, till the softness had its effect; then they are wrung out, flapped in another lixivium, wrung again; and this is repeated till all the grease and oil be purged out. When this is done, they are half dried, and palled over a fharpened iron instrument, placed perpendicular in a block, which opens, softens, and makes them gentle; laflly, they are thoroughly dried, and palled over the fame instrument again; which finifhes the preparation, and leaves them in form of shammy.

Kid and goat-skins are shamofed in the fame manner as thole of sheep, excepting that the hair is taken off without the use of any lime; and that when brought from the
the mill, they undergo a particular preparation called 
casting; the most delicate and dainty of all is that of
a Conch, for in this, that as soon as brought from the
shell, they are steeped in a stiff liquor, taken out, dried
on a round wooden lute, and the hair is scraped off with
the kind; this makes them fast, and, in working, to
call a kind of free keep. The difficulty is in preserving
them evenly.

SHAMOKIN, in Geography, a town of Pennsylvania,
in the northumberland county, containing 2,177 inhabitants.

SHANKIN CREEK, a town of Pennsylvania, which
runs into the Susquehanna. N. lat. 40° 31′; W. long. 70° 53′.

SHAMANGI, a town of Peria, in the province of
Laristan.

SHANCORI, a town of Perian Armenia; 12 miles
W. N.W. of Kars.

SHANDEGAN, in, a town of New York, in the
county of Ulster, 14 miles N.W. of Kingston.

SHANDEAN, Little, a town in the same county; 12 miles
N.W. of Kingston.

SHANDYMUNGOLM, a town of Hindostan, in
Baramaul; 8 miles E. of Namaul.

SHANEDI, a town of Nubia, on the right bank of
the Nile; 45 miles S.W. of Nubia.

SHANGOLDEN, a small post-town of Ireland, in the
county of Limerick; 114 miles W.S.W. from Dublin.

SHANGRA, a country of Africa, W. of Moscanga.

SHANGRAPOY, a town of Hindostan, in Mardwar;
20 miles S.S.E. of Trumman.

SHANK, in Conchology, the Shanferit name of that
species of shell, which gives its name in Europe to this
branch of natural history. French and other foreign writers
spell the word chank. The only substitution of a hard
for a soft initial, has led to a supposition that conch may
by early writers have been taken from the same source as
shank, or even derived from it. The Shank, or shank,
or conch, is the large biscumnum, and is often seen beautifully
coloured as a pheasant’s breast. With the Hindoos, the
shank is an object of mythical reverence. It is seen in one
of the four hands of their deity Visnu, and is one of his
commonest attributes. Images and pictures of him are
deed dilligently gifted more by this than by any other mark.
It has of course a fabulous or mythological origin; and we
accordingly find it among the “fourteen gems” that were
recovered from the ocean, after a general deluge, as related
under the article KUMMATARA of this work, where
the Shank is said to be “a shell conferring victory
on any one who should find it.” In the distribution of
the precious articles, the shell seems to have fallen to the share
of Vishnu.

Shells, as a rounding implements, were much used in early
Indian wars, as trumpets and drums are with us. In
the terrible civil wars between the Pandus, and their kinmen
the Kurus, as Homerically described in the Mahābhārata,
Krisna used a shell named Panchajanya, obtained in the
manner related under our article KANYA, from a sea-
monster named Sankshura, which fee. Each claw in the
wars alluded to bore a shell, to which, like the heralds of
our chivalrous knights, different and significative names are
given. In the portion of the Mahābhārata translated by Mr. Wilkins,
called Bhagavata Gita, the following passage occurs. “The
ancient chief, and brother of the grand sire of the Kurus,
then shouting with a voice like a roaring lion, blew his shell
to raise the spirit of the Kurus chief; and infallibly immensur-
able shells, and other warlike instruments, refounded on all
sides,—the clangour was excessive. Krishana and Arjuna,
standing in a splendid chariot drawn by white horses,
Vol. XXXII.

Printed by A. Stanun,
New-Street Square, London.
also dignifies it, as Virgil did the Po, with the title of Fluviorum Rex. Spencer too celebrates

"The spacious Shannon spreading like a sea."

And other poets have been eloquent in describing its majestic course, holy islands, and sublime scenery; but geographers are, in general, very brief, and sometimes contradictory in their accounts of this river. They do not even agree as to its source. According to Camden and Ware it rises in Slieve-carrtron, (i.e. the mountain of iron mines,) in the county of Leitrim; but Gough and Ferrar make it spring from the plains of Quilka, in the county of Cavan. Again, Dr. Beaufort says, Lough Clean is the fountain-head; while Boade, Pinkerton, and most other writers on the subject, make it Lough Allen. These differences, however, may be in some measure reconciled by observing, that Lough Allen receives the waters of the other sources above-mentioned, and that the Shannon does not take its name until it has passed this lake. As it is likewise the receptacle of most of the other current waters of the surrounding country, every stream that falls into it may claim some share in the disputed honour; but Lough Clean has the highest title, as contributing most largely by means of the river Duff. Lough Allen is nearly in the centre of the county of Leitrim; it is about twenty square miles in extent, and in some parts is said to be unfathomable. From this grand resevoir and copious spring, the Shannon falls in great force at a place called Balatana. The direction, at first, is south and south-east, dividing the provinces of Leinster and Munster from Connaught. It passes Limerick, where it turns nearly to the west, and, sixty miles below this city, falls into the Atlantic ocean, between Kerry Head and Cape Lean, after a course of two hundred miles. It is navigable nearly to Limerick for ships of the greatest burden, and for smaller vessels throughout the whole extent of its course.

This noble river traverses several large lakes, and forms many extensive bays and estuaries, interspersed with beautiful islands. It receives above thirty other rivers in its course, and diffuses verdure and fertility over the banks of ten counties; namely, Leitrim, Roscommon, Galway, and Clare, on the right; and on the left, Longford, Westmeath, King's County, Tipperary, Limerick, and Kerry.

The principal towns situated on its banks are Leitrim, Carrick, Jamestown, Laneborough, Athlone, Banagher, Portumna, Killaloe, Calféconnel, Tarbert, and Kilrush; besides the city of Limerick, which it accompanies by different branches, and in some measure inflates.

The largest lakes which it passes through are, Lough Bofin, Lough Ree or Reghit, and Lough Derg or Dergart. The first, which is about ten square miles in extent, is situated at the confines of the counties of Leitrim, Longford, and Roscommon. Lough Ree extends nearly from Laneborough to Athlone, a distance of about sixteen miles, and is from two to five miles in breadth. It contains above fifty islands, many of which are covered with wood and good pasturage. Lough Derg is eighteen miles long, and from two to seven broad. It is divided into about sixty islands, one of which, called Innismore, contains above a hundred acres of good land; and on another, called the Holy Island, are the ruins of seven churches, and a round tower. This lake extends nearly from Portumna to Killaloe. There is also below Limerick, at the confluence of the Fergus river, an immense estuary, or firth, of many square miles in extent, interspersed with several rich and romantic islands.

The principal rivers that fall in from the right bank, or Connaught side, are the Key, Suck, Scariff, and Fergus. The confluence of the Key is at Carrick, and the Suck, which divides the counties of Roscommon and Galway, flows in at Conlerton above Banagher. Several smaller rivers fall in from the county of Galway; and from Clare flow the Scariff and Fergus; but the great weight of water comes from the other side by rivers running from east to west, which, it may be remarked, is different to the usual course in other parts of the world. The Inny is the first great river on the left bank: it is the boundary between the counties of Longford and Westmeath, and falls into Lough Ree, where it forms a large estuary. The second river on this side is the Great Broña, which forms a fine confluence with the Shannon above Banagher; and the Lesser Broña, united with the Birr river, falls in a few miles below that town. From hence to Limerick many smaller rivers flow in on the Ormond side, and below that city there are some larger ones: the principal are the Magy, Doel, Ovan, Cummage, Feak, Gare, and Caheen. Several of the above are navigable to a considerable distance from the Shannon.

From such an accumulation of rivers, lakes, and springs, the mouth of the Shannon is increased to an immense magnitude, being nearly ten miles in breadth, for the last fifteen miles, and from twenty to thirty fathoms deep. It is not only larger than any other insular river, but discharges much more water into the ocean than any continental stream whatever, running from a distance as two hundred miles. Camden seems to credit a tradition, commonly believed in his time, of a gradual increase in the number and fize of the lakes and rivers of Ireland. The supposition is curious, and may not be wholly unfounded.

As the Shannon from Limerick to the ocean is of great and increasing importance to the commercial world, we shall here give some particulars of its navigation from an hydrographical survey lately made. The distance is above sixty English miles, and the bearing nearly W. by S. The breadth of the river is various. If the length has been divided into three parts, the first will be from one to three miles broad; the middle division increases to about five, and the third to seven miles in breadth. The foundings of the mouth have been already mentioned: they decrease towards Limerick; but in all parts the river is of considerable depth, and is remarkable for its transparency.

The tides in the mouth of the Shannon rise from nine to fourteen feet perpendicular height; and they increase as the river becomes narrower, in remoteness that at the pool of Limerick, they are from twelve to twenty feet high. The current of the tide varies considerably in different parts of the stream, running at the rate of from two to five miles an hour. It is not, however, perceptible far above the city, owing to several cataracts.

There are many fine bays on the Clare side, which afford safe anchorage and good shelter for shipping. The principal are Kilbanah, Carigahault, Clonderla, and Lobheeda, besides the commodious harbour of Poolinishary, near Kilrush, and Tarbert bay on the Kerry side. It may be mentioned, that Kerry Head, also called Ballyheigh Point, is a long and narrow promontory; and that Cape Linn, or Loop Head, on the other side, is still narrower: having at its extremity a light-house, in lat. 52° 30', W. long. 10° 20'.

The navigation between the Upper and Lower Shannon was formerly impeded by the noted cataract near Calféconnel, called the Salmon's Leap, but of late years canals have been drawn round this rock as well as others called the Falls.

An important communication has been likewise opened between the Shannon and Dublin by means of the grand canal, which
which forms its junction at Beneleigh. (See our article Canal.) It may be observed, that the Shannon nearly bisects Connaught with the county of Clare; and that if a canal, of about four miles in length, were cut from Lough Clew to the river Bannet, which falls into Sligo bay, the inter mountain boundary would be complete, and the Shannon rendered navigable from sea to sea.

The bridges over this river are chiefly at the forementioned towns, but there are none below Limerick. In this city there are three, one of which, called Thomond bridge, contains fourteen arches; and about ten miles higher is O'Brien's bridge, which has nineteen arches.

The fisheries on the Shannon are numerous and productive, particularly for salmon, which is of the finest flavour. Mr. Arthur Young, in his Tour through Ireland, p. 359, observes of this river, that besides affording all sorts of wild fowl, the quantity and size of its fish are amazing. Pikes swarm and rise to the weight of colts each. Trout, bream, eel, gillarous, &c. are large and abundant, and perch are so plentiful, that, in some years, the poor almost live upon them. It may be added, that not only river fish, but even such as are generally denominated pond and lake fish, abound here; so that what Spenser says of the Trent may be truly applied to the bounteous Shannon, which

About itself enfeumes
Both thirty forts of fish, and thirty furnryreames.

The Shannon forms a very important subject in the ancient history of Ireland. Ptolemy mentions three large cities on its banks, called Regia, Macedicus, and Regia Altera. But his editors, Mercator and Ortelius, do not exactly agree in their maps as to the situations, and no vellages remain to settle the question. The general opinion is, that Regia was on the east side of Lough Ree, and the names correspond, as Ree signifies a king, in the Irish language. Macedicus is supposed, from the name, to have been at McLick, a village in the county of Galway, and Regia Altera at or near Limerick.

This river was of great political and military use before the English power was established in Ireland. It long served as a barrier between the territories of provincial kings, and not infrequently was the scene of naval engagements, particularly below Limerick. The following curious instance is recorded in the Annals of Munster, and quoted by Archdall. "This year (1665), Hugh O'Rueark, king of Brefine, in company with Thady O'Reily, king of Maine, were defeated by Hugh O'Connor, king of Connaught, who totally overthrew their whole army, and funk and disperfed their fleet on the Shannon." (Monachial Hibernicum, p. 280.) Even in modern times this river has been occasionally found of great military importance. See our articles Athlone, and Limerick.

The islands on the Shannon add an interesting feature to the history of the early progress of Christianity in Ireland; particularly from the fourth to the eighth century, when that country enjoyed a repose unknown on the continent, and was famed for the "Infusa Sacra et Salbitorus," or, to use the words of Dr. Johnston, "the pious and hospitable school of the west." During that period many of those islands were dedicated to the service of religion, and numerous vellages still are seen in the remains of churches, abbeys, and other monastic institutions. The holy island in Lough Derg has been already noticed, and there are many others of a familiar description, which are still held in pious veneration by the multitude, and are much resorted to on certain festivals. We shall mention only another, which is Inisnáit, in the mouth of the Shannon, about twenty miles from the ocean, and which is thus described by Archdall, p. 49.

"On the rich and beautiful island of Scattery, are the ruins of a monastery dedicated to St. Simon, who founded here an episcopal see for about the time of St. Patrick. There are like wise the ruins of seven churches, out of eleven which existed in Queen Elizabeth's time. An ancient round tower of one hundred and twenty feet in height, and in complete repair, rese the town." For a more particular account of their "Infusa Sacra Sena," see O'Goghty's Céad Mile Feirste Uilte, Wilton, Archdall, &c.

The views of the Shannon are in many parts highly picturesque and sublime. We shall fly resume the terriee of our country is from a beautiful hill in Lower Ormond, called Knocknagown, viz. O'Neill's hill, so named as being the Sacred residence of O'Shaugh, Spencer's Fairy Queen. From this eminence the river is seen to an extent of nearly twenty miles, apparently descending in its course. The second is from the admired ruins of Carrick O'Gumel, beyond Limerick; and the third from Knockpatrick, a lofty hill in the same county, and much nearer to the sea. It is celebrated by several writers as commanding the most grand and interesting prospect that can be imagined both of the river and the sea. Among these authors may be mentioned Necharm, an English poet and divine of the twelfth century, whose verses on the Shannon are thought worthy of quotation by Camden, and which we shall here transcribe, annexing a free translation.

"Fluminibus magnis lactatur Hibernia, Sine Rea
Inter Connatiun, Momomamque fluit.
Transit per muros Limerici, Nocm Patrce illium
Oceanu claustrum sub ditione videri."

"Amid majestic streams, Hibernia's pride,
The noble Shannon bids her plains divide.
Leinster and Munster to the callward bear,
With Connaught to the right, and lofty Clare;
By Limrick's walls he rends his lordly way,
While tributary streams their homage pay.
Till proud Knockpatrick views, from Deimond's coast,
This world of waters in the ocean loth!"

SHANNON, a river of Canada, which runs into the N.E. part of lake Ontario.

SHANSCRIT, Sanscrit, Samserit, Sanscrotam, or Hanseecrit language, is the original language of the Hindoos and Gentoos, in which their Shaffish, or Shaffer, is written, &c. The grand source of Indian literature, the parent of almost every dialect, from the Persian gulf to the China seas, says the learned Halhed, in the Preface to his Grammar of the Bengale Language, is the Shanseerit; a language of the most venerable and unfashionable antiquity, which, although at present flut up in the libraries of Brumis and appropriated solely to the records of their religion, appears to have been current over most part of the oriental world; and traces of its original extent may still be discovered in almost every district of Asia. It is apparent to find the finitude of Shanseerit words with those of Persian and Arabic, and even of Latin and Greek; and those not in technical and metaphorphical terms, which the fluctuation of refined arts and improved manners might have occasionally introduced; but in the main ground-work of language, in monosyllables, in the names of numbers, and in the appellations of such things as would be first discriminated in the immediate dawn of civilization. The coins of Assam, Nau- paul, Cashmire, and many other kingdoms, are all stamped with
with Shanfcrit letters, and mostly contain allusions to the old
Shanfcrit mythology: the fame conformity is also observa-
table in the imprefions of feals from Boothan and Tibet.
Befides, the arrangement of the Shanfcrit alphabet is very
different from that of any other quarter of the world.
This extraordinary mode of combination still exists in the
greater part of the Eaft, from the Indus to Pegu, in dialects
now apparently unconnected, and in characters completely
diffimilar; and affords a forcible argument that they are
all derived from the fame fource. Moreover, the names of
perfons and places, of titles and dignities, which are open to
general notice, and which are found even to the furthest
limits of Asia, prefent manifold traces of the Shanfcrit.
Another circumstance deferves to be mentioned, and that is,
that the raja of Khfenagur, a very learned and able anti-
quary of Bengal, affirmed, that he had in his own poffeffion
books which give an account of a communication formerly
fubfifting between India and Egypt, in which the Egyptians
are described as disciples, and not as instructors; and as
seeking that liberal education and thofe fciences at Hind-
doflaffi, which none of their own countrymen had fufficient
knowledge to impart. But though thefe feveral proofs of
the former prevalence of the Shanfcrit are now thinfly ftrent-
ted over an immense continent, and interconfedered with an
infinte variety of extraneous matter, arizing from every
poftible revolution in the manners and principles of the
nation: as an example, or by turns cultivated or deftroyed it;
that part of Asia, between the Indus and the Ganges, still pre-
ferves the whole language pure and inviolate; thefe offer a
thousand books to the perusal of the curious, many of
which have been religiously handed down from the earlick
periods of human existence.

H. T. Colebrooke, eqq. has given us in the Aflatic Re-
searches (vol. vii. p. 199, &c.), a literal tranflation of two
paffages cited from a treatife on rhetoric, compiled for the
ufe of Manieya Chandra, raja of Trabhuhtti, or Tirhut, in
which are enumerated the languages ufed by Hindoo poets.
The fift is as follows: “Sanfcrita, Pracrita, Paifachi, and
Magadhi, are in fhort the four paths of poetry.” The
gods, &c. speak Sanfcrita; benevolent genius, Pracrita;
wicked daemons, Paifachi; and men of low tribes and the
reft, Magadhi. But fages deem Sanfcrita the chief of
these four languages. It is ufed three ways: in profe, in
verfe, and in a mixture of both.” Again, “Language,
the virtuous have declared to be fourfold, Sanfcrita, or
the polished dialect; Pracrita, or the vulgar dialect;
Apabranja, or jargon; and Mifra, or mixed. Sanfcrita
is the fpeech of the celeftials, framed in grammatical in-
fluences; Pracrita is similar to it, butmanual as a pro-
vincial dialect; and otherwife, and thofe languages which
are ungrammatical, are spoken in their repective diftricts.”
The Paifachi, fays Mr. Colebrooke, seems to be gibberifh,
which dramatic poets make the daemons speak, when they
bring these fantaftic beings on the fstage. The mixture of
languages, noticed in the fefond quotation, is that which
is employed in dramas, as is expressly faid by the fame
author in a fubfrequent verfe. It is not then a compound
language, but a mixed dialogue, in which different perfonals
of the drama employ different idioms. Both the paffages
above quoted are therefore eafily reconciled. They, in
fact, notice only three tongues. 1. Shanfcrit, a polished
dialect, the inflexions of which, with all its numerous
anomalies, are taught in grammatical infiuences. This the
dramatic poets put into the mouths of gods and of holy per-
fonages. 2. Pracrita, conflufing of provincial dialects, which
are lefs reined, and have a more imperfect grammar. In
dramas it is spoken by women, benevolent genius, &c.

3. Magadhi, or Apabranja, a jargon deftinate of regular
grammar. It is ufed by the vulgar, and varies in different
diftricts: the poets accordingly introduce into the dialogue
of plays a provincial jargon, fpoken by the lowest perfonal
of the drama.

Sanfcrita is the passive particle of a compound verb,
formed by prefixing the preposition gam to the crude verb
ciri, and by interpofing the letter s, when this compound
is ufed in the feme of embellishment. Itsliteral meaning
then is “adored,” and when applied to a language, it
signifies “polifhed.” Pracrita is a familiar derivative from
the fame crude verb, with pra prefixed: the most common
acceptation of this word is “outcast, or man of the lowest
class;” as applied to a language, it signifies “vulgar.”
Apabranja is derived from braja, to fall down: it signifies
a word, or dialect, which falls off from correct etymology.
Grammarians ufe the Sanfcrita as signifying “daily formed
or regularly infiuled;” and Apabranja for false grammar.
The languages of India are all comprehended in these
three categories. The first contains Shanfcrit, a moft polifhed
tongue, which was gradually refined until it became fixed
in the clasfes of the writings of many elegant poets, moft of whom
are reputed to have flourifhed in the century preceding the
Christian era. It is cultivated by learned Hindoos throughout
India, as the language of science and of literature,
and as the repository of their law, civil and religious.
It evidently draws its origin (and some steps of its pro-
gress may even now be traced) from a primeval tongue,
which was gradually refined until it became fixed
in the clasfes of the writings of many elegant poets, moft of whom
are reputed to have flourifhed in the century preceding the
Christian era. It is cultivated by learned Hindoos throughout
India, as the language of science and of literature,
and as the repository of their law, civil and religious.

The Shanscrit

Shanscrit.

ordinate length; the whole sentence too, or even whole periods, may, at the pleasure of the author, be combined like the elements of a single word, and general rules do not apply. None but well-known compounds would be used by any speaker who wished to be understood, and each word would be distinctly articulated, and definitely of the terms which precede and follow it. Such indeed is the present practice of those who still speak the Shanscrit language; and they deliver themselves with such fluency as is sufficient to prove, that Shanscrit may have been spoken in former tunes as much facility as the contemporary dialects of the Greek language, or the more modern dialects of the Arabic tongue.

The father of Shanscrit grammar, who first composed those grammatical inutiles in which this language is formed, or by which words are correctly formed or inflected, was Panini, who lived in the remote age, that he ranks among those ancient sages, whose fabulous history occupies a conspicuous place in the "Puranas," or Indian theogonies. According to the Panarica legends, Panini was the grandson of Devala, an inspired legislator; but whatever may be his history, to him the Sutras, or fanciful aphorisms of grammar, are attributed by universal consent.

His mystic is grounded on a profound investigation of the analogies in both the regular and the anomalous inflections of the Shanscrit language. He has combined those analogies in a very artificial manner; and has thus composed a most copious etymology into a very narrow compass. His precepts are indeed numerous, but they have been framed with the utmost care; and this great brevity is the result of very ingenious methods which have been contrived for this end, and for the purpose of afflicting the student's memory. In Panini's system the mutual relation of all the parts marks that it must have been completed by its author; it certainly bears internal evidence of its having been accomplished by a single effort, and even the corrections, which are needed, cannot be interwoven with the text. It must not be hence inferred, that Panini was unaided by the labours of earlier grammarians; in many of his precepts he cites the authority of his predecessors, sometimes for a deviation from a general rule, often for a grammatical canon which has universal cogency. He has even employed some technical terms without defining them, because, as his commentators remark, those terms were already introduced by earlier grammarians. None of the more ancient works, however, seem to be now extant; being superseded by his, they have probably been diffused for ages, and are now perhaps totally lost.

The inaccuracy of the Paniniana grammar were corrected by Catayana, an inspired saint and lawyer, whose history is involved in the impenetrable darkness of mythology. The amended rules of grammar have been formed into a memorial verity by Bhartrihari, whose metaphysical aphorisms, entitled "Carica," have almost equal authority with the precepts of Panini, and emendations of Catayana. Bhartrihari is said to have lived in the century preceding the Christian era. The text of Panini being concise and ambiguous, many commentators were composed to elucidate it, of the chief of which Mr. Colebrooke has given an account. The brief and most concise commentary now extant, is entitled the "Carica vritti," or commentary composed at Varanasi. Within a few centuries past, a grammar, well adapted for aiding the student in acquiring a critical knowledge of the Shanscrit tongue, has been compiled by Rama- chandra, entitled "Pracriyacacumudi."

When Shanscrit was the language of Indian courts, and was cultivated not only by persons who devoted themselves to religion and literature, but also by princes, lawyers, doctors, physicians, and sages; in short, by the first three classes, and by many classes included in the four; an easy and popular grammar must have been needed by persons who could not waste the best years of their lives in the study of words. Such grammars must always have been in use; but, however, which are now studied are not, we believe, of very ancient date. The most esteemed is the "Saraswata," together with its commentary named "Chandra.

It seems to have been formed on one of the Caumudis by translating Panini's rules into a language that is intelligible, independently of the gloss, and without the necessity of referring to a different context.

Another popular grammar, which is in high repute in Bengal, is entitled "Mugdhob'dha," and is accompanied by a commentary. It is in the work of Vepadeva, and proceeds upon a plan grounded on that of the Caumudis; but the author has not been content to translate the rules of Panini, and to adopt his technical terms. He has, on the contrary, invented new terms, and contrived new abbreviations. The same author likewise composed a metrical catalogue of verbs alphabetically arranged. It is named "Caviclatapruma," and is intended as a substitute for the "Dhatupata."

The best and most esteemed vocabulary of the Shanscrit is the "Amera cola," which, like most other Shanscrit dictionaries, is arranged in verse to aid the memory. Numerous commentaries have been written on this vocabulary; the chief object of which is to explain the derivations of the nouns, and to supply the principal deficiencies of the text. Shanscrit etymologists carefully acknowledge a single primitive amongst the nouns. When unable to trace an etymology which may be consistent with the acceptation of the word, they are content to derive it accordingly as grammatical rules from some root to which the word has no affinity in sense. At other times they adopt fanciful etymologies from Puranas or from Tantras. But in general the derivations are accurate and instructive.

Amera's dictionary does not contain more than ten thousand different words. Yet the Shanscrit language is very copious. The insertion of derivatives, that does not at all deviate from their regular and obvious import, has been very properly deemed superfluous. Compound epithets, and other compound terms, in which the Shanscrit language is peculiarly rich, are likewise omitted; excepting such as are especially appropriated, by a limited acceptation, either as titles of deities, or as names of plants, animals, &c. In fact, compound terms are formed at pleasure, according to the rules of grammar; and must generally be interpreted in strict conformity with those rules. Technical terms too are mostly excluded from general dictionaries, and confined to technical nomenclatures. The "Amera colin" then is less defective than might be inferred from the small number of words explained in it. Still, however, it needs a supplement. The remaining deficiencies of the Amera colin are supplied by consultative, or easier dictionaries and vocabularies, which are very numerous.

The Shanscrit language is very copious and vigorous; but the style of the best authors wonderfully concise. It far exceeds the Greek and Arabic in the variety of its etymology, and, like them, has a prodigious number of derivatives from each primary root. The grammatical rules are also numerous and difficult, though there are not many anomalies. "The Shanscrit language," says Sir William Jones, (Aiat. Ref. vol. i. p. 422), "whatever be its antiquity, is of a wonderful structure, more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either; yet bearing to both of them a stronger affinity, both
both in the roots of verbs, and in the forms of grammar, than could possibly have been produced by accident; so strong, indeed, that no philologer could examine them all three without believing them to have sprung from some common source, which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a very different idiom, had the same origin with the Shanfcrit, and the old Persian might be added to the same family."

The fundamental part of the Shanfcrit language is divided into three classes; viz. dhat, or roots of verbs, *fiubhi, or original nouns, and *srya, or particles. The latter are always indeclinable, as in other nations; but the words comprehend in the two former classes must be prepared by certain additions and inflections to fit them for a place in composition. Here the art of the grammarians interposes, as not a syllable, nor a letter, can be added or altered but by regimen; nor the most trifling variation of the sense in the minutest subdivision of declension or conjugation be effected without the application of several rules; and all the different terms for every change of gender, number, case, person, tense, mood or degree, are methodically arranged for the assistance of the memory; resemblying, though on an infinitely more extensive scale, the compilations of *propria que maribus and in present.

In the Shanfcrit language, the three distinctions of genders, viz. masculine, feminine, and neuter, are preferred in their common number and order. A Shanfcrit noun, in its first formation from the general root, exists equally independent of case as of gender. It is neither nominative, nor genitive, nor accusative, nor is it imprefied with any of those modifications, which mark the relation and connection between the several members of a sentence. In this state it is called an imperfect, or crude noun. To make a nominative any noun, the termination must be changed, and a new form supplied. Thus we see that, in the Shanfcrit at least, the nominative has an equal right with any other inflexion to be called a case. The Shanfcrit has seven declensions of nouns, which are all used in the singular, dual, and plural number, and differently formed, as they terminate with a confonant, and with a long or short vowel; and also as they are of different genders. The seven changes of inflexion are exclusive of the vocative, and therefore the Shanfcrit comprehends two more than even those of the Latin: they are as follow, viz. 1. The nominative, or *agent in a sentence; 2. The passive case, or subjunct of the action; 3. The causal case, pointing out the cause by which a thing is done; or the instrument with which it is done; or the subject in or by which it is suffered; 4. The dative, with the sign to or for; 5. The ablative, implying the subject from whence any thing proceeds; 6. The possessive case, called by us, the genitive; 7. The locative case, different of situation, and generally known by the sign in. The vocative is excluded from the number of cases, as no inflexion is employed in its formation.

The Shanfcrit, the Arabic, the Greek, and the Latin verbs are furnished with a set of inflexions and terminations fo comprehensive, and so complete, that by their form alone they can express all the different distinctions both of person and time. Three separate qualities are in them perfectly blended and united. Thus by their root, they denote a particular act; and by their inflexion, both point out the time when it takes place, and number of the agents. Every Shanfcrit verb has a form equivalent to the middle voice of the Greek, used through all the tenses with a reflexive sense; and the former is even the most extensive of the two in its use and offices; for in Greek the reflexive idea can only be adopted introactively, when the action of the verb descends to no extraneous subject; but in Shanfcrit the verb is both reciprocal and transitive at the same time. The verbal substantive of the Shanfcrit very nearly resembles those of the Greek and Latin; but perhaps it would not be suspected that all the verbs in *mi are formed exactly upon the same principle with the Shanfcrit conjunctions, even in the minutest particulars. All the terms which serve to qualify, to distinguish, or to augment either *substance or action, are called by the Shanfcrit grammarians under a head, literally signifying infixed or addition. According to this arrangement, a single sentence consists of three numbers: the agent, the action, and the subject; which, in a grammatical sense, are reduced to two, viz. the noun (whether agent or subject) and the verb. All such words as tend to specificate or to amplify the noun, are denominated by a term, which signifies *adjectives or *epithets; and such as are supplied to define must be relation or connection, are called *consonants of nouns, and by European grammarians, *propositions: those particles which in any manner affect the verb are denominated *attributes of verbs.

The Shanfcrit alphabet contains fifty letters; and it is one boast of the Bramins, that it exceeds all other alphabets in this respect. But when we consider that of their thirty-four consonants, nearly half are combined sounds, and that fix of their vowels are merely the correspondent long ones to as many which are short, the advantage seems to be little more than imaginary. The Shanfcrit character, used in Upper Hindoostan, is said to be the same original letter that was first delivered to the people by Brihima, and is called Dzdnagar, or the language of angels; whereas the character used by the Bramins of Bengal is by no means so ancient, and is evidently a corruption of the former. In the four beids, or vedas, which constitute the original and facred text of the great Hindoo creator and legislator Brihima, the length of the vowels is expressed by a musical note or sign placed over every word; and in reading the beids, their distinctions of tone and time must be observed; so that they produce all the effect of a laboured recitative. It is remarkable, that the Jews in their synagogues chant the Pentateuch in the same kind of melody, and it is supposed that this usage has defended itself from the remotest ages. Some writers have erroneously asserted, that the four beids are in verse; whereas they are written in a kind of measured prose; and they are now scarcely intelligible to the most learned pundits or lawyers; they are also scarce, and difficult to be found. However, comments have been written upon them from the earliest periods; of which one of the most ancient and approved was composed by Bifeft Mamamome, or the Moll Wife, a great writer and prophet, who is said to have lived in the futfte jogue, or firit age of the world. See Halihed's Pre- face to his translation of the Code of Gento Laws, printed in 1776.

Dr. Leyden, in his account of the languages and literature of the Indo-Chinese nations, (AsiaU. Researches, vol. x.) has shewn, that the "Pali," as it is generally written, or "Bali" language, as it is commonly pronounced, occupies the same place among the Indo-Chinese nations, which Shanfcrit holds among the Hindoos, or Arabic among the followers of Islam. Throughout the greater part of the maritime countries, which lie between India and China, it is the language of religion, law, literature, and science; and has had an extensive influence in modifying the vernacular language of those regions. La Loubere, on the authority of d'Hercbelot, has stated that the ancient Peric language was termed Paahalvi (Pahalvi), and that the Persians do not distinguish in writing between Pahali and Bahali. P. Paulinus, however, applies this term Bali inaccurately to the square Bali character, instead
SHANSCRIT.

of the Language. This Language, notwithstanding its exten-
tive use among so many nations, and the degree of culti-
vation which it has received from the different tribes by
which it is employed, has hitherto attracted little attention
among Europeans. The 'Bali alphabet, according to Dr.
Leyden, seems, in its origin, to be a derivative from the
Devanagari; though it has not only acquired considerable
differences of form, but has been also modified to a certain
degree, in the power of the letters, by the monosyllabic
pronunciation of the Indo-Chinese nations. The form of
the Bili character varies essentially among the different
nations by which it is used.

The Bili is an ancient dialect of Shanscr, which some-
times approaches very near the original. When allowance
is made for the regular interchange of certain letters, the
elision of harsh consonants, and the contraction of similar
syllables, all the vocables which occur in its ancient books,
seem to be purely Shanscr. In Claritas and later composi-
tions, however, some words of the popular languages of
the country sometimes imitate themselves, in the same
manner as Tamil, Telunga, and Canara vocables occasionally
occur, in the later ShanScr compositions of the Deekhin.
The Bili, while it retains almost the whole extent of
ShanScr flexions, both in nouns and verbs, nevertheless
employs this variety rather sparingly in composition, and
affects the frequent introduction of the preterite partici-
ple, and the use of imperforal verbs. It also uses the
cater of nouns in a more indeterminate manner than the
ShanScr, and often confounds the active, neuter, and pas-
tive tenses of verbs. Like other derivative dialects, it occa-
sionally uses ShanScr nouns and participles in an oblique
fence; but notwithstanding all these circumstances, it ap-
proaches much nearer the pure ShanScr, than any other
dialect, and exhibits a close affinity to the Prakrit, and the
Zend.

These three dialects, the Prakrit, the Bili, and the
Zend, are probably the most ancient derivatives from the
ShanScr. The great mass of vocables in all the three,
and even the forms of flexions, both in verbs and nouns,
are derived from the ShanScr, according to regular laws of
elision, contraction, and permutation of letters. Some-
times, in purifying these analogies, they nearly coincide,
sometimes they differ considerably, sometimes one, and
sometimes another of them approaches nearest to the origi-
nal ShanScr. Their connection with this parent language
was perceived, and pointed out by Sir W. Jones, and has
also been alluded to by P. Paulinus, who derives his infor-
mation concerning the Bili, from Carpanus and Mante-
gatus. The fate of these three languages is also, in some
degree, similar. The Prakrit is the language which con-
tains the greater part of the sacred books of the Jains;
the Bili is equally revered among the followers of Buddh'ia;
while the Zend, or sacred language of ancient Iran, has
long enjoyed a similar rank among the Parisis or hostsprers
of fire, and been the repository of the sacred books of Zo-
readers. It is perhaps, however, more accurate to consider
all the three, rather as different dialects of the same derived
language, than as different languages; and conformably
to this idea, the Bili itself may be reckoned a dialect of
Prakrit. The term Prakrit, both in books, and in common
use among the Brahmis, is employed with some degree of
latitude. Sometimes the term is confined to a particular
dialect employed by the Jains, as the language of religion
and science, and appropriated to females, and respectable
characters of an inferior class, in drama. Sometimes it
includes all the dialects derived immediately from the Shan-
Scr, whether denominated Prakrit, Magadhi, Suratien,
Paisali, or Apabhraasta; and sometimes it is even extend-
ed to the Dei b'hishki, or popular tongues of India, as
Marathit or Maharrta, Canara, Telunga, Udha and Ben-
gali. According to the extended use of the term Prakrit, it
can certainly include both Bili and Zend; and if more ex-
tensive research should justify the idea derived from an
imperfect investigation, Dr. Leyden apprehends that the Bili
may be identified with the Magadhi, and the Zend with
the Surati, or ShanScr authors. These three dialects, the Prakrit, Bili, and Zend,
have been regularly cultivated and fixed by composition.
The same laws of derivation are applicable to the forma-
tion of all the three; but yet there is often considerable
diversity in the forms which particular words assume, as
appears from the comparative specimen given by Dr. Ley-
den.

The learned Mr. Colebrooke has published in the 1oth
volume of the Asiatic Researches, an elaborate essay on
ShanScr and Prakrit poetry. He observes, that the profusy
of ShanScr will be found, from the examples which he has
adduced, to be richer than that of any other known language,
in variations of metre, regulated either by quantity or by
number of syllables, both with and without rhyme, and
subject to laws imposing in some instances rigid restric-
tions, in others allowing ample latitude. The rules relative
to Prakrit profody, are applicable, for the most part, to Shan-
Scr profody also; since the laws of verification in both
languages are nearly the same.

ShanScr profody admits of two sorts of metre; one
governed by the number of syllables; and which is mostly
uniform or monoschematic in profuse poetry, but altogether
arbitrary in various metrical passages of the Vedas. The
other is in fact measured by feet, like the hexameters of the
Greek and Latin; but only one sort of this metre, which is
denominated Arya, is acknowledged to be so regulated;
while another sort is governed by the number of syllabic
inflants or matras.

The most common ShanScr metre is the stanza of four
verses, containing eight syllables each; and denominated
from the name of the class "Aumshihth," for an account of
which, and of other kinds of metres, we refer to fuller
books.

The ShanScr writers notice different species of prose. They discriminate three and even four sorts, under distinct
names. 1. Simple prose, admitting no compound terms.
It is denominated "Mukta." This is little used in polished
compositions; unless in the familiar dialogue of dramas.
It must undoubtedly have been the colloquial style, at
the period when ShanScr was a spoken language. 2. Prose,
in which compound terms are sparingly admitted. It is
called "Culaca." This and the preceding sort are by some
considered as varieties of a single species named Churnica.
It is of course a common style of composition; and, when
polished, is the most elegant as it is the chastest. But it
does not command the admiration of Hindoo readers.
3. Prose abounding in compound words. It bears the
appellation of "Uchchaca praya." Examples of it exhibit
compounds of the most inordinate length; and a single
word exceeding a hundred syllables is not unprecedented.
This extravagant style of composition, being useful to
the taste of the Indian learned, is common in the most ela-
borate works of their favourite authors, 4. Prose modu-
lated so as to frequently exhibit portions of verse. It is
named "Vratacandithi." It will occur without study, and
even against design, in elevated compositions; and may be
expected in the works of the best writers.

Some of the most elegant and highly wrought works in
prose are reckoned among poems, as already intimated, in
like
like manner as the “Telemachus” of Fenelon and “Tod Abdal” of Gellner. The most celebrated are the “Vafavardatta” of Subandhu, the “Dafa Cumara” of Dandi, and the “Cadambri” of Vana.

For a further account of the Shanferit, see Language of Bengal, or Bengal. Exclusive of the Shanferit, there are three different dialects in the kingdom of Bungal, viz. the Pherian, the Hindooftan, and the proper Bengal. See Persia and Pers. Language, Hindoostanee, and Bengal.

SHAN-SI, in Geography. See Shan-si.

SHAONA, a town of Egypt, on the W. coast of the Red Sea; 90 miles S.S.E. of Coiffe.

SHAOUMRE, a town of Arabia, in the province of Hedjjas; 25 miles from Calaat el Moolah.

SHAOUN, a town of Arabia, in the province of Hedjas; 45 miles S. of Jambo.

SHAPARY, a town of Hindooftan, in the circuit of Gangpou; 20 miles S. of Padi.

SHAPE, Inflammation of, among neat cattle, an affection in cows, arising from the hot weather after taking the bull; and which is shown by a swelling of the parts with boils or eruptions. It is observable by the animal rubbing her hind parts in the hedges, &c. In the cure Mr. Downing advises, after free bleeding, the following: Nitre in powder, two ounces; cream of tartar, three ounces; Cattle soap, one ounce; and aniseed powder, one ounce; which are to be mixed for a dose, and to be given in a quart of warm whey, repeating them as there may be occasion.

To Shape the Coursie, in Sea Language, is to direct or appoint the track of a ship, in order to prosecute a voyage.

SHAPINSAY, in Geography, one of the Orkney islands, Scotland, is situated to the N. of the Mainland of Orkney, at the distance of three miles from Kirkwall, the capital of all the islands. It measures about seven miles in length and five in breadth, and formerly constituted part of the territorialities of the bishopric of Orkney. Almost the whole of it is capable of cultivation; but a great part yet remains in a neglected state, to the detriment, as well as the disgrace of the proprietors. Nevertheless, sufficient grain is raised for the supply of the inhabitants. Kelp is produced in great abundance, and is much used as a manure. Lead ore is likewise abundant in the south-west corner of this island, and was for some time wrought, but the work is now entirely abandoned.

In common with most of the Orkney islands, Shapinsay exhibits some monuments of antiquity; among these may be reckoned, besides several Popish chapels, a numerous collection of Pits-house ranged along the shores, like so many forts, together with tumuli, or barrows, in various situations. A monumental stone of large dimensions raises its venerable head in a plain near its eastern extremity; and on the northern shore is the stone Odin.

To the south of Shapinsay, at the distance of a furlong, is situated the beautiful islet of Elgar or Ellerholm, which bears evident traces of former habitation, and of having been, at no very distant period, attached to the principal island. At present it furnishes pasture for a number of sheep and young cattle during summer, and serves to give, by its favourable position, the utmost security to the harbour of Elwick, which is one of the finest in the Orkneys.

Barry's History of the Orkney Islands, 2d edit. by J. Headrick, London. 1808.

SHAPLEIGH, a poht-town of America, in Massachusetts, in the province of Maine, incorporated in 1785; 108 miles N. of Bollten.

SHAPPOOTA HILLS, a mountainous ridge of Hindooftan, between the Nerbuddah and Taptot; 60 miles E. of Surat.

SHAPORA, a town of Hindooftan, in the circuit of Rantamper; 45 miles W. of Rantamper.

SHAPOUR, a city of Persia, in the province of Fariftan, is said to have been originally founded by Taimur Devehund, who called it Deen Dar; it was destroyed by Alexander the Great, and subsequently built by Sapor, the son of Artaexerxes Babgan, who named it after himself. The ruins of this ancient city are distinct about 16 miles from Kazeroun; and if we may form an idea from the breadth and circumference of the ramparts, and the remains of some other public buildings, it must have been a city of great extent and magnificence. It is situated immediately on the eastern range of mountains, on the banks of a small but rapid river, and in a wild, romantic spot, amidst rocks and precipices, many of which are decorated with pieces of sculpture similar to those near Persepolis, for a description of which we refer to Kinners Memoir of the Persian Empire, p. 66. The hills in the immediate vicinity of these ruins appear to have been formerly fortified; and an extraordinary cavern, farther up the river, has given rise to many fabulous stories.

SHAP, an island in the Chepapeak; 27 miles S.S.E. of Annapolis. N. lat. 38° 40'. W. long. 70° 25'.

SHAR, or SHEAR-HOG, in Agriculture, a term signifying a yearling sheep, which has been once shorn. The name lamb-hog. See Sheep.

SHARAF BENI GATE, in Geography, a town of Arabia, in the province of Hedjas; 25 miles N. of Madian.

SHARBASHI, a town of Turkih Armenia; 18 miles S.E. of Moueth.

SHARBASI, a town of Turkih Armenia; 18 miles S.E. of Moueth.

SHARIBIN, a town of Egypt; 16 miles S.S.W. of Damietta.

SHARD, in Agriculture, a term applied to a fragment of an earthen vessel, or the gap in a hedge.

SHARE of a Plough, that part which enters, cuts, and breaks up the ground, the extremity forward being formed with a sharp-pointed iron, called the point of the share; and the end towards the wood behind, the tail of the share. This part constitutes a portion of what is usually denominated the t h r o a t, which is of very great importance in the construction of this implement. (See Plough.) The dimensions are these: the length of the whole share from point to tail, according to Tull, should be three feet nine inches, but in modern ploughs much shorter; at the top of the iron it hath sometimes an upright piece called the fin; and near the iron, at the other end, there is an oblong-square hollow called the socket; the use of which is to receive the bottom of the share. Near the tail there is a thin plate of iron, well riveted to the wood; by means of this plate, the tail of the share is held firmly to the hinder flint of the plough by a small iron-pin, with a screw at the end, and a nut screwed on it, on the inner or right side of the share. But shares are made in different forms.

The point of the share is that part in which it does not run up to the fin; this point is generally made three inches and a half in length, and should be flat underneath, and round at the top, and the lower part of it must be of hard steel. The edge of the fin should also be well flinted, and should make an acute angle with the share. The socket is a fort of mortar; it should be a foot long and about two inches deep; the fore-end of it must not be perpendicular, but oblique, conformable to the end of the share which enters into it. The upper edge of the fore-part must be always...
always made to bear up against the sheet; but if this end of
the bucket should not be quite to oblique as the sheet,
it may be helped by parting off a small part of the wood at
the point.

However, in modern ploughs, the shares, as has been seen,
are very different, according to their constructions and the
uses for which they are intended.

Lately, improved cast-iron plough-shares have been made
by R. Ramsone, of Ipswich, Suffolk, for which he has ob-
tained a patent. These shares are made hard on one side
and soft on the other, which affords the great advantage of
wearing them, as it is found by farmers that those made
in the common way wear thick, with a bush on the under-side,
which obstructs their entering into hard or strong soils, and
at the same time increases the labour of the team, as well as
pals over weeds without cutting or eradicating them.
The same person also makes plough-grounds, which are so con-
structed, as that by turning a screw the plough is made to work
more or less to the land with the greatest ease and facility.

And both these constructions are said to be capable of being
applied to all sorts of ploughs which have been already con-
This species has been long known to the inhabitants of the
fourth and west of Ireland and Scotland, and tho' of Caern-
arnvonshire and Anglesea; they quit the bays of these
Welsh counties about Michaelmas, and the frith of Clyde,
and the Hebrides, about the latter end of July. They have
nothing of the fierce and voracious nature of the shark
kind, but are so tame as to suffer themselves to be stroked;
lying motionless on the surface of the water, commonly on
their bellies, but sometimes on their backs, as if to fun
themselves; whence they are called balking sharks. Their
food seems to consist entirely of sea-plants. Linnaeus says
they feed on medusze. At certain times they are seen sport-
ing on the waves, and leaping with great agility several feet
out of the water; they swim deliberately, with the dorad fons
above water; their length is from three to twelve yards,
and they are sometimes longer; their form is slender; the
upper jaw much longer than the lower, and blunt at the end.
the mouth placed beneath, and each jaw furnished
with numbers of small teeth; those before being much bent,
and those more remote in the jaws being conic, and sharp-
pointed; on the sides of the neck there are five large
transverse apertures to the gills; on the back two fins; the
first very large, nearer the head than the middle; the other
small, and situated near the tail; on the lower part there are
two others; viz. two pectoral fins, two ventral fins, and a
small anal fin; near these, the male has two genitals, as in
other sharks; and between these fins was situated the pudendum of the female; the tail very large, having the
upper part much longer than the lower; the colour of the
upper part of the body a deep leaden, and the belly white;
the skin rough, like hidegren, but lefs so on the belly than on
the back; within side the mouth, towards the throat,
was a very short fork of whalebone; the liver is of a great
size, that of the female being the largest, and is melted into
a pure and sweet oil, fit for lamps, and much used by the
people, who take it to cure bruises, burns, and rheumatic
complaints. A large fish will yield eight barrels of oil.
These fishes are viviparous, a young one, a foot in length,
having been found in the belly of one of them. When
they are struck with a harpoon, and wounded, they lill
up their tails, and plunge headlong to the bottom, rolling
the rope round them, and attempting to disengage them-
elves from the harpoon, by rolling on the ground. They
swim away with such rapidity and violence, that there has
been an instance of a velfet of seventy tons having been
towed away against a fresh gale; and they will employ the
filifers for twelve, and sometimes twenty-four hours,
before they are subdued. Pennant's British Zoology, vol. iii.
p. 101, &c.

SHARK, Hammer-headed, Squalus zydena, a fish of the
shark kind, called also the balance-fish.

It is an extremely singular and remarkable fish, and differs
not only from all the other sharks, but from all the fish in
the figure of its head; this is not placed, as in
all other fishes, longitudinally, or in a line with the body,
but is set on transversely, as the head of a hammer or mallet
upon the handle. This is femicircular at the front, and
runs to fo thin and sharp an edge, that as the fish swims for-
ward with violence, it may cut other fishes, and is terminated
at each end by an eye; these are very large, and so placed,
that they more conveniently look down than either upward
or sidewise. In the farther part of the forehead also, near
the eyes, on each side, there is a large oblong foramen,
serving either for hearing or smelling, or perhaps for both;
the mouth is very large, and placed under the head, and
armed with four rows of extremely sharp and strong teeth,
flat, and serrated at their edges; the tail is composed of
two fins, one vastly larger than the other; the body is
rounded and very long, and is not covered with scales, but
a thick skin; the back is ash-coloured, and the belly white.
Rondelet, de Aquat, p. 549.

It is caught in the Mediterranean, and sometimes in dif-
ferent parts of the ocean. Some authors have called it
zydai, and others libella; which last answers to the English
name of the balance-fish.

SHARK, Pickled. See Acanthias and Squalus.

SHARK, Long-tailed. See Sea-Fox and Squalus
Pulcher.

SHARK, Spotted, Squalus Canicula of Linneus. See
Squalus Catus.

SHARK, Ottfer spotted, called the morgan, or rough
bound-fish, Squalus Canicula of Linneus. See Squalus
Catus.

SHARK, Smooth, Squalus Mysto!us of Linneus. See
Squalus Mysto!us.

SHARK, called the tope, Squalus Galeus of Linneus. See
Squalus Galeus.

SHARK, called the angel or monk-fish, Squalus Squatina of
Linneus. See Squalus Squatina.

SHARK River, in Geography, a river of New Jersey,
which runs into the Atlantic, N. lat. 40° 10'. W. long.
74° 4'.

SHARKIND, a town of Sweden, in East Gothland;
9 miles S.S.W. of Nordkioping.

SHARKSTOWN, a town of Maryland, on the island
of Kent; 28 miles S.E. of Baltimore.

SHARM el Kemn, or Sharm el Kaman, a port on the
Red Sea, on the coasts of Egypt. N. lat. 24° 44'.

SHARMA, a town of Arabia, in the province of Hadra-
mant; 30 miles E.N.E. of Sahar.

SHARMAGOL, a town of Persia, in the province of
Chorofan; 12 miles S. of Nefa.

SHARMAK, a sea-port of Africa, on the Gold Coast;
13 miles W. of Commedo.

SHARMALIK, a town of African Turkey, in the
province of Diarbekir; 15 miles S.W. of Ourfa.

SHAROKIE. See Schon.

SHARON, a town of the province of Maine; 40 miles
N. of Portland.—Alfo, a town of Connecticut; 12 miles
N.W. of Litchfield.—Alfo, a post-town of the state
of New York; 25 miles W. of Albany.—Alfo, a township
of Massachusetts; 10 miles S.W. of Bolton.—Alfo, a
township of Vermont, on White river; 6 miles N.W.
of Norwich.

SHARP, Abraham, in Biography, an eminent mathel-
matician, mechanist, and altronomer, was descended from a
family of Little Horton, near Bradford, in Yorkshire,
where he was born about 1651. After he had received
a good education, he was put apprentice at Mancheller, but
being steadily attached to mathematical pursuits, he quitted
buffines and removed to Liverpool. Here he applied with
great diligence to his favourite study, and to procure a sub-
ficiency he opened a school, where he taught written and the
elements of arithmetic. He next went to London, with the view
of associating with Mr. Flamhead, by whole inter-
tell he obtained a profitable employment in the deck-yard
at Chatham, where he remained till he was invited to become
the affiant of Flamhead at the Royal Observatorv at Green-
wich. In this situation he continued to make observations,
and had a large share in forming a catalogue of 3200 fixed
stars, with their longitudes and magnitudes; their right af-
cension and polar distance, and the variations of the fame,
while they change their longitude by one degree. In this
employment he injured his health, and was obliged to retire to
to his native air, at Horton, where he fitted up an observatory of his own, having constructed a very curious machine for turning all kinds of work in wood and brass. He constructed most of the tools used by joiners, clock-makers, opticians, and mathematical instrument-makers. He manufactured entirely his own telescopes and other astronomical instruments.

He next materially assisted Mr. Flamstead in calculating most of the tables in the second volume of his "Historia Celestis," and made curious drawings of the constellation, which were sent to Amsterdam to be engraved, and though executed by a masterly hand, the originals were lost, having been carried to and from England under difficulties of a beauty and accuracy. In 1670 Mr. Flamstead completed his mural arc at Greenwich, in which he had been greatly assisted by his friend Mr. Sharp, who had been some time in the observatory as his amanuensis. Mr. Smeaton, in a paper published in the Philosophical Transactions for the year 1741, speaking of this mural arc, says, it may be considered as the first good instrument of the kind, and that Mr. Sharp was the first person who cut accurate and delicate divisions upon astronomical instruments.

In 1717, Mr. Sharp published a work entitled "Geometry Improved," in which he engraved the figures as well as composed the work. This treatise contains: 1. A large and accurate table of segments of circles, with the method of its construction, and various uses in the solution of difficult problems. 2. A concise treatise of polyedra, or solid bodies of many hales, both the regular and irregular ones, to which are added twelve new ones, with various methods of forming them, and their exact dimensions in words or species, and also in numbers. In the year 1699 he undertook, for his own private amusement, the quadrature of the circle, deduced from two different series, by which the truth of it was demonstrated to 72 places of figures. Mr. Sharp maintained an epistolary correspondence with the most eminent mathematicians and astronomers of the day; among these were the illustrious Newton, Dr. Halley, and Dr. Wallis. It appears from a great variety of letters which remained after his death, written to him by these celebrated men, that he spared neither pains nor time to promote the interests of real science. Being duly reckoned one of the ablest calculators of his time, his assistance was required by, and freely given to Flamstead, Sir John Moore, Dr. Halley, and others, in all difficult calculations. When he quitted Mr. Flamstead, he retired to Little Horton, in Yorkshire, where he spent the remainder of his days, and where he died in July 1742, in the 41st year of his age. He was of very retired habits, and admitted few visitors, excepting two gentlemen, at Bradford, one a mathematician and the other an ingenious apothecary. Many of his singularities are recorded in the General Biography, and also in Hutton's Mathematical Dictionary, to which the reader is referred.

Sharp, John, archbishop of York, a celebrated divine of the church of England, was the son of a respectable tradesman at Bradford, in Yorkshire, where he was born in 1644. He was admitted of Christ's college, Cambridge, in 1660, and in 1667 he commenced master of arts, and was ordained. He was now appointed private tutor to the four sons of Sir Heneage Finch, a station which he occupied about five years, when he obtained, through his patron's recommendation, the archdeaconry of Berkshire. When Sir Heneage was raised to the poll of keeper of the great seal, he manifested such confidence in the fidelity and judgment of his friend, as to commit to him the nomination of the characters of applicants for church livings in the gift of the crown. A sermon which he preached in 1674, reflecting upon those who defected from the church, gave rise to a controversy, in which Dr. Swell, Baxter, and others engaged. In 1677 he was instituted to the rectory of St. Gore's, Chelmsford, in which parish he resided ten years. Among his pupils was Richard Baxter, who, though he was himself a preacher on Sunday evenings, was a constant bearer of the lecture in the mornings; and those two excellent men, notwithstanding their different points of doctrine, lived together upon the most friendly terms. In 1679 Mr. Sharp succeeded D.D., and in 1681 he was promoted to the deanship of Norwich. On the death of Charles II., to whom he had been a chaplain, he drew up the addenda of the second part of London to its successor, to whom he was also commonly chaplain. After this he preached against papism, and thus exciting the royal displeasure, he was obliged to quit the metropolis, and reside altogether at his deanship. He employed himself in forming a cabinet of coins, chiefly British, Saxons, and English. Being wearied with his exclusion from his function in London, he presented a very humble petition to the king, in consequence of which, he was allowed to return to his duty in the metropolis, and he was extremely careful never after to give offence, as he had done before. After the abdication of the monarch, Dr. Sharp visited the adherents to William, by some offensive passages in a prayer and sermon, which he delivered before the house of commons, who at first refused him their accustomed thanks, which, however, were voted afterwards. In 1689, Dr. Sharp was appointed the facultor to Dr. Tillotson in the deanery of Canterbury, and he was nominated one of the commissioners for revising the liturgy. At this period several bishops had been deprived of their fees for refusing to take the oaths to William and Mary, and Dr. Sharp might have succeeded to almost any of them, but he refused, not through any scruple of conscience, but on account of his friendship for the persons deprived. When, however, the archbishopric of York became vacant in a different way, he readily accepted the high office, and he was consecrated in July 1691. He filled this exalted station in a manner, which has cau ed him to be represented as a model of prelatical virtues, and which procured him general respect and esteem. He died at Bath in 1714, in the 69th year of his age. His only writings were sermons, of which were published two volumes, consisting of such occasional discourses as he had printed during his life-time, and five others, that were selected after his decease. He was reckoned an excellent preacher, and his style and doctrine are said to be equally of the standard purity. Biogr. Brit.

Sharp, Thomas, younger son of the preceding, was born in Yorkshire, and admitted of Trinity college, Cambridge, about 1703, when he was of the age of 15. He obtained a fellowship in 1729, and took his doctor's degree the same year. Archbishop Dawes appointed him his chaplain, and in 1720 he was collated to the rectory of Rotherby, in Northumberland. He was afterwards preferred to a prebend in Durham cathedral, and also to the archdeaconry of Northumberland. He died in 1758. Dr. Sharp wrote two dissertations concerning the etymology of the Hebrew words Elohim and Berith—"Discourses on the Antiquity of the Hebrew Tongue and Character." He left a son, Granville, to whose fine character as a genuine English patriot, we shall endeavour to do justice in the next article.

Sharp, Granville, son of the preceding, a most distinguished philanthropist and friend to the liberties of mankind, was born in the year 1734. He was educated for 3 E 7 the
the bar, but did not practice at it. When he quitted the legal profession, he obtained a place in the ordnance office, which he resigned at the commencement of the American war; the principles of which were abhorrent from his mind. He now took chambers in the Temple, and devoted himself to a life of idly; at the same time, laying himself out for public utility. He first became known to the public in the case of a poor and friendless Negro, of the name of Somerset. This person had been brought from the West Indies to England by a master, whose name we should gladly hand down to the execution of public utility, if it were in our power; and falling into bad health, was abandoned by him as a useless article of property, and turned into the streets, without a shilling to his name. To this day, he is the only one of these unhappy objects of charity. In this destitute state, almost, it is said, on the point of expiring on the pavement of one of the public streets of London, Mr. Sharp chanced to see him. He instantly had him removed to St. Bartholomew's hospital, attended personally to his wants, and in a short time had the happiness to see him restored to health. Mr. Sharp now clothed him, and procured him comfortable employment in the service of a lady. Two years had elapsed, and the circumstance almost, and the name of the poor Negro, had escaped the memory of his benefactor, when Mr. Sharp received a letter from a person, signing himself Somerset, confined in the Poultry Compter, stating no cause for his commitment, but intreating his interference to save him from a greater calamity even than the death from which he had before rescued him. Mr. Sharp instantly went to the prison, and found the Negro, who in fickness and misery had been deserted by his master, sent to prison as a runaway slave. The efficient patriot went immediately to the lord mayor, William Nash, Esq., who caused the parties to be brought to trial, to grant a meritorious fugitive, by an upright magistrate declare that the master had no property in the person of the Negro, in this country, and gave the Negro his liberty. The matter instantly collared him, in the presence of Mr. Sharp and the lord mayor, and infilled on his right to keep him as his property. Mr. Sharp now claimed the protection of the English law, caused the matter to be taken into custody, and exhibited articles of peace against him for an assault and battery. After various legal proceedings, supported by him with most undaunted spirit, the twelve judges unanimously concurred in an opinion that the matter had acted criminally. Thus did Mr. Sharp emancipate for ever the race of blacks from a state of slavery, while on British ground, and in fact banished slavery from Great Britain. Such an incident could not fail deeply to impress a benevolent mind; and slavery, in every shape and country, became the object of his unceasing hostility.

In 1769 he published a work, entitled "A Representation of the Injustice and dangerous Tendency of tolerating Slavery, or of admitting the claim of private Property in the Persons of Men in England." Having succeeded in the case of an individual Negro, he interested himself in the condition of the many others, who were seen wandering about the streets of London, and at his own expense collected a number of them, whom he sent back to Africa, where they formed a colony on the river Sierra Leone. He performed a still more essential service to humanity, by becoming the instigator of the "Society for the Abolition of the Slave Trade;" which, after contending against a vast mass of opposition, at length gloriously succeeded, as far as this country was concerned in the horrible traffic.

Mr. Granville Sharp is mentioned in connection with this business, in terms of the highest commendation, by Mr. Clark, in his "History of the Abolition of the Slave Trade." (See vol. i. p. 63—70.) The following short account of him is extracted from the Edinburgh Review, vol. xii.

"We think it a duty to mention the name of Mr. Granville Sharp. Regardles of the dangers to which he exposed himself, both in his person and his fortune, Mr. Sharp stood forward in every cause as the courageous friend of the poor Africans in England, in direct opposition to an opinion of York and Talbot, the attorney and solicitor-general for the time being. This opinion had been acted upon; and so high was its authority, that, after it had been made public, it was held as the settled law of the land, that a slave, neither by baptism, or arrival in Great Britain or Ireland, nor by reason of being born in the British or British Possessions, became free by being brought back to the plantations. Discouraged by judge Blackstone, and several other eminent lawyers, Mr. Sharp devoted three years of his life to the English law, that he might render himself the more effectual advocate of these friendless strangers. In his work, entitled "A Representation of the Injustice and dangerous Tendency of tolerating Slavery in England," published in the year 1769, and afterwards in his learned and laborious "Inquiry into the Principles of Villenages," he refuted the opinion of York and Talbot by unanswerable arguments, and neutralized their authority by the counter opinion of the great lord chief justice Holt, who many years before had decided, that as force could be used against no man in England without legal process, every slave coming into England became free, inasmuch as the laws of England recognized the distinction between person and property as perpetual and sacred. Finally, in the great case of Somerset, which was argued at three different fittings, in January, in February, and in May, of the year 1772, (the opinion of the judges having been taken up on the pleadings,) it was at last, after the time, and declared to be the law of the land, that as soon as ever any slave set his foot upon English territory, he became free. Among the heroes and fages of British story, we can think of few whom we should feel a greater glow of honest pride in claiming as an ancestor, than the man to whom we owe our power of repeating with truth,

"Slaves cannot breathe in England; if their lungs Receive our air, that moment they are free; They touch our country, and their shackles fall."

Similar principles led Mr. Sharp to use his endeavours to restrain the arbitrary practice of marine imprisonment; and a citizen of London having been carried off by a press-warrant, Mr. Sharp obtained a habeas corpus from the court of king's bench, to bring him back from a vestil at the Nore; and by his arguments obliged the court to liberate him. In his political principles he was always the ardent and zealous friend to liberty, and he neglected no opportunity to defend its principles, and assert the rights of the people. He was the warm advocate of "parliamentary reform," and published, in 1778, the second edition of an excellent little work, full of constitutional knowledge and sound reasoning, entitled "A Declaration of the People's natural Right to a Share in the Legislature, which is the fundamental Principle of the British Constitution of State." He was, in 1794, as zealously attached to the cause as he had been twenty years before; though, perhaps, he did not feel himself sufficiently active to engage in it as a partisan, when it was a subject of obloquy. He was not, however, an unconcerned spectator of the dreadful tyranny, which, but for the intervention of an honest English jury, would have overwhelmed the land. He went, to one of the persons at that time confined in the Tower of London, a copy of the work.
work referred to, with assurances of a readiness to do any thing in his power to stem the torrent leting in against the Liberties of the country.

Mr. Sharp's plan of reform recommended to the public, was founded on the earliest principles and practices of the British constitution. He proposed to reform the ancient libels, bannings, bounds, &c.; and the whole body of the people were to form a national militia, each thousand to constitute a regiment, the alderman or magistrare to be the colonel; and each hundred to constitute a company, the contable of each for the time being to be their captain. So many of the thousands to be summoned once in every year, by their magistrates, as would have a right to vote in their respective hundreds, before the contable, in the choice of their part of the representative legislature. Mr. Sharp has shown that the division of this kingdom into counties and hundreds was instituted by the immortal Alfred; that such a division is consistent with the most perfect state of liberty that man is capable of enjoying, and yet fully competent to answer all the purposes of mutual defence, to secure the due execution of the laws, and maintain public peace.

Mr. Sharp was educated in the principles of the established church, and through life fostered a warm attachment to them. He always, even at the close of life, had a thorough dread of Popery, but was candid and liberal to Protestant dissenters of all parties. His zeal for the established religion of the country led him to recommend an episcopal church in America; and he introduced the first hitherto from that country to the archbishop of Canterbury for consecration.

Mr. Sharp died in July 1713, and like Cato, though advanced to the age of 79, he purfied his studies with all the ardour of youth. He was an able linguist, deeply read in theology, and was well acquainted with the scriptures in the original tongues. He was pious and devout, without gloom, strictly moral and temperate, a great lover of music, and cheerful in conversation. His services to humanity were very distinguished, and few persons in private life have deserved a higher or more honourable commemoration.

As a writer, his pieces are very numerous. From these we learn that he was a believer in the doctrines as set forth in the articles of the church, as that of original sin, the existence and operations of the devil on the human mind, and of the Athenian mystery of the Trinity. He also, from studying the book of Revelation, fully expected the commencement of the Millennium, or personal reign of Christ on earth, in the spring of 1811; but he lived long enough to see his error. He possessed a very extensive library, in which the theologian, lawyer, classical scholar, politician, antiquary, and orientalist, might find almost every thing of which they could flound in need; and his collection of books was esteemed the best in the kingdom.

The principal works of Mr. Sharp, besides those already mentioned, are "Remarks on several very important Propositions," "Remarks on the Uses of the Deutero-Canonical Article in the Greek of the New Testament, containing many new Proofs of the Divinity of Christ," &c. This occasioned "Six Letters" to be addressed to him, in vindication of his theory; and also "Six more Letters," &c., by Gregory Blunt, esq., which is a work of great talent, profound learning, and masterly wit. It has long since been out of print, and the author is probably known only to two or three persons; the designation Blunt being assumed to conceal the real name. Mr. Sharp's last work was entitled "Remarks on the 68th Psalm, addressed to the Confederation of the House of Israel." Monthly Mag. Gent-
To which is prefixed a biographical preface, from which the foregoing facts have been extracted.

SHARPING CORN, a customary present of corn, which, at every Christmas, the farmers in some parts of England make to their smith, for sharpening their ploughing-harrow-tines, &c.

SHARPING, in Ichthyology, the English name of the gaiterofetus. See Stickle-Back.

SHARPSBURG, in Geography, a town of America, in Maryland; 69 miles N.W. of Baltimore.

SHARUM, a town of Arabia, in Hadramaut; 15 miles S.W. of Kefchim.

SHARUT, Shahrat, or Sharoot, a small town of Persia, in Atarabad, called also Biitan, is surrounded in some parts with a flight earthen wall. The houses, from a want of wood, are built of unburnt bricks, and covered with a flat arch of the same materials. In its vicinity are seen many people, whose noses, fingers, and toes have been destroyed by the frost, which is laid to be severer at this place than in any part of Persia. This town, with its dependencies, yields a revenue of 1599 tomans. The position of the town is determined by two routes, one from Tehran and the other from Tarabih.

SHASAD, or Shazadrany, a town of Hindooftan, in the circuit of Sumbul; 16 miles S. of Sumbul.

SHASAVA, a town of Hindooftan; 15 miles S. of Agra.

SHASH, or Takshund.

SHASHTI, in Mythology, a name of the Hindoo goddefs Parwati; which see.

SHASK, in Geography, a town of Hindooftan, in Baglan; 15 miles S. of Bahbelgong.

SHASSAIR, a town of Africa, in Biledulgerid; 7 miles N. of Fighig.

SHASTAH, Shaster, or Sastra, which latter is said to be the correct spelling and pronunciation, the name of a Sacred book, in high estimation among the idolaters of Hindooftan, containing all the dogmas of the religion of the Bramins, and all the ceremonies of their worship, and serving as a commentary on the Vedam.

The word is derived from a root signifying to ordain, and means generally an ordinance, and particularly a sacred ordinance delivered by inspiration: properly, therefore, the word is applicable chiefly to sacred literature.

The term Shaster denotes fience or fystem; and is applied to other works of astronomy and philosophy, which have no relation to the religion of the Indians. None but the Bramins and rajas of India are allowed to read the Vedam; the priests of the Brahmans, called fusterers, may read the Shaster; and the people, in general, are allowed to read only the Parar or Poursan, which is a commentary on the Shaster.

The Shaster is divided into three parts; the first containing the moral law of the Indians; the second, the rites and ceremonies of their religion; and the third, the distribution of the people into tribes and classes, with the duties pertaining to each class.

The principal precepts of morality contained in the first part of the Shaster, are the following: that no animal be killed, because the Indians attribute souls to brute animals as well as to mankind; that they neither hear nor speak evil, nor drink wine, nor eat flesh; nor touch any thing that is unclean; that they observe the feasts, prayers, and washings, which their law prescribes; that they tell no lies, nor are guilty of deceit in trade; that they neither oppress nor offer violence to one another; that they celebrate the solemn feasts and feasts, and appropriate certain hours of ordinary sleep to cultivate a disposition for prayer; and that they do not steal, or defraud one another.

The ceremonies contained in the second part of the Shaster, are such as these: that they wash often in the rivers, hereby obtaining the pardon of their sins; that they mark their forehead with red, in token of their relation to the Deity; that they present offerings and prayers under certain trees, set apart for this purpose; that they pray in the temple, make oblations to their pagodas, or idols, sing hymns, and make processions; &c. that they perform pilgrimages to dilated rivers, and especially to the Ganges, there to wash themselves, and make offerings; that they make vows to particular saints, according to their respective departments; that they render homage to the Deity, at the first flight of the sun; that they pay their respect to the sun and moon, which are the two eyes of the Deity; and that they treat with particular veneration, those animals that are deemed more pure than others, as the cow, buffalo, &c. because the souls of men have transmigrated into these animals.

The third part of the Shaster records the distribution of the people into four classes; the first being that of the Bramins, or priests, appointed to instruct the people: the second, of the Malabar and feris, or nobles, which are the magistrates; the third, that of the Shuddars, or Gents; and the fourth, that of the mechanics. Each person is required to remain in the class in which he was born, and to pursue the occupation assigned to him by the Shaster. According to the Bramins, the Shaster was imparted by God himself to Brahma, and by him to the Bramins, who communicated the contents of it to the people.

Modern writers have given us very different accounts of the antiquity and importance of the Shaster. Mr. Holwell, who had made a considerable progress in the translation of this book, apprehends, that the mythology, as well as the cosmogony of the Egyptians, Greeks, and Romans, were borrowed from the doctrines of the Bramins contained in it, even to the copying of their exteriors of worship, and the distribution of their idols, though grossly mutilated and adulterated. With respect to the Vedam and Shaster, or scriptures of the Gentoo, this writer informs us that Vedam, in the Malabar language, signifies the name as Shaster in the Shaster; and that the first book is followed by the Gentoo, that of the Malabar, and the Malabar contains the island of Ceylon. The Shaster is followed by the Gentoo, that of the provinces of Bengal, and by all the Gentoo of the rest of India, commonly called India Proper, along the course of the rivers Ganges and Jumna to the Indus. Both these books, he says, contain the institutes of their respective religion and worship, as well as the history of their ancient rajahs and princes; often couched under allegory and fable: their antiquity is contended for by the partisans of each; but he thinks, that the similitude of their names, idols, and great part of their worship, leaves little room to doubt, nay, plainly evinces, that both those scriptures were originally one. He adds, if we compare the great purity and chaste manners of the Shafan, with the great aburities and impurities of the Vedam, we need not hesitate to pronounce the latter a corruption of the former.

With regard to the high original of these scriptures, the account of the Bramins is chiefly as follows. Brahma, q. d. Mighty Spirit, about four thousand eight hundred and sixty fix years ago, assumed the form of man, and the government of Hindooftan. He translated the divine law (designed for the reformation of mankind, who had offended in a pro-exilent state,
SHASTAH.

Aest, and who are now in the last scene of probation, to the dignity from which they were degraded,) out of the language of angels into the well-known Sanskrit language, and called his translation the "Charittha Bhaede Shastaho" of Bir- 
num, or the Six Scriptures of the Divine Words of the Mighty Spirit. He appointed the Bramins, deriving their name from him, to preach the word of God; and the doctrines of the 
Shastah were accordingly preached in their original purity a thousand years. About this time there was published a 
paraphrase on the Charittha Bhaede and the Vedams, which, according to the Gentoo account, is three thousand three hundred and sixty-six years ago, their polytheism commenced; and the principles of 
religion became obscure, and their ceremonies to numerous, that every head of a family was obliged to keep a Bramm, 
as a guide both in faith and practice. Mr. Holwell is of opinion, that the Charittha Bhaede, or original scriptures, are 
not copied from any other system of theology, promulgated to, or obtruded upon mankind. The Gentoo do not at 
tribute them to Zoroaster; and Mr. Holwell supposes, that 
both Zoroaster and Pythagoras visited Hindoo land, not to 
instruct, but to be instructed.

From the account of Mr. Dow we learn, that the books which contain the religion and philosophy of the Hindoos, 
are distinguished by the name of Bedas; that they are four 
in number, and, like the sacred writings of other nations, 
failed to be penned by the divinity. Bedas, he says, in the 
Sanskrit language, literally signifies science; and these books 
treat not only of religion and moral duties, but of every branch of philosophic knowledge. The Bramins maintain, 
that the Bedas are the divine laws, which Brahmas, at the 
creation of the world, delivered for the instruction of man-
kind; but they affirm, that their meaning was perverted in the first age by the ignorance and wickedness of some princes, 
whom they represented as evil spirits, who then haunted the 
earth. The first credible account we have of the Bedas is, that about the commencement of the callug, of which era the 
year 1768 was the 4586th year, they were written, or rather 
collected, by a great philosopher, and reputed prophet, called 
Beafs Muni, or Beafs the Inspired.

The Hindoos, says Mr. Dow, are divided into two great 
religious sects; the followers of the doctrine of Bedans, 
which is the original Shalffer, or commentary upon the 
Bedas; and those who adhere to the principles of the Ne-
adiran. The original Shalffer is called Bedang, and is a 
commentary upon the Bedas. This, he says, is erroneously 
called, in Europe, the Vedam. It is ascribed to Beafs Muni, 
and said to have been revised some years after by one 
Serrender Swami, since which it has been reckoned sacred, 
and not subject to any further alterations. Almost all the 
Hindoos of the Deccan, and those of the Malabar and Coro-
mandel coasts, are of this sect. The followers of the Bedang 
Shalffer do not allow that any physical evil exists; they 
maintain that God created all things perfectly good, but 
that man, being a free agent, may be guilty of moral evil, 
which may be injurious to himself, but can be of no deter-
mint to the general system of nature. God, they say, being 
perfectly benevolent, never punished the wicked otherwise 
than by the pain and affliction which are the natural con-
sequences of evil actions; and, therefore, it is either a 
condemnation of our evil.

The Vedanit Shalffer is said to have been written by a 
philosopher called Gyntari, near four thousand years ago. 
The Bramins, from Mr. Dow's account of their sacred 
books, appear to believe more in the unity, eternity, 
immortality, and omnipotency of God; and the polytheism, 
of which they have been accused, is no more than a sym-
bolical worship of the divine attributes, which they divide 
into three classes. Under the name of Brahmas, they worship 
the wisdom and creative power of God; under the appella-
tion of Bulhens, his providential and preserving character; 
and under that of Shibah, that attribute which tends to 
destroy.

According to M. de Sainte-Croix, the Shalffer, however 
entailed in Europe with respect to its antiquity, is posterior 
the Vedam, being no more than the explication of the 
Hollowell's Interesting Historical Events, &c. 8vo. Dow's 
History of Hindoo land, 4to. 1768. L'Entour Vedam, &c. 
by M. de Sainte-Croix, 12mo. Paris, 1779. See Gentoo, 
Shanshit, and Vedan.

Six Safiras are commonly described as of superior fantic 
y, and are called the proper Safiras: in these are com-
prired the four Vedas, the eighteen Puranas, commentaries 
on the Vedas, called Upaveda, and others. (See Veda, and 
Purana.) The Sudra, or lowest of the four classes of 
Hindoos, are not permitted to study these six Safiras, as 
being too holy for such profane contemplation. (See 
Sudra.) As noticed under the article Ramavarna, that 
book is reckoned too sublime for the perusal of a inferior 
class. The Sudras may bear it read. An ample field, how-
ever, remains for them in the study of profane literature, 
comprised in a multitude of popular books, which correspond 
with the several Safiras, and abound with beauties of every 
kind. All the tracts on medicine must indeed be studied by 
the Vaidyas, or those who are born physicians; and this 
profession is confined chiefly to the Sudras. The Vaidyas 
are said to have often more learning than many Bramins, with 
far less pride than any. They are usually poets, grammarians, rhetoricians, &c. and may be esteemed in general 
among the most amiable and virtuous of the Hindoos. See 
Vaidya.

The word Safira, however, applied more extensively than 
the above account may seem to imply. For instance, a col-
lection of tracts on arts and manufactures, is called Sipl 
Safira. The name of Niti Safira is given to a system of 
ethics. The Derrama Safira is indeed one of the six superior, 
and gives an explanation of the principles of the six 
philosophical schools; a brief notice of which is given under 
the article Philosophy of the Hindoos. An analysis of this 
work would shew that many of its theories are either 
selves of similar doctrines propounded in later times in 
Greece, or borrowed from the same source with them. Other 
collections of tracts, and some separate works, bear also 
the denomination of Safira; and it is sometimes rather vaguely 
alled. A Brahman deeply versed in sacred literature has 
the honourable title of Safira added to his name; equivalent 
to our clerics. Sometimes he is distinguished by it alone, 
and called the Safira. There is also the Dharma Safira, a 
body of ethics and ritual observances; the Agama Safira, 
or occult ordinances. This latter has been fulfilled to 
have some reference to the Ogham of the west. See Oghiam, 
and O.'
SHA

Sañtri, which was omitted in its proper place, is a name for the Hindoo deity Buddha, or Bodd. The name signifies wisdom, or a wise man; and is still applied to, or assumed by, individuals, especially Bramins, who are supposed to have acquired an extraordinary degree of learning or wisdom. As all profitable wisdom is presumed to be comprised in the Sañtri, or sacred books, the title of Sañtri is thence derived. It is sometimes appended similarly to the scholar's name; and he is at others called the Sañtri, or Sañtri fahib,—Mr. Sañtri.

SHASUMAN, in Geography, a town of Peru, in the province of Mazzanderan; 30 miles E. of Eterabad.

SHAT-EL-AMAAR, a name given by the Arabs to the Tigris.

SHAT-EL-DEAAL, a river which runs from the north, and enters the Tigris near Bagdad.

SHAT-EL-DEGELA, a river or canal, so called by the Arabs, which communicates with another named Shat-El-Hie, which is a branch of the Tigris.

SHAT-EL-FRAATE, a name given by the Arabs to the Euphrates.

SHAT-TI-KATU, in Mythology, one of the names of the Hindoo Indra, regent of the firmament. It means the hundred facrices; that is, to whom a hundred facrices are offered; or rather, perhaps, he who has offered them. Indra, it is fabled, obtained his present dignity by the great facrice of a hundred horses. An offering of a horse is called Afwamedha, and is attended with infinite trouble and expense, as laid down in the Hindoo rituals.

See Indra, Naramedha, and Rihema.

SHATNUF, in Geography, a town of Egypt, on the right bank of the Nile; 9 miles N. of Cairo.

SHATOOR, a town of Hindoostan, in Madura; 30 miles N.N.W. of Coilpetta.

SHATORE, a town of Hindoostan, in Madura; 12 miles N.E. of Coilpetta.

SHAL-UL-ARAB, one of the noblest rivers in the East, formed by the combined streams of the Euphrates and Tigris. The union of these streams takes place near Korna, or Corny, which is one of the three Apameas, built by Seleucus in honour of his first wife, Apama. On the western bank of this river, and 70 miles from its mouth, in N. lat. 31° 30', is situated the city of Bushora or Bafra; and the river is navigable as far as the city for ships of 500 tons burthen. The city is sometimes so completely deluged by the river, that it appears like an island in the middle of a lake. The combined stream of the Shat-ul-Arab has generally been thought to enter the Persian gulf by a variety of mouths; but the fact is, that this noble river has, at this time, only one mouth, and probably never had any other. The inland, or delta, between the Shat-ul-Arab and the Eamilthera (the ancient Medena) was formerly included in the pachicel of Bagdad, but having been conquered by Sulek Soliman from the Turks, has remained in the possession of his successors. This is a low and fertile tract; the northern parts of which, towards the Hafir, are intersected by a number of canals, and are in a tolerable state of cultivation. Extensive ruins are visible in many places, and the borders of the Shat-ul-Arab, as far down as Chubda, are covered with date-trees. The river "Shat-el-Ajew," signifying in Arabic a river of Persia, discharges itself on the Persian side into the Shat-ul-Arab, near Margill.

SHATZAM, a town of Turkestan, in the province of Mokran; 210 miles S.E. of Arakhage.

SHAVAKAT, a town of Turkestan, on the Sirr; 20 miles S. of Tashkund.

SHUABACO, a town of Egypt, on the left bank of the Nile; 16 miles S. of Cairo.

SHAVE CRASS, in Botany. See Equefmet.

SHAVING-IRONS, among Gardener's tools to keep a garden free from weeds, otherwise called edge-ing-irons.

SHAVINGS, Horn, in Agriculture. See Manure.

SHAW, or Shalw, an article of female draps, much prized in the Eail, and now well known in England. As the shals all come from Cashmere, or Cachemir, it was generally concluded, that the materials from which they were fabricated was of the growth of that country. It was said to be the hair of a particular goat, and the fine under hair from a camel's beard; but we now certainly know that it is the produce of a 'Hilbet sheep. Bernier relates, that in his time, shals made for the great omrahs of the Thibetan wool, coat a hundred and fifty rupees; whereas those made of the wool of the country never coat more than fifty. For an account of their manufacture and value, see Cashmere.

SHAVOYA, or Shavoia, in Geography, a province of the empire of Morocco, situated to the S. of the kingdom of Fez, and W. of Touda; inhabited by mountaineers addicted to robbery and violence. Towards the latter end of the last century refusing to pay tribute to the emperor, Mulay Ishmael, he marched an army, which, surrounding its strong holds on the mountains, compelled them to flight, leaving their wives and children, who were put to the sword, and the plunder distributive among the soldiers.

SHAUR, a small island in the Red sea. N. lat. 27° 20'. E. long. 34° 58'.

SHAUS. See Chaus.

SHAVUNGUNK, a mountain of New York; 20 miles S. of Kingston.

SHAW, Thomas, in Geography, was born at Kendal in...
SHAW.

SHAW, Peter, a physician, and contemporary of the former, was the author of several works, which enjoyed a considerable reputation in their day. His first publication was entitled "New Practice of Physic," in two volumes, and first printed in 1726; it contained a brief description of diseases and the methods of treating them. His next work was an "Enquiry into the Virtues of Scarborough Spaw Waters," which he visited during the season; it was printed in 1734. In the same year he published also "Chymical Lectures publicly read in London 1731, 1732, and Scarborough 1733." This was deemed a scientific and valuable work, and was translated into French. He published some minor works, "A Portable Laboratory of 1731," "On Scurvy" 1736; "Ellays in Artificial Philosophy," 1738; "On the Juice of the Grape," 1739; and he edited the "Difpensatory of the College of Physicians of Edinburgh," in 1737. See Eloy Déf. Hist. de la Méd.; and the works mentioned.

SHAW, George, the younger of two sons of the reverend Timothy Shaw, was born December 16th, 1751, at Newington, in Buckinghamshire, of which place his father was vicar. He shewed, at a very early age, a great inclination to study; and when he was only four years old, instead of following the amusements common to young children, he usually entertained himself with books, or by the side of ditches and rivulets catching insects, and taking them home, and would spend all his leisure time in watching their motions and examining their structure. He was educated entirely by his father, and before he was fourteen years of age, his proficiency was such as allowed him to enter with great advantage upon a course of college studies. In 1765 he was entered at Magdalen-hall, Oxford, where he was no less distinguished by the regularity of his conduct, than by an uncommon diligence in application to his studies. In 1769 he was admitted to the degree of B.A. and in May 1772 to that of M.A. In order that he might assist his father in his clerical duties, he took orders, and was ordained deacon in 1774, at Buckden, by Dr. Green, bishop of Lincoln, and regularly performed the duty at Stoke and Buckland, two chapels, each three miles apart from the mother church. As soon as an opportunity offered, he began to pursue his theological career, which was never quite congenial to his mind, and went to Edinburgh, to qualify himself for the profession of physic. Having attended the lectures of Black, Cullen, and other eminent professors for three years, he returned to Oxford, where he was appointed deputy botanical lecturer. In this office he acquired much celebrity. He had been appointed to his office by Dr. Sibthorp, the botanical professor, who was then upon the eve of setting out upon his travels into Greece. (See Sibthorp.) Upon the death of this gentleman, Dr. Shaw became candidate for the vacant professorship; in which he would unquestionably have been successful, had not an old statute been found, which prohibits a prebend in orders from filling the office. In 1783 he was admitted to the degrees of bachelor and doctor of medicine; it appears that at this time he had removed from Magdalen-hall to Magdalen college. In the same year he removed to London, where he practised as a physician. Shortly after this, several gentlemen, distinguished for their attachment to the study of, and eminent for their acquisitions in natural history, established a society for the advancement of this science, under the denomination of the Linnean Society. Dr. (now Sir James) Smith was elevated to the presidency, and Dr. Shaw was nominated one of the vice-presidents. To the Transactions of this Society Dr. Shaw contributed the following papers. "Description of the Stylephorus Cordatus," which see; "Description of the Cancer Magnificus;" "Remarks on the Scolophendra Elektrica and Scolophendra Subterranica;" "A Note on Mr. Kirby's Description of the new Species of Hymenoptera;" "Account of a minute Insectorum;" "Description of the Species of Mycerix;" "Description of the Minera Basta; and Tubularia Magnifica."

Dr. Shaw at this period delivered a course of lectures at the Leiceter Museum, and never failed, as well before, as after, that rich and magnificent collection was removed from Leicester Fields, to attract very large and frequent audiences. In 1789 Dr. Shaw began to publish "The Naturalist's Miscellany," which came out in monthly numbers, and continued to his decease, when 280 parts had been published, and, according to the biography of the author given in the Gentleman's Magazine, a posthumous number, with an index, was to terminate the work, which is described as a most beautiful and extensive production, comprising, in 1064 plates, figures of the more curious and remarkable productions of the three kingdoms of nature, more particularly of the animal kingdom, with descriptions in Latin and English. In this year Dr. Shaw was elected a fellow of the Royal Society, and in 1790 he projected a work in 4to. entitled "Speculum Linneum; or Linnean Zoology," but it probably did not promise success, as a single number only appeared. In 1791 Dr. Shaw became a candidate for the office of a librarian in the British Museum, and his qualifications, which were of the first order, procured him the appointment of assistant keeper of the natural history. He now quitted the duties of physician, and devoted himself entirely to researches in natural science. Between the years 1792-6, appeared the following work: "Mufes Linneiani explicatio Anglica et Latina, opera et studio Georgii Shaw, M.D. F. R. S. Adduntur figuræ elegantissimi sculpturae et coloris. Impensis Jacobi Parkinfigii." In 1794 Dr. Shaw, in conjunction with Dr. Smith and Mr. Sowerby, engaged in a splendid publication, illustrative of the acquirements which had been made in natural science on the shores of New Holland. The animals peculiar to that country were described by Dr. Shaw in a work entitled "The Zoology of New Holland," the figures were delineated by Mr. Sowerby; and the botanical part was written by Dr. Smith, and published under the title of "The Botany of New Holland." Sixty large plates published by Miller, the editor of the Cramer's Dictionary, under the title of "Various Subjects in Natural History, wherein are delineated Birds, Animals, and many curious Plants, being judged defective from want of letter-prefx. Dr. Shaw supplied the deficiency in a work entitled "Cimelia Physicia: Figures of rare and curious Quadrupeds, Birds, &c. together with several most elegant Plants, engraved and coloured from the Subjects themselves: with Descriptions by George Shaw, M.D. F.R.S."

In the year 1800, Dr. Shaw began his great work, entitled "General Zoology, or Natural History, with Plates from the best Authorities, and most select Specimens." This work had proceeded to the eighth volume during the life-time of the author, and a ninth was left ready for the press. In this work he intended to comprise the whole of the history of the animal world. It began with quadrupeds, and had proceeded through fishes, amphibia, insects, and part of the birds. The Linnean arrangement, with occasional variations, has been pursued throughout.

In the years 1800 and 1802, Dr. Shaw delivered a course of zoological lectures, which were published in 1809 in two large volumes 8vo. In the first nine lectures the author has compiled the substance of what he had delivered in the General Zoology, and in the three remaining lectures is a sketch
a sketch of what, had his life been spared, he intended to accomplish in completing the General Zoology. In 1809, upon the death of Dr. Gray, keeper of Natural History in the British Museum, Dr. Shaw was promoted to that office. An abridgment of the Transactions of the Royal Society was begun in 1809, of which the department of natural history fell to the lot of Dr. Shaw. It is said he abridged 1500 distinct articles, which he rendered still more interesting than the originals, by the insertion of Linnaean and specific names, and by occasional annotations, and considerable references to subsequent authors of most celebrity, who had treated on these subjects. This was the last work in which he engaged. His time was wholly occupied upon the "Naturalist's Miscellany" and the "General Zoology," when death terminated his active and very useful life on the 22d of July, 1813, in the 62d year of his age. His illness was but of a few days' continuance: his fevers and his recollection only forsook him with his breath. He died, as he had lived, with philosophic composure and serenity of mind, which neither the acute pain which he endured, nor the awful change which he was well aware he was about to experience, could in any degree disturb.

"As few men have left behind them a character more estimable, his name will be transmitted to posterity among those who give utile to their age and country, who do honour to human nature by their virtues, and who contribute to the advancement of science, and the interests of literature, by their superior talents. Endowed by nature with considerable intellectual parts, and thence improved by affiduous cultivation, he acquired a vast stock of general knowledge. His extensive information was trenched up without confusion, applied in his works with discernment, and communicated to every enquirer with cheerfulness and freedom." Gentleman's Magazine, 1813, p. 290.

Shaw, Stebbing, a divine and antiquary, was born at Stowe, in Staffordshire, in 1762, and educated first at Repton school, and afterwards at Queen's college, Cambridge, where he took his degrees and obtained a fellowship. In 1787 he made a tour in the Highlands of Scotland, of which he published an account without his name. In the following year he made another tour in the west of England, an account of which he also published. In 1789 he commenced, in conjunction with a friend, a periodical publication, called The Topographer, chiefly containing extracts made from curious books and MSS. in the British Museum. This work was discontinued in about two years. He next undertook the "History of Staffordshire," of which the first vol. in folio, was published in 1798; in 1801 the first part of the second volume was given to the public, and he died in 1803.

Shaw, in our Old Writers, a grove of trees, or a wood. Shaw Fowle, an artificial fowl made for fowlers to shoot at.

Shaw's Island, in Geography, a small island in the North Pacific ocean, at the entrance of Cook's Inlet. N. lat. 56°. E. long. 207° 16'.

Shawabad, a town of Hindoostan, in the circuit of Rantapour; 35 miles S. of Suliopour.

Shawanee, a town of America, in the county of Randolph, and territory of Illinois, containing 830 in. inhabitants.

Shawanese, the denomination of a tribe of Indians who inhabit Lousiana, on the Missilippi and St. Francis. The number of warriors is 300; that of the inhabitants 800; they trade requires 1000 dollars of merchandise; the value of their returns is 3000; their commerce is carried on in their villages or settlements. The Indians of this tribe have four towns on the Tallapookee river. By the treaty of peace, Aug. 3, 1795, the United States agreed to pay this tribe a fund in hand, and 1000 dollars annually for ever in goods. They inhabit on the Scioto river, and a branch of the Muskingum, and have their hunting grounds between Ohio river and lake Erie. They are generally of a small size, rather handline in their features, and a cheerful crafty people. Counselling among the elder, and dancing among the young men and women, take up a great part of their time.

Shawangunk, a post-town in Ulster county, New York; containing 2800 inhabitants; 20 miles from Goshen and 12 from New Paltz.

Shawunge, a town of Hiwiadan, in Oude, on the left bank of Dewah, opposite to Fryzabad.

Shawgur, a town of Hindoostan, in Allahabad; 32 miles N. of Gazypour.

Shawlia, in Betang, received its name in honour of the celebrated oriental traveller, Dr. Thomas Shaw, who has given a catalogue, in alphabetical order, accompanied with rude plates, of the rarer plants, observed by him in Barbary, Egypt, and Arabia. The species amount to 632, and the catalogue is enriched with several synonyms, as well as occasional descriptions and remarks. His dried specimens are preferred at Oxford. The orthography of the name is attended with difficulty to foreigners, our w being as unmanageable to them, as their multiplied consonants are to us. Some of them blunder into Schawzia, Shawnia, or Shavria. Perhaps the latter might be tolerated, were it not for the ludicrous ambiguity of Shawins itself, applied by facetious Oxonians to the above famous traveller and his namesake.—Forth. Gen. t. 18. Prodr. 58. Schreb. Gen. 958. Mart. Mill. Dict. v. 4. Jull. 180. Lamarch Dict. v. 7. 148.—Chis. and order, Syngena Monogamia, Forl. S. Polygama-fregellate, Schreb. Nat. Ord. Compositae bifoliadice, Linn. Corymbylum, Jull.

Gen. Ch. Cal. Perianth imbricated, cylindrical, of five or six oblong scales; the three innermost longest, and nearly equal. Cor. of one petal, funnel-shaped, short; limb in five linear spreading segments. Stam. Filaments, five, capillary; anthers united into a cylindrical tube. Pet. 5. Germs oblong, below the corolla, superior with respect to the calyx; style thread-shaped, longer than the corolla; stigma divided, spreading. Peric. none, except the unchanged pervalv calyx. Seed solitary, oblong. Down capillary, woolly at its base. Recept. naked.

1. S. paniculata. Forth. Prodr. n. 1.—Native of New Zealand. We have seen no specimen of this plant. The younger Linnaeus, in his copy of Forster's book, has made a note of its being referred by Banks and Solander to Salvia, under the name of undulata. Perhaps this is the most natural way of disposing of it, though if the calyx never contains but one floret, and is not in any way aggregate, the genus should stand in Pentandria Monogynia, along with Corymbium, at least according to the strict laws of artificial arrangement; but we should hardly, in either case, recommend such a measure.

Shawle, in Agriculture, a name applied to a shovel used in winnowing corn, in some places.

Shawmungo, in Geography, a town of Bengal; 18 miles W. of Rungpour. N. lat. 25° 27'. E. long. 88° 46'.
of Moulatan; 70 miles N.E. of Moultan. N. lat. 30° 40'. E. long. 72° 58'.

SHAWPOUR, a town of Bengal; 42 miles S.E. of Moolthabad.—Alno, a town of Bengal; 30 miles S. of Calcutta. N. lat. 22° 5'. E. long. 88° 26'.—Alno, a town of Hindooftan, in the ecart of Suryoga; 28 miles N. of Suryoga. N. lat. 23° 35'. E. long. 83° 25'.—Alno, a town of Hindooftan, in Berar; 45 miles N.W. of Maltoo.

SHAW, a town of Syria, in the pachac of Aleppo, situated in a romantic country, where the river Orontes winds majestically through the plain. The town is populous, and has a good caravanserai. Adjacent to it is a good stone bridge of seven arches. These conveniences have been originally provided for the caravan, which rests here in its route from Constantinople to Mecca.

SHAWROWAL, a town of Hindooftan, in the ecart of Chandree; 45 miles W. of Chandree.

SHAWSHEEN, a considerable stream of America, in Massachusetts, which rises in Bedford county, Middlesex, and passing through Billerica, Tewksbury, and Andover, discharges itself into Merrimack river.

SHAYE, a town of Hindooftan, in Guzerat; 33 miles N.E. of Junagar.

SHAYSHAR, a town of Syria, anciently called La-tzife, on the Orontes; 10 miles N. of Hamah.

SHAZADABAD, a town of Hindooftan, in Allahabad, on the right bank of the Ganges; 30 miles N.W. of Allahabad. N. lat. 25° 42'. E. long. 81° 43'.

SHAZADPOUR, a town of Hindooftan, in Bengal; 25 miles S.E. of Nattore. N. lat. 24° 12'. E. long. 89° 43'.

SHEDING, a riding, living, or division, in the Isle of Man; the whole island being divided into fixed foldings, in every one of which is a coroner, or chief constable, appointed by the delivery of a rod at the annual convention.

SHEAF, in Agriculture, a bundle of corn, as bound up in the field. Sheafs are made of very different sizes in different places, but they are bell when not made too large. See HARVEST.

SHEAF-Corn, such grain as is in the state of ear in the straw before being threshed out. It is sometimes employed in this state as fodder for different sorts of live-flock.

SHEAF OF AROSE, a bundle confining of 24 in number. SHEAFGUR, in Geography, town of Hindooftan, in Myfors; 4 miles W.N.W. of Vampanbad.

SHEALINGS, in Rural Economy, the portions of rich grass-land in the more hilly and mountainous parts of the country, which were fixed upon, and taken possession of, by the farming inhabitants at an early period of society, for the purpose of retaining to, and grazing their cattle flock upon, at certain seasons of the year. Some snug well-fertilized spot in such hilly ranges was always fixed on in this intention, which was removed from one to another whenever the cattle had consumed the grasses of it; huts or cobs being provided for the accompanying persons to live in, who had the care of the animals, &c.; a trusty tenant being usually first heaven to secure the spot, and drive away any wandering and trespassing cattle from it. This person was denominated the pounder, perhaps because he was authorized to point or confine troublesome flock, and fix the fine established for the trespassers. In some cases there were more than one such spots, and where they were very rich, as near lakes, brooks, or in valleys, the grass was consumed in common by two or more of them associating together. The shealings were by no means, as some have supposed, depopulated at random, but according to the flock, or as they were pleased. See Sow.

These small-holder farmers lived with great hospitality, and on some oatmeal, and the produce of the dairy, with the same time a contact on their corn for their farms or household purposes. For the sake of performing different parts of work on their farms, the sheaf, weet, &c., was the left to be done by the women.

Though some of these shealings still exist in the same way in the northern parts of S. Iland, they are fast falling into dilute. In the room of such small shealings is placed during the former feaste, the dish of grain are frequently dispensed from the farmer's homestead, and left to shepherds, who live there all the year round, attending their flocks, in a modern kind of substantial maslin work.

In this mode of occupation, the landlord is forced to draw more rent from his glees and mountainous property, and the farmers are at liberty, during the bell feaon of the year, to ply the necessary and variety of labours wanted, for the improvement of their arable grounds, which, to indigenous men, are never at an end.

The shealings feasting was, and is, as far as it yet continues, that of contentment, of festivity, of health, and of joy. The women are employed in spinning wool to clothe their families, and in making butter and cheese for part of their winter provisions. The youth are employed in filling and wrestling, or athletic exercises, which put their swiftness and courage to the test, as a preparation for the more serious conflicts of a field of battle. When the several labours of the day are ended, the whole hamlet retires to rest, and to drown their fatigue in the foundent flumbers, on a bed of health, the mellifluous fragrance of which perfume the whole dwelling. See the Agricultural Report of the County of Inverness.

SHEALY, in Geography, a town of Hindooftan, in the Carnatic; 10 miles S.W. of Tanjore.

SHEAR, in Agriculture, a provincial word, signifying the reaping of grain. It is also applied to sheep, as one-shear or two-shear, which signifies one or two years old.

SHEAR-OFF, in the Sea Language. See SHEERING.

SHEAR-WATER, in Ornithology, the Procellaria puffina of Linnaeus, and called by some winters avis diomedis, is a bird about fifteen inches long, and thirty-one inches broad; the bill is an inch and three quarters broad; the nostril tubular; the head and whole upper side of the body, wings, tail, and thighs, are of a bovity and so the under side, from the chin to tail, and inner coverings of the wings, white; the legs, weak, and compressed sideways, dusky behind, and whitish before.

These birds are found in the Calf of Man, whither they return in February; taking possession of the rabbit-burrows, and then disappearing till April; the young, which are fit to be taken in the beginning of August, are killed in great number, salted, and barrelled; and when boiled, eaten with potatoes. They quit the isle the latter end of August, or beginning of September; and there is reason to imagine, that, like the Cormorant, they are dispersed over the whole Atlantic ocean. In the Orkney isles this species, called the 'lyre,' is much valued for food, and for its feathers. They are taken and salted in August for winter provisions. See Puffin.

SHEARDAY, in Agriculture, provincially the sheep shearing.

SHEARING, a term applied to the cutting of grain, and to a sheep that has been once shorn. See Silep.

SHEARING, Sheep. See SHEEP-SHEARING.

SHEARING, in the Woollen Manufacture. See SHEERING.
SHEARLING, another term commonly applied to a sheep that has been once shorn by sheep-maillers.

SHEARPUR, in Geography, a town of Hindustan, in Bengal, on the Burhampooter; 82 miles W.N.W. of Dacca. N. lat. 24° 53'. E. long. 89° 54'.

SHEET, or Sheets, a name by which some call a young horn.

Sheets, or Sheets, in a Ship. See Sheet.

If the main-fall sheets are haled aft, it is in order to make a ship keep by a wind, but when the fore-sheets are haled aft, it is that the ship may fall off from the wind; and if she will not do it readily, they then hale the fore-fall, by the sheet, flat in, as near the ship's fides as they can; and this they call航运ing the fore-fall. When they say, caje the sheet, they mean veer it, or let it go out gently; but when the word is, let fly the sheet, they mean let it go all at once, and run out as fast as it can; and then the fall will hang loofe, and hold no wind. The feamen fay, when they would have the sheets of the main or fore-fall haled aft, tally the sheets. In a very great gale, or guilt of wind, there is another rope bent to the clues of the main-fall and fore-fall, above the sheet-block, to foccur and cafe the sheet, and this they call a false fheet.

Sheats, in a Ship, also are those planks under water which come along her run, and are closed into the flernpoft: so also that part within board, in the run of the ship, is called the flern-sheets.

Sheat, Falfe, See SHEAT.

Sheat, Overhale the, in Sea Language, a word of command to hale upon the flanding part of the sheet.

Sheat-Anchor, in a Ship. See Anchor.

Sheat of a Plough, in Agriculture, that part of the plough which passes through the beam, and is fattened to the share. It is sometimes called sheath.

And the shear, or as it is sometimes called, the fore-sheat, there being another piece of timber behind it, which is called the hinder-sheat, in other are two inchcs wide, and fattened to the beam by a refch (a piece of iron with two legs), and by a wedge driven by it into the hole of the beam. But in the modern construction of this tool, the sheat is fattened without having recourse to these means. The angle contained betwixt the sheat and the beam of the plough should be about forty-two degrees.

Sheath, in Botany, is synonymous with path, perichelium, and vagina. In the first instance it belongs to the single-leaved covering, burbling longitudinally, which Linneas reckons a kind of calyx, differing from a perianthium in being more or less remote from the flower. Such occurs in Galanthus, Narcifius, Allum, and others of the Hexandrous clas; as also in Arum; and more especially in the natural order of Palme. The perigeeum, see that article, is the fealy sheath, or calyx, of Moflen. Vagina, which will be further explained in its place, is the flheeting part of a leaf.

Sheathing of a Ship, is the caulking that part of her hull which is to be under water with something to keep the worms from eating into her planks.

It is usually done by laying tar and hair, mixed together, all over the old planks, and then nailing on thin new boards. But this hinders a ship's failing; and therefore, of late, some have been sheathed with milled lead, which is much smoother, and consequently better for failing; and also more cheap and durable than the other way. It was first invented by Sir Philip Howard, and major Watfon.

The sheathing with copper is a still later invention, and anwes better than any other.

It is very well worth the trying what the new flone pitch will do in this cafe; if it will defend from the worm, as perhaps it may, a ship might be paid with it cheaper than with the crown pitch; and it will not crack nor fale off, as that will do, but keeps always soft and smooth. It has been found to take in thirteen months, and to remain very black and foft all the time.

Sheave, a cylindrical wheel, made of hard wood or metal, moveable round a pin as its axis in a mortife, as being used to raife or increase the mechanical powers, as a pulley, applayed to remove or lift weighty bodies. Sheaves are either fixed in blocks, to form tackles, or let through the ship's fides, for affifiting to lead the tacks and sheats on board, or in mortifes cut through the masts, yards, caps, &c. to facilitate the working of the rigging, and outer ends of the cat-heads, to form the cat-tackle to raife the anchor to the bow.

Sheaves, in Rural Economy, provisionally the broken parts of the items of flax which come away in dreeling. Also the small bundles of grain in the flraw.

Sheb, in Geography, a town of Nubia, on the borders of Egypt, on the route from Charjie to Cobe; 175 miles N. of Charjie. This place is occasionally infected by a tribe of the wandering Arabs, called Ababds, who come from the neighbourhood of the Nile. Sher is marked by the production of a great quantity of native alnum, as the name imports. The surface, from which the alnum is found, abounds with a reddish flone; and in many places is seen argillaceous earth.

Shebat, in Chronology, the eleventh month of the Jewish eccclifiaical year, anwering to part of our January and February.

Sheoby, or Shelby, as Morfe has it, in Geography, a county of Kentucky, in the United States, containing 14,453 inhabitants, of whom 2900 are flaves.

Shebyville, a town of the forementioned county, containing 424 inhabitants, of whom 218 are flaves; fo that the total in the county and town includes 14,877 inhabitants.

Shebshir, a town of Egypt; 9 miles S. of Amrus.

Shebster, a town of Perfia, in the moft pictureque, and, at the fame time, the moft flourishing division of Azerbijan, which lies along the N. and W. borders of the lake of Urumea, from Tabreez to the confines of Armenia. Shebster is a large and flourishing town.

Shecatica Bay, a bay on the S. coast of Labrador. N. lat. 51° 20'. W. long. 58° 20'.

Shechallin, or Shchallin, a lofty mountain in the parish of Fortingall, diàit of Rannoch, and county of Perth, Scotland, is situated in the immediate vicinity of Loch Rannoch. It rifes in a conical form, and hence derives its name, which signifies the maiden's breast. According to mensuration, its height is 3364 feet above the level of its base, which nearly coincides with that of the ocean. This mountain is rocky and barren; but is particularly remarkable from the circulation of its having been chosen by Dr. Mankelyne, late alroner royal, for ascertaining the power of mountains in attracting the pendulum. Sinclair's Statistical Account of Scotland, vol. ii. 1792. See At traction of Mountains, and Mountains.

Shechinah, in the Jewish History, the name of that miraculous light, or violet glory, which was a fymbol of the special presence of the Deity. This shechinah, after it had conducted the Israelites through the wilderness, had its more flated residence in the tabernacle and the temple. See Ark of the Covenant.

For a farther account of this miraculous phenomenon, the
It is evident that sheep are animals of the utmost importance to mankind, whether considered in the light of affording food and clothing, or in that of the valuable implement and profit which they produce in various systems of management to which they are subjected by the farmer; in some instances constituting a very large proportion, and in others nearly the whole of his dependence and support. There is also another point of view in which they appear equally advantageous and interesting, which is that of their becoming thus beneficial in situations and upon lands that must otherwise be nearly if not wholly unsuited. Also in the view of affording the raw material for one of the most extensive staple manufactures of the kingdom, the advantages which they afford are almost incalculable.

But besides the wool, the skins and other parts of these animals afford a variety of other equally useful and important articles and products, such as those of parchment, leather, glue, fuel, and many others, which are of great value for different intentions and purposes in the arts and other ways, and which employ a great number of labourers in forming and preparing them. In short, there is hardly a part of the sheep that does not afford an useful and valuable product of some sort or other. In usefulness they may, of course, be placed at least next to, if not before, the cow. In disposition, almost all the improved breeds are extremely mild, tame, and gentle, which is a proof of their value as grazing stock: but those which have been least attended to, or which continue more in their native or original state, are much less tractable, as those which inhabit the downs, heaths, and mountains in different parts of the island.

The character of stupidity, want of sagacity, and of some other valuable properties, which the naturalist Buffon has given these animals, seems by no means well-founded. It is probably the offspring of prejudice, and the improper examination of the subject.

The increase or growth of the sheep continues to advance till at least three years old, when it is in general considered as in the most proper state for the purposes of the grazer, though it is employed in this way till a much later period, sometimes even till five or six, and also with the view of breeding; but an early maturity is a property of much conformation, especially for the grazer. Of sheep, the breeds or varieties that are dispersed over the globe are almost endless; even in this country they are so extremely numerous as scarcely to be described with any correctness.

The characteristic circumstances by which they have been chiefly distinguished, are those of their possessing horns, or being wholly without them, and from the length or shortness and fineness of the wool or coat, as well as the situation in which they are chiefly found. It has been flayed by Lord Somerville, in his "System of the Board of Agriculture," that all the breeds of sheep in this kingdom may be arranged into two classes; those which shear the short or clothing, and those which shear the long or combing wool. And that the quality of the flesh in each class follows the character of the wool; the short-woolled sheep being clove in the grain as to flesh, consequently heavy in the scale, and high-flavoured as to the taste, the pulled long-woolled sheep more open and loose in the grain, and larger in size. And by the author of "The present State of Husbandry in Great Britain," they have been distributed under three general divisions, as below:

1. The mountain breed;
2. The short-woolled breed;
3. The long-woolled breed.

And among the first are comprised several varieties, as the black-faced, which range on the mountains of Wales, etc.
SHEEP.

Wiltmoreland, Cumberland, Yorkshire, and those in the south, west, and north of Scotland, and in the Shetland islands; the Cheviot hills, in the south of Scotland and north of England; and the forest and common sheep of the last-mentioned country. In the second division are included those of Hereford, Dorset, Sulles, Norfolk, and some parts of Cumberland. And the third division comprehends all those varieties that are dispersed over the more rich and fertile parts of England, and which are distinguished under the titles of the Durham or Teeswaters, the Lincolnshires, the old and new Leicestershires, &c.

But others divide them into long, short, and middle-wooled kinds.

And a still more clear and concise view of the various breeds of British sheep, is afforded in the tabular form given by Mr. Culley, as enlarged and corrected by the author of the "General Treatise on Cattle," and others.

</table>

There are a few other breeds met with in different districts, as noticed below.

Since it is found by the grazier that the more an animal approaches towards perfection in its form, the better, in general, it is adapted to the purpose of fattening; it is obviously a matter of much importance to be well acquainted with the peculiar disposition and connection of parts which constitute such excellence or perfection of form; these have been already fully explained in speaking of the nature and principles of breeding animals, as well as in considering the nature and management of cattle. And the same thing is to be aimed at in sheep flock; as the more any breed may approximate to such an excellence of shape, the more perfect it must be. A sort of model to be aimed at, in so far as shape is concerned, in the improvement of these animals, due attention being always had to other properties, has been given by Mr. Culley, in his description of a ram, and which may be seen under that head. (See Ram.) The nature and combination of the various points and parts should, of course, be well understood and impressed on the mind of the breeding and grazing farmer, in order that he may always rear or procure these animals to the greatest advantage.

The varieties of this most useful animal are endowed with different particular qualities, properties, powers, and propensities, which it is necessary to ascertain, in order for the farmer to draw and produce the utmost advantage possible from the combing, croffing, and rearing of them. All the breeds of sheep are the most distribut while they are kept or left in the state of nature.

The common and usual descriptions of the several breeds are the following:

Teeswater Breed or Variety.—This is a breed of sheep said to be the largest in the island; it is at present the most prevalent in the rich, fine, fertile, inclosed lands on the banks of the Tees in Yorkshire. In this breed, which is supposed to be from the same blood as those of the Lincoln, greater attention seems to have been paid to fleece than wool. It is, however, a breed only calculated for warm rich pastures, where they are kept in small lots, in small inclosures, and well supported with food in severe winter fowens. The produce in weight of mutton is large, but then, from their requiring so much longer time and richer keep, and being admitted in so much smaller proportions on the acre, they are probably not, upon the whole, so profitable, even in situations where they can be kept with the greatest chance of success, as the smaller more quick-feeding breeds. In the eyes there is, however, a property which is of much consequence, which is, that in general they are very prolific, bringing two and frequently three lambs, and in some cases a greater number each, according to Mr. Culley. He gives the following description of the breed. The legs are longer, finer boned, and support a thicker and more fine and heavy carcass than the Lincolnshires; the sheep are much wider on the backs and sides, and afford a fatter and finer grained mutton. The weight per quarter in two-years old
old wethers is from 25bs. to 45bs., and in particular instances to 55bs. or more. The wool is shorter and lets heavier than that bred elsewhere. However, the writer of the “Treatise on Cattle,” thinks that the breed is nearly worn out; but admits that there is a distinct breed in Ireland.

This is a sort of sheep that has been little attended to, but which, when improved by proper methods, it is supposed would answer and pay well in districts where it could be well supported. In the Considered Report of the Society of Agriculture in the West Riding of Yorkshire, Mr. Parkin supposes that an useful kind is capable of being bred by crooking the ewes of this sort with Dishley rams, in a careful manner. And it is added, that by the use of these, and those of the Northumberland kind, the quality of the wool and the mutton has not only been greatly improved, but the quantity of bone and offal much increased; and, at the same time, the fattening property considerably increased; they becoming fatter at two years old than the others are at three. The wethers of this improved sort generally fell unhorned, at two years old, from 45s. to 55s. a-piece, and weigh from twenty-four to thirty pounds the quarter. They sell a great deal higher at the present time.

Lincolnshire Breed or Variety.—This is a breed of sheep which is characterized by their having horns; white faces; long, thick, weak carcasses; thick, rough, white legs; bones large; pelts thick; and wool coarse-grained. The weight per quarter in ewes from 14lbs. to 20lbs.; in three-year old wethers from 25lbs. to 35lbs.; the wool from 10 to 18 inches in length. And it is chiefly prevalent in the district which gives the name, and other rich grazing ones. But the writer of the work on Livestock supposes that this breed is now so generally improved by new Leicester rams, that they are probably, in a great measure, freed from those defects of the old breed, of which Mr. Colley, with much reason, complained, namely, wool of ill form, and too much bone, and coarse-grained flesh. It must not, however, be denied, that a good old Lincoln has ever been, and the name, at least, still continues a great favourite at Smithfield, and the flavour of the Lincoln mutton has been generally held superior, as more savory than the Dishley. The new or improved Lincoln now have finer bone, with broader legs and trussed carcasses, and are among the best, if not actually the best, long-wooled sheep we have. Many will recollect the ridiculous and indecorous squabes, some years ago, between two eminent breeders concerning these two breeds of sheep. About this time, they attempted to feed Lincoln sheep on the Fifeshire wafhes, and pretended the flock degenerated, which might happen from insufficiency of winter keep, or, if they were breeding flocks, from crossing with other breeds, an everlasting and unregarded practice in those not profusely breeding counties. This has been suggested as a breed only capable of being made fat on the coarse grazing lands; but that in such cases it may probably be kept till three years old, with greater profit than the new Leicester kind. The proportion of bone to mutton is considerable, and the latter not very fine in quality. But the principal excellence of the breed is in the large quantity which it affords, which pays for their being kept longer before they are fattened. Such breeds as feed quicker should however be preferred by the farmer on most sorts of land.

New Leicester, or Dishley Breed or Variety.—This is an improved breed of sheep, which is readily distinguished from the other long-wooled sorts, according to Colley, by having fine lively eyes; clean heads, without horns; straight, broad, flat backs; round or barrel-shaped bones; fine small bones; thin pelts; and a disposition to make fat at an early age; to which may be added a superiority in the fineness of the grain and the flavour of the mutton to that of either sheep of the large long-wooled kinds. The weight per quarter in ewes three or four years old from 18lbs. to 20lbs.; in two year old wethers, from 20lbs. to 30lbs.; the length of wool from six to fourteen inches.

But the author of the “Treatise on Cattle,” who seems chiefly to object to the Leicester breed, from its too great propensity to fatten, which, it is supposed, also abates the proce-
procreative and laitiherous powers, says, “Pure Diflby sheep are by no means the molt prolific, nor the belt nurxes.” And adds, that the heads of the improvers having had time to cool, it is no longer boastful, that new Leiceflcr sheep are able to fulfill, and even thrive, on the shorteft commons. In fine, it is contended, the merits of this flock as an improving crofs, (their grand point of utility,) being fo undeniably great, their difadvantages have been overlooked, and com- parifons have been ufually made with fuch only as had a ftrong need of improvement, in which the new Leiceflers in course were few to triumph. And further, that though the Diflby crofs has made its way into every part of this ifland, to the Land’s End, to the bottoms of the Welch mountains, and of the Scottifh Highlands, to Ireland, and even to Russia, its general succes has been attended with various particular inftances of failure, a remarkable one of which is given by lord Somervile, in his Facts, in refpeét to the Bampton or Western long-woolled sheep. The crofs is sometimes very injudiciously used with short or carding wool flock, excepting where the intention is only forward lamb. On flock naturally good and improvable, this peculiar effect of the new Leicefler crofs has refulted, the improved have confiderably furpafled, in the molt valuable properties, their improvers. Of this many examples may be fnen, it is suppoled, in the improved Lincoln, Northumberland, and Midland county sheep.

The following is a table of the value of new Leicefler sheep, at various ages, as given on the authority of different eminent breeders in the Lincolnshire Agricultural Survey.

<table>
<thead>
<tr>
<th>Age</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 months</td>

The advantages and difadvantages of the Lincoln and new Leicefler breeds of sheep have been very fully confidered in the Agricultural Survey of the former county; and the refluts flated as below in the ditfifins of it.

Circumstances of compariion between the Lincoln and Leicefler breeds of sheep.

- Bolton. Lincoln better than Leicefler, on general experience and particular experiment.
- Brothertoft. In experiment, very little difference.
- Ewerby. Leicefler tenderer than Lincoln. Lincoln pay beet for keeping to three-fliear.
- Hackington. Last year of Lincolns pay beet.
- Ewerby. Old ftood the winter better, and pay better than young.
- Owerby. Shearling Leiceflers have, at Wakefield, fold as high as two-fliear Lincolns. Difference of wool has been as 8 to 16. Leiceflers tenderer in winter.
- Normanby. Lincoln fleece 2lbs. heavier than Leicefler. Leicefler off-hearlings; Lincolns two or three-fliear, but the latter pay well, if kept to three-fliear. Leiceflers finer grained mutton.
- Leiceflers rather thicker on the land, but Lincolns considerably larger.
- As much wool per acre from Leiceflers as Lincolns.
- Walcot. Leicefler fleeces, though not fo heavy as Lincoln, fold, in one instance, for as much money.
- Barton. Leicefler not tenderer in winter than Lincoln. Old breed of Lincoln used to go lean at two years old.
- Now, Leiceflers fat at the fame age.
- No difference in number on the fame land.
- Wool the fame.
- Leiceflers come to fame sooner, but will not bear cold, wet land in winter so well, nor heat or cold after shearing, as the Lincoln.
- Bonby. Leiceflers have refifted hardships on the worft land better.
- Barrow. Five Leiceflers where four Lincolns; and Leiceflers have refifted hardships on the worft land better.

Brockleby.
SHEEP.

Brocklesby. Lincoln more profitable than Leicester.

Lumber. Where a man can keep, by means of marsh, to three-shear, Lincoln most profitable, but not otherwise. Not more Leicesters kept on the same land. Leicester wool is a tod more than Lincoln. Leicester more liable to the fly.

Cadney. Leicester will feed a little faster, and run a little thicker.

Beefby. Leicester one in six more on the same land, but both go at the same age. Leicesters harder, and have less offal. Tallow equal: wool higher priced. Gives corn to Leicesters, but did not to Lincolns.

Alesby. Leicesters feed quicker, and have less offal; wethers and hogs less wool, but ewes equal, and on the whole more per acre; harder, and bear driving better. Go off at the same age, but Leicesters fatter. Five kept instead of four. Lamb easier: necessary to give corn.

Humberston. More pride than profit in the new fort. Leicesters 24 lbs. less wool than Lincolns, and not better; but run one in ten thicker.

Louth. Leicesters feed quicker, and have lighter offals. No difference in hardiness. Lincoln belt.

Tathwell. Lincolns and Leicesters being put together into the marsh, and sent thence at same time to Smithfield; the former yielded 42 a. head more, and 57 a. head more wool.

Cookswold. Marsh graziers all prefer Lincoln. No difference in number kept.

Tathwell. Lincoln wool 4 lbs. heavier than Leicester. At two-shear, Lincoln heavier by 2 lbs. a quarter; at three-shear, 6 lbs. In tallow, 6 lbs. at three-shear, in favour of Lincoln. In number per acre no difference. In hardiness, Lincoln belt. Leicesters less wool, and less mutton per acre.

Driby. No difference in number kept.

Spilsby. Leicesters as fat at Lady-day, coming two-shear, as Lincolns at Lammas. Same number per acre. No difference in hardiness; Leicesters have corn.

Horneastle. Three-shear better than two, as sure to find more tallow.

Asgarby. Leicesters bred too fine; fine-headed ones do not yield wool enough.

Frampton. As many of one as the other per acre. Lincolns travel best, and pay best.

Randby. Leicesters thicker on land, as five to four.

Alderkerk. In an experiment of the two breeds on the same land, of the same weight and age, the Lincolns considerably superior.

Thoresway. True Lincolns most saleable, and most profitable to breed.

Sudbrook. One-third more Leicesters on the same land.

Risuelom. Boston graziers not judges, for they can get good Lincolns, but not Leicesters, as the breeders of these can fat them themselves. Leicesters run one-fourth thicker on the land. From six to twelve months old, rather tenderer than Lincolns; Leicesters travel best.

Claypool. Leicesters as fat at one year as Lincolns at two, and with less trouble, and one-tenth thicker. Do as well as Lincolns in winter on wet land.

Marlton. Leicesters belt, and run one-fifth thicker.

Woolthorpe. Leicesters by far the belt; but more apt to be barren than Lincoln. Drape ewes far more valuable.

Grantham. Leicesters travel belt, and are the belt; and much less los in lambing; run one third thicker.

A clear distinction is to be drawn, as the writer remarks, between the rich south-eastern district and inferior soils; for, upon the former, the information is strong in favour of Lincoln. However, in general, he should observe, that the new Leicesters are spreading very rapidly over the country, probably faster than they have done in any other, one or two only excepted, which may be attributed to the general goodnes of the soil; for this breed makes a much more respectable figure here than it has done in various trials made on counties inferior to it in soil; and the breed driving-out the Lincolns so much as it has done in the poorer parts of this county, is a fact which unites with this circumstance. The true Lincoln is a large sheep, and with a longer wool, and therefore demands better pasturage; where it finds such, there the old breed remains; subject, perhaps, to little more change than fashion may cause. Upon inferior land the Leicester establishes itself; and upon land still inferior in other counties, experiments prove unsuccessful for the same reason; that of the necessity of having a smaller size and shorter wool.

But some of the original pure long-wooll'd polled breed of sheep, are still to be met with in the midland districts, which are a larger boned, longer formed, deeper coated, and more coarse flock than the improved fort. And that, from the coarsetwo and larger size of the head and neck in the old fort, the ewes lamb with more difficulty than in the true Didsbury breed.

The new Leicester fort of sheep is found a very advantageous breed on some kinds of land in the county of Oxford, as on the flone-brash; there are some farmers indeed, who think that no other fort comes nearly up to them, when all their valuable properties are taken into the account.

Coatswoold or Gloucester Breed or Variety.—This is a breed of sheep which, according to a late writer on them, is of the fine combing wool fort, deriving the finewool of their fleece from the same source as the new Leicesters. This part of that county formerly, and within memory, bred, it is said, small fine-wool'd sheep of the Ryeland kind, which in past times had been cotted, but the practice was discontinued. These sheep, being judged too small for the improving state of the country, have been, by gradual crossings with Midland longwooll'd rams, chiefly Warwicks, completely changed from short to large long-wooll'd flock. The writer saw a picked lot of Cotwolds last year, he says, which answerd the following description: long coarse head, with a particular blunt, wide nose: a top-knot of wool on the forehead, running under the ears: rather long neck: great length and breadth of back and loin; full thigh, with more sub stance than the hinder than fore-quarters; bone somewhat fine: legs not long: fleece soft, like that of the Didsbury, but in chiefness and darkens of colour, bearing more resemblance to short or carding wool. Although very fat, they had all the appearance of sheep that were full of solid flesh, which would come heavy to the scale. It is added, that it is said, some of these sheep have reached 40c, and even 50lbs, a quarter,
a quarter, at two years and a half old, giving 11 lbs. to 14 lbs. of wool each sheep, and being fat, they are indubitably among the largest breeds in England. A single dip, continues he, of new Leicceler gives the Cotswolds a fulness in the fore-quarter; but any farther crosses of that kind, it appears, diminishes their fleece. The strange crosses of Wilts horned sheep has been recurred to in some parts, for no possible good purpose, he should apprehend, either to the car- cafe or wool; and it is probable, supposing such large flock profitable, that the chief alteration required by the Cotswolds, is to encourage length of staple in their fleece or wool.

In this breed the ewes are usually put to the tup, so as to have lambs at two years old, mostly producing two lambs each, in the proportion of nearly one-third of the whole, where kept well, which must always be done. They may be kept for breeding till three or four years old, if they are of the proper improved sort. But it is said that the wethers afford more profit when killed so early as at two years old, as they are apt to become too fat when kept longer.

The Cotswolds or Gloucesters, and the half Leiccelers and half Gloucesters, and other mixtures of these breeds, are considered as very excellent sorts of sheep flock in many parts of Oxfordshire; they are of a good size, bear plenty of wool, and flanders penning well. But penning or folding is not thought beneficial by some farmers, as more and better sheep may be kept without it.

The native Cotswolds, if they are any where to be found, would be, it is said, at two-year from twenty-eight to thirty-two pounds the quarter: they are a long sort of sheep, not full in the sides, sharp in the chine, not full in the fore-flank, coarse in the bone, not straight but good in the hind-quarters; will not fatten so early as when crossed; and of wool, the two-year wether affords three and a half fleeces to the tod. The new Leicceler, it is contended, is calculated to correct every one of the deficiencies which have been noticed, and to bring a greater disposition to fatten. Between all Cotswold and all Leicceler, the average difference of wool, it is said, is three pounds.

In Devonshire, some, it is said, have succeeded in the crosses of new Leicceler upon the Cotswold, the equal breed of which is attempted to be preferred as much as possible. Wethers of this kind, at eighteen months old, will average nineteen pounds the quarter, and seven pounds of unwashed wool the fleece. When kept on for another twelvemonth, the age at which they are mostly killed in this county, this cross will attain the size of twenty-five pounds the quarter, and yield nine pounds of wool to the fleece. This wool is allowed by the flapers to be one penny the pound superior to that of the Exmoor, Bamptons, South Devon, and Dartmoor sheep, yet still the common price of one shilling. The pound is only allowed for it. In the young wethers of this breed, the loose fat is flated to be nine pounds, with nearly three pounds of kidney fat on each side. The larger wethers are said to produce thirteen pounds of rough fat, and four pounds of kidney fat on the side.

Romney-Marsh Breed or Variety.—This is a kind which is described by Mr. Young, as being a breed of sheep without horns; white faces and legs; rather long in the legs; good size; body rather long, but well barrel-shaped; bones rather large; and it is said that the weight per quarter, in fat wethers at two years old, is usually from 22 lbs. to 28 lbs. In respect to the wool, it is fine, long, and of a delicate white colour, when in its perfect state. On this Marsh 20 lbs. of wool are supposed to be produced per acre. In this breed there is a property of arriving at the state of fatness at an early age, as well as that of producing a large fleece of fine long combing wool, of course it is a valuable sort; however, from the size, and great weight of the coarse, it is not capable of being supported and fattened on the rich kinds of marsh pasture; and on those which extend from Halings to Rye, in Kent, according to the Sussex Agricultural Report, the graziers find it much more beneficial than the South Down; the marsh wethers fattening more quickly. The wool afforded by such fat wethers averaging fix pounds, and in breeding ewes five pounds, but not equal in quality to the wool clipped from shearlings. And the author of the "Synopsis of Husbandry" remarks, that a convincing proof of the great value of this breed of sheep, as well as of the land on which they are fed, is seen in the manner of flocking, which in fogs is from four to seven per acre, in fattening wethers from fix to eight, in barrens from two to three, and in couples three; which is certainly a great flock. And this is a breed that might probably undergo much improvement without croffing; by proper care and attention, and being left exposed in the winter fafon.

In the old Romney-Marsh breed, the sheep were remarkable for having large heads; for being large, long, and tub- bellied; also for being large in their bones, long in their legs, and coarse in their wool; which form is still held in estimation by some, in consequence of improper prejudices, to the great injury of the grazer and community in general; but the pure breed of this sort, Mr. Price says, is distinguished by a thickness and length of head, a broad forehead, with a tuft of wool upon it, a long thick neck, a great length and thickness of carcase; being flat-fided, and having a sharp chine, tolerably wide on the loin, but the breast narrow, not deep, the fore-quarter not heavy or full, a good clef; the thigh full and broad, the belly large and tubby; the tail thick, long, and coarse, the legs thick with large feet, the mule of coarse and the bone large; the wool long and not fine; coarse on the breech: the sheep prove good, and are great favourites with the butchers. But this description is not now, it is said, to apply as it was some time ago, when most of them had horns.

The same writer, in his account of the sheep management in this marsh district, has remarked, that the introduction of the Leicceler breed has very perceptibly altered the form and properties of the original breed or flock of this tract, so that in a few years it will scarcely be distinguishable, and that it is probably the general opinion that it has been injurious to it, in reducing the size and value of the animal, as well as the quality and quantity of its wool, though it has still many advocates, and has certainly contributed much to its improvement. The principal objections which the graziers of this Marsh seem to have to the mixing of the Leiccelers with their own breed, are, that they have seldom or ever twin lambs, which are very desirable and beneficial in this situation; that the lambs are more tender, and, of course, a greater loss liable to be sustained, especially in an open exposed tract of this sort; that their lambs do not winter so well as those of the native breed upon the uplands; they are much less hardy, consequently cannot stand cold and hardships so well, which is very disadvantageous; that their wool is not in such abundance, or so valuable, which is a great defect; that there is a want of proof in them, which renders them a great deal less saleable to the butcher; this may, however, be no disadvantage to the breeder or grazer, as it shews other more valuable properties and dispositions; and that they are too short in their bodies and legs, so as to stand too low in their pens at the market. These are, however, probably improved valuable properties, which must be rather beneficial than hurtful. Some improvement has, however, been given to the Marsh breed by the Leicceler crofs, as 

This breed of sheep is thought to be highly valuable for cold exposed situations, as being easily bred, and standing in need of no artificial food in the most severe winters, except a little hay; they are very hardy for their size, have now many improved qualities, and may probably be made the most profitable of any for rich pastures, as affording the largest proportion of meat at the least expense. In wethers, the general average is now from ten to twelve stone weight each; and in ewes, when fat, from nine to eleven.

**Dartmoor, Devonshire, Hamp and Nott Breed or Variety.**—This is a breed of great fame, which is chiefly distinguished by having no horns; white faces and legs, thick necks, backs narrow, and back-bones high; sides good; legs short, and bones large; and probably without any material objection, being a variety of the common horned sheep. According to Mr. Culley, the weight of wethers on the average about 250 lbs. a quarter; in wethers, at two years and a half old, 350 lbs. Length of wool much the same as in the Romney-Marsh breed. It is a breed found to be prevalent in the districts from which it has derived its name. And it is supposed to have received considerable improvement by being crossed with the new Leicester or Dihiley improved fort within these few late years.

Besides the forest from which it takes its name, this breed is met with in some other parts of the county. The Dartmoor wethers at five years old will average about 160 lbs. per quarter, and produce from four pounds and a half to six pounds and a half of unwashed wool to the fleece. This breed of sheep, though they do not feed so quickly, when put to good keep, as the new Leicester fort, yet, when fat, they constantly prove the very best mutton, and never fail to command a superior price. They also stand the climate in a favourable manner, and the ewes are good nurses.

The old Devonshire dun-faced wethers were formerly held in high estimation, as a native breed of some parts of this county. It is, however, a crooked-backed, flat-sided, closely banded and woolled wool, but which has been much improved by crossing with the new Leicester fort, its principal defects are by those means improved, and greater disposition to fat at an earlier period given, while at the same time, however, the fleece, as well as the weight of the carcase, has been increased, the former from fifteen to eighteen pounds of unwashed wool to the fleece, and the latter from twenty-two to twenty-six pounds the quarter. In order to recompose which, the animal comes to market earlier; the wether at two years old, with advantage; that is, after being twice sheared as a wether, and once as a lamb, equals the average already stated. This influence is more created with the new Leicesters, will arrive, it is said, still earlier to the same perfection.

In the Hamp and Nott breed, the wethers will, at twenty months old, weigh twenty-two pounds the quarter, and shear six pounds and a half of wool to the fleece; also the same sheep, well wintered, and kept on for another twelvemonth, will average twenty-three pounds the quarter, and yield eight pounds of unwashed wool to the fleece. The price of the wool at present is about 10d. the pound.

The first cross of this breed with the new Leicesters is fast growing into great esteem in this district, in consequence of its improving the form, and bringing the animal three months sooner to market; but though so far useful and desirable, any more of that blood is thought disadvantageous, as rendering them too tender while young, and to require too much care and nursing.

The Hamp and Nott crossed with the new Leicesters is also a breed much approved of in several parts of the county, especially when carried to the fourth degree, or four parts of the Leicesters to one of the native sorts. This cross, it is said, comes earlier to market, and at two years old will generally average twenty pounds the quarter, and eight pounds of yarn wool to the fleece, which is worth about 10d. the pound. And the old Leicester crossed upon the Hamp makes a large and handsome animal, which feeds kindly and tailows well within. The wethers of two years old will average, with advantage, thirty pounds the quarter, and shear ten pounds of yarn wool to the fleece. It is valued in some places. But the new Leicester crossed upon the same sheep, will, in some situations bring forward wethers at twenty months old, weighing twenty-two pounds the quarter, with a shear of eight pounds of yarn wool to the fleece, both of which are at this time worth 10d. the pound, weighing, according to the custom of unwashed wool, twenty-one pounds for every score. This sort is highly valued by some in different parts of this county. The Hamp and Nott crossed is more hardy than the new Leicesters, and suits some places better.
Table of the different Breeds, Croffes, and Produce of the Sheep of this and neighbouring Districts.

The washed wool of all the long-coated sheep is sold from 14d. to 15d. per lb. These sheep are not sent to the forests.

In most cases of a cross with the new Leicelster upon long full fleeced sheep, a deficiency of wool is observable under the belly and breast of the animal.
Exmoor Breed or Variety—This is a sort of sheep which is characterized by having horns, white faces and legs; by being very delicate in the bone, neck and head, or what is sometimes denominatod deer-necked; by the form of the carcase being indifferant, narrow, and flat-sided. According to Mr. Culley, the weight per quarter in wethers at two years and a half old, is from 15 lbs. to 18 lbs.; and the weight of wool much less than in the Devonshire breed. It is a small breed of long-woolled sheep, principally produced on or in the neighbourhood of the moor from which it takes its name, which is in the northern extremity of the county. Mr. Lawrence supposes that in their present state they are by no means to be considered as a profitable sort of sheep-flock, either in what relates to flesh or wool; on which account it would be for the interest of the county to change them for the best fine-woolled breed. It is remarked by Mr. Billingley, that this breed of sheep is frequently kept two or three years, merely for the annual profit of their fleeces, which often do not exceed more than four pounds in weight; and that from their being kept upon very bare and indifferant pastures while young, they are suppos'd by many sheep-farmers to be a very profligate sort of stock.

This horned breed has a moderately long flable of wool, which formerly, before the cloth manufacture of the county of Devon fled into Yorkshire, was much in demand by the clothiers of several different places. The fattened wethers of this breed, at three years old, will usually weigh about 45 lbs. the quarter, and average 44 lbs. of washed wool to the fleece; which is worth at present about 5d. the pound. Attempts have been lately made in different places to improve the wool of this breed or sort of sheep, by a cross with the Merino or Spanish ram, and the results of the trials thus made are as below:

<table>
<thead>
<tr>

In which improvement of the fleece the carcase is said to be rather advanced than the contrary.

In the crofs of the old Leicesther upon the Exmoor breed, the wethers, which are the produce at three years old, average about 24 lbs. the quarter, and carry 6½ lbs. of yoke wool to the fleece. The Exmoor sheep have also been crossed with the new Leicesther; the wether produce of which, at two years old, will weigh 18 lbs. the quarter, and yield 6 lbs. of unswaled wool to the fleece; the price of the two latter qts. the pound. Much lost is often, it is said, fulfilled in this left cross at the time of yeaning, in consequence of the great size of the shoulders of the lambs retardng or preventing their exclussion. This will, however, be remedied in the produce of this cross.

The Exmoor breed is a hardy sort of sheep on wet exposed land while young. The ewes under such circumstances, in lambing, are also superior to the Bampton kind.

Cornish Breed or Variety.—The true breed of this sort is said to have grey faces and legs, coarse short thick necks, standing lower than behind, narrow backs, flat-topped sides, a fleece of coarse wool, weighing about two or three pounds, of eighteen ounces each; their mutton, which is seldom fat, from eight to ten pounds the quarter.

However, from the various crofses which have been introduced into the county at different times, in consequence of the use of rams of the Exmoor, Dartmoor, North and South Devon, Dorset, Gloucester, and Leicester kinds, the pure breed of this description is said to be now become rare, but that, from the inferior nature and value of its properties the total extinction of it need not be lamented. The district is now capable of supporting a much better and more improved breed of this sort of animal.

Black-faced Heath Breed or Variety.—This is a kind or breed of sheep which, according to Mr. Culley, have large spiral horns, black faces and legs, a fierce wild-looking eye, short firm carcases, from 12 lbs. to 16 lbs. per quarter, covered with long, open, coarse-hagged wool, fleeces 3 lbs. or 4 lbs. each, wool worth at present about 6d. per pound. They are an active hardy sort, running with amazing agility, and best adapted, of all other breeds, to exposed, heathy and mountainous districts; seldom fed until three, four, or five years old, when they feed well, and make the finest mutton, having a high-flavoured gravy. The sheep of this wild-looking breed are natives of the north-west of Yorkshire, and are of that mountainous tract of country adjoining the Irish sea, from Lancashire to Fort William; they have been of late years introduced into the Western highlands of Scotland. And the writer of the "Treatise on Live Stock," supposes the black-faced Lintons, or short sheep of Scotland, to be a variety of the Heath sheep. They have been crossed with the Cheviot breed, and Mr. Culley, it is noticed, recommends a Dithley cross, meaning, a doublecross, for the use of the low lands. If he may be allowed to give an opinion, he would, for upland situations, recommend a Spanish cross, with good winter management, in preference to all others. It is disgraceful, he contends, to the rural economy of Britain, that so excellent a breed of sheep should be uselessly compelled to brave the rigour of the seasons, in such loose, ragged, and beggarly clothing, when they might, with a few years' pains, and without any deterioration of the carcases, produce a fleece of high value and consequent to the manufactures of the country. And he adds, that Mr. Henry King, fableman of Newgate market, and an eminent grrazier, informs him, that he once fed a lot of these northern heath sheep, and made excellent mutton of them, about 16 lbs. a quarter; but that their wool hanging down their quarters like goat's hair, was so execrably bad, that it could be sold only for mop yarn.

But what are termed black-faced, or short sheep, are said to have been originally short-woolled, the present length of it having proceeded from crossing; and it is not well ascertained whether they are a native Scotch breed, or have been introduced from the moor-lands of Yorkshire. Besides the objection to these black-faced sheep, on the ground of the coarse lofty nature of their wool, they are said to be subject to the braexy, a disease that was unknown in the Highlands before their introduction. And it is remarked, in the able Agricultural Survey of East Lothian, that the kind of sheep breed and moit generally kept in Lammermuir, is the black-faced, or more properly, what is called the bracken faced, a sort of dirty-looking mixture of black and white; they are for the most part horned; when they are fed, the wethers weigh from 10 lbs. to 12 lbs. per quarter, and the ewes from 8 lbs. to 10 lbs. on an average. It will take eight or nine fleeces of the ewes and hogs, and six or seven of the wethers, to make a stone of seventeen pounds (twenty-ounces to the pound); the quality, and consequently the price, vary much. The difference of quality may result from various circumstances; it is owing partly to the quantity of tar put upon the sheep in falling; partly, it is supposed, to the situation in which they pasture, as those fed on high grounds and coarse mossy herbage, are thought to have inferior wool; and partly to the general
general attention and care which farmers bestow upon their flocks, in which some are greatly superior to others. But the black-faced sheep feeds the writer thinks, to be capable of very considerable improvement; it does not, indeed, appear, that much has been done for improving that breed, which certainly places them in an unfavourable situation, when their merits come to be discussed in opposition to others which have received great attention. There can hardly be a doubt that the weight of the carcass and the quantity and quality of the wool might all be increased, by sufficient care to select the strongest, healthiest, and best feeding among them for the purpose of breeding. It has been observed, that those which feed belt have the greatest quantity of wool, and generally of the best quality; and it is natural to suppose that it should be the case, as they must be the healthiest and strongest.

**Herefordshire, Rofs, or Ryeland Breed or Variety.—** This is a sort of sheep which is distinguished by the author of the "Treatise on Live Stock," by the want of horns, and having white legs and faces; by being small in size; and the wool growing close to the eyes; by the carcass being pretty well formed; and by the excellence of the mutton. Weight per quarter from 10 lbs. to 13 lbs. Wool fine and short, the lean poor-fed sheep producing the finest. It is the true breed of this sort of sheep which is properly denominated Ryelands. In the Agricultural Report of that district, they are said, in symmetry of shape, and the flavour of the meat, to be superior to most flocks in the country. They lamb in February and March. It is a breed which, Mr. Knight says, is found to be remarkably easy in respect to food, but which, in its management, requires cotting in the winter season, and being fed with hay or pease-haulm. In some cafes they are hunted all the year round in the night-time. The cotes are low covered buildings, proportioned to the extent of the flocks. In the Herefordshire Agricultural Report, it is observed that the cotting materially contributes to the health of the animal and the fineness of its fleece. The quantity shorn from each of the small original breed does not average more than two pounds; but the quality is such as almost to rival that imported from Spain. The price has often been as high as thirty-three shillings the troy of twelve pounds and a half unstruck, when the coarse wool has brought but ten or twelve shillings. They are said, by Culley, to fatten the belt at four years old. The Auchenfield, or true Herefordshire breed, is said to afford the finest wool, except the Spanish. It is suggested by Mr. Knight, that the disposition of sheep to fatten in the north-west part of that district is in the proportion to the fineness of the wool; but he is not certain of its being so in this breed; however, it seems to him that where the wool is close and fine, there are many advantages; less nourishment is drawn from the body in its support than in the contrary case. The long coarse-woofed fleece admits the rain more freely, and by dividing on the back lets it down to the skin. It also takes in a larger weight of water, which muff more inconveniently the animal already heavily loaded. The fine close fleece of this breed admits the water with difficulty, even when immersed in it in washing, and is never wet through by rain. On account of the chafeness of the texture, it only lodges on the outside, and is easily removed by the animal shaking itself. Besides, a fleece of this kind is much more warm and light. For these reasons it is supposed that no breed of sheep in the island is capable of subsisting on so small a proportion of food as this.

This animal, in Mr. Knight's opinion, appears to be much more patient of hunger, and to keep itself in better condition on a less quantity of food than any other which he has had an opportunity of observing. To the great fineness of the pulture on which it is usually condemned to feed, is to be attributed the fineness of its fleece; for the quality of this becomes immediately impaired by a copious supply of food; and this circumstance should be attended to, in every county where these sheep are introduced.

Some attention has lately been paid to its improvement, and although the wool is somewhats less fine in its quality than it formerly was, it is still the finest in the island, with the exception of the Spanish fort recently imported; and the animal must be allowed, on the whole, to have been consideredly benefited. The quantity of wool afforded by the improved fort of Ryelands, although increased, is still far from large; a three-years old wether rarely yields more than three pounds and a half. But as a large number of sheep will fatten on a small portion of ground, and the wool is still worth two shillings and twopence the pound, its value, compared with the quantity of food consumed by the animals, is probably much greater than that afforded by any other breed.

And the Ryeland sheep readily acquires, on a very moderate pasture, that degree of fatness which renders its flesh more acceptable, but it is wholly incapable of being loaded with fat in the manner of Mr. Bakewell's. It appears to him to fatten somewhat more quickly than those he has seen of the South Down breed.

In the Agricultural Survey of Herefordshire it is suggested, that a cross between the Ryeland and real Spanish seems the most probable mode of adding to the fineness and value of the wool; and amongst many spirited breeders who are now making the experiment, colonel Scudamore of Kentchurch, fold the fleeces of a flock crossed at forty shillings per roome, in the fair at Rofs, m the course of last year. The first stage of the crosses materially detraets from the beauty of the Ryeland's form, but by continued crossing, this objection will probably be removed, and the flavour of the mutton is uninjured. Lord Soperville has found that they feed quickly, and that they weigh heavily, although their form be not attractive; but perhaps form in this animal is of little comparative consequence. An ox rarely fattens well, or has flesh of good quality, unless it be in one particular shape; but sheep fatten well, and the meat is of prime quality in those of very different forms. Two Leicesters which were fed by Mr. Hever, of Abergavenny, and slaughtered before the Agricultural Society of this county in March last, weighed no less than fifty-one pounds in each fore-quarter, and forty-five in each hind-quarter. But notwithstanding this great weight, the Leicesters are often found less heavy than they appear to be, while the half Spanish weighs more than is generally expected from its size.

A cross of the Merino on the Ryeland breed has been tried in some parts of Devonshire with an appearance of success. The three-years old wethers of this cross, when fattened to their frame, being, it is said, estimated to run from fourteen to fifteen pounds the quarter, and to throw off from three pounds and a quarter to four pounds of washed wool to the fleece. In experiments made by some on this cross in other parts, it appears that three-years old wethers of the first cross will weigh about fifteen pounds the quarter, and shear from fix pounds and a half to seven pounds of wool in the year to the fleece, which is worth 2S. 9d. the pound. The sheep are, however, greatly exposed to the foot rot.

The crosses between the Ryeland and the Spanish has been made in some other parts, which has completely succeeded as to fleece, as the produce of the third cross of this breed readily sells for 32. 6d. the pound; it is, however, objected to by many on account of its not affording an equal acreable proportion of mutton with the native sheep.
SHEEP.

In crossing this breed with the Dihiley, an useful kind of sheep has, however, been produced, both the wool and carcasse being increased in weight, but much injured in respect to fineness; and it is contended by some, that the breed is rendered much less hardy by it.

Warlike Cragg Breed or Variety.—This is a sort or variety of sheep which is principally met with in the district of the above name, and that of Silverdale, in the northern part of the county of Lancashire. These Craig sheep are greatly esteemed for the fine flavour of their mutton, their ready disposition to fatten, and the fineness of their wool. They are a close compact well-made breed of sheep, commonly with white or mottled black and white faces and legs. Their fleeces are short and close-in the wool, which usually sells high. Their nature is chiefly that of the poor short rocky lime-bone kind. They are devoring of more attention than has hitherto been bestowed upon them by the farmers of the neighbourhouds where they prevail.

The Shropshire or Mof Breed or Variety.—This is a sort which, according to the writer on live flock, has small horns, with speckled dark or black faces and legs; they have the full character of real fine-woollen sheep, and have been, for centuries, bred in Shropshire, Staffordshire, Worcestershire, and the vicinity. Their fleece is nearly all fine, and it is said, superior to the Ryeland wool, since the crossing which has taken place in that flock. Mr. Pitt, of Pendeford, in a letter to lord Somervile, dated 1759, estimates the extent of Morf commom, or wales, at 3600 acres, and the number of sheep nummered thereon, at 15,800, to the annual profit of fifteen shillings per acre in wool only, on a moderate calculation, eight fleeces and a half to the flock of 14 lbs. Nothing is reckoned on account of carcasse, as the sheep have some extra keep during winter. It is added, that the Shropshire commone produce good fine wool, but none equal to Morf by sixpence a pound.

The Dorsetshire Breed or Variety.—This breed is known by having the face, row, and legs white, head rather long, but broad, and the forehead woolly, as in the Spanish and Ryeland sorts; the horn round and bold, middle-sized, and standing from the head; the shoulders broad at top, but lower than the hinder quarters; the back tolerably straight; carcasse deep, and loins broad; legs long, not very fine in the bone. Weight per quarter in wethers, at three years, and a half old, from 15 lbs. to 20 lbs. Mr. Billinghame says, that the wool is fine and short. It is a breed which has the peculiar property of producing lambs at any period in the season, even so early as September and October, as to fit the carcase of the lamb-flockker. It has been found to answer well in some of the midland districts, and, from its close make, to be equally advantageous with almost any other. It is, however, supposed capable of improvement by being crossed with rams of a larger size. There are varieties of it met with in several districts. And it is said by some, that the Dorset breeders pay great attention to preserve the colour of their flacks from mixture, since white lambs are the most esteemed in the London markets, from a prefixed superior delicacy in the meat. It is believed this is one of the best breeds in England, if not superior to all others, considering its various qualifications. Their property of bringing twins, and making our highest priced house lamb, must be considered first; they are both good hill sheep and pature sheep, and their flesh is an excellent medium between the delicate mutton of the hills, and the rich and juicy meat of the best lowland sheep. The later Dorset lambs, when fattened, make the earliest grafts lamb. By the practice of this county, the lambs which the breeders retain are born at Mulfummer, having been taken from the ewes in May; produce of wool, one pound to a pound and a half each, the price a penny per pound nearly, under the price of sheep's wool. A three-fourth sheep may produce four or five pounds of middling fine wool, which it would be highly advantageous to improve to the utmost, on this excellent breed.

This is a breed, or sort of sheep, which seems to prevail among the generality of farmers in the high lands, and some other parts of the county of Devon, which borders on the above, in which they are found to answer very well.

And there is a breed or variety nearly connected with thee in the Mendip hilly district. They are smaller than than breed, having smaller horns, more deer-headed, the wool less in weight; the mutton excellent in its flavour. It has been observed by the author of the "General Treatise on Cattle," that in the West Riding of Yorkshire, and in the adjoining parts of Wiltshire, they have a breed of horned and white-faced sheep, bearing a strong affinity to the Dorsets; they are called Cranew and Wensleydale sheep, but more generally Penjilin, from the market town where they are sold. They are a good down or hill sheep, in their pure state, and give a fleece of coarse flart wool, weighing between two and three pounds, the carcasse good mutton, about fifteen pounds per quarter. They are variously crossed in that district, with Cheviot, Dihiley, and Northumberland tops; with the two last, for the purpose of making pasturage sheep, in which case the weight of carcasse is increased to twenty or thirty pounds per quarter. In the north, this breed is generally crossed with the Heather sheep, which gives them black or grey faces and legs, with sometimes a black spot on the top of the neck, the wool coarse and open, instead of being close and thick set upon the skin, as a defence against the severity of the climate of that hilly and exposed country in which they are fed; defects for which the remedy is obvious. Ryeland tops have been tried with the Penjilin ewes, a cross which made a considerable improvement.

The Wiltshire Breed or Variety.—This is a sort which has sometimes the title of horned-cros. The writer on live flock distinguishes the breed, as having a large head and eyes, Roman nose, wide nostrils, horns bending down the cheeks, colour all white, wide bofon, deep greyhound breast, back rather straight, carcasse substantial, legs long, bone coarse, fine middle wool, very thin on the belly, which is sometimes bare. He supposes, with Culley, that the basis of this breed is doublets the Dorset, enlarged by some long-woollen crosses; but how the horns come to take a direction so contrary, is not easy, he thinks, to conjecture; he has sometimes imagined it must be the result of some foreign, probably Tartarian, crosses. The old Hertforders were, he says, supposed a kindred breed with the Wilts, but at present, the few of this kind breed in Herts are of smaller size, longer and coarser wool. These large and leggy Wilts' sheep work well in the fold, and have always had the character of good thrivers at corn, oil-cake, and the beet meat, making very large mutton, and very deep in flesh, which is highly-flavoured, yielding the dark-coloured gravy. The breed is, he adds, every where on the decline, generally supplanted by the South Downs, of which the farmers find they can, on the same quantity of land, keep more than one and a half, for one of the Wilts, the former, moreover, producing both better mutton and better wool. The disease called the goggle, is said to peculiar to the Wilts sheep. It is stated, that this breed has been long used, more or less, in the counties bordering on Wilts, and in Surrey, Kent, Herts, Essex, and Middlesex. But that it is a breed not worth preserving; perhaps the only thing to be done with it to advantage, is to cross it with the Merino. The Hampshire variety of this breed is said, for what reason he knows not, to be more hardy. It is a breed, however, which is esteemed in some places.
SHEEP.

The Berkshire Breed, or the Variety called Notts.—This is a fort which the same writer describes by having considerable length and bone, straight made like horses, full fore-flank, Roman faced, with distinct black spots, high on the leg, thick fleece, of considerable length. He supposes them to clasp with the long-wooled breeds, and to bear some affinity to the breed of Oxfordshire, which is, he is told, a peculiar variety.

The peculiar qualities of the Berkshire nott breed seem to be its great size, height on the legs, and weight when fattened. It would appear, contrary to the opinion of some, that this breed is well suited for the strong low lands of its native district, though the South Down fort are fat supplanting it in many places, probably without sufficient experience of them in such situations. In contrasting them with the horned Wiltshire sheep, it is found by some that the polled Berkshire or nott fort are as certainly more properly adapted to the low and cold lands, as they are proved to be more hardy for the fold, to fat fooner, and to be less liable to injury from the fly, than the horned sheep. When fat, the sheep vary as much as from fourteen to forty pounds the quarter, in weight. These polled or nott sheep are, however, not of so large a size as the horned fort of the same district. The fleece of this breed of sheep is not fine, and on the average it will take eight of them to a tod of wool. The mutton is rather coarse, as in all large breeds of animals. The utility of crossing this breed is by no means decided. Some advice to breed from the bell of this fort, but to cross for fattening. Crosses are, however, very common between many different forts, as between the notts and the Wiltshires, the Cotwolds, the Leiceffers, and different mixed breeds.

The Berkshire nott breed is much valued in some parts of Oxfordshire, especially for regular breeding as well as landing the fold. They are strong, active, and able to travel, and hold unusually well; against which good qualities they are, however, long in fattening, &c. The crosses with the Leiceffler improves them considerably, still they are fast giving way to the South Down and some other breeds.

And it is observed in the Norfolk Agricultural Report, that the Wiltshire sheep have proved, in various trials, an unprofitable breed, as well as the Norfolks; but it is remarkable that for turnips, no sheep are said, by many practical and experienced husbandmen, to pay better, if so well. In Hertfordshire, many who turnip-feed adhere to that breed, who admit the South Downs to be a superior fort for grass-feeding.

Heath-Croppers or Wood for Forest Breed or Variety.—This is a small ill-shaped breed of little value, found abundantly in the parishes which lie within the precincts of the forest of Windsor in Berkshire. It is a breed which affords a very sweet kind of mutton. A quarter of it will weigh about twelve or fourteen pounds. And in regard to the wool, about thirteen fleeces will make a tod. It is of equal value with that of the South Down breed. The term heath-croppers is very commonly, though vulgarly, applied to sheep of this breed.

The South Down Breed or Variety.—This is a very valuable fort of sheep, which Culley has distinguished by having no horns, grey faces and legs, fine bones, long small necks, and by being rather low before, high on the shouder, and light in the fore-quarter, fides good, loin tolerably broad, back-bone rather high, thigh full, twist good, mutton fine in grain, and well-flavoured. Wool short, very close and fine, in the length of the staple from two to three inches. Weight per quarter in wethers at two years old 18 lbs. It is a breed which prevails on the dry chalky downs in Sussex, as well as the hills of Surrey and Kent, and which has lately been much improved, both in carcase and wool, being much enlarged forward, carrying a good fore-flank; and for the short legs fertile hilly pastures is an excellent fort, as feeding close. The sheep are hardy, and disposed to fatten quickly; and where the ewes are full kept, they frequently produce twin lambs, nearly in the proportion of one-third of the whole, which are, when dropped, well-wooled. The wethers are capable of being disposed of at an early age, being seldom kept longer than two years old, and often fed at eighteen months; which is a very valuable property. But according to the Suffolk Agricultural Survey, the ewes are commonly kept till between four and five. They are said to answer well to the graziers in the neighbourhood, as well as the farmers in Norfolk and the adjoining counties, in the place of home-bred sheep, as being more expeditious feeders, and equally adapted for the purpose of the fold. It has been observed, that it is in fact a breed of sheep which, from the compactness of their form, and their legs being stouter, considerably outweigh both the Dorfed and Norfolk breeds, in proportion to the size of the carcase, being heavy in a small compass. Their hardiness is estimated according to the darkenes of the colour in the face and legs; but as there is inconvenience in the produce on this account, from the wool, especially about the head and neck, becoming spotted with black, and thereby thrown aside by the flaker, as only of half the full value, a middle degree of colour may be best. As an open country breed, they are sufficiently gentle and tractable. They are capable of travelling well, and of refilling the effects of exposure to cold. The wool is scarcely, if at all, inferior in finenes to that of the Herefordshire kind; as the practice of forting, which is common in that district, is not in use on the Downs. The excellent properties of this breed have been brought fully to the notice of the farmer, by the great patrons of improvement in Bedfordshire and Norfolk, and its superior merits on trial have been such as to have induced the sheep-farmers in various districts to introduce them in preference to other breeds. It is stated, in the Annals of Agriculture, that they have been found to consume less food, in proportion to weight, than the Norfolks, yet keeping in better order. Young sheep produce the best lambs; the crones are of course constantly fold at four or five years old; and if it were done earlier, it is supposed, it would be more profitable. The author of the "General Treatise on Cattle" fuggets, that the most noted variety is that of Mr. Ellman, of Glynd, in Suffolk, who, he believes, first enlarged the Down breed, by the aid of polled or not Berkshire tups. From this enlarged crof, he underlines, originated the flocks of the duke of Bedford and Mr. Coke; the South Downs of Mr. Coke being generally acknowledged the largell and finest in England, a very pregnant proof of which was given at lord Somerville's cattle show, in a two-bear Holkham South Down wether, which weighed more than 40 lbs. per quarter. Although quick and early feeders, they tallow within remarkably. And in answer to the complaints of those who knew the old Down sheep, that their wool is become so much coarser than formerly, from the modern habit of feeding the sheep with rape, cabbage, and oil-cake; they seem totally to forget the middle and long-wooled crofs, by which the carcase of the South Downs of the present day has been enlarged, and their weight of wool increased, and rendered more coarse. The mutton is still excellent, although probably not so high-flavoured as the old Down mutton. It is also further fuggeted, that it would be difficult to point out any part of the illand for which this breed would be unfit, but extremely easy to name a vast number of districts where it would be a most advantageous substitue for the native Rocks. It is supposed, that all the South.
South Downs want is the noble covering of a Spanish fleece, and how little their carcase would suffer by the crofs, has, it is faid, been demonstrated by lord Somerville, in the exhibition of a very fine ewe, large enough for any purpose, half Spanish and half South Down. But in order to form a comparison between the Norfolks and South Downs, Mr. Overman of Norfolk, on March 27th, 1799, took from turnips twenty-four two-years old Norfolk wethers, and ten South Down of the fame age, having always lived together from the time they were lambed, and two hours afterwards they weighed as follows:

Norfolk superior by

|                      | 0 3 11\f |         |

Besides these Norfolk sheep losing 11 lb. 10 oz. more of their respective weight (taken full and empty) is a strong circumstance against them. The Downs are run much thicker on the land than the Norfolks. And Mr. Hill of the fame district estimates the difference of flocking between Norfolks

Vol. XXXII.
ing the fold well, and as requiring much expence in winter keep, an acre of turnips being the usual allowance for half a dozen besides hay, has lately given way to the South Downs, which are supposed by some to be harder, les nice in their food, sooner ready for the fold, and more quiet. This last fort has lately gained much ground. The wool might be improved by a Spanish crofs, but little other advantage would be gained. It has been remarked, in refpeft to the quick tainting of this mutton, by Mr. Vyle, butcher of Eaton college, that the Norfolk mutton certainly will taint sooner than any other, in very hot weather; neither is there any fort (that he knows) of a worse flavour at that time, though inferior to none in cool weather. Many very fine and fat Norfolks do not please on the table. The fat runs away in roasting, if they are laid to a hot fire; and they rarely are fo sweet as the South Downs. The latter are in hot weather worth a halfpenny a pound more than the Norfolks. When both are completely fatted, it is hard to lay, (fupposing the fat and cool,) which upon an average is fattell: the flavour too, in such a feafon, he thinks, is equal, and as to coarse meat, there is none in either fort. But if they are killed in cool weather, before they are very fat, the preference must be given to the Norfolks, because the meat will in that cafe eat better, and there is a probability of much more fat within. With refpeft to profit to the feeder, if they are fed entirely with grafs and upon good land, his opinion is decidedly in favour of the South Downs; or if they eat turnips in the winter, and after that are kept two or three months upon grafs in the spring, it is the fame; but if they are half fat against winter, and are to be completed at turnips, he believes no sheep are more profitable than Norfolks, perhaps none fo much fo. But both forts should be kept where there is both turnip and grafs land. These are varieties of this breed in Cambridge and Suffolk, with coarse wooll, and weighing about 18 lbs. or 20 lbs. the quarter.

Crofses of the Norfolk, with the South Down and many breeds of other kinds, are met with and highly valued in different situations.

A great diversity of opinion prevails, in regard to the superiorty of the Norfolk and the South Down, which has led an experienced sheep farmer, at Finchfield in Eflex, to make the very accurate trial which is detailed below. In September 1791, he purchased in Suffolk a lot of ewe lambs, at 6 l. 10s. the score; and in Suffolk, in the Otober following, a lot of South Down ewe lambs, at 13 l. the score. These lots of sheep were depauperated together, and received in every refpeft the fame treatment until the 25th of the fame month in 1793; when a single sheep, which was adjudged to be the only of each lot, was taken out, and after both of them had fofted twenty-six hours, they were weighed alive, the South Down weighing 96 lbs. and the Norfolk 95 lbs.; they were then killed, and the refults of the trial were as follow.

Total difference in favour of Norfolk sheep 9s. 8d.

It is noticed, that neither of those ewes had any lambs, but at the time of trial, the Norfolk was more than half gone with lamb, and the South Down had but just taken the ram.

In short, the leading and characteristic qualities of the high and full-bred Norfolk and South Down sheep, seem upon comparison to be chiefly thefe, the wool of both is found to be of the firft clothing quality, but the larger quantity is produced by the South Down: the mutton of both is equally delicious. But the quiet gentle South Down in the paffure, must be oppofed to the wild impatient ramblings of the Norfolk, whose deftant exertions not only excites continual appetite, but at the fame time occasions considerable waste in the paffure, by treading down and unnecessarily spoiling a great deal of food they do not eat. For this extraordinary exertion on the part of the Norfolk sheep in thus, as it were, wantonly destroying a large portion of food which is prepared for its fubfiftence, there does not appear, from the trial already noticed, to be the smallest occasion at leaff, to put it on an equal footing with the South Down in that particular; for it is evidently demonstrated by that trial, that in an equally fized fheep, the heaviest, and most capacious stomach, and consequently requiring the greatest quantity of food, is found to appertaine to the Norfolk fheep. The hardinefs of the South Down, enduring wet and cold lodging, and a greater degree of abfence and fatigue than the Norfolk in the fold, is an superiority of much moment; and only to be equalled by another, which they poifefs in a very inferior degree, which is that of doing well upon coarse four paffures. These are fairly to be controlled with the delicate constitution, and the tender aromatic herbage, required by the Norfolk; to all which it may be added, that the South Down is an equally good turnip fheep; and for every poftible purpofe, whether for its flefh, for its wool, for breeding, for folding, or for the butcher, they demand a lefs supply of food, and of an inferior quality to that which, in every situation, would appear indispenfible to the well doing of the Norfolk. On the score of the firft cotf of thefe, an objection may, it is faid, be very juftly flated as to their general ufe; but when the South Down are more generally bred and increafed through the country, in that proportion will the prefent obfervation be done away; and though they may continue in equal estimation, they will nevertheless, by their being more generally distributed and increafed ev ery where, be brought to a more equal level, in point of price, with the Norfolk, Welsh, and all those breeds fo juftly held in reparation for the finenes of their wool, and the superior excellence in the flavour of their mutton.

The value of the crofses which have been made between the Norfolk and Welsh sheep, by the South Down rams, are far from being decided, some sheep-farmers thinking them
them highly beneficial, while others strongly reprobate them.

Dumnes Forest Breed or Variety. — This is a breed of forest of sheep, which is found about the forest of that name, in the county of Chester. In point of shape, the animals are said not to be unlike those of a diminutive Norfolk lot, having the faces and legs black, grey, brown, and white, generally with small horns. The breed is small, the wethers weighing more than from 8 lbs. to 12 lbs. the quarter, at four years old. The mutton is in common much esteemed, and the wool is valuable, telling about the year 1828 at 2l. 12s. 6d. the wool of 20lbs; the fleeces are, however, small, often not weighing more than 2 lbs. The wool is commonly purchased by the manufacturers of cluthe in Yorkshire.

Herwick Breed or Variety. — This is a breed which is characterized by Mr. Cullerby having no horns, and the face and legs being speckled; the larger the portion of white, with fewer black spots, the purer the breed; legs fine, small, clean; the lambs well covered, when dropped; the weight per quarter, in the ewes, from 6lbs. to 8 lbs.; in the wethers of four years and a half old, from 9 lbs. to 12 lbs.; the wool short, thick, and matted in the fleece. It is a breed peculiar to the elevated mountainous tract of the mountains of the British Isles, and Duddon in Cumberland, where they are let in herds, at an annual sum: whence the name. At present they are said to pollies the property of being extremely hardy in constitution, and capable of supporting themselves on the rocky bare mountains, with the trilling support of a little hay in the winter season; scratching down to the heat, during the snows, for their sufficiency; and by their constantly moving about, not being liable to be drifted over by snow. From the nature of the climate, the ewes produce their lambs late, and are generally kept as long as they produce lambs. But the wether flock is usually dispersed of from the mountains, without being put in the pastures, at from four to five years old. It is observed, that the fleece in this breed is finer than that of the Heath flock, but coarser than any of the short-woollen breeds. It is a breed that hands in need of a cross with some of the finer-woollen breeds, and the Spanih has beenoggled as proper for the purpose. The property of the flock, as well as of the mountains, is in Lord Muncaster, the lord of the soil; and the farmer of the principal flock is now Mr. Tyson, who family, it is said, have inhabited this wild and ferreterted spot through four centuries. Mr. Tyson is a tup breeder, and sells a number of Herdwick rams yearly, some at several guineas each, to the adjoining districts, where their known hardy qualities are desirable.

Cheviot Breed or Variety. — This breed of sheep is known by the want of horns; by the face and legs being mostly white, and the eyes lively and prominent; the belly long; little depth in the breast; narrow there and on the chin; clean, fine, small-boned legs, and thin pelts; the weight per quarter, when fat, from 12 lbs. to 18 lbs.; the wool partly fine, and partly coarse. Mr. Cullerby considers this as a valuable breed of mountain sheep, where the herbage season is chiefly of the natural grass kind, which is the cafe in the situations where these are found the most prevalent, and from which they have obtained their name. It is a breed which has undergone much improvement within these few years, in respect to its form and other qualities, and has been lately introduced into the most northern districts; and from its hardiness, it affords a portion of fine wool, and being quick in fattening, it is necessary well in such situations. The Spanish and South Down have been advised as proper crosses for this sort of sheep.

And it is observed by the writer of the Argyllshire Report, that the Cheviot sheep are in every respect incomparable to the black-faced kind, and found to be equally fit for a mountainous situation. They are hardy, fine-woollen, and well shaped. They are long-bodied and long-legged, which fits them for climbing steep mountains, and for travelling, either for seeking their food, or going to a distant market. Their fleece, too, is finer, closer, and warmer. They have every property that should be found in a mountain sheep, and accordingly they have been found to thrive in every part of the Highlands in which they have been tried, and are said to be less subject to diseases than the black-faced kind. Some of them have been lately introduced into the county by the duke of Argyll, and by Mr. Campbell of Auch, in the highest parts of Glenorchay, and found to answer exceedingly well. And Lord Breadalbane, a few years ago, made a present of some Cheviot wethers to several of his tenants in Glenorchay, in order to try how they would fare on the same pastures with the black-faced kind; and the writer was informed by some of the farmers, that they perceived no difference in their thriving. Indeed no part of this county is more inclement than that from which they came, where the hills are sometimes covered with snow for three or four months in a year, and where many of the lower walks consist of peat-bogs and deep morasses; so that with us their situation would be mended, a circumstance which will always ensure success.

It is likewise stated in the twelfth volume of the Statistical Account of Scotland, that the following experiment, made in the parish of Barr, in Argyshire, shews the comparative hardiness and value of the Cheviot breed. In June, 1792, a ram and two score of ewe hogs, of the Cheviot breed, were put upon one of the highest and coldest farms in the parish. The harvest was wet, the winter and spring stormy, and the lads of the native sheep, through poverty and distemper, was considerible; yet all these, through strangers, and in such a situation, did well. The wool of the native sheep, taking ten fleeces to the stone (24 lbs.), folded at 72. 6d.; the wool of the Cheviot kind, taking only seven and a half to the stone, folded at 97. The profit here was greater; but how much more, if the wool had fetched its real value of 20. the stone! And in "The Observations on different Breeds of Sheep," it is stated that in 1793, the Cheviot wool fold from 18. to 20. the furred, and from 20. to 22. the white; from five to eight fleeces of the first, and from eight to nine of the last, going to the stone. Some went as high as 25.; and it is thought it will soon be improved so as to fetch 30. if not 40. Draft ewes fold from 12. to 16., and three-year old wethers from 18. to 22. In Etterick, Eyrewdale, and Liddeddale, they are now converting their flocks as quickly as possible into the Cheviot breed. The Roxburgh Agricultural Report also says, that Liddeddale is the worst district, yet the Cheviot breed thrive in it. The writer of the first of these Reports remarks, that it is difficult for those who have already got another kind to change the breed; but new beginners ought undoubtedly to flock with the Cheviot kind. It is said that the Yorkshire graziers have a prejudice against this kind; probably because they would then have more rivals in the trade, which is now in few hands; as the cartage, and not the wool, is the principal object of attention. Whatever there may be in this, the introduction of the Cheviot, which would treble the price of wool, would more than balance it. And he adds, from the same volume of the Statistical Account of Scotland, that even they who have another flock, and cannot conveniently change it, might yet at least cross it with the Cheviot breed, which might
be done with little trouble, and to great advantage. In the years 1787, 1788, and 1789, an intelligent farmer, in the parish of Moffat, put Cheviot rams to his black-faced ewes. In 1790 he fold the wool of the sheep produced by that cross at 1s. the six fleeces; and the wool of his other flock of the black-faced kind, which went exactly on the same paiture, only at 6s. 3d. the seven fleeces. The sheep thus produced were as healthy as his other sheep, the car- cafe not materially altered, and the weight of the wool increased a fourth part, and its price more than a third. The farm on which they were as high ground as almost any in Scotland.

And the sheep which are at present known by the title of Long Hill sheep, by the northern farmers, are a hornless, white-faced, loofe-shaped breed, having a coat of ordinary short or fine wool, perhaps raised by crossing, through time, the old country breed with those of the Cheviot kind. They are said to be more tender than the short or black-faced breed, but to answer well with good care and keep. However, from the practice of milking ewes of this breed, for the purpose of making cheefe, being found to be pre- judicial, it has lately been much left off by the beet sheep- farmers in these districts.

The Dun-faced Breed or Variety.—This is a small breed which Culley says has no horns; the face in common of a dun tawny colour; the fize small; the tail short; the mutton fine in texture; the weight often only 6 lbs. or 7 lbs. the quarter; the wool variously streaked and blended with dif- ferent colours, some of which is very fine. He supposes it to partake of the Spanish breed, but it is not so hardy as the Cheviot breed. The mutton of this breed is excellent in flavour. They aresupposed by some to have had a Spanish origin; but they have been naturalized, for a great length of time, on the Grampian and other hilly districts in Scotland.

The Shetland Breed or Variety.—This is a small breed, and mofly without horns; but what more particularly dif- tinguishes it from other breeds, is the uncommon smallness and shortness of the tail; the weight per quarter from 7 lbs. to 10 lbs.; the wool very fine, and of various colours. The breed is very hardy, but much too wild in its dispo- sition to be confined in inclosed pastures, and of course lefs proper for the purpofes of the grazer. There is a fort of this breed of sheep, which, according to Mr. Johnfon, carries coarse wool above, and fine soft wool underneath; and the sheep have three different successions of wool an- nually, two of which seem long hairs rather than wool, and are by the common people termed fers and feuada. As soon as the wool begins to loofen at the roots, which is mofly about February, the hairs or feuada spring up; and when the wool is cautiously pulled off, the tough hairs con- tinue faith, until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired two months’ growth, or there- abouts, the rough hairs, termed fers, spring up and keep root, until the proper season for pulling it arrives, when it is plucked off along with the wool, and is separated from it, at the time of dressing the fleece, by an operation called forfing. The feuada remains upon the skin, as if it were a thick coat, a protection against the inclemency of the season. But the native or kindred breed, that bear the soft cottony fleeces, according to Mr. Culley, are rather dele- cate; though the fact of their eating the tea-weed greedily, when the ground is covered with snow, and often during long and severe frosts, when they have little cloe to live on, seems to prove the contrary. Nature, he says, seems to have imparted to them a perfect knowledge of the times at which this food may be procured; for immediately upon the tide beginning to fall, they in one body run directly down to the sea-shores, although feeding on hills several miles distant from the sea, where they remain until the tide returns, and obliges them to seek their usual haunts. They are very hardy, and the wildfet of all the breeds of these animals.

But in respect to the wool of these beaver sheep, as they are sometimes termed, it is short and open, and deftitute of a covering of long hairs. These fine loft fleeces are liable to be rubbed off during winter, or early spring, which, it is supposed, might be prevented, by clipping the sheep in the usual way, instead of the absurd mode of pulling them off, which tends to weaken the sheep, and decrease the length of the blanket of the wool. In regard to colour this wool is various, as flaver grey, which is the finest and softefl; the pure white, which is mostly of the greatest value for all the purpofes of the finest combing wool; the black, and the mowrat or brown, which are very little inferior; the whole of the softest texture, fit for the finest manufactures, and in some instances rivalling even Spanish wool, than which it is somewhat longer in the blanket, and not so elastic. And it is flated to have been manufactured into stockings of ex- traordinary fineness; and that the fleece attached to the skin affords a fur of great value. This breed was formerly a native of the higher parts of Aberdeenhife, and in the districts to the northward of it; but it has been since much crossed, and it is now mostly confined to the Orkney and Shetland ifles, the purest breed being to be found in the latter. The number of the beaver sheep in these ifles amounted to ninety thousand, some years fince; and five or fix of them are faid to be capable of being fed with the food required for one English sheep. In the Weft Riding of Yorkshire, Mr. Beaumont is faid to have made a trial of these sheep; the result of which was, that they did not f rum, but grow, which fews that their size would improve with that of the fof; their wool also improved in length. But the original old breed of the Highlands are faid to partake of the nature of the goat and deer; their coat conftituting of a fort of fur or down, covered by long, straight, rigid hairs, like thofe of the beaver, rather than wool; tail short, slender, tapering, not larger than that of the deer or goat, and thinly covered with brown, fivery hairs; the face covered with fleck hairs, like the face of the deer, with his prominent eyes. They are tame, delicate of frame, and requiring to be houfed in winter; their fflf of high venifon flavour. The breed is found in its original purity, in the central Highlands, on the southern banks of Strath Tay, and between thofe and Strath Brand; and on the banks of Loch Nefs, in the northern Highlands, as well as in the Shetland iflands.

The Merino or Spanish Breed or Variety.—In this breed of sheep the males have horns, but the females are without them. They have, according to lord Somerville, white faces and legs; the body not very perfect in ihape; rather long in the legs; fine in the bone; a degree of throatiness, or production of loft pendulous skin under the neck; and the pelt fine and clear; weight, when tolerably fat, per quarter, in the rams about 17 lbs., in the ewes 11 lbs.; the wool very fine. It is a breed that is affected by some to be tolerably hardy, and to possess a disposition to fatten readily; but others maintain the contrary opinion.

His majefly took the lead in the introduction of the Merino breed into this country, and his firft flock was imported in 1793; but other nations seem to have got the start in this refept, as Sweden had them even in 1723, where they have fince greatly increafed; and in France, Germany, and some other
SHEEP.

other states, they were probably known long before. They have lately spread much in this country, and been greatly improved in different respects, by judicious crossing with other breeds. The horns in the true Merino rams are now of a middle size; the faces and legs darkish-white, the latter rather inclined to be too long. The wool is uncommonly fine, and weighs about 34 lbs. to the fleece, not being liable to deteriorate in this climate. The fleeces have a dark brown tinge in their surfaces, formed by dust sticking on the greasy woolly property of its pilus: the contrast between which and the rich white coloured wethers, and the rosy hue of the skin, is very striking on the first view.

Some crofs the Merino rams with Devonshire ewes, but the Ryelands are more commonly preferred. They consider five crofts as necessary for reaching perfection; and on that ground properly conclude, that the wool of the five crofts can only reasonably be supposed to be worth about 7d. the pound more than that of the maternal flock, on the idea that it will, in five crofts, be of the value of 3s. above that of the Ryeland ewe; making an improvement of about 7d. in each croft. And that if the wool, when this is mixed with the most valued native breeds, does not gain its necessary degree of fineness in less than five crofts, it is unreasonable to expect the full price for it at one croft. It is, however, certain that the animal is improved by a mixture with the Ryelands, and that the wool will not ultimately be found inferior to that of the Spanish flock. The Spanish crofs with the South Down and Ryeland, in several degrees, is diffusing itself in many districts with great benefit. With the latter, in Devonshire, the wether produce, at two years old, weigh 15 lbs. the quarter, and afford a fleece of 5 lbs. each, worth 3s. the pound. In other cases, the weight of mutton is greater in the five crofts; and the sheaf of wool from 64 lbs. to 7 lbs. in the year to the fleece, at the same age. Crofts with some other fine-woollen breeds are likewise made with great utility.

But according to Dr. Parry, who has had great experience of this breed, they are, as rated in a late work on Live-stock, entirely enveloped in wool, which grows under the jaws, down the forehead to the eyes, under the belly, and down the legs to the very feet. It is astonishing to see how thickly it covers the skin; it will scarcely give way to the pressure of the hand, but yields as it were by flairs, like the close short hair of an extremely fine clothes-brush. In washing them, the waters penetrate to the skin with great difficulty. This fleece is heavier, in proportion to the carcass, than that of any other known breed in Europe. In the raw state (unwashed on the sheep's back or afterwards), the fleeces of the two-years old ewes average at 45 lbs. avoirdupois, and the weight of the living ewe being about 66 lbs. the proportion of wool to that of carcass is about 11b. to 12lbs. The fleece of a fat wether of the same age will be from 66 lbs. to 71 lbs. In eight shearing rams, weighed alive, after having been clipped, the weight of the fleece to that of the living animal, was as one to about twelve and three quarters. The wool from the head and behind the ears, and the rest of the refuse, generally called daglocks, had been previously taken away. It is added, that had sheebe been washed before shearing, their fleeces would have lost about a ninth part. And that the length of the staple or filaments varies. In a shearing ram, thorn when a lamb, a sample of the wool cut close to the skin above the shouldcr, was three inches and a half in length; and that of the breech, or middle of the back part of the thigh, three inches and three quarters; of an ewe of the same age, about a quarter of an inch shorter; the average according very exactly with the specimens taken from newly imported Spanish sheep. An instance of the extraordinary length of staple, of four inches and three quarters, is related, which from the current fleece produced a sample more than five inches long. The proportion of fine wool in the fleeces of the Spanish sheep is much greater than those of any pure English breed. Thus, while in the Ryeland, which is probably divided into four or five farts, the least wool from the neck and shoulders does not make above one-eighth part of the whole fleece: in that of his majesty's flock, the fine wool formed near four-fifths of the whole.

It is farther observed, that of Dr. Parry's wool, consisting of whole fleeces taken from fleece which had not more than three or four crofts of the Spaniard, and divided into three farts (R. F. T.), according to the Spanish method, 155 lbs. produced of R. or Rambous, or superfine, 104 lbs. more than two-thirds of the whole. And the uniformity of fineness in the improved wool is such, that in shearing specimens from these different parts of the same animal, (the shoulder and the breech,) which are generally considered as producing the belt and the worst wool; the doctor never met with any three persons who could agree which was the finest, and many good judges actually decided in favour of the latter. This wool contains a great deal of yolk, or oil, which is apt to entangle the dust of the fields, so as often to form a kind of mat of nearly an inch in thickness; it is remarkably, or rather wholly free from felts, or kernels. Brown fleeces in the wool of any particular sheet is an indication of inferior fineness (and such was the colour of the ancient fine-woollen sheep, and we need not look for the cause in any peculiar quality of oil or composition mixed with the wool); it will nevertheless fibric white. But according to lord Somerville, this dark-brown tinge on the surface of the belt fleeces amounts almost to a black, which is formed by dust adhering to the greasy woolly properties of its pilus; and the contrast between it and the rich white colour within, as well as that rosy hue of the skin, particularly denoting high proof, surprise at first sight. The harder the fleece is, and the more it refits any outward pressure of the hand, the more close and fine will be the wool. Here and there a fine pile may be formed with an open fleece, though but rarely. And in Mr. Tulloet's Spanish flock, purchased from lord Somerville, the average weight of each Spanish fleece in the grease was 5lbs. 13 oz., and the lightest ewe fleece 5lbs. 4 oz., and the heaviest ram fleece 6lbs. 12 oz. of very good quality. This ram was twelve and a half or thirteen months old at shear day, and was adjudged to weigh 20 lbs. per quarter. Mr. Tulloet declined the price of two hundred guineas for them, likewise that of one hundred for the use of him during the tappning season: he does not wash his Merino sheep before shearing, since, from the closeness of the fleece, it is not much liable to the intuuction of dirt: as it does not lose quite half its weight in scouring by the manufacturer, an ultimate may be made after that rate of the value of the fleece in the yolk. The fleece of the young ram produced upwards of 35r. and the average produce of the whole unwashed Merino wool 18s. 9d. each fleece. The price of the superfine more than four-fifths of the whole, 6s. 3d. and 6s. per pound of the third part, or free, which was but about one pound in the whole quantity. Mr. Bartley has somewhere mentioned, that four wethers of this breed produced the quantity of 352 lbs. of wool; and of several ewes which produced 8 lbs. each, and of a wether which gave 12 lbs.

In the introduction of this breed his majesty, as has been seen, has taken the lead, and from his flock a great number of the improvers of it have been supplied in the different
SHEEP.

Different flocks that have been made since its first establishment. In the sale of 1803, in Kew Lane, under the direction of sir Joseph Banks, the numbers sold, according to some, were twenty-four shearing rams, which produced the sum of 402l. 6s.; seven full-mouthecl and four toothed rams, 17l. 13s. 6d.; fourteen ewes, 118l. 8s.; amounting in all for the forty-five fheep to 662l. 10s. 6d. The highest price of the shearing was 42 guineas, the lowest 6d. 7s. Of the full-mouthecl rams, 28 guineas were the highest, and £1 3s. 6d. the lowest price. Of the ewes, 11 guineas the highest, 6d. the lowest. The rams were put up at fix guineas, the ewes at two guineas; the former prices at which they were allowed.

The wool has been sold this year unsorted at 4s. 6d. per pound. The size of the ewes somewhat under our pure Ryelands, but above several of our small breeds; heads sharp and well-shaped, with occasionally a black spot or two; wool externally having a dirty tinge, but without that red-brown hue which has been before mentioned; ears pendulous; perfect ewe-neck, with the linking or cavity both before and behind the shoulder, the top of which is generally higher than the rump; capacious belly, the animal flanding wide and well upon the legs; the rams generally of a good size, some of them large enough for any purpose whatever, and of a great bone, but flat and symmetrical; several of them were of as good and useful form as need be feen, having compact loins and shoulders, and straight backs. Two or three individuals remembled very strikingly our Dorset and Hampshire flock; the characteristic velvet or silk-en glofs on the thorn faces of the rams was remarkable, and their countenance put one in mind of the fair-haired human complexion. Mouths by no means fine.

And it has been observed, that the large tuft of wool covering the face of Merino sheep is extremely inconvenient in northern countries, where they have frequent heavy drifts of snow. And that it is lord Somerville's practice to clip this and the leg-wool two or three times a-year, beginning about fix weeks after shearing. But that in winter, and in very rigorous climates, it may not be proper to leave the head too bare and exposed, as it may produce disease. These clippings may be proper for inferior purposes, and the fleece be rendered more pure and valuable without them. The tuft on the head, and even the throating, or protruberance in the throat, characteristic of the Spanish fift, are, as it is affirmed, discoverable, in degrees, in some of the native breeds, particularly the Ryeland, shewing its origin. And a good judge, Mr. Knight, contends, that the produce of a crofs with this breed, and the Archenfifd or true Ryeland fift, is extremely ugly, and, according to his information, subjéct to the foot-rot. On some rich pastures in Middlesex this has also been found to be the case in both the true and crofsed breed.

The Mugged Breed or Variety.—This is a singular breed of sheep, which formerly prevailed throughout all the low lands of Northumberland. They had a short, coarse, curled wool, covering their heads, faces, and legs, and grew down to their feet; in form they resembled hill sheep; their shoulders low and sharp; faces flat; back rather arched; loins thin. It has been suggested, that this mugged appearance may have been the refult of a Spanish crofs. This fift of sheep has extended to Yorkshire; and traces of them are still visible; although they have long since given place to thep of the long-woolled kinds. They are now chiefly met with in the northern counties.

The Welsh Sheep or Variety.—These, which are the most general breed in the hill districts, are small-horned, and all over of a white colour. They are not compact sheep. There is likewise a polled short-woolled fift of sheep in the parts of the country, which are effecled by some. And the genuine Welsh mutton, from its smallness and delicate flavour, is commonly well-known, highly esteemed, and sold at a high price. But the fattening of the small Welsh sheep has not in general been found to answer in the southern districts of the kingdom. In short, this is a breed which flands in need of much improvement, and which is capable of admitting of it with much advantage to the sheep-farmers of that district.

The Woolly or Variegated Breed.—This breed is described in this way by Culley. These sheep are supported by very long, thick, crooked, grey legs; their heads long and ugly, with large flagging ears, grey faces, and eyes sunk; necks long, and set on below the shoulders; breasts narrow and short, hollow before and behind the shoulders; flat-sided, with high, narrow, herring-backs; hind-quarters drooping, and tail set low. In short, they are almost in every refept contrary to what he apprehends a well-formed sheep should be. The spirit of improvement in sheep-flock has however extended itself to Ireland, and there can be no doubt, therefore, that they will soon improve this as well as other forts of live-stock.

Indeed, since the period in which the above account of Irish sheep was given, many useful and important alterations and improvements have been produced by judicious selection and crossing in this fort of flock, in several different parts of that country. However, independent of these numerous breeds or varieties of sheep, which are inhabitants of this island, there are in other countries many other kinds, which may be just noticed for the sake of curiosity, as they are occasionally seen in parks and pleasure-grounds in this intention. The more cold districts of Iceland and Russia afford a many-horned breed of sheep, molly from four to seven or eight; having a coat of dark-brown coloured hairy wool, weighing about four pounds, and covering an interior one of short soft fur. Also in Russian Tartary, a large lop-eared, polled aquiline-nosed breed of sheep, somewhat resembling the Wiltshire and Dorset breeds in their shape, are produced, and which have a long thick wool, of a black and white mixed or roano colour, and in the place of a tail, a large cushion of fat occupying the rump; hence some naturalists have called them fat-rumped sheep. This and the broad-tailed breed are sometimes called the Kalmuck and Altchan breeds. The projection of fat, in this, has an exquisite delicate marrowy taste. Some lay the wool is rather short, not coarse, but having hair growing through it. They are said to be so prolific as to bring two or three young at once. And in Walachia, Crete, and through most of the Archipelago islands, there is a breed of sheep which have singular horns, twilled in a spiral or screw-like manner, standing in a perpendicular or diverging extending manner from the fore-part of the head, to some height. In size and shape tolerable, bearing a long flabby but not coarse coat. Likewise in the extended districts of Persia, Syria, Egypt, and Barbary, the broad-tailed sheep are met with, the tail in some of which grows to the breadth of a foot, and to a length to bring them to the weight of from twenty to fifty pounds, on which account the shepherds are sometimes under the necessity of support-
Sheep.

ing them on a carriage to prevent them from galling and exhausting the animal. These appendages are mostly also esteemed as a great delicacy, being of a nature between fat and marrow. Further, some of this breed of sheep, especially those of the mountainous parts, have a wool of extraordinary length and fineness, from which are made the expensive Indian shawls, and some other fabrics.

And the Guiana breed of sheep, said to be common in tropical climates, is large, strong, and swift, and though domesticated, are often found in a wild state; having coarse, hairy coats, short horns, pendulous ears, and a coat of development at the chin.

What is called the Madagaascar breed of sheep, is also of a good size, and well covered with a close pile of smooth glossy hair in the place of wool.

The Bucharian breed of sheep is also hairy, and kept in large flocks in Great Tartary. The island of Antigua has likewise a breed of the same kind. Sheep of this sort were imported from Spain by Sir Joseph Banks, with coats as sleek and smooth as those of a horse, and which never, at any season exhibited the leafy appearance of wool or down, or any thing of a similar kind.

It may be noticed, that it has been well flated in a late practical work, that in the breeds of sheep there are evident differences in their fizes, forms, flesh, wool, and other properties, that admirably adapt them for different sorts of pastures, situations, and uses of the farmer. And that the large long-wool'd breeds, from their being more flowy, heavy, and tame in their dispositions than most other kinds, are in general the most proper for the rich inclosed pasture districts: the breeds which possess greater length in the legs, more activity in walking, and a lefs burthen of wool, are suited to the more elevated lands, such as the downs, moors, and heaths in different parts of the island, where the pasture is lefs fertile and luxuriant; and that the small light caracol'd hardy breeds are most adapted to the exposed mountainous situations, where the food is more sparing, and obtained with greater difficulty and expense. And in the Rural Economy of the Midland Counties, it has been observed that a very long-wool'd breed of sheep, as the old Lincolnshire or Teeswater body, is necessarily also in the view of our fknell wrought manufactures; and another, such as that of the new Leicester, for the inferior kind of grasslands, and the rich inclosed arable lands, where the folding system is not in use; for the supplying the materials of the coarser sorts of worsteds, stockings, coarse, coarse cloths, blankets, carpets, and other articles of the same kind: while a middling-wool'd breed, as the Wiltshire, the Norfolk, or the South Down, is wanted for the well-soiled arable lands, where the practice of the fold is in ufe, in the view of making cloths of the narrow medium kinds; a very fine-wool'd breed, as the Herefordshire Ryeland, for the finest cloths; and the Shropshire, or some of the more hardy breeds, for the hearty mountainous situations. The Spanish and Cheviot breeds may also be proper in the last intentions. What is therefore chiefly necessary to be regarded in the introducing of new breeds of sheep, is to consider with attention the nature and situation of the pastures on which they are to be supported, and to carefully avoid making use of larger or finer breeds than can be properly sustained: as upon due management in this respect, much of the success in the improvement of sheep-flock must necessarily depend. Where bettering the form of the animal, and improving the quality of the wool or coat, are the principal objects, they may be effected by judicious crossing with proper breeds for the particular purpose, on the principles that have been explained in speaking of the care of breeding, and which is farther shown below. (See Breeds, Breeding, and Lives of Men.) Indeed this last circumstance is one which should particularly engage the notice of the farmer in the business of flocking his lands with sheep, as it is seen from numerous statements, that wool of the best quality may be produced in this country by means of Spanish sheep, and then being properly crossed with the crossed breeds, which is a matter of the greatest national importance, as affording a probable means of rendering us independent of the foreign supply of this expensive but indispensable article. The breeding sheep farmer should therefore be particularly interested in promulgating this sort of improvement, in all situations where the nature of his land will admit of it, which lord Somersville has shown may be the case in most instances where the short-wool'd breeds of sheep can be properly kept, or probably on more than one-half of the pasture-lands of the island. And he has remarked that there is one inducement to this, which is that of its not interfering with the production of the most valuable sort of mutton, a point to which the sheep-breeders of this country have till lately been particularly attentive, almost without regarding the quality of the wool; as it has been found that the quality of the sheep is the different qualities of wool; as it has been found that the quality of the wool is the different qualities of sheep inclines to the nature of the wool, the short-wool'd sheep being close in the grain of their flesh, of course heavy in the scale, and in the tale high-flavoured; while the pulled long-woool'd fort are more open and loose in this respect, larger in size, and the mutton more coarse, and in general less saleable in the different markets in the kingdom.

In sheep there are certain good or bad qualities, properties, or dispositions which mark their value and importance in the view of the farmer, grazer, and breeder. That such certain peculiar properties and dispositions prevail, is well known to experienced persons of these descriptions, by sheep in exactly similar circumstances in every respect becoming more or less quickly in the taste of fatteners, &c.; as an improved disposition in them signifies an aptitude to convert their food or nourishment into flesh and fat. Thus, in a number of sheep of the same kind and age, under the very same management, when handled, a vast difference will be found in their condition and state of fatness, &c. Some will be in a flate to go off many months before the others are ready, although put on the same land in equal fles; and others, though kept far beyond the usual period of time, will never get into sufficient condition. The disposition of the former must, of course, be very beneficial and desirable to such sheep-farmers, as well as advantageous to the community, while that of the latter is quite the reverse. This is likewise the case in the breeding of ewes, as those which have it well and in the bell rate at the lambing time. But there are, it is supposed, some influences of exception in this and other dispositions of sheep, which poffefs good qualities, that have been improved, that such sheep improves as the above should also be careful in detecting, otherwise they may be liable to suffer considerable injury and loss; and it is frequently seen on killing different kinds of sheep, that there is great difference in individuals of the same breed and variety.

There are several circumstances which are supposed to form or contribute to this goodness of disposition in these animals; they must be well bred, or come from such as have good properties; they must not be permitted ever to be in a state of want of food, or be reduced in flesh; they must have constantly good food in sufficient abundance, the richer, to some extent, the better; they must have their...
frame or bone not too large for the quality of their keep; they must have a due relative proportion of parts; they must handle free and mellow in their flesh; they must have a peculiar appearance of countenance; and they must be perfectly tame and quiet. There are also other causes which in some measure conduces to this end, but they are of less certainty in their operation, such as the stature and action of the blood in the system, &c. The external forms and qualities of sheep which shew a good disposition are, a smallness of the head, a thinness and shortness of the neck, a deep wide breast, a wideness over the shoulders, a broad, straight and deep carcase or barrel, a smallness of bone and feet, the joints moderately short, the muscles or flesh plump and full, with a thinness about the infection: the skin middleingly thin and mellow, of a fine texture, and a clear red and white colour; the wool of a yellowish-white appearance, a curly nature, and neither too long nor too short, but thickly set, the fat and flesh soft, with some sort of firmness in handling, and the countenance pleasant, and inclined to quietness.

The improved disposition or quality of sheep is promoted by taking them from poorer or inferior keep or foils, to such as are of a better and more rich kind, as in the case of fedds: but the removing of them from rich soils or keep, to such as are of a worse nature, has directly the contrary effect. The quality of the flesh, in one case, becomes soft and mellow, while in the other it gets more close and hard.

The nature and quality of the land or foil, when any breed of sheep are kept upon it for a length of time, will, it is believed, throw out the suitable size for it, and certain accidental qualities will occur according to its fort, which, when properly managed by the breeder, will afford an improved disposition in the animals. In such a case improvements may have a probability of being produced, by having the male smaller in size than the female, and by changing him from too good or rich keep, so that his constitution may be in some measure delicate, by the female having her nourishment regular, and so as at no time to be lowered in flesh; and when a more full supply of food may be wanted, by the increase being moderate, so as to preserve rich keep for the young, in its advancing growth; by breeding from such sheep as are the most kindly, th' the bell disposition, and allow the fullest profit, on the particular foil or land on which they are bred and fattured; by choosing and selecting the middle-sized sheep of the flock to breed from, and not the largest, as it is favourable to be rather under than over the quality of the foil or land for forming good disposition; by restraining to breed from sheep displyasing a bad disposition, or which have defects; and by cautiously using for this purpose ewes which have had lambs, and are not too old, as disposition is supposed more likely to be produced from the second than the first lamb: and lastly, by the mode of breeding that is called in and in, or in the same line, which greatly contributes to form disposition.

In the degenerated form of sheep, the reverse of all this will, of course, mostly take place; they will have thes qualities or properties in a larger or smaller degree; their heads will be generally short and thick, though occasionally rather long, and of a coarse nature; the neck, for the most part, long, thick, and concave in the higher part; the carcase long and thin, and the ribs flat, usually termed "flat-fided," while in improved sheep they bow out almost at right angles with the spine, in somewhat the barrel manner. Narrow shoulders, the loin not wide, the back not straight, and the belly gutty; the breast or chest contracted, without being deeply set down; the legs long, and thighs not full or fleshy; the flesh thin, of a close texture, and thick about the infection of the muscular parts; the feet large and coarse; the flesh hard in handling, or what is sometimes denominated "flicky;" the countenance far from pleasant, and the nature wild; the wool coarse and hampy; but capable of improvement by attention; difficult, or requiring time in fattening; the mutton often of good quality, for eating, of a firm grain, sweet flavour, and abounding in gravy.

Sheep of this kind in general require a much greater quantity of food for their growth and support, and for fattening, than the improved fort, which is a circumstance that must evidently be disadvantageous to the breeder, grazer, and the whole community.

All such persons as are in the habit of breeding and fattening sheep, and have sufficient experience, find that they depend on the qualities or properties of their breeds for growth and improvement: some will not fatten at all, or be as long again in fattening as others, and this moit commonly occurs in such as are not of the individual's own particular breed or kind. The degeneracy of sheep is readily seen and easily proved in the management of them. And once confider almost the whole of the breeds or varieties of this country to be more or less in this state, or that there is not probably more than one which can be said to be truly in an improved condition, on the exact principles of improved forms.

This degeneracy is in a great measure the conquence of neglect or error in the breeders and managers of sheep, as when they thrive and fatten well, that is to be attributed to proper selection, suitable keep, and a due regard to the true and exact principles of management; but when, on the contrary, they do not go on to fatten well, but decline into a state of degeneracy, it proceeds from neglect, starvation, and the want of such true principles in their regulation and management. As though a lamb may pooffes good proportions, yet from neglect and other caufes, it may be reduced to a state of poverty; which, when it takes place, its degeneracy may be dated from that period, as its constitution is injured, and an unfavourable action is given to the system. The longer it is kept in this state, and the more frequent the changes it may undergo, the more confpicious will its degeneracy be. Nature, then, it is supposed, will throw out indications in conformity to this: the head will increase in size in a greater proportion than the other parts. The body will become thin and long; the bones will be irregular in their growth; and there will be a want of symmetry in the whole system. The caufe which are the foundation of such degeneracy are believed to be these; the rams being too large in size, and kept in too high a manner; these and the ewes not being well adapted to the foil, but too large; the lambs being kept in an occasional state of want or starvation; the neglect in not breeding a proper number for the purpose of selection; the ignorance of breeders in regard to the true principles, in respect to the forms of sheep or their management; the frequent crossings of varieties of the same breed; the presence of dry summers and hard winters, which tend to incline the constitution to an unfavourable action, and consequent degeneracy; and the want of good water, which is very prejudicial to sheep.

It is fuppofed, that it is to be lamented, that almost all the breeds, in every situation, are found to have one or other of the bad properties or qualities already noticed. However, of all sheep, the shape or form of that of the Indian fort is probably the worst which is produced; and the Wiltshire, the Welsh, and many other breeds, are not without partaking of too many of the properties and imperfections of the same kind, in addition to
It is to be hoped, however, that a more active exertion, and investigation of the matter, in sheep-farming, will in a short time be productive of the requisite improvement in the art of live-stock, and that by having recourse to superior modes of breeding, rearing, and management, an equal pace will be kept in the advancement with that of any other branch of the farmer’s art.

It may be noticed, notwithstanding what has been already said, that it is hard to be almost universally and unanimously the practice of the breeders on the South Down hills, to exchange the rams every third, fourth, or fifth year, as it is conceived essentially necessary to the preservation of the health, the fize, and the bone of the flocks, though quite contrary to the maxims laid down by some eminent sheep-farmers, who are frequent promoters of the method of breeding in as, or in the same line, continually, when there is a good breed or sort of sheep. Flocks that are rated to have been nearly ruined in constitution and habit by this means, are said to have had a wonderful improvement by the change of the rams. See Breeding.

The question concerning the best and most profitable fize of sheep for the purpose of the grazing farmer, and for producing the largest acreable quantity of food and other products for the use of the community, is a matter of very great interest and importance. Though it cannot probably be disputed but that different fized animals of this sort must be had recourse to for different situations, forts, and qualities of land, &c. yet the considerate sheep-farmer will, perhaps, most properly perceive the property of having his ground stocked with not too large a sort of sheep. It will most likely be the best way for such farmers to fully consult the nature and properties of the soils of their pasture or other lands, previously to their fixing upon the fize of their sheep-flock, which will be the most suitable and advantageous for them, as where their pasture or other grounds are inferior in their nature and richness, the fize, of the live-stock of this sort, which is admitted, cannot with propriety be so large as in the contrary circumstances, even where light flocking is practiced, for hard and pinching feasons will reduce the flock to the quality of the land. Though many are advocates for very large-fized sheep, probably from want of sufficiently considering the nature of the subject, it is never found that those who flock with fuch large animals, ever produce so much mutton on the acre, or gain so great a profit on it, as those who make use of a middling-fized stock. Some indeed think that four small-fized sheep may be kept on the same extent of land which is required for three large ones; and that in some cases, allowing the sheep to be equal in disposition, the same number of small ones, of about nine ftons each, may be fattened on the land that will barely be sufficient to feed three of from ten to twelve ftons. Small-fized sheep-flock have also many other advantages attending them. Many make complaints against sheep with improved forms, such as the new Leicesters, as being too small, from the mistaken idea of their close form, as although they may be short and compact, there is a greater width and depth of carcass in them; by which they do not come much, if any thing, short of the weight of the more apparently large breeds.

It is unquestionably a great error to think that the fheep-grazing principle to choose sheep of too large a size for the constitution of the soil, and the quality of the keep which it affords. The nature of keep will indeed itself be the cause of different fizes in sheep-flock, if they be readily maintained on the same sort of land for some length of time, and this in some measure has produced the differences of fize in the different breeds of this animal.

The particular advantages of the different fizes of sheep may be summed up somewhat in this way. Those of the largest sort are humped capable of being kept in equal proportions, on the same quantity of land, and of bringing a more profit at the market, than the smaller breeds; they are likewise conserved to fatten in a more kind manner. If the bulk of these considerations were true, they would certainly have a decided superiority, but the result of well-known trials shows that equal proportions on the same pastures, shew the contrary to be the case. And in regard to the latter, it has probably proceeded from its being noticed that the large sheep are mostly the strongest and best shaped, without considering that they are always below the quality or constitution of the soil or land on which they are fed or fattened; hence it is by no means in favour of large sheep on all kinds of land. And though it is from what generally allowed, that two small sheep of the same breed will equal in weight one large one, yet the latter will have less offal in proportion than they, which is certainly a desirable property in large flock of this kind.

Small sheep-flock are however more active, and feed clover, than large sheep; as well as on food which is of an inferior quality; they are capable of being folded in the proportion of three to two on the land; they will produce more meat on the acre, and be more hardy than large breeds; they injure pastures less than large flocks; they will, where the proportions are the same in relation to the fizes, soonest become fat in the smallers, in any two sheep. This may probably be concluded as always the case, where the regularity of form and proportions are equally good and exact; as small sheep reach the rate of maturity sooner than large ones, the smaller breeds are ready for sale five, six, or more months before the large, which is beneficial in every way; the smaller breeds of sheep are almost constantly preferred by the butchers, as the mutton is more fuitable, faleable, and desirable at particular fasons, and as having two and five quarters instead of one, where the weights are equal. It may, therefore, upon the whole, be considered as the interest and advantage of grazing farmers in general to breed, rear, and fatten sheep which are of the middling fize, however they may have hitherto been led away by other circumstances, such as great fize, extreme fatness, &c. without sufficiently taking into the account the expense at which they are produced.

What regards the proof of sheep is more the interest of the butcher than the grazing farmer; but it has much to do with the difference of breed, as all the more thin-fledged breeds of sheep, as the South Down, the Norfolk, the Welsh, and several others, mostly die well for the advantage of the butcher, while those of the fleety sort, which have improved dispositions, such as the new Leicesters, &c. commonly die to his disadvantage; so that where the great object is proof, such breeds must be chosen as approach the mott to the former. It is not, however, probably the breed simply, but the form of the sheep that gives the proof. But as such sheep as afford great proof mostly require a longer time in fattening, the grazing farmer should be careful not to breed or purchase such sheep as are not formed to convert their food into tallow, in the place of enlarging the size of their muscular parts, and producing meat of a sufficiently fat quality.

The age of sheep has also much to do in the proof which is afforded by them, as the older they are, in general, the better they die in this particular, as their full growth allows the nourishment to go for fat & tallow, according to the nature of the sheep, as where the form is inclined to be bad there will be more tallow, but where the disposition has a tendency to be good, more fat produced on the outside. Keep has likewise some influence on proof as the belt pastures, and such
as are the closest flocked, are found in common to afford sheep that give the belt proof, but it has probably left effect in this way than is generally imagined, as particular breeds give a superiority of proof on poor lands, to that of others on very rich. Time has considerable effect in giving proof to sheep, as by its fat is enabled to be collected and formed internally; but if the proof of the animals at short periods constitutes the great advantage of the grazing farmer, and he has no reason to breed and fatten his flock for the benefit of the butcher and other dealers in tallow. The management in regard to breeding and cropping, as well as the nature of the wool, are said to influence the proof in these animals, as where the more ordinary forms are adhered to, the proof will be greater than in the contrary circumstances, as they have a greater tendency to form tallow and lose in fat. And though some think long white warty wool favourable to proof, others suppose it the contrary, as denoting a disposition to fatten quickly, and as preventing inside fat by taking away the nourishment, thereby concluding fine short-woolled sheep more disposed to afford good proof. The good or bad forms and feel of particular parts, as of the head, the neck, the breast, the back, the barrel, the bone, the skin or pelt, and the flesh, often afford indications of proof, though not always such as are certain; 'as when the first is large, the second long and thin, the third narrow, thin, and high, the back thin and straight, the carcass thin and not well rounded, the bone long and large, the hide or skin flaky and hard, and the flesh hard. But these different indications of proof cannot, it is evident, always be wholly depended on, as sheep may have one or more of the marks or properties which denote good proof, but which may be counterbalanced by others that favour disposition and other similar qualities to the contrary; consequently where two sheep are similarly formed, that which has the largest head and firmest flesh may most likely be concluded to give the best proof. The opinions on proof ought, in fact, constantly to be formed from the greatest combination of the marks of it met with in the particular animals examined.

Perhaps, so far as proof is capable of being judged of before the animals are killed, it may be known by the feel of the fat glandular part, which extends from the bottom part of the neck to the shoulder, which in lean sheep is so very small as scarcely to be felt, while in those that are properly fattened by sufficient time, or fatted, as it is sometimes termed, there is a different sized cushion or projection of the same fat glandular part extending to the thick portion of the shoulder; by the feel on the ribs and tail or dock, which, when it is thick, fat, and mellow, the sheep will commonly, be thought, die well for proof. A thick loin is sometimes also thought a mark of proof in the kidney and weight. The feel of the fore dug of barren ewes and the cod of wethers, likewise shew, it is thought, proof. Many of these marks must, however, be allowed to be precarious and uncertain.

It cannot on the whole be doubted, from what has been flated on the subject of proof, that the interrelents of the butcher and the grazing farmer are at variance as matters stand at present, as what is the gain of one must be the loss of the other, where the thing is well understood.

In the Agricultural Survey of the County of Norfolk, lately published, it is noticed, that the South Downs breed is getting rapidly into the possession of all the country from Swaffham to Holkham; but that from Brandon to Swaffham many Norfolks remain. However, same mixture was observed even in that district. And it is flated that Mr. Coke was well satisfied of the advantage of the breed from Leicester eves and Bakewell tups. His flock of 160 new Leicesters eves produced, in 1802, 100 lambs; his flock of 630 South Downs produced 830 lambs living in June. The farm, it is added, yields a moat interesting competition between Norfolks and South Downs; his former flock was 800 Norfolks, selling all the produce; he planted 700 acres, and now has 800 South Downs, keeping all the produce. Further, that his new Leicester hogs and heaves produced 8lbs. of wool each in the same year, yet they had been hard kept on feeds fed very bare. And it is flated, that though he had a high opinion formerly of the crosses between the new Leicesters tup and Norfolk ewe, now (1803) his opinion is changed from much experience; so that he prefers the crosses of a South Down ram on a Norfolk ewe to that of a Leicesters ram. And it is added, that Mr. Holf has had the same crosses, and they come to 32lbs. a quarter, at two-hear.

Mr. Coke put a Norfolk tup and a Bakewell tup at the same time to the same parcel of Norfolk eves, and at St. Ives' fair fold the lambs fat at six months old, and the Bakewells brought a double the price of the Norfolks. In April 1799, Mr. Coke, on sending Norfolk, South Downs, and new Leicesters three-hear wethers to Smithfield, that had been fed together, the return was:

And in May following above 100 going, the South Downs beat the new Leicellers by 2s. a-head. It is also observed, that at Waterden, Mr. Money Hill, with about 500 acres land and large and at present, kept 27 score breeding Norfolk eves, and fold the produce of lambs: now he has 35 score South Down eves, and keeps their produce, selling his wool at 5s. a more than the Norfolk. And further, that Mr. Bevan, in 1792, had a South Down flock, of 32 score, on one farm, and having a flock of Norfolks on an adjoining farm at Knattishall, he had an opportunity of comparing the wool exactly: 34 score of Norfolks produced 43 toad at 21s.; and 34 score of South Downs produced 61 toad; which 61, kept till November, became 64, but the summer very wet.

Superiority, jilt 4lb. each | 504 lbs.

Also that in 1791, the shepherd would not let his own Norfolk ewes take the South Down ram; but in 1792 he was ready enough. He said they would eat harder than the Norfolks; and would eat what the Norfolks would not; that they are more quiet and obedient than the Norfolks; so that he has done with them what he could not do with the Norfolks; folded them almost to an inch without hurdles. And that a neighbouring farmer bought three rams of Mr. Bevan, at 5s. 5s. each; but afterwards repenting, because they would fleece his flock, Mr. Bevan offered him 6d. a-head, for all their lambs, more than he folding his Norfolks, for, in the same flock, at Ipswich fair. The offer was accepted; the price proved 6d. 3d. for the ewe lambs, and 9d. for the wethers. Mr. Bevan refolded the ewes 9d., and the wethers for 10d. 6d., or 2s. 1d. a-head in favour of the half-breeds. Further, that when his sheep were Norfolks, he kept 500; but in 1794, he had 960 South Downs. That the produce
duce of 116 ewe-lambs, bred by Mr. Bevan at Riddleworth, 1792, was:

Farther, it is also added, that he was early in trying South Down sheep, but finding them tender at lambing, went into a new Leicesters crofs; these he abandoned, and got back to the South Downs, but still eftorts them a tender breed, and that they ought to have yards sheltered and litted for lambing in bad weather; remarking, that all the farmers he knows on the South Downs have these yards for that purpose. It is likewise slated, that Mr. Bircham, at Hackford, declares against having any favourites; he has generally bought Norfolks, and half-bred lambs; some few South Downs, but they did not answer; has had some Leicesters; any fort he can get worth his money. Little farmers, who keep a few sheep, find the polled breeds very convenient from their quietness, and therefore prefer them. Norfolk lambs bred near Cromer, bought by Mr. G. Jones at 14s., were run on flusses in the autumn, and put to turnips at Christmas, then to layers of the first year, probably at the best food for sheep, and fold shearing wethers at Michaelmas at 5s. each; 25lbs. to 24lbs. a quarter. And colonel Butler, at Haydon, is said to be convinced that Norfolks answer better than South Downs: shearlings sometimes amounting 20lbs. and 25lbs. a quarter, and 15lbs. of tallow; he has a breeding flock of 400, and fold his wether lambs at 26s. and his ewe lambs at 24s. Mr. Johnston, of Thurings, has 40 score of South Downs, which he has been rearing these six years, having bought many ewes, and got good tups. He has, however, a good opinion of Norfolks, and will not be surprized to see them come into fashion again. In May 1792, he sold two-score Norfolks at Smithfield for 3l. each. He admits their rambling disposition, which is much against them; and he is clear that he cannot keep so many on his farm as of South Downs. The South Down wool is not, on good keep, so good as Norfolk wool, but the fleece is heavier. Five years ago he got a lot of Yorkshires from the Wolds, white faces, polled, and the wool very coarse, but they throw wonderfully; never having had any sheep that did better, infasmuch, that he was heartily when he parted with them. Norfolks, he thinks, will bear folding better than South Downs. The latter will, however, come to hand rather sooner, but not on ring: has had three-score South Downs of 28lbs. a quarter. Also at Snattisham, Mr. Staleyman, the writer affirms, keeps 2000 of various breeds, South Downs, new Leicesters, and half and half; in number considerably more than when, on the same land, he kept Norfolks; his farm may, and probably does, produce more sheep-food than it did at that time; but he is perfectly clear in the great superiority of the number, this circumstance deduced, and that the profit is considerably greater; and he is clear also in the superior hardiness and kindliness of feeding of the new breeds. Of all other breeds, he thinks the first crofs of the Leicesters tup on the Norfolk ewe the best, and that wool now (1822) sells at 46d. a tod; fleeces 40s. And at Hilligdon, all are either Norfolks or half-breds, a Leicesters tup on a Norfolk ewe. Captain Beachér thinks there are no sheep in the island which the Leicesters will not improve. He has grazed many Whithares, and thinks them the best of all for coles-grazing in the lanes. But Mr. Beck, of Castle Rising, has had South Downs thirteen years, beginning with some from Mr. Tyrrells, of Lamporn, and has imported three or four times since. He has now 800, and is quite convinced of their superiority to Norfolks: when he was in that breed, he had not half the number; but after abating fully for improved husbandry, and every other circumstance, he is clear that there is a superiority of four to three. His fences are and must be bad, and in such a farm quietness is a vast object; his farm 460 acres. He gained the first prize for ewes, both the last and this year at Swaffham, and also at Holkham. The surveyor examined his flock attentively, and it certainly is a very beautiful one. His wool now averages eight to a tod, equally of hogs and ewes; his Norfolks topped twelve; he is clear that, take the country through, they average half as much again as Norfolks. Before he took the farm there were fifty sheep on it, and a dairy of cows. What an improvement! However, in the vicinity of Downham are found all sorts of breeds; towards the river, Lincolns and Leicesters; higher up, Norfolks and South Downs. Mr. Saffery likes the South Downs best, but thinks that as much care and attention had been exerted to improve the breed of Norfolks as the South Downs have experienced, they would by this time have been a very different sheep. Norfolk three-score wethers sold in April last at St. Ives, at from 47s. to 47s. 10d. each. At Brethenham, Mr. Twisits keeps 68 score of breeding Norfolk ewes on 1800 acres of poor land. He had a South Down tup some years ago from Mr. Crow, but he could not perceive that the breed did better than Norfolks, though they flood the fold to the full as well.

In the district called Marshland, Mr. Dennis, of Wigenhall, St. Mary, grazes only the best Lincoln wether; he buys from May-day to Midsummer; keeps them over-year, clipping twice, average price 50s. to 60s. and sells at 65s. to 75s. getting 15lbs. in the two fleeces: his good land will carry fix per acre, on an average, in summer; in winter, two to three acres; and these will quite preserve their fleeces; if the season be favourable, will get something: he thinks that there is no other breed so profitable here; even a fan of the new Leicesters is hurtful, as they will not stand the winter so well. Sheep the chief flock, though some Lincoln bullocks. He never gives hay to sheep, nothing but grass; 32lbs. a quarter his average of fat wethers. But Mr. Swayne, of Walpole, prefers the crofs between Lincoln and Leicesters; he buys them shearing-wethers, about Lady-day; last year 37 to 37. 10d. each, but has had them at 36s. and 13s. He clips the bell twice, three to a rod, which he likes better than heavier fleeces of sheep demanding more food. Some give 17lbs. or 18lbs. of wool. At Michaelmas he pulls the worst, or buys cole for them, if reasonable; sells all by Midsummer, making 6s. or 10s. a head, when bought in high, besides the wool. Very few sheep are kept.

Also in Hertfordshire, some prefer the South Downs to Wiltshires as the latter are the poggles often, but the South Downs never. But the long-legged Wiltshires suffer less in folding on wet land. But in other places the result of the comparison seems to be, that South Downs do better on...
grafs land than Wiltshires, and will in that cafe thrive more, and better support the hardships of short food; but on arable land with plenty of turnips, clover, rye, tares, &c. in ample provision, the Wiltshires are more profitable than the South Downs. The Wiltshires are large sheep, and consequently require to be well kept. In the trials of Mr. Hale, of King’s Waldon, for five or six years, nothing beats South Downs, where there is much grass; but on artificial grass and turnips, without a breadth of natural grass, they will not do like the Wiltshires; for which reason Mr. Roberts, on his own farm, keeps Wiltshire ewes, and crocloses them with South Down rams; so that they lamb in March. When put to grass they are folded, and some lambs are fold at 3/4 in the beginning of harvest; some twins at 3/1.6d.; and the belt are kept. He approves so much of them, that he intends to continue them. Mr. Hale’s flock is a capital one, and the wool remarkably fine. And between thirty and forty years since, Mr. Calvert of Albury had Lincoln sheep, but fold them, from conviction that they did not answer: he was then, for about twenty years, in the Wiltshire breed; and lastly, he changed thee for the South Downs, which he has had for the last seven or eight years, and prefers them to all. He has no other but lord Peham’s breed, both lambs and ewes, and considers the modern better, to evade a finer race, as likely to prove mischievous: he will not have any thing to do with them. His fix-toothed wethers weigh eleven stone and a half. He finds the breed extremely healthy: they very rarely die; and are subject to much fewer ailments than the Wiltshires. And Mr. Smith has changed Wiltshires for South Downs. He has about 400 in all, some of them Wiltshires; they are fed and worked together, and folded on wet lands. The South Downs in exceeding good order, but the Wiltshires very inferior. But about Barkway, South Downs are not yet introduced; Mr. Whittle, however, gave it as his decided opinion, that fed and worked Wiltshires and South Downs together in the same manner, and the former will prove to be the most profitable; the latter are much injured by the dirt, as they are too short in hair and legs; it was tried at Kimpton Hoo, and such was the result. He has fold Wiltshire wethers three times, at 7l. 14s. each. And Mr. Doe, of Bygrave, keeps Wiltshire ewes, which he crocloses every year by new Leicelcer rams; but goes no farther than the first cros. Thes3 ANSWER greatly, whether the fale be fat lambs or shearlings. He does not approve of South Downs, on account of their inferior weight.

However, from the high character which South Down sheep have lately attained, it may not be uninteresting to give Mr. Young’s account of their first introduction into Norfolk. He remarks, that when once an improvement has spread so much as to become an object of importance, there are generally many claimants for the merit; and if such claimants are only heard of many years after, but little attention is due to them. With regard to the neighbouring county of Suffolk, he can speak with some accuracy, but should not mention it on this occasion, were not the fact connected with the introduction into Norfolk. In May, 1785, he published an account of an observation he had made in 1784, the year he brought them into Suffolk from Suffolk; and it being printed at the time, the fact will admit of no doubt. He recommended them strongly to every gentleman and farmer he conversed with on the subject; and at his persuasion, as many well know, the late Mr. Macrafo, of Barrow, purchased that flock which the earl of Orford, after his death, bought and established at Houghton. Mr. Macrafo died in 1789. And in a paper printed in the Annals, in 1790, he (Mr. Young) remarks, “I have had six and twenty years’ experience in Norfolk sheep, and once thought fo well of them, as to carry them into Hertfordshire; but in the advance of my practice, I began gradually to doubt the superior merit of that breed. I thought that of all the sheep which I had examined particularly, none promised fo answcr so well for the general purpose of the counties of Norfolk and Suffolk as the South Downs. I began the import in 1784, and in 1790 had 350. I had too much friendship for the late Mr. Macrafo, to advise him to try any experiment that I was not clear would answer to him. I repeatedly urged him to try the South Downs; he listened to me with attention for some time, but would not determine, till having seen the number I kept proportionately to the quantity of land, and at the same time with some Nor- folks, it proved to him that the South Downs were worth attending to; and the journey I persuaded him to take into Suffolk, giving him an opportunity to converse with various noted sheep-masters there, he determined to make the experiment; he went over, previous to Lewis fair, and bought a flock of them. The lambs fold well at Ipswich fair. Mr. Le Blanc, at Cavenham, also turned South Down rams to 700 Norfolk ewes; he found no difficulty at Ips- wich; and his shepherd, after three years’ obfinate preference to Norfolks, gave up his old friends, and actually fet South Downs for his shepherd’s flock. Whether the breed should or should not, in the long run, eftablish itself, I have the satisfaction of feeling that I have done no ill office to my brother farmers by introducing it. From the daily accounts I receive, I have good reason to believe that it will be eftablished.”

The farmers in Oxfordshire employ many different sorts of sheep, as the Wiltshire, Berkshire, and some others; but the South Down and new Leicelcer, and their crocloses, are fall driving the other sorts out of the county, as being more profitable in the number that can be kept on the fame extent of land, in fattening more expeditiously, and at earlier periods of their growth, in folding equally well, and in the value of their wool. Some, however, think, that the espoused sheep are very profitable on farms of the flem-brath kind, and have large flocks of that fort. In this diftribut, in general, the quantity of sheep that is kept is large, in proportion to that of the extent of the farms.

In Berkshire, the large Wiltshires and the breed of the county are giving way to the South Down, and other small- fixed breeds, as yielding more profit, fattening quicker, and doing better in general. The new Leicelcer, so far as they have been tried in proper situations, have also answered well. Some crocloses of these smaller breeds have likewise been employed with considerable success.

In the county of Essex, several forts of sheep-flock are made use of by the farmers, as the Norfolks, Wiltshires, Lincoln, new Leicelces, South Downs, and different crocloses kinds; but the superiority and advantage of the Downs are now almost evety where admitted. The Dihiley or new Leicelcer fort is also held in much elmination in many places, efcpecially where the soil is of a dry light nature; as the wether lambs of this breed, and that of the Downs, on being conftantly kept together on the fame land, until they became fat, the former were invariably drawn off the firt, and were the fatter and heaviest. Besides, rams of this fort are preferred for being put to Norfolk ewes, to those of the other breed; as the produce is larger, and fooner fat. The new Leicelces are by fome, however, thought inferior to the South Downs, as being fuch bad breeders; one hundred of them only producing eighty lambs, while the fame number of the Downs will bring one hundred and twenty.
Here, however, it is necessary to pause, it is true, as the experiment is already decisive of the point, that at this age of six months, a raised inسوف, these two breeds were so much more advanced than the others, that they might be profitably crossed from the land, and a third breed sent in. It will remain, it is said, for the future progress of the trial, to ascertain whether such fresh breed would not pay better, than continuing the old; and for this purpose it may be calculated, that the sheep new fold at the above market at 34s., with the addition of 32d. for wool; pay for sixty-four weeks 7s. the pound from the time of their being lamb'd. This is noticed to be a very considerable profit; and that if it should turn out, that keeping them much longer is not attended with an advantage, it would not be the most advantageous of all to succeed in the half-bred. The following is a specimen of the superior advantage of that breed, which may be got rid of at early an age. And it is thought worthy of remark, that not one of the true New Leicesters being in any condition in to be drawn off in the full lot for market, is a circumstance most strangely contradictory of all others; it was the amount of the natural peculiarly a characteristic of this breed.

To proceed with the trial.

It is noticed, that this result is not very different from what might have been expected; for as the Romney-Marnies and new Leicesters were very much behind the South Downs and half-breds ten weeks before, it was natural to suppose, that when they did begin to thrive, they would do it in a more rapid manner.

It is considered as very material, in all trials of this nature, to note the losses, as making such attempts of, not by not only weighing when the sheep thrived, but by considering, by marking when they go backward, and which breed is most capable of withstanding those circumstances which operate against them all. In the above scale, the difference is not very material. In that lot which did the world, the losses, it is said, amounts to about 1d. per week; but that it is unsuitable to every lot, that in a period including the best part of the autumn, as sheep should thrive, when the weather suitable, deep into the month of November, and some of them should have gained, which they ought to have done considerably. Their pasture, however, though good in quality, was bad. The result being found, the sheep were ordered to be sheared for twenty-four hours; and after which, to be turned out for other twenty-four hours; allowing, by thus weighing them, to ascertain the quantity of food eaten, and the quantity voided: it being rightly conceived, that if, upon the repetition of such trials, there existed any remarkable superiority, or any material difference, between the respective breeds, it might throw some light upon the general inquiry.

South
SHEEP.

Weighed and Lbs. by Starring. Lbs. per 100 lbs.
South Downs - - 8 3 0
Leicesters - - 11 4 0
Half-breds - - 17 4 6
Romney-Marches - - 5 0 14

The sheep were then turned out, and twice weighed, after twenty-four hours eating each time.

Gain in the Gain in the Total Gain
1st 24 Hours. 2nd 24 Hours. per 100 lbs.
South Downs 1 6 7 2 10
Leicesters 6 6 12 4 13
Half-breds 10 9 19 6 12
Romney-Marches 0 5 5 1 13

The result of these weighings shows that the half-breds lost most, and gained most; that the Romney-Marches lost least, and ate least; that the Leicesters lost more than the South Downs, and ate more. It is suggested, that such trials must be repeated many times, before conclusions can be fairly drawn. How the Romney-Marches, in the first twenty-four hours, could gain nothing, is not to be accounted for, as the weighing was performed with accuracy.

Weighed again in the succeeding month of March, in the next year, which, as it will mark the loss sustained by the severer part of the winter season, deserves particular attention. They were at grafts the whole of the time.

Weighed Lbs. in 4 Months. Lbs. per 100 lbs.
South Downs 253 11 4
Leicesters 214 37 14
Half-breds 253 29 10
Romney-Marches 254 15 5

The result here shows that the Leicesters, which is remarkable, suffered the most; from which it is thought, that it may fairly be concluded, so far as one trial goes, that the great peculiarity of that breed is not by any means what has been contended for, a capability of supporting itself on little food; but that, on the contrary, it demands a very plentiful nourishment, and will bear the want of it worse than any of the other breeds.

The half-breds are the next in the order of merit: the South Downs are the best of all.

Weighed Gain in Gain
12 Weeks. per 100 lbs.
South Downs 299 46 18
Leicesters 275 61 28
Half-breds 310 57 22
Romney-Marches 317 63 24

The period from the 30th of March to the 19th of June necessarily forms another interesting portion of the trial, as it takes in the whole flush of the spring growth of grafs. Here the result, it is said, is also remarkable, and strongly in confirmation of the preceding observations on the Leicesters; for when in favourable circumstances in regard to food, as in the present cafe, from feafoin, they exceed all the rest. The Romney-Marches, however, approach near to them; and as there had lost, in pinching circumstances, much lefs, their superiority upon these two weighings seems to be clearly ascertained; and which will appear the plainest, by comparing the weight of December 1st with that of June 19th.

South Downs 204 299 35 13
Leicesters 251 275 24 9
Half-breds 282 310 28 9
Romney-Marches 269 317 48 17

The merit of the Romney-Marches, in this stage of the trial, is, it is said, conspicuous. The South Downs are next, the Leicesters and half-breds being equal.

Weighed Gain per 100 lbs.
South Downs 316 5
Leicesters 312 8
Half-breds 310 8
Romney-Marches 337 6

The Leicesters here, it is observed, continue to take the lead throughout the summer. So long as the food is plentiful, they beat all the others; and this part of the experiment goes to prove a most important point, which has indeed been long suspected, that in good situations no breed is to profitable to the grazer. The half-breds are found the next to these.

The five remaining Romney-Marches were sent to Smithfield on the 4th of July, and brought 45s. each; and on August 7th, ten of the remaining Leicesters went at 48s. each, also seven at 42s. each; so that the profit for two years and two months food, added to the value of the wool, is, it is said, 5d. and a fraction per week for the Romney-Marches, and from 4d. to 4½d. for the Leicesters, from the time of their being lambed.

The former part of the experiment will shew that the South-Downs and half-breds in 64 weeks age gave 7½d. per week profit; and that the Romney-Marches and Leicesters, kept until they were nearly twice the age of the others, namely, 108 weeks the former, and 117 the latter, only gave a profit of from 4d. to 5½d. per week. This is, it is said, a most intersting cirkumstance, which manifestly tends to ascertain how much better it would be to the grazer to get rid of these sheep at an earlier age, and relodge his land with those which are most faleable at the earliest period.

November 21st to December 25th. Weighed again.

Weighed Gain Gaine per 100 lbs.
South Downs - 320 4 1
Leicesters - 326 14 4
Half-breds - 346 6 1
Romney-Marches - 331 60 6

This, it is supposed, is perhaps the most striking period of the experiment. By the last weighing, if turned to, it will be seen that the Leicesters had outstripped all the rest, and that the superiority is still maintained.

The above details of the practises of different districts, experiments, and remarks, must place the profits and advantages of different breeds of sheep for the purposes of the sheep-farmer, in a clear, satisfactory, and striking point of view. With respect to the wool of different sheep, we refer to the next article, and Wool.

Different Kinds of Sheep-Management.—In the practice of sheep husbandry, different systems are had recourse to, according to the extent and nature of the farms on which they are kept and the methods of farming that are adopted on them; but under all circumstances, the best sheep-masters constantly
constantly endeavour to preserve them in as good condition as possible at all seasons. With the pature kinds of sheep this is particularly the case; and with the view of accomplishing it in the most complete manner, it is useful to divide them into different parcels or lots, in respect to their ages and fortes, as by that practice they may be kept with greater convenience and benefit than in large flocks together, under a mixture of different kinds; as in this way there is not only less waste of food, but the animals thrive better, and the patures are fed with much more ease. The advantage of this management has been fully experienced in many of the northern districts, where they usually divide the flock into lambs, yearlings, wethers, and breeding ewes; and in this method it appears not improbable that a much larger proportion of flock may be kept, and the sheep be preserved in a more healthy condition.

The nature of the management with a breeding flock is that the sheep-maister must act according to his circumstances, situation, and the capital which he possest, either selling the lambs to go to keep, fattening them for grazs-lamb, flocking them for house-lamb, or keeping them on to be grazed and fold as flore or fat wethers; the ewes being fold lean, as they are called, or fattened, as circumstances, profit, and convenience, may point out. Another practice, but which requires much capital, as well as knowledge, experience, and attention, is that of breeding and fattening off all lambs, both wethers and ewes, especially where markets for their sale, when fat, are conveniently situated. But where this system is too extensive, it may be partially acted upon, varying the plan according to capital, circumstances, and the nature of the times. In which case, whenever flock becomes extravagantly high, it is mostly a good way to sell. But a method which is attended with the least trouble and hazard, is that of purchasing a store flock, as lambs, wethers, and what are termed crones, or old ewes; some of the last fort often proving with lamb, may be fattened off with them to good account. It is likewise often the case that ewes are disposed of in lamb, or with lambs by their fides, in what are termed coupled, in which circumstances it is frequently a good practice to make annual purchases of them, in order to the fattening of both, and selling them in that state within the year. The system of breeding can only be had recourse to with effect and advantage in situations or on farms, where there are extensive tracts of land fit for the patureing and support of these animals, but not the fattening of them; the more rich deep grases-lands being adapted to their fattening, and thereby affording a better profit, especially when quickly performed with a proper fort of this kind of flock, as that of good wethers.

But in the purchasing of sheep, which is often done from very distant fairs and markets, much care and circumvention are necessary, whatever the fort or intention with which they are bought may be. In these cases much advantage, especially when at a considerable distance, may be derived by employing a saleman upon the spot.

And the appearances which shew the sheep to be in a proper sound state of health, are a rather wild or lively briskness, a brilliant clearness in the eye, a fluid ruddy colour on theinside of the eyelids and what are termed the eye livers, as well as in the gums, a fatness in the teeth, a sweet fragrance in the breath, a dryness of the nose and eyes, breathing easy and regular, a coolness in the feet, dung properly formed, coat or fleece firmly attached to the skin, and unbroken, the skin exhibiting a florid red appearance, especially upon the brisklet. Where there are discharges from the nose and eyes, it indicates their having taken cold; and should be attended to by putting them in dry sheltered situations. This is a necessary precaution also in bringing them from one situation to another while on the road.

It may be noticed that, with sheep-farmers, the common practice, except in particular instances, has been to leave the ewes for the purpose of breeding without any selection; but where good sheep-flock is the object, much attention should be paid in choosing such as are the most perfect, and that polletts, in the highest degree, those qualities or properties which are wanted, whatever the breed or variety of sheep may be; as is only in this way that a good flock can be raised and preferred. And it is a business that should always be performed at the time they are turned to the ram, if it has not been done before; and this is equally necessary in regard to the rams, that they may be adapted to the ewes.

The author of the Farmer's Calendar has observed, that the late duke of Bedford, in attending to this subject, had every ram with the lambs got by him the preceding year put in different pens, that he might not only examine them but their progeny, previous to his deciding "what ewes to draw off for him," which is certainly a method highly deserving of imitation by sheep-farmers in general. Such attention, united with a careful selection of suck lambs, must, the writer thinks, keep a flock in a state of progressive improvement, proportioned to the accuracy of judgment, eye, and hand of the farmer who practises it. And it is observed in the Agricultural Report of Norfolk lately published, that Mr. Coke readily affirms, not only his tenants, but other neighbouring farmers, in fortifying and selecting their South Down ewes, &c. and distributing them in lots to the rams according to the shapes and qualities of each. He puts on his shepherds'smock, and superintends the pens, to the sure improvement of the flock; his judgment is superior and admitted. The writer has seen him, and the late duke of Bedford, thus accounted, work all the day, and not quit the business till the darkens forced them to dinner. See Sorting Sheep-Stock.

Further, it has been remarked in a late practical work, that the most advantageous and proper age for ewes, taking the ram in the different breeds, has not been fully known; but from a year to a year and a half old may be sufficient, according to the forwardness of the breed and the goodnes of the keep. Some judge of this by the production of broad or sheep's teeth. It should not, perhaps, be done while too young in any case. And in regard to the season of putting the rams to the ewes, it must be directed by the period at which the fall of the lambs may be most desirable, which must depend on the nature of the keep which the particular situation affords, but the most usual time is about the beginning of October, except in the Dorsetshire ewes, where the intention is for flocking for house-lamb, in which case it should be much earlier, in order that the lambs may be sufficiently forward. But, by being kept very well, any of the breeds will take the ram at a much earlier period. Where the rams are young, the number of ewes should seldom exceed sixty for each ram; but in older rams a greater number may be admitted without inconvenience, as from one to two hundred; but letting them have too many should be cautiously avoided, as by such means the farmer may sustain great losses in the number of the lambs. It is found that the ewe goes with lamb about the space of five months, consequently the most common lambing-feast is March, or the early part of April; but it has been observed, that in many of the more southern districts, where sheep-breeding is carried on to a considerable extent, some parts of the ewe-stock are put to the rams at much earlier periods, so as to lamb a month or two weeks sooner; a practice which is attended with much profit and advantage in many situations where early graze-lamb is in great demand. It is usual for the
the rams to remain with the ewes for a month or fix weeks, and in some cases longer, in order to complete the business of impregnation, which in some districts is ascertained by smearing the fore-bows of the rams with some colouring substance. The method formerly in practice, and which is too commonly the case at present, of turning a number of rams among the flocks, is highly exceptional, as tending to prevent the main object, and injure the rams. A better way is to let each ram have a proper number of ewes, and with very choice flock to keep the ram in an inclosed small pasture, turning a few ewes to him, and as they are served replacing them with others. By this means there is more certainty, and more ewes may be impregnated. In such fort of fine flock, it is likewise of great utility to keep the rams during this season in a high manner. In this view a little oats in the straw, or a mixture of barley and pea-meal, are excellent. Where ewes are backward in taking the ram, the belt means to be employed are those of good stimulating keep. The rams should always be continued with the ewes a sufficient length of time. It is staled in the General Treatise on Cattle, that the ewe will breed twice and even thrice a year, if it be made a point to produce such an effect by attention and high keep, since the will receive the male indifferently at any season, and, like the rabbit, very soon after bringing forth. And that Little gives an instance of three of his ewes, well kept, lambing at Christmas, fattening off their lambs at Lady-day, and producing lambs again the first week in June. It seems they stole the ram immediately after lambing, but brought the second time only single lambs, although of a breed that generally produces twins. The former writer thinks there is no doubt but the sheep would produce young thrice a year, were the bad practice reftored to, which has so frequently recommended with the rabbit, of allowing the male immediately after parturition; the ready way to render both the female and her progeny worthless. Could the lambs be advantageously weaned at two months, sufficient time would, he conceives, remain for the ewe to bring forth twice within the year; for example, suppose the young ewe tapp'd in August, the lamb would be dropped in the middle of January, and might be weaned in April. In March, the ewe again receive the ram on the turn of the milk; the ewe, perhaps in or before April, she would then bring forth within the twelve months, or in August. This plan would, he thinks, at least injure the dam infinitely less than fulfilling during gestation.

And it is necessary, that during the time the ewes are in lamb they should be kept in pastures, and as free from disturbance as possible, being carefully attended to, in order to prevent accidents, which are liable to take place at this time, such as those of their being caff in the furrows, &c. Where any of the ewes flip their lambs, it is advised by Mr. Bannfier that they should be immediately removed from the flock. They also require, under these circumstances, to be kept as well as the nature of the farm will admit, in order that there may be less loss at lambing-time, from the ewes being stronger, and the lambs more healthy, and better capable of contending with the state of the season at which they may be dropped. At lambing-time every possible attention is to be paid. The shepherd should at this period be particularly careful and attentive to afford his assistance where it may be necessary. He should continually have regard to the suckling of the lambs, and to see that the udders of the ewes are not defaced. His attendance will often be required in the night as well as the day. At this season covered sheep-folds are often of very great advantage, in keeping and protecting both ewes and their lambs. And in respect to the number of lambs, it is remarked by the author of the work on Live-rock, that the ewe brings most commonly one, next in degree of frequency, two, rarely from three to five lambs at a birth. This property of double birth is, he says, in some instances, specific; the Dorset sheep usually yielding twins; and the large-poled Belgian sheep, with their descendants, our Teffwater, doing the same, and producing occasionally more at a birth. Other breeds bring twins in the proportion of one-third of the flock, which is supposed to depend considerably on good keep. A certain number of ewes per centum prove barren annually: the caufe very rarely, natural defect; sometimes over-fatness, a morbid state of body, from poverty, or neglect of the ram; in other words, want of yflem in the sheep.

Further, it has been recommended, that where rich pastures, or other forts of good grals-lands cannot be reftored for their support, turnips, or other kinds of green food, should be provided for the purpose, and given them in a suitable manner, but where it can be done, it is always better to leave this fort of food untouched till about the period of lambing, when it should be regularly supplied, in proportion to the necessity there may be for it. The ewes also demand at this time much care, to fee that they are put upon a dry sheltered pasture, free from disturbance, and that neither they nor their lambs suffer injury from the too great severity of the season. Whenever this is the case, they should be carefully removed into a proper degree of warmth and shelter, until perfectly restored. It is likewise a necessary, as well as a useful practice, as they lamb down, to take them and their lambs away from the common flock, putting them into a piece of turnips, or fresh dry pasture, where there is shelter when necessary, as by this means much fewer lambs will be lost than would otherwise be the case. It is also found, that by a proper supply of turnips, or other similar green food at this period, the milk of the ewes is much increased, and the growth of the lambs greatly promoted; which is of much future importance, as when they are flinted at this early period of their existence, they never turn out to be as well forwards for the farmer. With the green and root crops, and preferred after-gras, hay, straw, corn, and oil-cake, are in some cases made use of in the winter support of sheep-rock. With turnips, where the soil is not sufficiently dry to admit the sheep, it is the practice to draw them and convey them to a found firm pasture, that the ewes may be kept upon them once or twice in the day, as there may be occasion, care being taken that they are eaten up clean, as the circumstance of their being thus eaten may serve as a guide to the farmer for the supply that may be daily necessary. In this way this fort of food will be consumed with the greatest economy. Where the land is perfectly dry, and the intention is to manure it for a grain crop, eating the turnips on the land, by means of portions horded off as wanted, is a good practice. And with this fort of food, especially where it produces scouring in the ewes, green rnen hay, cut straw, or pea-halm, should constantly be given, and also with rape, &c. Mr. Young has staled, that in some parts of the kingdom, the bell farmers give their ewes and lambs bran and oats, or oil-cake, in troughs, while they are feeding on turnips; but he fuggefs, at the same time, that it must be a good breed for such a practice to repay. And it has been advised, when the weather is very wet, stomy, or there is much snow upon the ground, that the ewes and lambs should have hay given them in rafts as may be necessary, which is readily done in covered moveable racks, a portion being given fresh every day. It is, however, much better to have it cut up to stuff, and given in troughs, as much less waste is made. There is still a better practice of feeding made use of by some farmers, with ewe-rock of the
the more improved kinds, and which is said to have been found to answer better than the common kind in particular cases; which is that of employing parishes or cottars with hay of the green reenk kind, or a portion of peas, beans, or barley meal. In such cases, a malt comb, with pastures and hay, &c. These sorts of sheep are, however, obviously much too expensive, except under particular circumstances, and for the more improved breeds.

It is evident, that where shelter can be provided, it will always be of much benefit to the sheep. But it has been observed, that the practice of letting them to the haysicks, which is common with some farmers, is slavishly and wastefully, and which, though it may afford a degree of shelter, should never be attempted when the other methods can be had recourse to. It has also been suggested by Mr. Young, as an excellent method, though not effectually necessary, to allow the sheep, whether the weather be bad or not, a small proportion of hay daily while at turnips. And it is supposed that by this careful management, and the use of fluffable turnips when necessary, the ewe and lamb-flock may be well supported through the severity of the leasen, and be brought on in the best possible condition until the turnips are finished in March, which should always be the case when the preferred grass or roun be ready to receive them; which is considered by some as the most to be depended upon through the same period, with which, the first week in May, is the most difficult period of the year to the flock-farmer. On dry meadows and pastures it is invaluable in this view, though at first sight it may have an unpromising appearance, from the covering of decayed autumnal grasses that is upon it; but which, when removed, presents a new growth of fresh green grasses, five or six inches in height, brought up by the shelter and warmth afforded by the covering of old grasses. This is found to agree remarkably well with the sheep, as they consume both together, having, as it were, both hay and grass in the same bite. It is, indeed, supposed impossible to keep a full flock of sheep so cheaply in April by any other method as by this. Tolerable roun will carry ten ewes an acre, with their lambs, through the whole month. Such roun may be worth in autumn ten or twelve thillings an acre; in April it is worth thirty or forty thillings; and if it be a backward season, a farmer that has it would not be tempted to fell it for much more. But in the support of his sheep and lamb-flock, if the farmer be provided with a sufficient extent of watered meadow, he may fully depend upon that without any other provision for this period.

But in cafes, however, where these cannot be fully depended on for the support of the sheep-flock at this difficult season, the more improved practice is, in place of depending on turnips and hay with rye fown for the purpose, young wheats, and the run of the pastures, to let the turnips continue, so as that their floots may become an object of sheep food, and to have annually a portion of tolerable good land, sufficient to the extent of the flock, under rye-gras and clover, so as to be ready in the spring to take the sheep from turnips, and support them till the time of turning upon the pastures. The same writer remarks, that this method is an improvement on the other, as it gets rid of three great evils: depending on rye, which is soon eaten; feeding on wheat, which is pernicious to the crops; and turning too soon into the general pastures. But at the same time that it effects this advantage, it is open to some objections, which make further improvement necessary. Keeping the turnips long in the spring is very bad husbandry. It damages greatly the barley crop, both in robbing the land, and preventing it from being in proper tone; nor is the food of great consequence, as many sort of turnip-tops are not equal, the number of which used to be proportionate to the flock of sheep, and the same may be multiplied with help of the clover mixed with it; ellings are the same as before, though at the season, and a great loss in a field to be given and not be allowed; the lamb won't be feed much by the sheep. A turnip should never be seen on the ground after March. For the month of April the farmer should have a field of cabbages ready, which, yielding a great produce on a small breadth of ground, reduces the evil of a late spring fowing; and, if he manages as he ought, totally excludes it. The turnip-cabbage, and ruta bag, will last as long as wanted; and though they run to feed, yet the bulbs will not be fanny. The green borecole may be fed off several times: it is impenetrable to frost, and will make shoots in the winter. And another crop, continues Mr. Young, for feeding sheep in spring, which is of particular merit, is burnt. An acre of itmanaged properly, will at this season yield much more food than an acre of clover and ray-gras. It should be four or five inches high in November, and left so through the winter. Burnet has the singular quality of maintaining its green leaves through the winter; so that, under deep snows, you find some luxuriance of vegetation. From November to February the crop will gain two or three inches in growth in the young leaves, and then be ready for feed. It will be better in March, and if kept, ready in April, not only for sheep, but horses, cows, or any other flock. These symtoms of feeding and management are, however, in practice much varied according to the nature of the farm and the kind of sheep that are kept. In Norfolk, with Mr. Bevan's flock, which consists of forty-five score of the South Down kind, the following is the arrangement. The clover are put to the ewes about the 10th of September, for two months, being fed on the layers and pastures, and are folded on the old layers for wheat: after wheat-fowing they are folded on the pastures and layers till the time of weaning, during which they lie on the pastures without fold, and have turnips thrown to them, with plenty of good hay. The fattening sheep are on turnips and hay, from Michaelmas to the end of March, follow'd by the hoggets. In April the couples go to cole-feed in hirdles; from cole to rye; from rye to the new layers, if forward enough, otherwise to the water-meadows, till the beginning of May; and from thence to the new layers, being full in hirdles, with a good deal of room to fall back, and continue so on the layers till about the 16th of June, when the ewes are ready for clipping; and until the lambs be weaned; the ewes then go to fold with the sheardings on the fellows intended for turnips, and the lambs are put to fresh grass reserved for that purpose: all the sheep on turnips and cole having hay, they consume about twenty-five tons. The general winter provision is 30 acres of turnips, 20 of cole, and 50 of rye, for the spring. Mr. Bevan ploughs his rye-elblubes before the stocks are carried to turn in the scattered feed, harrowing in half a peck of cole-feed for sheep-feed in the spring, and finds it of very great service. The latter, after feeding, stands for a crop. He values his turnips on the average at 32s. per acre, and cole at 27s. After turnip-fowing, the stock
flock is folded on old layers for rye, till the end of August, when the ewes intended for breeding are put to good pature till the consequent are let in. But in 1802, the rups now put to the ewes were a week later, and the lambs not weaned till the latter end of June. Provision this year, 100 acres of turnips, 30 cole, 30 rye, for 25 score breeding ewes, 15 score hoggets, 20 tups, 10 score fattening flock; 51 score in all.

Turnips, as a holding-out winter food for sheep, are unquestionably excellent, particularly when not given in too large quantities, and with some sort of dry food with them, as saffron hay in this season, common hay, cut pea, bean, or wheat-straw. There is also said to be an advantage in having them drawn one or two days before they are used, in some districts, and even in having them forked. But potatoes are thought a much better food than turnips in other parts where sheep are a great object, as being more fully and regularly to be depended on, and as preventing the diseases to which the animals are liable in a more effectual manner. The Swedish turnip come into use the latest, as in the early spring.

It is stated in the Corrected Agricultural Report of the County of Suffolk, that general Murray fed 5000 sheep with potatoes and hay, 1651 of his breeding ewes ate 51 builths every day, giving a quart to each; and which, for 120 days, is 121.20 builths; while the Norfolk flock-farmer provides for 720 sheep, 80 acres of turnips, 16 tons of hay, 20 acres of rye. The following is the comparison of the value, &c. of the provision.

It is said, that if 720 sheep require 80 acres of turnips, 2240, the upland flock at general Murray’s, will require 248 acres of turnips; but they have only 50. That if 720 sheep require 16 tons of hay, 10 acres, 2240 should require 40; instead of which they have 120, which is 71 surplus, or, at one load and an half the acre, 48 acres. And that, if 720 sheep require 20 acres of rye, 2240 should require 62, instead of which they have none at all.

Winter food of 2240 sheep, as provided for in Norfolk.

Which is, it is said, a difference of 63 per cent. This vast difference is to be attributed, it is supposed, in a great measure, to the distinction between the breeds of the flocks, as one being the Norfolk, and the other the South Down, as all the circumstances are in favour of it; but it may be partly owing to potatoes being a cheaper food than turnips. As to the feeding of sheep with potatoes, however, it is, though ascertained on the above farm on a very large scale, a more disputed and doubtful circumstance; and for this reason, they are allowed, limited, or limited in their consumption, which is not the case with turnips: these, on the Norfolk farm, are fed off on the land, and, of course, in the greatest plenty. The other accidents and objections to which they are constantly liable, are also not to be overlooked; while potatoes are a regular certain crop, and subject to few accidents or inconveniences. When these circumstances are therefore well considered, in the pinch of a severe season, it will be readily agreed that the introduction of this root, and the proof of its advantage by the above extensive trial, as a winter and spring provision for sheep-flock, is really important.

The quantity of a quart every day of this root for each sheep is probably, however, much too small, as in fattening them with it in suitable yards for the purpose, a far greater quantity has been found necessary. But lean sheep certainly do not require the same proportion for keeping them as for requisite in the fattening system, as may be seen below, in speaking of that fort of management.

Cabbages, as a food for sheep, are of great importance and utility in many situations, particularly in those where the land is suitable for raising them, though it may not be of the very rich quality. They are of vast service in carrying on improvements in sheep husbandry, and as the means of keeping a greatly increased flock, where good management is followed.

The artificial grasses, such as ray-grass and red clover, are of much consequence as spring food for sheep; the first is early, and comes in after common turnips, when much wanted. It may be cultivated to advantage when the latter will not succeed. The clover comes into use in this way at a later period, and on stronger descriptions of land. Many other grasses of this sort, as well as some of the natural grass kind, might be very beneficially grown in this intention, as the cock’s-foot in some cafes, fainfoin, &c. on soils of the calcareous kind, and some of the poas and alopecurus, in other circumstances; by which means earliness, quantity, and quality of keep might be secured.

Tares,
Tares, rye, and cole, are in great request as spring food for sheep-flock, the first being raised on the stouter parts of land, the second on such as are of a lighter quality, and the last on many kinds, even the lighter calcareous sort. They are all sufficiently early for being fed in April, or the following month, when turnips are done. These crops are likewise often put up to be fed off at the close of the autumn. The practice answers very well; but mixed crops of tares and rye never do well for the purpose of sheep-feed, as they do not by any means come well together, or course there is much loss. These and other mixed crops are, however, frequently had recourse to in his sort of management, with evident benefit.

The bulbous turnip system of food is very good in this sort of husbandry, for late spring or other feed; whereupon such kinds take well in succession to those of other sorts.

The plan of preferring grasses for the purpose of sheep-feed is certainly very useful, especially for the support of ewes and lambs in the early spring. It provides well for the time of scarcity.

The practice of converting young wheat crops to spring sheeps-food is seldom good. It is mostly the business of necessity and want of forethought in the sheep manager. On light and dry lands it may occasionally be useful, but it often does much harm.

Winter barleys, and some other sorts of crops, have also been tried as sheep-food, but hitherto only by particular individuals on a small scale.

Whatever the nature of the food which is raised with this design may be, it should always be provided in ample abundance to the quantity of sheep-flock which is to be kept, as no sort of pitching ever answers any good purpose in this management. Good water should likewise be constantly attended to in this practice.

By thus cultivating proper quantities of proper sheep-food in connection with the keeping and managing of flocks of this sort, many important benefits and advantages would necessarily result, a far greater quantity of sheep would be kept on the same extent of ground, they would be preserved in a much better state of condition, and they would be in a much more favorable situation for the purposes of breeding or being fattened, and consequently be in every way greatly more profitable to the sheep-farmer; while the growth of such sorts of food would prepare admirably for grain crops, by which little expense would be incurred. Besides these, it would contribute in several other less important ways to the benefit of the flock-farmer, in many cases and situations.

And it is observed that, by the means which have been detailed above, the sheep and lambs are capable of being continued in good healthy condition, a matter of great consequence to the flock, until the period of turning on the pastures, when they should be separated, where the land is inclosed, into proper divisions, in proportion to the quantity each pasture can support, care being taken not to over-fill the fields. Though hard flocking in some cases may be beneficial. With some farmers they are put upon the richest pasture of the farm, while with others it is the custom to let them have thence of the inferior kinds. This must depend much upon circumstances; but whatever mode is adopted, the point of having the flock preserved in good condition is never to be lost sight of. It is advised, that in keeping sheep on inclosed pastures, particularly where the lands are much occupied with wood, constant care is necessary, in order to guard against the mischief of the fly, as its effects are often irreparable in the course of a very short time in such situations, if not attended to, in hot seasons. With the view of fully preserving, all this, a very frequent and particular attention must be made by the sheep-farmer.

Further, on this subject it may be noted, that the next consideration is the management of the land so that we may have the land, which is a subject that has been visited when they are three to four months old, and also yearly, but it is some of great importance and distinct from others. And to effect in the land, it must be a general matter, a proper reserve of some good pasture grass, when there may be a good feed for the young feed upon, should be had recourse to, as it is of much consequence that in the summer provision of the land be made, in order that the growth of this young flock may not suffer by any check in being taken from the mother. When they have been continued to long as to graze with the dams, they will be fattened in their separation, it turned upon such good food. Some advice in this matter is, as the flock taking for food in this instance, and with others fawneth rouch is highly valued for the same purpose. When good feed is not provided, of some of these kinds, the lambs soon decline in flesh, or in the technical language of the shepherd, the flock are said to pitch; and when once this happens, they never afterwards thrive so well, however good the management may be.

With regard to the ewes, they should be removed to such distant pastures or other places, as that they may not be heard by the lambs, which would cause them to be disturbed in their feeding. And where the ewes are fed on any convenience from their milk, as by their udders swelling, it should be drawn once or twice, as by this means bad consequences may be prevented. And as soon as the lambs have been removed, the ewes are returned upon the pastures defined for their summer support. There is, however, one caution to be attended to in first turning the lambs upon rich keep, which is that of letting them be in some degree satisfied with food previously, that they may not be fretted by too quick and full feeding, and leave or leave, as it is termed; keeping them gently moving about the fields has also been advised in this intention. In some places where the lands are of the more poor kind, it is a custom to feed the lambs to the more rich vale or marsh districts, to be brought forward in condition, or fattened. In those cases, where the lambs of the male kind are reared on the home lands, as wethers, they are usually returned to the flock in the latter end of the year, but which is not by any means a good practice, as they often suffer for want of proper keep in the winter, and lose what they had previously gained in growth and condition.

And in the usual management of sheep-flocks, it is the common practice to remove a certain number of the old ewes or crones every year, replacing them by the belt lambs, in order that they may be kept up in the greatest perfection; it is, of course, a matter of considerable importance to have this done in a proper manner. And in almost all the sheep districts of the southern part of the land, this festering, or setting of the land-flock, is performed about August, at which period the fairs for the sale of lambs mostly take place. And as at this time the whole are collected together for drawing into different lots, it is a very sufficient period for selecting or choosing those that are to supply such deficiencies in the breeding flocks. In his Calendar of Husbandry, Mr. Young has well remarked, that in making this festering, the farmer or his shepherd usually (whatever the breed may be) rejects all that manifest any departure from certain figures of the true breed: thus, in a Norfolk flock, a white leg, and a face not of a hue sufficiently dark, would be excluded;
however well-formed; in the same manner a white face on the South Downs; in Wiltshire, a black face would be an exclusion, or a horn that does not fall back; in Dorsetshire, a horn that does not project, &c. &c. And where the produce is annually fold lean, there is, he maintains, reafon in all this; for customers who have been bred to and prefer certain breeds, as having paid them well, are apt to be fatisfied when they purchase. Some farmers in this fection look chiefly at size, always keeping the largest frames; but this is probably erroneous, unless they keep very high. It connects with a queftion by no means accounted, whether sheep do or do not eat a quantity of food proportioned to their weight? In general it is a safer rule to choose a well-formed lamb, or that indicates the probability of making a well-formed ewe, rather than to felect for fize. The attention that is to be paid to wool in the breeds that produce the carding fort, will depend on the price to be received: if the farmer lives in a diftrict where the price of the year is given equally to all flocks; there is little encouragement to refrain from quantity for the fake of quality; retaining, however, the idea, the fact that both are attainable, that it is very common to fee coarse, bred sheep with light fleeces, and thofe of a fine quality heavy in weight. The Spanifh fleeces, which are finer than any other, are heavier than thofe of our finest woolled sheep. With combing wool the importance of the fleece depends still more on price; we have seen it at £5, a ton; and it has lately been £60. Quality is of very little confideration indeed, comprifed with quantity. When wool falls high, no prudent breeder will let his flock without being governed considerably by this objeft. And it is added by the fame writer, that the high prices at which new Leicelfer and new South Down rams let and fell, has opened a field of fpeculation in fheep-breeding. It is fufficient to remark, that this spirit of breeding, whether it shall prove durable or not, whether much money shall or fhall not be made in it in future, is not what any prudent man beginning buifinesf will adventure in, but with great caution: men of fuch immense fortune are now taking a lead in it, and are in many repects doing it on fuch liberal principles, that the fwife conduct of fuch farmers as he may be fuppofed to address, is to take proper opportunities of converting their experiments to their own advantage. In feeding a flock of lambs, therefore, you may mark a fcore of the bell, for a future ram to be picked up when opportunity offers; or, better still, to fend to the top of fome ram-letter that takes them in at a reafonable price per head. By every year feleeting five or fix per cent. and by every year covering that number by a ram better than your own, the flock must be on the improving hand; and this may be done at a very small expence. Alfo at this period, besides filling up the deficiencies in the ewe-flock, the increasing or diminishing the quantity of flock usually kept, by referring a larger or smaller number than that of the old sheep which are disposed of, is also a point that demands particular notice. Mr. Young has given the following ufeful directions on this fubjeét in his Calendar of Husbandry.

On a farm, fays he, with a given stationary fheep-walk, it is probably regulated by circumstances that rarely change; but on inclosed farms, where the fheep are supported by fields alternately in grafs and tillage, variations may eafily be fuppofted, and the quafion of hard or light flock-fod, that is of clofe feeding or a head of grafs, then comes in to decide the number kept. If the produce or profit per head is looked to, the conduct to be pursued is evidently to flock lightly; but if the return is looked for in corn from fields laid down for refrehment by reft, then clofe feeding is a very material point, and the number kept will depend on it. With all graffes, &c. that do not decline from age, the more fheep you keep the more you may keep, and the more corn you will reap when fuch are ploughed; a circumftance too important to be forgotten. But the young farmer will remember, that upon this fyllem he muft not have a fhow flock, or let the variety of a farm have the lead influence with him: if in this way he will have a fomething to talk of, a fcore or two of pampered favourites, the fewer the better, for they may cost him more than they are worth. And as foon as this has been properly executed, the ewe and wether lambs that are left are moltly fen to the neighbouring famb-fairs to be fold off. But where the fairs for this purpofe happen later than the above period, as in the beginning or latter end of September, as is the cafe in fome circumftances, it has been advised by the writer firft mentioned, that great care be taken to keep them in forcing food, as in fpring fares, early fowm rape, good grafs of the right degree of bite, &c. &c. in order to promote their growth and increafe their value; but to fell in August is more beneficial.

It cannot but be obvious, that in the management of breeding flocks, the lambs come to be difpoled of at different periods; frit those that have been bucked or fattenfed in the houfe, in which fyllem of fattenfed, much attention is required to have them early, to their being well, regu- larly, and very cleanly kept and fuckled, as well as to the ewes being of the right fort, and the bell milkers that can be provided, and to their being fully fupplied with food of the moft nourifhing and fucculent kinds. Their tails and udders should have the wool well clipped away from them in order that they may be preferred in a perfectly clean flate. The lambs also require, especially towards the clofe of their fattening, to have regular supplies of barley, wheat, and peas, meal ground together in combination with fine green rouen hay, &c. See Lamb-Suckling.

And as foon as thefe have been fold off, the lambs which have been fattened on the belt grafs-land will be ready to fucceed them at the markets, in the fpring and fummer months, and thefe will be followed by the fale of the fore- lambs at the different autumal fairs.

Further, there are different local practices also adopted in different counties, to fuit the particular methods in which their fheep husbandry is conducted, as well as the particular objets of it. The following is given as a hint from Joseph Banks, by the writer of the Lincolnshire Agricultural Survey, on the fheep fyllem of that ex tend e f dist r i f e d: that as tups are there always bred by the breeders, the lambs may be faid to be purchased before they are born; a year’s credit, however, is given on this occasion, they are not paid for till the actual value can be fairly estimated; if, therefore, any one who has hired a tup at a confiderable price, finds the lambs he has got not sufficiently above the ordinary fort to pay him the difference, with intereft, he complains to the tup-man, who generally views the lambs with him, and makes a fair abatement, which is generally settled by the price of the hire of the next year’s tup; this regulates the price of letting, and makes the tup-men a molt ufeful fet of people. The great maps of breeders in Lincolnshire fell their heeder lambs about old Michaelmas time, or a little after: a fuccesion of fairs for that purpofe are held in a village called Partney. These lambs are rebold in the fpring at Lincoln fair, under the name of hogs; at Midsummer their owners clip, and then winter them; the fucceeding fpring they are carried to Bolton, where, in a long fuc- cefion of markets, they are old to the graziers, with their wool
wood on, under the name of shearlings, and immediately turned into the marsh to fatten; the graziers take their fleeces, and having wintered them, get the kindled to Smithfield in the course of the preceding spring; thence they are sent to Middx, are got, and are sold there in the course of the next autumn. Here you see a well-formed flocks of sheep culture, for as the animals are usually either on grazing hands or yielding fleeces, they make a return of some kind or other to their owners, nearly half-yearly; on the time of their birth, to that of their final dilution at Smithfield. See R. 31a.

In the sheep system of management which is practiced on the large rich tracts of the Romney, Wotton, and Donze marshes in the county of Kent, there is also a local peculiarity and difference which is worthy of notice. The usual practice with the lambs in those marshes, is that of selling them the beginning of September to be kept by the neighboring upland or hill farmers during the winter. They go in separate lots, being received at certain appointed places by the farmers, and driven to the houses, or taken to the farms by their servants. They are then commonly put upon the stubbles or graminious, as they are called; but in some cases they have also pastures to run upon, though too little attention is, in general, paid to the changing of them, by which they suffer much, and are often greatly injured, especially such as are weakly and delicate. Much advantage would probably be gained by having them put, in separate lots, in different fields, and by giving them in wet fields, once a day, some sort of dry food, such as hay, or those of better kinds to particular cases. It is not improbable, indeed, that lambs might be safely kept in those marshes through the winter, by the use of such food and proper care. It is found that there is a prodigious benefit in keeping the lambs in winter, in such situations, in having the grounds dry and warm, instead of being of a cold, wet, clayey nature. Lambs should by no means be flocked along with the ewes, as the old sheep will constantly take the feed, and fleece the land, by which the lambs may be greatly hurt. They should always be flocked separately, and the pastures be frequently changed, circumstances which are little regarded here. Some think that lambs do not thrive well on being put to grass, after having been fed on luxuriant food, such as turnips, old tares, rye-grass, &c.

The price of the keeping of lambs in these cases is very different; some paying only 2. 6d. the lamb, while others pay 5.; and where no flock are kept, they charge as high as from 6. to 6. 6d. the head, for the space of about six months. This is but a late advance; however, it makes the price of keep a serious subject. The lots of lambs in this system of winter management, is occasionally considerable, but depends much on the nature of the feason, as to mildness or severity, amounting in some cases to four or more in a hundred.

The tegs or one-year old lambs, in this system are brought from the uplands, where they have been wintered too often a low state of condition, for the supply of the marsh graziers, which enables them to keep more ewes and fattening sheep on the marsh lands. This is done about the beginning of April, when the upland farmers are indulged with a feast or treat at the expense of the graziers, as a compenence for their care and attention to the lambs, in which liberality has a great effect. As the flocks reach the marsh, they are put upon the poorest pastures, at the rate of five to the acre, their old sheep being just field to make room for them. These are commonly the bell conditioned legs, in which there may sometimes be lots from the hidden transition from poor to too good keep, though they are not, in general, to suffer in some sorts of disease at the old ones, or such changes being made in their food.

The marsh sheep graziers have lately been much in the practice of prevailing on the farmers to keep such flocks a fortnight, or even double that time, on our pastures, which has the advantage of enabling them to double the stock on the same pastures during the summer; while on the other hand, it is evident, that when they are too hard worked early in the spring, they can neither have luxuriant growth, nor be to full of grass. The pastures are likewise raised gradually, as the fat ewes or wether-s are taken off, and their places supplied by the wether-tegs, while the ewes are furthered to remain on their natural pastures, until they are selected, or set for going to the races.

In the ewe management of the marsh system, which is by no means well regulated, the ewe-tegs, one-lamb, two-lamb, and three-lamb ewes, are all mixed together, so that they cannot be distinguished by the grazier, as they are not marked until turned off for fattening. A better and more convenient way would, however, probably be to keep the different kinds separate as much as possible, as many advantages would result from it. In winter the land stocked in proportion of from two to three ewes on the acre, as it may be of a more or less good quality, and in summer with from three to four and their lambs. In ease of twin lambs, with not ever more than three to the acre upon the belt pastures. The farmer flocking with ewes is here supposed to have too much uniformity in it, though it may perhaps be proper in the winter, yet that feeding is mild more might certainly be kept than under the contrary circumstances, for which no sort of allowance is made. It is conceived, that it would be a public policy, when there is the probability of plenty of keep, to increase the number of ewes on the breeding pastures, though there should be a necessity, on that account, to provide an additional pasture field or two; however, so prejudiced are many sheep-farmers in favour of the common practice, that they do not even make the necessary additions of flock to keep the grass properly under, by which means it is apt to become bony, the pusture injured, and considerable waste sustained. The old sheep, or those which have had the third lamb, are commonly cast off for fattening, and the others marked for fiores, and weaned from their lambs, by putting them into one of the pasture fields for some days; which not only improves the field, but prevents the ewes from receiving injury by the flow of milk. This is a practice which in the marsh management termed bleating the ewes. Some reject this mode, and put the ewes immediately on the fattening ground, from the conviction that more injury is likely to ensue by keeping them in a starved condition, for even a short time, than by throwing them at once into fresh keep. Whichever of these is the most eligible practice is not attempted to be decided, but the most general one is that of bleating; aged sheep are not so liable to be ill used with disease as young ones in such cases, or the season of the year for favourable.

The system of the marsh for the management of the wethers, and the time of drawing them for the market, is thus; the wether-tegs are in the general practice put upon the fattening land for the winter about Michaelmas, in the proportion of from two to three upon the acre, as may best suit the designs of the grazier. Those who intend to keep them for a whole year, commonly put three on each acre of the belt pastures for the winter flock; but those whose intention is to make a second or third return, are satisfied with two upon the same extent; in which case, however, it is necessary that they be put more early upon the land, in order that they
SHEEP.

may get properly fat before winter, and go off sufficiently early, which would otherwise not be the case. The latter method is thought unquestionably to be the most profitable; but those who have not a sufficient supply of funner pasture, conceive that it will pay them better to keep three to the acre, in barely a thriving state, and fatten them in the following spring and fummer. However, though they may continue to increase in size, it is most likely they will not be of more value at Michaelmas than they were in the spring; so that there is a clear loss of the whole fummer keep; as mutton may often fall for 6s. or 7s. the Roome in the spring, and not bring more than from 4s. to 5s. at that period in the autumn. It has been a question, whether other sheep or old barrens fatten the most quickly, on which it may be noticed, that any incease in the food of full-grown sheep must have a tendency to the formation of fat, whereas in wethers or other young sheep, it must be partly expended in the evolution and development of their frames, and, of course, less fat be produced. Much, however, will depend upon the size and disposition of the sheep.

There is great difference in the practice of different graziers, in regard to the time and manner of drawing the sheep for the market, some beginning much earlier than others, though the sheep were all put into the fattening pastures at the same time. Some draw the worth of the sheep first, conceiving that the prime sheep pay the belt for keeping; while others fend them to market as they get fat, by which means, time is given for the advancement of the more common ones. Which of these methods is the most to be preferred, it is not at all attempted to determine; but the fending of inferior mutton to market, it may be remarked, is only giving it away, while, on the contrary, the retaining of such sheep as are deficient in disposition to fatten, is a complete loss of the keep of them. Towards the end of the fummer, keep, however, is of but little value, and, of course, their remaining a little longer is not of any material consequence. It is therefore thought, perhaps, the belt not to part with them until the approach of autumn, when inferior mutton often falls well in the vicinity of the marsh, or to dispose of them to lamb butchers at a somewhat reduced price. This inconvenience would, however, be much removed by a better and more proper selection of the sheep than that which at present is the case.

In fending the sheep to market, care should be taken to have them as nearly as possible of the same size and condition, as a few inferior ones are apt to lower the value with the butchers. In this intention they are by some divided into two or three lots, while others send them in one only; the former, however, in general obtain the highest prices. By more attention to the regulation of size and keep, a greater equality would be met with in the wether sheep on the fattening pastures of the district than that which at present prevails.

In the fystem of these marshes, the ewes which are designed for breeding ram-lambs from, are selected and drawn before the riding time, as directly upon the weaning season, or a few weeks previous to giving them the ram; there being great differences in the forms and sizes which are thought the belt calculated for this purpose, in the notions of different graziers; some preferring large, others middling sizes, while many esteem mott, such as have long legs and bodies. There is here, however, much too little principle in the management of this business: Such ewe lambs as come from ram-lamb ewes, should be so marked as to distinguish them, and be constantly preferred for breeding ram-lambs from. The ram-lamb ewes are mostly lambed by themselves, and have superior keep. Those which do not suit the intention of the grazier are castrated; while such as are to be faved have a small part of the tip end of the ferom cut off, and two marks fixed upon them, one on the shoulder and the other on the hip; being constantly indulged with the belt fattening keep, as it is the common opinion that they cannot be too large. They are sent to particular situations on the neighbouring hills during the winter seafon, where they are tended with the utmost care and circumspection, having hay and turnips occasionally given them. On being brought back to the marshes in the spring, they have the run of the belt pastures, being focked so lightly upon them, as to be in every way adapted for the breeding farmer. Another selection sometimes takes place for the same object, by which the fummer, in which, those which do not fuit are either sent to market, or netted, while those which are approved are employed in the ensuing riding time. These young rams should only have a few ewes, as thirty or forty, as more greatly injures their growth, &c. They are usually sold or hired out, by which much money is often made.

It is the practice here to keep too many rams together in the same pature, as much loss is sometimes sustained by it. The usual time of putting the rams to the ewes here is about the middle of November, though some prefer a month, and others a week or a fortnight sooner, as their notions may be in regard to the conveniences of lambing and other matters. A week or two before the riding time the ewes are prepared by being put into the larger fields; only one ram being admitted in each, unless it be so large as to liband in need of two, when with the old ram a young one is admitted. This management prevents fighting and all inconveniences of that kind. The rams commonly remain with the ewes a month, care being taken that they perform their business properly; some change the rams occasionally, as after the first fortnight, and at other times according to circumstances. Sixty ewes are usually allowed to an old ram, and thirty to a tug ram in this marsh system. See STOCKING LAND.

It may be observed that there is some difference in the method of managing heath, down, and mountain flocks of sheep, from those which are purfued on the inclosed pature lands, though in the selecting and providing the rams and breeding flock, the same practices are followed by the belt sheep-masters. The principal difference consists in the manner of keeping them, by putting them as early as possible in the spring months, as in the beginning of April, upon the downs, heaths, and commons, and keeping them upon them until the approach of the autumn, as the beginning of October; the fine soft sweet herbage in these fefs preferring them in a state of tolerably good condition. And where it begins to grow scanty and decline in goodnes, other ferts of feed which have been previously provided are had recourse to, such as turnips, clole, &c. on which they are ffold during the autumn and winter till confumed, when hay has been focked for the purpose in fuch situations, is employed until the graft has again advanced to a proper bife. In these fefs the fystem of folding is generally recurfed to during the whole year, in the fummer and autumn chiefly on the ground in a flate of preparation for the wheat crops, but in the winter feafon often on the ftrubbles, though more extensively upon the downs and pastures; while in the fpring feafon the lands under preparation for the barley crops receive them. This fystem is confidered as very benefical by the farmers in those districts where it is in use. And in the more hilly and elevated situations in the northern parts of the kingdom, other methods of management with this fort of flock are employed. In Argyleshire the principal circumstances attended to by the molt intelligent heep-farmers are these: to fock lightly, which will mend the fize of the sheep, with
with the quantity and quality of the wool; and all tapers on their age. In part, I refer to disease. In all these respects, it is allowed by good judges, that those kept well, will return to impress that they kept red, nearly. To test the heif, lambs, and flocks I have the test, called, and when a good wood, for the part, and breeding ewes, and to eat and play the world. To test a change of the feed, etc., and of breeding ewes occasionall.

It may be noticed that it is, however, only in the Lamer-muir district that sheep husbandry can be said to be regularly practised, the management of which is this, according to Mr. Hay of Hopes. All fleur-farmers of any extent keep two fleurs, or one ewe and one yearling of yield 3, or 4, and 5, and onwards in number, and has and 5 at what ages had, for the year old and 1 year old, and upwards, starts are made to break for a week, down to the first of July, and then they are started again.

The lambs, after being reared to full pelt, called the lam, which has been kept for breeding, is run till the end of August, when they are fitted to the heif, sheep, called the heif, and are laved from the water, the year, and kept in winter. The sheep at the March market, called the weeding, which is kept for breeding and them, are put with the lambs into the field, for the winter. All sheep are featured, that is, laved, in dry or the barren, at the rate of two to three each. They are laved to a Scotch part of tar, which they are six to ten sheep, at the expense of about 10, or 12 each. The wool at from five to nine, and the iron, lime, and the wool may amount to from eight to ten to 25 to 30; deducting the expenses of his family, the rent, pay up the wool, and in a few at 30 per head, sometimes a little more or less, very resembling the price of wool. Upon dry heathy grounds, the ewes are drafted, and held to green past, in the month of March; but upon wet grounds, which are dangerous, and such as the shepherd called the east, they are carried, and kept in October. Few fleur-farmers (whence) in Lamer-muir breed as many sheep as keep up the trade; they have to buy yearly a parcel of sheep which are usually weeded. Linton, in Tweedside, is the great market for these weeder hopes. These weeder sheep keep for two years, and sell them to the feeders. Some of the most judicious fleur-farmers have totally given up the practice of milking the ewes, after weeding; and others milk for a shorter space than formerly; and they now allow the lambs to suck longer, which considerably improves their bone, and is thought not to prevent them from the wool as the milking. This practice, however, still prevails in Wales; the fleece made from ewe-milk being highly esteemed, such milk being said to be four times as rich as that of cows. The sheep are lated to give a quart of milk per day each, and being milked three months, the return is lated at ten tinnings per ewe.

It is also further lated by the writer of the above Report, that the method of managing the arable land in that district has been changed much for the better, within these few years. When in grass, it is sowed; and when taken up, it gives three crops; and is then followed, and town out, the first crop with grass-seeds; and they generally follow the same practice with the new grounds taken in by fellow and lime, which has now become a general practice through Lamer-muir; and lime, when applied to dry ground, is certain of making a lasting improvement upon the grass, which is, and always ought to be, the great object upon fleur-farms. However, since this account was given, much improvement has been made in this sort of husbandry, which is now carried on in a very systematic manner, it is said.

It is worthy of notice, that the practice of cutting or salving is now, even in these situations, much on the decline; and in the more northern parts of the island, not at all employed. See SALTING & SHAPE.

In the sheep districts, in the more elevated and exposed northern parts of the island, a still better practice is had recourse to; the sheep being mostly left to provide for themselves, even in the most severe and inclement feasons, when
when the bleak tracts on which they live are deeply covered with snow. According to the writer of the Perthshire Agricultural Report, in these cases the sheep have their chief dependence for subsistence on their own habits, which lead them to remove the snow by their feet with great facility, till they reach the heath or withered herbage. But when the snow is falling, or blown by a storm, the sheep drive their flocks, without intermission, round the top of a hill in a circle, in order to keep them from lowering, and being drifted up or smothered. It has been the practice, in some districts, to erect a fort of circular folds on the tops of low hills, for the same purpose; and when the heath is all covered, they sometimes rake or harrow the snow, in order to bring up the heath, with a fort of long-toothed rake or small harrow. With some sheep-farmers it is the mode to have recourse to feeding with hay, or unthreshed oats, which is depotted in handrails upon the snow. Mr. Marshall has suggested, that cultivating plots of furze, broom, juniper, &c. by sod-drying, and rippling the surface, or by other more eligible means, could not fail of proving beneficial upon the wintering grounds of a sheep-farm. By means of these, as a resource in the deepset snow, when the herbage of the bracken was buried too deep and too evenly to be uncovered by the raking of the sheep, by keeping the most exposed parts of the bracken in full herbage for feeding the sheep, and by reserve of rape for the feaston of lambing, even ewe-docks might be supported through the winter with some degree of certainty, without dry fodder, and without being left to the uncertainty of the feasons, and the mercy of the winds and weather, as they are at present.

The practice of herfelling, where no more lambs are kept than what is necessary for drawing the flock, is now much objected to by some, though it may be beneficial in rearing wether hogs; as they are found not only to do much better, when at large with the ewes, but there is much less destruction of grass by trampling, and the pastures are fed down more properly, and with less injury to, and loss of, the sheep. Besides, the sheep thrive better, and are kept in far better condition, while much less herding is required, by which there is a considerable saving of expense.

There are several different modes of rearing the lamb hogs in these situations; as by laying them, when lambs, upon a certain part of the ground, and keeping them separate from the old sheep, through the whole winter and spring, until they are clipped, and then blending them again with the old sheep, putting more lambs upon the same ground, &c.; by allowing the hog lambs, when gimmers, to remain upon the same land on which they were bred, and breeding the hogs on a different part of it, and continuing them on that also until they are gimmers or dimonots, and then introducing them among the old sheep, the lambs being every year laid on the land where such gimmers or dimonots had been the previous year; by keeping the hogs and dimonots or gimmers together, and putting the gimmers or dimonots only among the old sheep, and the lambs among the hogs, in the same place, &c.; and by breeding the hogs among the old sheep. The three last of these modes of management are supposed the most useful, but the last the most powerful in preventing disease; though the first and second probably afford the most equal flock of this description, in such exposed situations.

Profit of Sheep Management.—It is evident that there is a variety of circumstances in the practice of sheep husbandry, that must affect any statement that can be made, in respect to the profit that may be derived from it; the nature of the system of management pursued, and that of the breed of sheep employed, must operate so much in this way, as to leave the profits of no two sheep-farmers scarcely the same. But our limits will not allow us to introduce any particular statements on the subject.

In all sorts of sheep-grazing management, it should be the constant aim of this kind of farmer to regulate his pasture or other land so flocked and provided, as to derive the greatest possible profit from it; as where this is not the case, he not only injures himself, but the whole community. Where fyllems and practices of this nature are followed, which are not sufficiently profitable, they should be given up, and changed for such as are more fully beneficial. The same plan cannot, however, be always equally productive of advantage, as the fluctuation in the value of stock in different places, and from the ease or difficulty of providing it, at different times, as well as the nature of the feason, must be the causes of much diversity in it, which are invariably to be well attended to by the sheep-grazer, and turned as much as possible to his own account. See Grazing, and Stocking Land.

The practices and profits of different sheep-grazing farmers are often very different in the same situations, as scarcely any two farms of this kind are conducted exactly in the same manner for the whole of the same years, or probably the same farms for two succeeding years together; as farmers of the same fort will be fetched and regulated in their management by times, circumstances, and seasons, so as to have their lands flocked according to the growth, or the probability of the growth, of grass on them; taking care to have them always provided during the early summer months. Peculiar local circumstances, and the difference in the conduct and management of individuals, as well as capita, may also have great influence on the profit. On these grounds, the ordinary profit may amount, in favourable cases, to one pound the acre, and from that to two or three, as they are less or more favourable. The difference of practice which is had recourse to, as it relates to the forts of flock, may likewise further increase it.

The employing sheep-flock wholly is probably the most profitable plan of all others, where such flock can be readily and reasonably procured, at all times, in the lean flate; but which is not always the case. And where the grazing farmer, as in the Romney-Marsh practice, can either feed them readily to the uplands for the winter, or feed them on turnips, and have their lands well kept, and fend out a sufficient number, as well of them and the legs or their management by times, circumstances, and seasons, so as to have their lands flocked according to the growth, or the probability of the growth, of grass on them; taking care to have them always provided during the early summer months. Peculiar local circumstances, and the difference in the conduct and management of individuals, as well as capital, may also have great influence on the profit. On these grounds, the ordinary profit may amount, in favourable cases, to one pound the acre, and from that to two or three, as they are less or more favourable. The difference of practice which is had recourse to, as it relates to the forts of flock, may likewise further increase it.

The employing sheep-flock wholly is probably the most profitable plan of all others, where such flock can be readily and reasonably procured, at all times, in the lean flate; but which is not always the case. And where the grazing farmer, as in the Romney-Marsh practice, can either feed them readily to the uplands for the winter, or feed them on turnips, and have their lands well kept, and send out a sufficient number, as well of them and the legs or their management by times, circumstances, and seasons, so as to have their lands flocked according to the growth, or the probability of the growth, of grass on them; taking care to have them always provided during the early summer months. The difference of practice which is had recourse to, as it relates to the forts of flock, may likewise further increase it.
fuch pastures be improved; which should be the constant aim of the sheep-grazing farmer, whenever the expenses will allow of it. Further, the expenses of labour and keeping such pasture-lands is proper order, loaves of flock, &c., must take greatly away from the profits of this kind of farming. It is, on the whole, thought, that through the profits of the breeding flocks may fluctuate considerably, it will not be so great as in some other modes of sheep-grazing. The breeding sheep-farmer may, it is said, have a large or a small crop of lambs; he may lose a great many, or only a few ewes. There may be an increase or decrease in the value of the lambs, old sheep, or wool; there may be a profitable or faulty crop, an increase or decrease of rent; which circumstances cannot fail to alter the profits of a breeding flocks. But that lately, for many years, the great demand for lean sheep and wool has contributed greatly to the profits of farmers of this kind. The profits and advantages of the fattening fylle of sheep management, which is more varying, will be afterwards particularly considered, and in some meafure compared with the breeding practice.

The original differences in the value of lean sheep, for the purposes of the breeding sheep-farmer, and as they may happen to be in a better or more reduced condition, must have a further effect on the profit of this fylle of management, as often amounting to not less than from three or four to eight or nine shillings the head.

**Fattening-Management of Sheep.**—In the business of fattening flocks sheep, there are many circumstances that should be carefully attended to, as well as that of managing the breeding and other flocks. The kind of sheep that are most advantageous under the different forts of keep, situations and kinds of land, must be well considered; the differences in the forts of food, in regard to the improvement of the sheep; and the most benefical methods of employing it in different cases; and lastly, the markets. And as the sheep under this treatment should never be suffered to have any fort of want of fresh food, they should never be kept too long upon any inclosure or gras-piece, or any other fort of keep, so as to be compelled to feed upon the fullled or trampled food, as it always greatly retards the fattening of the animals, or what is termed proof, which is conflantly the most promoted by the allowance of only the prime fresh food.

There are many different forts of food made use of in this busifnes, such as the different forts of turnips, which are very extensively applied in this fylle, and some use them alone; but it is probably a better practice to give some fort of dry food with them, especially where the common turnip is employed, as it is more watery and less nutrient than that of the Swedish kind. Cut hay, chaff, bran, corn, oil-cake, all answer well in this intention; and of the first two or three forts they should have a pretty full supply; but the latter, from their expense, should be more sparingly given; several pounds of oats will however be required for each sheep per day, according to the kind and fite. It is stated in the Norfolk Agricultural Survey, lately published, that captain Beach having 700 fatting sheep, and turnips running short, put 200 of them to oats (out ground); he found that the practice would not answer if oats were not allowed to them, so as to cover the sheep's heads and neck, &c., at a defter rate, as wet is not only prejudicial to the sheep, but spoils the cake. A rack for hay, fixed over the trough, might probably be made to answer in this intention, when it would be very convenitent for holding that material, and preventing waste. The whole should be hand on wheels, and be made adjustable, and a sufficient number for the quantity of sheep be always ready.

Steamed or baked potatoes, cheap convenient, continues for the preparation of which have been lately invented, have been supplied by time to be preferable to turnips as a food in this intention. And they have been employed raw in the proportion of eight or ten pounds per sheep in the course of the day or night; but they are certainly a much better food in their prepared state. The quantity of common turnips consumed by each sheep in the same length of time, is usually about eighteen or twenty pounds. Where this last fort of crop is good, an acre is supposed to support about five score sheep in the field, six or seven weeks in the winter season: an acre of good grass supporting at the rate of one hundred couples from five days to a week.

In the fattening of wethers, the use of barley meal, with grafs or some other fort of green food, has likewise been found highly benefical, and when it can be procured at a reasonable rate, should not be neglected, as it is quick in rendering them fat, and the mutton is excellent.

Different other articles are occasionally made use of as the fattening food of sheep, such as peas and beans, or pea and bean meal in the winter season, and some substances of other kinds. It is not known that any fort of pure farinaceous matter has ever yet been tried in this intention in sheep, but it is probable that it could not fail having the effect in a very expeditious manner, if the expense of it would allow of its application in such a way; and it might be conveniently given, in small quantities at a time, in mixture with chaff, cut hay, bran, or any other similar fort of material, in covered troughs or bins for the purposes, suitable other forts of food being had recourse to at the same time.

On the most usual fort of food for this use, that of turnips, sheep are very apt to go backward, unless fattened out before the winter feaon sets in. Indeed the losts from keeping fat sheep through the winter is often so considerable, that it is advisable to have them ready to fell at the close of summer, to prevent the winter keep from being thrown away. The most benefical application of this fort of food in fattening sheep, has, however, probably not yet been fully shown, as some kinds of sheep are said to pay well in winter fattening.

In fattening sheep in yards with potatoes, some take them in towards the latter end of the year, and keep them until they are ready for sale about the beginning of March. They have the potatoes sliced, and put into covered sheep-troughs, a gallon being sufficient for a sheep in a day. They mostly prove well, and the fort of food, so that if a fair trial be made, the potato fylle will probably be found the most expeditious of any in fattening these animals. When compared with different forts of grain, oil-cake, &c., by means of accurate trials with sheep in every way the same, it has been proved to be the most ready in effecting the busines. A little hay is mostly given with the potatoes, morning and evening. A vast mass of excellent manure is likewise raised by this practice, where due care is bestowed in the preparation of the yard. Many other substances tried in the same way, may possibly be equally benefical in this intention, though they have not yet been made use of by sheep-farmers.

In regard to the profits of the fattening practice of sheep, a number
management on the more rich lands of the marsh kind, they must vary much according to the nature of the methods which are pursued by different sheep-grazing and fattening farmers, as some will make their land carry nearly one-third more flock than others, though the quality of it may be the same, while such flock will do equally well, if not better. Such commonly make the largest profits as have constantly the best supply of additional sheep-flock to succeed such as are taken away, and who regard the number more than the quality of them. The fattening practice may likewise be carried further than is proper and beneficial, by which the profits of the individuals will be lessened, and a loss sustained by the nation at large. The nature of the breeds of this fort of flock will have some influence, as they make a more or less quick return, and as they may come to a more sheep or dear market. The belt way in general, is to fill the fat flock of this fort when ready, without waiting, but which is not always the case. Where more returns than one are made in the year, there is commonly the most profit made to the sheep-farmer; and the practical management which has had recourse to in such cases, will have a great effect on the profits, as different rich sheep-fattening districts have many different practices, which are more or less profitable, as that of flocking the land with sheep, at the rate of three to the acre, from the beginning of one autumn to that of another, and having recourse to mixed flock of other forts during the summer for producing the profits: that of flocking with barren ewes which have had lambs, at the same time, but only at the rate of two to the acre, so that the keep may render them in a great measure fat by the beginning of the new year, and they may be fold off in March or the following month, in their wool, so that the advance in their price may more than compensate for having it, by keeping them on until May. And after these are gone, by again flocking the same land with sheep brought in from the markets, fairs, hills, or neighbourly high grounds, or the two years old wethers that have been kept out, or, which is perhaps the belt flock in these cases, with such tugs as have been well kept through the winter, and which are equal in weight with flaved or tilled two-yearlings. This is a most profitable sheep-fattening fytlem, where it can be carried into practice, that of putting, what are denominated made bars, or such ewes as have missed going to lamb, upon the fattening land; but as these will not form the necessary supply of flock, other shee or mixed flock must be provided to produce sufficient profit. It is never a good practice to turn poor lean sheep directly upon the rich fattening lands, but to keep them some time on the inferior pastures, as they are in danger of becoming diseased by the former method. But half-fat shee may be put immediately upon them without danger, and be fed out, often in the course of two months or less, by which the sheep-grazing farmer is enabled to have another return, which may contribute greatly to his profits.

In the sheep-fattening fytlem, it is often of advantage to have a portion of land, of a superior rich quality, for the purpose of finishing them out upon; as by such means not only more sheep can be fed out and returned, than if the regular quantity of flock was kept upon the different fields, but the less rich pastures be flocked in a more clofe manner, and as the more quick feeding sheep advance, be taken into the rich finishing portion.

There are several other circumstances which have much effect in this fytlem of sheep management; but the profits will materially depend on the proportion, the richnels, and the quality of the farmer's fattening to his other lands, on the judgment which he posesses in the buying in lean flock, the nature of the season, the state of the markets, the looses sustained, the expenses of the management, &c. as already feen.

Though the size of sheep is by no means a point of much consequence in the breeding practice, it should not on any account be overlooked in that of fattening.

The average profit of middling-priced fat rich pature sheep may be stated to be from about one pound to one pound four or five, or even ten shillings, or even more in some cases.

**Folding-Management of Sheep.**—In the management of sheep there is a practice made use of in some districts, which requires to be noticed; and which is that of folding. It was formerly thought to be indispensably neccesary to the successes of the farmer in different districts; but of late a different opinion has prevailed, except in particular cases, and it is considered as merely enriching one field at the expense of another. The practice may, however, be beneficial where there are downs, heaths, or commons. The ideas of farmers are not, however, uniform on this subject, as will be seen by the following details from the Norfolk or Hertfordshire Reports on the agriculture of these districts.

In the former it is remarked, that near Brandon there is a practice, introduced about ten years ago, paid to be from Kent, which is, to fold their flocks for five or six hours in the middle of the day in hot weather. And that, in laying out the inclosures of the farm at Waterden, from fifteen to fifty acres each, much attention was paid in the arrangement to have every field of the farm open into a lane, that leads through the whole, so that by dividing the flock for flocking, according to varying circumstances, Mr. Hill can keep at least one-fourth more than when all the breeding ewes and lambs were in one flock, and the food dried by driving to fold; by this means there is not a bent on the farm, the flocking being equal. He is not, however, entirely without a fold: when the lambs are weaned (usually about old Midsummer) the ewes are folded for about two months, principally to prevent their breaking pature, when the lambs are taken from them: and while thus folded, he finds that it takes one-half more land to feed them than if they were left allotted, as since the rest of the year. That folding lessens the value of the lambs he has not a doubt, and that conferably; they do not bring so high a price as others not folded. This is not opinion, but fact. The ewes are also in doubly better condition, from lying still and quiet. That the teat will, in certain cases, be unequally given, he does not deny; but it is not difficult to remedy this by the dung-cart; to fold a lot in its own lay, is also a remedy, and is the only sort of folding he can approve. In regard to the effect on wool, he is clearly of opinion that folding does not render it finer, it makes the fleece lighter, but never finer. And folding is generally given up by all who have South Downs; not because they will not bear it, for they bear it better than any sheep in the illand; but because the flock is so valuable that it is worth the farmer's attention to contrive, by every means, to keep as many as possible. And it is added, that one circumstance, though a small one, deserves mentioning, for the use of those who form separating sheep-pens: which is, that Mr. Hill has sliding-gates from one to the other; the writer remarked that when a pen is full of sheep, the gates cannot be opened with convenience; but by their sliding in the fence, this is avoided in a very easy manner.

Further, Mr. England, of Binham, does not fold. When not folded, he thinks, they do with less food; and as to the common objections, of their drawing under hedges for shelter, in forms, &c. so much the better; it is what they ought not
not to be prevented from doing. The task is much more than left as mutton. And Mr. Reeve, of Wighton, never folds: it being from layers, upon fallow, is only robbing one field to feed another. He is clear in this point; and also in the fact, that if sheep (whatever the breed) are driven by foul weather to a hedge, there is the proper place for them, and not by penning left to abide the beating of the storm. Mr. H. Blythe, of Burnham, sometimes folds, but never from choice, but solely by reason of the openness of his farm; nor does he approve the practice. And he explained a point in his management for wheat, which, the writer fays, comes home to the question: he never saws tempered land with wheat, without either oaken, or muck, except as pieces from which the sheep were not folded while feeding the layers. And Mr. Durbridge fays, that, folded sheep certainly demand more food than those which are not folded; a quarter of a ton of rapeseed is equal to the fold; and the flock, without any doubt, fuffers more than that value by folding. In short, folding is to gain one shilling in manure, by the loss of two in flesh. Some, however, fold with large flocks. But Mr. Beck, of Rivington, does not fold; and he is very certain that if he did fold, he could not keep any thing like the number of his present flock. It is added, that as the writer rode across a layer of forty or fifty acres, on Mr. Overman’s farm, he observed a great difference in the verdure, to a line across it, the appearance of one side of that line being so much superior to the other; and on his remarking it, he was informed, that it was an accidental experiment, which was well worth attention: there was no other difference in the management, to make one part of that layer better than another, except the sheep that fed it being from one part of it folded on another arable field during the summer, but from the other part they were not folded at all, but left in the layered night and day. The difference was very considerable, and might have been discerned half a mile off. This experiment made that farmer give up folding, except when his flock was in a half-marsh; and Mr. Tottle, a neighbour, averted, he would never fold at all had he no marshes. Nor does Mr. Etheridge, of Stanhow, fold. These facts shou’d, the writer fays, be combined with another, that of heaths and sheep-walks that have been fed with sheep for centuries; but those sheep constantly fed on other lands, are so far from improving them, that they are to all appearance as poor as they could have been at any former period. It is further stated, that Mr. Styleman, at Snettisham, turned his flock loose, and without folding, in twenty acres of all land every night, for the fame period that would have folded it in the common manner. The sheep did much better than they would have done had they been folded; the land of the herbage materially improved during the period, and upon ploughing it up for wheat the crop was equal to what it would have been with folding, and foweded by a regular verdure, that they had distributed the manure equally in every part. He conjectures that lambs fell 32. a-head lower on account of folding, than they would do without it; but this is only his opinion. He thinks also that the ewe is much injured.

But Mr. Pitts, of Thorpe Abbotts, finds that no muckin, on his burning grasses, will do so much good as the fold, and especially on a white clover and trefoil layer for barley. And in the clay distrat of the county of Hertford, Mr. Byde remarks that sheep have been too much lefiened. Of all the common manures, he considers the fold as the best; and he has observed in many farms the general appearance of the crops decline, as the number of the sheep kept has lefiened. That at the Hadhams, every man folds the sheep which he keeps; a little farmer will even let four hurdles, if he has not sheep for more. But that of the manure of the field is, Mr. Chapman has found by trial in the fame field, for turnips, that yard-dung was much better than both fold and mulch together. However, Mr. Roberts, of King’s Walden, thinks nothing is equal to the fold; he never reckoned it worth less than 42. per acre, corn being cheap; but of late much more; he folds two poles of ground with twenty sheep. And Mr. Siddons, of Rickmanworth, solemnly in favo’re of folding on all farms.

See Remarks on Sheep.

It has been observed by Mr. Ellman, in the Annals of Agriculture, that the lower South Downs sheep (in a large part, a hard number) will fold one rod per night; three thousand two hundred will fold one English acre per night.

We value the manure at from 35. to 50. per acre, the good of which depends on the manner in which the sheep are kept; if kept on artificial food, such as turnips, rape, clover, turnips, &c. they will drop more foul than if fed on grasses only. Supposing we estimate the folding at 40s. per acre, it will amount per year to 42.- 63d. per sheep; 251.- 16s. 3d. per hundred; or 325.- 2s. 6d. per thousand, supposing the sheep folded throughout the year. If it is a breeding flock, it might be well to omit folding for five or six weeks immediately after lambing, as the young lambs might suffer from being trampled upon, and from driving to and from fold, would often lose their dams, and suffer in that way more than if they remained quiet. There is, however, another method of folding, by which all the advantages may be obtained during winter on all folds, without the inconveniences of the former plan. This is to fold them at night in a sheep-yard, well and regularly littered with straw, rubble, or fern; by which means you keep your flock warm and healthy in bad seasons, and, at the same time, obtain a surprising quantity of dung, so great a quantity, if you have plenty of litter, that the profit will be better than folding on the land. A great improvement in this method would be giving the sheep all their food (except their pasture) in such yard, viz. hay and turnips, for which purpose they may be brought up, not only at night but also at noon, to be bated; but if their pasture be at a distance, they should then, instead of bating at noon, come to the yard earlier in the evening, and go out later in the morning. This is a practice which cannot be too much recommended; for so warm a lodging is a great matter to young lambs, and will tend much to forward their growth; the sheep will also be kept in good health, and, what is a point of consequence to all farms, the quantity of dung raised will be very great. If this method is pursued throughout the months of December, January, February, March, and April, with plenty of litter, a hundred sheep will make a dunghill of, at least, sixty loads of excellent illuf, which will amply manure two acres of land, whereas one hundred sheep folded (supposing the grass dry enough) will not in that time equally manure one acre.

And in Norfolk, Mr. Bevan finds a yard well fenced for standing fold for littering and for one fold in bad weather convenient; and it is generally of the great advantage of it. He intends in future to have his flock in it for yearning, whether the season be good or bad. And in Hertfordshire, the earl of Clarendon has a fold which contains good room for three hundred sheep, the number kept in it: an open field surrounds it, except on one side, where a barn is the fence; the outside of the field is formed of wattled hurdle-work, without straw or other materials, for coolness, left a greater coolness should make the yard too hot: it is all kept well litted with rubble, and yields, from three hundred sheep, eighty large cart-loads of manure. This system agrees perfectly well with the sheep, and keeps...
them more healthy than when they were left in the fields in the common manner. His lordship has another yard for lambing, which has also a field. These sorts of yards, from their beneficial tendency in different views, should be more generally made use of by sheep-farmers in all situations. See Sheep-House.

This practice is had recourse to on arable land for raising different sorts of crops of the corn and green kind, as well as on graps-lands. It is suppos'd by some, that a flock of about five hundred sheep will be sufficient to pen twenty-eight square perches of land each night, which will amount to about fifty acres in the year, where the practice is discontinued for two months in the course of that time. The value of this is different in different districts, as from above thirty to more than forty shillings the acre, which, for five hundred sheep, would be from 87l. to 10l. for fifty acres, which, taking the average at 9s. for that amount of flock, the annual advantage of the fold may be set at 32. 9d. a-head, or rather more; taking it at 10l. it would be 4r. 2s. 6d., or rather more. This shews the great utility of it in some places. All sorts of sheep, except the fattening ones, and those disposed to that flate, are mostly folded. It forms a sort of moving dunghill, which enricles the land at but little expense, and which may probably be rendered further useful by a greater division of the flocks. It is also beneficial in preventing the waste of food on graps-lands, as well as in confuming particular sorts of crops. See Sheep-Fold.

Hurdling-Management of Sheep.—It may be noticed, that the great utility of hurdles or different kinds of green crops, in confuming them by sheep, has been long known and practis'd; and equal advantage may be derived in many cases, by having recourse to the fame method on rich graps-lands in large inchofures, so as to let the animals have a fresh face or bite every day. The sheep are found to thrive better, and the fame extent of land to support considerably more in number, while the land is at the same time much improved. And it is not improvable, but that other sorts of flock may be managed in the fame way with similar advantage. In these cases the hurdles must be fit according to the nature of the graps; where it is bare and thin, larger pieces should be folded, than in the contrary circumstance. See Hurdles.

Washing-Management of Sheep.—From the fleeces of sheep becoming much loaded and filled with dust and dirt of various kinds, in the hot summer season, by way of preparation for shearing, it is necessary to have recourse to the operation of washing. It was formerly the method of performing this busines to have the wafhers flandering up to the brat in the water; but from the inconvenience and danger of it, the men requiring a large supply of spiritufl liquors, and being liable to be attacked with colds, rheumatifs, and other diseases, as well as being apt to dispatch the work with too much expedition, fo as to leave the wool insuficiently clean; it has been propos'd by Mr. Young, in his Calendar, to roll off a portion of the water (in a stream or pond) for the sheep to walk into by a flope mouth at one end, with a depth sufficient at one part for them to swim; and to pave the whole: the breadth need not be more than six or seven feet; at one spot to let in on each side of this passag[e, where the depth is just sufficient for the water to flow over the sheep's back, a calf other fixed or ledged, for a man to stand in dry; the sheep being in the water between the sheep, they are washed in perfection, and pulling them on, they swim through the deep part, and walk out at the other mouth, where a clean pen, or a very clean dry pature, is to receive them; of course there is a bridge railway to the tubs, and a pen at the first mouth of the water, whence the sheep are turned into it, where they may be soaking a few minutes before being driven to the walkers. But other more cheap contrivaces may be provided where there is clean water at hand for the purposes. And sheep should on no account be driven on dry or dulky roads after this operation.

But in all cases before this work commences, the lambs should be separated from the ewes and other sheep, and each be put in separate pens. With these it is seldom necessary to do much more than just fwill them through the water, without their being touched by the walkers. As soon as they have been washed, the sheep should have a clean hard pature for a few days, until they are perfectly dry, and in a proper condition to be florn. The lambs are generally florn, especially in the northern districts, a few weeks after the old fheep, and the operation is termed flerefling. The lambs that are sold in Smithfield market are, we believe, seldom or ever florn. See Sheep-Shearing, and Sheflfing of Lambs.

The practice of washing the sheep before they are florn is a custom that prevails over most part of the kingdom, especially with the long-woodied breeds, and pretty generally with those of the short-woodied kinds also, but which is performed with more difficulty in them from the close-lined nature of the fleeces. It is said, however, to have been the custom in Devonshire, for a great length of time, never to wash the short-woodied sheep, but to shear them dry, as is confantly the cafe in Spain.

The practice of washing the sheep before shearing now, however, begins to prevail in some parts of it, according to the writer of the Agricultural Report of the county. This has at length been enforced, it is suppos'd, by the difference in the price which the wool-buyers make between wool in the yolk and washed wool, which is no less than 50 per cent. even in the Dorset fort of wool; and though it is not so much, it is greatly more than proportionate in the coarser fleeces, besides the over-weight of 5 per cent. The wool of the Dorset fat wether sheep, which is about five pounds each when washed in the yolk, rarely sells for more than 1s. the pound, but when washed, it as commonly commands 1s. 6d. The weight of a fleece in the yolk, is to the same fleece when washed, it is said, as fix and three quarters to five, and the consequent value is as 6s. 9d. to 7s. 6d. the fleece. This has, at length, been made evident to the sheep-farmers of this district, who now willingly agree, that it is advantageous to wash short-woodied sheep before shearing, but to sell the long and coarse flaped fleeces in the yolk.

Good clean wafehing is a matter of great confequence to the wool; and it is of much advantage to it as well as the sheep to have the weather fair and fine at the time it is performed, as they are much less liable to have colds.

Shearing-Time.—In respect to the proper period of clipping or shearing sheep, it must be directed by the state of the weather, and the climate in the particular district; and by this means the danger of injury by cold, from depriving the sheep of their coats at too early a season, and from heat, by permitting them to continue on them too long, may be avoided in the best manner. But another circumstance, that should likewise be attended to in this busines, is to that of the wool being fully grown, or at the state of maturity, at which the clipping proceeds that period, it is said, in the Annals of Agriculture, to be weak, and fearedly capable of being spun; and if protracted later, it is yellow, failed, and of an imperfect nature. It has been flatsed, that for the more warm sheltered situations in the southern parts of the kingdom, the beginning or middle of June, when the weather is fine, may be in general the most proper; but in the more exposed districts, in the northern parts
parts of the island, the middle or latter end of the same mount may be more suitable, provided the season be favourable. But with the fattening sheep in the meadows, it will mostly he necessary to perform the work at an earlier period, in every situation; as the great increase of heat, from the setting in of the summer weather, added to the warmth of the fleece, becomes very oppressive and injurious to them, in their feeding and other properties.

It is an excellent practice with many good sheep-farmers, to clip off all the coarse wool, as well as the larger quantity of wool, some weeks before the usual time of washing and clipping the sheep; as by this means the sheep are kept clean and cool, when the season is hot, and with ease, the udders are prevented from becoming sore. This practice is common with some South Down sheep-masters, as well as in Yorkshire. In the former situation, Mr. Ellman tells his flock, as locks, at 3½d. per pound, having about four ounces from each sheep.

By some it has been proposed to shear sheep two or three times in the course of the year, with the view of having finer wool, as well as a larger quantity of wool; but it is probable that such a practice can never be of any general advantage, though the trials that have been made in Northumberland in this way seem to have shewn that advantages may be derived in both these intentions; but the disadvantages in respect to the sheep do not seem to have been sufficiently attended to. And with the same view, the clothing of sheep has been had recourse to. In experiments made in this way in Scotland, the advantage in respect to wool is stated to have been very considerable, and the expense not more than 7d. per sheep. By having recourse to this practice with that of the above, it has been suggested that combing wool may be rendered fit for the purpose of clothing, and at the same time the mutton rendered more valuable. The trials in these ways have, however, hitherto been but few, and do not seem to extend.

It may also be noticed, that in the general management of sheep, it is usual, after the shearing has been performed, to mark the sheep with redde, orke, or some similar substance; and some also cut the ear in different ways. The mark has been said to be a characteristical, but where a small quantity is only employed, little injury can be sustained. And in almost all the sheep districts of the kingdom, except in Dorsetshire, the tails of sheep are shortened, which seems to be an useful practice in keeping the animals more clean behind, and of course less liable to be driven with the flies. It has, however, been suggested in the ninth volume of Annals of Agriculture, that by this custom the sheep may be rendered less able to drive away the flies. The general prevalence of the practice would, however, seem to prove its being of advantage. There is much difference in the manner of performing the business in different districts, with respect to the length; but four or five inches being left, are quite sufficient. It is usually done while the animals are young. In all sheep-paitories the hedges should be very clear from briers, as their coats are often injured by being torn by them; and all sorts of pernicious reptiles should be as much as possible destroyed, and removed from such land.

Further, in respect to the business of castrating or gelding the lambs, it may be performed any time from the age of a fortnight or three weeks to that of a month or fix weeks; and in some districts it is deferred to a considerably later period. It is, however, the safest method to have it executed early, as there is less danger of too much inflammation taking place. But in all cases, the lambs should be in a healthy state, when it is done; as under other circumstances, they are liable to be destroyed by it. The operation is usually performed by the shepherd, by opening the testicles or cod, and drawing out the testicles, with the spermathe cord. This he often does with his teeth, in the young state of the animal. But where the operation is performed at a later period, it is usual to have recourse to the knife; the arteries being taken up, and secured by means of ligatures or the feaming-iron. The business, if possible, should be done in fine weather, when not too warm; and the gelded lambs be kept in a dry, sheltered, quiet situation, for a few days, until the inflammation is gone off. If it should happen to be wet at the time, it may be advisable to have them under some sort of shelter, where they can have room to move freely about.

It is now well known that the mode of ascertaining the age of these animals is chiefly by their teeth; but they are likewise sometimes named from the number of coats or fleeces that have been worn from them, as one-shear, two-shear, &c. The sheep of one-shear having two broad teeth before; of two-shear, four; of three, five; and of that of four, eight; which is full-mouthed. See Age of Sheep.

And they have also different names in different districts. After being weaned, the ram or wether-lamb is sometimes termed hog, hoggit, teg or tag, during the whole of the first year; and the female lamb, an ewe or gimmer-lamb, and ewe-teg. The second year, the wether has the title of shear-hog, or a two-toothed teg or tag; and the ewe is called a thieve, thaver, or two-toothed ewe. In the third year, a shear-hog, or four-toothed wether; and a four-toothed ewe, or thaver. The fourth year, a six-toothed wether, or ewe. And in some places, from the time of lambing till that of springing, the males are called tup-lambs; and from that period till the time of shearing, tup-hogs; and ever afterwards, tops; the females in the same order being termed ewe-lambs, ewe-hogs, gimmers, young ewes, old ewes. The gelded male lambs, castrated wether-lambs, wether-hogs, dambongs, or dambots, swadders. Crotos also signify old ewes; and there are several other provincial names, which are explained in their proper places, under their different heads. See Sheep, Names of.

In the management of this fort of flock, it must be sufficiently evident that a great deal of the profit and advantage must depend upon having a careful attentive shepherd, who perfectly understands his business, and is at all times willing to perform it. See Shepherd.

Sheep are subject to a variety of diseases, which should be carefully attended to by those who have the care of such a fort of flock, as soon as ever they shall themselves; as a very short time often renders them irreparable. The nature of them, and the means of removal, are described under the proper heads to which they belong.

The above accounts, observations, and details, may serve to afford the inquirer a general knowledge of the nature of sheep husbandry, and of the usual methods of management which are required with that fort of live-stock, as well as the advantages and benefits which may be derived from it in many different ways.

Sheep, and their Varieties, chiefly in connection with the Woollen Manufacture, History of. Of all the animals that have been domesticated by man, none have rendered him more essential service than the sheep. A large part of the food and clothing of the civilized world is supplied by this useful animal. The culture, improvement, and manufacture of its fleece, have constantly accompanied and marked the progress of civilization, both in ancient and modern times.
In the early ages of society, sheep appear to have been principally domesticated for the sake of the skin, or the fleece; we shall, therefore, first take a short view of their cultivation and improvement in different countries, as wool-bearing animals; whether as producing fine or coarse wool, or as long or short-woolled sheep; the produce of the two latter differing from each other in the mode of manufacture, and the uses to which it is applied, more than silk and cotton, considered as articles of manufacture.

It is not a little remarkable, that the domesticated sheep depends for its subsistence almost entirely on the care of man, and is never found at any great distance from his habitation. Left to itself, it becomes the subject of disease, and the prey of ferocious animals; or if these should spare it, its own fleece becomes the abode of insects, which continually nourish themselves with its blood, and destroy its constitution. Its enemies are indeed so numerous, and constantly at hand, that it has no chance of escaping them.”

Naturalists are not fully agreed from what animal the different varieties of domestic sheep originally sprang. The Siberian argali, as described by Pallas, was most probably the parent of all the cultivated flocks in Asia, from whence they have spread to other parts of the world. This animal, the argali, which in the Siberian language means wild sheep, is called by the Russians kancer or baran, or sheep of the rocks, from its ordinary place of abode. According to Pallas, it is the same with the mufmon of Pliny, and the ophion of the Greeks. It is found, in all its native wildness, vigour, and activity, inhabiting the vall chain of mountains which run through the centre of Asia to the Eastern sea, and the various branches of this chain, extending through Great Tartary, China, the north of Hindooostan, and Peria. The argali delights to bask in the sun on the bare rocks, but avoids the woods and shade; it feeds on alpine plants and shrubs; it prefers a temperate climate, but is found also amongst the rocks of Asia Minor. This animal loves a state of solitude, and flees the haunts of men. According to professor Pallas, nothing but the surrounding sea can account for the argali being found on an inhabited island, as it sometimes did.

The ewe of the argali brings forth before the melting of the snow: the lamb resembles a young kid, except that it has a flat protuberance in place of horns, and is covered with dark grey hair, frizzled and woolly. There are few animals more difficult to overtake than the argali. When pursued, it turns and doubles like a hare, scrambling over the rocks with wonderful agility. Though the adult animal is untameable, the lamb is easily domesticated, when taken young, and fed on milk, and afterwards on fodder, which is proved by numerous experiments made in the Russian settlements.

The argali is about the size of the fallow deer, but its make is more robust, being less elegant than the deer, and its neck and legs are shorter. Its head resembles that of a ram, with long straggling hairs about the mouth, but no beard like the goat. The horns, according to the drawing given by Pallas, bear a similitude to those of the Merino rams; their weight is about sixteen pounds; the tail is short. The summer covering of the argali is a short fleecy hair, resembling that of the deer; the winter coat consists of wool, like down, generally of a white colour, and intermixed with longer hair. See Argali.

From the facility with which the young of the argali is domesticated, and from the character of this animal, as well as its situation, we may with much probability infer that it was the parent of the Asiatic flocks. According to other travellers, the coat of the argali is of a grey or nut-brown colour: probably it may be of different colours in the different districts it inhabits. In early ages the flocks of domestic sheep appear to have been all of a dark colour: such was the flock of Laban, in Mesopotamia; and the narrative of the manner in which the change was effected, may serve to.shew that, previously to that time, the common colour of the sheep was black or dark-brown. The improvement in the quality, as well as the colour of the fleece, has always been closely connected with the progress of the arts; for we uniformly find in countries, where these have flourished, a race of sheep which yield wool of a superior quality to those around them. In Peru and Syria, the influence of ancient manufactures is still visible in the superiority of their sheep, as fine-woolled animals. From Asia Minor these animals were transported into Greece, and thence into Italy and Sicily. They were dispensed by the Romans over various parts of Europe; and the Tarentine sheep, formerly celebrated for their fine soft wool, were introduced into Spain, where they have flourished for fifteen centuries; the present Merino race being their immediate descendants, but rendered more hardy by an intermixture with the original native sheep of Spain.

From the writings of Columella, and the incidental circumstances mentioned by ancient historians, we may infer that the fine flocks of Greece and Italy were of the short-woolled kind, producing clothing wool, which was manufactured into woollen cloth, similar to what is at present worn; but probably more flexible, from not undergoing to completely the milling or felting process. (See Wool.) Indeed, from the remains of the Tarentine flocks at present in Italy, we can be at no loss to determine the nature of the former Tarentine fleece. Thirty centuries of neglect and cultivation, and intermixture with other breeds, have not been sufficient to obliterate the labours of former times. From what we have seen of the finer Italian wools, we have no hesitation in affirming, that by judicious and careful felection, it would be practicable to restore the Tarentine race once more to its original purity, in the course of a few years; were it found to poskfs some superior merit, compared with the fine-woolled sheep of Spain. The circumstances respecting the management of the Tarentine flocks, recorded by ancient writers, when compared with the present treatment of the Merino flocks in Spain, leave no doubt respecting the origin of the latter.

The term Merino, in the Spanish language, is an adjective, derived from the corrupt Latin merinus, or majorinus: when united with ovijas, it signifies the royal judge, or superintendent of the sheep-walk. At the period when the trophumantes, or travelling flocks in Spain, were established, they became the objects of police, and were placed under the exclusive jurisdiction of mayors, with public walks and large districts allotted for their sustenance, and were termed Merinos ovijas, or the sheep under the care of other lords or mayors. The names peculiar to the establishment of these flocks, such as melas, caucasas, &c. are derived, not from the Moriscos, but from the provincial Latin that prevailed in Spain before and after it was subdued by the Goths. (See Mesta.) The management of the flocks is peculiarly Roman; the merino, or mayor, corresponds exactly with the magister pecoris of Varro and Columella, and was superior to the obliiones and pallores. The practice of destroying half the sheep at their birth, and of skilfully each of the survivors on two ewes; of sweating the sheep before they were born, to increase the softness of the fleece; and of conducing them from their winter to their summer stations, by long journeys through public sheep-walks, has been derived from Roman institutions, with this difference, that in Italy their migrations were
were confined to the coarse-wooled sheep, while the molles over, or fine-wooled flocks of antiquity, were always housed.

The experiment of Columella's uncle appears the early introduction of fine-wooled sheep to Spain. Having procured some wild African rams at Cadiz of a coarse fleece, but of an admirable quality, he gave them to some fine-wooled ewes, and the lambs produced, again given to Tarentine ewes, the offspring, with their descendants, united the paternal colour with the peculiar fineness of the maternal fleece. Columella's uncle resided in Bética, which comprehended the modern Extremadura; and as Columella flourished under the emperor Claudius, the Tarentine breed must have been introduced into that province at the commencement of the Christian era. Whatever was the peculiar quality which the elder Columella introduced by means of African rams into his Tarentine flock, we may conclude that the same successful expedition was employed by other agriculturists of Bética, to convert these coarse into fine-wooled breeds, and to communicate the pure white to the black or parti-coloured native flocks, which, according to Pliny, were common in Spain. The original intermixture of different breeds of native Spanish sheep with the Tarentine in different parts of Spain, may be inferred from other circumstances: each cvana, or flock, forms a distinct breed; and the Nigrette no more resembles the Paulaec, than the Merino South Down resembles the Merino Cheviot. The genuine unmixed descendants of the Tarentine breed would have preferred one uniform character; but the native flocks crossed with Tarentine rams would retain their distinctive varieties, and transmit them to each cvana.

That the Merino is a mixed race, seems to be further indicated by the tender constitutions of the fine-wooled flocks of antiquity. Of these, the Tarentine were most celebrated in Italy, and the Mikelan in Aisia Minor. They were termed pelite and tecte over, from the coverings of skin with which they were clothed to defend the fleece. They were denominated allo molles over, not only from the softness of the fleece, but from the delicacy of the constitution. They were always fed in the house; and though fattened with brambles, or the coarsest food, they are described as a most voracious breed: a diminution of their allowance from the fraud of servants, or the parsimony of the owner, was attended with certain destruction to the flock. (Plin. lib. viii. cap. 47.) As there was no male for the lambs, nor any profit from the milk of a Tarentine flock, half the lambs were destroyed at the birth. The ram-lambs were chiefly reared, and were killed at two years, when their pelts sold to the merchant at an advanced price, on account of the beauty of the pille. This breed demanded constant care, when in the field, to preserve their coverings from being torn, and the fleece destroyed. At home they required even greater care than abroad, as they were not daily conducted to their pastures. They were frequently uncovered and cooled for refreshment. The staples of the fleece were opened and disparted, and were frequently moistened with wine and oil. The whole flock was washed three times a-year, when the weather was warm. The flables were frequently swept, cleaned, and fumigated: for these different offices two shepherds were constantly required for every hundred sheep.

The excessive care bestowed on these flocks by the nations of antiquity, shews in what estimation their flocks were held; and though such attention is remote from modern practice, we are fully convinced that, by selecting the very finest and fittest Merino flocks, and covering the wool, and frequently anointing and washing, it would give to the pille that degree of softness which is so much wanted in the manufacture of shawls, and other costly articles of luxury, but which we seek for in vain in the finest fleeces of modern Europe. However expensive such attention might prove, we have no doubt that, on a limited scale, it would well repay the labour of the judicious experimentall, as the wool would be worth more than 20s. per pound, could it be made to equal that of India in softness. It would appear that the Tarentine breed were selected with much care for breeding, and every experiment adopted, which was proved by experience to attemper and soften the pille. The transmission of these delicate animals into the Merinos of Spain, which are a hardy race, can only be explained by supposing that other agriculturists hadimitated Columella, and obtained a fine-wooled race, by crossing their native breeds with the more delicate animals from Italy. The beginning of this improvement is indeed described by Strabo in the reign of Viborine: he informs us that the inhabitants of Trudistia had formerly imported many garments, but that their wool in his time surpassed that of the Coraxi, and excelled it in beauty so much, that a talent, equal to two hundred guineas, was the rated price of a ram to breed from; and that they excelled also in the fabrics which the Saltiate manufactured. Trudistia, according to Strabo, comprehended the province of Bética, from the Guadiara to the confines of Lusitania, and southward to Gibraltar, and eastward to Toledo. The wool of the Coraxi, with which Strabo compares that of this part of Spain, we are informed, in his account of Pontus, was from the fritellated Miliane sheep. Such high prices as a talent must have been produced by a very general demand for rams, not for the use of the Tarentine flocks, which could occasion no such competition, but for the purpose of crossing the indigenous breeds of the province, which, from the earliest period, appears to have abounded in sheep.

The travelling flocks were not at that time introduced, as the mountainous regions had been till then infested by native as well as Lusitanian robbers, whom the Romans deflowered from their villages, and dispersed into cantons. (Diocorus Siculus, lib. v. cap. 32.) The Moorish looms of Andalusia and Catalonia, and those of the Christians at Segovia, in the 13th century, must have been supplied by the fine-wooled flocks introduced by the Romans. The vacant mountains, when cleared of banditti, offered a vast range of pasture from Extremadura northward, towards Galicia and the Asturias. A similar opportunity occurred to establish or renew the introduction of travelling flocks when the Christians defended, in the middle of the 13th century, to occupy the conquered provinces of Andalusia and Murcia. After that time the travelling flocks became so well established, that the menagge, or tolls, on their passage through the mountains, from province to province, the servicio, or tax to the crown, and the laws of the mella, were imposed or ratified by government, in the middle of the 15th century, before the Moorish kingdom of Granada had been finally reduced.

We are thus enabled from history to trace the introduction and establishment of the Merino race of sheep in Spain, from which, or from their descendants, nearly all the manufactories of fine cloth in Europe are at present supplied with wool. See Wool.

The native breeds of Bética were originally and gradually converted into fine-wooled animals, by repeated crosses with the Tarentine breeds, and thus an immense number of hardy sheep, producing a most valuable pille, were spread over the country, and survived the successive conquests of the Goths and Vandals, and the protracted warfare
fare of many centuries. The pure Tarentine breed in Greece and Italy being more delicate, is said to have become extinct with the destruction of the Roman empire; but the mixture of this race with the original flocks of Italy may still be distinctly traced, particularly in the middle and southern parts. The Italian wool was finer than that of any other country in Europe, except Spain, prior to the improvements which have recently taken place by the introduction of the Merinos. It is not improbable that the fine-woolled flocks of England, though greatly inferior to the Merinos in the quality of the wool, were also originally descended from crosses with the Tarentine breed introduced by the Romans, when they established a manufacture of woollen cloth at Winchelsea.

The deterioration or diminution of the improved flocks in the ages of barbarism which succeeded the fall of the Roman empire, was the natural consequence of the decay of the manufactures, and of a total inattention to prevent the inter-mixture with coarser breeds. In Spain alone, the improved race had taken such complete possession of the mountainous districts, that it remained unmixed and unimpaired till the revival of commerce and the arts, when that country supplied the neighbouring nations with fine wool, and was supplied to poffefs some peculiar advantages of soil and climate, which it would be vain to seek for elsewhere. The opinion that the superior fineness of the Spanish flocks was derived entirely from some peculiarity of the soil and climate, had obtained so generally, and was so firmly believed, even twenty-five years since, in this country, that he who afrected the contrary, was regarded by agriculturists and clothiers as a speculator theorist, only deferving their pity.

It is not a little remarkable, that this prejudice continued undiminished nearly a century after the Merino sheep had been introduced into Sweden and Saxony, and had continued to produce wool in those countries, equally fine with that of their parent flocks in the Spanish peninsula.

It might have been previously supposed that the climate of Sweden, being much colder than that of Great Britain, and more remote from the annual mean temperature of Spain, would render that country peculiarly unfriendly to the Merino race and to the production of fine wool. This prejudice respecting the influence of climate would have been removed by considering that almost all the finest furs are the production of cold climates, and that the growth of fine wool and fur is a provision of nature, to defend animals against the severe cold of the districts nearer the poles.

Mr. Alltromer, who had previously endeavoured to ameliorate the breed of sheep in Sweden, by importations from England and Germany, obtained a flock of Merinos, which he introduced into that country in the year 1723. In the year 1739, the Swedish government, for the promotion of this race, instituted a school of shepherds, under the direction of Mr. Alltromer, and public funds were appointed for granting premiums to those who fold frams of the Swedish breed; and from the same period, to 1780, a premium of twenty-five per cent. was also granted on the sale of fine wools of a good quality. These premiums were afterwards reduced, and finally discontinued in 1792, being no longer necessary. From exact accounts, it appears that the fine wool sold from 1751 to the year 1790, amounted to 3,402,961 francs.

The quantity of fine wool actually produced was much greater than what had been fold to receive the premium, a considerable part having been consumed in domestic manufactures by the growers and others; and the distaince of the public magazines, where the wools were sent to receive the premium, prevented the public returns from including the real quantity of fine wool grown. In the year 1764, there were in Sweden 65,369 sheep of the pure Merino race, and 23,384 of a mixed breed, producing fine wool. The Swedish Merinos prefer their primitive form; their fleece, very close, and the wool has not deteriorated in fineness length, or elasticity; and the sheep produce as great a weight of fleece as in Spain, wherever they are supplied with a sufficient quantity of food. This race, now naturalized in Sweden, are larger and stronger than the Spanish sheep. M. Laylefeir examined the flock of Mr. Schulzenheim, at Gronf, in the province of Upland, which had been introduced from Spain 55 years. On comparing the wool with that of other Spanish sheep recently imported, he did not find it inferior either in beauty or fineness. M. Schulzenheim preferred the descendants of sheep which he imported from Spain to the fifth generation, and the comparison of their flocks proved that they had not in the least degenerated. These facts prove decidedly that the Spanish sheep do not lose the good qualities of their wool by a removal to cold countries. At the same time it must be observed, that those sheep degenerated which had been neglected, or treated in the same wretched manner as the native flocks, by confining them in damp, infected, and dirty stalls during a part of the year, and omitting the requisite quantity of food; or paffuring them in summer in forests and marshes, or in low moist situations, where they could neither find the proper kind nor due quantity of herbage.

The introduction of the Merinos into Saxony took place in 1765, and again in the year 1778. The first flock consisted of one hundred rams and two hundred ewes, chosen for the electors of Saxony from the best flocks in Spain; they were placed under the care of a Spanish major, or mayor, at Stolpen, fix leagues from Dresden, on the frontiers of Bohemia.

After ten years' experience, it was found that they had preferred all the original good qualities of the fleece, and the wool from the mixed breed had also acquired a degree of fineness which did not yield to that from Spain. As soon as it was ascertained, by experience, that it was easy to naturalize the Spanish sheep in Saxony, and that the crosses from this race with the native flocks were so greatly ameliorated, the attention of the agriculturists was directed to the general improvement of the flocks, and such has been the success, that their produce is at present one of the greatest sources of profit to the cultivator. During the last fifteen years, a very considerable quantity of fine wool has been imported from Saxony into England, and the price of the bell lot is greater than that of the finest Spanish wool, a sufficient proof of the estimation in which it is held by the manufacturers. It is better suited for the finest kerseymeres, and the more delicate articles of the woollen trade, as it can be spun to a greater length than any other kind of carded wool grown in Europe; it is also superior in fineness, but owing to the scarcity of winter food, it is generally less found than the best Spanish, and not so well suited for flute cloths. See Wool.

The Merino race has since been introduced into Denmark, the Prussian states, Austria, France, Holland, Italy, the Cape of Good Hope, and the United States of America. Of its introduction into England, we shall afterwards speak.

As Saxony is the only country which has yet cultivated the Merinos so extensively, as to come in competition with Spain in the exportation of fine wool, it may be proper to state the modes of treatment adopted in that country. It is generally believed in Saxony, and in other parts of Germany and Holland, that the practice of breeding from the same race
race, or what the English graziers technically denominate "breeding in and in," occasions a deterioration of the flock; owing to this prejudice, the Swedish farmers frequently change the rams of the Spanish race for others of the same race from neighbouring flocks, and some proprietors bind their farmers to renew a certain quantity of rams every year. But this practice is useless, where the rams upon an estate are already of a good quality; if the contrary were the case, there could not exist a perfect Merino sheep in Spain, as these sheep have continued to breed from the same flock, without any attention to confangunty, for many centuries. The good quality of a race of sheep may be preferred, either by selecting the most perfect from the same flock to breed from, or by constantly taking out those which are most defective.

The common food of sheep in Saxony, during winter, is hay, which is distributed three times a day, in a greater or less quantity, according to the flock of the farmer: those who have not sufficient hay, subdivide pea-flax, veteches, and lentils. They take care to mow the crops before maturity, that they may be more nutritious, and to prevent the fall of the leaves before mowing. Some farmers supply the deficiency of hay with powdered oil-cakes, crushed seeds, and meal; they put the cake or meal into troughs with water, which they give the sheep to drink, and afterwards they give them the solid residue, which sinks to the bottom of the trough. This treatment serves to keep them in a healthy state, at a season when they cannot have fresh food. Eight pounds of cake or meal diffused in water are given to every hundred sheep. When the snow remains long on the ground, they sometimes give them straw which has not been thrashed, and even corn; but as this is expensive, they generally substitute roots of different kinds, such as beets, turnips, and carrots, but particularly potatoes.

The Saxonic farmers collect with great care the horse-chefnats in autumn, which they give their sheep as a remedy against the rot. The nuts are cut small, to prevent them getting into the throat, and choking the animal.

They fend out their sheep in winter, when the weather permits, and the snow is not too deep, to the woods or dry situations sheltered with underwood. Proprietors who have no winter pastures, leave their sheep in the sheep-houses from the beginning of November to April, but they take care to turn them out each day in the fresh air, for three or four hours, and they keep open the doors, to cause a constant ventilation. Some proprietors keep their sheep outside, and to prevent copulation, they confine the whole year; and where the sheep-houses are kept clean, and the sheep are supplied with proper food, this practice is not found to injure either the wool or the animal.

During fine weather in summer, they are allowed to range in the pastures. They leave the sheep-house after the dew is entirely dissipated, and they repose in the shade during the heat of the day. This practice of providing shade during the hot weather cannot be too strongly recommended to the cultivators of fine wool in England, both with respect to the health of the animal and the improvement of the wool. Nor is another practice less deserving their attention, which is, to shelter them during heavy rains, hail-storms, and thick fogs. In many sheep-houses, water is conducted in troughs, from which the sheep may drink at pleasure. Saxon farmers consider salt not only as necessary to the health of sheep, but as contributing to the fineness of the fleece; it is sprinkled in their forage, and diffused in their drink; it is given principally in summer, when the weather is dry. They cease to give it them the two or three weeks before lambing, because they think that the excess of water which it occasions them to drink, is injurious to them at that time, and that it also prevents them from licking their lambs.

The rams and ewes are not put together before the age of two or three years; they allow one ram to twenty-five ewes, and leave them together day and night during the liaison. The lambs are kept in the sheep-houses, but some proprietors allow them to go out with the ewes after eight days.

Before shearing, the sheep are washed in the English manner, but with greater care. First they make them run through a river or dam; the following day they are again driven through, and plunged in separately, and the fleece prefled with the hands, beginning from the head, and passing on to the extremities of the body; they are again driven through the water in the afternoon. The fleece is suffered to dry during two or three days, and then on the third. Saxonic wool, thus washed, is much cleaner than the English, which generally undergoes but one washing. It loses by a further scouring by the manufacturer, about 12 per cent., more than Spanish wool already scourcd. English wool loses about 25 per cent. in the hands of the manufacturer.

The general treatment of the Saxonic Merino sheep we consider as judicious, but we have frequently noticed that the wool had been sometimes injured by want of sufficient nourishment in winter, which renders it darker. The hay being given in racks, seeds and straw fall into the fleece, when the animal is eating, which the English manufacturer finds great difficulty in eradicating; this might be prevented, in a considerable degree, by lowering the racks, so that the food might be level with the head, or somewhat below.

As France is perhaps the most formidable rival which our manufacturers of fine cloths will meet in foreign markets, the progress made in the amelioration of her native flocks becomes an object of interest to the English agriculturalist and clothier. The celebrated minister Colbert first formed the design of improving the breeds of French sheep, by importations from England and Spain. But his intentions were at that time opposed. It was not till the year 1775 that the Spanish breed was introduced into France by M. M. Trudaine, intendant of finances, under the direction of the celebrated naturalist d'Aubenton. The experiments which he made on these sheep, and numerous crosses from them, with seven distinct breeds, which he had on his estate in Auxois, demonstrated to the government, that it was easy to introduce and preserve a race of sheep in France, producing superfine wool; and in the year 1786, a selection of 376 rams and ewes, from the finest flocks in Spain, was conducted, under the care of a mayor, to the farm of Ramboillet. They consisted of individuals of extraordinary beauty, superior to any previously introduced into France, but having been chosen from a number of different flocks, they presented great varieties of shape and size, which have since disappeared by intermixture; and a new race has been formed, differing from any of the primitive flock, but which equals the best of them in form and constitution, and in the fineness, length, softness, elasticity, and quantity of wool.

It is to be observed, that the wool-dealers and manufacturers in France were at first disposed to depreciate the value of the wool; but numerous accurate experiments having proved that the cloths manufactured from it were in every respect equal to those made from the finest Spanish wool, these prejudices disappeared, and the republican government, as well as that of the emperor Napoleon, interested themselves in the further introduction of Spanish sheep into France. In the year 1802 it was calculated that there were one million sheep in France, either of pure Merinos, or of an ameliorated
SHEEP.

florated mixed breed. Since that time many large flocks have been imported from Spain, the temporary command which the French obtained of that country having afforded them facilities for their introduction. In the course of a very few years France will, in all probability, produce a sufficient supply of superfine wool for her extensive woollen manufactories.

The experiments which have been made by the introduction of the Merino sheep into the United States of America, the Cape of Good Hope, and New Holland, prove that fine wool may be grown wherever there are intelligent cultivators, and that it is not the gift of a peculiar soil or climate. We are, however, fully convinced, that very elevated temperatures will require greater care to prevent deterioration. The specimens of wool which we have seen from New Holland, appear to have been affected by an arid sandy soil, and by the great heat of the sun, which has in some degree injured the softness of the fleece. Between the tropics, elevated mountains and shade would be essentially requisite to preserve a race of fine-wooled sheep from degenerating.

The advantages which the Merino sheep posses as wool-bearing animals, over the native breeds of English fine-wooled sheep, consist in three important peculiarities: 1st, the wool is much finer; 2dly, it is more regularly fine over the body; and 3dly, it is grown in a larger quantity from the same surface of skin. That the Merino wool is finer than the best English, is proved from this circumstance; the best Merino Spanish wool, or the R. wool, as it is called, from the finest flocks, falls at nearly double the price of the best English furred wool, or what the wool-staplers call the prime and picked lock. These English flocks which yield a portion of the best fett, generally contain a larger portion of inferior sorts; sometimes eight ferts will be found in one flock, and the finest will not constitute one-eighth of the whole.

On the contrary, the fleeces of the Merino sheep are so regularly fine over the whole body, as generally to yield from two-thirds to three-fourths of the superfine or R. wool. The second fett, called the F. wool, is also fine; and with the T. wool, or third fett, bears a higher price than the best English wool. The quantity of wool on a Merino sheep is considerable greater than on an English sheep of the fame fett: this is not owing to the greater length of the wool, but to the animal being more fully clothed over the body and legs; and the wool is also grown closer on English sheep; that is, there are more filaments on the same surface. A moderate fized well-clad Merino sheep will yield a fleece which, when brought to the same state of purity as the English wool, will weigh 3lbs. A Rycland, Norfolk, or South Down sheep of the same fett, will produce a fleece only weighing about 2lbs. The value will be nearly as five to two in favour of the Merino fleece. In this fett, however, the Merino fleece is not clean, as the wool imported from Spain, which are fcoured after they are fhorn, and before they are fettered, by which means it is much cleaner than it can be made by washing on the back of the animal. The Merino rams are horned, which is not generally the cafe with the ewes. The average weight of a fat ram per quarter, is about 17lbs. of a ewe, about 11lbs. per quarter.

The shape of these animals by no means corresponds with the symmetry of form which an English grazier considers as the criterion of excellence. The legs are rather long, the neck curved, and from the throat there hangs a pendulous skin, or dewlap, which is very offensive to those who are only accustomed to view the improved breeds of English sheep. This appendage is valued in Spain, as indicating a tendency to produce wool. The colour of the skin beneath the wool, on the back and sides, is of a rofe red colour: this is also confidered by the Spaniards as a flign of a robust constitution, and an abundant fleece. The only English sheep which have the fame coloured skin with the pendulous dewlap, are the Ryeland, which produce also the finest English wool. These circumstances, with the ancient practice of houing the sheep, continued in Herefordshire, where it is called eating, confirm the opinion before advanced, that the Ryeland sheep were defended from the Tarentine race introduced by the Romans into this country.

It is not to be wondered at, that the Merino sheep, which are cultivated in Spain almost exclusively for their wool, and not for their fleece, should present that deformity of shape which at first was particularly offensive to the eye of the English farmer, accustomed to the fine Leicesters and South Down sheep. There cannot, however, be a doubt that the Merino breed is as susceptible of improvement as the English. Indeed there is a very great diversity of form in the flocks in different parts of Spain; and were the fame attention paid to selecting the most perfect to breed from, as has been given in England to the South Down sheep, there is every reason to believe that a new race would be formed, possessing all the good qualities which both the grazier and the manufacturer might require. The South Down sheep, which have been greatly improved, and rendered almost perfect in form, have preferred all the good qualities of the fleece. This alone is sufficient to prove, that there is no necessary connection between deformity of shape, and the fineness of the wool.

The Spanish breed of sheep were first introduced into Great Britain in the year 1767. Some individuals of the black and spotted sheep had indeed been procured, and kept in the parks of noblemen previously, but without any regard to the wool; nor was much interest excited by the flock introduced in 1787. The sheep, however, lived, though treated in the English manner, and the wool had not deteriorated. These facts having proved that the Merino race might be naturalized in England, his majesty George III., obtained from the marquis of Campo Alano five rams and thirty-five ewes of the Nigrette race. They were imported in the year 1792, and were for some time at Ostlands, the seat of his royal highness the duke of York. On their arrival they were extremely low in fhee, but they soon began to improve; and the decaifs with which they had been affected, were removed by a plentiful supply of food. They left Ostlands greatly advanced in bulk, and with renovated constitutions; and the quantity and quality of the wool were greatly admired.

The prejudices of the manufacturers were not so speedily to be furred, as the difficulties attending the naturalization of the Merino sheep. Though the wool was admitted to be equally fine with the best imported wool from Spain, they would not offer a proportionate price, fearing that it might not prove equally good, when manufactured. It ought, however, to be rated, that the condition in which the English Merino wool was offered for sale, either very imperfectly washed, or entirely in the grease, prevented the manufacturer from forming a just comparison with the wools from Spain, which came to this country clean scoured, and regularly sorted; nor could they appreciate the lofs it would sufibr, in scouring, which is not less than from 20 to 70 per cent. We are well persuaded that this uncertainty respecting the lofs in scouring has, more than any other circumstance, retarded the sale of the English Merino wool, from the year 1792 to the present time. Nor will
The sheep manufacturers ever greatly encourage the growth of the breed, until it be brought to market, either for export or for sale. Many manufacturers, who have purchased it, have been greatly disappointed not in the quality, which was excellent, but in the small quantity which remained after finishing. In consequence of the manufacturers declining to purchase his majesty's wool, it became necessary to have it manufactured on his majesty's account, to demonstrate its fitness for superfine cloths. This was done till the year 1796, when it was resolved to sell the wool at the price which was offered, that the manufacturers might have a trial. The clip was saved that year for 22. per pound, and the following year for 21. 1s. 6d. In the years 1797 and 1798 the wool was torrid in the Spanish manner, and scoured, after having been previously washed on the sheep's back. The following is an account of the produce.

Eighty-nine ewes and wether fleeces washed on the back

Loses by subsequent scouring

Pure wool

Which yielded, Raisinos, or R. wool, 167 lbs. at 51.

\[

\]

The prices have, since that time, progressively increased with the price of Spanish wool, and have been nearly equal to that of the best piles from Spain. In the year 1801, the right honourable lord Somerville took a voyage to the peninsula, for the purpose of selecting such sheep as united in the greatest degree the excellence of the fleece with a good carcase. His efforts were in a considerable degree successful, and, as far as related to the fleece, completely so. Since that time, particular political events have increased the facility of procuring Merino sheep from the various Spanish flocks; and the fleece of these sheep in England at present is sufficiently great to change, in a few years, the whole race of fine-woolled sheep in Great Britain, were such a change desirable. Many of the native flocks of fine-woolled sheep in England have been considerably diminished in the last forty years, owing to the numerous enclosures of forests and commons, that were formerly only suited to pasture a race of small light sheep; but which, in consequence of improvement, are now capable of maintaining a heavier race of animals; the former requiring a light dry soil, and an ex-
HEEP.

ing quality of the wool. This is so well known to the Yorkshire manufacturers, that they always avoid the woods grown on chalk foils, when they want a soft thick pile to the cloth. The fine wool from the South Down fheep is chiefly used for light goods, such as kerseymeres and pelisse cloths, which require very little milling or felting. When the South Down sheep are removed from chalk lands, the wool may be grown remarkably soft, and possesses all the good qualities of the best native English wool.

The action of the soil on the fleece was long known to manufacturers, viz. that woods grown on argillaceous soils were softer, and proved better in the processes of manufacture, than those on chalky soils. The cause of this was involved in much obscurity, and generally supposed to be owing to the quality of the herbage on different foils. Mr. Bakewell, of Wakefield, in Yorkshire, in a little tract, "On the Influence of Soil and Climate on Wool," proved that the influence of the soil on the fleece arose from the action of the minute particles on the surface of the fibre or staple.

Not only can this action affect the quality, but impart indelibly the colour of the soil to the wool. In part of Gloucestershire the fleece acquires a deep orange colour from the soil. In Hertfordshire and part of Warwickshire, and in every country having a red soil, the wool is inclined to brownish-red. Wool on chalky soils are distinguished by their whiteness; and in every district England the action of the soil is evinced, by communicating its own colour to the fleece. The colour thus acquired is as indelibly fixed in the wool as the colouring matter of an artificial dye, nor can its whiteness be perfectly restored by any artificial processes hitherto known.

That the same cause can change the hardnes or softness of wool, is proved from the different effects which argillaceous, siliceous, and calcareous soils are invariably found to have on these qualities. This is perhaps no where more clearly shown than in the northern part of Derbyshire, where the Irata are so abruptly broken, that two adjoining farms, separated by a small brook, will not unfrequently be found, the one upon lime-stone, the other on a siliceous grit or sand-stone. The difference of the wool on these two farms, from the same breed of sheep, was so distinctly marked, that the grower always obtained a higher price when grown upon the latter soil. My wool is grit-stone, and I expect a better price than my neighbour.' was the language in common use, and the meaning was well understood by the buyer. In the processes of separating wool from the skin by the fell-monger, the pelts are steeped some days in lime and water. The softest wools, when thus exposed to the action of lime, lose their distinguisishing excellence, and acquire all the hardnes of wools grown on lime-stone foils."

To remedy this injurious effect of calcareous soils, Mr. Bakewell recommends the practice of the farmers in Northumberland, and in North Britain, of anointing the skin of the animal with butter, in which a small quantity of tar is melted to give it consistence. In Northumberland this is practiced with the fine-woollen sheep on the Cheviots; and the wool from these sheep bears a higher price in Yorkshire, in proportion to its relative fineness, than any other English wool, on account of the superior softness of the cloth made from it. The ointment is also found to defend the animal against flies and sheep-ticks, and to be a preventive against the feverity of the weather. The only inconvenience is, that the whitens of the wool is in some degree affected by it; and it is not suited for white flaved cloth, or for any delicate colours. Could any good and cheap substitute for tar be devised, there cannot be a doubt that the practice would be of great benefit to the South Down fleeces on their native chalky foils. It is, in fact, similar to what the Romans adopted with the Tarentine breed, which were frequently washed, and the skins anointed with the dregs of olive-oil, mixed with other ingredients. A similar treatment of all English sheep, after being born, would be found a most effective remedy against flies and insects when the skin is exposed: it is also proved by experience to be a peculiar against the fcab.

The South Down breed, so far as relates to the fleece, will admit of considerable improvement in the following particulars. First; it might attain a degree of fineness more nearly approaching that of the Merino fleece; secondly, the fleece might be grown more uniformly fine over the body: and thirdly, almost all the South Down fleeces have a few grey or black hairs intermixed, which is a great defect where the goods made from it are intended to be flaved white. At present, the finest part of the South Down fleeces, called by the wool-flaper the prime, does not bear half the price of the prime Spanish, or R wool, from the best Merino flocks. In the South Down fleeces very rarely more than one-fourth part is of the best quality; but in the Merino breed full two-thirds of each fleece will be of one uniform quality, and that the prime or R wool. In the South Down fleeces, these parts from the buttocks and shanks will also be as coarse as the coarsest wool from heavy sheep. These defects in the South Down fleece are not common to almost all our native fine-woollen fleece, except the Ryeland; but we conceive they admit of a remedy, without any injury to the form of the animal, or the weight of the fleece. If the opinion of an intelligent wool-flaper were first taken on the qualities of the different fleeces of those ewes from which it was proposed to raise a stock, and selecting for them some of the best formed rams bred from South Downs and Merinos, called Anglo-merinos; from this progeny the most perfect forms might be again chosen: and if these were still too strongly marked with the character of the Merino form, another cross with perfect South Down ewes would produce a progeny from which a race might be selected polishing whatever was desirable in the carcass, with a considerable amelioration of the fleece, both in the fineness of the wool and the regularity of the quality, over the greater part of the skin. The uniformity of the fleece would also be increased, for the wool is grown closer and thicker on the Merinos than on any of the English breeds; and this property continues in the croffes from that breed. The advantage of employing an intelligent wool-flaper to judge of the quality of the fleeces will be admitted, when we consider that a fibre of the finest wool is perhaps little more than the two-thousandth part of an inch in diameter; and that a variation from this, which is too small to be visible by the unpractised eye, may occasion a difference in price not less than 40 per cent. Indeed, it is truly astonishing that the eye can detect this microscopic difference unaided by instruments. Nothing but long and constant practice can secure the facility of determining the fineness of wool; and the most experienced dealer in English fine wool, were he to discontinue entirely the examination of wool for three months, would not be able, at first sight, to ascertain its quality and value to 15 or 20 per cent., supposing no change to have taken place in the markets. Can it then be supposed that a grazer, who has never acquired this fine sense of vision, and to whom wool is only an object of particular attention at one season of the year, we say, can it be possible for such a person to be an accurate judge of the quality of wool, and the comparative fineness of fibres ranging between the fifteen-hundredth and
the two-thousandth part of an inch? Yet many of our
English wool-growers will decide, with the utmost con-
dience, whether their wool be finer or coarser than it was
in the former year; or rather, they will decide that their
wool is always growing finer. To this great confidence
of the wool-growers, and to their real ignorance of this subject,
much more than any other cause, may be ascribed the little
improvement in the culture of English fine wools prior to
the introduction of the Merino breed into Britain.

The South Down breed, in its improved state, is likely to
supplant most of the English fine-woolled breeds, except
perhaps the Cheviats in Northumberland, which are become
habituated to the severity of the climate, on the elevated
hills in the northern parts of that county bordering on
Scotland. This race we think much better suited to sup-
plant the coarser-woolled sheep in the Highlands of Scot-
land, than another of our English breeds. The Cheviot
sheep are described by Mr. Culley, an intelligent farmer in
Northumberland, as hornless; the faces and legs are, in
general, white: the left kind have a fine open countenance,
with lively prominent eyes; the body long, fore-quarter
wanting depth in the breast, and breadth both there and
on the chin; fine, clean, small-boned legs; thin pelts;
weight of carcase, when fat, from 13 lbs. to 15lbs. per
quarter; fleeces from 3lbs. to 5lbs. The qualities of the
Cheviot fleeces are various; some of them contain a small
portion of fine wool, which, as we have before remarked,
is more soft than any of our native English wools. The
price at lord Somerville’s annual show in 1813, for the bell
cloth from English wool, was given to Mr. J. F. Smith,
for a piece of cloth manufactured from the prime part of the
Cheviot fleeces.

In general, the quality of these fleeces might be much
improved by a judicious selection. The great defect is,
that in the finest fleeces only, a small part is of the belt
good. Some of the Cheviot sheep are speckled on the
face and legs; but these are probably a mixed breed, from
crossing at different times with Heath sheep, to whom
they have long been neighbours; for leaving the heights of
Annandale to the eastward, we insensibly lose the Heath sheep
and mixed breeds; after which all the extensive fine green
hills on the Scotch and English borders from the sides
of the Cheviots to the barren heaths of Lammer-muir are
covered with the Cheviot breed. The best kind of these
sheep is certainly a valuable mountain-sheep, where the
fusture is mostly green sward, or contains a large portion
of that kind of herbage, which is the cafe with all the hills
around the Cheviots, where these sheep are bred; and the
fine herbage which the border hills everywhere produce,
supports them so well in summer, as to enable them to
stand the severities of the winter.

The shape of this breed of sheep has been greatly im-
proved of late years, but will still admit of much improve-
ment. We cannot (says Mr. Culley) expect the perfe-
cion of this breed of sheep can be obtained at once, it must
proceed by slow gradation, as every other improvement hath
done.

That breed of sheep which brings the most profit to the
farmer will always be preferred, but this object is not to be
obtained in this district by fine wool alone. Perfect moun-
tain sheep should be hardy, well-formed, and quick feeders.
These qualities will always recommend them to the grazier;
but if to these qualities, so essential to the fale of a moun-
tain farmer’s flock, can be added a fleece of fine wool, a breed
of sheep might then be obtained, the proper for a hilly
district of any we have yet seen. There is little doubt but
this may be accomplished by proper selection, and probably
the best kind of Cheviot sheep, from their hardarts, and
producing a portion of fine wool, are the properst stock
for laying the foundation of a desirable change.”

With these sentiments of Mr. Culley we entirely agree, and par-
ticularly in the propriety of selecting from the belt Cheviots
to lay the foundation of a valuable flock of mountain sheep,
which might plant the coarse-woolled Heath sheep on
North Britain. Every situation may be said to have its
peculiar advantages for particular breeds of sheep; and the
rage for improvement, and desire of change, have in late
influences been carried too far. There can be no doubt, that
the rich pastures on the eastern side of England are better
suited for heavy long-woolled sheep than for South Downs
or Merinos, whilst it would be fully to attempt to flock
the mountainous parts of Britain with the Difley or Lincoln-
shire breeds. But many of the flocks in the uplands are
susceptible of much improvement by selection, without any
admixture, and in very exposed situations it might not be
desirable to attempt improvement by introducing a less
hardy race. In dry and moderately elevated situations there
are none of the fme-woolled native or Anglo-morino breeds,
that might not be cultivated with advantage; but we are
well persuaded, that with the present demand for, and price
of animal food, the breed which will send into the market
the largest quantity of good meat in the shortest time, will
have the preference over any superior quality of the wool
alone. On which account the improvement of the South
Down breed, which combines both advantages, is perhaps
an object the belt deserving attention, in all situations suited
for fine-woolled sheep, that are not too much exposed to
the inclemency of the climate.

A particular race of sheep exist in the Shetland islands,
which produce a fleece more like that from the sheep on
the mountains of Thibet, than any of the European sheep with
which we are acquainted. From the report of Mr. Thomas
Johnson, addrest to the British Wool Society, it appears
that there are two varieties of Shetland sheep.

One of these varieties carry coarse wool above and soft
wool below, and have three different successions of wool
yearly, two of which refemble long hairs more than wool,
and are termed by the common people fars and fudda.
When the wool begins to hoosen at the roots, which gene-
rally happens about the month of February, the hairs or
seuda spring up; and when the wool is carefully pulled off,
the tough hairs continue fall until the new wool grows up
about a quarter of an inch in length, then they gradually
wear off; and when the new fleece has acquired about two
months’ growth, the rough hairs termed fars springing up, and
keep root till the proper season for pulling it arrives,
when it is plucked off along with the wool, and is separated
from it at dressing the fleeces, by an operation called furing.
The fudda remains upon the skin of the animal, as if it were
a thick coat or fence against the inclemency of the seaons,
which provident nature has furnished for supplying the want
of the fleece. See the preceding article Sheep.

The native or kindly breed, which bear the soft cottony
fleeces (as they are called), are rather of a delicate nature;
their wool is short and open, and deliijuate of a covering
of long hairs. These soft-woolled fleeces are very often lost
or rubbed off, during the winter or early in the spring,
which it is supposed might be prevented by clipping or
shearing the sheep, in place of pulling off the wool, a bar-
barous practice, tending to weaken the sheep and hurt the
length of the staple.

The Shetland sheep are of various colours; the silver-grey
wool is thought to be the finest and softest, but the black,
the white, the mouarit, or brown, is very little inferior; it

SHEEP.
SHEEP.

is all of the finest texture, fit for the finest manufacture, and in some instances has been found to rival Spanish wool itself; but the purest white is generally the most valuable for all the finer purposes for which combing wool can be used. For softnesses and for lustr, no wool equals it; and the finest, with the fleece on, can be converted into a fur of very great value, some specimens of which have already been sent to the China market.

They are in general very hardy. In the winter season, when the ground is covered with snow, they eat the unplowed very greedily, and often during long and severe snows they have little else to live upon. Nature seems to have imparted to them a perfect knowledge of the time at which this food may be procured; for immediately upon the tide beginning to fall, the sheep in one body run directly down to the sea-shores, although feeding on the hills several miles distant from the sea, where they remain until the tide returns and obliges them to seek their usual haunt.

It is to be regretted, that we know so little of this peculiar race of sheep, or of the time when they were introduced, and the country from whence they came. The wool, though intermixed with coarse hairs,possesses a most extraordinary degree of softness, approaching, if not equaling, that from the sheep of Thibet, and might, if proper attention were paid to it, be applied with advantage to the manufacture of shawls and other articles now imported from the East. None of the European woods which we have seen, possess this quality in any degree to be compared with that from the Shetland sheep. The circumstance of the fine wool growing as down under a pile of coarse wool or hair, is not peculiar to these sheep. We believe that unmixed fine wool is rather a product of cultivation than natural to the animal in a wild state. In the argali, as well as in numerous animals, the inhabitants of cold countries, the skin is covered with a short fine down, and this is protected by a covering of longer coarse hair growing through the former. By regular keeping and warmth, the coarse hairs fall off in many animals, and this has probably been the case originally with all our fine-wooled sheep, many of which, if neglected, shew indications of their original condition, growing coarse hair intermixed with the finer parts of the fleece. Even in the coarsest-wooled sheep of cold countries, such as the Heath sheep in the Highlands of Scotland, we have often seen a small portion of fine wool growing under the coarse fleeces with which these animals are covered. It appears to be a beneficent provision of the Author of nature, to accommodate animals to different climates. European sheep removed between the tropics, languish and become sickly from excessive heat, and lose their fleeces in the course of the ensuing year. They are afterwards covered with a thin crop of coarse short hair. We have seen a finely-shaped ram, of the European breed, brought from Louisiana, which was entirely covered with white hair, as coarse and short as that on a dog. We have no doubt, however, that in hot climates, where sheep have the advantage of a mountain pasture, that with care and proper shelter these fleeces might be procured, but they would certainly be a useless incumbrance. Fine fleeces seem to be more peculiarly the produce of cool or temperate climates; for it is observed, in most of our English sheep, that the part of the wool or staple which is grown during winter, is finer than that part which is grown in summer. Extreme heat and cold appear to have both an effect upon the skins-of-sheep, to cover them with coarse hair; but in cold climates there is also a tendency in the animal to produce a fine down underneath. It is not probable that the Shetland sheep may have been originally descended from the Tarentine breed, the "molles ovem," which the Romans had introduced into Britain; their inferior situation protecting them, in a considerable degree, from intermixture. For, according to Dr. Anderton, though the coarse-wooled Heath sheep are introduced into these isles, the native active sheep frequenting the more defolate wilds at the greatest distance from man, withdraw themselves from the others, and thus the breed is only partially debased by accidental stragglers. The whole system of management, respecting these sheep, is directly the reverse of what it should be, and it is truly astonishing that they have preferred for long the peculiar softness of the wool. Could these sheep be introduced into more favourable situations, and proper attention paid to them, we have no doubt that their wool might be grown free from the coarse hairs with which it is at present intermixed; it would then be of far greater value than the finest Merino fleeces, as it might be applied to the manufacture of shawls, approaching in softness to those of Cashmere.

We have now to describe the long-wooled breed of sheep, which may be considered as almost peculiar to Great Britain and Ireland; for though sheep of this breed are found in Flanders, and some other parts of Europe, their number is inconsiderable; and they no where exist with the same perfection of form, and producing the same quality or quality of wool as in the united kingdoms. Their fleece is the envy of the other manufacturing countries of Europe, and can only be grown upon rich pastures. Long combing wool, and the varieties, will be described under the article Wool; but it may be necessary here to state that the longer kind varies from fix to about nine or more inches in the length of the staple, or filaments. In the manufacture of this wool by the comb, the fibres are laid parallel; whereas in short-combing wool, they are broken in all directions by the cards.

Long wool is manufactured into shawls, camlets, manteaux, bombazine, and various other articles; and a large quantity is also manufactured into what is called hore-crumble, consisting of grits, fringes, and other articles of use or ornament in equipages. The coarser kind makes the warps for carpets.

Short combing wool is manufactured into hosiery. The Lincolnshire sheep may be considered as the original of our heavy sheep in England. These, with the new Leicester or Dibthey breed, have nearly supplanting the other varieties of long-wooled sheep. The Lincolnshire breed has also been generally somewhat changed of late, by an intermixture with the Leicester breed. The original Lincolnshire sheep have no horns, and long carcasses; the ewes weighing from 14 lbs. to 20 lbs. per quarter, the three-year-old wethers from 20 lbs. to 30 lbs. The average weight of the fleece is about 9½ lbs., or three fleeces to the toad of 28 lbs. Some of the heavier fleeces weigh 14 lbs. The richer parts of Lincolnshire will support five of these sheep on the acre; and when we take into account the price of the wool, which in 1814 was 25. per pound, it will be seen that the sheep of this description are the most profitable for the lands to which they are suited. The improvement made in their form, by the mixture with the Leicester breed, reduced the weight of the fleece; but the extraordinary demand for heavy combing wool is inducing some of the farmers to return to their heavy breed. It is probable that this kind of wool will not soon fall under 12. 6d. per pound; and the production of a fleece, which weighs 10 or 12 lbs., must be an object of attention to the grower, not less than that of the carcass. For though the wool from the Leicester breed is somewhat finer, the weight seldom exceeds 7 lbs., and the difference of price is not more than about 2s. per
The peculiar characters of these sheep have been well described by Mr. Culley, an eminent grazier in Northumberland, who introduced the breed into that part of England. The Ditheley breed are particularly distinguished from other long-woollled breeds, by their fine, lively eyes, clean heads, straight, broad, flat backs, round (barrel-like) bodies, very fine small bones, thick pelts, and inclination to fat at an early age. The fat property is probably owing to the before-specified qualities, which, from observation and experience, there is reason to believe extend generally through every species of domestic quadrupeds. The Ditheley breed is not only peculiar for its mutton being fat, but also for the fines of the gam: the flavour is superior to the mutton of most other long-woollled breeds. The weight of the carcase may be flated in general: ewes, three, or four years old, from 18 lbs. to 26 lbs. per quarter; wethers, two years old, from 20 lbs. to 30 lbs. The fleece is flated by Mr. Culley at 18 lbs.; but in Leicester-shire, we believe, the average weight is not more than 6 or 7 lbs., about four and five to the yard. The wool is finer and shorter than the Lincoln flate, and a portion of it is better suited for the hosiery trade than for the goods, such as flannels, &c.; but considering the difference of weight, the fleece is more profitable to the grower as that from the Ditheley sheep.

There are two reasons for killing the wethers of the Ditheley breed at two years old: first, they leave the mohm profit; and, secondly, it keeps them, they grow too fat for dressed tables. It is very common for two years old wethers to cut four inches thick of fat on the ribs, and from two to three inches down the back. Even one of this kind, which have bred and muckle lambs till July, when killed about the Christmas following, will frequently measure four or five inches thick of fat on the sides, and two or three inches down the back, all the way from the head to the tail, and though sheep of this breed are not eminent for much tallow, yet cases, under such circumstances, generally produce from 18 lbs. to 24 lbs. of tallow each. This mutton is not so sporting as the leaner kinds, but it finds a ready market among the manufacturing and laborious part of the community.

The graziers in different parts of England, who had been too negligent respecting the improvement of flock, no longer became sensible of the possibility of forming a race of sheep, that would produce a large weight of meat in a much shorter time than before known, than they became desirous of introducing the breed; and the table for growing fat meat became generally adopted, and in many instances without proper regard to other considerations. In some instances, fine-woollled flocks were crossed with this breed, and it was faintly expected that they should preserve the quality of the wool, and masure the carcase at the same time. In other instances, the Leicester-shire breed were introduced on land only suited for a lighter race of sheep; and even where the pastures were suitable, the propensity to fat was encouraged, until it became a disease, and the animal was scarcely able to move under its own weight. Whatever the advocates of this breed may advance in its support, it cannot be contended that the mutton is equal in flavour to that of the smaller sheep.

The object of Mr. Bakewell was to introduce these instances mistaken: it was not to produce meat for the tables of the rich, but to supply substantial nourishment for the working classes. We have heard him say, "a small quantity of this fat meat, cooked over a large dish of potatoes, is a good dinner for a poor man's family; and this is what I proposed in the selection of this breed."

The increased demand for animal food could not have been supplied had not some improvement taken place, and the working classes will ever prefer the fattest meat. In this respect they resemble the North American Indians and the back setters, who regard fat as the only nutritious part of meat, and accordingly Volney describes the lean by a name which signifies meat breed. The race for excessively fat meat has in some degree fubheded, and the new Leicester's are likely to be confined to those districts which are peculiarly suited for their growth, and the object of the grazier will be directed to producing a large quantity of meat for the consumption of the working classes. Instead of attempting to improve the fine-woollled breeds by crosses with a heavy race, it would be more judicious to pursue the same plan of improvement with those breeds which Mr. Bakewell attempted with such success in the heavy sheep.

The improvement of the carcase may, we are convinced, be effected without injuring the quality or diminishing the quantity of the wool. Of this Mr. Bakewell was well aware,
SHEEP.

aware, but the price of wool in England at the time of the American war (the period of his celebrity) was so low, that he used to say, it would be defirable to grow sheep without wool, and confine the attention to the carcasse exclusively.

In selecting the most profitable breed of sheep for a farm, it can never answer to flock hilly districts with a heavy race of sheep, and in such districts the improvement of the wool is an object more particularly deserving attention, because we believe it would be possible to grow an equal weight of wool of a much finer quality than what is produced by many of our coarse-wooled breeds of sheep, and particularly by the Heath sheep, which pasture the mountainous parts of North Britain.

In rich pastures, weight of carcasse must in a considerable degree supercede the improvement of the wool, at least so far as relates to its finefens; for the real interest of the grower of long wool is to produce a heavier fleece. At the present price of wool, a Lincolnshire fleece of twelve pounds being more valuable than any other native English fleeces. To combine, therefore, the perfection of form in the Dihleby breed with the heavy fleece of Lincoln, is what will baffle the owners of long-wooled flocks.

There are, besides long and short-wooled sheep, numerous flocks which produce wool suited for the comb, but of a finer and shorter kind than the heavy combing wool. The worsted yarn made from this wool is spun soft, and manufactured into hofery. A very considerable quantity of wool, suited for hofery, is grown in the county of Kent; but the breed of sheep which produce it, has not any distinctive name, and appears to have originated from an intermixture of the short-wooled sheep of the southern counties with heavy long-wooled sheep. We believe there is no country in Europe, which at present produces combing wool of this kind equal in quality to that grown in England. See Wool, and Worsted.

SHEEP, Stealing of, is now made felony without benefit of clergy. See Cattle.

By an ancient statute, no person shall keep, at one time, above two thousand sheep; but lambs are not to be accounted sheep till they are a year old. (25 Hen. VIII. c. 13.) Perons exporting sheep shall forfeit them, and 20l. for every sheep, &c. (12 Car. II. c. 4.) And perons in the counties of Kent and Suffolk, within ten miles of the sea, are to give an account, in writing, after sheep-fearing, of the number of fleeces, to the next officer of the customs, &c. (9 & 10 W. III. c. 40.) See Wool.

SHEEP, Clutting of, in Agriculture, a term given to the busines of preparing the ewes of them for lambing in some places, which commonly takes place about a week before the lambing season commences. In such cases the ewes are usually driven into a pound, when the clatter, looker, or shepherd, draws them out lingly and separately, turning them upon their backs, and removes with the shears the locks of wool from the underfides of their tails, from about their udders, and from the infides of their thighs. This becomes necessary, in consequence of the dirt and filth which often adhere to the wool about these parts, especially in moist growing spring fheons, when the ewes are affected with much purging. The wool being removed in this manner, not only renders the parts more neat, but enables the lamb, or person who has the care and direction of the busines of lambing, to distinguish when the ewes have lambed, by the mark or stain which is generally left on the back parts of the udders; as, if such marks were not to occur, he would sometimes be at a loss, as the young ewes not unfrequently defert their lambs, and endeavour to escape along with the other ewes, paffuring as unconcernedly as if nothing had happened to them.

Some think, that it would also be a good method at this time to have the different ewes marked in a different way about the face, in the order of their lambing, and to have those of different forwardness put together into separate suitable pastures, to be taken care of in the most proper ways.

The barren ewes, or those not with lamb, are likewise now distinguished by the clatter, looker, &c. by their not having any enlargement of their udders or their bellies, as well as by their jumping and slipping about in a nimble manner; such being usually turned off directly upon the fattening grounds.

SHEEP, Lambing of, the busines of managing the lambing of the ewe flocks, which is very effential and important, though but little known or attended to in many places, even where sheep are almost the whole flock of the farmer. However, in conquence of this, and the employing of unskilled persons, much loss is not unfrequently sustained, to the great injury and inconvenience of the sheep-grazing farmer. In some situations, as those of the inclosed, dry, and warm kind, and the more poor mountainous ones, as well as the upland pastures and downs, it is such a very minute attention to this busines need not, perhaps, be bestowed, as accidents loss frequently occur, than on rich pastures or marshes, where the lambs are much exposed to danger and destruction from many caufes, unless very carefully attended to at this time. The nature of the principles and practices which are necessary in the busines of lambing, are, in short, yet much too confined and too little known to sheep-farmers in general to be of any great advantage. The first thing which is requisite in preparing for this busines, is the making choice of proper dry warm fields and pastures for the purpose, and having them made as safe and secure as possible from the danger of all sorts of accidents and inconveniences to the lambs. Where they have large wet open exposed ditches, or any other sort of inconvenient fences on their fides or other parts, they should be well guarded and secured by means of suitable low dead or other hedges being raised on the fides of them, by the ufe of small light hurdles, about two feet in height, with two racks, fixed down around them or in the most dangerous parts; by placing in brufh-fuggets of a proper fize round the fides of their banks, and flaking them well down to prevent their being disturbed by the winds and fstorms; by hanging old fefuets along their banks or borders; or by some other kind of cheap low defence, which the local nature of the situation may fuggest. The nature of the pastures for this ufe should constantly be such as are fine and fhort in their grafs, and neither of too poor nor too rich a quality, as inconveniences are liable to take place from each of these flates.

It was formerly the practice to have the lambing of the ewe flocks performed on a great breadth of paffure-land, as two or three to the acre, or in a very thin manner, which was extremely troublesome; but it is now found that much benefit attends its being done in a clofer or thicker way, as ten or twelve more to the acre, in some fakes; as it is not only more convenient and successful, but far more profitable. By thus doing it in a narrow compafs, according to the flate of the grafs, the work is more fafely gone on with, is more under the direction of the manager, and more convenient in cafe of difficulties arising in it, while there is much loss danger of lofs among the ewes in conquence of the nature of the keep, which is very material, as it is often
SHEEP.

often by no means inconsiderable, especially in certain circumstances and situations towards the close of the lambing season.

In some places it is not unusual, before the lambing takes place, to provide a better sort of pasture-field for the reception of such ewes as may chance to have twin-lambs, more food is required for them. This is a bell when in or near the middle part of the lambing pastures, as the ewes and lambs, in that case, can be the most readily and conveniently removed, whereas in other circumstances there is often much trouble and difficulty caused with the young lamb, which should always be marked and removed as soon as they are enabled to walk.

The next preparatory buffets, in some situations, is that of clattering the ewes, which commonly takes place a little time before the lambing begins; but in many places this is wholly neglected and thought quite useless. See SHEEP. Clattering of.

The lambing time takes place at different periods in different places, according to the nature of the situation and other circumstances, and often a week or ten days sooner or later in the same situation, as the season may be more or less severe, and the feeding of the herd has been more light or more hard. But about the beginning of April is probably the bell and most general time. Early lambing is most advantageous, where the circumstances of the land will admit of it. The season of lambing mostly continues about a month, and in some places, where lambers are employed without any lookers, two guineas and the lamb-skins are paid for that time.

In the actual buffets of lambing, much care and attention are necessary in the person who has the direction and management of it. In all natural cases of this sort the less that is done, perhaps, in general, the better, as nature will for the most part effect the buffets in the safest and most proper manner. The chief difficulty, it has been said, consists in knowing when ewes should be affiled, as young persons employed in this management are much too apt to interfere, from which much mischief and loss not infrequently proceed. The nature of the particular cafe, and the workings of the ewes, should constantly be the principal directors in this matter. Some conceive, that when ewes have been at work some length of time, they should be affiled; others, that when the lambs' tongues are protruded from the mouths, they should have affilation; but neither of these rules is always to be depended upon. There are still others who think, that when the ewes rife and walk off on being approached without any thing being the matter, they require no interference; but that when they will not rife, but appear a good deal spent, they should have immediate affilation. Some also suppose, that a considerable force may be exerted in such cases without danger. But though there may be some truth in the remark, it is always necessary that much caution should be taken where force is employed on these occasions. Besides these, something may probably depend upon the state of the feasons in this buffets, as affilation will be less necessary in such as are cold, than when they are warm. The ewes should, in fact, never be meddled with in their lambing, in these cases, until there is an absolute necessity.

In all unnatural cases of this kind, which vary very much in different situations, according to the nature of the usual part of the lamb which may present itself, and which require the affilation of proper persons those who have had the fullest experience, and are the most cool and cautious, will be the most proper for performing the buffets, as where this is not the case, there will often be great loss of lambs, as well as of ewes. In every case of this nature, where much force, or any other means are necessary to be employed, very great care and circumspection should constantly be used to have it exerted as little as in the most gentle, deliberate, and safe manner possible, as otherwise much danger and inconvenience may arise, that might have been avoided.

In some instances, where the lambs are apparently dead when they are lambed, they may be recovered and restored by forcing air into their lungs in an easy manner. This should however always be done almost immediately afterwards, otherwise it seldom succeeds.

As soon as the lambs are brought forth, they have commonly some milk from their mothers given them, or are allowed to suck them for some little time, which are supposed to increase the affection of the ewes for them; the lambs being at first left as close by the boxes of the ewes as possible, which should be done quickly, that they may not go away without noticing them. The lambs are always greatly strengthened and improved by the ewes licking them, which they constantly do, where they have a proper affection for them. When lambs drop and hang their heads immediately after they are lambed, they are bad and unfavourable signs, as showing them to be in a weak and dangerous state. The practice often made use of in some places, of putting the tail of the lamb, which is just lambed, into the ewe's mouth, in order to promote her affection for it, is very silly, and of no avail.

In the catching of all ewes is the lambing time, every fort of exertion, trouble, and fatigue, is as to injure them, should be avoided as much as possible, in order that they may lamb, or be affiled to lamb, in a cool suitable state.

In the catching of all ewes is the lambing time, every fort of exertion, trouble, and fatigue, is as to injure them, should be avoided as much as possible, in order that they may lamb, or be affiled to lamb, in a cool suitable state.

During the time of lambing, the looker, or other person who has the management, should be very careful and attentive early in the mornings, and at other times, in looking over the ewes and lambs, to see that they are not injured or left by neglect in any way.

In cafes where this business is carried on upon a large scale, when every thing has been properly prepared and got in readiness, the lamb'er, or other person employed in the management, begins his laborious and difficult undertaking, by entering and going over the lambing pastures at the time of day-break, with his lamb-hook in his hand, that he may notice and examine the ewes, raise up such as have lain down, and determine whether such lambs as are dropped be capable of suckling, which is commonly readily decided by the distinction of the belly. In cafes where this left is not able to be done, the ewes are either caught, and the lambs stucked, or the lamb'er is provided with some ewe's milk in a bottle for the purpose, a precaution which is essentially proper on many occasions, as when the weather is severe, wet, and tempestuous, in which circumstances the lambs quickly perish, if not supplied with such food. This attention often strengthens the lambs in a wonderful manner, and prevents much trouble in removing them and the ewes to the pounds. The continuance of the affection of the ewes is proved by the callings and noise they make. The twin lambs are now usually marked, to prevent confusion, as the ewes frequently leave one of them, after which they are not meddled or interfered with for some little time, as a few hours, or a day, as their strength may be; but as soon as they can walk, they are mostly removed with the mothers into better keep. The ewes which have single lambs commonly remain in the pasture-fields where they have lambed, unless the number be great, in which case, the lambs with the ewes are occasionally removed into the pasture-fields, where they are intended to be kept during

Vol. XXXII.
Sheep.

The fummer. It is supposed, that by the above practice the lambing pastures are sometimes less discommoded, than is the case where too great a number of ewes and lambs are crowded together. Sometimes, when an ewe has lost her lamb by any accident, and yet is deemed capable of bringing one up, a twin lamb is given her. When a weakly lamb, however, is put to an old ewe, the milk is often too strong for it, and will speedily cause its destruction, by scouring or in other ways; such lambs are likewise incapable of keeping the udders of the ewes properly drawn, by which means much injury is frequently done to them. These ewes are therefore often better turned off for fattening, than being employed in this way. Various methods are practised with the ewes which have dead lambs, by using such lambs so as that their affections may be increased, and the ewe be drawn into the pounds, and have other lambs put to them. All such measures, however, often fail. The custom of running the ewes down to get them into the pound is always very bad, as frequently causing their destruction. The ears of ewes being flapped down, and the ewes not looking back, are in every case bad signs of affection, but the contrary good ones. Lambs pounds are mostly supplied with suitable pens or coops for the convenience of flocking the strange lambs in. And the coats of the natural lambs are sometimes employed on the others. Whatever is done in this way, must, however, be done by deception, and not force, as the ewes are very refractory. Many other modes are had recourse to in different cases for taming the refractory ewes, and causing them to suckle the lambs in a proper manner.

It will now be necessary for the lamb to be particularly careful of the twin and other lambs, to see that they are regularly kept, and properly suckled in all cases, especially those which are in a weakly state. For this purpose some milk of the cow or other kinds is often carried and made use of by him, which prevents trouble afterwards. In these intentions, it is proper to go over the fields twice or oftener during the day; and to be particularly attentive in cold stormy weather. All sorts of accidents and dangers are at these times to be looked to, and guarded against in the most cautious manner.

About the end of the first week of the lambing season, one-half of the ewes will mostly have lambed, and more than two-thirds of them probably at the termination of the second, when the ewes may be brought into a leafy compas, and the lambing-field or pasture be cleared of all the twins and most of the single lambs, and they which are necessary may be had ready to cut, which in suitable circumstances is often done at this early period, by which the manager will be freed from much of his future labour and trouble.

By this sort of cautious attention and management in the lambing of the ewe flocks, and the use of proper forts of shelter, a vast saving of lambs and ewes may in all cafes be made, and the interests and profits of the sheep-breeding farmer be very greatly aided and promoted. See Sheep.

Sheep, Names of, the several names which are given, applied, or appropriated to them, at different ages, in different parts and places where they are much kept. These are very numerous, and of a very local nature; but the following are the greatest part of them.

These arbitrary names, which are given to sheep at different periods of their existence, in different parts of the country, serve to guide the breeding and grazing sheep-farmers of such places in their management with these animals.

Sheep, Smear of, the practice of falving or laying them over with some sort of substance of the unsociable kind, for the purpose of improving the wool, and preferring the animals from disease. It is only had recourse to in some districts, and those mostly in the northern parts of the kingdom. See Salving of Sheep.

Raw unboiled tar, not mixed with butter, is sometimes very dangerous and hurtful to sheep, especially rams, when laid on in large, or even moderate quantities. There are, indeed, some forts of tar which are very acrid, and blisters sheep, causing the wool to fall off, and the death of the animals. When it is thin, and appears black on stirring, with an offensive smell, and caustic acrid taint, it should never be used for sheep, especially without boiling, to destroy such properties. The personas engaged in the work of smear often find proofs of the danger of this fort of tar, in the burning effects which it has on their fingers. Good smeared tar, it is said, on being filtered, has a thick, brown, ropy
SHEEP.

ropy appearance, and a more pleasant smell, with a left
and tail than the other kind. Tar should probably always
be well mixed with butter in performing this work.

Sheep. The teeth of the part of the mouth of these animals
by which their age is often, if not in measure, ascertained.
When the mutton, they have usually eight teeth of the
inner kind in the lower jaw. They throw up two licks each
year until this takes place, by which means their bands
are replaced or lost. See Arts of Sheep, and Perfor.

Sheep-Shearing, is a Rural Diversion, the business of shearing
or cutting off the ears on account of the sheep by means
of shears contrived for the purpose, which are termed
shearers. It is sometimes figures the notion in which
this art of work is usually performed, which was formerly,
and is even in some cases at present, a sort of festivity.
The operation is performed in different ways by different persons,
but the best mode is that of the circular, or round the sheeps,
neither of the longitudinal, which is at present most in use.
It is usually performed about June or July, according to
situation and season, but should not be done either too early
or too long protracted, as injury and inconvenience may
attend either extreme. A good clipper is capable of clipping
from seven to fourteen or fifteen, and up to twenty or
twenty-five in the day; and more are frequently done by
very expert persons. Great care should be taken not to cut
or prick the animals; but where this accident happens in the
northern parts of the kingdom, they touch the part with a
little tar, or sheep-salve; and in Sweden it is often done with
train-oil and resin melted together. And in addition to
what has been already observed on this subject, it may be
stated, that much improvement has taken place in this art,
especially in the more southern districts of the kingdom, in
making use of the mode of clipping round the sheep, which
has gradually extended itself from the northern districts of
the island; by which left wool is lost by being left upon the
sheep, and the business performed in a more expeditious, neat,
and convenient manner. It was much the practice formerly
to clip lengthways of the sheep, and in some cases in many
different directions, according to the convenience of the
person who executed the work, by which means it was often
ill done. And in Ireland it has been stated, that they clip in
short strokes, catching a bit of wool first in one place and
then in another; and that if they are not looked narrowly
after, they will leave many parts, such as the heads, tails,
and undersides of the thighs, untouched.

We have, in speaking of sheep, noticed the most proper
periods of performing this very important operation; and
the following remarks, by Mr. Price, an excellent sheep-
farmer in the county of Kent, with the comments of Mr.
Culley, as stated in the Annals of Agriculture, will shew
the proper mode of managing the sheep in the time of shearing,
as well as the manner of executing the businets with these
sheep-madders. It is stated by the former, that the sheep-shearing in Romney-March commences about Midsummer,
and finishes about the middle of July. Those who
shear first, think they escape the effects of the fly, and those
that shear later, apprehend they gain half a pound weight in
evety fleece, by the increased perspiration of the sheep.
In early shearing the wool has not the condition which it afterwards acquires, but the hot weather occasions a good deal of
trouble in detecting the fly. In order to begin, a large pen
is marked with sheep ready for the coming of the shearsers, it
number from 1200 to 1500, and these men would take the
flock. The time employed is from two to four days. The
sheep are let into a small pen, thirty or forty at a time,
and when taken out to be sheared, all except three, more are
put in, because one or two only left would be apt to jump
out. A boy keeps the gate, and the amount of the num-
ber sheared, with all he can tell. Their heads by
preference differ much as to quantity and method of
performance; never by early, but are finished with the
least ten hour shearing; a goodower will shear three or four
shears, or bad one. The common method is to clip each whole
part of the sheep, not excellent for persons, as it is long and
often pulled about a side and back in manner, and
wounded by the hands with cuts of the length of three
to four inches, and the wound left open. In some manner, it is
then applied carefully by the boy, order to keep all the flax. The milt of officcr is usually to give the pitch-marks, and when one field is finished, the
sheep are returned, and others are in readi itsit to take their
place.

The common mode of catching the sheep is by the
linder leg, drawing the animal backward to the adjacent
shearing-place, the hand holding the leg to be kept low;
when at the place it is turned on its back. Or they are
moved bodily, or one hand placed on the neck, and
another behind, and in that manner walked along; the shift,
or common mode, he thinks the most safe. The parts of sheep fed
on rich pastures, and lathy, if handled hard, and bruised,
are liable to fatal mortification; an accident which often
happens, on which account the pens upon some lands are
obliged to be lined with woodens, or many would die from
brufes. The price of shearing is 2d. or 2½ score, with a dinner,
and 2½, 2½d. or 1d. a sheep without vici-
tuals, but with drink. They vary much in different
places. A good winder will wind 400 fleeces a day,
at the same price per hundred as the shearer has per score.
The method of shearing—the left side of the sheep to the
shearer's left leg, his left foot at the root of the sheep's tail,
and his left knee at the sheep's left shoulder. The precedes
commences with the shears at the crown of the sheep's
head, with a straight cut along to the loin, returning to the
shoulder, and making a circular shear round the off-side
to the middle of the belly; the off hinder leg next; then the
left hand holding the tail, a circular shear of the rump to the
near bick of the sheep's hind leg; the two fore-feet are next
taken in the left hand, the sheep rafled, and the shears set in
at the breast, when the remaining part of the belly is sheared
round to the near flite; lastly, the operator kneeling
down on his right knee, and the sheep's neck being laid over
his left thigh, he shears along the remaining side.

However, on these statements Mr. Culley has made the
following practical comments; namely, that Mr. Price's ob-
servation is just, with regard to the benefit arising to wool
from being late clipped, and that it is consonant with the
opinion of the Lincolnshire graziers and breeders, who have
paid more attention to the subject, and understand it better
than any other of the profession in this island; but very great
attention is required from the shepherd to keep the sheep,
under the circumstances of late clipping, free from the fly
and maggots, also from the danger of being beaten by small
flies, which fallen on those parts where the points of the
shears have made the smallest friztch. But that, in regard
to shearing even or ten sheep in an hour, nothing can be
more absurd and improper than such attempts, since it is im-
posible for the best shearer to clip the lowest number within
the time, and perform it well; as it ought to be done. Forty
years ago, the same absurd method of clipping sixty or seventy
of that large breed in a day; but the consequence of such imprudent
hafe was, that besides imperfect shearing, large pieces of
skin were cut, particularly from the bellies of the sheep,
which,
The use of sheep in agriculture is discussed, including their clipping, shearing, and the care of the fleece. The writer describes the process of shearing, including the clipping of the wool and the use of shears. The sheep are kept in shearing houses, and the fleece is collected for sale. Shearing is an important part of the sheep's care, and it is done annually. The fleece is then sent to the wool lofts, and the sheep are left to graze in the fields. The sheep are also used for their meat, and the writer mentions the different cuts of meat that can be obtained from the sheep. The sheep are treated with care and respect, and their welfare is a priority. The writer concludes by emphasizing the importance of the sheep in agriculture and the need for continued care and attention to ensure their health and well-being.

Sheep.

The sheep fold, in agriculture, is a space of arable or other land, used for the feeding and grazing of sheep. The sheep fold is an important part of the sheep's care, and it provides them with a safe and comfortable environment. The sheep fold is typically a large open space, with a well-drained surface to prevent waterlogging. The sheep are kept in the fold during the day, and they are taken to the fields at night to graze. The sheep fold is also used for the purpose of shearing, and the sheep are taken to the shearing house to have their fleece removed. The wool is then collected and sent to the wool lofts, where it is processed for sale.

The sheep are also used for their meat, and the writer mentions the different cuts of meat that can be obtained from the sheep. The sheep are treated with care and respect, and their welfare is a priority. The writer concludes by emphasizing the importance of the sheep in agriculture and the need for continued care and attention to ensure their health and well-being.

The writer of the "General Treatise on Cattle," states, that the royal flocks of fine-wooled sheep in Spain are sheared in the beginning of May. There are shearing huts, each of which will contain twenty thousand sheep, and costs in building above five thousand pounds sterling. To sheer a flock of sixteen thousand sheep requires one hundred and twenty men; a man shearing twelve ewes, or eight rams, in a day. The sheep are sheared previously to being sheared, in a long, narrow, low hut, called the shearing place, where they remain a night, crowded as close together as the sheep can keep them. The flock is then permitted to go to pasture if the weather be fine, returning home in the evening, to pass the night within the shelter of the walls, or in the huts, if cold or cloudy; by which means they are brought by degrees to endure the open air.

And it is a point of great consequence in this business to have a person well conversant with the winding of the wool, in order that it may be well performed, and look in a proper manner to the buyer. In some places the wool is laid in a heap on being wound, and conveyed in the evening of the same day to the wool lofts, or other depots. Some store their wool constantly in upper chambers, as the moisture which is produced by it on ground floors, when it is continued there for any length of time, is supposed to be very injurious to it.

See Wool.
moveable, either by means of wheels or other contrivances, being drawn to different situations according as they may be wanted. See Sheep-House.

There is likewise another sort of more imperfect sheep-field, which is formed by the planting of trees in different methods, in order to afford the animals a sort of protection from the severity of the winter season, as well as from the excessive heats of the summer. These are termed tree fields, and sometimes plantation fields, from the manner in which they are formed. See Tree Field.

In the construction of the second sort of sheep-fields, which were mostly termed in some distinct parts of the farm, in which cases they were often denominated 'flanking-out fields,' a cheap and simple method was had recourse to be an excellent sheep-farmer in Suffolk (Mr. Moreo). He inclosed a double fold with the threety dozen of old hurdles seven feet long each, formed of wads, and raised a hazel fence around them, composed of upwards of sixty loads of wheat stubble, the area of the fold being littered with about thirty loads more; in this the flock were to be lodged where the field fold was unsafe, or could not be removed from place to place, on account of frost, snow, or flood; and if it is stated, that he made during the same winter season, 403 loads of manure, improving at the same time the condition of his flock. The land, it is observed, lay at too great a distance to be measured from the home-farm. He likewise adds, that before he thought of this plan, his sheep were always obliged to lie in bad weather, upon a certain sheltered part of the heath, where the fold manure was not only lost to his farm, but the grass on which the dung was heaped in such quantity became so coarse and sour, that nothing would eat it; and that, exclusive of this injury, he used to lose by mortality from wet or severe fevers, during yeaming time, a much greater number of both sheep and lambs, for want of the dry warm lodging of a sheltered fold, the advantage of which he estimated at thirty or forty pounds a-year at least. He states that, by his improved plan than thirty lambs in a year, besides sheep amounting to a greater number of lambs than he usually reared in one year during the period of his farming business.

And by the forming of these folds in any other cheap convenient manner, similar benefits may be derived by the sheep-farmer. In all these cases, the sheep should be littered down as above as often as necessary, and be well fed, twice in the day at least, with such food as has been provided, being let out during the middle of the day, except when the weather is very stormy and severe.

It is stated in the Annals of Agriculture, that one hundred and thirty-four sheep confined in this way for the period of six weeks, and littered with five loads of forty trusses each of oat-straws, forty loads to the truss, made twenty-eight large loads of manure, confining two acres of turnips within the time.

The great superiority of this sort of fold over that of the naked movable kind, is therefore sufficiently obvious, and may probably be had recourse to at all fensoms with some advantage. See Sheep, and Fodding of Sheep. Also Sheep Yard.

A sheep-fold has been lately invented by Mr. Plowman of Bracon, near Norwich, upon an improved and very simple principle, combining many advantages over the old and expensive method of folding by hurdles; and as the whole fold can be removed with ease at all times, it will be found peculiarly useful in feeding off turnips on the land in frothy weather, when hurdles cannot be used. It is stated that the expense, in the first instance, will exceed that of hurdles for the same given quantity of sheep; but having had one in use nearly three years, he is satisfied the saving will be very considerable: for, before he adopted this method of folding, he lost from thirty to forty sheep during the year, owing to the land being bad and dry; which renders hurdles almost useless, as they never can be fix'd with great shelter, and deflection of hurdles. He is also clearly of opinion, that the flock of sheep will be greatly increased when this method of folding becomes more known; and that it will enable many small farmers to keep from 50 to 100 sheep, who are now deterred from it on account of the small quantity of feed they have not a sufficient and certain for that purpose only; but by this plan, they may keep a low at 35 or 40 lbs. per week, who can attend on 10 or 20 lbs. sheep, and move the fold themselves without any of these. In many cases of wind it frequently happens that the hurdles are blown down, and the sheep of course become Harry carriage over the crops do inculcable mischief which cannot happen with this fold. And in some countries in England, where hogs are folded, great difficulties are experienced for want of strawage, for them to feed off winter turnips, &c. &c. from rooting up every flake or hurdle; and having tried the experiment, he is certain this fold will keep them in, and defray their attempts to displace it. And an abundant quantity of time is saved, as a man can remove a fold to contain 300 sheep in five minutes, which by the old method frequently takes some hours to accomplish. Many are now using folds from his model; and he received for the invention the gold medal of the Society for the Encouragement of Arts, &c.

It is further remarked, that where the fold is wanted to be used on very hilly ground, it must be begun at the top and worked down to the bottom for the sake of removing it, and then drawn up again with a hurdle. Thus, however, he has never had occasion to do, for his land is ploughed in a contrary direction, and he works the fold in the same course as the ridges. By this means the inconvenience is avoided of crossing the furrows; and they are also a guide to keep the fold in a straight direction. With respect to the sheep getting under, he does not recollect that circumstance to have ever happened, nor does he conceive that any land, which is cultivated, can be so uneven as to admit of it.

This sheep-fold is twenty-one feet in length and three feet eleven inches in height, being composed of a top-rail, and bars below pased through uprights; the whole moving on low cast-iron wheels, and made strong, but in a light manner.

Sheep-House, a sort of flight wooden building, constructed for the purpose of containing and protecting sheep in bad weather, &c. Houses of this kind are usually made low, for the sake of warmth in the winter, being mostly a third part longer than they have breadth; they should also be sufficiently large for the quantity of sheep they are to contain. The sides should be lined with boards, and the bottoms be laid in an even manner with stone or some other material, that the litter may be well impregnated with the urine of the sheep. And it has been advised to have the sides exposed to the sun, set with lined moveable hurdles, that when it thaws the whole may be laid open, to afford due refreshment, and give the sheep an opportunity of feeding upon the pasture wherein they stand. They should be well and securely covered with some sort of proper material upon the tops. They are sometimes fixed in particular situations, but in other cases, which is the more improved method, so constructed as to be capable of being removed as they may be wanted. One of the latter kind, employed on the farm of the Hon. George Villiers, in Hertfordshire, which is very complete, is described, with a plate, in the Corrected Agricultural Survey.
SHEEP.

In this sheep-house the wheels are fixed to the sides, being sixteen inches in diameter, and having an axle-tree to harness the horse to, with weather-boarded flaps hung with hinges, to turn up and button against the flaps when it is removed. It has also folding doors to open when the sheep are let in or out, and fixed weather-boarding, with cover-boarded windows to open on hinges in slits, in order to put fodder into the racks. Likewise a canvas roof, with open railing for air.

It is observed, that the length of the building is from twenty feet to any length; the width to be such as to enable the building to pass through the field-gates; the weather-boarding and flaps to be made as thin as possible, and covered with pitch.

But how far the advantages of houses of this fort may compensate the expenses of constructing and keeping them in repair, has not been fully shown; nor has perhaps a sufficient number of trials been made to show the advantage of confining sheep in covered houses or folds, or whether the economy of the animals is well suited to such a system. Some circumstances of advantage attending the practice of housing sheep have certainly been stated, but no satisfactory comparative experiments have, so far as we know, been made. And from the plan being little or not at all adopted in many extensive sheep districts, and in others where it once prevailed being either wholly in diffuse or much on the decline, as is well known to be the case in Gloucestershire and the county of Hereford, there seems reason at least to presume that it is not so necessary or so well suited to the habits of the animal, nor even so beneficial as has been supposed by some writers on the subject. See SHEEP, and FOLDING of Sheep.

Houses of this nature, for the purpose of sheltering sheep and lambs in bad weather, are formed in a very cheap and simple manner in Romney-Marsh, as may be seen in Price's account of the sheep-husbandry of that district.

Sheep-Hurdles, the flanes or fort of fence-gates which are let up so as to confine sheep at the time of folding them on arable land, or while they are feeding down, or upon any particular fort of food. They are of several different kinds, and either close or open; but the former are in general to be preferred, as affording the most shelter. It is obvious that the number required to inclose a certain space must depend upon the length. See Hurdle.

Sheep-Husbandry or Farming, that fort of farm management which relates to or has sheep for its principal object. There are various modifications of this fort of farming, depending upon the differences in the circumstances of the lands, their nature and situations, as well as other local matters. See SHEEP.

It is not improbable but that in this fort of husbandry and farming, the most benefit and advantage may often be derived where there is a judicious intermixture and conjuction of other forts of management, as those of cultivation, cattle, planting, and some others, sheep being constantly the great object. By such means advantages are afforded and brought forth in a great variety of different ways to the individuals themselves as well as the community at large.

In this fort of farming management it is of much conquence to have recourse to the fixing upon such plans and methods as are the belt and most suited to the flat or nature of the farms and markets for the sales of the animals. In cases where the farms are high, and of a cold exposed nature, the weather system may often enter largely into the plan which is to be adopted. Where they are of the most mixed nature, and composed of high, as well as low lands, they may sometimes be most suitably fitted, in a partial manner, with ewes and lambs, and with wethers. In those of the more common fort, the breeding or rearing systems, according to circumstances, may frequently be the most profitable modes. And in rich grazed land and mixed farms, which are provided with parks and pastures, as well as arable lands, the sheep-farmer may not unfrequently be tempted to fatten the saleable part of his sheep-flock, particularly where the markets are convenient for him in respect to distance.

In all these forts of farms in this kind of husbandry, the breeds or kinds of sheep should always be selected and provided with a perfect consideration of their nature, and the management of the sheep to be carefully directed with the same intention. The means of disposing of them should also be well regarded. Many other circumstances likewise require attention in this fort of husbandry and management. The inquirer may find much useful information on the subject of Highland sheep-farms and sheep-farming, in the third volume of the "Transactions of the Highland Society."

Sheep-Marks, and Marking, the marks and means of performing those which are put upon sheep in different ways and manners; as by means of tar, ochre, redde, wad, and other similar substances, and by cutting the ears of the animals in different forms and methods. Thesre are useful and necessary to the sheep-farmer on many occasions and accounts; they serve to distinguish his particular sheep and flocks from those of others, to discriminate the several different kinds, and to point out the various forts of management which are necessary with different kinds of sheep and lambs, as well as to answer different purposes in the sale of them, &c. In the marking with tar, a tool or contrivance having letters fixed to the end of it, is mostly made use of, the initials of the name of the farmer being most commonly employed. With the other matters different methods are taken; such as writing and rubbing them on plates, flones, or other matters, and then marking the sheep with them in the ways that may be thought necessary. Sheep and lambs are marked by these means in many different parts, as in the faces, on the sides, the hips, and in several other places; the work being mostly done according to the fancy of the person engaged in it, or of the owner of the flock, often in different curious modes and forms, as straight lines, curves, circles, and a variety of other more out-of-the-way methods. The marking of the sheep in the ears is performed by cutting them with a sharp knife in different forms and manners, as in that of a fork, an under and upper flan, an under and upper square, an under and upper notch, a flape, an under and upper flit, straight flit, a crop, a crop and flit, a hole, a hole and flit, &c. All these several modes may be seen represented in Price's System of Romney-Marsh Sheep-grazing.

Marking sheep in the ears, in these or other methods, forms excellent and correct means of distinguishing, for knowing them by, in a variety of cases and circumstances in sheep-farming.

Dr. Lewis recommends the following composition for marking sheep: mix melted tallow, with so much charcoal, in fine powder, stirred into it, as is sufficient to make it of a full black colour, and of a thick consistence. This mixture, being applied warm, with a marking-iron, on pieces of flannel, quickly fixed or hardened, bore moderate rubbing, refulted the fun and rain, and yet could be washed out freely with soap, or ley, or flate urine. In order to render it still more durable, and prevent its being rubbed off, with the tallow may be melted an eighth, sixtli, or fourth of its weight.
weight of tar, which will readily wash out along with it from the wood. Lewis's Com. Phil. Techn. p. 561.

Sheep. *Pens*, the divisions made by the small moveable gates or hurdles, which are set up to keep sheep in the particular situation. They are usually formed on a dry place, about the corners where different inclosures of the pasture kinds meet, to as to be convenient for the whole. They are useful in examining and feeding the sheep, being divided so as to contain about three dozen sheep each, as by this means they are always at the command of the shepherd for any purpose he may have in view. The bottoms should be firm and dry, so that the sheep may not be fouled.

Pens or coops are likewise made and used in the pounds, which are enclosed and put in some sheep districts. These are usually about two feet seven or eight inches in the square, into each of which one ewe and the lamb are put, and fenced, where there is a difference in the ewes to let their own lambs suck, as occasionally happens, and where strange lambs are put to them. Two of the side-boards of these pens are capable of being lifted up and let down so as just to admit the ewes; in which they move with difficulty, consequently are not able to reach the lambs to eat them away; by which means they thus find an opportunity of sucking against the wills of the ewes. These pens are therefore often very convenient in these cases, two of which are mostly kept in each lambing-ground or yard. See *Sheep-Pound*.

Sheep-Pound, any sort of narrow inclosure for the confining of sheep. Pounds of this kind are of many different sorts, and useful for several different purposes in the management of sheep-flocks, as those of lambing, catching, sorting, and dressing them in different ways, &c. They sometimes occupy pretty large spaces of ground, but at other times are only of very small extent.

Sheep Rubbing-Pots, the small pots and pieces of wood which are fixed up in sheep-paupiers for them to rub themselves against. They are sometimes simple upright pots, but at others they have crofs pieces put through them. They are very necessary and useful to the animals. See Rubbing-Pots.

Sheep-Scraps, the ears used in clipping or shearing of sheep. They are the frequently termed wool-shears. They are made with a spring on the handle part, which causes them to open readily in working with them. The handle part is mostly about six inches in length, and that of the blade about five; but shears of this kind vary much in size in different places.

Sheep-Skin, or Pelts, the common covering by which the sheep is surrounded and defended. The skins of these animals differ much in thickness, size, and other properties, according to the nature of the different breeds. Sheep pelts, or skins, sometimes form an article of great utility and profit to sheep-farmers, being sold to the fell-mongers, or other persons in their neighbourhood, under contract by the year, at different prices; as from the time of shearing to Michaelmas, at from 12 to 11 6d. from that till Shrove-tide, at from 21 to 20 6d. and from Shrove-tide till Michaelmas, at from 21 to 31 6d. Sometimes of this method is pursued by the South Down sheep-farmers in the sale of their sheep-skins, as well as by those of several other great sheep districts, by which great advantage often arises.

Sheep Wallowing-Hooks, the long-handled hooks which are made use of in washing sheep in some places. The hooks are in these cases fixed at the small ends of the long handles, in several different forms, as in that of somewhat the manner of an S; that of two small forks of half circles, with a little

**SHEEP.**

Sheep-Yard, any sort of inclosure in which the sheep are confined and kept at certain times of the year, for the purpose of raising very young lambs, and for the purpose of other matters, such as shearing, or the like. These yards are now becoming pretty generally made, as well as in all eyes. They are of several different ways, as the nature of a square, or an outside yard and other round yards, as well as often made in ells, sheep-yards, as in the case of Stover, Southfield, and Stover-Hay.

It is stated in the Agricultural Report of the County of Oxford, that at Chilton, Mr. Leach, has one of the most complete sheep-yards in it; a small farm and three sides of it, in which are racks and hurdles for the sheep to take their food from; it is forty yards in length and sixteen in breadth; the heds being five yards broad. This sheep-yard does very well for two hundred ewes. The ewes are usually brought into the yard from four to six weeks before the lambing-time, and continued in it until that is over, going out however in the day-time. This is said to be considered as a very excellent method, but attention must be paid in it, that the dung does not accumulate, as by its fermentation the sheep are liable to be injured. It should, of course, be carted out in a repeated manner. When not removed too often as to prevent its taking on heat, it has also been found, in Elne, to prove dangerous to lambing ewes, as well as ewes and lambs.

The heds may be raised on the sides of these yards so as to serve as fences also. Stubble, haulm, and other similar matters, may likewise be made to form warm walls as the outside fences of them.

All yards of this sort should be kept constantly well littered with suitable substances of that kind, upon foundations laid with good earth, sand, or some other proper material.

In some large sheep districts, as the South Down, in Sussex, the farmers have sometimes two or three of these yards, which are well sheltered for the sheep to lie down in at night, in very rainy and stormy weather. In some instances a yard of this nature, including the heds, comprehends a space of not less than three hundred and fifty-five square yards; the heds around which are about four yards wide. The whole are kept, for the most part, thoroughly well littered down. They are commonly extremely warm, and found to preserve many lambs in bad weather. The whole of the circumference around them, in some cases, has a rack for containing hay.

In the Dorchester district of the first of the above counties, natural grass being extremely scarce, straw is given in large quantities to sheep, as soon as ever the frosty mornings come on; barley-straw is had recourse to in these yards, or in lambing pens; and afterwards bean and pea-straw, which they are very fond of; they pick off the pods and tops, and do very well with these substances. These sorts of straw are occasionally carted to the field for their use; and what they do not consume, brought back to the yards; a practice which is pursued to the saving a great many tons of hay. Such dung as is made in this way is found to be very good.

Peas may likewise be applied in these yards, or other ways, in fattening lambs, the mothers of which are at turnips. They are given in troughs, six or eight weeks after the lambs have been dropped. By the lambs having the liberty of running through the openings in the hurdles, where the field mode is followed, it is often some time before they will take to this
fort of food, but they mostly come on gradually, until a score will eat a peck a day. Peas are sometimes given in this manner, till they reach six shillings a bushel, and found to answer. A great many forts of food of these and other kinds may be used with superior advantage for sheep in these yards, and a vast supply of good manure be provided at the same time.

_Sheep._

Sheep-Clatter, in Rural Economy, a term applied in some sheep districts to the person who has the care of clattering the ewes just before the lambing-time begins.

Sheep-Lander, a name given to the person who has the care and management of the ewe-flocks, which are under the state of lambing, in some sheep districts. It is of very great advantage to a sheep-farmer to have a careful, tidy, active lambner, unless he attends to the business himself, which is always the best way where it can be done; as few will be found who are sufficiently attentive and diligent at this period, and, of course, much loss may be sustained. Where persons are hired for this purpose, they should, it is supposed, be rather elderly than young, as being more experienced and less apt to be hasty, as the business is intricate, tedious, and often subject to much trouble, confusion, and disorder, which stand in need of a great deal of patience to have them properly attended to and rectified. If they are, or have been lookers, it is so much the better, but this is far from being always the case, even in the principal situations where sheep are kept. In the great sheep district of Romney-Marsh, it is the custom for the lamners to have the fkins of the dead lambs as a perquisite, which are usually sold at about 5s. the dozen. This is certainly a bad practice, as it tends to the making of rogues. The interest of the sheep-master and his servant, which ought to be the same, are separated, as what is the loss of the one is the gain of the other, and much injury and disappointment result from it.

In the above great district for sheep, it is usual for the lamner to go his regular rounds at four o’clock in the mornings, and to continue with the ewes until about seven or eight, returning to the fields until dinner-time; then going off again at one, and returning about five; setting off on his last round at six o’clock, when he does not return until dark. There is indeed sometimes so much to do, that he cannot come home above once or twice a day; the lambing should on no account be ever left until the lamner has every thing in a fair way, especially at the time of night.

Sheep-looker, the name of the person who has the over-looking and management of the sheep-flocks, in some districts. Persons of this kind should always be of careful, tidy, active dispositions; with sufficient experience, and a full knowledge of the different modes of sheep management. See Shepherd.

Sheep-Lambing-Hooks and Marks, the instruments of the hook and mark kind, which are made of iron in laying hold of the lambs, and in marking them, in particular cases and circumstances. In the former the handle is about seven feet in length, the head, or circular open part, three inches in width; the neck, or opening part to it, two inches and one-eighth wide; and the guide, or bill, six inches and a half in length. The latter have the handles about seven inches and a half long, with straight and curved or circular marks at the ends, one inch and three-eighths in length, and one inch and two-thirds in width, inside the circle. These instruments are very useful on many occasions.

Sheep Hay-Rack, that sort of rack which is provided for the use of sheep in their consumption of hay and other sorts of fodder of the same nature. They are made in many different ways, as open or covered on the tops, and boarded or barred up a little height at the bottom part, as well as railed on low wheels, or wholly without them.

They are usually from about fix to nine feet in length, and about two feet and a half in height; the space for the hay at the top about two feet ten inches, but which is sometimes contracted at the bottom so as for the two sides to come nearly together, standing out in the manner of common horse racks. The openings for the sheep to feed through from three, four, or five inches to seven or eight. The smaller they are the less loss there will be, provided they are sufficient for the sheep getting at the fodder. The bars and boards put at bottom in some sorts of these racks prevent the animals getting into them. When formed with covers and screens for keeping the hay or other food, and the sheep, while feeding, from being wet; they are the most complete, especially if, at the same time, they be provided with low wheels, so as to be capable of being moved from place to place. In small racks, where wheels are put at one end, they can be easily moved about.

These racks are of very great use and convenience on all farms where sheep are kept in any quantity. See Rack.

Sheep Corn-Bin, any sort of trough or bin formed for the purpose of containing the corn, or any other similar kind of food for sheep, either in fattening, or in other modes of managing them. Bins or troughs of this nature are usually contrived in a light manner, so as to be moveable on low wheels, having covers at some height over them, supported from below by the ends and upright pieces in somewhat the roof-form, so that the wet may be prevented from getting to such provisions, and the sheep enabled to feed dry. They are generally made very narrow, but of considerable length, the box or trough for the food having only the depth of a few inches.

Sheep-bins of this sort are very necessary and useful in many kinds of sheep management.

Sheep-Dung, the manure afforded by sheep, which, by means of proper folding in yards properly littered with straw, flubble, &c. may, in many cases, be increased to a considerable extent, so as to render it an object with the farmer. See Dung, Folding of Sheep, and Manure.

Sheep-Drains, a name sometimes given to those small drains which are frequently formed upon the more loft and damp sheep-walks and pastures in different parts of the kingdom, in order to render them in a state of greater dryness. They are often made not more than two feet in width at the surface, and one foot and a half in depth. They are most suited to that sort of wettons where the bottom is of a clayey or tily nature. Such sort of work can, in some places, often be done at three-halfpence the rod of six Scotch ells. These drains should constantly have a gentle slope or declination across the declivities of the grounds on which they are made.

Sheep-Farm, that sort of farm which is principally conducted under some system of sheep management. Many situations are suited to some branch of this husbandry, which cannot be converted to the purposes of raising grain or fattening cattle, &c. See Sheep, and Farm.

The more dry the lands are, and the more fine and short the grass is which is upon them, the better and more proper and suitable they are, in general, for the purposes of sheep-farms. Where the substratum is of a lime-stone quality, this is most likely the case, in the most favourable degree. But in many instances now, arable farms are likewise sheep-farms, to a very considerable extent; artificial food being grown and raised for the sheep-flock in sufficiently suitable proportions. There is probably much advantage in this combination in all cases in which it can be properly admitted. Sheep-farms
farms should constantly be kept with great attention to the nature of the grass, the capitula, and the fuller for the animals. They should also be kept dry and in good order on the surface, with every sort of proper convenience for the management of sheep. See Sheep-Husbandry, and Farming.

Sheep-Law, a term applied to pasture-laid appropriated to the feeding or supporting of sheep; or any sort of pasture-laid on which this kind of animal or live-stock is kept.

Sheep-Plant, that kind of dry, firm pasture-laid which is suitable for the purposes of grazing, feeding, and fattening sheep. Many sorts of mild land are not at all proper for, or adapted to this use, though well suited for some other sorts of farm management.

Sheep's Trotters, a refuse material procured from fell-mongers, which is made use of in some places as a maturable to be turned into the land. They are bought at about 6d. the bushel, hoofed heaped, in some places, and sold about 2d. more in carriage, being used in the proportion of from twenty to forty bushels the acre, being afterwards picked in to prevent their being eaten by dogs, crows, &c. They answer well on such lands as are rather dry, and where the fea-son is rather mild. They contain a large proportion of lime, and are often adulterated by being mixed with sand, as well as oak saw-dust; which last is laid not to injure them. Forresters' cuttings are nearly the same, and made use of in a similar manner.

Sheep's Cree, in Geography, a bay on the E. coast of Newfoundland, between Bay Robert and Port Graves.

Sheep Island, a small island near the coast of South Wales, E. of the entrance into Milford Haven. N. lat. 51° 38'. W. long. 5° 9'.—Also, a small island on the northern coast of the county of Antrim, Ireland, opposite to the extreme point of the head-land, between Ballintoy and Ballycastle, not far from the remarkable rock, called Carrick-a-Rede. N. lat. 55° 15'. W. long. 5° 41'.

Sheep-Faced Grasfs, in Agriculture, a sort of grass which, while it has been much prized by some as useful in pastures, has been condemned by others as of little importance from its smallness, and being liable to be burnt up in dry seasons. It is said to succeed with less moisture than most other sorts of grasses. As forming a close-matted turf, where no great produce is required, it may be found a beneficial plant. See Festuca ovina, and Grass.

Sheep-Node-Worms, in Natural History, a species of fly-worm, found in the noes of sheep, goats, and fags, and produced there from the egg of a large two-winged fly. The frontal sinuses above the nose in sheep, and other animals, are the places where these worms live, and attain their full growth. These sinuses are always full of a soft white matter, which furnishes these worms with a proper nourishment, and are sufficiently large for their habitation; and when they have here acquired their defined growth, in which they are fit to undergo their changes for the fly-state, they leave their old habitation, and, falling to the earth, bury themselves there; and when these are hatched into flies, the female, when she has been impregnated by the male, knows that the nose of a sheep, or other animal, is the only place for her to deposit her eggs, in order to their coming to maturity. Mr. Valintini, to whom the world owes so many discoveries in the insect class, is the first who has given any true account of the origin of these worms. But though their true history had been, till that time, unknown, the creatures themselves were very early decoyed, and many ages since were esteemed great medicines in epilepsies.

The fly, produced from the worm, is all the time of its life a very lazy div, 611111, and does not like to use any use of its lighter wing. In full grown nymphs together are about as long as its body, while the head of five rays, forked on the back, a pair of yellow, and brown, are there dipped in irregular spots; the body has the same colours, but they are there more regularly disposed. For the brown here makes three lines, one in the middle, and one on each side, and all the intermediate spaces are yellow; the wings are early of the same length with the body, and there are a little inclined in their points, as to be upon the body; they do not, however, cover it, but a naked space is left between them, the alar, or petty wings, which are found under each of these wings, are of a whitish colour, and perfectly cover the balancers, so that they are not to be seen without lifting up the head.

The fly will live five weeks after it is first produced, but will take no nourishment of any kind; and perhaps it may be of the same nature with the butterflies, which never take any food during the whole time of their living in that state. Reaumur Hist. Inf. vol. 16. p. 532; &c.

Sheep-Scabius, in Botany. See Jasione.

Sheep-Shank, in Sea Language, is a sort of short, or butch, call on a rope, to shorten it as occasion requires; particularly to increase the sweep or length of a tackle, by contracting its runner. By this contrivance the body, to which the tackle is applied, may be hoisted much higher, or removed much farther, in a shorter time. Falconer.

Thus, if any heavy body is to be hoisted into a ship, &c. and it be found that the blocks of the tackle meet, or black and black, before the object can reach the top of the side, it will be neccessary to lower it again, or large by some other method, till the runner of the tackle be sheep-shanked, by which the blocks will again be prepared to a competent distance. See Rigging. Plate 1. fig. 16.

Sheep-Case, in Agriculture, a name provincially applied to the large sheep-bough.

Sheepent, or Sheepscot, in Geography, a river of America, in the district of Maine, which runs into the sea, N. lat. 43° 43'. W. long. 69° 38'.

Sheep-Haven, a harbour on the northern coast of the county of Donegal, Ireland, situated well of the Mulroy, and separated from it by a long, and, in some parts, very narrow peninsula. The surrounding country is mountainous, and thinly inhabited; nor is there any town of confluence in the neighbourhood. Dunfanaghy, near Hornhead, is no more than a village, though runs near it seem to indicate that it was formerly much larger. The fisher- man's land found in this district is of excellent quality for making glafs, and it is carried to Belfast for that purpose. Under the article Hornhead, a promontory which forms the western boundry of the harbour, we noticed, on the authority of the late Dr. William Hamilton, in the Transactions of the Royal Irish Academy, the effect of drifting farce in overwhelming the vertigos of cultivation; and the change thus produced in the appearance of a country. A similar effect took place on the eastern side, which is thus described by the same writer. "About 4 years ago, an elegant edition, according to the table of that year, was built on the peninsula, between the harbours of Sheepscot and Mulroy, which at present stands like Tadpole of the Tail, a solitary wonder of a surrounding desert." The yard are totally decimated of trees and shrubs by the fury of the western winds; their walls, usually to stand the mouth of overbearing fairs, have bent in four the celebrated pefure, and, overthrown in numberless places, have given free paillage.
passage to this reflecs enemy of all fertility. The courts, the lights of shops, the terraces, are all involved in equal ruin; and their limits only discoverable by tops of embattled walls, visible amid hills of sand. The mansion itself, yielding to the unconquerable fury of the tempest, approaches fast to destruction: the freighted whirlwind howling through every avenue and crevice, bears ineffectually along its drifted burden, which has already filled the lower apartments of the building, and begins now to rise above the once elevated thresholds. Fields, fences, villages, involved in common defolation, are reduced to one undistinguished scene of sterile uniformity, and twelve hundred acres of land are fain thus to have been buried, within a short period, in irrecoverable ruin."

"The lower parts of the Shetland Islands, are the greater number of them, but the inhabitants of the Orkney Islands, are the less thans of the same; and the inhabitants of the Shetland Islands, are the greatest number of them, and the inhabitants of the Orkney Islands, are the least." A distance of eighty miles, separates the town of Shetland, from the town of Orkney. The former is a town of considerable size, and is the chief seat of government, and the residence of the noble family of the Earl of Shetland, who are the principal landowners of the island. The latter town is a town of smaller size, and is the residence of the Bishop of Orkney, who is the spiritual, as well as the temporal, ruler of the island.

**SHEER**, or SHEERING, in the Woolen Manufactures, the cloth-worker or dresser's craft, or office; or the cutting off, with large sheers, the too long and superfluous knaps, or shag, found on the surface of woolen fluffs, fustians, cottons, &c. in order to make them more smooth and even.

Stuffs are shorn more or fewer times, according to their quality and fineness.

Some use the phrastic sheering of huts, for the paxing of hats made of wool over the flame of a clear fire made of straw, or sprays, to take off the long hairs: others call this flaming, and others figuring. Other hats, as callers, femiliners, &c. are shorn, by rubbing them, over with pumice-stone. See Hat.

**Sheer**, or Shering, in Sea Language, a term used for the motion of a ship, when the deviates from the line of the course, either to the right or left, so as to form a crooked and irregular path through the water, either by reason that she is not sheered steadily, or on account of the swift running of the tide, &c. in which case she is said to sheer, or go a sheering. Hence, to sheer off, is to remove to a greater distance.

When she lies at anchor, near port, &c. by reason of the swift running of the tide-gate, &c. she is often said to be in danger of sheering home her anchor, or sheering afofe. See Chest-Rope.

**SHEER MOHAMMED PETT**, in Geography, a town of Hindooftan, in the circar of Condapilly, on the borders of Golconda; 21 miles W.N.W. of Condapilli.

**SHEERNESS**, a sea-port and market-town in the Isle of Sheppey, and county of Kent, England, is seated at the mouth of the river Medway, and has derived its origin and importance from this circumstance. In the reign of king Charles II. it was deemed advisable to form a fort here, to protect the entrance to the river; and in 1667 that monarch, with an engineer and other officers, surveyed this spot, and strengthened the works. The Dutch, however, sent a fleet to this point, deformed the fortifications, and failed up the Medway, as far as Upnor Castle. After returning again from this enterprise, the government directed some firing works to be formed here, because the spot was deemed of great importance. A regular fortres was soon constructed, and mounted with a line of large and heavy cannon; and at the same time several smaller forts were built at different flations on the banks of the river. Since that time Sheerness has progressively been augmented and strengthened by new works, and now constitutes a regular garrison. It is commanded by a governor, lieutenant-governor, a fort-major, and inferior officers: and the ordnance establishment is under the control of a store-keeper, a clerk of the cheque, and a clerk of the survey. Adjoining the fort is the king's yard or dock, which has been made subseque unto the former. This yard is chiefly used for the repair of ships that have been slightly damaged, and for building frigates and smaller vessels. A resident commisioner,
SHE

SHE

fuser, with two clerks, a master's signature, and other
officers, with theirs, are laced and laced.

A second chapel has been erected at the expense of
Figure; but it is a little more open and spacious than
that of the present house of Merton. According to
the popular report of 1611, Sheerholf was visited by
13,500 soldiers, who executed the works; and it is said
that in 1649 the victory was due to the skill of the
architect, who had been trained in the hulk. The
hull of this ship, called the "Queen," is unique in the
seventeenth century, as a vessel of this size, weighing
600 tons, was not built before 1655. The Great
hulk experienced a peculiarity of fresh water, the chief
supply being brought in vessels from Chatham; but it was
determined by the Board of Ordnance, that an attempt
should be made to fix a well within the hulk, and the execution
of this was entrusted to Sir Thomas Pagge, an able en-
gineer, whose skill and perseverance were found fully equal
to the task that had been proposed in him. The preparation
of the materials, and the boring, to ascertain the different strata,
were begun in April, 1785; and the linking of the well
was commenced in June following. Thelanding-springs, &c.
which greatly interrupted the progress of the work during
the first half of the year, were excluded by regularly fi-
etting the inside of the well; till, at length, the workmen
came to an immense quantity of chalk, which prevented
the further necessity of fi-netting, and enabled them to pro-
cceed with less inconvenience. They went on, however,
with great caution, and having dug to the vault depth of
325 feet, the auger with which they were trying the strata
dropped down, and the water rushed up with such velocity,
that the workmen could hardly be drawn out with sufficient
haste to escape drowning. In six hours it rose 189 feet,
and in a few days it was within eight feet of the top; and it
never since produced a never-failing supply; for, though con-
stantly drawn from, it has never been lowered more than
200 feet. The quality of the water is fine and soft, and its
temperature is somewhat warmer than commonly happens
in other wells. From this well, conjointly with that of
Queensborough, not only the garrison and inhabitants are
supplied, but also the shipping which lie at anchor at the entrance of the Medway. (See QUEENSBOROUGH.) Havett's
History, &c., of the County of Kent, vol. i. 8vo, edit.
by E. W. Brayley, 8vo, 1806.

SHEEP, a town of Hindoostan, in Bahar; 43
miles S.S.W. of Patna. N. lat. 24° 55'. E. long. 87° 10'.
Also, a town of Hindostan; 32 miles E. of Delhi.—
Also, a town of Hindoostan, in Mewar; 25 miles N.E. of
Dug.

SHEARING, in Ship-Building, two masts or spars, set
slopes at the upper end of each other, and there lathed
together with tackles depending from the intersection; and
they are kept upright by guys extending each way from
the heads. The bows are lashed and lathed, or cleated, to
prevent their slipping. By this contrivance very heavy
bodies are raised, such as the stem, stern-frame, and the
frame-timbers of ships; large ships are mated by these,
or have their masts taken out where there is no sheer-hulk.

SHEET, in the Engineer. See CARRIAGE.

Sheet, in Ship Languages, a rope fastened to one or both
the lower corners of a sail, to extend and retain it in a par-

built
the	house
in
St.
James's
park, which has, during this reign, been the principal
residence of the queen. At the great change of the ministry
in 1710, he was again introduced, first as secretary of the
house-
household, and then as president of the council. After the death of queen Anne he was an opponent of the court, and employed his time chiefly in literary pursuits, till his death, in 1721.

The duke had been thrice married, and each time to a widow: his last wife was a natural daughter of James II., by whom he had a son that survived him. Following the example of the court of Charles II., he freely indulged in licentious amours; nevertheless, it has been said that he had occasionally serious thoughts of religion, though probably not restricted to any particular party. The following is the epitaph which he composed for himself: "Deditus

he fed non improbus vivit: incertus morior, fed inturbatus: humanum et necire et errare. Chirilium adverceror : Deo

condido omnipotens, benevolentissimus: Enims emit misere mei." This was inscribed on his magnificent monument in Welminster Abbey, with the exception of the clause respecting Chrift, which bishop Atterbury rejected, thinking simple veneration a derogatory expression applied to the second person in the Trinity.

In the capacity of poet, the duke of Buckinghamshire does not rank very high; his compositions are on a variety of topics, of which, however, the chief is "An Essay on Poetry," which, according to Dr. Johnson, contains judicious precepts, which are sometimes new, and often happily expressed, but with many weak lines, and some strange instances of negligence. In his "Essay on Satire," he is supposed to have been assisted by Dryden, who, for some peculiarities in it, had the misfortune to be taken as the real author.

The duke of Buckinghamshire composed two tragedies, entitled "Julius Cæsar," and the "Death of Brutus;" for the latter of which, at his request, Pope wrote two choruses: of these Warburton says, that they have the usual effect of ill-placed ornaments, they make the meanners of the piece more conspicuous. In the collection of the duke's works are likewise historical memoirs, speeches, essays, &c.

Sheffield, or Sheﬃeld, in Geogra phy, a large and populous market and manufacturing town in the south division of the wapentake of Strafford and Tackhill, liberty of Hallamshire, West Riding of Yorkshire, England, is situated at the distance of 36 miles S. from Leeds, and 162 N.W. from London. The origin and remote history of this town are totally unknown. In the 13th century it was noted as a staple for articles of iron manufacture. Chaucer, who wrote in the reign of Edward III., mentions the "Sheffield Whittle" in one of his poems. At that period it was likewise distinguished by a strong cattle, which roost at the north-east of the town, and is said to have been built during the sovereignty of Henry III. This cattle descended from the Lovetots to the Nevis, lords Furnival, and passed from them to the Talbots, earls of Shrewsbury, and subsequently to the Howards, dukes of Norfolk, in whose family the lordship of the manor is still vested. During the civil wars between Charles I. and his parliament, Sheffield cattle sustained a long siege in the cauld of royalty, but eventually surrendered upon honourable terms, on the 10th of August, 1644, and was soon afterwards ordered to be demolished, which seems to have been done most effectually, as scarcely a vestige of it can now be discovered.

Sheffield, as already said, was considered as a staple for iron manufactures at a very early period, its trade, for several centuries, was comparatively confined and precarious, and confifted almost entirely in the making of thistles, knives, scissors, sickles, and scythes. About the commencement of the 17th century, an ordinary kind of tobacco-box of iron, and Jews' harps, began to be manufactured here; and in 1625 the major manufacturers were first incorporated by the style of "The Company of Cutlers of Hallamshire." This corporation is governed by a master, elected annually, six searchers, and twenty-four affitants, and is the only body corporate yet existing in Sheffield. It was not, however, till after the year 1750, that this town assumed the rank it now holds in manufacturing opulence. Previously to that period, none of the manufactu rs had extended their trade beyond the limits of Great Britain; but in the same year Mr. Joseph Broadbent opened a direct trade with the continent; and in 1751, the river Don having been rendered navigable to within three miles of the town, that facility was given to exportation, which has since proved so beneficial to its manufacturing interests. Soon afterwards Mr. Thomas Bolfver began to plate brass and copper buttons with silver; and in 1758 the silver plated manufacture was commenced on an extensive scale by Mr. Joseph Hancock, and has subse quently been prosecuted with great advantage by a numerous class of individuals. The opulence and population of the town increased from that time with great rapidity, and soon gave rise to numerous conveniences and improvements, both useful and ornamental. In 1760, the first stage-coach started from Sheffield for London; and in 1762, the theatre and assembly-room were built by subscription. In 1770, the first bank in Sheffield was opened by Mr. Roe buck; and in 1786, the new market-place was formed, about the same time that Meffrs. Proctors erected the first steam-engine grinding-wheel. In 1793, hackney coaches were introduced; and in the same year also was laid the foundation of the General Infirmary. These circumstances are mentioned, because they are calculated to display the progressive benefits resulting from successful industry and ingenuity, the contemplation of which can scarcely fail to excite pleasurable emotions in every breast.

To notice particularly the various articles manufactured at Sheffield of late years, would occupy too considerable a space to admit of the attempt. The two great divisions of them are into cutlery and plated goods, each of which branch out into numerous ramifications. The manufacture of the latter is almost entirely confined to the town, and comprehends a great diversity of articles: such as tea-uris, coffee-pots, taskards, cups, candlesticks, and other pieces of table furniture. The cutlery division embraces the making of edge-tools, combs, cafes, buttons, fenders, files, anvils, joiners' tools, lancets, forks, hafts, ink-stands, nails, knives of every description, scissors, fcythes, sickles, awl-blades, bellows, &c. to which we shall only further add the refining of steel. Many of these manufactures are carried on in the country, as well as in the town, especially in the villages and hamlets of Aler cliffe, Brentgreen, Brightside, Butterthwaite, Carbrook, Darnall, Dyson-holmes, Dungworth, Ecclesfield, Greeno side, Grimethorpe, Hallam, Miln-houses, Newfield-Green, Owlerston, Pittmoor, Stannington, Shiregreen, Upper Heely, Wadsley, Woodates, &c.; all of which are situated within seven miles of Sheffield. Besides the above manufactures, there are in the town and its vicinity several extensive foundries for iron, brass, and white metal.

Sheffield occupies a fine eminence at the confluence of two rivers, the Sheaf, whence the name of the town is derived, and the Don. In former times the houles were entirely built of stone but for the last century they have been chiefly composed of brick. There are few towns which surpass it in the regularity of its streets, many of them running in a direct line, and displaying a series of uniform and respectable edifices. Sheffield extends about a mile
a mile in length, from north to south, and nearly as much in breadth, from east to west. According to the population census of 1811, it contained 7977 houses, and 35,874 inhabitants, being an increase of 4576 persons since 1801, the date of the preceding report, notwithstanding the retardation its manufacturing prosperity has sustained during that eventful period. According to Gilly's plan of the town, made in 1764, there were 32 streets in Sheffield at that time; in 1774, there were increased by 25 new streets; and in 1791, fifteen additional streets had been made.

Sheffield is not particularly distinguished by the superiority of its public buildings, which are rather calculated for purposes of utility than for show. The principal of them are the 'Town-hall,' built in 1760, Cutler's-hall, the General Infirmary, the almshouses, and the four churches belonging to the establishment. Neither the Town-hall nor Cutler's-hall deserve attention as architectural productions, but the infirmary and theatre are handsome structures. The former, commenced in 1763, stands on the west side of the town; and in respect of situation, plan, medical aid, and comfortable treatment, may vie with almost any similar institution in Great Britain. The latter, which occupies the same building with the assembly-room, stands in Norfolk-street. The four churches are Trinity church, St. Paul's, St. James', and a chapel belonging to the Duke of Norfolk's hospital. Trinity church, anciently called St. Peter's, is the parish church of Sheffield, and appears to have been erected as early as the reign of Henry I. On the south side of the chancel is the Shrewsbury chapel, which contains four monuments to the memory of the earls of Shrewsbury of the family of Talbot; and on the north side is a monument commemorating Sir Humphrey de Brome, was erected in 1525, and contains the remains of William Walker, of Darwen, in this parish, who was found executors of Charles I. Besides the above churches, Sheffield contains seven meeting-houses for Prot- estant dissenters, one for Unitarians, two for Methodists, one for Quakers, and a Roman Catholic chapel.

The duke of Norfolk's hospital, mentioned above, stands on the easterly bank of the Sheaf. It was founded and endowed in 1559, by Henry, earl of Norfolk, and received a considerable accruement of property by Edward, duke of Norfolk, in 1714. The building consists of two quadrangles, each containing eighteen dwelling, for the accommodation of eighteen men, and the same number of women, all of whom receive five shillings a week, with clothing and coal. There is also an hospital founded by Mr. Thomas Hollis, a merchant of London, in 1724, for poor cutters' widows; his wife a free grammar-school, and two charity-schools, one for boys, and another for girls.

The other objects of a public kind which remain to be noticed are, the military barracks, situated at the north-eastern extremity of the town; and the bridges thrown over the Sheaf and the Don. That upon the latter river is called Lady's bridge, from a religious house, which formerly stood near it, and was dedicated to the Virgin Mary. It was built in 1495, but underwent great alterations and improvements in 1762.

Sheffield has two market days, weekly, Tuesday and Saturday; the first for corn, &c., and the second for butchers' meat. There are also fairs-markets on Monday and Thursday, and two annual fairs, one on the first Tuesday after Whitsun week, and another on the 28th of November. A new market-place, with extensive and commodious stables and other conveniences, was formed and finished here Aug. 31, 1786. Sheffield supports a weekly newspaper, called the "Iras," which is edited by Mr. James Montgomery, the author of "The World before the Flood," and other interesting works.

The scenery in the vicinity of the town may be characterized as romantic. It is bounded by lofty hills, commanding fine views over a populous and cultivated country. At the distance of about a mile and a half to the eastward, the southern end of Sheffield, the easternmost point of the county, presents a wondrously beautiful prospect. The high ground above the town is a characteristic landscape of the country, and the beauty of the scene is enhanced by the breadth of its prospect. The town is bordered on the north, west, and south by a broad plain, which supplies water for several mills and water works. South mountain extends along the whole length of the town, on the E. side of the river.

SHEFFIELD, a town of America, in the state of Vermont, and county of Caledonia, containing 4554 inhabitants. — Sheffield, a town of the county of Middlesex, in the county of Berkshire ; incorporated in 1733, and containing 2439 inhabitants. It is traversed by Houlton's river, which supplies water for several mills and water works. South mountain extends along the whole length of the town, on the E. side of the river.

SHEFFIELDIA, in Botany, Earl. Gen. t. 9, was so called by Forster in honour of the Rev. Mr. Sheffield, whom he designates as the chief hand at Oxford. This gentleman was, we believe, one of the companions of the illustrious Banks, in the early part of his studies, and retained to the last a love of the science, though without having materially contributed to its advancement. He was living as a fellow of a college, at rather an advanced age, in 1785. The genius in question is now sunk in obscurity; see that article.

SHEFFORD, in Geography, a market-town in the parish of Compton, hundred of Clifton, in the county of Bedford, England, is situated at the distance of 10 miles S.E. from Bedford, and 41 miles N.N.W. from London. It was formerly a place of much more importance than at present, and had a large weekly market on Friday, which has now become almost nominal. Still, however, it possesses the advantages arising from a fair annual fair, held on the 23d of January, Easter Monday, the 19th of May, and the 10th of October. The two first usually afford a large supply of sheep and crows; the third is his important; and the fourth is now only a holiday fair. Sheffield is a chapel, having two parishes of its own, and maintaining its own poor. Here is a Roman Catholic chapel, endowed with an annual stipend left in trust for that purpose. According to the parliamentary returns of 1811, this town contained 213 houses and 526 inhabitants.

In the north of Fitchett, and at the distance of about four miles from Sheffield, is Wrel Park, the seat of baronets Lucas, a representative of the family of the Greys, earls and dukes of Kent. In its present state the house retains little appearance of a mansion, having been at various times added to and modernized. It contains a large collection of portraits, forming nearly a complete series of all the members of the noble family just mentioned, from Henry, Earl of Kent, one of the peers who sat on the trial of Mary, queen.
queen of Scots, down to the present time. Here are likewise several portraits of the crew family, and others; among which are Sir Randolph Crew, lord chief justice of the court of king's bench; a fine picture of Thomas lord Crew, by Sir Peter Lely; Nathaniel lord Crew, bishop of Durham; and the late lord chancellor Hardwicke.

The garden attached to this mansion exhibits a specimen of the old style of arrangement and ornament, modified and improved by the celebrated Brown, who formed the serpentine canal, which nearly surrounds the garden, and is supplied by a spring rising near the house. At the springhead is a cold bath, over which is a building, designed by Sir William Chambers, in imitation of a Roman temple. The late duke of Kent, who was very partial to this residence, adorned the gardens with obelisks, and other buildings, particularly a magnificent banquetting house, which terminates a spacious avenue in front of the house. Lyfons's Magna Britannia, Bedfordshire, 4to. 1806. Beauties of England and Wales, vol. i. by John Britton and E. W. Brayley, 8vo. 1803.

SHEFNAI. See Shiffnal.

SHEHERON, a town of Persia, in the province of Irak; 15 miles E. of Kermanshaw.

SHEHERVERD, a town of Persia, in the province of Irak; 50 miles S.W. of Sultana.

SHEHOUN, a town of Syria, under the jurisdiction of an independent age, anciently called "Caparras;" 18 miles N. of Hamah.

SHEHRAN, or Sheeran, a town of the Arabian Irak, on the Dial; 50 miles N. of Bagdad. N. lat. 34° 8'. E. long. 44° 9'.

SHEHRIGHERD, a town of Persia, in the province of Irak; 33 miles W.S.W. of Kom.

SHEHRISTAN, a town of Persia, in Khorsafan; 210 miles W. of Herat. N. lat. 35° 10'. E. long. 56° 20'.

Alfo, a town of Persia, in the province of Chufillan, or Kuzzilan; 50 miles N.W. of Schiras.

SHEIB, a lake of Egypt; 48 miles E.N.E. of Cairo.

SHEIDEK, a mountain of Switzerland, in the S.E. part of the canton of Berne; 10 miles S.E. of Interlachen.

SHEIK, or Schiek, in the Oriental Customs, the person who has the care of the mosques in Egypt: his duty is the same as that of the imams at Conflantinople. There are more or fewer of these to every mosque, according to its size or revenues. One of these is head over the rest, and answers to a regular priest with us, and has under him, in large mosques, the readers and people who cry out to go to prayers; but in small mosques the sheik is obliged to do all himself. In such it are his bunfons to open the mosque, to cry to prayers, and to begin their short devotions at the head of the congregation, who fland rank and file in great order, and make all their motions together. Every Friday the sheik makes an harangue to his congregation. Pococke's Egypt, p. 171.

SHEIK-BELLET, the name of an officer in the Oriental nations.

In Egypt the sheik-ballet is the head of a city, and is appointed by the pacha. The bunfons of this officer is to take care that no innovation be made, which may be prejudicial to the Porte, and that they fend no orders which may hurt the liberties of the people. But all his authority depends on his credit and interell, not his office; for the government of Egypt is of such a kind, that often the people of the least power by their polls have the greatest influence; and a casa of the janizaries, or Arabs, and sometimes one of their meanest officers, an oda-bafia, finds means, by his parts and abilities, to govern all things. Pococke's Egypt, p. 161.

SHEIKHAUT, in Geography, a town of Bengal; 8 miles N. of Tannahat.

SHEIKH-UL-JEBAL, Dominions of, or lord of the mountains (commonly called the old man of the mountain) comprised the whole of that elevated tract in the province of Azerbaijan in the Persian empire, which runs parallel with the course of the Kizilozain and the greater part of Chilai. When destroyed by Holak, the Houfesinees, or Afafins, possession upwards of 100 strongholds; but the residence of the prince was generally confined to the castles Roudbar and Allah Ahmaur, both of which are situated in the Khor Caucasie, near Azaaren.

SHEIKPOUR, a town of Hindoosin, in Bahar; 28 miles E. of Bahar. N. lat. 25° 3'. E. long. 86° 3'.

SHEIMERKS, a town of New Jersey; 34 miles N.W. of Morritown.

SHEK ABADIE, a town of Egypt, anciently called Antinoe; 8 miles N. of Abu Girge.

SHEK Abdolla, a village of Syria, in the phalich of Aleppo, where are some springs of water; 20 miles S.E. of Aleppo.

SHEK Abu Ennar, a town of Egypt; 7 miles S. of Beninfeet.

SHEK Ammer, a town of Egypt, situated on the Nile; 17 miles N. of Syene.

SHEK Embose, a town of Egypt, on the right bank of the Nile; 16 miles S.S.E. of Girge.

SHEK Ered, or Haradi, a town of Egypt, on the E. side of the Nile. Here is the tomb of a Turkish sultan, who after his death is said to have been metamorphosed into a serpent, which never dies, and is consulted as a physician; 8 miles N.N.E. of Achrim.

SHEK ii Eiman, a town of Egypt, on the Nile; 7 miles S.S.W. of Cairo.

SHEK Fadale, a town of Egypt, on the right bank of the Nile; 10 miles S. of Abu Girge.

SHEK Zeineddin, a town of Egypt, on the left bank of the Nile; 3 miles N. of Tahta.

SHEKEL, Shekile, Checkle, Siclus, an ancient Hebrew silver coin, which was originally a didrachm, but, after the Maccabees, about the value of the Greek tetradrachm, or four Attick drachmas, or four Roman denarii, allowing the drachma and denarius to be of the same value; and, according to Mr. Raper's valuation of the drachma at 97.296, equal to 77.-144. See DEXARIUS and DRACHM.

In the Bible, the shekel is sometimes also rendered solidus, and sometimes flater.

The Jewish doctors are in great doubt about the weight of the shekel; and it is only by conjecture, and by the weight of the modern shekel, that the ancient one is judged equal to four Attick drachmas.

Father Socquet has described several of these shekels in his Dillertation on the Hebrew Medals. By the way he observes, that the third and fourth parts of a shekel, described by Waferus, de Ant. Numb. Heb. are counterfeit of that author.

The Hebrew shekel, according to F. Merfenne, weighs 268 grains, and is composed of 20 oboli, each obolus weighing 16 grains of wheat. This, he says, is the just weight, as he found by weighing one in the French king's cabinet. He adds, that such as come short of this weight have been filed or clipped. Bishop Cumberland tells us, he has weighed severall, and always found them near the weight of a Roman semuncia, or half ounce. Mr. Raper infers from various considerations (see DRACHM), that the mean
She.

The eldest, of 133 tons, was very near its full weight, and its last, of 60 tons, that of the youngest. The weight of the ship would then be about 450 tons.

Some are of opinion that the "Hirloom" had two kinds of thick felloes, the fuzil, or plaited felloe, called the fuzil felloe; and the felloe of the forecast, which had the well to be double the former. By this expedient they think it might get clear of some difficulties occurring in Scutagone; where things are mentioned as of incredible weight; particularly that passage where it is said, that every time Ablood cut off his hair, the weight of which used to be considerable, he cut off the weight of two hundred felloes.

But Villalba and liis will not hear of such a disjuncture; nor do liis, at Cambridge, M. Murgan, Greaves, &c. take the opinion to have any foundation. The fuzil felloe, or felloe of four fuzils, they agree, was the same with the fuzil felloe; and it was only called by this last name, because the standard of it was kept in the lunatick by the pupils.

Greaves apprehends, that the fuzil are, or 30 pieces of silver, which were given to Judas, as the reward of his treason, were 30 felloes. Some modern writers, he says, imagine they were 30 deniers, and others, that they are regina fuzil, or regina fuzilata. Greaves's Works, vol. 1. p. 237., note n.

It is maintained by several, that the Jews had also a gold felloe, fusa aurea, of the same weight with the silver one; and valued at 1 d. 166. 6d. sterling.

The felloe is supposed to have been first struck in the D. M. &t, on the footing of 100 to the Attic mna, weighing 160 grains of wheat, and current for 10 geriors, or obols; but that afterwards they were struck of double that weight.

Some will have the felloe to be the oldest piece of money in the world, as being in use in Abraham's time; but this was not coined, nor flanged, nor had any other value besides its intrinsic worth.

Xenophon mentions felloes as current in Arabia; and Du Cange speaks of others struck and current in England.

Pikerton, in his Essay on Medals, (vol. 1. p. 291.) suggests, that the Hebrew felloe, and also the brass coins, with Samaritan characters, were at most of them later than the Chalifian era, and generally the fabrications of modern Jews. At any rate, the same impression of a spiring on one side, and a safe upon the other, runs through all the coins of that barbarous nation; and the admission of both of them is rightly esteemed to be almost a disgrace to a cabinet.

Shekidej, in Geography, a town of Grand Bu\n
charsa; 60 miles N.W. of Sagadon.

Shekabad, a town of Hindu, in Deob; 60 miles W. of Canoge. N. lat. 27°. E. long. 79°. 2'.

Sheelah, a town of Alcap' Turkey, in Natalia, near the Black sea; 12 miles N. of Ilium.

Sheilan, a town of Persia, in the province of Far\n
sian, near the Perisan gulf; 75 miles S.S.W. of Jaron.

Shelburn, a town of America, in the province of Vermont, and county of Chutebun, on the E. side of Lake Champlain, containing 957 inhabitants.

Shelburn Bay, a bay on the N. coast of New Hol\n
land, between Oxforders and Cape Grosvenor.

Shelburne, sometimes called Port Festav, a sea\n
port town of Nova Scotia, at the head of a bay, in the S.W. part of the province. At the conclusion of the American war, this place was made the seat of royalty, and it was designed to erect many buildings here, and in 1783 it contained above 600 families; but being neglected and unable to defend themselves, many of them afterwards left the town; 90 miles W. of Halifax. N. lat. 43° 50'. W. long. 63° 15'.

Sheffield, a town of Anchor, in the county of Yorks, and county town of the shire of Yorks; 50 miles W. of Buxton. - Also, a town of New Hampshire, in the county of York, seated in 1769, and containing 1700 inhabitants.

Sheidelberg, a name given to several parts of the kingdom for the chancellors.

Sheeldon, Gentleman, in Biography, archbishop of Canterbury, was born 1563, at Tristam, in Suffolk. His father was a natural servant of Gilbert, earl of Shrews\n
bury, though descended from an ancient family in Shrewsbury.

The subject of this article took his name from the earl, who was his god father. Having had the foundation of a good education, he was entered at Trinity college, Oxford, in 1614, and after taking the usual degrees was elected fellow of All Souls' college, in 1622. When he had taken orders he became chaplain to lord keeper Coventry, who made use of his services on various important occasions. As a reward for these services he presented him with a prebend of Glo\n
celler, and recommended him to his majesty, as one extremely well versed in political affairs. When he had taken his doctor's degree, in 1634, he was elected warden of All Souls' college. He was also chaplain in ordinary to the king, and clerk of the college, and was in the road to farther preferment when the civil wars broke out, and checked his career.

He was a zealous adherent to the royal cause, attended the king on various occasions, and rendered himself obnoxious to the parliament: on which account he was ejected from his wardenship, and imprisoned for six months. On his liberation, he retired to his friends in the country, and from his own purse, and the contributions of others, he sent frequent supplies to Charles II. during his exile. On the restoration he received ample rewards for his sufferings and steady loyalty, being restored to his offices, and promotoed to the see of London.

The conference between the episcopal and presbyterian divines in 1661, was held at the Savoy, in bishop Sheldon's lodgings. On this occasion he is accused by the opposite party of want of fairness, and he rejected the proposal of an amicable discussion, and insisted that the Presbyterians should first bring in writing all their objections against the liturgy, and all the additions which they proposed. He did not appear often at the conference, and never entered into disputation, yet he was known to have had the principal share in the determination. To conciliate was not his object; he was resolved to carry his point by power: when it was debated in council in August 1662, whether the act of Uniformity should be punctually executed that month, or be suspended for a time, bishop Sheldon pleaded against the fulfiment, and carried the council with him. "If," says his biographer, "in these and other instances he appears too much the political churchman, in public spirit and munifi\n
\ncence he blushed, after an exemplary manner, the char\n
adeter of a great prelate. He expanded large sums upon the episcopal houses of the see of London, and being in 1665 translated to that of Canterbury, he rebuilt the library at Lambeth, and made many additions to its contents."

On the removal of lord Cheddon from the chancellorship of the university of Oxford, he was chosen to succeed him in December 1667, and he immortalized his name in that university by the erection, at his sole expense, of the celebrated theatre at Oxford. Of this act bishop Lowth says, "Munus dignum factum—quidcum cum utore et circum\n

\ntuque videor inhi in sua Roma, vel in medius Athenis, antiques
tiquis illis, et cum maxime florentibus verlari.” This edifice was opened in July 1679, and almost immediately after the archbishop resigned the chancellorship, and retired from all public business: during the latter part of his life he chiefly resided at Croydon. He died at Lambeth, on the 9th of November, 1677, in the 80th year of his age.

This prelate appears to have been more attached to the duties of morality, than to the profession of any particular doctrines of religion: to young men of rank his advice was always this: “Let it be your principal aim to become honest men, and afterwards be as devout and religious as you will. No piety will be of advantage to yourselves or others, unless you are honest and moral men.” Burnet says that “he seemed not to have a deep desire of religion, if any at all, and spoke of it commonly as an engine of government, and a matter of policy;” but he allows that he was a very generous and charitable man. From his own books it appears, that from the time of his becoming bishop of London till his death, he expended for public and charitable uses 66,000L. He published a sermon at the thanksgiving for the king’s restoration. He was intimate with Chillingworth, and found means to overcome his scruples respecting subscription to the articles of the church of England.

SHELDON, formerly Hungerford, in Geography, a post-town of America, in the state of Vermont, and county of Franklin, containing 883 inhabitants; 14 miles E. of Lake Champlain.

SHELF, a river of England, in the county of Northumberland, which runs into the Tyne, near its head. SHELF, a term used by the miners in many parts of England, to express a diminution of the inner structure of the earth, so little known to philosophers, that they have no word to express it by. These workmen sometimes also express it by the term “fool ground,” or “fool country.” What they mean by this is, that part of the earth, which they find lying even, and in an orderly manner, and evidently having attained its primitive form and situation, unmoved by the waters of the general deluge, while the circumjacent, and upper strata, have plainly been removed, and toss’d about.

It is evident to reason, that there must have been a very violent concussion of the superficial part of the earth, in the time of its being covered by the waters of the deluge; and experience as much evinces this as reason. Before this concussion it appears probable, that the uppermost surface of mineral veins, or loads, did in most places lie even with the then surface of the earth. The remains of this surface, found at different depths in digging, the miners express by the word shelf.

In this concussion of the waters covering the whole earth, its natural surface, together with the uppermost surface of those mineral veins, were then in many places lost, and torn off; and the earth, and with it the mineral nodules, called “fool-flores,” were carried down with the descending waters from hills into the adjacent valleys, and sometimes into the streams of rivers, by which they were washed to yet greater distances from their original place. On this depends the method of training mines. Phil. Trans. No 69. See Training.

SHELFY, or SLaty Soil, in Agriculture, that sort which is chiefly formed of a kind of thin laminated, brittle, flaty material, or which has it much mixed and incorporated with its other earthy parts. It is a prevailing sort of land in some districts; this sort of rotten flaty matter being largely intermixed with the light loamy mould that constitutes the earthy parts of it.

Where the subfoil or substratum is a schistus, or fofl
 SHELLS. 

About Brazil, and in the gulf of Mexico, there are found 
mollusks and shells of extreme beauty, and also a great variety 
of porcelains, purpurz, periwcks, nautili, baccare, or heart-
shells, and elegant limpets. 

The isle of Cayenne affords one of the most beautiful of 
the buccaneer kind, and the Midas car is found principally 
about this place. 

Japan, and the island of Barbadoes, have their shells 
covered with porcelains, chame, and baucis; and at St. 
Domingo there are found almost all the same species of shells 
that we have from the East Indies, though they are less 
beautiful, and the colors more pale and dead. The pearl oyster 
is found also on this coast, but smaller than in the Pernian 
gulf. At Martinico there are found in general the same 
shells as at St. Domingo, but yet less beautiful. 

About Canada are found the violet chame, and the lakes 
of that country abound with muscles of very elegant pale 
blue and pale red colors; some species of these are remark-
ably light and thin; others are very thick and heavy. 

The Great Bank of Newfoundland is very barren in 
shells; the principal kinds found there are muscles of several 
species, some of which are of considerable beauty. 

About Carthage there are many mother-of-pearl shells, 
but they are not of so brilliant colors as those of the Pernian 
gulf. 

The island of Magellan, at the southern point of America, 
contains us with a very remarkable species of muscle, called 
by its name; and several very elegant species of limpets are 
found there, particularly the pyramidal. 

In Africa, on the coast of Guinea, there is a prodigious 
quantity of that small species of porcelains, which is used 
there as money; and there is another species of porcelains 
on the same coast, which is all over white: the women make 
bracelets of these, and the people of the Levant adorn their 
hair with them. 

The coast of Zanguebar is very rich in shells; we find 
there a vast variety of the large porcelains, many of them of 
great beauty; and the nau mari, or sea-nut, is very fre-
quent there. Before these, and many other shells, there are 
found on this coast all the species of nautili, many of which 
are very beautiful. 

The Canary flies are found to abound with a vast variety 
of the nautili, and some other good shells; and we have 
from Madeira great variety of the echini, or sea-eggs, dif-
ferent from those of the European seas. Several species 
of muscles are also common there, and the auris marina is no 
where more abundant. 

The Red sea is beyond all other parts of the world abun-
dant in shells, so that scarcely any kind is wanting there; but 
those we principally have from thence are the purpurz, porce-
lain, and echini marini. 

The Mediterranean and Northern ocean contain a great 
variety of shells, and many of very remarkable elegance and 
beauty: they are upon the whole, however, greatly inferior 
to those of the East Indies. The Mediterranean abounds 
much more in shells than the ocean. 

The gulf of Tarentum affords great variety of purpurz, 
porcelains, nautili, and elegant oysters; the coasts of 
Naples and Sardina afford also the same, and with them is 
a vast number of the folens of all the known species. 

The island of Sicily is famous for a very elegant kind of 
oyster, which is white all over; pinnz marina and porce-
lain are also found in great plenty there, with tellez and 
chame of many species, and a great variety of other beauti-
tiful shells. 

Corfica is famous beyond all other places for vast quan-

ties of the pinnz marina, and many other very beautiful 
shells are found there. 

About Syracuse are found the gondola shell, the arum 
mures, and a great variety of elegant shells, with those of 
the delia and nautili. 

The Adriatic sea, or gulf of Venice, is less favored 
than almost any of the seas throughout. Muscles 
and oysters of several species are, however, found there, 
and some of the cordiformes or heart-shells; there are also 
the tellins. About Ancona there are found vast numbers 
of the phalades buried in stone, and the aure marina are 

The ports of Marseilles, Toulon, and Antibes, are full 
of pinnz marina, muscles, tellins, and chame. The coasts 
of Bretagne afford great numbers of the conch arietifere 
and poulpeids; they are found on old rotten boards, on 
tiles, shingles, and upon cluters of pignons. The other 
ports of France, as Rochelle, Dunkirk, Brit, St. Malo, 
and others, furnish oysters, excellent for the table, but of 
the common kind, and of no beauty in their shells; great 
numbers of muscles are also found there; and the common 
tellin, the mussel, the oyster, the folens, and conch ari-
etifere, are also frequent there. At Granville, in Lower 
Normandy, there are found very beautiful pectens, and some 
of the cordiformes, or heart-shells. Our own English coasts 
are not the least fruitful in shells; though they do not pro-
duce such elegantly painted ones as the Indies. 

About Plymouth are found oysters, muscles, and folens, 
in great abundance; and there, and on coast of our other 
shores, the aeres marina and dentalia, with pectens, which 
are very excellent food; and many elegant species of the chame tellin, are fish up in the sea about 
Scarborough, and other places. 

Ireland affords us great numbers of muscles, and some very 
elegant scallop shells in great abundance, and the phalades 
are frequent on coast of our shores. We have also great 
variety of the buccina and cochleze, some volutes; and on the 
Guernsey coast a peculiarly beautiful fair, called the 
Guernsey fair. 

The coasts of Spain and Portugal afford much the same 
variety of shells with the East Indies, but they are of much 
fainter colors, and greatly inferior in beauty. Hitt. Nat. 
Eclairc. p. 171. 

There are, according to Tavennier and others, some rivers 
in Bavaria, in which there are found pearls of a fine water. 
About Cadiz there are found very large pinnez marina, and 
some fine buccins. The isles of Majorca and Minorca afford 
a great variety of extremely elegant shells. The pinnz marina 
are also very numerous there, and their shell is 
wrought into gloves, stockings, and other things. The 
Baltic affords a great many beautiful species, but parti-
cularly an orange-coloured pecten, or scallop shell, which 
is not known in any other part of the world. 

The fresh-water shells are found much more frequently, 
and in much greater plenty, than the sea kinds; there is 
scarcely a pond, a ditch, or a river of fresh water, in any part 
of the world, in which there are not found vast numbers 
of these shells with the fish living in them. All these shells 
are small, and they are of very little beauty, being usu-
ally of a plain greyish or brownish color. Our ditches afford 
us chame, buccins, tellins, and some patellae; but the Nile, 
and some other rivers, furnished the ancients with a species 
of tellins, which was large and estable, and so much superior 
to the common sea tellins in flavor, that it is commonly 
known by the name of tellins regia, the royal tellins. 

VOL. XXXII.
SHELLS.

We have a small species of buccinum common in our fresh waters, which is very elegant, and always has its operculum in the manner of the larger buccin; a small kind of mufcle is also very common, which is so extremely thin and tender, that it can hardly be handled without breaking to pieces.

The large fresh-water mufcle, commonly called in England the horfe mufcle, is too well known to need a description, and the size of this gives it a difference from all other fresh-water shells.

**SHELLS, Polishing of.** (See Conchology.) This is an art of no long standing in the world, in its present perfection; and as the love of sea-shells is become so common among us, it may not be disagreeable to the reader to find some instructions in executing so pleasing a method of adding to their natural beauty, the rules for which are at present so little known, though the effect of them be so much esteemed.

Among the immense variety of shells which we are acquainted with, some are taken out of the sea, or found on its shores in all their perfection and beauty; their colours being all spread by nature upon the surface, and their natural polish superior to any thing that art could give. Where nature is in herself thus perfect, it were madness to attempt to add any thing to her charms; but in others, where the beauties are latent and covered with a coarser outer skin, it is to be called in, and the outer veil being taken off, all the internal beauties appear.

Among the shells which are found naturally polished are the porcelains, or cowries, the casclanders, the dolia, or conchæ globofas; some baccina, the volutes, and the cylinders, or olives, or, as they are generally though improperly called, the rhombi; excepting only two or three, as the tiara, the plume, and the butter-tub rhombus; where there is an unpromising film on the surface, hiding a very great glare of beauty within. Though the generality of the shells of these genera are taken out of the sea in all their beauty, and in their utmost natural polish, there are several other genera, in which all, or most of the species, are taken up naturally rough and foul, and covered with an epidermis, or coarse outer skin, which is in many rough and downy, or hairy. The tellins, the mufcles, the cochleas, and many others, are of this kind. The more nice collectors, as naturalists, infilt upon having all their shells in their native and genuine appearance, as they are found when living at sea; but the ladies who make collections hate the disagreeable outsidies, and will have all such polished. It would be very advisable, however, for both kinds of collectors to have the same shells in different specimens, both rough and polished; the naturalist would, by this means, besides knowing the outside of the shell, be better acquainted with its internal characters than he otherwise could be, and the lady would have a pleasure in comparing the beauties of the shell, in its wrought state, to its coarse appearance as nature gives it.

How many elegancies in this part of the creation must be wholly lost to us, if it were not for the assistance of an art of this kind! Many shells in their native state are like rough diamonds, and we can form no just idea of their beauties till they have been polished and wrought into form.

Though the art of polishing shells is a very valuable one, yet it is very dangerous to the shells; for without the utmost care, the means used to polish and beautify a shell often wholly destroy it. When a shell is to be polished, the first thing to be examined is whether it have naturally a smooth surface, or be covered with tubercles or prominences.

A shell which has a smooth surface, and a natural dull polish, need only be rubbed with the hand, or with a piece of chamois leather, with some tripoli, or fine rotten stone, and will become of a perfectly bright and fine polish. Emery is not to be used on this occasion, because it wears away too much of the shell. This operation requires the hands of an experienced person, that knows how superficial the work must be, and where he is to stop; for in many of these shells the lines are only on the surface, and the wearing away ever so little of the shell defaces them. A shell that is rough, foul, and crufdy, or covered with a tartareous coat, must be left a whole day steeping in hot water; when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a stick, or with the blade of a knife, in order to get off the coat. After this it may be dipped in diluted aqua fortis, spirit of salt, or any other acid; and after remaining a few moments in it, be again plunged into common water. This will greatly add to the speed of the work. After this it is to be well rubbed with linen cloths impregnated with common soap; and when by these several means it is made perfectly clean, the polishing is to be finished with fine emery and a hair-brush. If after this the shell when dry appears not to have so good a polish as was desired, it must be rubbed over with a solution of gum arabic; and this will add greatly to its gloss, without doing it any fort of injury. The gun water must not be too thick, and then it gives no sensible coat, only heightening the colours. The white of an egg answers this purpose alo very well; but it is subject to turn yellow. If the shell has an epidermis, which will by no means admit the polishing of it, it is to be dipped several times in diluted aqua fortis, that this may be eaten off; and then the shell is to be polished in the usual way with putty, fine emery, or tripoli, on the hair of a fine brush. When it is only a pellicle that hides the colours, the shells must be steeped in hot water, and after that the skin worked off by degrees with an old file. This is the cafe with several of the cylinders, which have not the natural polish of the reif.

When a shell is covered with a thick and fatty epidermis, as is the case with several of the mufcles and tellins; in this case aqua fortis will do no service, as it will not touch the skin; then a rough bruffh and coarse emery are to be used; and if this does not succeed, feal-kin, or, as the workmen call it, fibb-kin and prominate-lones, are to be employed.

When a shell has a thick crust, which will not give way to any of these means, the only way left is to plunge it several times into sirong aqua fortis, till the stubborn crust is wholly eroded. The limpets, auris marina, the helmet-shells, and several other species of this kind, must have this fort of management; but as the design is to dwell the hidden beauties under the crust, and not to destroy the natural beauty and polish of the inside of the shell, the method of using the aqua fortis must be this; a long piece of wax must be provided, and one end of it made perfectly to cover the whole mouth of the shell; the other end will then serve as a handle, and the mouth being floated by the wax, the liquor cannot get in to the inside to spoil it; then there must be placed on a table a vesel full of aqua fortis, and another full of common water.

The shell is to be plunged into the aqua fortis; and after remaining a few minutes in it, is to be taken out, and plunged into the common water. The progress the aqua fortis makes in eroding the surface is thus to be carefully observed ever time it is taken out; the point of the shell, and any other tender parts, are to be covered with wax, to prevent the aqua fortis from eating them away; and if there be any worm-holes, they also must be floated up with wax, other-
The shells, when polished, appear all over of a fine pearly colour; but when it is polished away to a small depth, it appears of a fine yellowish colour, with dully hairs. The burrows, when entirely cleared of its coat, is of the most beautiful pearl colour; but when only slightly eroded, it appears of a variegated mixture of green and red; whence it has been called the parrot-mouth. The common helmet-shell, when wrought, is of the colour of the finest agate; and the mussels, in general, though very plain shells, in their common appearance, become very beautiful when polished, and shew large veins of the most elegant colours. The Persian shell, in its natural state, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and polished, it appears of a bright yellow, covered with spots and veins of a very bright and highly polished white. The limpets, in general, become very different when polished, most of them shewing very elegant colours; amongst them the tortoise-shell limpet is the principal; it does not appear at all of that colour or transparence, till it has been wrought.

That elegant species of shell called the junqui-chama, which has deceived so many judges of these things into an opinion of its being a new species, is only a white chama, with a reticulated surface; but when this is polished, it looses at once its reticular work and its colour, and becomes perfectly smooth, and of a fine bright yellow, and the violet-coloured chama of New England, when worked down and polished, is of a fine milk-white, with a great number of blue veins, disposed like the variegations in agate.

The alys ear-shell, when polished, after working it down with the file, becomes extremely glossy, and obtains a fine-rose-colour all about the mouth. These are some of the most frequent among an endless variety of changes wrought on shells by polishing; and we find there are many of the very greatest beauties of this part of the creation which must have been lost, but for this method of searching deep in the substance of the shell for them.

The Dutch are very fond of shells, and are very nice in their manner of working them; they are under no restraint, however, in their works, but use the most violent methods, so as often to destroy all the beauty of the shell. They file them down on all sides, and often take them to the wheel, when it must destroy all the variegated colour of the species. Nor do they stop at this, but determined to have beauty at any rate, they are for improving upon nature, and frequently add some lines and colours with a pencil, afterwards covering them with a fine coat of varnish; so that they seem the natural lines that of the shell. The Dutch cabinets are by
SHELLS.

this means made very beautiful, but they are by no means to be regarded as instruc- tors in natural history. There are some artificers of this nation who have a way of covering shells all over with a different tinge from that which nature gives them; and the curious are often deceived by these tricks into the purchasing of them as new species.

There is another kind of work belted on certain species of shells, particularly the nautilus; this is the engraving on it lines and circles, and figures of stars, and other things: this is too obvious a work of art to suffer any one to suppose it natural. Bonani has figured several of these wrought shells at the end of his work; but it is miserably throwing away labour to do them: the shells are spoiled as objects of natural history by it, and the engraving is seldom worth any thing. They are principally done in the East Indies.

Shells are subject to several imperfections: some of these are natural, and others accidental: the natural ones are the effect of age, or sicknees in the fish. The greatest mischief happens to shells by the fish dying in them. The curious in these things pretend to be always able to distinguish a shell taken up with the fish alive, from one found on the shores: they call the first a living, the second a dead shell, and say that the colours are always much the faintest in the dead shells. When the shells have lain long dead on the shores, they are subject to many injuries, of which the being eaten by sea-worms is not the least: age renders the finest shells livid or dead in their colours.

The finest shells are those which are filled up at sea, not found on the shores. The other natural defects of shells are their having morbid cavities, or protruberances, in parts where there should be none. When the shell is valuable, these faults may be hid, and much added to the beauty of the specimen, without at all injuring it as an object of natural history, which should always be the great end of collecting these things. The cavities may be filled up with matter, dissolved in spirit of wine, or with infusions: these substances must be either coloured to the tinge of the shell, or else a pencil dipped in water-colours must finish them up to the resemblance of the real, and then the whole shell being rubbed over with gum-water, or with the white of an egg, fear ay any eye can perceive the artifice: the fame substances may also be used to repair the battered edge of a shell, provided the pieces chipped off be not too large. And when the excrections of a shell are faulty, they are to be taken down with a fine file. If the lip of a shell be so battered, that it will not admit of repairing by any cement, the whole must be filed down to an evenness, or ground on the wheel.

SHELLS, Fossil. See CONCHOLOGY and PETRIFICATIONS.

Shells are frequently found under ground, in places far remote from the sea, in mines, and even on the tops of mountains; but how they should come thither is a thing that naturalists are greatly divided about. The most usual and cary opinion is, that those parts have been formerly sea, or, at least, have been overflows therein; and many even go back as far as the grand deluge for this. Others take thefe to be the natural places of their birth or formation, some of them being found little other than crude clay, others of the fame texture with the rock to which they grow, though others feem of as absolute a fehly substance as any in the fea. In effect, they say, there may be only so many different gradations of nature, which can as well produce shells in mines as in the sea, there being no want of false or earthy particles for the purpose; nor is there any great difference between some sorts of spars and sea-shells.

Dr. Lister judges, that the shells found in stone quarries were never any part of an animal, and gives this reafon for it, that quarries of different stone yield quite different species of shells; different not only from one another, but from any thing in nature besides, which either sea or land does yield. This opinion has been since proved erroneous, and all these bodies to have been really once parts of living animals. See FOSSILS, ADVENTITIOUS, MARINE REMAINS, and FORMED STONES.

Of these shells, some are found remaining almost entirely in their native flate, but others are variously altered, by being impregnated with particles of stone, and of other fossils; in the place of others there is found mere stone or spar, or other native mineral body, expressing all their lineaments in the greatest nicety, as having been formed wholly from them, the shell having been first deposited in some solid matrix, and thence dissolved by very slow degrees, and this matter left in its place, on the cavities of stone and other solid substanfes, out of which shells had been dissolved and washed away, being afterwards filled up with slowy with these different substances, whether spar or whatever else: these substances, so filling the cavities, can necessarily be of no other form than that of the shell, to the absence of which the cavity was owing, though all the nicer lineaments may not be so exactly expressed. Before these, we have also in many places maifles of stone formed within various shells; and these having been received into the cavities of the shells, while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the shell, when the shell itself should be worn away, or perished from their outside. The various species we find of these are in many genera as numerous as the known recent ones; and as we have in our own island not only the shells of our own shores, but those of many other very distant ones, so we have also many species, and those in great numbers, which are in their recent flate, the inhabitants of other yet unknown or unpeared seas and shores.

The cockles, musicles, oysters, and the other common bivalves of our own seas, are very abundant; but we have also an amazing number of the nautilus kind, particularly the nautilus grucorium, which though a shell not found living in our own, or any neighbouring seas, yet it is found buried in all our clay-pits about London and elsewhere; and the most frequent of all foifile shells in some of our counties, are the conica anomia, which yet we know not of in any part of the world in their recent flate. Of this fort also are the cornua ammonis and the gryphities, with several of the echitinae and others.

The exact similitude of the known shells, recent and fossil, in their several kinds, will by no means sufer us to believe, that these, though not yet known to us in their living state, are, as some have idly thought, a sort of fufs nature.

It is certain, that of the many known shores, very few, not even those of our own island, have been yet carefully searched for the shell-fish that inhabit them; and as we see in the nautilus grucorium an imitation of shells being brought from very distant parts of the world to be buried there, we cannot wonder, that yet unknown shores, or the unknown bottoms of deep seas, should have furnished us with many unknown shell-fishes, which may have been brought with the reef; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means to be left in the yet unhardened mass of our stone and clayey strata. Hill's Hist. of Foss. p. 616.

Fossil shells are found to be of great use in manuring land. See MANURING.
SHELLS.

They are much used in France for this purpose; and Mr. Reaumur treats of their effects in fertilizing the earth very fully, concluding his official account of these substances by observing, that it is much more easy to account for the manner of their acting upon land, than for the manner of their coming where they are found. It has been the favourite system of Dr. Woodward, that all these shells were the remains of the universal deluge, which having overflowed the whole earth, might easily leave them in all places; but Mr. Reaumur has much more rationally accounted for their coming to those parts of France, where they are found at this time in such vast abundance, by carefully tracing the course of the beds of them, so far as known there, and easily proving that all that extent of country, under which they are found, may have been once overflowed by the sea without a deluge; it being the very track that a large body of waters, let in at one part of the kingdom, must have taken, in order to get out at another. Mem. de l’Acad. Par. 1729.

Shell, Ariston, a name given by some to a species of porcelain-shell, not because it is found on the coast of Arabia, but because its lines and variegations are supposed to represent the figures of Arabian characters.

Shell, Arion, a very remarkable species of shell-fish, found in cabinets of the curiosity. It is of the figure of a bird, having a head, wings, and tail, and is of a flame-colour; it owes much of its beauty, however, to art and accident; the shell is an oyster of a peculiar variation of figure from the common one; the head of the bird is the carmo or hinge; the wings are the body of the shells; and the tail is a peculiar procefs, like that of the martante, only fingle.

It is naturally of a dusky brown on the outside, and pearly within, but when its rough coat is taken off, it appears of this beautiful flame-colour.

Shell, Caterpillar. See Turbo.

Shell, Cenere, a name given to the balanus marinus, a kind of sea-shell of the multivalve kind, with an open mouth, frequently found fixed to the bottoms of ships, and other things covered with sea-water. See Balanus and Conchology.

Shell, Chaldee, or Cup-fish, a species of the balanus. See Balanus.

Shell, China-letter, a name given by many to that species of chama, usually called by authors the chama Arabica. It is of a pale brownish ground, and is variegated with a great number of black lines, which are so slender as the strokes of a pen, and are of such odd figures, that they represent some of the Arabic, or, as others fancy, Chinese characters. See Chama.

Shell, Crown Imperial, a species of the voluta. See Conchology.

Shell, Dog-tooth, a species of dentalis. See Conchology.

Shell, Euir, See Auris.

Shell, Guinea, the English name for a very beautiful variegated species of voluta, called by the French la fleculation.

Shell, Heart. See Cardium, under Conchology.

Shell, Helmet, the name of a kind of murex, of which there are several species. They all approach somewhat towards a triangular figure, and are free from any long spines.

Shell, Leopard, the English name of the pardus, a kind of voluta, so called from its spots resembling those of a leopard. There are three kinds of this, one spotted with black, another with yellow, and another with red.

Shell, Leopard, a name given by many to a species of porcelain-shell, resembling a young hare in colour.

Shell, Lightning, a name given by some authors to a species of murex, with variegations on its body, resembling the pictures we commonly see of flakes of lightning.

Shell, Map, the name given by some to a peculiar species of porcelain-shell, the figures on which represent the lines on a map.

Shell, Needle. See Centonia and Needle.

Shell, Nervi; Ark. See Noah.

Shell, Oyster. See Oyster.

Shell, Old Wife, the name given by some to that species of chama, which the French also have called ovaux ridis.

Shell, Onion, a species of oyster.

Shell, Pipe. See Entaliun.

Shell, Saddle, the name of a species of oyster, which in some degree represents a saddle in its shape.

Shell, St. James’s, a name given by writers on shells to a very beautiful species of variegated pechen.

Shell, St. Michael’s, a name given by authors to a species of pechen, or scallop-shell. It is of a bright yellow colour.

Shell, Scorpion, the name of a species of murex, very much approaching to the nature of the spider-shell. This is a common shell in cabinets; it is of a yellow colour, and very deeply ridged, and full of tubercles; there arise from the lip of the shell five large spines, or, as they are usually called, fingers, and two others, which are very much bent, the one from the head, the other from the tail; these are very elegantly radiated with white, and a fine violet colour on the lips.

Shell, Screw. See Turbo.

Shell, Small-pox, a name given to a remarkable kind of concha veneera, or porcelain-shell, the protuberances on the surface of which are supposed to represent the pustules of the small-pox. There are two species of this shell, the one white, with flatish protuberances, the other greenish, with more elevated ones.

Shell, Snake, the name given by many to that beautiful species of porcelain-shell, the spots of which represent those of a snake’s skin.

Shell, Spider. See Aranea.

Shell, Strawberry, a name given by collectors of shells to a very beautiful species of cordiforms, spotted with small round red spots.

Shell, Swallow, a name given by authors to a species of oyster, which in some degree represents the figure of a small bird flying.

Shell, Tiger, the name of a species of porcelin, or concha veneera, supposed to represent the spots on a tiger’s skin.

Shell, Tor. See Pollicipes.

Shell, Tortoise. See Tortoise.

Shell, Trumpet. See Trumpet.

Shell, Turbo. See Turban.

Shell, Turnip. This is a species of sea-shell, by others called the radish shell; it is exactly of the shape of a turnip, and is of the dolium, or concha globosa kind. Those who have called it the radish shell, allude to the great black round-rooted radish, not to our common radish.

Shell, Turtle, the name of two species of shells. See Murex and Voluta.

Shell, in Agriculture, a term applied to a hard, and as it were floury covering, with which certain sublunatics and animals are defended, and thence in the latter case called shell-fish. It is observed that the vail beds of fossil shells found at great depth in the earth, as well as those found lying
lying on the sea-shore, make an excellent manure for cold clayey lands. See Sand and Clay.

It is likewise a term applied to the light calcined pieces of calcareous flint, which have been converted into lime; and also to the rim of turnips scooped by sheep, which are mostly applied to the purpose of feeding the fowlsheep. See Lime and Turnips.

**Shell-Apple.** In Ornithology, an English name for the loxia or crolforn, given from his manner of splitting an apple, and feeding on the kernels, leaving the shell of the pulp untouched.

**Shell-Drake.** A common English name for the tadorna.

**Shell-Fish.** A collective name for fishes naturally included in shells. These animals are in general oviparous, very few instances having been found of such as are viviparous.

Among the oviparous kinds, aniphiptera have found that some species are of different sexes in the different individuals of the same species; but others are hermaphrodites, every one being in itself both male and female; in both males their incecal is very numerous, and scarcely inferior to that of plants, or of the most fruitful of the infect clafs. The eggs are very small, and are hung together in a fort of clusters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frogs' spawn; by means of this they are not only kept together in the parcel, but the whole cluster is fastened to the rocks, shells, or other solid subjacent bodies, and thus they are preserved from being driven on shore by the waves, and left where they cannot succeed.

**Shell-Gall-Infect.** An infect of the gall-infect clafs, some what resembling those which are called the boat-fashioned ones, but differing in this, that as the two ends of that species are not very different in form, in this kind one of the ends is sharp and pointed in comparison with the other.

It has its name of shell-infect from the resemblance it bears to a mufcle-shell; as it is, in its whole form, not unlike one of the two shells in which the common mufcle is included, but the pointed end of this infect is much more ex tended in length than the smaller end of this shell.

This species is extremely small, and may be easily mistaken for the minute cafe out of which some small infect has escaped; or in another case, for the shell in which some small infect had deposited its eggs; but if the affilance of the microscope be called in, they will easily be discovered to be true gall-insects, even as soon as they are hatched from the eggs. This species, at its full growth, is so small, that it requires good eyes to discover it: it is brown, very smooth, and polished on the surface, and much of the colour of the bark of some trees; it has usually an edge of a cottony matter, visible where its fides touch the tree, and its eggs are always deposited on a fine cottony bed; the young ones are white, flat, and have two small horns, and six legs; in this state they are known to be of the gall-infect class, not by their likenesses to their parent, but to the young gall-infects of other species. They march about very briskly for some time after they are hatched, and after that fix themselves, and then begin to grow, and by degrees alter their form, till they at length are of the same general shape with their parent. Reamur, Hist. Inf. tom. iv. p. 69, 70.

**Shell-Marl.** In Agriculture, a subfubance of the marly kind, which is of a flaky or shellly nature. Though Mr. Marshall has not seen this material made use of in any of the southern parts of this country, he supposes it highly probable, that in the more northern counties it may be found in considerable quantity; and that in different parts of Scotland, it is in common use as a manure. And he considers it as usually found in low moist situations, under what is termed bog-meadow, a fort of half-reclaimed marshes; namely, tough, coarse, sword, formed upon a depth of black moory earth, which reeks on the marl; this being, in some instances, several feet in depth. In respect to appearance, the colour is nearly white. Its confluence, in the pit, is of a soft curd, roughly broken; with the perceptible remains of small shells interpersed among it; and generally with some portion of earthy particles. It was found by analysis, that one hundred grains of a specimen taken in 1793, from the extraordinary pits on the estate of Aucherterye, belonging to the late fir William Murray, on the southern skirts of the highlands of Perthshire, yielded eighty-two grains of calcareous earth: the residue being brown earthy matter, mostly, it is probable, animal mould, with a slight intermixture of vegetable fibres. One hundred grains, taken from a pit in Strath Tay, within the central highlands, yielded seventy-four grains of chalk; the residue being similar to the above. The search for this species of marl is so obvious and easy, that nothing but undiscernable neglect can suffer a quantity of it to remain within an estate (situated in a country where it is known to abound) unknown to its manager. Wherever, in valleys and dries of surface, level water-formed lands (whether they are already rewarded over, or yet remain in a state of moras) are found, there infert the borers; may in one place only, but in various parts of it; that no hollow receptacle of marl may be filled by the farmer.

And with marls of the foifile kinds it is remarked, that where, by analysis, the proportion of chalk is found to be small, as not more than one-third of the whole; if the earthy matter with which it is combined appears to be of a rich fertilizing nature, such marle becomes, he thinks, a proper subject of trial in the field. And a good method for making this fort of trial, is to spread the marle, at a leisure time, as in winter, or the early part of summer, upon graves-land; and catching a favourable opportunity, when the foil is in a mellow friable state, between wet and dry, to break down and spread the lumps, with the roller and harrow, to give freedom to the grass, and an opportunity of gathering off the flones and rubbish, which may have been carried on with the marle; and in order that summer showers may wash the finer parts of it down into the soil, while it is open to receive them; repeating the operation as often as it may be required. And he knows no better method than this, by which to apply marles, on a large scale, in practice.

**Shell-Sand.** A name given by the farmers, in some parts of England, to the fragments of shells found on the shores, and ground to a fort of powder, so that they resemble sand. See Manuring.

There is also another kind, used as this is, in some parts of Cornwall, and composed of fragments of a fort of tender white coral. This is found principally about Falmouth, and is called by the same name of shell-fand, though very improperly. All the kinds are of great use in agriculture, but they are differently esteemed by the farmers, as they are more or less rich, which they know by their colours: the reddish kind is esteemed more of all; next to this the blue is judged the best, and after this the white. Such as is dredged up from under the water, is always found better than such as is found dry on the shores; and such as is entirely composed of shells is to be chosen, rather than such as has fragments of flone among it, which is a very common cafe. See Sand, and Shelly Sand.

**Shell-Toothed.** In the Mangee, an appellation given to a horse that from four years old to old age, naturally, and without
without any artifice, bears mark in all his fore-teeth; and there still keeps that hollow place with the black mark, which is called in French genre de fesse, i.e., the sign of a beam, innumerable, that at all times in the apes with the mark of a life that is not yet past; for in the support of other bones, the hollow place is filled, and the mark disappears towards the sixteenth, by reason of the wearing of the teeth. Among the English it is not worth note in the minding teeth, and towards the sixteenth year it disappears in the other teeth; but after a hundred staves holes is marked, he marks itself usually in theWISE, the minding, and the corner teeth, which proceeds from this, that having harder teeth than other horses, its teeth do not wear, and for he does not wear black foot.

Among the Polish, Hungarian, and Croatian horses, we find a great many of them hollow-mouthed, and generally the marks are more apt to be so than the horses.

Shell, in Artillery. See Bomb and Mortar.

Shells, M. A. jays, are hollow shells, within which are included a letter, or other papers; the fuse-hole is filled up with wood or cork, and the shells are fired into a garrison or camp.

Shell of a Block, in Mechanics, is the outer frame or cafe, in which the sheave or wheel is contained, and travels about its axis.

Shell-Room, in Ship-Building, a compartment in a bomb-vessel, fitted up with strong shelves, excased fo as to receive the bomb-shells when charged; it is therefore built as secure as possible, to prevent accident from fire.

Shells, Littoral. See Littoral.

Shell-Gold. See Gold.

Shell-Silver. See Silver.

Shell Island, in Geography, a small island near the coast of Carolina, in Pamlico Sound. N. lat. 34° 50'. W. long. 76° 30'.

Shell Key, a small island, or rather rock, in the gulf of Mexico. N. lat. 29° 48'. W. long. 89° 15'.

HELLA, a walled town of Morocco, on the eastern side of Rabat, in N. lat. 34° 31'. This is a bad ground, and contains many Moorish tombs, that are held in great veneration; and the town is a faced citadel, only entered by Mahometans. Sheela was probably the Carthaginian metropolis on the coast of the ocean. Various Roman and ancient African coins were frequently dug up here, but their high price induced the Jews to imitate them, and thus to deceive amateurs, and hence has arisen a suspicion even of the antiquities themselves. The place is now in a state of decay: 4 miles E. of Salem.

SHELLACK POINT, a cape of the island of Man, forming the N. part of Ramfay bay.

SHELLBRAKE River, a river of Canada, which runs into the river St. Lawrence, N. lat. 50° 20'. W. long. 64° 50'.

SHELLENBERG, a mountain of Bavaria, occupied by the Swedes, and strongly fortified in the 30 years' war; 3 miles N.E. of Donauwet.

SHELLIF, the Chimala of antiquity, a river of Africa, and the most considerable in the kingdom of Acrees, which rises in the northern side of the Atlas, and runs into the Mediterranean N. lat. 36° 10'. E. long. 0° 24'.

SHELLNESS, a cape at the E. end of the island of Shepey. N. lat. 51° 22'. E. long. 0° 50'.

SHELLHUIS, a chief of the inhabitants in the dominions of the emperor of Morocco, who occupy the Atlas mountains, and the various borders of them S. of Morocco; living generally in towns, and, for the most part, occupied in husbandry like the Beraberes, though differing from them in their language, dress, and manners. They live almost wholly on Alkaius (barley meal mixed with water), but are not satisfied, and they call it "Zitfut." They naturally solve the use of "Cinfusio," or nutritive farce, and make of granulated flour, and afterwards boiled in them, and mixed with butter, mutton, fowl, and vegetables. Many families among them are tiled to be descended from the Portuguese, who formerly conducted all the parts of the coast, but those, after the discovery of America, gradually withdrew thinner. East of Morocco, near the sea, on the Atlas mountains, there is still remaining a church, having inscriptions in Latin over the entrance, supposed to have been built by them, which, being superstitiously reported to be haunted, has escaped destruction. Their language is called Amazirik.

SHELPGUR, a town of Hindoostan, in the Carnatic; 18 miles N.W. of Trichon.

SHELTER, in Agriculture, a term applied to the means of affording warmth, and procuring protection for lands and live-stock in situations which are too much exposed to storms and inclement seasons. This is mostly accomplished by the use of trees, which should be chosen of the most proper kinds and kinds for effecting the purpose, as those which are the most branchy from the ground, and the most permanent and close in their foliage. The fir tribe, the holly, and the beech, are probably the most suited to this intention, though there are great numbers that may be made use of in this way.

Proper shelter has the effect of producing much improvement in land, trees, plants, and live-stock. See Sheltering Plantations.

SHELTER ISLAND, in Geography, a small island at the E. end of Long island, in Suffolk county, New York, about five miles from E. to W., and from E. to S. It is fertile, and contains about 800 acres; it was incorporated in 1798, and is said to contain 401 inhabitants. It furnishes cattle, sheep, and poultry.

SHELTERING PLANTATIONS, in Agriculture, the means of guarding and protecting them, so as to promote the growth and advancement of the young trees. This is frequently necessary, and of very great utility. In some very exposed situations, trees cannot indeed be raised to any advantage without it. The business is performed in different manners, according to their nature and circumstances. See Plantation.

SHELTERS, Horizontal. See Horizontal.

SHELIE, the name of a small, but strong kind of horse, found in the island of Zetland, commonly called Skel-ldand. In the country, the price of one of these horses was formerly about a guinea.

SHELVES, in Sea Language, a general name given to any dangerous shallows, sand banks, or rocks; lying immediately under the surface of the water, so as to intercept any ship in her passage, and endanger her destruction.

SHELVING-ROADS, in Rural Economy, are such as are formed in a somewhat shelving manner, either on both sides from the middle part, or in the whole front side to side. It is a mode that forms a great improvement in making roads in different situations; as a greater travelable breadth is gained without ruin being formed. And it is particularly applicable in making the side roads on the declivities of hills.

SHELVINGS, in Agriculture, a name applied to the moveable side rails of a waggon or cart, which are occasionally put on for top loads.

SHEMEN,
SHE

SHEMEN, in Geography, a town of Curdiátan; 44 miles N.W. of Kerkuk.

SHEMIUM, a town of Periá, in the province of Khosrafit; 10 miles N.W. of Herat.

SHEANDOAH, a county of Virginia, bounded N. by Frederick, and S. by Rockingham. It contains 13,640 inhabitants, of whom 1038 are slaves. Its chief town is Woodstock.

SHEANDOAH, or Shenandoah, a river of Virginia, which rises in Augulda county, and after running a N.E. course of about 200 miles, joins the Patowmack in about N. lat. 39° 41', just before the latter bursts through Blue Ridge. This river is composed of four branches, S. river, Middle river, N. river, and Shenandoah, which, though the smallest branch, gives name to the united streams. It is navigable about 100 miles, and might be rendered so through its whole course, at a small expense. When this is done, it will convey the produce of the richest part of the state to Washington.

SHEANDOAH Valley, a valley which extends from Winchester in Virginia, to Carlisle and the Susquehannah in Pennsylvania, chiefly inhabited by Germans and Dutch.

SHEANGO, a town of Pennsylvania, in Crawford county, containing 727 inhabitants.

SHEAW, a town of Austria; 4 miles S. of Kirch Schlag.

SHECCOTTY, a town of Hindoottan; 45 miles N.E. of Travancore.

SHENECTADY. See Schenectady.

SHEANGA, a town of Hindooftan, in the Carnatic; 25 miles S.S.W. of Madura.

SHEKNAFELD, a town of Austria; 5 miles W. of Freyltadt.

SHEE-SEE. See Cheeni.

SHEENSEN, in Rural Economy, a term applied, in some districts, as Devonshire, to dried cow and horse-dung, which is laid out and used as fuel for the winter leafoon.

SHEENSHL, in Geography, a town of Egypt, on the right bank of the Nile; 2 miles N. of Achmin.

SHESTONE, William, in Biography, a poet of celebrity, was born at Hales Owen, in Shropshire, in the year 1714. His father was an uneducated gentleman farmer, who cultivated an estate of his own called the Leafowes, which the son afterwards rendered celebrated. William received the elements of instruction from a village dame, whom he has finely described in one of his poems. After this he was sent to the grammar-school at Hales Owen, whence he was removed to that of a clergyman at Solihull, from whom he not only acquired solid learning in classical knowledge, but a cultivated taste. In 1732 he was entered of Pembroke college, Oxford, where he did not make a large acquaintance, but he was one of a few who met at each other's rooms to read and examine the best works in English literature. Here it was he discovered his poetical genius, and produced some compositions of considerable merit, and he had thoughts of taking his degrees, and proceeding to study for a profession, but coming, by the death of his father, into the full possession of his paternal property, he gave himself up to literary ease, and rural retirement, abandoning at once all intentions of active pursuits; hence his biographer justly remarks, "that nothing is more unfavourable to the exertion of those energies which lead to a useful and honourable application in society, than the early possession of a fortune just sufficient to gratify present wishes, and preclude the necessity of immediate entrance into any vigorous course of action." An acquaintance which Shenfstone formed with Mr. Graves of Mickleton, in Gloucestershire, inspired him with an affection for that gentleman's sifter; but the passion of love, which, in some minds, operates as a stimulus to enterprise, seems to him to have waffed its force on plaintive elegies, and other effusions of sentimental poetry. To one species of employment, indeed, he was probably animated by his visit to Mr. Graves,—that of rural embellishment,—which he afterwards bestowed on his favourite place of the Leafowes, with a taste that conduced more to his celebrity than his comfort.

In 1737 he printed, but without his name, a small volume of juvenile poems, which obtained fearcely any notice. In 1740 he came to London, and was introduced to Doddley, who printed his poem of "The Judgment of Hercules," dedicated to Lord Littleton. This was followed by "The School-mistres," of which the heroine was the village dame already referred to. This is thought, by some very respectable critics, to stand at the head of Shenstone's compositions.

Shenstone, from this time, devoted himself to improving the picturesque beauties of the Leafowes, and sometimes excelling his pen in effusions of verfe and prose. The celebrity of this place led him into expences which his fortune was unequal to, and he was perpetually under the preasure of poverty; which, with the deficiency of regular employment, and the perpetual desire of doing more, and appearing better off, than his means admitted, preyed on his spirits, and rendered him the miserable inhabitant of the Eden which his tastes and genius had created. Grey has described him in the following sentence, which may in some respects be rather a caricature likenesses. "Poor man! he was always willing for money, for fame, and for other distinctions; and his whole philosophy consisted in living against his will in retirement, and in a place which his taste had adorned, but which he only enjoyed when people of note came to see and commend it." It has been thought a matter of surprize, considering his connexions, that nothing was done to place him in easier circumstances. Application was said to have been made to lord Bute to procure him a pension from the privy purse, but before the wishes of his friends could be realized he died. This event took place in February 1763, when he was in the 50th year of his age; he was interred in the church-yard of Hales Owen.

Of his poetical compositions many were insertet in Doddley's collection of original pieces; and after his death, his "Works in Verfe and Prose" were published in two vols. 8vo. in 1764, and a third volume, consisting of "Letters," was published in 1769. "Of his poetry," says the critic, "the general opinion was almost uniform; it is regarded as commonly elegant, melodious, tender, and correct in sentiment, and often pleasing and natural in description, but verging to the languid and feeble, and never exhibiting either the powers of the imagination, or the energy and splendour of diction, that characterize compositions of a higher order. His prose writings display good sense and a cultivated taste, and contain just and sometimes new and acute observations on mankind."

SHENUZAN, in Geography, a town of Candahar; 42 miles E. of Ghizni.

SHEEY, Isle of, an island within the liberty of the fame, late of Sway, and county of Kent, England, is situated near the mouth of the river Thames, and is separated from the mainland by a narrow arm of the sea, called the Swale, which bounds it on the south, while the estuary of the Medway, and the German ocean, bound it on the west, north, and east. It is uncertain by what name this island was known to the Romans; for though Ptolemy, in his Geography, mentions two islands in this part of Britain by the
of Tothabil and Comus, he does not describe that of Tothabur. In the text is a matter of dispute among our modern commentators: Camden and Bateley contend for Tothabil, and Lambard, Leland, and others, for Comus. In Saxan times it was called Serpentine, or the island of sheep, from the great number of that animal which were then pastured upon it, whence originated, by corruption, the name by which it is now distinguished. Baxter, in his "Cleric," under the word Mala, remarks, "Verucum Patria, or the island of sheep, now named Shepey." This is corrupted by the book of Rackham, "Maxaca, by the Britons Verex," but these observations are rather conjectural than well authenticated.

The life of Shepey, including the small adjoining isles of Elmsley and Harry, by which he at the south end of it, measures about 42 miles in circumference, being about 15 miles long and fix breeds. On the southern side the lands are flat and marshy, but the interior is diversified by hills, and the northern shore presents a range of cliffs, extending six miles in direct length. These cliffs are chiefly composed of a loose flinty marl, abounding in pyrites, and in some places rising perpendicularly to the height of 50 feet. They belong principally to the three manors of Minster, Shurland, and Wardens, the owners of which let them to the copperers makers, who employ the poor inhabitants to collect the pyrites, or copperers stones, which are continually washed out of the cliffs by the force of the waves, and are of various forms, as globular, oblong, &c. Their external covering is a ferruginous coat; and within they are of a tritified texture, commonly radiated from a centre. The ludi Helmontii also abound in these cliffs. They are in general of a compressed form, from twelve inches to two feet, and a half long, and covered with a thick crust of indurated clay. Where the clay is most tenacious, fossil bones are found of several varieties. Large nodules of petrified wood, retaining the appearance and grain of oak, are likewise met with in these cliffs and on the shores; also a vast number of fruits; but as these are always saturated with pyritic matter, they soon fall to pieces. Animal remains have likewise been found here of many different kinds; as the thigh-bones, tails, and grinders of elephants; two species of tortoises; the heads, tails, and palates of fish; the teeth and vertebrae of sharks; crabs, lobsters, shells, &c.

The great part of this island is of an exceedingly stiff clay soil, and consists chiefly of upland pastures and marish lands. Towards the north side, however, in the parish of Minster and Ewlchurch, it is very fertile in corn, the inclosures of which are small, and surrounded with thick hedge-rows of elm. The roads throughout the island are very good during the whole year, owing to the great plenty of fine gravel found in the beach-pits, and the prospects from them are very pleasing and extensive on every side. Fresh water is very scarce, and the greatest part of it brackish, though between Ewlchurch and Minster there are a few springs, which, notwithstanding they nigh the sea, the waters of them are perfectly good and fresh. The air is generally thick, and much subject to noxious vapours, arising from the large quantity of marshes in and near it. Hence, and from the basins of the water, few people of subidence live in it, the inhabitants consisting in general of lookers, bailiffs, farmers, and ferrants. The garnish of frank and Sherrifs, and its environs, the reader will however be more assured except from this observation, where there are many gentlemen employed in the government service constantly resident. See Sherness.

The water which flows between this island and the main land is called the Swale, and the two extremities of it the East and West Swale. It reaches about twelve miles in length, and is navigable for ships of two hundred tons burden. This water seems formerly to have been connected a part of the river Thames, and to have been the usual, as being the safest passage for the shipping between London and the North Foreland. Accordingly Sands of Naze is frequently visited by our ancient historians London, or the Thames mouth, being the name given to it by the Saxons, and the town of Milton is built by them to stand on the south bank of the Thames. Leland in particular lays, in his Itinerary, "that these lands on an arm of the Tannic," and he speaks of the point against "Quinborough entering into the marine Ferry." The usual passage to the island is by a ferry, called King's Ferry, for carriages, horses, cattle, and passengers. The ferry-boat is moved forward by a long pole, or about one hundred and forty fathoms, or more, which being fastened at each end across the Swale, serves to move it forward by hand. On the side opposite to the island there is a small house of stone, in the room of one formerly erected by one George Fox, who having lived a long while in the cold waiting for the boat, and being much affected by it, built it to shelter others from the like inconvenience.

The very convenient situation of the life of Shepey for the defeating pursuits of the Danes, occasioned it to be made their accustomed rendezvous; and they sometimes wintered here during the course of the ninth century. The inhabitants were then but few, and chiefly congregated in the neighbourhood of Minster, where Sexburga, widow of Ercobert, king of Kent, had founded a nunnery, which, after being several times plundered by the invaders, was at length, in a great measure, destroyed, and the nuns dispersed. The large tumuli in the lower or southern part of the site, and which are termed coterets by the country people, are supposed to cover the remains of different Danes chief, who were slain in battle during their piratical incursions. The years which have been particularly recorded as those wherein these marauders were most active here, are 842, 854, 851, and 852: in the year 1016, King Canute is said to have collected the scattered remains of his army in this island after his defeat in the vicinity of Orford, by Edmund Ironside. Hasted's History and Antiquities of Kent, sv. 1798. Costumes of England and Wales, vol. iii. by E. W. Brayley and John Britton, sv. 1856.

SHEPHERD, in Agriculture, a labourer or other person who has the care and management of a flock of sheep. It is a business that requires much care, attention, and knowledge of the various methods of treating animals of this kind. Mr. Bannister thinks, that it is necessary to have for the employment a person who is well skilled in the nature and management of sheep, and hath been brought up in that employment from his infancy; who is sober, diligent, and good-natured; qualities essentially necessary in a shepherd, who, although he may seem to live a life of idleness, when controlled with the more laborious servants of the farm, need rarely to have a minute's time hang heavily on his hands, if he will be attentive to his business, which will furnish him with sufficient employment throughout the day, particularly in the lambing season, or where there are two folds at work; nor will he want opportunity for the exercise of his patience and good temper, in his attendance on the sheep, which are by nature animals of great obstinacy and perseverance, and which have often paid the forfeit of their lives for these innate qualities, where the shepherd was a man of morals and fair dispositions. It is said that on the continent they have schools wherein young shepherds are instructed in the necessary

 Vol. XXXII.
cessary knowledge of their butinets, as well as the anatomy and physiolog of sheen, the food and treatment proper for them in different seasons, and the nature of their diseases, and the common operations respecting them, especiially regarding the parturgion of the eyes, &c. And in the General Treatise on Cattle, it is remarked, that the method of encouragement, adopted in some districts, of allowing the shepherd to posselfs a small flock, or as many eves as his means will allow, is probably one of the most powerful. It gives him that steadiness appertaining to property, and is an additional and strong incentive to the attainment of knowledge in his business. A shepherd should be naturally active, both in body and mind, clear-headed and clear-sighted; such an one, for instance, as can distinguish the individual countenances of a numerous flock, and running over them with his bodily and mental eye, instantly give the exact number and condition; or perceive at a glance, a bird's nest in the thickest quickset. Fond of animals and attractive to them, the latter quality of which is well known to inhere in some perfons; polishing a musical voice and thrill whistle; hardly, patient, watchful; satisfied with little sleep, and temperate in drink. It is conceived that he ought never to be suffered, if he prospers, to practise physic, nor any but the most easy and common operations, a farce that too often ends in a tragedy; for if of two evils we ought to choose the leaf, the office of medical practice had better devote on the matter. And for his comfort in the severe weather, in some situations, the moveable wooden houfe on wheels may be of use. Alfo that he ought to be clad during winter, withSubstantial woolen next his skin, from his feet upwards, as the belt defence against those rheumatic ails to which he must be necessarily subject; and he should always go provided with the instriments proper to his profficion, ready for immediate occasions, namely, scissors, knife, steel, sleaves, valve-box, &c. And in folding, as the shepherd will have the flock perpetually under his eye, the first writer thinks, he will be capable of judging with certainty and precision respecting the rate of every individual, fo that the earliest remedy may be applied to every disorder, and such sheep may be turned out of the fold which are found not to be able to go through their work without manifelt injury to their health; and if a sheep or lamb be feized with a dangerous and incurable malady, to kill and drefs it immediately; for it is one part of the business of a shepherd to be truly skilled in the butcher's trade, to be able to slaughter, dres, and dres a sheep on occasion. Further, that a good shepherd will be careful that his flock be driven late to fold of an evening, and released early in the morning from their confinement, in order that they may enjoy the coolest parts of the day on the food. He will be cautious that they are allowed a sufficient time to graze in the uplands previous to their being driven into the fold, that they may retire to rest with full bellies, by which the quantity of the dung and urine will be considerably augmented. He will likewise be careful in reviewing the hurdles, and providing that there are fixed in the ground, left by any accident they should be thrown down during the night, and the flock by these means get into mischief, or intermix with other sheep; he will count his sheep regularly every evening when he drives them to the fold, and take a fresh tale in the morning, when he turns them on their feed; he will, previous to dishing them from the fold, worry them gently round the flame, in order to caufe them to dung and itale plentifully, that the manure may be left in the field, otherwise the greaste part of the trudles will be drop on the road, or carried on to the mirth, where lying thin, this dressing can do but little service, and where in truth it is not wanted; he will bellow a particular attention on every individual in his flock, and for those which shew any appearance of being flung by the fly, he will be prepared with a pair of fleers to clip away the wool from the part, and having taken out the maggots, will anoint the place with a mixture of train-oil and stradion; but if slightly attacked, he will destroy the maggots by drawing on them powder of white lead; and if any of the flock should haply break with the scab, a diforder to which folding sheep are continually subject, and which seldom fails to shew itself in the spring and fall, he will be provided with a proper remedy to keep it under, and prevent the contagion from spreading. See Scab.

It is likewise thought, that one shepherd will be able to look after three hundred sheep.

In respect to the necessity of a dog, as an affillant to the shepherd, Mr. Lawrence thinks, that it has of late very rationally become a questration among the most intelligent sheep-masters: it may probably be thus settled,—there can be no occasion for such aid, nor any necessity for incurring the danger of it, amidst convenient inclosures, or where quiet breeds of sheep are kept, and where it is made an object to render them tame and docile: and if upon extensive wastes and mountain districts, the service of dogs cannot well be dispensed with, it ought to be made a main point, that they be trained early to a kindnes for the sheep, and to view them rather as their companions, than their prey; a thing which he knows by experience to be most easy; and he also knows that such dogs are infinitely of the greater use, as the sheep, far from dreading or shunning, will run to them, in cafe of need, for protection; and he has often witneffed the carefles and symbols of thefe and the lambs, with a delight which he never experienced in the combats of animals.

Shepherds of Egypt, Shepherd kings, or royal Shepherds, in Ancient History, the denomination of a clafs of inhabitants of a part of Egypt, concerning whole origin, place of abode, and migration, ancient and modern writers have entertained different opinions. Some sketches of their history, will be found under the articles Auritfe, Cush, Dispersion of Mankind, and Egypt. The learned Bryant has publifhed, besides several notices that occur in his "Analysis of Ancient Mythology," an elaborate "Difcription" on this subject. Differing from others concerning the situation of the land of Cushen, (see Cushen,) he conveys it to have been the Nome called the Arabian, from the Arabian shepherds who had formerly settled in those parts, and held them for many years, and denominated by the LXX, ΤΟνΑ ΤΗΣ ΔΡΦΗΕΩΝ. The province of Arabia, says this author, was one of the three most remarkable names, the other two being those of Bubastis and Helipolis. These three names were contiguous to each other, and towards the summit of Lower Egypt. The nome of Helipolis, according to his statement, was a Mediterranean district; and consequently two provinces, or that of Phacuas (i.e. the Arabian nome), and that of Bubastis, that are always mentioned with the former, were loke likewise. Phacuas, mentioned by Strabo only as a village, was the province at whose summit the Nile was first divided, where stood the city of Cercarca. It was called the Arabian nome for the reason above-mentioned, and had for its metropolis Phacuas, and the places situated upon its borders were Babylon, Helipolis, and Heroaum. From Syncellus we learn, that Egypt had been in subjection to a three-fold race of kings, who are termed the Aurite, the Melites, and the Egyptian. The Aurite were the Arabian shepherds and their kings, who reigned here a considerable time, maintaining themselves by force; till, after many struggles, they
they were finally expelled by the natives. According to Manetho, the whole body of the people bore the appellation of Hukites, that is, royal shepherds; the first syllable, in the faced dialect, signifies a king, and the latter, in the popular language, signifies a shepherd; and by a composition of these two words was formed the word Hukites. These people are said to have been Arabians. Josephus further informs us from Manetho, that the shepherds maintained themselves in Egypt 111 years. At last the people of Upper Egypt rose in opposition to them, and after some time expelled them the country. However, on their departure, they were afraid of going towards Assyria, and therefore returned to the country called afterwards Judea, and built Jerusalem. We learn also, from the same authority, that another class of people foun'dered in Egypt in the reign of Amenophis; and that they were treated as slaves by the prince of the country, because they were infected with the leprosy. As their number very much increased, he employed them in the hene quaries that lay on the east side of the Nile, in company with some of the Egyptians. Upon a remonstrance afterwards made to him, he granted them a retreat the city of Abaris, where the former shepherds had refixed, that now lay desolate. The people belonging to each of the two classes now mentioned were shepherds; the firfl shepherds were lords and controllers of the others were servants, to whom was assigned the city which the former had evacuated. The latter were Israelites, as appears from the name of their leader and lawgiver, Moses; and the former were Arabians, who are said to have come from the East, and that they are, without doubt, the Aurites, who founded the city of Auran or Abaris, which is no other than the city ΕΥΩΡ ΟΥΡ or Aur, signifying light and fire, of which element the Aurites must have been worshippers, as all the Arabians were. Their chief god was Aburas, (Al Orus.) the god of fire. According to the shepherds were called Aurites from the chief object of their worship, and their kings were styled priest of Abaris, or, according to the Greeks, priests of Vulcan. Hence it has been inferred that they came from Babylonia, a country that lay due east from Egypt, which country was the original seat of the genuine Arabians, and the true source whence their religion flowed. The two principal cities of that country were Ur or Ur, and Babylon: in memory of which they built two of the same name in Egypt. Wherever they refixed, they introduced the Tzeba Schanain, or Zabian worship, together with the worship of fire. Hence we are informed by Herodotus, that Vulcan was particularly honoured at Heliopolis and Memphis, which places they are said to have built. The true name of these people, says Bryant, who were called by the Greeks and Romans Arabians, was Cufian or Cufars, the name that they gave to the province where they settled. (See pro.) These strangers, therefore, who settled in Egypt, were no other than the Cufars; and they have been styled Arabian shepherds, because all the primitive Arabians were Nomades, or shepherds. These people becoming lords of the country, undoubtedly chose that part which was the most eligible, and their profession would lead them to the best land for pasturage; in respect of which Gothen had not its equal. For it was part of the ΚΑΛΟΝ ΑΓΕΝΔΟΝ, the rich campaign of Egypt; so that this circumstance among others would induce one to think that they settled here. This is confirmed by the worship which they settled on these parts; the cities they built; and the names which they bequeathed to the province. According to the Mosaic account, the land of Gothen is repeatedly said to be in the land of Egypt, "in the bell of the land;" and yet the LXX call it ΕΥΩΡ ΟΥΡ, which could be owing to another reason besides its being the land of Cufians. (Cufars,) which was interpreted Arabian; for in Arabia it was not situated. Hence it has been concluded, that the place where the children of Israel refixed in Egypt was the principal Arabian nome, at the extreme and highest part of Lower Egypt, called Cufians.

This was the land to which the children of Israel succeeded after it had been abandoned by its former inhabitants; but it is uncertain at what interval. It appears to have been an unoccupied district; and as it was the bell of the land, there is no accounting for its being unoccupied but by the felicitation of the Cufians, whose property it had lately been. Accordingly Manetho expressly affirms, that the second shepherds succeeded to the places which had been deserted by the former; and he moreover says, that the city of Abaris, which had been built by the first shepherd king, was given to those of their body who were employed in the quarries.

Bryant fuggels, that the migration of the shepherds was about the time of Serug or Nahor: and this is the time when archbishop Uthor says it to have happened, who refers it to the year of the world 10920, according to the Hebrew computation, in the 10th year of the life of Serug, the 7th from Noah, and the 53rd year of Terah, 53 years before the birth of Abraham. Bishop Cumberland supposes that the shepherds invaded Egypt A.M. 1797, in the time of the fame patriarchs, according to the Hebrew chronology. Our author has alleged several arguments to prove, that the Arabian shepherds were distinct from the Israelites, and prior to them. When the Arabians came into Egypt, they are said to have been 240,000 in number, whereas the Israelites were but 70 perfons. The former took possession by force, the latter were invited, and had a grant of all that they possessed. The one held the people in slavery; the others were themselves enslaved. The Arabians were driven out of the land; the Israelites were not suffered to depart. See Bryant's Observations and Inquiries, &c. Cont. 1767.

Shepherd's Islands, in Geography. See New Hebrides.

Shepherd's Dog, a variety of the common dog, used in guarding flocks, or driving herds of cattle. See Dog.

Shepherd's Needles, or Venus's Comb, in Botany. See Scandia.

Shepherd's Pouch, Burra poflorin, a common weed in moat parts of England, which propagates itself by feet, as not to be easily elected where they are permitted to lie; for it so far do the feed ripen, and the plants come up, that there are commonly four or five generations of them in a year; they cannot, therefore, be too carefully rooted out of a garden or field. It is early, and lasts most part of the year. It may be destroyed by frequent ploughing, and preventing its going to feed. In the Linnaean system, this is a species of the ibadyn.

This is an officinal plant; its juice has been reputed astringent and vulnerary, and as such is used against hemorrhages, dysenteries, diarrhœas, &c.

The country people apply it to cuts and fresh wounds, and some hold it of great virtue when made up into a cataplasm, and applied to the wounds against tertians and quarcans; but Dr. Lewis observes, that he could perceive no pungency or astringency, either in the leaves of this plant, or in the extracts made by water and rectified spirit, and that a decoction of them strikes no degree of blackness with solution of chalkybeate vitriol. Hence he infers, that there seems to be no foundation for the strong hypotptic virtues, for which this herb has been generally recommended by writers.
in the materia medica, or for the acid inflammatory power which some (probably misled by its botanic affinity with mulled, and some other acid vegetables) have ascribed to it. Lewis's Mat. Med.,

Shepherd's Staff, or Shepherd's Rod. See Træcle.

Shepherdstown, in Geography, a post-town of America, in the state of Virginia, and county of Jefferson, on the S. side of Patowmaack river. Its situation is agreeable and healthy, and the neighbouring country fertile and well cultivated. It is said to contain 1033 inhabitants, chiefly of German extraction.

Shepherdsville, a post-town in Bullitt county, Kentucky: 640 miles from Washington.

Sheppick, in Agriculture, the provincial name of a prong or fort of hay-lork, employed in some places.

Sheppey, in Geography. See Shepey.

Shepreve, John, in Biography, an English poet, was born in Berkshire, and educated at Corpus Christi college, Oxford, where he took his degrees in arts, and became Hebrew professor about the year 1558. He had a moit surprifing memory, and was one of the most learned men in his time. He died in the year 1542. His works are "Summa et Synopsi Novel Test." &c.; "Hippolytus Ovidiam Phaedra respondens," &c. Wood.

Shepton Mallet, in Geography, a market-town in the hundred of Whitecliffe and county of Somerset, England, is situated about five miles E. from the city of Wells, and 115 W. by S. from London. This town has been long celebrated for its manufacture of woollen cloths and knit stockings, which affords employment to upwards of 2000 persons resident in the town or its vicinity. Edward II. granted a charter for a market to be held here on Monday, weekly; but it is now kept on Friday; besides which there is an annual fair, called Silver-freet fair, which takes place on the 8th of August. The market-place is remarkable for a very curious stone cross, which appears, from an inscription upon it, to have been erected in the year 1500, by "Walter Buckland and Agnes his wyff." It consists of five arches, supported by pentagonal pillars, with an hexagonal column in the centre. From the roof, which is perfectly flat, rises a lofty pyramidal spire, adorned with Gothic niches, and crowned with an oblong entablature, on which are repreffed figures of our Saviour on the cross between the two malefactors; also thofe of several saints. Lands of considerable value are appropriated for the repair of this fingular structure. The church here is a large and handsome edifice in the pointed style of architecture, and composed of a nave, chancel, north and south side aisles, and tranfept, with a tower at the west end, ornamented with effigies in niches of the Virgin Mary, St. Peter, and St. Paul. The pulpit and font are each cut out of one fold stone, and from the rudeness of their workmanship would feem to be of very great antiquity. In two of the windows are some remains of stained glafs, displaying the mutilated effigies of knights Templars, faid to repreffent the two Williams Mallet, who had commands in an expedition to the Holy Land during the reign of king Henry II. The monuments in this church are numerous, but none of them are particularly remarkable, either for their style of execution, or for the charafter of the person they commemorate.

Shepton Mallet, in ancient times, formed part of the manor of Pilton, which king Ina gave to the abbey of Glastonbury, A.D. 705. At the time of the Conquest it was held from the abbot by Roger de Carcelle; but four afterwards paffed into the polleffion of the barons Mallet, from whom it derived the latter part of its name. After a

variety of changes, this manor was divided into two moieties, one of which came to the crown, and was annexed to the duchy of Cornwall, to which it still belongs. The other moiety became the property of the family of Shepton.

Shepton Mallet is noted as the birth-place of three men of distinguished talents and learning; viz. Hugh Inge, D.D. archbishop of Dublin, and chancellor of Ireland, who died in 1528; Dr. Walter Charleton, an eminent physician, and author of Chorea Gigantum, or an account of Stonehenge, who died in 1707; and Simon Browne, a learned difenting minister, celebrated for his controversial writings against Woolfston and Tindal, who died in 1732.

The parish of Shepton Mallet is of small extent, but populous, containing, according to the parliamentary returns of 1811, 1129 houses, and 4638 inhabitants. Within its bounds are situated the county Bridewell, and a large parish workhouse. The History and Antiquities of the County of Somerset; by the Rev. J. Collinson, F.A.S. iv. vol. iii. Bath, 1791.

SHERARD, William, in Biography, a very learned and munificent botanist, on whom the titles of prince and Marcellas of botany have been, more justly than usual, bestowed, was the son of George Sherwood, (for so it seems the name was written by the father,) of Buffby, in Leicestershire.

He was born in 1659; educated first at Merchant Taylors' school, and then at St. John's college, Oxford, where he entered in 1677. He subsequently became a fellow of this college, and took the degree of Bachelor of Law, December 11, 1683. Being appointed travelling tutor, successively, to Charles, afterwards the second vicount Townshend, and to Wriothesley lord Howard, son of the murdered lord Ruffell, who in 1700 became the second duke of Bedford, Sherard made two succeflive tours through Holland, France, Italy, &c. returning from the latter, with the usual, not much before the year 1700, when his last-mentioned pupil was twenty years old.

Dr. Pulteney supposes him to have come back in 1693, led perhaps by the date of Ray's Sylloge Stirpiunm Europaeorum, printed in 1694, to which Sherard communicated a catalogue of plants gathered on mount Jura, Saleve, and the neighbourhood of Geneva. These were probably collected in his first journey; for it should seem by Collins's Peerage, that the lord Howard, so created on account of his union with the heirs of the Howard family, was married to her in May 1695, when he was little more than fourteen years of age. He was made a peer June 13, 1695; "after which," says Collins, "he travelled into France and Italy." So youthful a bridegroom was, doubtless, sent in the hands of his tutor, in a distant country from his, still more youthful, spouse. The subject of our memoir is said to have fulfilled his trust to the satisfaction of both the noble families who confided in him. His visit to his friend Sir Arthur Rawdon, at Moira, in Ireland, was apparently made in the interval of these two foreign journeys. Long before either of them, he had travelled over various parts of England, and proceeded to Jersey, for the purpose of botanical investigation; and the fruits of his discoveries enriched the publications of the illustrious Ray; see that article.

Botany was ever the prominent pursuit of Sherard in all his journeys. He cultivated the friendship and correspondence of the most able men on the continent, such as Boerhaave, Hermann, Tournefort, Vaillant, Micheli, &c. He is universally believed to have been the author of a 12mo. volume, entitled Schola Botanica, published at Amfterdam in 1689, and reprinted in 1691 and 1699. This is a philomatic catalogue of the Paris garden. Its preface, dated London, Nov. 1688, is signed S.W.A., which the French
French writers have interpreted Samuel Wharton, Anglia, under which name the book occurs in Halliwell's Bibliotheca Britannica, v. i. 445. But as no one ever lived of such a name as Wharton, and the preface is, in question dispels the obscurity and defects of one of the first rank, who could certainly not be genuine in falsity, the above notices are presumed to be William Sherard, to whom these indeed, with or without a signature, that prefixed could belong.

Its writer is described as having attended three courses of Tournefort's botanical lectures, in 1686, 87, and 88, all which years, he says, he spent at Paris. In the summer of 1688 he describes himself as having passed some time in Holland, collecting specimens of plants from the rich gardens of that country and getting them named by professor Herman himself, who allowed him to peruse the manuscript rudiments of his Paradisi Bataevum, to examine his herbarium, and to compose a Prodromus of that work, which is subjoined to the little volume now under our consideration. All this can apply to Sherard only, who became the editor of Herman's book itself, and who in his preface, dated from Geneva in 1697, appears under his own name, and speaks of himself as having long enjoyed the friendship and communications of that eminent man, whose judgment and talents he justly commemo rates, and of whose various literary performances, as well as of his botanical principles, he gives an account.

Dr. Polteney conceives this preface to have been written during a third tour of its author to the continent; but we presume him to have then been with the young lord Howland, and consequently on his second tour only.

Sherard communicated to the Royal Society, in 1700, a paper relative to the making of Chinese or Japan varnishes, which is printed in the Philosophical Transactions, v. 22. The information which it contains was sent by the Jesuits to the grand duke of Tuscany, and probably obtained by our author at Florence.

He now entered on a more public walk of life, becoming one of the commissioners for sick and wounded seamen at Portsmoutb, and about the year 1702, or soon after, was sent out as British consul to Smyrna. Here his botanical taste met with fresh gratification; nor was he neglectful of other curiosities of science or literature. He visited the seven churches of Asia, copied several ancient inscriptions, and communicated to the Royal Society an account of the new volcanic island, near Santorini, which rose out of the sea May 12, 1707.

Botany, however, continued to be his leading object. He had a villa at Sedekis, near Smyrna, where he could with the more ease resign himself to the contemplation of plants, and where he began to treat of his book of which we shall speak hereafter. Hafcielqui visited this spot, with the devotion of a pilgrim, in the spring of 1740. He saw the house, with a small garden laid out by Sherard, but not enriched at any great expense, nor stored with extensive collections of exotics. Many of the latter indeed might, in the course of thirty-two years, have disappeared. Whatever specimens Sherard could obtain from Greece, and the neighbouring countries, he here carefully preserved; and being well aware of the insufficiency of Baudin's Pinnia, as a clue to the botanical knowledge then in the world, he is said to have here formed the project of continuing it, and even to have made some progress in that arduous undertaking, before he returned to his native country in 1718.

Soon after his return he received at Oxford the degree of L.L.D.

In 1721 Dr. Sherard revisited the continent. Vaillant was now in a declining state of health, and died in May 1722. Previous to his death he concluded, through the mediation of Sir John, the first royal society in the dominions of Paris, part of a subscription, and in 1729 the splendid Transactions of Paris. This is not the place to enter into the cultivation of his talents, would doubtless have been his happiness, neither the superintendence of Sherard, who pulled a face with Boerhaave in revising the manuscript. Our author had already dedicated a more pertinent fervor to his favourite science by his friend with him from Geneva, in August 1721, the celebrated Dillenius, in the same year.

By a comparison of dates, it appears that Sherard made several visits to the continent. He went from Paris to Holland in 1721, and thence with Dillenius, the same year, to England. He stayed some time with Boerhaave in 1724, or perhaps 1725. We know not precisely when or where it happened that he was, like Leibnitz in Norway, in danger of being shot for a wall, or a thief, by some half-humanized rude, akin to the thievish and Oxfordshire justices, who seized upon another illustrious botanist, of our time, as a highwayman.

What principally attached Sherard to Dillenius, was the fineness of their talents respecting the subtlest tribes of vegetable, now termed cryptogams. To the latter the author of both had long been directed, and hence originated the cultivation, which this line of botanical study he received, from that period, in England and Germany. This taste, however, was not exclusive; for these friends and fellow labourers left no department of botany unimproved. James Sherard, seven years younger than his brother, who had acquired opulence by medical practice, first as an apothecary, and then as a physician, in London, had a great fondness for the same pursuit, and resided at his county seat at Eltham, a number of exotic plants, from every climate. Hither the more learned subject of our present article frequently resorted. He had acquired influence by his public appointments, but his style of living was simple and private. Devoted to the cultivation of knowledge in himself, and to the diffusion of that of others, he lent his aid to all who required it, without coming forward condescendingly as an author. He shielded Catesby with information and with money, to bring out his Natural History of Carolina, though neither that work, nor the Historia Elbammenfis of Dillenius, appeared till some time after his decease, which happened on the 12th of August, 1722, when he was 69 years of age. Of the place of his interment we find no mention. His brother died Feb. 12, 1737, aged 72, and is buried in Evangston church, near Lislecleric, with his wife, whose maiden name was Lockwood, by whom he had no children.

The most observant and splendid service to botany, though it for a long time yielded but little fruit, was rendered by the will of Dr. William Sherard, who left 5000l. to found and support a botanical professorship at Oxford, of which we have spoken under the biographical article Dillenius. He bequeathed to this establishment his choice botanical library, his ample herbarium, and the manuscript of his Pinda, the completion of which he intended should be one of the objects and duties of the new professor. We have already expressed our doubts whether the failure of the latter, in this point, were any great loss to science. Nevertheless, the manuscript, as Sherard left it, would probably have been a great acquisition to the world, and might still be worthy of publication. Dillenius accomplished more appropriate, and perhaps more difficult designs; but every scientific object slept with his successor for forty years. Sherard has sometimes been blamed for excluding clergymen from
from his professorship, and it is usual to hear a complaint at Oxford, that this order of men has no interest therein. If by interest is meant the acquisition of a very moderate stipend, which only one can enjoy, the complaint is just: but surely the more important interest of a whole university confisits in having this, or any other, science taught in the best manner. Sherard therefore would have done much more wisely, instead of limiting the appointment at all, to have left it open, like the Cambridge professorship and garden, to all the world; and to have placed the choice in the hands of those who would perceive their own advantage, and probably feel some sense of duty, in not making any professorship a sinecure or a job.

The herbarium of Sherard is perhaps, except that of Linnaeus, the most ample, authentic, and valuable botanical record in the world. In it may be seen original specimens from Tournefort, and all the writers of that day, named by themselves, accompanied by remarks, or by queries scarcely less instructive. He collected also copies of original drawings, from botanists whose specimens were not to be had, such as Plummer. The most rare, and even unique, books are to be found in his library, as the first volume of Rudbeck's Campfj Elpis. (See REDBECK.) All these precious collections are still in good preservation, though the noble stone building, originally constructed to receive them, was faciijed a few years since to public convenience, that the adointing street might be widened.

The name of Sherard has been commemorated by Vail- lant, in some plants referred by Linnaeus to Verbena. Dillenius established a Sideraria, which has remained; see the next article. Pulteney's Sketches of Botany. Haller's Letters, and Bibl. Bot. Aikin's Gen. Biog. S.

Gen. Ch. Cal. Perianth superior, small, with fix teeth, permanent. Cor. of one petal, funnelf-shaped; tube cylin- drical, various in length; limb flat, in four acute deep seg- ments. Stam. Filaments four, inserted into the top of the tube, between the segments of the limb, anthers roundish, two-lobed. Pfl. Germen inferior, oblong, two-grained; stylic thread-shaped, divided at the upper part; filaments blunt. Peric. none. Fruit oblong, crowned, separating lengthwise into two parts. Seeds two, oblong, convex at the outside, flat on the other, each crowned with three points.

Eff. Ch. Corolla of one petal, funnelf-shaped, superior. Seeds two, naked, each crowned with three teeth.

Flowers terminal.—Native of cultivated or fallow fields, throughout Europe, from Sweden to Greece, flowering all summer long. The root is annual, fibrous, small. Herb generally hairy. Stems several, branched, leafy, angular, spreading in every direction, from three to five inches long; stem slender at the base. Leaves spreading, mostly fix in each whorl, elliptical or obovate, pointed, entire, roughish at the edges and keel. Flowers from four to six or eight, in a little termi-
SHERBORNE.

SHERBORNE.

On London. It is a town of very high antiquity, but its origin is not precisely ascertained. Baxter contends that it was the Arianus, or Aramus of Ravenstall, deriving its name from "Arian Urfe, Argenticus Fluxus Aquar," or "Iona Clarus." This opinion, however, is refuted entirely by the most complete and authentic records of the Saxons in the town. It seems, therefore, more probable that it had its commencement in Saxon times, and was colonized from a religious motive, in order to check the conversion of the Saxons to Christianity. This monastery was reckoned as one of the noblest and largest in the kingdom, and was composed of the sons of kings and great officers of the nation. At the dissolution, its revenues were rated, according to Speed and Dugdale, at £120 14s. 7d. per annum.

Sherborne was further distinguished in ancient times, as the seat of an episcopal see, having been constituted such by King Ina, on the division of the bishopric of Winchester, A.D. 764. The first Bishop of this diocese was Aldhelm, bishop of Ina, who is reported to have been a man of extraordinary talents, and a great benefactor to the see. His successors have been differently named by different writers, so that much uncertainty prevails respecting them. The most probable view of the subject, however, is, that they were twenty-five in number, and conjointly presided over a period of 506 years. The most celebrated among them was Aelfwine, who wrote the life of Alfred the Great, and aided him in his literary pursuits. In his time the see of Sherborne comprehended the counties of Dorset, Bucks, Wilts, Somerset, Devon, and Cornwall; but, in 904, shortly after his death, the three latter counties were separated from it, and united to other bishoprics, by a bull of Pope Gregory III. Herman, the 22d Bishop, attempted to remove the seat of the bishopric to Malmesbury, but his intentions were thwarted by Godwin, earl of Kent, and the monks of that church. He succeeded, however, in effecting its removal some years afterwards, viz., in 1055, to Old Sarum, a consequence of the edict of the council of London, which directed that all bishops' seats should be transferred from chiefer places to the most important town in each diocese.

SHERFORD.

SHERFORD.

From the great eagerness of Herman to quit Sherborne, it might reasonably be inferred that it become a town of much less extent and importance than it was under his predecessors. Accordingly such is the fact, and the circumstance is easily accounted for; it being flated by historians, that it was laid in ashes by the Danes, under King Sweyne, during one of his vindictive excursions through this part of the kingdom. Befides, both Matthew of Westminster and William of Malmesbury describe it as "a small street, in which was nothing agreeable in number of inhabitants, or pleasantness of situation; and that it was matter of reproach and wonder that an episcopal see had continued there so long." In this situation it appears to have remained for several centuries; but in the time of Edward II. it had recovered itself very considerably, as we find Sherborne mentioned in his Itinerary as the most frequented town in the county, and that in which the woollen trade was turned to the best account. After his time, however, this branch of business was much decreased; and the manufacture of buttons, haberdashery wares, and bone-lace, introduced in its stead. These trades have also decreased, and

Besides the established church, there were formerly in Sherborne two meeting-houses for dissenters; but at present there is only one, situated in Long-street. The other public structures here are the market-houfe, the work-houfe, an almshoufe, and a free grammar-school. The almshoufe was formerly a religious hospital dedicated to St. Augustin, and has a chapel attached to it, which appears to have been erected in the fifteenth century, and contains a very curious ancient painting upon oak in high preservation. This picture consists of three pieces, representing three of our Saviour's most remarkable miracles, and is characterized by Mr. Hutchins, in his History of Dorsetshire, as "very beautiful, and evidently executed by a masterly hand." The free grammar-school was founded and endowed by King Edward VI., and the government of it vested, by charter, in twenty principal inhabitants of Sherborne. At present, there are two masters attached to this school, who must be clergymen, and graduates of one or other of the universities. The buildings occupy the site of part of the ancient abbey, some considerable portions of which are still standing. The plan of education adopted here is similar to that of Eton. There are likewise in Sherborne two charity-schools on a contracted scale, three benefit societies, two for men, and one for women; and an institution of rather an unusual kind, called the Green Girls' Society, which, from its excellent tendency, deems it more generally adopted. It was established in 1771. The members pay into it a small sum weekly, and wear, till they arrive at a certain age, green gowns and straw hats. When a girl attains the age of eighteen, she is at liberty to leave it, and if married before she is twenty-five, is entitled to 12l. on her wedding-day, and 1l. on the birth of her first child. If unmarried till twenty-five, she is then entitled to the full sum, provided she has lived a sober and virtuous life, otherwise her claims are forfeited to the society. The founder of this institution was the late Mr. John Toogood.

The parish of Sherborne extends about three miles and a half in length, and two miles and a half in breadth, and contains, according to the population census of 1811, 597 houses, and 3370 inhabitants, of whom above 2000 reside in the town. The late eminent Dr. Joseph Towers is generally flated to have been born at Sherborne, but we know from authority that he was not even a native of the county.

In a hamlet, or suburb called Caileton, about half a mile eastward from the town, stood the ancient castle of Sherborne. This fortres was built by Roger, third bishop of Salisbury, and occupied a rocky eminence on the north bank of the river Tre. The area contained within the deep fosse, which inclosed the whole works, measured about four acres in extent. Few castles surpassed this in strength and magnificence of structure. It was one of the three, erected by the fame bishop, which William of Malmsbury mentions among the wonders of the world. It was of an octagonal form, and had seven courts, with strong battlements surrounding it, and was built after the plan of a spider's web. It had also a tower at each angle, there being sixteen in all without the citadel, and appears to have been in every respect admirably calculated for security and defence; for if any one of the courts were scaled or taken, the folders in the gallery above would so annoy the assailants with their arrows and other missile weapons, as to render it impossible for them to retain possession of it. But notwithstanding the strength and importance of this castle, it does not appear to have been the scene of any events of interest in the history of the kingdom, till the reign of Charles I., when it was one of the first besieged by the parliament, and one of the last which abandoned the cause of the king. Since that time it has been gradually falling into ruin, so that only a few fragments of it now remain.

The manor of Sherborne was very early granted to the fee, and continued attached to it, during its successive removals, till the reign of King Henry VIII., who compelled bishop Pieris to alienate it to the crown. Queen Elizabeth granted it to Sir Walter Raleigh, on whose unjust execution by King James I. it was seized and given to the favourite Carr, notwithstanding the intercession of various distinguished individuals to obtain it for the family of its great, though unfortunate possessor. It afterwards became the property of Sir John Digby, whose descendants still continue to enjoy it. The History and Antiquities of the County of Dorset, by John Hutchins, M.A., 2d edition, corrected and improved by Richard Gough, esq. and John Bowyer Nichols, esq. vol. iv. fol. 1815.

SHERBURN, a market-town in a parish of the same name, partly within the liberty of St. Peter of York, and partly in the upper division of the wapentake of Barkston Ash, Welf Riding of Yorkshire, England, is situated at the distance of 14 miles S.W. from the city of York, and 181 miles W. by N. from London. The market is held on Friday weekly, but is little frequented, and there is only one annual fair, on the 25th of September. This place was formerly, however, much more important, and was distinguished by a palace belonging to the archbishops of York, of which not a vestige now remains. It is only at present, therefore, remarkable for a particular species of plum called the Winefour, which grows in the vicinity. Sherburn township, according to the parliamentary returns of 1811, contains 188 houses, and 558 inhabitants. Beauties of England and Wales, vol. xvi. by John Bigland, 1812.

SHERBURN, Edward, in Biography, an ingenious writer, was born in London in 1618, and educated under Farnaby, after which he went abroad, but returned in 1641, and succeeded, on the death of his father, to the office of clerk of the ordnance. He was imprisoned for some time by the parliament, and, on his recovering his liberty, joined the king, whom he served with fidelity and great bravery, by which he suffered considerably in his estate. After the battle of Edgehill he went to Oxford, where he was created master of arts. At the restoration he recovered his situation under government, was knighted, and made commissary-general of the artillery. He died in 1702. He translated Seneca's tragedies, the Sphere of Marcus Manilius, and other works, into the English language, and was author of a volume of poems.

SHERBURN, in Geography, a poll-town of America, in Chenango county, New York; containing 1282 inhabitants. — Alto, a town in the state of Massachusetts, and island of Nantucket. The island contains 6587 inhabitants. (See Nantucket.) — Alto, a town in Middlesex county, Massachusetts, containing 770 inhabitants; 18 miles S.W. of Bolton. — Alto, a town of Herkimer county, New York; containing, by the census in 1796, 483 inhabitants. — Alto, a town of Rutland county, Vermont; containing 116 inhabitants.

SHERBATO, Prince; in Biography, a learned Ruffian nobleman, who published several works in his own language, the chief of which is "The History of Ruffia from the Earliest Times," which is said to be well arranged, and faithfully drawn up. Mr. Cox, in speaking of this writer, says, several perfons have published collections of flat-papers and other documents, but the honour of composing a complete history of Ruffia is probably deserved for prince Sherbato; who, if we except Mr. Muller, has contributed
III, order.

The learned editor of a work of "A Journal of Peter the Great," vol. iv. which he founded in the archives, and published by order of the emperors of the Russian fable, in The Ruffian History, by an ancient Annalet, from the beginning of the reign of Vladimir Monomachus, 1114 to 1172; "The Life of Peter the Great," in the Russian language, first published at Venice, which the prince reprinted in 1724, and, according to his usual custom, enriched with many historical observations. Of his History, already referred to, our author says, "I have read the German translation of this performance, which appears to me a most valuable addition to the history of the North. The author has had access to the imperial archives; he draws his information from the most ancient and unquestionable sources, is particularly exact in quoting his authorities, and ranges the events in a chronological series with great pertinacity." *Coxe's Travels*, vol. iii.

SHERET, in Geography, a town of Asia Minor, in the province of Trebizond, 30 miles S.W. of Trebizond.

SHEREFZOUR, or Sherezour, or Scherezour, a town of Curdish, the capital of a government, and residence of a Turkish pasha; 150 miles N. of Bagdad. N. lat. 35° 46'. E. long. 44° 25'.

SHERIDAN, see Sherrin.

SHERIDAN, Thomas, in Biography, was born probably about the year 1684, in the county of Cavan, where his parents lived in such a state of indigence, as not to be able to afford him the advantages of a liberal education; but being observed to give early indications of genius, he attracted the notice of a friend to his family, who sent him to the college of Dublin, and contributed towards his support, while he remained there. Afterwards he proceeded to a doctor's degree, and took orders, and set up a school in Dublin, which long maintained a very high degree of reputation, as well for the attention bestowed on the morals of the scholars, as for their proficiency in literature. He does not appear to have had any considerable preferment; but his intimacy with Swift procured for him, in 1725, a living in the south of Ireland, worth about 150l. per annum, which he went to take possession of; and, by an act of inadvertence, it is said, destroyed all his future expectations of rising in the church: for being at Cork on the 1st of August, the anniversary of the king's birth-day, he preached from the text "Sufficient for the day is the evil thereof." The report of the fact was spread abroad: he was struck out of the list of chaplains to the lord-lieutenant, and forbidden the castle. He afterwards changed his living for that of Dunboyne, which by the knavery of the farmers and power of the gentlemen in the neighbourhood, fell in value to 80l. per annum. He willingly refrained it for the free-school of Cavan, where he might have lived well; but the air being moist, and as he thought unhealthy, and being disgusted with some of his parishioners, he sold the school for about 400l.; and having spent the money, he fell into ill health, and died September 10th, 1758, in the 55th year of his age. He is thus characterized by lord Corke: "Dr. Sheridan was a schoolmaster, and in many influences perfectly adapted to that situation. He was deeply versed in the Greek and Roman languages, and in their customs and antiquities. He had that kind of good nature, which absence of mind, insouciance of body, and carelessness of fortune, produce; and though not over-horic in his own conduct, yet he took care of the morals of his scholars, whom he led to the university remarkably well grounded in all kinds of classical learning, and not ill instructed in the local duties of life. He was clever, indigent, and cheerful."

Vol. XXXII.

He saw books much better than men, but he knew the value of every book of all. In this situation, and with this debt hanging, Swift fell upon him as upon prey, with which he intended to ruin his fell, when he, in spite, should profect his. Dr. Sheridan published a prose translation of Periplus, to which he added the last verses of former editors, together with some very judicious notes of his own. He also translated the Histories of Sopher.

SHERIDAN, Thomas, son of the preceding, was born at Quakes, in the county of Cavan, in Ireland; and there lived, for his god-father, dean Swift. The early part of his education he received from his father, who afterwards sent him to Westminster school, and at a time when he could very ill afford it. Here, upon examination, he attracted notice; and although a mere stranger, he was elected a king's scholar, on account of his merit. But their maintenance sometimes running short, the doctor was too poor that he could not add fourteen pounds, to enable his son to finish the year; which if he had been able to have done, he would have been removed to a higher class, and in another year would have been sent off to a fellowship at college. Being thus reduced to Dublin, he went to the house of Mr. Spence, where he obtained an exhibition, and in 1738 he took his degree of M.A. Having no interest in the church, nor the means of preparing himself for one of the liberal professions, he resolved to seek a support on the stage. He was received with great applause, and in a short time became manager of the Dublin theatre; in which capacity he successfully undertook the curbing of that licentiousness, which had long reigned with an almost unlimited empire behind the scenes, and the putting a stop to the liberties daily taken by the young men with the female attellies. During eight years Mr. Sheridan policed this important office of manager of the Dublin theatre with all the success, both with respect to fame and fortune, that could well be expected, when an unfortunate circumstance led him to oppose the wishes of the public, which obliged him to withdraw from the management of the theatre, and even to quit the country. He continued in England till the year 1756, when he returned to Dublin, and was again received on the stage with the highest applause; but he did not continue long in that situation, being opposed and ruined by rival actors.

In 1757 he published a plan, in which he proposed to the Irish the establishment of an academy, for the accomplishment of youth in every qualification necessary for a gentleman. In the formation of this design he included oratory, as one of the essentials; and in order to give a stranger idea of the utility of that art, he opened his plans to the public in some orations, which were so well written, and so admirably delivered, as to give the highest proofs of the ability of the proposer, and of his fitness for the office of superintendent of such an institution, for which post he had offered himself. Nevertheless, though the plan was, in a measure, carried into execution, Mr. Sheridan was excluded from any share in the conduct of it. He now came again to England, and delivered lectures on elocution and oratory in the theatres of Oxford and Cambridge, to very numerous audiences, and with the highest reputation. From thence he again came to London, where he was engaged as an actor and a lecturer. In 1778 he published "A Pronouncing Dictionary of the English Language," and after this he became a manager of the Drury-lane theatre, under his son, the present Mr. Sheridan, who was then one of the patentees. He died in August, 1788. His works are as follow: 1. "A Dictionary of the English Language," 2. "Lectures on the Art of Reading." 3. "British Education, or the Source of the Disorders of Great Britain." 4. "A Difficitation on the Causes of the Difficulties in
which occur in learning the English Tongue.” 5. “A Course of Lectures on Eloquence.” 6. “The Life of Swift,” prefixed to an edition of his works, edited by Mr. Sheridan. 7. “Elements of English.” His wife Frances, whose maiden name was Chamberlaine, was a very ingenious woman, and was author of a novel, entitled “Sidney Biddulph;” a moral romance, entitled “Nourjahad;” “The Difcovery,” a comedy; and another, entitled “The Dupe.” She died at Blois, in 1767.

Sheridan, the late Mrs., was daughter of the excellent musician, Mr. Linley, so well known at Bath, by his professional merit as a matter, by the beauty and talents of his family, and by his vocal compositions, particularly his Elegies. If this were a place to celebrate the beauty and fascinating manners of Mrs. Sheridan, we could dwell upon them as long as on her voice and musical talents; but to these we must confine ourselves. There was a brilliancy, a spirit, and a mellifluous sweetness in the tone of her voice, which infantly penetrated the hearts of her hearers, as much as her angelic looks delighted their eyes. Her voice was perfect, her modulation truth itself, and the agility of her throat equal to any difficulty and rapidity that was pleasing. But in Handel’s pathetic songs, in Purcell’s “Mad Bel,” in the upper part of serious glees, or whatever vocal music had impassioned words to express, she was sure to make them felt by every hearer poifossed of intelligence and sensibility.

She knew music so well, that she was sure to do justice to every kind of Italian composition, as much as a foreigner ever did to a language not her own; though the energy and accent given by the natives of Italy, particularly in recitative, is ever comparatively deficient in the bell fingers of all other countries; as nothing but a long residence, early in life, in a foreign country, can acquire the correct pronunciation of its music, any more than of its language. It was observed by Sacchini, who heard Miss Linley sing at Oxford for the last time, that if the had happened to have been born in Italy, she would have been as much superior to all Italian fingers, as she was then to those of her own country.

Sheriff, in the Egyptian Orders, the relations of Mahomet, the same tribe of persons called emir by the Turks.

The word is Persian, and signifies great or noble; and these persons have the privilege of being exempt from appearing before any judge but their own head; and if any of the military orders are obliged to punish them for any misdemeanor, they will take off their green turban, in respect to their character; and the same is done even when they are punished by their own magistrate.

The sheriff, sherriff, or sefherif of Mecca, is the title of the descendants of Mahomet by Haffan ibn Ali. Although this branch of the potters of Mahomet has never attained to the dignities of caliph or imam, it appears to have always enjoyed the sovereignty over most of the cities in the Arabian province of Hedsjas. The family of Ali-Bunemi, being one branch of the descendants of Haffan ibn Ali, and consisting of at least 300 individuals, enjoys the sole right to the throne of Mecca. This family is likewise subdivided into two subordinate branches, of which sometimes the one, sometimes the other, has given sovereigns to Mecca and Medina, when these were separate states; but the Turkish sultan is indifferent about the order of succession in the family, rather willing to favour the strongest, that he may weaken them all. As the order of succession is not absolutely fixed, and the sheriffs may all aspire alike to the sovereign power, this uncertainty of right, aided by the intrigues of the Turkish officers, occasion frequent revolutions. The grand sherriff is seldom able to maintain himself on the throne; and it still seldom happens, that his reign is not disturbed by the revolt of his nearest relations. The dominions of the sherriff comprehend the cities of Mecca, Medina, Jambo, Taaf, Sadie, Guhufude, Halil, and thirteen other less considerable, all situated in Hedsjas. As these dominions are neither extensive nor opulent, the revenue of their sovereign cannot be considerable. He finds a rich resource, however, in the imposts levied on pilgrims, and in the gratuities offered him by Mussulman monarchs. Every pilgrim pays a tax of from 10 to 100 crowns, in proportion to his ability. The Grand Mogul remits annually 60,000 rupees to the sheriff, by an arrangement on the government of Surat; but since the English have made themselves masters of this city, and the territory belonging to it, the nabob of Surat has no longer been able to pay the sum. The power of the sheriff extends not to spiritual matters: these are entirely managed by the heads of the clergy of different sects, who are resident at Mecca. Rigid Mussulman, such as the Turks, are not very favourable in their sentiments of the sheriffs, but suspect their orthodoxy, and look upon them as tacitly attached to the tolerant sect of the Zeids. See Sheriff.

Sheriff, or Shire-reeve, an officer in each county of England, of very great antiquity; his name being derived from the two Saxon words fære, province or fære; or rather from fēor, to divide, and gerefa, grave, reeve, or prefect; the sheriff being demominated from the first division of the kingdom into counties.

He is called in Latin vice-comes, as being the deputy of the earl or comes, to whom the custody of the shire is said to have been committed at the first division of this kingdom into counties: but the earls being afterwards unable, by reason of their high employments, and attendance on the king’s person, to transact the business of the county, the labour was committed to the sheriff; who now performs all the king’s busineses in the county; and though he be still called vice-comes, yet he is entirely independent of, and not subject to, the earl: the king, by his letters patent, committing e working, confirms to the sheriff.

Sheriffs were formerly chosen by the inhabitants of the several counties; in confirmation of which, it was ordained by 28 Edw. I. c. 8, that the people should have election of sheriffs in every shire, where the sheriffalty is not of inheritance; for anciently in some counties the sheriffs were here- ditary as judge Blackstone apprehends they were in Scotland, till the statute 20 Geo. II. c. 43, and still continue in the county of Wiltshire as such to the present day: the city of London having also the inheritance of the sheriffalty of Middlesex vested in their body by charter. This election, says the same author, was, in all probability, not absolutely vested in the commons, but required the royal approbation. For in the Gothic constitution, the judges of their counties (which office is exercised by our sheriffs) were elected by the people, but confirmed by the king; and the form of their election was thus managed: the people, or inole ter- ritorii, chose twelve electors, and they nominated three persons, ex quibus rex eum confirmabat. But with us in England, these popular elections growing tumultuous, were put an end to by the statute 9 Edw. II. r. 2, which enacted, that the sheriffs should henceforth be assigned by the chancellor, treasurer, and the judges, as being persons in whom the same truth might with confidence be repose. By statutes 14 Edw. III. c. 7, 23 Hen. VI. c. 8, and 21 Hen. VIII. c. 20, the chancellor, treasurer, president of the king’s council, chief justices, and chief baron, are to make this election on the morrow of All-Souls in the exchequer; and the king’s letters patent, appointing the new sheriffs,
SHERIFF.

used commonly to bear date the sixth day of November.
12 Edw. IV. c. 1.

And the custom now is, which has obtained since the time of Henry VI. that all the judges, together with the other great officers, meet in the exchequer chamber on the morrow of All Saints yearly (which day is now altered to the morrow of St. Martin, by the last act for abbreviating Michaelmas term), and then there propound three persons to the king, who afterwards appoint one of them to be sheriff.

This custom of the twelve judges proposing three persons, seems borrowed from the Gothic constitution before-mentioned; with this difference, that among the Goths the twelve nomines were first elected by the people themselves: which usage of ours was probably founded upon some statute, though not now to be found among our printed laws. But notwithstanding an unanimous resolution of all the judges of England to this purpose, entered in the council-book of 3 March, 34 Hen. VI. and the statute 35 & 36 Hen. VIII. cap. 26. feet. 61. which expressly recognises this to be the law of the land; some of our writers have affirmed, that the king, by his prerogative, may name whom he pleases to be sheriff, whether chosen by the judges or not. This is grounded on a very particular case in the fifth year of queen Elizabeth, when, by reason of the plague, there was no Michaelmas term kept at Westminster, so that the judges could not meet there in ergo animat., to nominate the sheriffs; upon which the queen named them herself, without such previous assembly, appointing for the most part one of the two remaining in the last year's list. And this case, so circumstance, is the only authority in our books for making these extraordinary sheriffs.

However, it must be acknowledged, that the practice of occasionally naming what are called pocket-sheriffs, by the sole authority of the crown, hath uniformly continued to the reign of his present majesty, George III.; in which, says Blackstone, few, if any, instances have occurred.

By four several statutes it is enacted, that no one shall be sheriff, except he have sufficient land within the shire to answer the king and the people in any manner of complaint. 9 Edw. II. fl. 2. 4 Edw. III. c. 9. 5 Edw. III. c. 413 & 14 Car. II. c. 21.

It has been judged, that an attorney is exempted from the office of sheriff, by reason of his attendance on the courts of Westminster.

By 3 Geo III. c. 20. no person, during the time he is acting as a militia-officer, shall be obliged to serve the office of sheriff.

Protestant dissenters, who are exempted by the Toleration act from the obligation of complying with the requirishment of the Corporation act, and who can plead their non-compliance as a reasonable and sufficient excuse, are not compellable to serve this office, nor of course to pay any fine for refusal. See Furnace's Letters to Blackstone, ed. 2. and particularly the Appendix, containing lord Mansfield's speech in the house of lords 1767, on the cause between the city of London and the dissenters, when the house affirmed the unanimous judgment of the commissioners' delegates, who delivered their opinions feriatim on the 6th of July, 1762, after hearing counsel several days.

By a by-law of the city of London, palled in a common-council June 13th, 1799, amending an act of April the 7th, 1748, no Freeman chosen sheriff, &c. shall be excused, unless he voluntarily swears he is not worth 20,000l. &c. which oath shall be attested by the oaths of six other freemen; and if he refuses to take the office, he incurs a forfeiture of 400l. and twenty marks towards the maintenance of the ministers of the several prisons within the city, together with the usual fines. If, however, he shall afterwards take upon himself the office of an alderman of the city, he shall be eligible to the said office of sheriffalty, notwithstanding the foregoing payment.

The sheriff, before he exercises any part of his office, and before his patent is made out, is to give security in the king's remembrancer's office in the exchequer, under penalty of 200l., for the payment of his proctors, and all other profits of the sheriffwicke; he must also take the oaths of allegiance and abjuration, and all, except the sheriffs of Wales and Cheflcr, an oath appointed by 3 Geo. I. cap. 15. sect. 18. for the due execution of their office. This oath may be administered in pursuance of a writ of dolium prefectum.

Sheriffs, by virtue of several old statutes, are to continue in their office no longer than one year; and yet it hath been said, that a sheriff may be appointed durante bene placito, or during the king's pleasure, and for the form of the royal writ; therefore, till a new sheriff be named, his office cannot be determined, unless by his own death, or the demise of the king.

And by 1 Anno. fl. 1. c. 8. all officers appointed by the preceding king may hold their offices for his months after the king's demise, unless sooner displaced by the successor.

We may farther observe, that by 1 Rich. II. c. 11. no man, that has served the office of sheriff for one year, can be compelled to serve the same again within three years after.

The power and duty of a sheriff are those that belong to him as a judge, as a keeper of the king's peace, as a ministerial officer of the superior courts of justice, or as the king's bailiff.

In his judicial capacity he is to hear and determine all causes of forty shillings value and under, in his county-court; and he has also a judicial power in divers other civil causes. He is likewise to decide the elections of knights of the shire (subject to the control of the house of commons), of coroners, and of verderors; to judge of the qualification of voters; and to return such as he shall determine to be duly elected, but incapable of being elected himself for the county, &c. of which he is returning officer.

As the keeper of the king's peace, both by common law and special commission, he is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it; and may bind any one in a recognizance to keep the peace. He may, and is bound, ex officio, to pursue and take all traitors, murderers, felons, and other misdemeanours, and commit them to gaol for safe custody. He is also to defend his county against any of the king's enemies when they come into the land; and, for this purpose, as well as for keeping the peace and pursuing felons, he may raise the pell motius.

However, by the express directions of the great charter, the sheriff, together with the constable, coroner, and certain other officers of the king, are forbidden to hold any pleas of the crown, or, in other words, to try any criminal offence; for it would be highly unbecoming, that the executioners of justice should be also the judges; should impose as well as levy fines and amercements; should one day condemn a man to death, and personally execute him the next.

Neither may he act as an ordinary justice of the peace during the time of his office, for this would be equally ineffectual, he being in many respects the servant of the justices.

In his ministerial capacity, the sheriff is bound to execute all process issuing from the king's courts of justice. In the commencement of civil causes, he is to serve the writ, to arrest, and to take bail: when the cause comes to trial, he must
must summon, and return the jury; when it is determined, he must see the judgment of the court carried into execution. In criminal matters, he also arrests and imprisons; he returns the jury; he has the custody of the delinquent; and he executes the sentence of the court, though it extend to death itself.

As the king's bailiff, it is the sheriff's business to preserve the rights of the king within his bailiwick; for so his county is frequently called in the writs. He must feize, to the king's use, all lands devoted to the crown by attainer or eleetion; must levy all fines and forfeitures; must feize and keep all waifs, wrecks, elrays, and the like, unless they be granted to some subject; and must also collect the king's rents within his bailiwick, if commanded by process from the exchequer.

To execute these various offices, the sheriff has under him many inferior officers, an under-sheriff, bailiffs, and gaolers, who must neither buy, sell, nor farm their offices, on forfeiture of 500l. 3 Geo. I. c. 15.

The under-sheriff usually performs all the duties of office, excepted, with regard to which the personal presence of the high sheriff is necessary. But no under-sheriff shall abide in his office above one year by 42 Edw. III. c. 9, and if he does, by 23 Hen. VI. c. 8. he forfeits 200l.; and no under-sheriff, or sheriff's officer, shall practice as an attorney during the time he continues in such office, by 1 Hen. V. c. 4. But these regulations are evaded, by practising in the names of other attorneys, and putting in them deputies by way of nominal under-sheriffs.

The under-sheriff, before he enters upon his office, is to be sworn, by 27 Eliz. c. 12. And by 3 Geo. I. c. 15. sect. 19, it is enacted, that all under-sheriffs of any counties in South Britain, except those in counties in Wales, and the county palatine of Chester, shall take an oath for the due execution of their office. Blackf. Com. b. 1.

SHERILL, in Geography, a town of Asiatic Turkey, in the province of Diarbekir, on the Euphrates; 20 miles E. of Anah.

SHERILLA, a town of Africa, in Kaarta. N. lat. 14° 29'. W. long. 6° 25'.

SHERLING, or Shirling Lambs, in Rural Economy, the practice of cutting or flearing the short woolly coats or coverings of these young animals in the summer season, about the time at which the old sheep are clipped. Both the term and the custom are common in the northern districts, though they are scarcely known in the more southern parts of the island. Probably the greatest part of the lambs which are brought to Smithfield market, as well as of those which are bought by the butchers of the metropolis, are never fleared or freed from their coats, by which a very great individual as well as national loss is sustained. Perhaps the lambs are more saleable when kept in their full coats. The practice is, however, worthy of being more attended to in all situations.

The clipping or shirling of the lambs in some districts has, however, been considered as injurious, by the operation's hurting the growth of them; though no such effect has been discovered to take place in the South Down sheep tract of the county of Suffiao, or those of many other parts of the north. The profit in the above district is, however, thought to be trifling, or such as only to repay the expenses, and a little more; but it has a tendency to improve the wool, and cause it to throw out a more luxuriant staple. See Wool.

SHERLOCK, WILLIAM, in Biography, an eminent divine in the English church, was born in London in 1641. He was educated at Eton, and thence he went to Peter-House, Cambridge, where he applied himself with much avidity to his studies, obtained a great reputation, took orders, and officiated as a curate till the year 1669, when he was presented to the rectory of St. George's, Botolph Lane, London. He flooded high in character among the London clergy, when he published "A Discourse concerning the Knowledge of Christ, and our Communion with Him," being intended as a confirmation of the Antinomian doctrine, which brought upon him several antagonists, against whom he vindicated himself with judgment and zeal. In 1668 he took the degree of D.D. and in the following year he obtained a prebend in the cathedral of St. Paul's. The discovery of what was called the Rye-house plot, having called forth the spirit of loyalty, Dr. Sherlock appeared as an apostle of the doctrine of non-resistance, in a work entitled "The Case of Religion in order to the Supreme Powers dated and refolved, according to the Doctrines of the Holy Scriptures." In this piece he maintained that the authority of the sovereign was in his person, and not in the law; and that he does not receive his authority from the laws, but that the laws receive their power from him; and that it does not become a man who can reason at all to talk of the authority of the laws in derogation to the authority of the sovereign power. From these principles he did not in the least swerve, even after the accession of James II. had filled more endangered the public liberties and religion of the country. His notion of passive obedience did not, however, prevent him from opposing Popery, for he was among the first who, in those times, engaged in controversy with the Papists, in which he wrote a great number of tracts.

After the revolution, Dr. Sherlock for some time remained firm in his high monarchical principles; and refusing to take the oaths to the new government, was suspended from all his preferments, among which was the mastership of the Temple. It was during this suspension from his labours as a preacher, that he published the treatise on "Death," to which he is chiefly indebted for celebrity as an author. It was entitled "A Practical Discourse concerning Death," and few works have been more popular among all classes. It went through thirty editions in a short space of time, has been printed in all fizes and forms, and has been applauded by the most able critics.

Not long after the publication of this work, Dr. Sherlock's scruples with respect to government gave way; he took the oaths, and was reinstated in all his preferments.

This step of course exposted him to the censure of the party with whom he had long acted, and to vindicate himself he published a piece, entitled "The Case of the Allegiance due to sovereign Powers dated and resolved." In 1692 he published his "Vindication of the Doctrine of the Holy and Ever-blessed Trinity." In this he maintained that there were three eternal minds, which exposted him to the charge of tritheism; it did not, however, prevent his promotion to the deanship of St. Paul's, on the recommendation of Dr. Tillotson, who was raised to the archbishopric of Canterbury.

This rife in the church exasperated still more those who were already indigested against him for his defection of his former principles, and Dr. South published in 1693, Antidotes upon Dr. Sherlock's Book, &c. An eager controversy followed, in which the university of Oxford took part, by confounding in a public decree the hypothesis of Dr. Sherlock, as maintained by a preacher that place. The contest being carried on with great acrimony, the king, at the
the office of the bishops, interpreted with a prohibition of the
use of new terms in the exposition of the doctrine of the
Trinity.
In 1684 Dr. Sherlock published "A Discourse on the
Immutability of the Soul," in which he made an attack on
Locke's opinion concerning fate ideas. He died in 1698,
in the 76th year of his age. After his death, his remains,
which had been printed during his life, were collected, and
with others printed in two volumes, 8vo.
Sherlock, Thomas, a distinguished prelate, all of the
proceeds, was born in London in 1678. He received his
classical education at Eton, and from thence he removed
to Cambridge, and, about the year 1693. In process of
time he became a fellow of that college, entered into
orders, and, upon the resignation of his father in 1704,
his succeeded to the office of master of the Temple. In
the duties of this office he exerted himself with so much suc-
cess, that few English divines have acquired a high reputa-
tion for pulpitu oratory, in the qualities of strength and
fidelity of reasoning, and forcible and manly eloquence.
He commenced his duties in 1690, and in 1714
was elected master of Catharineholt. Being promoted
to the dignity of Chancellor in 1716, he lost after made his
dignitary appearance in print, as a champion of the establishment,
in "A Vindication of the Corporation and Test Acts, in
answer to the Bishop of Bangor's Reasons for the Repul-
se of them." This was replied to by the worthy prelate, and
supported in a rejoinder by the dean.
Dr. Sherlock's next work was entitled "The Use and
Intent of Prophecy in the several Ages of the World,
which was the subject of a sermon preached in the
Temple church, occasioned by the controversy between
Collins and several divines on the subject of prophecy. In
1728 he was promoted to the see of Bangor, in which he
succeeded his antagonist Howland, as he did, in 1738, in that
of Salisbury. As a member of the upper house, he took
an active part in its debates, and was always a supporter of the
interests of the crown and the church. He was con-
 sidered, in parliament, as a great authority in ecclesiastical
law, and frequently led the judgment of the house; and
such at length was the reputation which he had in the episco-
copal character, that upon the death of archbishop Potter,
in 1747, he was offered to succeed him in the see of Can-
terbury, which he declined on account of ill health, but after-
wards recovering, he accepted the see of London in 1749.
In 1751 he refused the leadership of the Temple; and was
very soon after incapacitated for any very active service: he
nearly lost the use of his limbs and speech, but still retained
the vigour of his understanding, and was capable of revising
and correcting a volume of sermons: this was followed by
four others, which are in high estimation. The bishop died
in 1761, in the 84th year of his age.
SHERMA, or CHERMA, in Geography, a province of
the kingdom of Morroco, which lies between the province
of Eia and that of Morocco, and has been dismembered
from that of Eia. See SHERMA.
SHERMAN, a town of America, in the state of Con-
necticut and county of Fairfield, containing 940 inhabi-
tants.

tolia; 48 miles W. of Bursa.
SHERONIA, a town of Egypt, on the right bank of
the Nile; 8 miles N. of Abu Gargé.
SHERRINGTON, in Biography, a composer of songs
in parts during the reign of Henry VHI, which have been
preferred with those of other contemporary composers in
the Fairfax MS. the most ancient book of the kind that we
have ever been able to discover. See FAIRFAX.
SHERRELL, a coast town of Africa, in the
kingdom of Allaba, generally 100 to 120 miles north of
Jamaica, and by the younger Juba named Carthage, in compli-
nance to Antinous. The town, was Dr. Shaw saw it, in
the year 1740, was of great extent for building, clear
water, and, such iron tools as are wanted in the
neighborhood; but a few years afterwards (1758) it was
entirely torn down by an earthquake. The town which
this town was situated, is not far from it to the
of Carthage; and we may likewise conceive that the
upper part of its town was founded from the river Niger.
and water's edge, and the same Moljac inscriptions,
that are very well preserved. They have a tradition,
that the ancient city was destroyed, as the new one was
lately, by an earthquake; and that the part, formerly very
large and considerable, was destroyed by the asenical
and other adjacent buildings being thrown into it by the
shock. The cotton, or sedenial harbor, that had a
communication with the western part of the town, is the bell
of this tradition; for when the sea is calm, and the water low,
(as frequently happens after long storms or earld s) all
over the area of it to many miles pillar and pieces of great
walls may be seen, that it cannot well be conceived how
they should have there without such a concurrence.
The port is nearly of a circular form, of 200 yards in diameter;
but the sealest part of it, which, till of late was towards
the coast, is now filled up with a bank of sand, that daily
increases. However, there still lies in the mouth of it a
small rocky island, which at present is the main shelter and
defence against the northern tempest. N. lat. 36° 35'.

SHEW-BREAD, in the Jewish Economy. The Hebrew (Exod. xxv. 30.) ד"^Josh 12", signifies literally "bread of faces, or of the faces." This denomination was given to the loaves of bread, which the priest of the week placed every Sabbath-day on the golden table in the sanctuary, before the Lord. These loaves were of a square form, with four faces, as the rabbins say, and were twelve in number, representing the twelve tribes of Israel. They supplied the place of those which had been expounded the whole week, and none could lawfully eat them but the priests. This offering was accompanied with frankincense and salt. Of the first fruits and tenth presented by the Israelites to the priests, the latter took that which was necessary for making the shew-bread, and for supplying the service of the temple with any thing else which it was their duty to furnish.

SHIBBOLETH, or Sibboletli, a Hebrew word which signified spica, or an ear of corn. It was used by way of distinguishing the Ephraimites from the men of Gil-lead. For the latter having killed a great number of the former, sent guards at all the pales of Jordan; and when an Ephraimite, who had escaped, came to the water-side, and desired to pass over, they asked him if he was not an Ephraimite? If he said no, they bade him pronounce Shibbolet. But he pronouncing it Shibboleth, according to the manner of the Ephraimites, and thus not enunciating the first letter, was killed on the spot: on this occasion, 42,000 Ephraimites were killed. By thus not distinguishing between the ש and the ח, the hebra and the shin, they exposed themselves to this massacre: hence the terms have been used to denote the trivial grounds on which contending parties, particularly in theological disputes, often proceed, and do so, till they can no longer imagine there could be, and actually to perforce, another one another.

SHIBKAH, in Geography, an extensive salt-plain of Algiers, overflowed in winter, but dry in summer; 10 miles S. of Oran.

SHICARAN, a town of Aftalian Turkey, in the province of Diarbekir; 18 miles W.S.W. of Hazon.

SHIDES. See Shingles.

SHIEL, Loch, in Geography, a lake in the parish of Ardnamurchan, and county of Inverness, Scotland; extending ten miles in length, and two in breadth. Near its centre rises an islet, called Island Fian, which contains the ruins of a chapel dedicated to the saint of that name. This lake discharges its waters into the Western ocean at Castle Tiorn, by the river Shiel. Statistical Account of Scotland, by Sir John Sinclair, vol. ii. 1792.

SHIELD, an ancient weapon of defence, in form of a light buckler, borne on the arm to fend off lances, darts, &c.

The form of the shield is represented by the escutcheon in coats of arms.

The shield was that part of the ancient armour on which the perions of distinction in the field of battle always had their arms painted; and most of the words used at this time to express the space that held the arms of families, are derived from the Latin name for a shield, suetus. The French escuyer, and esquifon, and the English word, escutcheon, or, as we commonly speak it, scutcheon, is evidently from this origin; and the Italian scudo signifies both the shield of arms, and that used in war.

The Latin name escusus, for the same thing, seems also to be derived from the Greek word ἔστου, to engrave; and it had this name from the several figures engraved on it, as marks of distinction of the person who wore it.

The shield in war, among the Greeks and Romans, was not only useful in the defence of the body, but it was also a token or badge of honour to the wearer, and he who returned from battle without it, was always treated with infancy afterwards.

People have at all times thought this honourable piece of armour the properest place to engrave or figure on the shields of dignity of the polifer of it; and hence, when arms came to be painted for families in after-times, the heralds always chose to represent them upon the figure of a shield, but with several exterior additions and ornaments, as the helmet, supporters, and the rest.

The form of the shield has not only been found different in various nations, but even the people of the same nation, at different times, have varied its form extremely; and among several people there have been shields of several forms and fizes in use, at the same period of time, and suited to different occasions.

The most ancient and universal form of shields, in the earlier ages, seems to have been the triangular, vulgarly called the heater shield, from its resemblance to that instrument of houfieyry. This we see instances of in all the monuments and gems of antiquity: our own most early monuments shew it to have been the most antique figure also with us, and the heralds have found it the most convenient for their purposes, when they had any odd number of figures to represent; as if three, then two in the broad bottom part, and one in the narrow upper end, it held them very well; or if five, they stood as conveniently, as three below, and two above. Most of the monumental figures of croisled legged knights are armed with triangular shields, which are generally a little convex, or curved in their breadth; their upper extremity terminated by a Line parallel to the horizon, and their sides formed by the interference of the segments of two circles. Such are generally represented on ancient feals and windows: sometimes, though not often, their surfaces are flat. On the inside of the Norman shields were two or more loops of leather, or wooden handles, through which the arm and hand were passed, when the shield was bared, and prepared for use; at other times it was carried by a leathern thong worn round the neck. The other form of a shield, now universally used, is square, rounded, and pointed at the bottom: this is taken from the figure of the Samnite shield used by the Romans, and since copied very generally by the English, French, and Germans. See Target.

The shield, though it was not entirely relinquished so long as the use of the long and short bows continued, seems to have undergone some alteration in its form; the triangular, or heater shield, gradually giving place to those of a circular or rectangular figure. Shields were first left off by the cavalry; they were, however, used in the army of King Edward I., at the siege of Karlavok, in the year 1300. A fort
A list of shields was worn by the Scots at the battle of Musselburgh, in the first year of Edward VI. Shields or bucklers seem to have been used in arrays and private quarters, by persons in the civil war, as late as the reigns of Elizabeth and King James I. The common appellation for a quarrelsome or fighting fellow about that period was a swallbuckler, that is, a breaker orehler of bucklers. Maurice, prince of Orange, was a great advocate for the shield, and even attempted to revive the use of it. This company of Dutch guards was armed with targets and roundels, and he formed a regular plan of exercise for them. The target and broad sword were the favourite arms of the Scotch Highlanders as late as the year 1746, and even after. Swords and bucklers were annually borne before great military officers, as insignia of their dignity: those carried before King Edward III. in France, are shown in Weilminster Abbey. The shield borne before the commandant of the forces on board the Spanish Armada, is preferred in the Tower, and a sword was borne before the bishop of Norwich, as commander of the troops with which he intended to serve King Richard II. Many of the ornamented metal shields, and many of the very large swords, were designed for this use.

The Spaniards and Portuguese have the like general form of shields, but they are round at the bottom, without the point; and the Germans, beside the Samnite shield, have two others pretty much in use: these are, 1. The bulging shield, distinguished by its swelling or bulging out at the flanks; and, 2. The indent shield, or shield chancree, which has a number of notches and indentings all round its sides. The use of the ancient shield of this form was, that the notches served to retl the lance upon, that it might be firm while it gave the thrust; but this form being less proper for the receiving armorial figures, the two former have been much more used in the heraldy of that nation.

Another form of shield derived its name rounded, or rondache, from its circular figure; it was made of ovals, boards of light wood, finewor or ropes, covered with leather, plates of metal, or flueck full of nails, in concentric circles, or other figures. The shields and roundels of metal, particularly those richly engraved or embossed, seem rather to have been insignia of dignity, anciently borne before generals or great officers, than calculated for war; most of them being either too heavy for convenient use, or too light to reflect the violence of a stroke either from a sword or battle-axe. Although most roundels are convex, yet there are many that are concave, and consequently an umbo. The handles are placed as in the shield and target. The roundel seems, in many instances, to resemble the Roman palm. For another form of shield, see PAVIAN.

Besides this different form of the shield in heraldry, we find them also often distinguished by their different positions, some of them standing erect, and others standing various ways, and in different degrees; this the heralds express by the word pendent, hanging, they seeming to be hung up, not by the centre, but by the right or left corner. The French call these en pendent, and the common antique triangular ones en ancien. The Italians call this fuoco pendente; and the reason given for exhibiting the shield in these figures in heraldry is, that in the ancient tilts and tournaments, they who were to joust at these military exercises, were obliged to hang up their shields, with their armories or coats of arms on them, out at the windows and balconies of the houses near the place; or upon trees, pavilions, or the barriers of the ground, if the exercise was to be performed in the field. Those who were to fight on foot, according to Columbier, had their shields hung up by the right corner, and those who were to fight on horse-back, had theirs hung up by the left.

This position of the shields in heraldry is called en aile by some writers, though by the generality pendente.

It was very frequent in all parts of Europe, it is even given between the eleventh and fourteenth centuries; but it is to be observed, that the hanging by the left corner, as it was the token of the owner's being to fight on horse-back, for it was esteemed the most honorable and noble situation; and all the pendant shields of the tom of the royal family of Scotland and England, and of our nobility, at that time, are thus hanging from the left corner. The hanging on this corner was a token of the owner's being of noble birth, and having fought in the tournaments before; but no sovereign ever had a shield pendant any way, but always erect, as they never formally entered the lists of the tournament.

The Italian generally have their shields of arms of an oval form; this seems to be done in imitation of those of the popes, and other dignified clergy; but their herald, Petrou Saneto, seems to regret the use of this figure of the shield, as an innovation brought in by the painters and engravers, as most convenient for holding the figures, but derogatory to the honour of the popes, as not representing either antiquity, or honours won in war, but rather the honours of some citizen, or person of learning. Some have carried it so far, as to say that these, who either have an ancient title to nobility, or have fulfilled it by any unworthy action, cannot any longer wear their arms in shields properly figured, but were obliged to have them painted in an oval or round shield.

In Flanders, where this author lived, the round and oval shields are in the direst he speaks of; but in Italy, besides the popes and dignified prelates, many of the first families of the laity have them.

The secular princes, in many other countries, also retain this form of the shield, as the most ancient, and truly expressive of the Roman clypeus. Niflet's Heraldry, p. 12. Componille, Herald.

SHIELD, in Heraldry, denotes the escutcheon, or field whereon the bearings of the armoury are placed. See ESCUTCHEON.

SHIELDRAKE. See TADorna.

SHIELDS, WILLIAM, in Biography. Though this musical professor, for the happiness of his acquaintance, still ranks with the living, and we can tell our contemporaries nothing concerning his worth and talents which is not already well known, yet as his name has penetrated into Germany, and has furnished an article in Gerber's Continuation of Walther's Musical Lexicon, we cannot refuse confessing the account given of his compositions in that work.

SHIELDS, North, in Geography, a market-town and sea-port in Cottleward, county of Northumberland, England, is situated near the entrance of the river Tyne, on its northern bank, at the distance of half a mile W.S.W. from the town of Tynemouth, and 279 miles N. by W. from London. This town is indebted for its origin to the monks of Tynemouth priory, who erected a number of houses here, and encouraged the settlement of ship-owners and tradesmen, early in the reign of Edward I. They at the same time formed a harbour here for lading and unloading of ships, and established a weekly market and fairs; but the exercise of these privileges having been disputed by the corporation of Newcastle, they were prohibited by a decree of the inferior judges. From that period it continued to be a mere fishing village till the middle of the seventeenth century, when new efforts were made to render it an important sea-port, for which purpose its situation is admirably adapted. Cromwell, who then held the reins of government, with the consent of
parliament passed an act, in which it was ordered, "that sufficient and well-fenced ballast-ponds, quays, and slipways, be built at Shields," and "that North Shields be made a market-town two days in the week, for the relief of the country and garrison of Tynemouth, and for all the great confluence of people and fleets of ships."

In consequence of this act, North Shields would soon have become a place of great commercial importance; but on the reformation, the rights claimed by the corporation of Newcastle were restored; and North Shields was deprived of its markets and fairs. From that time every mean which a narrow and illiberal policy could devise, was employed to retard the growing prosperity of this port; but towards the conclusion of last century, many of the unjust restrictions which formerly prohibited were removed, and the different trades permitted to be followed without molestation. It was only, however, in the year 1804, that North Shields obtained the privilege of holding a weekly market and fairs, by petition of the inhabitants to the duke of Northumberland, as lord of the manor of Tynemouth, in which the feite of North Shields is included. The day of the first opening of the market was ushered in with great rejoicings, and at noon a salute of cannon announced the completion of the long wished-for event. The market-day is Friday, and the fairs are held on the last Friday in April, and the first Friday in November.

North Shields, from these circumstances, and the patriotic exertions of the duke of Northumberland, is become, in the course of a few years, a large and populous town. It contains many handsome streets, and two elegant squares, besides the market-place, lately formed, which may rival any provincial market-place in the kingdom. On one side is a spacious quay, with a crane for the delivery of goods, where ships of 500 tons burden may discharge or take in cargoes with perfect safety. Another side is adorned with a noble flone building, which is now used as an inn, and is surmounted with the Percy arms. North Shields, forming part of the parish of Tynemouth, has no parish church, but it poifesses several chapels of ease, and meeting-houses for almoft every class of dissenters. The other public structures and establishments here are a theatre, a dispensary, and a large school-house, erected by subscription, in commemoration of the royal jubilee, where a great number of boys and girls are educated on the Lancastrian plan. Here are likewise many well-conducted and flourishing benevolent societies, an asylum for sick and friendless seamen, and a lying-in-hospital. A subscription library has also been opened in North Shields, and is said to contain an extensive collection of valuable books.

The harbour of North Shields is calculated to accommodate 2500 fall of ships; and in spring tides, vessels of 500 tons burden can pass the bar without danger. The vessels belonging to this port, exclusive of small coalers, are stated in the "Historical View of Northumberland," to amount to 1000; but this number, we presume, includes the shipping of Newcastle and South Shields also, of which North Shields may justly claim one half. One great inconvenience complained of by the commercial interest here and at South Shields, is the want of an independent custom-house; which obliges the captains of all vessels falling from this port to clear their ships at Newcastle, a distance of ten miles up the river.

The principal trade of North Shields, as of the river Tyne generally, consists in the exportation of coals to London, and other parts of the eastern coast of England; but some vessels are likewise employed in the Baltic and American trade; and during the late wars, a great number was hired to government for the transport service. The manufactures established here are chiefly such as depend upon the shipping interest, as ship and boat-building, rope and sail-cloth making, brewing, baking, &c.; but there are likewise in North Shields a foundery for cast iron, an extensive tannery, one kilnery, a tobacco manufactury, a glove manufactury, and five hat manufactories.

The feamen of this port are frequently very riotous and turbulent, when they want a rife of wages, or are in any way dissatisfied with the conduct of the ship-owners. In these instances they have generally acted upon a regular plan; forcing every sailor to remain on board, and preventing any vessel from proceeding to sea until their demands were complied with. An alarming combination of this kind was formed in the months of September and October last, (1815,) and threatened such serious consequences, as to render government interference necessary, when order was happily restored without bloodshed.

North Shields, according to the parliamentary returns of 1811, contains 824 houses, and a population of 7699 persons.

For some further account of this port and the adjoining country, see the articles Newcastle, Tyne, Tynemouth, and South Shields. A Historical and Descriptive View of the County of Northumberland, &c. two vols. 8vo. Newcastle, 1812.

Shields, South, a market-town and sea-port in the parishes of Jarrow, east division of Chelfer ward, and county palatine of Durham, situate directly opposite to North Shields, at the distance of 21 miles N.N.E. from the city of Durham, and 278 N.N.E. from London. Like North Shields, it owes its importance chiefly to the coal trade and shipping interest, but the proportion of manufactures carried on here is greater than at the former town. About fifty years ago this place was divided upward of two hundred salt pans, but that branch of businefs has greatly declined, and others of higher importance are substituted in its stead, as ship-building, and the manufacture of glass, soap, &c. South Shields was constituted a market-town by bishop Trevor, in the year 1770. The market-day is Wednesday, and there are two annual fairs, on the 24th of June and the 4th of September. The vessels belonging to this port amount to about 300 in number. The church, which is a chapel of ease under Jarrow, is evidently a structure of great antiquity; the style of its architecture being that of the Anglo-Norman era. Some antiquaries are of opinion that there was a Roman station at the point of land near South Shields, which formed the southern entrance into the Tyne, and the conjecture is certainly probable, though by no means authenticated as a fact.

South Shields, like North Shields, has of late years greatly increased in population and extent; but it is deficient of many of the advantages possessed by the other. Here are, beside the established church, several dissenting meeting-houses; also several benefit societies and charity-schools. The petty feclions for the east division of Chelfer ward are held in the town-house here, which is a respectable building, situate in the centre of the market-place. Most of the Iterets of this town, however, are narrow, and the houses very indifferently built. According to the parliamentary returns of 1811, it contains 528 houses, and a population of 9501 persons.

About two miles to the westward of South Shields is the village of Jarrow, celebrated for its monastery, which was originally founded about the year 683; but has since been frequently rebuilt. This religious house was dedicated to St. Paul, and appropriated to the reception of Benedictine monks.
works. Its remains, together with the church of Jarrow, occupy the summit of an elevated ridge, but display little worthy of notice. The History and Antiquities of the County Palatine of Durham, by W. Hutchinson, 1815.

SHIFRAL, a market town in the parish of Shifnal, hundred of Bridleway, and county of Salop, England, is situated at the distance of 19 miles E. by S. from Shrewsbury, and 143 miles N.N.W. from London. The market day here is Friday weekly, and there are fairs on the 1st of August and the 22d of November. The petty fairs for Shifnal division of the hundred are held here; but in other respects this town is a thriving place, the whole parish, which is extensive, and includes four townships, containing, according to the parliamentary returns of 1811, only 868 houses, and 4,061 inhabitants.

SHIFT, a term in Music, used for conducting the hand on the finger-board of the violin, and instruments with a neck.

By moving the left hand a little towards the bridge, and placing the first finger where the second was, on the second string of the violin, in the natural position of the hand, it will produce C unaltered in B, and the little finger will then produce C on the first string, its octave; and this is called the half shift. The first, or whole shift, is placing the first finger where the third was, in the natural position of the hand, which will produce D on the second string, and the little finger its octave on the first. The next movement of the hand towards the bridge is placing the first finger on E of the second string, when the little finger will give its octave on the first string, and this is termed the double shift; each shift commanding all the intermediate notes of an octave to the first finger. By this means a half, a whole note, or any number of notes, may be gained upwards upon each string, to the end of the finger-board. A readiness at these shifts, on short notice, in all keys, and in true intonation, is said to be knowing the finger-board well. At present (1809) high lute parts for the violincello are written in the treble clef.

Shifts, in Ship-Building, a term applied to disposing the butts of the planks, &c. so that they may over-arch each other, without reducing the length, and so as to gain the most strength. The planks of the bottom, in British-built ships of war, have a fix-feet shift, with three planks between each butt, so that the planks run twenty-four feet long. In the bottoms of merchant-ships, they have a fix-feet shift, with only two planks between each butt, making but eight feet planks in length. The shift of the timbers is from three feet to ten feet six inches in length, according to the size of the ship.

SHIFTED, in Sea Language, denotes the state of a ship's ballast or cargo, when it is shaken from one side to the other, either by the violence of her rolling in a turbulent sea, or by an extraordinary inclination to one side, when under a great preflure of wind. This circumstance rarely happens, unless to those cargoes which are loaded in bulk, as corn, salt, and such materials.

Shifter, as expressed of the wind, implies altered.

Shifter, a person appointed to assist the ship's cook, particularly in washing, steeping, and shifting the salt provisions.

SHIFTING, in Ship-Building, the act of setting off the length of the planks, &c. of a ship, so that the butts may over-arch each other, as to produce a good shift. (See Shift.) Replacing old fluff with new is also called shifting.

Vol. XXXII.
mer. In performing the business, it is mostly proper to remove the plants from the smaller to the larger pots, with the balls of earth about the roots, either wholly, or some of the outward old earth, the dry or matted radical fibres only being carefully trimmed away, so as not to disturb the principal roots in the bodies of them, as by this means the plants receive but little check in their growth by the removal. Sometimes, when any particular plants, shrubs, or trees, &c. in their pots, discover by their tops that they are in a declining state, as probably the defect may be either in the root, or the old balls of earth, it may be proper to shake all the earth entirely away, in order to examine the roots, and to trim and dress them as the case may require, replanting them in entire fresh compost or mould.

And in preparing for this sort of work, where necessary to give larger pots, &c. it is proper to provide them of suitable sizes, in some regulargradation larger than the old ones, according to the nature and growth of the plants, the whole being placed ready, with a proper quantity of fresh compost earth, in proportion to the number and size of the plants intended to be shifted; then let the whole plants intended to be removed with balls, be taken out of their old pots separately, with the whole balls or clumps of earth about the roots as entire as possible; and when large, or tolerably full, with a knife trim off some of the outward loofed earth, and the extreme fibres of the roots; but when small, and adhering together compactly, the whole may be preferred entire; and in either case, where there are very small, dry, or decayed fibres surrounding the balls, they should be trimmed as it may seem necessary: in those of a fresh lively growth, the loose straggling parts only should be cut away. The requisite pruning, trimming, or dressing in the heads or tops, should also be given where it may seem proper, according to the state of growth, and the natural habit of the different plants; but many sorts require little or none of this sort of attention.

Then having prepared the intended pots for the reception of the plants, by placing some pieces of tile or oyster-shell, &c. loosely over the holes at bottom, and laid in a little fresh earth, two, three, or four inches deep, or more, according to the size of the pot, the plant should be set in with its ball of earth, as above, filling up around it with more fresh mould, raising it an inch or two over the top of the ball; and giving directly a moderate watering, to let the earth close about the ball and roots regularly in every part, in a proper manner. If such cafes where the ball in particular plants appears very compactly hard and binding, it may be proper to loosen it a little, by thrashing a sharp-pointed stick down into the earth in different parts, giving it a gentle wrench, to open the earth moderately; or sometimes it may also be proper to trim away some of the old earth on the top and sides, then planting it as above, and filling up round and over the ball with fresh earth, and watering it afterwards.

Also, in shifting hardy or tender, shrubby, succulent, or herbaceous plants, when any appear of a fickle, weak, or unhealthy growth, it may be advisable to clear off a considerable part of the outward old earth from the balls about the roots, or, in some cafes, to shake it wholly away, that the defects in the growths, occasioned either by faults in the roots or in the earth, may be removed by pruning out any decayed or bad parts of the roots, and replanting them wholly in fresh earth.

And sometimes particular sorts of plants in pots require shifting, more for the advantage of having fresh earth, than for want of new, or larger pots; and as in this cafe some of the fame pots may be still of an eligible size to repot them in, these pots should be well cleaned from all the adhering parts of the old earth, and be replenished with entire new, at the time of repotting the plants; which being removed out of their pots, either with the entire balls about the roots, and part of the old mould cleaned off all round, to admit of a larger portion of fresh earth in the pot at replanting; or in some, appearing of an injurious or declining habit, the whole balls of old earth displaced clean to the roots; then having furnished the pots with fresh earth, the plants should be replaced in them, filling up the pots regularly with a sufficiency of the fame fresh mould, and fulfilling with a moderate watering to settle the whole close about their roots.

Likewise after shifting, when the plants are not watered at the time, a moderate watering, both to the earth in the pots to settle it close about the roots, and in mossy forts highly over the tops or heads of the plants, should be given, in order to wash off any fineness, then the pots of plants should be let in their respective situations in the garden, &c.: the hardy kinds, if warm sunny weather, may be placed in a shady border for two or three weeks, till they have fresh fresh root in the new earth: the tender sorts should be placed in their places among the green-house and house-plants, or to have the benefit of those in the middle of hot sunny days, till fresh struck, or probably some of the more tender particular sorts may require to be plunged in a hot-bed or bark-bed, especially some of the flou kinds: some principal sorts of the more curious or tender green-house plants, in order to expedite their fresh-rooting more effectually; and sometimes tender annuals in hot-beds, potted in their early young growth, may require to be replanted in the hot-bed to fresh strike, and forward them till June; but generally all the full ground or open air plants only require a little occasional shade in hot dry weather the first two or three weeks, and some shifted with full balls about the roots, only need occasional watering; afterwards, on the whole, both the hardy and tender kinds should have repeated moderate waterings given them, according to their kinds.

SHIFTS, such parts of a farm as are allotted for the reception of either rock or crops. It is also a term applied to the rotations of cropping lands: thus we have three, four, five, and fixe-course shifts. See Course of Crops.

SHIASCHEKOTAN, in Geography. See S ASKUTAN. SHIITES, in the History of Mohammedan Sects, were the opponents of the Kharijites; see that article. This name properly signifies feilqciras or adherents in general, but is peculiarly used to denote those of Ali Ebn Abi Taleh; who maintain him to be lawful caliph and imam, and that the supreme authority, both in spirituals and temporals, of right belongs to his descendants, notwithstanding they may be decried of it by the injustice of others, or their own fear. They also teach, that the office of imam is not a common thing, depending on the will of the vulgar, so that they may fet up whom they please; but a fundamental affair of religion, and an article which the prophet could not have neglected, or left to the fancy of the common people; nay some, thence called Imamians, go so far as to assert, that religion conficts solely in the knowledge of the true imam. The principal sects of the Shiites are five, which are sub-divided into an almost incredible number; so that some understand Mohammed's prophecy of the seventy odd sects, of the Shiites only. Their general opinions are, 1. That the peculiar designation of the imam, and the testimonies of the Koran and Mohammed concerning him, are necessary points. 2. That the imams ought necelarily to keep themselves free from light sins as well as more grievous. 3. That every one ought publicly to declare who it is that he ad-
here to, and from whom he separates himself, by word, deed, and instrument, and that hence there should be no dissimulation. But in this last point some of the Zendases, a fact to named from Zend, the seat of Ah, turned Zoroaster, and great grandchild of Ah, differed from the rest of the Shiites. As to other articles, wherein they agreed not, some of them were pretty near to the notions of the Mozaffarites, others to those of the Moplillah holies, and others to those of the Sunnites. Among the latter of those, Mohammed al Baker, another son of Zoroaster, seems to claim a place: for, in opposition to the will of God, that was, that God will the something on us, and the something from us, and that he will the from us to be hath revealed to us, for which reason it thought it proper that we should employ our thoughts about these things which God will have in us, and neglect the other in which he will have us; and as to God's decree, he held that the way lay in the middle, and that there was neither compulsion nor free liberty. A sect of the Khattabians, or disciples of one Ibn Khattab, is too peculiar to be omitted. These maintained a paradise to be no other than the pleasures of this world, and kill-fire to be the pains thereof, and that the world will never decay: which propitious being first laid down, it is no wonder they were further, and declared it lawful to indulge themselves in drinking wine and whoring, and to do other things forbidden by the law, and also to omit doing the things commanded by the law.

Many of the Shiites carried their veneration for Ali and his descendants so far, that they transgressed all bounds of reason and decency; though some of them were less extravagant than others. The Gholaites, who had their name from their evergreen zeal for their imams, were so highly transported therewith, that they raised them above the degree of created beings, and attributed divine properties to them; transgressing on either hand, by deifying of mortal men, and by making God corporeal: for one while they liken one of their imams to God, and another while they liken God to a creature. The sects of these are various, and have various appellations in different countries. Abd'allah Ebn Saba, (who had been a Jew, and had adhered the same thing of Josua the son of Nun,) was the ring-leader of one of them. This man gave the following salutation to Ali, viz. Thou art thou, i.e. thou art God: and hereupon the Gholaites became divided into several species; some maintaining the same thing, or something like it, of Ali, and others of some of one of his descendants; affirming that he was not dead, but would return again in the clouds, and fill the earth with justice. But howsoever their disagreements in other things, they unanimously held a metamorphosis, and what they call Al Haqul, or the defects of God on his creatures; meaning thereby that God is present in every place, and speaks with every tongue, and appears in every individual person; and hence some of them affected their imams to be prophets, and at length gods. The Nofarian, and the 19shans taught that spiritual substances appear in großer bodies; and that the angels and the devil have appeared in this manner. They also affect that God hath appeared in the form of certain men; and since, after Mohammed, there hath been no man more excellent than Ali, and, after him, his sons have excelled all other men, that God hath appeared in their form, spoken with their tongue, and made use of their hands, for which reason, say they, we attribute divinity to them. And to support these blasphemies, they tell several miraculous things of Ali, as his moving the gates of Khabar, which they urge as a plain proof that he was endowed with a particle of divinity, and with sovereign power, and that he was the person in whole from God appeared, with what he had created all things, and with what things he was possessed; and hence they say that he was a god, not of earth and earth. In this respect, if they speak well these things, which are God himself, they apply them to Ali. This was the case among the Shiites, however, in making their faith in the divine nature, and the property of God, of the divine character, and far from being pernicious to this faith, that most of the other Mohammedans that are treated with the same mode: they have many famed among them, and among the Shiites especially, who pretend to be really related to heaven, and who hold of strange revelations before the credulous people. To this account of the Shiites of the first and second father, a brief mention of the great schism at this day following between the Sunnites and the Shiites, or partisans of Ali, and maintain on either side with implacable hatred and furious zeal. Though the difference arise at first on a political occasion, it has, notwithstanding, been so well supported by additional circumstances, and the spirit of contradiction, that each party denied and anathematized the other as abominable heretics, and farther from the truth than the heathenish or the Jews. The Shiites point wherein they differ are, 1. That the Shiites reject Ali, Omer, Osman, and Othman, the three first caliphs as usurpers and intruders; whereas the Sunnites acknowledge and respect them as rightful imams. 2. The Shiites prefer Ali to Mohammed, or, at least, esteem them both equal; but the Sunnites admit neither Ali, nor any of the prophets, to be equal to Mohammed. 3. The Shiites charge the Shiites with corrupting the Koran, and neglecting its precepts; and the Shiites retort the same charge on the Sunnites. 4. The Sunnites receive the Sana, or book of traditions of their prophet, as of canonical authority; whereas the Shiites reject it as apocryphal and unworthy of credit. And to these disputes, and some others of less moment, is principally owing the antipathy which has long reigned between the Turks, who are Sunnites, and the Persians, who are of the sect of Ali. Sale's Koran, introd.

SHILACON, in Geography, a town of Egypt, on the E. side of the Nile; 8 miles N. of Cairo.

SHILL, in Agriculture, provincially to separate the rind, bulk, or skin, as of cats, or other crops. It also signifies the turning a small portion of milk into curd.

SHILLAY, in Geography, a small island near the W. coast of the island of Lewis; 5 miles W.S.W. of Toe Head. N. lat. 53° 48'. W. long. 7° 14'.

SHILLELAH, a town of Algiers, anciently Taraphtium; 10 miles S.W. of Burg Hamza.

SHILLER-STONE, or Shiller-Spar, in Mineralogy, the disseh metalloid of Halyj, a mineral nearly allied to serpentine. (See SERPENTINE.) It is considered by some mineralogists as a crystalline variety of that rock; in which it generally occurs, either in beds or disseminated. Its colour is commonly olive-green, with a shining luster, which is sometimes semi-metallic. The structure is lamellar, with joints in one direction: it yields to the knife. In the vicinity of New Radnor, in Wales, there is a rock of this mineral intermixed with slate.

SHILLING, an English silver coin, equal to twelve pence, or the twentieth part of a pound.

Froboesus derives the Saxon seilling, whence our shilling, from a corruption of sambia; proving the derivation by several texts of law, and among others, by the twenty-sixth law, De annuis legatis. Skinner deduces it from the Saxon field, shield, by reason of the escutcheon of arms upon it.

Bishop Hooper derives it from the Arabic fede, signi-
SHILLING.

fying a weight; but others, with greater probability, deduce it from the Latin *sicilicus*, which signified in that language, a quarter of an ounce, or the forty-eighth part of a Roman pound. In confirmation of this etymology, it is alleged, that the shilling kept its original signification, and bore the same proportion to the Saxon pound, as *sicilicus* did to the Roman and the Greek, being exactly the forty-eighth part of the Saxon pound; a discovery which we owe to Mr. Lambard. *Explicatio Rerum et Verborum in Legg. Sax. voc. Libra*.

Others say, that the shilling was at first a German appellation, *schelling*; coins of which name had been struck at Hamburg in 1407.

However, the Saxon laws reckon the pound in the round number at fifty shillings, but they really coined out of it only forty-eight; the value of the shilling was five-pence; but it was reduced to four-pence above a century before the Conquest; for several of the Saxon laws made in Athelstan's reign, oblige us to take this ultimate. Thus it continued to the Norman times, as one of the Conqueror's laws (Legg. Sax. p. 221.) sufficiently ascertains; and it seems to have been the common coin by which the English paymen was adjusted. After the Conquest, the French solide of twelve-pence, which was in use among the Normans, was called by the English name of shilling; and the Saxon shilling of four-pence took a Norman name, and was called the *great*, or great coin, because it was the largest English coin then known in England.

The *great*, from the French *gros*, a large piece, was introduced by Edward III. in 1354, and continues, though not in common circulation, to this day. The half-*great*, or two-pence, is of the same date and continuance. In Scotland, about the year 1553, were first coined *teltouns*, or shillings, bearing the bust of the queen, and the arms of France and Scotland on the reverse: they being of the same intrinsic value as that of England, were then worth four shillings, and the half-*teltoun* two, Scotch money.

It has been the opinion of bishops Fleetwood and Gibson, and of the antiquaries in general, that though the method of reckoning by pounds, marks, and shillings, as well as by pence and farthings, had been in constant use even from the Saxon times, long before the Norman conquest, there never was such a coin in England as either a pound or a mark, nor any shilling or *teltoun*, till the year 1553, 1504, or 1505; but in the twentieth year of King Henry VII. (A.D. 1505) a few silver shillings, or twopence, were coined, being about one-half the size of the modern shillings, or forty out of a pound weight of silver, which were fair and broad pieces. These, however, it is said, have long since been solely confined to the cabinets of collectors.

Mr. Clarke combats this opinion, alleging, that some coins mentioned by Mr. Folkes, under Edward I. were probably Saxon shillings new minted, and that archbishop Aelfric (Gram. Sax. p. 52, at the end of Sommer's *Saxon Diction*), expressly says, that the Saxons had three names for their money, *viz.* manceues, *schellings*, and *pennies*. He also urges the different value of the Saxon shilling at different times, and its uniform proportion to the pound, as an argument, that their shilling was a coin; and the testimony of the Saxon gospels, in which the word we have translated *pieces of silver*, is rendered shillings, which, he says, they would hardly have done, if there had been no such coin as a shilling then in use. Accordingly, the Saxons expressed their shilling in Latin by *sicilus* and *argentus*.

He farther adds, that the Saxon shilling was never ex-preffed by *solidus*, till after the Norman settlements in England; and howsoever it altered during the long period that elapsed from the Conquest to the time of Henry VII. it was the most constant denomination of money in all payments, though it was then only a species of account, or the twentieth part of the pound *sterling*; and when it was again revived as a coin, it lefled gradually as the pound *sterling* lefled, from the twenty-eighth of Edward III. to the forty-third of Elizabeth. Clarke on Coins, &c. p. 120. 152. 155. 200. 376.

Silver farthings sealed with Edward VI., but the silver half-pence continued the folc coins till Charles II. The silver penny was much used to the end of the reign of George I., and so far from being no where to be found, as Hume affirms (Hist. vol. vi.), is superabundant of every reign since that period, not excepting even the present reign of George III.

In the year 1560, there was a peculiar fort of shilling struck in Ireland, of the value of nine-pence English, which passed in Ireland for twelve-pence. The motto on the reverse of thefe is, *POSUI DEUM, ADUOTORUM MEUM*.

Eighty-two of these shillings, according to Malynes, went to the pound, they therefore weighed twenty grains one-fourth each, which is somewhat heavier in proportion than the English shilling of that time, sixty-two of which went to the pound, each weighing ninety-two grains seven-eighths; and the Irish shilling being valued at the Tower at nine-pence English, that is, one-fourth part less than the English shilling, it should, therefore, proportionably weigh one-fourth part less, and its full weight be somewhat more than sixty-two grains; but some of them found at this time, though much worn, weighed sixty-nine grains. In the year 1598, five different pieces of money of this kind were struck in England for the service of the kingdom of Ireland.

There were shillings to be current in Ireland at twelvepence each; half shillings to be current at five-pence; and quarter shillings at three-pence.

Pennys and halfpennies were also struck of the same kind, and went for the payment of the army in Ireland. The money thus coined was of a very base mixture of copper and silver; and two years after there were more pieces of the same kinds struck for the same service, which were still worse; the former being three ounces of silver to nine ounces of copper; and the latter only two ounces eighteen pennyweights, to nine ounces two pennyweights of the alloy. Simon's Irish Coins.

The Dutch, Flemish, and Germans, have likewise their shilling, called *fcheling*, *felling*, *faden*, &c.; but these, though of the same weight or fineness with the English shilling, are not current at the same value. See *SHILLING* and *SKILLING*.

The pound Flemish in accounts is divided into twenty shillings, and subdivided into twelve gros or pence Flemish. The coins in Holland are good shillings, or ecalins, and half ditto, at fix and three fivers; untampered or bare shillings reckoned at five and a half fivers, and called fifthealls. At Hamburg, accounts are kept in shillings, fixteen of which are equal to a mark, and each containing twelve pence. Sometimes in pounds, shillings and pence Flemish; the pound being equal to twenty shillings, and the shilling equal to twelve-pence or gros.

The English shilling is worth about twenty-three French sous; thole of Holland and Germany about eleven sous and a half; thole of Flanders about nine. The Dutch shillings are also called *sols de gros*, because equal to twelve gros. The
The Danes have copper bullocks, worth about one-fourth of a farthing per head. See Coins.

SHILLUK, in Geography, a town of Africa, in the kingdom of Senmara, on the E. side of the river Behr-el-Ahmad, and not far removed from it. This town is built of clay, and its inhabitants are idolaters. They have no other clothing than bands of long gowns, which they pull round the waist and between the thighs. They are all black, and those of both sexes have their heads. The people of Shilluk have the dominion of the river, and take toll of all passengers, in such articles of trade as pass among them. These people, who alone import corn from their command of the river, are represented as hospitable to those who come among them in a peaceable manner, and as never betraying to whom they have once avowed friendship; 50 miles W. of Senmara.

SHILOH, in Scripture Criticism, a term that occurs in Jacob's celebrated prophecy concerning the Messiah (Gen. xlix. 10.): concerning the etymology and application of which, biblical commentators have differed in opinion. "The sceptre shall not depart from Judah, and a law-giver from between his feet; till Shiloh come: and to him shall the gathering of the people be." The word Shiloh, says one writer (Mr. Mann), is a modern reading: unknown in any other part of the scripture, or any of the old commentators; coined by the Jewish correctors of the lxx into שילוח, a word of no figurative signification; whereas the LXX read שָׁלֹה, that is, שֶׁלֹה; he, to whom it is; he, to whom it: שֶׁלֹֹב, sceptre, belongs; שֶׁלֹה, he for whom it is referred, as it is in the original belt copy of the LXX version, as Justin Martyr long ago affirmed, (Dial. cum Tryph.), and as it now stands in the Alexandrian MS. And if this be the true meaning, it plainly refers to the king of the Jews; for whom the sceptre was referred, and to whom the people were to be gathered. Mr. Amworth and some others render Shiloh the prophetor or safe-maker; others the peace-maker, from שלום, all which agree to the same person. But the most probable interpretation, as the author of Mordecai's Letters, (Mr. Taylor,) apprehends, is given us by the very learned and judicious Dr. Delitzsch, professor of Arabic at Oxford. He understands the true etymology of the word Shiloh to remain in the Arabic שלום, which bears the same idea as the Hebrew שָׁלֹה, and is etymologically equivalent to it. According to this etymology, Shiloh will be the deliverer of dills from destruction: a title, which justly belongs to Jesus Christ, the Lord of life, and Saviour of the world. If it should be objected to this etymology, that the text (1) is wanting in the Septuagint and the LXX, he observes, that in the Samaritan copy of Genesis, xxxix. 10. the word is written without the final letter ש, as it is likewise in one of the most ancient Hebrew MSS. which Dr. Kennicott has consultated on this text. Some moderns have pretended, in order to evade the prophetic force of the text, that the sceptre departed from Judah before the advent of Christ, by its falling into the hands of foreigners, which objection is sufficiently answered by Cunæus (De Republ. Heb. l. 50. c. 9.) and others, who have shown, that the text only regards the continuance of the Jewish state; and that Jews, as separated from Israel, should remain a kingdom till the coming of the Messiah. On the other hand, Abrahavan and others suppose, that the sceptre is not yet departed from Israel; and Mæstlin and other scholars, that it is still in the hands of the tribe of Judah. The ancients undoubtedly understood this text of the Messiah. The Chaldean Paraphrast says, "He that hath dominion shall not be taken away from Judah, nor a tribe from his children's children, until the time when Christ shall come, as the dominion, and he shall the people that sat not upon a throne." And the Jerusalem Targum says, "Kings shall not sit from the house of Judah, nor doctors that teach the law from the children of the children of Judah, until the time that Christ shall come, whose kingdom is, and all the kings of the earth shall be before him." So that both the Targums confirm the literal sense, that the people (i.e. both Jews and Gentiles) shall gather about Christ; or, in other words, that the people spoken of shall be the prime that should reign over them. The LXX read this in place; and that this should happen before Judah should cease to be a kingdom, which is verified by fact. Ben Meriba's Letter, Letter iv.

SHILOH or SHEL, in Ancient Geography, a famous city of Ephraim (Josh. xiii. xvi. xxvi.), 12 miles distant from Bethlehem or Saksim, according to Eusebius, or 10 miles according to Jerome, and situated, according to both, in Arabatha. In Jerom's time this city was ruined, nothing remaining but the foundation of the altar of burnt offerings, which had been erected when the tabernacle was there. At Shiloh, Joshua assembled the people to make the second distribution of the land of promise. (Josh. xvi. 1, 2, 3.) Here the tabernacle of the Lord was set up, when the people were settled in the country. (Josh. xix. 1.) The ark and the tabernacle of the Lord continued at Shiloh, from A.M. 2560, when it was set up by Joshua, to A.M. 5888, B.C. 1116, when it was taken by the Philistines, under the administration of the high-priest Eli. At Shiloh Samuel began to prophesy. (1 Sam. iv. 4.) Here the prophet Abijah dwelt. (1 Kings, xiv. 2.) Jeremiah foretold that the temple of Jerusalem should be reduced to the same condition as Shiloh was. (Jer. vii. 12, 14. xxvi. 6, 9.) After the return of the ark out of the country of the Philistines, instead of returning it to Shiloh, it was taken to Kirjath-jearim. (1 Sam. vi. 21.) Mr. Roland conjectures, that from the name Shiloh, Paulinas (l. vii. c. 24.) took occasion to say, that Silenus, the companion of Bacchus, was buried in Palestine. Benjamin of Tudela affirms, that the tomb of Samuel was to be seen here.

SHIM in Agriculture, a tool of the tillage kind, used in ploughing down, and reducing the more stiff and heavy parts of land, as well as cutting up and clearing them from weeds. They are made in different forms and constructions, to suit different purposes. In the Hertford Agricultural Survey by the Board of Agriculture, the writer remarks, that a tool of this kind is in use by Mr. Calvert, of Albury, which differs from those usually employed, in which the cutting-iron or blade, for which the work it is adapted for, that of cutting up weeds on two-bout or four-furrow Exile ridges, or of clearing land without ploughing or burying the soil, is a small segment of a large circle. It dispatches a ridge at a time, and is an implement that performs its business well, and which deserves the notice of the tillage-farmer in other places. It is readily altered for that work, and is said to be had recourse to by other farmers with success in the same district.

And an useful tool of this sort has also been recommended by Mr. Young, in his Annals, the hint of which he took from the Berkshire one, and to which the beam and block is capable of being applied. In a wide interval, the three shares may be worked on a level. Between the rows of cabbages, after earthing up, the two external shares may be set to cut the weeds that are apt to ride on the side of the ridges, without disturbing too much earth, and the central share sunk to form the bottom of the furrow. The centre one may also be worked alone, between narrow rows. In forging the shares of all hams, he has well observed, that the
the blacksmith should be careful to give them tendency enough into the ground, by bending them downwards: for want of this caution, he has found many of them to work badly. The wheel in the beam counteracts this tendency sufficiently when at work.

These tools should be upon all tillage farms, in all their different and best constructions.

Shin Potatoes, a tool of the shin kind, used for cleaning potato crops.

Shin, Loch, in Geography, an extensive lake in the county of Sutherland, Scotland. This lake extends above 20 miles in length, but no where exceeds two miles in breadth, and feldom above a mile and a half. The banks are finely covered with natural wood, particularly the southern bank. It is connected with the Northern ocean, at Dornoch Frith, by the river Shin, which abounds with salmon, and forms several falls in the short course of eight miles. Sinclair's Statistical Account of Scotland, vol. xi. 1791.

Shinaas, a small town of Perâia, in the province of Larîtan. This and Boftana lie between Lînga and Cape Boftana; but though they are small towns, they afford some refreshment. Lînga, the chief town of the piratical tribe of Jocarins on the Perâian shore, is situated close to the fea, in N. lat. 26° 3', about eight leagues from Kîshm. It has a secure road, where ships may ride out a north-west gale in five fathoms water. Cape Boftana forms to the eastward the roadstead of the town of Mogoo, which is one of the most secure in the gulf; and this roadstead has to the westward the point improperly called Cortes. This roadstead is capable of holding the largest fleets.

Shindan, a mountain of Perâia, between the provinces of Adiríbeitzan or Azerbaijân and Ghilan.

Shingaran, a town of Africa, in the country of Sahara, where falt is found; 9 miles N. of Walet.

Shingleat, a town of Africa, in the country of Bergoo; 50 miles W. of Wara.

Shingle, in Agriculture, a term sometimes applied to the thinnings of fir and other timber trees, in the northern districts, and which are of much use for various purposes in farming, as the making of fences, &c.

Shingle, a substance found and collected on the sea-beach, or shore, which is used for several purposes, as baling of ships, filling surface hollow drains, protecting the foundations of embankments, and other similar uses. See Surface Drain, and Surface Draining.

It is said to be a very valuable substance for the use of filling drains, as being particularly durable in its nature. In the county of Suffex, as well as in Essex, much of it is made use of in this way; in the former, under the denomination of sea-beach, or beach.

Shingle Shool, in Geography, a fishal in the English Channel, near the coast of Hampshire. N. lat. 50° 38'. W. long. 1° 26'.

Shingles. See Shambles.

Shingles, or Shibas, in Building, small pieces of wood, or quartered oak boards, fawed to a certain scantling, or more usually cleft to about an inch thick at one end, and made like wedges, four or five inches broad, and eight or nine inches long. They are used in covering, especially for churches and steeples, instead of tiles or shingles.

This covering is dear; yet where tiles, &c. are very scarce, and a light cover is required, it is preferable to thatch. If made of good oak, and cleft, not fawed, and well seafoned, shingles make a fire, light, and durable covering.

The building is first to be covered all over with boards, and the shingles then nailed thereon.

Shingles, in Medicine, the popular appellation of a vesicular eruption, which appears on the trunk of the body, extending generally half round, like a belt: whence probably the term is a corruption of the Latin word cinguulus, or cingulum, signifying a belt. It is the herpes zoster of medical writers, the Greek word, ζώστερ, having the same signification. It is sometimes called simply zona, or zoster. For the description and treatment of this curious and harmless affection, see Herpes Zoster. See also Bateman's Practical Synopsis of Cutan. Diseases, p. 226.

Shingling, in the Iron-Works, in many parts of England, is the operation of hammering the low, or cast iron, into blooms. The tongs, used for holding the iron in this operation, are called shingling-tongs, and the iron to be thus wrought is called a loop.

Shining Mountains, in Geography, mountains that bound Louisiana on the west, which, though little known, are supposed to terminate in N. lat. 47° or 48°; whence spring a number of rivers, that discharge themselves into the North Pacific ocean, Hudson's bay, the waters which lie between them, or the Atlantic ocean. They are also called the "mountains of bright flones," on account of the immense number of large crystals floating from the rocks, and sparkling in the rays of the sun, so as to be seen at a great distance.

Shiobert el Temei, a town of Egypt, on the right bank of the Nile; 8 miles S.E. of Mahallet Kebir.

Shionkan, a town of Pegh; 8 miles N. of Sîrian.

Ship, a general name for all large vessels navigated with sails. Among people unacquainted with marine definitions, this term has a very vague and indiscriminate acceptation. In the sea-language, however, it is more particularly applied to a vessel furnished with three masts, each of which is composed of a lower mast, topmast, and topgallant mast; with the usual rigging and appendages thereto belonging.

The hue Aubin defines a ship, a timber building, consisting of various parts and pieces, nailed and pinned together with iron and wood, in such form, as to be fit to float, and to be conducted by wind and sails from sea to sea.

The invention of ships is very ancient, and, at the same time, very uncertain. Mythologists attribute it to Dædalus, and pretend that the wings he invented to save himself from the labyrinth of Crete, were nothing but sails, which he firk gave to vessels, and with which he eluded the vigilance and pursuit of Minos. Others give the honour to Janus, on the credit of some ancient Greek and Latin coins, on one side of which is represented his double face, and on the reverse a ship. Lastly, others look to Noah to have been the first ship-builder.

The most celebrated ships of antiquity are, that of Ptolemay Philopater, which is said to have been two hundred and eighty cubits (i.e. four hundred and twenty feet) long, thirty-eight broad, and forty-eight high: it carried four thousand rowers, four hundred sailors, and three thousand soldiers. That which the name Prince to fail on the Nile, we are told, was three hundred and twelve feet long, forty-five feet broad, with a mast one hundred and twenty feet high. Yet these were nothing in comparison with Hiero's ship, built under the direction of Archimedes, on the fructus of which Mofchion, as we are told by Snellius, wrote a whole volume. There was wood enough employed in it to make sixty galleys. It had all the variety of apartments
ments of a palace; frequenting rooms, galleries, saloons, foyers, parlors, saloons, halls, and lobbies. It was a place where one could see great works of art, with wide halls and large rooms decorated with marble, particularly so, which showed a line of the hundred pounds, or a shot twelve yards long, the price of half a mile; with many other particulars related by Athenaeus. Deipnosophists, lib. vi. p. 2344 &c., Ed. Cantab. 1657.

A ship is indeed the mild machine that ever was invented, and contains of many various parts, that to form some idea of its importance and qualities, will require the attention of the gentleman and the artist.

All ships at first were of the same form, whatever uses they were designed for; but the various ends of navigation, some of which were better answered by one form, some by another, soon gave occasion to build and fit out ships, not only different in size, but also in their construction and rigging; and as trade gave occasion to the fitting out large fleets of different kinds of merchant-ships, so ships of war became necessary to preserve them to their just owners.

The gradually improving state of shipping, in the last century, has kept pace with the regular advancement of every other branch of mechanical science. For, prior to that period, even our first-rate ships, now equal in perfection to those of any other rate, were then extremely defective, as their want of stability made their magnitude highly objectionable. These disadvantages have gradually obviated, since the usual causes of instability have been discovered, the dimension enlarged, and the practical management familiarized; and they are now, in general, especially those that have most stability, admirable ships in most respects; as they sail well, and combine almost every good quality. Large as they are, they are perfectly manageable; and their evolutions are generally made with wonderful facility.

Second-rate ships, or those about ninety guns, have too generally those defects in their construction, which contribute to instability, arising from want of that capacity which most of the first-rates possess. The French, on this account, have discontinued this class of shipping.

Third-rate ships, or those of eighty and seventy-four guns upon two decks, are altogether the most useful and valuable ships in the navy; and possessing, in an eminent degree, all the properties of capacity, stability, and swiftness; the particulars of which last property will be found hereafter under Ships-Building, and this ship may be considered as the first of its class, from its great length and superior capacity.

The above are particularly distinguished as line-of-battle ships, and are found in general to suit the most powerful exigencies of the naval services. About ten years ago an additional lieutenant was appointed to the line-of-battle ships. See Rate.

Fourth-rate ships are those of fifty guns. They may be employed, if necessary, in the line-of-battle, but most suitable to be stationed amongst the foreign colonies, or on expediency of great service, since their vessels are often kept at sea for a considerable period of time.

First-rate ships, or those of one hundred and fifty guns, are the sum-total of all the former classes, and contain, as well as those two and two, a deck, and even one more. As soon as the number of guns in vessels exceeds one hundred, and the length of the ship is considered, the superior advantages of the galley-oar, which are very great, will disappear in the lead, and the conveyance of men and stores, to provide and to carry, to cruise and do battle, is to be expressed with less severity.

The first-rate ships are the second most valuable of the fleet, being made to come up against one, to confound all to have the various qualities which probably be wanted in one ship; if have, but not, her breadth and height are so proportioned to her length, that the may be brought down in the water to that depth which is allowed to be the best face in the ships in general. Ships of fifty and thirty-eight guns have four lieutenants. See Rate.

The fast-rate includes all the smaller class of vessels in the navy, except the yachts, fire-speeds, and fast-boats; they are claffed as fifth-rates, to increase the pay; the lesser by way of distinction, the latter on account of the dangers to which they are exposed. Frigates of twenty-eight, twenty-four, and twenty guns, are in this class, but those with the thirty-two gun ship, in the former class, are inferior to the forty-four and thirty-six gun frigate, and not to deceive notice nor contemn by a great maritime power. Ships of twenty guns, and all vessels upon the establishment of the fleet of war, have two lieutenants. See Rate.

The large troop of war and brig are very serviceable vessels to cruise against privateers, contraband trade, and for small convoys. Some of the latter have lately been built in this country, and are admirably adapted for good sea-boats, as well as good failers; they perform their upper works being light, all unnecessary top-hamper avoided, having a flaring stern, and apparently every good quality that can be expected in a vessel of this description.

One of these vessels, the Raven, upon being fitted for sea at Woolwich, under the directions of her very ingenious and active commander, Captain William Layman, had, agreeably to his recommendation and wishes, among other alterations, the two foremost ports closed up, and the guns taken away; in lieu of which was fitted in midships, immediately before the fore-card, a fifty-eight pounder carronade upon a fixed traverse carriage, so as to fire in almost every direction clear of the gunwale; and, in lieu of the two lars-shafts, a carronade of the same power, upon an inclined plane abait. The wonderful acception of force derived from these alterations, and the great advantages to be derived from them in chace, in clearing an enemy's coast, &c. are too obvious to need comment.

Ships in the royal navy are commanded by full-capitains to 22 guns; floops by master and commander.

The following Table furnishes a correct list of the dimensions of ships of different rates. See Rate, under which article a less perfect table is inserted.

Yacht, as a vessel of state, is usually employed to convey princes, ambassadors, or other great personages, from one kingdom to another, or even kings, to take pleasure in; of which our present gracious majesty was very fond. The Royal Sovereign yacht was launched for the particular service of his majesty at Deptford, in the year 1804; a ship whose exterior and interior are of incomparable beauty, but whose ornaments, splendid as they are, will scarcely be considered by the artilt as more than adequate to the beauties of her form; and her qualities as an excellent faier and good sea-boat, from experiment, is unrivalled. We have, therefore, given a plate of this excellent vessel, by a quarter of an inch scale.

Yachts, as may be expected from the purposes for which they are designed, are the most beautiful of all vessels which navigate the ocean; nor are they superb embellishments and flately apartments their highest excellencies. They are models, in which may be seen a combination of the best principles of the art.

The fire-ship differs but little in its outer construction from a sloop of war. She may be built light and very clean for fast sailing; but the inner part is very differently fitted, in the manner described under the article Fire-Ship.

The bomb-veffel is particularly constructed for throwing shells from a mortar. They are built very strong, and firmly riddled; are usually fitted with two bomb-beds, which are platforms or strong frames of thick fluff and timber, laid transversely over large beams, and are rabbed and solidly bolted all together. The mortar-bed, or carriage which carries the mortar, traverses on a large iron pivot, in the centre of the bomb-bed, in a circular excavation. The sides of the bomb-bed, round the mortar, are fitted with strong cheeks of oak, of an octagonal form; in every square of which are driven two ring-bolts, for traversing the mortar in any direction. The bomb-bed underneath, to support the shock in throwing the shell, has three ranges of large pillars, fix in a range, tenoned at the head and heel into large carlings fore and aft the bed, along the middle and fides, which are scored on the riders below, and into the beams above the pillars, flanding double in the middle of the bed athwart-ships.

A strong compartment, called the shell-room, is built round the outside of the pillars. See Shelf-Room. See also Bomb-Vessel and Ketch.

SHIP, Armed. See Arm.

SHIP, Guard, is a vessel of war appointed to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watch kept duly, by sending her guard-boats around them every night; she is also to receive seamen who are imperilled in time of war.

SHIP, Hospital, a vessel fitted up to attend on a fleet of men of war, and receive their sick or wounded; for which purpose
parpose her decks should be high, and her parts sufficiently large; her cables ought also to run upon the upper deck, to the end that the beds or cradles may be more commodiously placed between decks, and admit a free passage of the air, to deprive that which is offensive or corrupted.

Falconer.

Ship, Lee-ward. See Lee-ward Ship.

Ship, Merchant, a vessel employed in commerce, to carry commodities of various sorts from one port to another.

Merchant shipping, in general, being largely defendable into distinct classes, we cannot speak with that degree of precision of them as of those of the royal navy; because their respective forms and dimensions are dependent, almost entirely, on the local practice or ideas of their respective owners or contractors, and fluctuate accordingly. Those belonging to the East India Company are by far the largest, and are very fine ships, and of course rank in the first class of merchant ships.

Well India ships are little inferior to the former, but in size; and some of the largest have been employed occasionally either to the East or West Indies.

The East India ship (Plate XI.) has been actually built, and found upon trial to answer every purpose expected from her.

Some ships of a very fine model, being less burthenless than Well India ships, are employed in the Straits' trade; and others used in the East country trade, for carrying of timber, exceed either of the latter for size, the largest of them being no less than 720 tons.

Ship of War, Private. See Privates.

Ship, Store. A vessel employed to carry artillery or naval stores, for the use of a fleet, fortresses, or garrisons.

Ship, Troop. See Troop Ship.

We shall here observe in general, that it is highly necessary to the health of seamen, that ships should be cleared of foul air; for it has been found by frequent experience, that air shut up, and confined in a close place, without a succession and fresh supply of it, becomes unwholesome, and unfit for the use of life. This is more forcibly so, if any flagrating water be kept up with it. But it grows still worse as a result of this, in a mixture of impure air; that is, becomes more mephitic, and boggolised, by passing and repassing through the lungs.

The bad effects, in different degrees, according to the different manner in which air is included, are observed in many cases, particularly in deep wells and caverns of the earth, in prisons or close houses, where people are shut up with heat and no air; but most of all in large ships, in which, with the stench of water in the hold, many men being crowded up in those quarters, all the mentioned circumstances concur in producing greater mischief than would follow from any of them singly. For an account of Mr. Sutton's contrivance for clearing the holds of ships of the bad air contained in them, we refer to the article Air-Pipes.

The mixture used sometimes for covering the bottom and sides of ships is made of one part of tallow, of one part of brimstone, and of three parts nearly of resin. The tallow and resin are melted together, and the brimstone is shrunken into them; one hundred and forty pounds of brimstone will serve for a vessel of one hundred and forty tons. See Paux.

To prevent ships, whose bottoms are worn, eaten, from leaking, this method has been proposed. Caull well the inside planks or livers, then fill the vacant spaces between the timbers, and the out and inside planks, with boiling pitch or resin, so high as the main gun-deck. The pitch being put in very hot, will run into the filled crevices, and seal the ship as tight as a bottle. There will be no water for turning, as rats, &c., and the pitch will leave for other uses when taken off; therefore the expense will be but small. Phil. Trans. N. 476. p. 352.

For the laws relating to ships, &c. See Act of Trade. Navigation. See also Freight, Mariners, and Navy.

Ship, ball, broadside, cannon, clerk, company, corporate, flag, gun-casting, master, mine, register, rigging, run, fouling, spinnaker, play, forward, warp, esailing away, weather, in reference to a ship, see the respective articles.

For further particulars respecting ships, the reader is referred to the article Ship-Building.

Ships, The, in Sea Language, is used either actively, as to embark any person, or put any thing aboard ship; or passively, to receive any thing into a ship, as we shipped a heavy sea, &c.

To ship also implies to fix, as a thing in its place, as to ship the oars, to ship the swivel guns, &c., to fix them in their sockets, &c.

Ship of Pleasure, among the Ancients. See Thalassaeus.

Ships, in the Salt Works, is a large cistern, out of which the salt-pan's are supplied for boiling.

This cistern is built close to the faltern, and is made either of wood, brick, or clay; and it ought always to be covered with a shed, that the sea-water, contained in it, may be kept clean from foot, and other impurities, and not mixed with fresh water in rains; and it must be always placed so high, that the water may easily run out of it into the pans, to supply them for boiling.

Ship Gun. See Cannon.

Ship Cove, in Geography, a cove of Queen Charlotte's found, in the southern island of New Zealand. This harbour, according to captain Cook, is not inferior to any found, either for convenience or safety. It lies on the west side of the island, and is the southernmost of three coves, that are situated within the island of Motuara, which bears the same name as the famous cove in New York. Ship Cove may be entered either between Motuara and a long island called by the natives Hamotu, or between Motuara and the western shore. In the left of these two channels are ledges of rocks, three fathoms under water, which may be easily known by the sea-weed that grows upon them. S. lat. 42° 10'. E. long. 175° 45'.

Ship Island, a small island in the gulf of Mexico, near the coast of West Florida, nine miles long and two broad. It produces pine-trees and grass, and has a tolerable well of water. N. lat. 30° 3'. W. long. 88° 48'.—Alto, a small island of Upper Canada, in lake Erie.

Ship Point, a cape on the coast of North Carolina. N. lat. 35° 55'. W. long. 76° 30'.

Ship-Building, or Naval Architecture, is the art of constructing and rasing, or building, that noble fabric called a ship.

This science, or whatever relates to navigation, is, without doubt, one of the most important and most useful employments of the human mind; especially in a country whose marine is its bulwark, and its commerce the admiration, and we may add, the envy of the world.

Nevertheless, the scientific part of ship-building has been too much neglected; and although some few years have elapsed since mathematicians (particularly in France) have laboured with some success, yet their discoveries are so much developed in profund calculations, that ship-builders, in general, have scarcely been able to derive any advantage from them.

It must be allowed, that an exact knowledge of the
true principles upon which the construction of ships, so as to answer the particular purposes of war or commerce, is founded, must conduce to remedy all the present defects, to render the theory more perfect, and enable the English artificers to become as eminently skilful in the scientific, as they now confessedly are in the practical branches of shipbuilding.

In order to smooth the way in a science thought to incomprehensible, our readers must be made familiar with the several draughts and plans requisite to construct and raise to noble a body of architecture; for the proportional size of every part must be laid down, from whence the form and dimensions of the several timbers, and every particular part that enters into the construction, are to be obtained. Therefore, as a ship has length, breadth, and depth, three different plans at least are necessary to represent the form of the several parts of her; as in the fleer-draught, Plate I., of Ship-building, which comprehends the fleer-plan, the body-plan, and the half-breadth plan.

The fleer-plan, or, as it is called in civil architecture, the plan of elevation, is a vertical section passing through the vessel in its whole length, or fore and aft. Upon this plan the length and depth of the keel are represented, also the height and rake of the stem and stern-post; the situation and height of the midship and other frames; the waterlines; heights of the decks, gun-ports, and wales; the centres of the masts; the situation of the channels; length and depth of the head and rails, quarter-galleries, rudder, &c. &c.

The body-plan, or plan of projection, to the left of the fleer-plan, is a transverse section of the ship at the midship-frame, or broadest place perpendicular to the keel. The several breadths, and the particular form of every frame-trimmer, are described on this plan. Now as the two sides of the ship are, or should be, exactly similar to each other, it is therefore unnecessary to represent both; hence the frames contained in the fore-body, between the midship-frame and the stem, are described on the right-hand side of the middle line, and the aftermost frames on the left of the said middle line.

The half-breadth or floor-plan, under the fleer-plan, and parallel thereto, or as it is frequently called, the horizontal plan, contains the several half-breadths at every frame-trimmer, at the different heights of the water-lines, main-breadth, top-fide, ribband-lines, &c.

The consideration of these three principal plans is so much the more important, as it comprehends a sufficient knowledge of the figures of all vessels. For although these three plans do not really determine the figure of the vessel, and may belong to an infinity of different kinds, yet all these differences cannot exceed certain limits sufficiently confined; so that whatever idea we might form of the figure of the vessel, it cannot deviate considerably from the truth.

In order to explain this better, we will proceed to construct the fleer-draught, Plate I.; and here the nature, and all the properties of the vessel, according to her design for war or commerce, must be taken into consideration, upon which the whole theory of the art depends: such are, capacity, flability, velocity, and ease in the sea or at anchor. These properties are not to be adopted merely from speculative theory, but from those that have actually been demonstrated by repeated experiments. That our readers may have the clearest conception of the various parts of a ship, represented by the plates of the 74-guns ship, we will endeavour to describe them in as familiar a manner as possible, introducing also all that is necessary to be known as we proceed. The 74-guns ship is preferred as the medium between the first-rate and the frigate, and is esteemed the most useful of all others.

Therefore, the first thing to be determined is the length on the gun-deck; and here sufficient dilance must be allowed for the ports, which are fifteen in number, three feet five inches wide, or fore and aft, each, so as to have a sufficient dilance between each port for working the guns, which is about seven feet eight inches; likewise room forward, between the foremost-port and the stem, for the manger; and also abaft the after-port, to the tran-om: these considered make the length on the gun-deck 180 feet.

Draw therefore, as in fleer-plan, Plate I., a straight line, which represents the upper edge of the keel, and in naval ships the upper edge of the rabbet (East India ships and merchant-ships in general have the rabbet in the middle of the keel), leaving under this line sufficient space for the main and false keels, false, and half-breadth plan. Upon this line square up a perpendicular towards the right hand, leaving a sufficient space to represent the head, and call it the foremost-perpendicular; then, at 23 inches abaft it, square up the after-perpendicular, which is 185 feet by one-eighth of an inch to a foot, or the length on the gun-deck, from the after-fide of the rabbet to the fore-fide of the rabbet at the stern-post. Below the upper edge of the keel, and parallel thereto, let down two feet for the main and false keel, and under it draw the scale of equal parts, of one-eighth of an inch to a foot, and from this scale let off all the following dimensions. Observing, draughts in general are drawn from a scale of one quarter of an inch to a foot, but this, for convenience, to one-eighth.

The length between the foremost and aftermost perpendiculars, in merchant-ships, is given from the after-fide of the stern-post, at the height of the wing-tranom, to the fore-fide of the item, at the fame height.

The item, or fore-boundary of the ship, may now be drawn, and a segment of a circle for its lower part has long been considered as the belt form for dividing the fluids; therefore, fix its centre so that the after-fide of the rabbet (which is in the middle of the item, towards the upper part) may intersect the foremost-perpendicular at the height of the gun-deck; thus, set off from the foremost-perpendicular, as in Plate I., upon an horizontal line, 24 feet above the upper edge of the keel, 24 ft. 3 in.; and from thence, as the centre, draw an arc of a circle from the upper edge of the keel-line, and another arch 18 inches before it, from the same centre; then will the moulding, or fore and after-fides of the item, be represented: sweep likewise the rabbet, as in Plate I.; then set off 36 feet for the height of the head of the item, and at that height set forward 15 inches from the foremost-perpendicular; from thence draw a faint curve, to intersect with the foremost segment, and the fore-part of the item will be shown: continue upwards another parallel thereto, and the after-fide or whole item is completed, except the lower end or boxing, which will be determined hereafter.

The stern-post, or after-boundary under water, may be next drawn; thus, set up from the upper edge of the keel-line 26 ft. 10 in., which is the upper fide of the wing-tranom at the after-perpendicular, and upon that line set off from the perpendicular 1 ft. 10 in., and upon the upper edge of the keel, six inches before the after-perpendicular; then a line drawn through these points will represent the after-fide of the stern-post; another line, drawn at fourteen inches before the after-fide of the stern-post, at the wing-tranom, and at two feet one inch on the upper edge of the keel, will be the
the aft-side of the rabbet; and another line parallel thereto, before it (or at the thickest of the bottom back) in the fore-side of the rabbet, which will perfect the after-perpendicular at the stern-deck. Thus far the stern-post is perfect.

Having fixed on the length of the gun-deck, the next principal dimension to be considered is the main-breath, and this, in ships at war in general, is about three-eighths of the laid length for their moulded breadth, and a rule almost universally the three-twelfths of their length; excepting cutters and smaller vessels. The moulded breadth given in Plate 1 of the 74-gun ship, is 48 ft.

Before we proceed, it will be necessary here to remark, that much has been said in regard to the breadth to be given to a vessel in respect to her length, and in what part of that length it is best to place it; as being the section of the greatest area of the whole vessel, its true situation becomes an object of importance.

Those who would diminish the breadth have alleged, and truly, that a narrow vessel meets with less resistance in passage through the water, and by increasing in length, the vessel will drive less to leeward, and the water-lines consequently be more delicately formed to divide the fluid; that a long narrow ship will require less sail to gain velocity, consequently the masts will be lower, the rigging lighter, and the vessel navigated by fewer hands. On the contrary, a ship's being broader at the line of floatation will admit of being narrower on the floor, particularly at the fore and after parts, that by being broader it shall carry more sail, and more readily ride upon the waves than a narrow one. The breadth, and its situation, when determined on, require much skill in narrowing therefore, as we approach the keel, particularly forward aft, to give that form to the body under water that shall best answer in dividing the fluid, enable her to carry the larger tier of guns sufficiently out of the water, prevent her pitching, and give a free passage to the rudder, that she may readily answer her helm.

Now to prevent the vessel pitching, the fore-body must be so shaped, that its bearings should catch the vessel in its defent, that is, the harpin should increase in breadth upwards, and the bow be so formed, as rather to throw off the sea than pitch or bury in it: a long floor, with little rising afore and abaft, the displacement of the fore-body to be duly proportioned to the after-body, and hollow water-lines, or inflected curves at the fore part, are to be carefully avoided. Taking into consideration the weight of the anchors on the bows, we may easily conceive, that with the pressure of the wind upon the sails, without sufficient bearing in the fore-body, the bow would be pressed down into the hollow of every sea; and if the greatest part or midship-bend were placed too far aft, the support would only be in the after-body, and this would tend to plunge her bows still deeper, and retard her velocity, and the free passage of the water to the rudder.

In order that the ship should steer well, and quickly answer her helm, the wing-tranom must not be placed too low, nor the fashion-pieces too full below the load-water-line: and the narrowing of the floor, or half-breath of the rising, not continued too full towards aft, but that the water-lines, as they approach the stern-post, may taper handsomely into the same, so that every succeeding water-line, as they approach nearer the keel, may have their curvatures more delicate, as may be seen by referring to the half breadth plan in Plate 1. It is also evident, that the prompt effect of the rudder must depend in a great measure on the cleanness of the ship's run, so that the fluid shall have an unimpeded passage to it, whereby its inclination shall have the greatest effect from the water.

That a ship may carry her guns well above the water, a long floor timber will be necessary, and to make her run, the midship-timber should be very full, upper floor-timbers nearly straight, upper water very light, and kept as low as possible, and the wing-timbers not placed too high.

To make a ship carry her guns well above water, carry much sail, be a well built, and likewise floor well, are four such rare qualities, as are hardly to be united at the same time; because it would require a very full bottom and great breadth to gain the two former qualities, and less breadth and a sharp or clean bottom to gain the latter; but if we consider that a full ship will carry more sail than a sharp one, we may perceive the possibility of so constructing the body, as to possess these qualities, and they may be so united, that each of them may be discerned in some degree of excellence, for it is not possible that all of them can be united in one body to a degree of perfection; we must, therefore, while we retain a portion of each, give the superiority to that which is most consistent with the purposes for which the vessel is particularly designed.

Hence it is plain, that judiciously placing the midship-bend is of the utmost consequence in the construction of ships' bodies; and its being placed nearer the fore, will, consequently, make the fore-body more full, and will best answer every purpose, especially that of velocity, and although it is plain, that by so doing the entrance of the ship will be more full, and prevent apparently more absolute force against the resisting medium: than when the midship-bend is placed nearer to the middle of the ship's length; yet by placing it more forward, the body will decline horizontally so much the quicker, and part of the effect of that resistance, caused by the lateral pressure of the water, will be lessened, which must certainly be of more service to the velocity, then what is lost by making the fore-part of the ship somewhat fuller, and this seems to promote the connection of capacity with velocity, the two great objects to be pursued in the formation of ships' bodies under water. In addition to this, by carrying the midship-bend forward, a ship will steer better, and the rudder have the more command to bear up the ship in a gale of wind; for when a ship is under a press of sail, the water is forced up at the bow above the horizontal, and the bow likewise pressed down, which amounts to nearly the same, with respect to her helm, as if the ship was trimmed by the head again, that carry their helm amidships in light winds, require more a-weather when the wind blows.

After all that has been written concerning the placing of the midship-bend, all agree to place it before the middle of the length, or about five-twelfths of the length abait the foremost-perpendicular; but in Plate 1, which ship has stood the test of experiment, it was placed at 65 feet abaft the foremost-perpendicular, consequently this is the broadest part of the ship; called the midships, or dead-flat, known by this character z, and where all the heights in midships are set up. From b 2 the stations of all the timbers may be set off; but it will only be necessary to square up a perpendicular at the joint of every frame-timber, their distance being double that of the room and space, which in Plate 1, is two feet nine inches.

The dead-flat in Plate 1, is a single timber, and the perpendicular, marked z, the middle of it: therefore, for the joints of the annexed frames set off before z, two feet nine inches for the joint of A, and two feet one inch for the joint of (11), square up perpendiculars from the upper edge of the keel; then from (A) continue setting off five feet six inches for the joints of frame B, C, D, & X, in the fore-body, and the same distance abaft (11) for the joints of

frame
SHIP-BUILDING.

frame (3), 2, 4, 6, to 36 in the after-body, as shown in Plate 1. Now (2), (A), (1), (2), and (3), are called flats, as they are the timbers which are placed in the flat part of the ship amidships, have no bevelings, and consequently do not partake of the rising.

The lower height of breadth is an imaginary line, not only to affilt in the construction of the body, but a line confining the greatest breadths in the ship, all fore and afts, and should next be determined upon. Its height at $P$ is 21 feet 3 inches above the upper edge of the keel; and that the said height of breadth should be higher afore and abaft is only reasonable as a reserve, to be a support to the vessel when heeling by the preasure of the wind upon the falls; for when a ship is close-hauled by the wind, and lies much over, the weather-side would lose much of the breadth, whereas, on the contrary, the lee-side would then gain considerably, and meeting with a greater refistance, be enabled to carry the greater fall; therefore forward at the rabbot of the item its height is 29 feet, and abaft to the counter-timber 29 feet 6 inches; and all the heights between should form a fair curve, like the ticked line in the figure, Plate 1.

It may here be remarked, that flat-floored ships do not require their height of breadth to be raited so high forward and aft, for by their construction they are fuller under fall, and carry their weight of cargo low down.

The body below the lower height of breadth may now be formed, as the frames or bends, when put together, and the joint placed to the fore-mentioned perpendiculars, the sides of every part will be formed so as to cut none of the principal timbers, and are so disposed as to weaken the ship as little as possible. Now as capacity, velocity, &c. depend upon the figure of the imdered part of the body, and because the properties which every ship ought to possess are, in a manner, subversive of, or in opposition to, each other, as before observed, the great art certainly is to form the body, that none of the defined qualities shall be omitted, giving, at the same time, preference to that which is most required. In ships of war, capacity, stability, velocity, and strength, are essentially necessary; the first and second we shall endeavour to prove by calculations hereafter; the third may be affirmed, as the vessel was actually built, and answered that purpose; and the last is now so well established in the British navy as to need little addition.

The half-breadth plan must be next drawn: thus, draw a straight line below the figure-plan, as in Plate 1., the whole length of the ship, and parallel to the upper edge of the keel, which line will represent the middle line of the ship, at any height passing fore and aft, or lengthwise; observing to keep the said middle line sufficiently below the scale, so as to admit of the main half-breadth line coming clear of it.

Then square down from the figure-plan all the perpendiculars or joints of the frame-timbers, to the middle line of the half-breadth plan, and likewise the foremost and after-perpendicular. The main half-breadth line may now be drawn, by setting-off from the middle line in the plan the following half-breadths at each respective timber; thus, at $P$, 24 feet; at $F$, 23 feet 11 1/2 inches; at $H$, 23 feet 11 inches; at $K$, 23 feet 10 inches; at $M$, 23 feet 5 1/2 inches; at $O$, 23 feet; at $Q$, 22 feet 2 inches; at $S$, 20 feet 4 inches; at $U$, 17 feet 6 inches; at $X$, 12 feet 6 inches; and to end this line at the fore part, let the height of the breadth-line in the figure-plan, where it intersects the aft-side of the rabbot at the item, be squared down to the middle line in the half-breadth plan, and likewise the fore part of the item: upon the lines last squared down, set off the half-lining of the item from the middle line and parallel thereto, which is ten inches; then, with compasses, take the thicksets of the bottom plank, which is four inches, and describe the rebate of the item by the triangle shown in the half-breadth plan; from thence a fair curve line drawn through the half-breadths set off, forms the half-breadth line to $P$. In the same manner set off the half-breadths abaft $P$, and draw in the remainder of the half-breadth line, as the ending of it abaft will be described hereafter.

Observe, the various curves represented on the several plans used in ship-building, except where they are segments of circles, such as the fore part of the main half-breadth, &c. are drawn by small pliable battens confined thereto by weights, or by thin moulds made of pear-tree veneers, whose edges are made to geometrical curves of all kinds.

Now the main half-breadth line being drawn, we have a half section of the ship lengthwise at the broadest place, that is at the height, and in the direction of the lower height of breadth line in the figure-plan, Plate 1.

The imdered part, or body of the ship under water, must be next formed, and the capacity of the vessel ascertained, before the upper works, or that above the water, need come under consideration; it is therefore necessary to describe in what manner the several forms of ship's bodies are to be constructed. In the royal navy, the midship parts of the body of ships are formed by segments of circles called sweeps; such are the lower and upper breadth-sweeps, floor-sweep, and reconciling-sweep, their several centres being given by lines, except the reconciling-sweep, whose centre is without the limits of the draught. The lower-breadth and floor-sweeps are joined by the reconciling-sweep, and make a fair curve from the lower height of breadth to the rising-line, by which the floor-sweep is governed; then, by drawing a straight or curving line from the upper edge of the rabbot of the keel to touch the back of the floor-sweep, the form of the midship part of the body below the lower height of breadth will be complete.

Observe, the floor-sweep forms the body at the floor-heads, particularly along the midship part of the body, and is limited by an horizontal line above the keel in the body-plan, and its distance above the keel at the midship-timber is called the dead-rising. The rising of the floor in the figure-plan is a curve line intersecting the dead-rising at the midships; and in flat-floored, or burthensome ships, it continues nearly parallel with the keel for some distance afore and abaft the midship-timber; and all the timbers, where the rising is parallel with the keel, are called flats, as before observed. The rising-line, which governs the floor-sweeps, is not the least interesting of the ferrules, because it exhibits, on many points, general deductions, and tends to establish theories which may serve to direct future observations; and the method of constructing the midship-flours of ships, where velocity is preferred, by lengthening the radii of the floor-sweep forward and aft, is preferable to the rising-line, as used in constructing merchant-ships for burden, where the radii of the floor-sweeps all fore and aft are of the same length as at the midship-timber; because by the former method, every floor-timber from the dead-flat is graduated by a larger circle. By the latter method, not only the construction, but the laying-off the ship is facilitated, because in any ship constructed by the fame length of radii, we may venture, so far as the rising-line is continued, not only to form all the lower part of the ship on the draught, but also on the mould-loft-floor, without running any ribband or horizontal lines till that part is finished. Again, this method affords a greater facility, as by it the floors may be constructed all fore and aft; but the floors near the midships only can be constructed,
SHIP-BUILDING.

constructed, when the radius of the floor sweeps after much in their length.

Neither the rising-line in the floor-plan, nor the halfbreadth of the rising, would continue to be the curves as first constructed, if the form of the body still designed were to be altered in that part. It is evident, then, that the rising line may be drawn according to the judgment of the artist in the construction of any draught, observing to make it a fair elliptical curve, (for much depends on the construction of the lower part of the body,) by judiciously narrowing the floor-sweep, or half-breadth of the rising; for the more parallel it is kept with the middle line, the less will be the velocity of the ship. Again, the quicker this curve is, the less bearing will the ship have; and though it may be supposed, when the rising-line is drawn in the floor-plan, and likewise its half-breadth, it is reasonable to expect a fair body, yet we cannot be certain of its producing that form of body which is really intended agreeable to the use which the ship is designed for, unless by frequently designing of bodies we can form an exact idea before we proceed. Therefore the young artist should improve himself by drawing bodies constructed by the rising-line of ships of different properties, till he forms in his own judgment a perfect idea of this mode of construction. For instance, if it be required to make the ship cleaner, lift the rising-line in the floor-plan, and narrow its halfbreadth; and where it may be required to make the ship fuller, lower the rising-line in the floor-plan, and increase its halfbreadth; which sufficiently proves that the rising-line is as variable as the different forms of ships' bodies may require.

See for fulness the plate of the East India ship, the plates of the 74-gun ship, which is sharper, and also the frigate of 40 guns, which is sharper still; and we shall then find it a very complete method of constructing the lower parts of such ships fair, particularly those that require some provision or fulness of body to assist them in taking the ground. The further forward and aft the body is afforded by the risingline, the more merit there will be in the construction, and the greater certainty of producing a fair body: notwithstanding all this, some bodies are constructed without any floor-sweeps, which must be the case in very sharp bodies, such as cutters, &c.

It may be further observed, that the rising-line cannot, from its nature, be formed by any regular proportional method, from which there can be no variation without imprropriety; nor can it be constructed to any fixed proportion, unless ships of different classes were built exactly similar to each other, because the rising-line in ships of war, and those which are constructed for velocity, though suitable to the construction of the lower part of each ship, and likely to answer the purpose for which they are designed, cannot be equally proper for ships of the same length and breadth, if required chiefly for burden; as in the last case not only the form of the midship-bend, but every part of the bottom must be differently formed, which will be clearly seen by examining the plates of the 74 and 40-gun ships, and the plate of the East India ship, which was found to answer admirably well.

Whole-moulding was formerly a method of constructing the immersed part of ships' bodies, by the mould being made to the form of the midship-bend, which, with the addition of the floor-hollow, would mould all the timbers below the main-breadth in the square body. But since the art of ship-building has arrived to its present perfection, the method of whole-moulding, for the following reasons, has been justly laid aside. For by whole-moulding, more is narrowed at the floor than at the main-breadth, that is to say, the curves of each are kept parallel; nor must the rising-line in the floor-plan lift any more than the lower height of breadth, which, according to the form of the main-mold, would make a very ill-constructed body: for by continuing that nearly forward and aft, the ship would not only be incapable of rising in a heavy sea, but be deprived of a great measure of the more advantageous use of her rudder. Nevertheless this method is still continued in the formation of boats.

Proceed now to draw the plan of projection, or body-plan, thus: continue the line at the upper edge of the keel beyond the after-end of the floor-plan, as in Plate 1, and square up a perpendicular for the side-line of the fore-body, observing to keep it clear of the stern; from that perpendicular set off 4' feet, the ship's main breadth at dead-flat, and square up another perpendicular for the side-line of the after-body, and equally between both square up another perpendicular, which is the middle line to both bodies respectively; then the line prolonged from the upper edge of the keel is the base-line of the body-plan. Draw in the horizontal lines, as may be seen in the body-plan, Plate 1, at the lower heights of breadth, by transferring their heights from the floor-plan at the several frame-timbers: those before the dead-flat, let up in the body-plan to the right of the middle line, which are to represent the fore-body, and those heights abaft dead-flat, to the left hand for the after-body. Then from the half-breadth plan take the main half-breadth of each frame, and set it off from the middle line in the bodyplan, upon its corresponding height of breadth. The plan and from thence set off towards the middle line the length of their respective lower-breadth sweeps: thus, to describe the midship-timber, or dead-flat, extend the compasses to 18 feet 6 inches, the radius of lower-breadth sweeps at dead-flat, and draw part of a circle downwards, intersecting its main breadth at its horizontal height.

Then the centre heights of the floor-sweeps in the body-plan must be taken from the curve-line representing their heights in the floor-plan, which at dead-flat will be found to intersect the upper edge of the keel; but in the body-plan, its height at dead-flat is 11 feet 6 inches, and there in horizontal line is drawn to the distance of the centre, or its half-breadth from the middle line, and all the heights of centres are respectively set upwards above this line, on perpendiculars squared upwards at the half-breadth of the centre of each floor-sweep of its corresponding frame or timber, as taken from the half-breadth plan; and the reason for not keeping the said curve-line or heights in the floor-plan as in the body-plan, is because it would interfere with the curve-lines above. Now by inspecting Plate 1, it will be readily seen, that by raising the heights of those centres in the floor-plan, consecutively in the body-plan, and by narrowing their half-breadths in the half-breadth plan, their centres would be brought nearer the middle line in the body-plan, the floorrising would become quicker, and the ship have less bearing, and since very far more full and burthenone; thus must the rising and narrowing of the centres be adjusted till the body of the vessel has the capacity required for whatever service she may be designed.

But as in this mode of construction the centres only, and not the length of the floor-sweeps, are given, a diagonal ribband must be drawn in the half-breadth plan, as in Plate 1, by setting off from the middle line at A, 16 feet; at B, 15 feet 9 inches; at D, 15 feet 5 inches; at F, 15 feet 1 inch; at H, 14 feet 7 inches; at K, 14 feet; at M, 13 feet 8 inches; at O, 11 feet 11 inches; at Q, 10 feet 4 inches; at S, 8 feet 6 inches; at T, 6 feet 1 inch; and at X, 2 feet 5 inches. Then in the after-body, set off at 2, 15 feet 11 inches; at 4, 15 feet 13 inches; at 6, 15 feet 9 inches; at 8, 15 feet 6 inches; at 10, 15 feet 4 inches; at 12, 15 feet 1 inch; at 14, 14 feet.
SHIP-BUILDING.

14 feet 11 inches; at 16, 14 feet 5 inches; at 18, 14 feet; at 20, 13 feet 9 inches; at 22, 12 feet 5 inches; at 24, 11 feet 7 inches; at 26, 10 feet 5 inches; at 28, 9 feet 1 inch; at 30, 6 feet 7 inches; at 32, 5 feet 10 inches; at 34, 4 feet; and at 36, 2 feet.

Now to end this diagonal, it muft be drawn in the body-plan thus: fet up the middle line from the bafe 12 feet 2 inches, and on the bafe, from each side of the middle line, 11 feet 9 inches, then draw the diagonal ticked line, as fhewn in Plate I. In draughts, diagonal lines are distinguished by red ink. Then in the body-plan draw the half-fiding of the item in the fore-body, and the half-fiding of the Stern-post in the after-body: for the latter fet up 26 feet above the bafe, and at that height fet off from the middle line 10 inches in the half-fiding of the poll at the head, and 9 inches in the fore-body, the half-fiding of the item at that height; and on the bafe line 7½ inches from each side the middle line, the half-fiding of poll and item at the heel; then draw ftraight lines to each spot fet off, and the half-fiding of the Stern-post and item will be represented in the body-plan. Now to complete or end the diagonal line on the half-breath-pan, its height or interfection at the poll and item muft be taken in the body-plan, and transferred repectively to the fore-side of the rabbet of the item, and aft-side of the rabbet of the poll in the fheer-plan, and from thence let them be squared down to the middle line of the half-breath-pan; then take with companions the half-thicknes of the poll and item in the body-plan, in the direction of the faid diagonal line, and let them off repectively from the middle line in the half-breath-pan, on the lines half squared down; and from the interfection as a centre, sweep an arc towards the midships, with companions opened to the thicknes of the rabbet taken diagonally; then a fair curve drawn through all the spots as above fet off, touching the back of the arcs, will form the diagonal line at the floor-heads, as fhewn in the half-breath plan, Plate I.

Now may the timbers, as far as the floor-sweepes are ufeful, be completed in the body-plan below the lower height of breadth, beginning at dead-flat: thus, take the half-breath of the floor diagonal at 9 in the half-breath plan, and fet it down the diagonal from the middle line in the body-plan; then take the half-breath of the floor-sweepes in like manner, and fet it off from the middle line in the body-plan on the horizontal line before drawn at its height, and from the interfection extend the companions to the half-breath of the floor diagonal, and sweep an arc upwards from the dead-rifing, which is fix inches at 9; then with the reconciling-sweep, which is of a long radius compared with the others, unite the lower-breath sweep and floor-sweep together; for the more the midship-frames deviate from the segment of a circle, the less will be the rolling motion of the ship; unite the floor-sweep with the upper edge of the rabbet of the keel with a curve or ftraight line, and the midship-timber will be formed below the lower breadth. In the fame manner may be formed the frame-timbers B, D, F, H, and K, in the fore-body, and 2, 4, 6, 8, 10, 24 in the after-body, by letting off the half-breath of each frame’s diagonal as at 9, their correffponding heights of breadths, main half-breath, and centres of each fweep, as before directed, and by reconciling the lower-breath sweepes and floor-sweepes together, and ending them into the rabbet at the keel; thus the midship part of the body will be formed from K forward to 24 abait.

Hence it may be readily conceived, that bodies full or sharp, either for boreth or velocity, may be conftructed by altering the radii of the different sweepes; and unlefs bodies of ships could be conftructed from fome geometrical figure, a more certain method than the above cannot be given.

The body being thus far formed, that is from K forward to 24 abait, proceed to prove it by horizontal lines, and fift the remaining part forward and aft. These lines are generally called water-lines, as the ship’s bottom at the aftr of the water, fupposing the keel kept parallel thereto, would be of the fame figure as these lines repreffented in the half-breath-pan, with the addition of the thicknes of the bottom plank in that direction. The upper one is called the load-water-line, or line of floatation, when the vellicel is fupposed fit for sea, which will be treated of more particularly hereafter; the other water-lines may be equally divided between the upper or load-water-line, and upperedge of the keel or rabbet. Although a ship may draw more water abait than forward for her bell falling trim, yet to keep the feveral water-lines horizontal, or parallel with the upper edge of the keel, is the moft ufefull in contradiction; and the water-lines, as repreffented in the half-breath-pan, form curves, limiting the various half-breathes of the ship at the heights of their correffponding lines in the body-plan. They are generally drawn with green ink, but in Plate I. with correffponding dotted lines, and are repreffented by ftraight lines in the fheer-plan; and if parallel with the keel they will be horizontal lines in the body-plan, but if the vellicel is to be con- struted to draw much more water aft than forward, the water-lines will not of course be parallel with the upper edge of the keel; then, owing to their various heights at each timber in the fheer-plan, they will form curves at those heights in the body-plan, and the more they vary from an horizontal line, the les accurate will the limits of their half-breathes be defcribed in the half-breath-pan.

In Plate I. the upper horizontal water-line is 20 feet above the lower edge of the keel; and between that and the upper edge of the rabbet of the keel, are equally divided four more water-lines, as in the fheer-plan. The water-lines may now be drawn in the half-breath-pan from the body-plan, and as far as the timbers are there formed; thus, continue the water-lines aft from the fheer-plan across the body-plan, then take off with companions, or a flip of paper and pencil, their various half-breathes from the middle line, to the places where the feveral timbers interfet each water-line, and let them off on their correffponding timbers from the middle line in the half-breath-pan; then to end each water-line square down where they interfet the fore-part of the rabbet at the item, and aft-part of the rabbet at the Stern-post in the fheer-plan to the middle line of the half-breath-pan; then take the half-fiding of the item and the Stern-post at each water-line from the middle line in the body-plan, and let them repectively on the lines half squared down from the middle line in the half-breath-pan; from thence, as the centre, with companions opened to the thicknes of the bottom plank, make a sweep, the back of which is the ending of the line. Then complete the fore and after ends of each water-line with curves, as in the half-breath-pan, avoiding all inflected curves or hollow water-lines at the fore part, as they may be drawn by arcs of circles, although their centres may be without the limits of the plates of ship-building.

Now the whole of the body may be completed under the lower height of breadth, observing to sweep each timber below its height of breadth, as before directed; then by taking off the half-breath of each timber, where they interfet the water-lines from the middle line in the half-breath-pan, and letting them off on their correffponding water-lines from the middle line in the body-plan, curves paffing through thofe spots will shape the timber; but to end them into the rabbet, or complete the heeling, the keel must
must be drawn in the body-plan; thus, set off one inch on the base line from each side of the middle line, being the half-sidings of the keel, and also eight inches below the base line, which squared will represent the two water-lin section of the keel in midship; then, with compasses opened to the thickness of the bottom plank, fix one leg where the keel intersects the base line, which is the upper side of the rabat, and sweep an arc within the keel to intersect the side, and from that intersection sweep another and so upward; then a triangle drawn with that arc, represents the rabat of the keel as much as, and all the timbers along the midship, until the rabat opens, end where the rabat intersects the base line; but when the rabat opens by the timbers rising forward and aft, they will end over the back of the sweep to the inner edge of the rabat. The timbers near the after end of the keel must be ended agreeably to the tapering of the keel, which tapers in the identity from 2 to 1 in 2 to 1 inches at the after end; thus must be set off from the middle line in the half-breadth-plan, and the half-sidings of the keel taken at each timber, and set off on the upper edge of the keel from the middle line in the body-plan; then set within the half-sidings of the keel the thicknesses of the bottom plank, and that ends the timbers. But as the frames in the fore-body before O-beek, upon the stem, their thicknesses must be taken in the frame-plan, where they intersect the lower part of the rabat, and the height fix up in the body-plan upon the half-thickness of the stem; then with compasses opened to the thickness of the bottom plank, fix one leg in the height; half set off, and sweep a circle within the middle, and the half planes over the back of the circle, and the rabat completed by a square applied to the line of the timber, as to intersect the height set up, as shown in the plan of the fore-body, Plate 1.

Now, as a further proof of the correctness of the after body, draw four or five perpendicular sections, or, as they are commonly called, buttock-lines; but first prove the heels of the after timbers by the heading-line, thus; represent the half-thicknesses of the dead or rising wood in the body-plan, by drawing a perpendicular from the base line to the head of the stern-post. Then from the base line take the heights where the after timbers cross the half thicknesses of the dead wood, and set them up from the upper edge of the rabat on their corresponding timbers in the sheer-plan; then draw a curve through those heights, to break in fair with the fore-side of the rabat on the stern-post, and this curve will represent the heading-line in the sheer-plan, and limits the heels of the after timbers, as far as they cut off or pay against the dead-wood.

The heels of the timbers being found to agree with the heading-line, from the fairness of its curve (observe, the term fair, to often used in the delineation of the several plans of a ship, signifies that the variety of curved lines therein used have no inequalities; they, but are even as a circle described from its centre, as most of the lines in the formation of ships’ bodies are curves, but many of their centres are too distant for application; and the fairness required is, that where every different curve unites no angle may be divisible), proceed to prove the after timbers by the buttock-lines; thus, square up from the base line in the after-body plan five perpendiculars, equally divided between the outside of the wing-transom, and the half-thicknesses of the dead-wood; that is, the outer buttock-line at 15 feet 10 inches, and the intermediate four at 3 feet 2 inches asunder.

Then take the heights at the first buttock-line, or that next the pitt, at the intersection of each timber from the base line in the after-body, and let them up from the upper edge of the rabat on the corresponding timbers in the sheer-plan; and to end the buttock-lines, the upper side of the wing-transom and margin-line will be drawn in the several places; thus, set up 2½ feet below for the height of the upper side of the wing-transom, in the sheer and body-plans, drawing a horizontal line at the stern-post and across the body-plan; then from the middle line off one foot, the half-sidings of the wing-transom, and at that place let down below the upper side of the wing-transom, three inches, and from the arc, whose centre will be in the middle line, and the round up of the upper side of the wing-transom will be represented as in the body-plan, Plate 1; from the same centre sweep another arc six inches below the upper side of the wing-transom, which is called the margin-line. Then in the half-breadth-plan, two in the middle line of side of the wing-transom; thus, square down from the first line the profile of the rabat of the stern-post; where it cuts the upper side of the wing-transom, to the half-breadth plan, and upon the line so squared down, let off the half breadth of the wing-transom from the middle line, and at that place set forward seven inches, and sweep the arc representing the round- aft of the wing-transom, the centre of which is in the middle line.

Draw an horizontal line at six inches below the upper side of the wing-transom in the sheer-plan, and upon it square up the round forward of the wing-transom in the half-breadth plan; and from hence draw a line to the upper side of the wing-transom, on the rabat of the pitt, and the upper side of the wing-transom will be shown, both to its round down and forward in the sheer-plan. Transfer the height of the margin line from the body to the sheer-plan, and there draw a line parallel to the upper side of the wing-transom last drawn, and unite them at the part of the wing-transom by a line parallel to the rabat of the pitt. The margin-line must next be shown in the half-breadth plan, by squaring it down from the sheer-plan, and making it a parallel curve to the aft-side of the wing-transom; the distance, however small, being equal to the rake of the rabat of the pitt, in the depth of the margin at the aft-side of the wing-transom. The margin-line being drawn in every plan of Plate 1, proceed to end the buttock-lines in the sheer-plan; thus, take the distance of the buttock-lines square from the middle line of the body-plan, and let them off the same from the middle line in the half-breadth plan, drawing lines parallel thereto from the bottom of the wing-transom to the after square timber, which will represent the buttock-lines in the half-breadth-plan; then, where those lines intersect the margin-line in the half-breadth plan, square up spots to the margin-line in the sheer-plan, which spots will give the true ending of the buttock-lines, also square up the interference of the buttock-lines with the water-lines from the half-breadth to the sheer-plan; then transfer all the heights of the buttock-lines, where the timbers cross them in the body-plan, to the sheer-plan, as before directed, and draw fair curves through all the spots set off to the landings, and the part of the ship will be represented in the sheer-plan, as cut by those perpendicular sections, as in Plate 1.

Now if the buttock-lines make fair curves, the after timbers will be proved correct, and likewise the water-lines abait in the half-breadth plan; but if the buttock-lines to be made fair curves deviate from the spots as set off, then must the timbers be altered accordingly, and consequently the water-lines. But as a further proof to the correctness of the buttock, or that part of the body chief aft, square up one or two imaginary or proof timbers, equally between the after frame timber 37 and the wing-transom at the side, as represented by the ticked lines in the sheer-plan, Plate 1. Then take the heights on a perpendicular from the upper edge of the keel in the sheer-plan, where the proof.
proof-timbers intersect the buttock-lines and boarding-line, and transfer them to the body-plan above the base line upon each corresponding buttock-line, and half-thickness of the dead-wood; take also the half-breath of the proof-timbers where they intersect the water-lines in the half-breath plan, and transfer them to their respective water-lines in the body-plan; but though the proof-timbers cross the flern-poil, their heels may be set off, as before directed for the after-timbers; then if the spots fo set off produce fair curves, as the ticked timber shown in the body-plan, Plate I., we may conclude that the after-body is sufficiently proved and its fairness accurate. The fore-body may be proved by vertical sections, in a similar manner as described above, only their ends will be determined by squaring up their interficctions with the main-breath line, from the half-breath plan to the sheer-plan.

Having completed the form of the body thus far, it will be necessary to ascertain the capacity and stability of the part immersed, as in all ships of war there is a fixed height for the lower fill of the midship port above the load-water-line, allowing for six months’ stores, provisions, &c. to be on board; and the capacity should be sufficiently adequate for this purpose; for the nearer this is approached unto, the more merit is due to the constructor: it should not be more, to avoid superfluous expense in the building, and the additional men required to navigate her; nor should it be less, from an obvious general insufficiency to answer the required purpofes: the bias should rather lead to increase than diminish in capacity. In ships for commerce, an exact eflimation of their capacity is more frequently required to regulate the port duties, and the contracts between merchant owners and builders, than to infure their liability, a fixed line of floatation, and fail failing, as the charge may be regulated by their ability to support it, and their load-water-line may be confiderably varied, without any hurtful interference with other essential qualities.

Let us at present suppose the 74-gun ship, Plate I., as floating upon the water in equilibriun, and the upper water-line upon a level with the surface of the water, by which the ship is divided into two parts, the one above and the other under the water, which we call the immersed part of the body. In order to judge of this state of equilibrium, in which we suppose the vessel to be, it is necessary to take into consideration all the forces which act upon the vessel; and first the weight of the whole vessel presents itself, by which it is pressed down vertically in a line passing through the centre of gravity of the vessel. This force must therefore be counterbalanced by all the efforts which the water exerts upon the surface of the immersed part, and consequently it will be necessary to determine the pressure that each particle of the immersed surface sustains from the water, which requires researches very embarrassing, and a long series of calculations: but the following considerations will easily lead us to the defired end.

As the vessel occupies the water, by its immersed part, the cavity formed by the body under the upper water-line, let us compare this cove with another, the above cavity being filled with water: it is at first evident, that this mass of water will be in a perfect equilibrium with the water that surrounds it; and it is also plain, that this mass sustains from the part of the surrounding water, the same efforts which the vessel suffers from it. From whence we fee, that these efforts of the water balance the weight of the mass of water which we have just substituted in the place of the vessel. Therefore, since these fame efforts sustain also the weight of the whole vessel, it follows that this weight is precisely equal to the weight of the mass of water which fills the same cavity as formed by the body of the vessel under the upper water-line; or rather, whole volume is equal to the volume of the immersed part of the vessel.

Here, therefore, is the first great principle upon which is founded the theory of the floating of bodies that swim upon the water. It is, that the immersed part must always be equal in volume to a mass of water, which would have the same weight as that of the vessel; and it is from this principle that we determine the true weight of a vessel, by measuring the volume of its immersed part in the water; for then, by reckoning 64,375 lbs. avoidy pesos for each cubic foot, we shall find the weight of the vessel expressed in pounds.

However, this principle, only, is not sufficient to determine the state of the equilibrium of the vessel; another must be still joined to it, and which we shall find with the same facility. We have only to consider in Plate I. the centre of gravity of the masts of water under the upper water-line; then we shall easily conceive that all the efforts of the surrounding water are in equilibrium with a force equal to the weight of the masts of water displaced by the bottom under the upper water-line, which should act in a perpendicular direction through the centre of gravity of the said masts of water downwards; therefore, in order that the vessel may be in equilibrium with the same efforts, it is necessary that the centre of gravity of the vessel be in the same vertical line in which the centre of gravity of the immersed part is found. For that purpose we have only to mark within the vessel the very point where the centre of gravity of the immersed part would be, if it was composed of an homogeneous matter, and this point we shall term the centre of cavity.

Now the state of the equilibrium of any vessel will be determined from these two principles: 1st, that the immersed part must be equal in volume to a mass of water, whose weight would be equal to that of the vessel; and, 2dly, that the centre of gravity of the vessel, and the centre of cavity, fall in the same vertical line, which is the vertical axis of the vessel. With respect to the centre of cavity, it is evident that it must always fall below the load-water-line; and if the immersed part should prefer, in defending, every where the same surface, or that it had either a prismatic or cylindrical figure, then the centre of cavity would fall in the middle of the vertical axis between the load-water-line and the keel. But if the extent diminished uniformly from the load-water-line to the keel, and it at last terminated in a right line drawn through the keel, equal and parallel to the load-water-line, then the elevation of the centre of cavity would be two-thirds of the immersed part above the keel; and if the same immersed part should terminate in a point at the keel as a pyramid revered, then the centre of cavity would be three-fourths of the immersed part above the keel; but with respect to the centre of gravity of the vessel, it may fall either above or below the load-water-line, according as the lading should be distributed throughout the body of the vessel. Thus in Plate I. of ships of war in general, where the guns constitute a considerable part of the weight, since they are placed above the water, the centre of gravity will be situated above its surface.

The bottoms, or immersed parts of vessels in general not strictly agreeing with any of the above-mentioned geometrical forms, it will be necessary to gauge the form of the immersed part of the vessel's bottom, or, which is the same thing, the quantity of water displaced by the bottom; the weight of which, as before observed, is equal to the weight of the ship, its rigging, provisions, and every thing on board. If, therefore, the exact weight of the ship when ready for sea be calculated, and also the number of cubic feet of water displaced by the ship's bottom below the load-water-line, it will then be known if the load-water-line is properly placed.
SHIP-BUILDING.

SHIP BUILDING.

By the preceding estimate, we find the 74-gun ship, Pl. I., weighs, when brought down to her load-water-line, 2810 tons 745 pounds, that is to say, when fitted for sea, with six months' provisions on board. It may now be known, with some degree of certainty, if the upper water-line on the sheer-draught, Plate I., be properly placed, only by reducing the immered part of the bottom into cubic feet; for, if the 74-gun ship, when brought down to the load-water-line, weighs 2810 tons 745 pounds, the quantity of water displaced might also be 2810 tons 745 pounds, or 6,295,145 pounds. Now a cubic foot of salt-water being supposed to weigh 64,375 pounds, we shall therefore find, that if we divide 6,295,145 by 64,375, the quotient will be 97,788 solid feet, which is the contents of that volume of water which she must displace corresponding to her weight.

Displacement or Capacity.

The solid contents of a ship's bottom, were it any regular figure, might be easily calculated geometrically; but as its curves are to various, the following rule, by approximation, may be near enough for practice.

Take the half-breadths of every other frame, and double them, from 26 to O, in the half-breadth plan upon the upper water-line; then find the sum of theses, together with half the foremost frame O, and aftermost frame 26. Now, the frames being equidistant, multiply that sum by 11 feet, the distance between every other frame, and the product is the area of the water-line contained between the frames 26 and O; then find the area of that part of the water-line afore O, and abaft 26, by taking the half-breadth of every timber, and proceed as before, and multiply by 2 feet 9 inches; find also the area of the stem, knee, and grips, before the foremost-timber, also the area of the stern-poilt and rudder abaft the after-timber; then these areas being added to the first found, will be the area of the surface of the whole water-line. Note, the thickness of the bottom plank, as taken in that direction, must be added.

The areas of the other water-lines may be found in the same manner; then the sum of all these areas, except the uppermost and lowermost, of which only one-half of each must be taken, being multiplied by 3.6 feet, the distance between the water-lines (these lines in the sheer-plan being also equidistant from each other), and the product will be the solid content of the space contained between the lower and upper water-lines.

Add the area of the lower water-line to the area of the upper side of the keel; multiply half that sum by the distance between them, the product will be the solid content of that part between the lower water-line and upper edge of the keel.

The solid contents of the keel must be next found, by multiplying the area by its depth; then the sum of these solid contents will be the number of cubic feet contained in the immered part of the bottom, below the upper water-line.

The reason of the above rule will be obvious, by referring to the article Stereometry; for there, to find the solid contents of any irregular body, the area of the surfaces must be taken by ordinates (and such are the joints of the frames of a ship), and those surfaces multiplied by the depth or depths (and such are the water-lines), which will give the solid contents required.

The application of this rule, in finding the cubic feet contained in the bottom of the 74-gun ship, below the upper water-line in Plate 1.

</tbody>
</table>

**Displacement of the Bottom.**

| Half the area of the upper water line | 386 11 |
| Whole area of the fourth water line | 512 34 |
| Whole area of the third water line | 618 51 |
| Whole area of the second water line | 5119 96 |
| Whole area of the lower water line | 3704 84 |
| Half the area of the upper side of keel | 132 124 |

× by distance between the water-lines 26114 729

Area of the keel 265 ft. 9 in. × by 94010 6624
the depth, false keel included | 531 5 |

Cubic feet displaced 94542 162
× by pounds in a cubic foot of salt-water 64375

6880151 lbs.

As the estimated weight of the ship, with every thing on board, was 6,295,145 lbs. we find, by the above calculation, the upper water-line, as parallel with the keel, is placed too low, as the displacement is only equal to 6,086,151 lbs. Therefore proceed to find if the body of the ship is constructed to fail on an even keel, that is, whether the ship will be in her natural position when brought down to that line. For this purpose, let the centre of cavity, or centre of support, be next found, as then we may determine what proportion the displacement of the fore-part of the ship bears to the aft-part; for, should they not prove equal, the ship cannot be constructed to fail on an even keel.

**Method of finding the Centre of Displacement or Support.**

The centre of gravity of a ship, kept in the water, and in a state of equilibrium, is in a perpendicular line, passing through the keel, and dividing the upright into two equal and similar parts, in a certain distance from the stem and stern, above the keel.

To obtain the centre of displacement, or centre of gravity, of the immersed part of a ship's bottom or of any weight, as a rule of three, we have

<table>

<tr>
<th>6295145</th>
<th>940106624</th>
</tr>
</thead>
<tbody>
<tr>
<td>5315</td>
<td>64375</td>
</tr>
</tbody>
</table>

Then to find the centre of gravity of the system, in respect to the aft-side of the rudder, which is allowed for the first term of the momenta, we need not find the centre of gravity of each parallelogram, but divide the whole surface into three sections, and multiply their sums, as before, by the difference between the ordinates, and the product will be the area of each section.

Then to obtain the sum of the momenta of all the elementary parts of the surface, multiply the breadth of each ordinate into its distance from the axis of the ordinates, or first ordinate, and then take the sum of all these products; and, by multiplying this sum by the distance between the ordinates, we shall have the sum of all the momenta of the elementary parts of the surface, which, divided by the sum of the ordinates, will give the distance of the centre of gravity of the whole surface from the axis of the momenta.

Lastly, the areas of the several parallels of surface, and their momenta, being found, divide one by the other, and the quotient will be the distance of the centre of gravity of the whole section from the aft-side of the rudder.
SHIP-BUILDING.

</tbody>
</table>

Now 3770 65 ft. 10 1/2 in. divided by 3764 8 1/2 ft. of the in., the distance of the centre of gravity of the whole section of the first or lower horizontal water-line from the aft-side of the rudder.
SHIP-BUILDING.

Operation for the Plane of the Keel, &c.

To find the centre of gravity for the plane of the keel, &c.

The length on the upper side or plane of the keel, from the aft-side of the rudder, is 

\[ \text{177 ft.} \]

1 ft. 6 in.

Multiplied by its thickness

\[ \text{1 ft.} \]

8 in.

Area of the plane

\[ \text{265 ft.} \]

9 sq. ft.

Distance of its centre of gravity from the aft-side of the rudder, being equal to half its length

\[ \text{88 ft.} \]

7 in.

Now 265 feet 9 inches, multiplied by 88 feet 7 inches, is equal to the momentum 23,540 feet 1\frac{1}{2} inches.

The centres of gravity of the six planes having been found, the distance of the centre of gravity of the whole bottom of the ship, from the aft-side of the rudder, is obtained as follows:

From the principles already explained, the distance of the centre of gravity of the bottom, from the aft-side of the rudder, is equal to the sum of the moments of an infinite number of horizontal planes, divided by the sum of these planes; or, which is the same, by the solidity of the bottom. As, however, we have no more than six planes, we must conceive their moments as the ordinates of a curve, whose ordinates may be the same as that of the horizontal planes.

Now the sum of these ordinates, or planes, except the first and last, of which take but half, being multiplied by their distance, gives the surface of the curve; of which any ordinate whatever represents the momentum of the horizontal plane at the same height as these ordinates; and the whole surface will represent the sum of the moments of all the horizontal planes.

<table>
<thead>
<tr>

<td>first</td>
<td>3764</td>
</tr>
<tr>
<td>Half the keel</td>
<td>132</td>
</tr>
<tr>
<td>Sum</td>
<td>26114</td>
</tr>
</tbody>
</table>

Now 255337 feet 41 inches, divided by 26114 feet \( \frac{3}{4} \) of an inch, gives 97 feet 91 inches, the distance of the centre of gravity of the bottom of the ship from the aft-side of the rudder.

The height of the centre of gravity of the bottom may be thus found.

To half of the plane of the keel and half of the upper horizontal plane, add all the intermediate planes, and multiply them progressively as before, taking the upper side of the keel for the axis of the moments; then that sum being multiplied by the distance between the planes, and divided by the sum of the planes, taking half of the first and last, gives the height of the centre of gravity of the bottom above the keel.

<table>

</tr>
<tr>
<td>Half the fifth</td>
<td>3860</td>
<td>11</td>
</tr>
</tbody>
</table>

Sum | 26114 | 0 | 80668 | 54 |

Now 80,668 feet 5\(\frac{1}{2}\) inches, divided by 26,114 feet \(\frac{3}{4}\) of an inch, gives 3 feet \(\frac{3}{4}\) of an inch; which, multiplied by 3.6 feet, the distance between the horizontal sections, gives 11 feet \(\frac{3}{4}\) of an inch, the height of the centre of gravity of the bottom of the ship above the under side of the keel.

The height of the centre of gravity of the bottom of the ship, and its distance from the aft-side of the rudder, being found, the ship being supposed in an upright position, the centre of gravity will necessarily be in the perpendicular longitudinal section, supposed to divide the ship in two equal and similar parts at 97 feet 91 inches, the distance of the centre of gravity of the bottom of the ship before the aft-side of the rudder, which comes between the frame 6 and 2 in the after-body. It may now be ascertained whether the ship will be in her natural position when floating at the upper horizontal line, or constructed to sail on an even keel. Thus, separate the displacement of that part of the bottom before the centre of gravity or support, and see how it agrees with that part of the bottom abait it, as we may then examine the difference, if any, as in the following examples.
### Ship-Building.

SHIP-BUILDING.

By the result of the above calculation it appears, that the after-part of the bottom has a minus of 0.931,524 feet, its greatest being 2.324,32 feet less than the fore-part; and was the ship to be constructed to fail on an even keel, it would be necessary to fill the after-part half the difference, or 491,666 feet, and reduce the fore-part until it had lost the same quantity; but to alter the after-part of the ship from its present construction, or to make it fuller, would retard her velocity, and prevent the water collapsing at the rudder; for the run of a ship should be neither too fine nor too full, but so constructed that the column of water should exactly meet upon the stern-post, then the rudder will have its full power. The quarter above the load-water-line should be very full, to support the ship when riging forward to a sea, and also to enable her to fecud.

In regard to the falling trim of a vessel, it is the decided opinion of most scientific men, that ships or vessels of the larger classes should always be so constructed as to fail on, or nearly on an even keel, that is, so that the ship, when trimmed for failing, should have her keel parallel to the surface of the water; therefore, by much more than the force of the wind, the full length of the ship through the water has a constant tendency to depress the bow, so much should the ship be trimmed by the stern, as that will be found most advantageous both to their failing and fucking.

Many think it inconvenient to construct a ship to fail on an even keel, and yet to place the midship-bend or greatest breadth very forward. A ship fo intended to fail, ought, as they conceive, when launched, to have an equal bearing fore and aft, in order that, before the ballast is flowed, the ship may be on an even keel; and they think that the ballast, if not placed equally fore and aft, must inevitably strain the feather of the ship. Nevertheless, experience convinces us it is not materially detrimental; for many ships, when launched, will swim four feet by the stern, more or less, and yet when trimmed for failing, they are found to go fuller on an even keel, and receive little or no damage if carefully flowed.

Some ships are too clean abaft, and require to fail by the stern; because they have no bearing for fifteen or twenty feet from aft, till the buttock is brought well into the water; and even then, for want of being fuller lower down, when the sea leaves the buttock, the over-hanging of the stern will strain the ship, and occasion her to tremble, till the next sea, with redoubled force, strikes the buttock as the stern is failing, and so shake the ship; in which case it will be well, if some part of the masts be not carried away by the shock; however, this kind of motion must retard the velocity. This accident, though rare, is dangerous, and should be prevented in the construction of the ship.

With respect to ships that ought to fail some feet by the stern, on account of their insufficiency abaft, it is the opinion of many, that if a line were drawn to be well with the lower side of the keel, in the middle of the ship's length, and half the difference set up at the after-part of the stern-post from the lower side of the keel, and that part of the keel and dead-wood were taken off, and placed under the fore-part of the keel, with the after-end that was before to be forward, so as to make the lower part of the keel straight, as before, the ship would then fail somewhat faster, and be the better; for when a ship is brought so much down by the stern, the keel, not being parallel to the surface of the water, (to which the ship generally fails parallel,) must occasion a preasure at the under side of the keel, equal to the weight of water displaced by the breadth of the keel, and to the angle which the keel makes with the surface of the water in its own length. This may shew why so many ships, differently constructed, are found to fail on an even keel, although many of them were designed by the constructor to fail by the stern. I find the result rather in favour of an even keel, the 74, Plate I., was so constructed, as most likely to fail every part.

By that means the water-lines were drawn parallel to the bow, and were thereby more useful as well as more properly placed to form the body, for when the square timbers, and the water-lines, being square to the timber, properly agree with each other, and are fair curves, the riband-lines, or any other section, will likewise be fair, or as fair as they should be, allowing the preference to the water-lines and square timbers.

When water-lines are not designed to be parallel to the keel, the draught is generally formed by riband-lines, because the water-lines differing in height at every timber, require the square timbers to be formed before their height can be set off; and when the water-lines are run, if not approved of, much of the work must be done over again, the water-lines being more regarded than the riband-lines; for many ships are constructed by riband-lines only, which form to produce fair curves, yet forward, and aft, especially, they make a very unfair body, which is detrimental to velocity. Some vessels, as cutters, &c. draw much more water aft than forward, and their bows are more full in proportion to the after-part, nor would it answer so well were their line of floatation nearly parallel with the keel, but spreading as it does aloft, especially towards their bows, the bow meets the fluid in a more floating direction, and experiences far less resistance; and the depression of the stern, with the impetus of the aftermost fails, causes a proper counter-balance, and propels the vessel through the water with greater velocity than if otherwise constructed; for the after-part of those vessels is generally very clean or tapering, which necessarily contributes to make the vessel weatherly, and causes it, under judicious management, to turn as it were on a pivot.

A ship may be built to a precise draught of water, by which the construction will be founded upon true principles; but when a ship is not built to one precise draught more than another, it will be a very difficult, and one of the most complex questions in ship-building to determine this point. It may be imagined that no more is necessary than to make the ship swim in the water, so as to be capable of carrying the greatest sail; but when a ship is very deep in the water, it will greatly increase the resistance, and consequently retard her failing; hence a long ship will draw less water than a short one, which is a good property, and the resistance at the stern being less, the ship will therefore fail faster. The resistance, however, must be carefully calculated, not absolutely, but relatively, and in proportion to the fall the ship.

In ships of war, the load-water-line must be governed by the height of the lower ports above the water in midships; and this we find in line-of-battle ships should invariably be from five to six feet, in frigates from fix to seven feet, and in sloops, cutters, &c. from four to five feet.

Ships for commerce are generally constructed to carry a certain cargo, and their principal dimensions are determined according to the trade for which they are particularly designed; therefore the line of floatation, or load-water-line, is not confined in them to exactly a certain height.

Ships of the line, from long practice, have been found to fail best when inclined one foot, or rather more, by the stern. Thus, the 74-gun ship in Plate I. load-water-line, when fitted for sea, was 20 feet forward and 21 feet abaft; therefore it only remains to be ascertained, whether the whole displacement of the bottom under the load-water-line, or the displacement of the weight of the ship, &c. when fit for sea, by multiplying the mean area of the load and upper horizontal water-lines by six inches, the mean depth, and adding it to the displacement already found, as in the following operation.
SHIP-BUILDING.

Area of the Load-Water-Line.

We now find that the 74-gun ship, Plate I., load-water-line, is not only properly placed with regard to her belt failing trim, but the displacement also agrees with the estimated weight of the whole ship when fit for sea, which was 2810 tons 745 lbs., or exceeds it by 1 tons 430 lbs., which is better; as the bias should rather lead to increase than diminish in capacity, and favours any little inaccuracies in the measurements; though surely there is little room for error in either extreme, if proper attention be paid to the subject. In like manner may, therefore, the weight of any other ship be found; and, by reducing the displacement of the bottom into cubic feet, we may always ascertain if the load-water-line in the draught be properly placed.

Stability, or Stiffness.

The stability or stiffness of a ship comes next under consideration, being a quality no less essential to the safety of navigation than capacity; and without which a ship is totally disqualifed for the purposes of war, being unable to use her guns with effect, or carry a press of sail in case of emergency.

Before we proceed further, the following particulars, as they relate to vessels at rest, or in motion, should be defined.

The centre of gravity, or displacement, already mentioned, is the centre of gravity of the volume of water displaced by the immered part of the ship's bottom; and is also the centre of all the vertical force that the water exerts to support the vessel; for as heavy bodies by their gravity endeavor to approach the centre of the earth in a vertical line, passing through their centre of gravity, tending directly towards the centre of the earth; so the pressure of fluids endeavors to carry bodies in a vertical line tending from the centre of the earth towards their surface, and passing through the centre of gravity of the immered part, which forces them towards the surface; so also in any immered body at rest these two opposite forces coincide in the same vertical line, acting in a quite contrary direction to one another. Thus, every floating body is necessarily supported, or prefled upwards, by the fluid with a force equal to its weight, or pressure downwards, otherwise no body could remain at rest on a fluid, but would ascend or descend as the prevailing force determined; and the moments of all the forces with which a floating body presses on a fluid, and the moments of the forces of the fluid which supports the floating body, are equal and contrary, and are resolved into the same right line, perpendicular to the plane of the fluid. But as this centre depends upon the shape of the body immered, it of course varies with every inclination of a ship; and whilst the centre of cavity goes faster, and further over to the ship's side in her motions, so as to keep without the perpendicular of the centre of gravity, the ship will be supported; and the water will act upon the centre of cavity.
SHIP-BUILDING.

Gravity in the immersed body with more or less power, in proportion to its distance without the centre of gravity, to bring the ship upright, where the action force or power ceases which overbalanced the vessel to heel.

The line of support is the vertical or perpendicular line supposed to pass through the centre of gravity, and intersecting a line perpendicular to the keel of the vessel through the point, called the meta-centre. For if a floating body is inclined by any power which does not change the position of its centre of gravity, the line of support must necessarily pass between that power and the centre of gravity; and the force or moment of that power is equal to the weight of the floating body, multiplied into the distance of its centre of gravity from the line of support. As the line of support passes between the centre of gravity and the power applied to heel the vessel, the moment of that power, or its force, multiplied into its distance above the meta-centre, is equal to the moment of its gravity, or the weight of the floating body multiplied into the distance of the centre of gravity below the meta-centre.

Suppose the vessel inclined, or heeling by the power of the wind on the sails, if the line of support passes on the windward-side the vessel would upset, as the power and gravity are at the same side operating to incline it; but if it passes to the lee-side of that power, the vessel will be redressed, as the power and weight operate to that effect; and if the moment of the power and gravity be not equal, the body will not remain at rest, but will incline more or less, as the power or the weight prevail.

Hence it is plain, that the distance from the centre of gravity to the line of support, multiplied into the weight of the vessel, is the measure of the stability of the vessel, or its effort to redress itself when inclined, and that its stability is as that distance.

The meta-centre usually signifies a point to which, if the centre of gravity of a floating body be raised, the smallest lateral effort will make it incline. It is plain, that in an homogeneous cylinder, or sphere, the meta-centre, and centre of gravity, being always in the same point or centre of the sphere, however these bodies are inclined, have no stability. The centre of gravity must, by no means, be placed above the meta-centre, because if it were the vessel would overtop. This centre, which has likewise been called the floating centre, depends upon the situation of the centre of gravity, for it is that point where a vertical line drawn from the centre of gravity perpendicularly a line passing through the centre of gravity, and being perpendicular to the keel.

The centre of gravity of a ship, is that point by which it may be suspended, and the parts remain in perfect equilibrium. It is also the centre of all the forces, or moments, which pre- Lis vertically, or directly downwards towards the centre of the earth.

The lower the centre of gravity is placed, the farther is it from the line of support, and consequently the greater stability.

In ships of war, the centre of gravity can never be far removed from the load-water-line: for if the centre of gravity could be placed nearer the keel, it is not to be defined, as the farther it is removed from the load-water-line, the rolling of the ship becomes more uneasy.

The centre of motion is that point upon which a vessel oscillates or rolls when put in motion. This centre is always in a line with the water’s edge, when the centre of gravity is even with, or below the surface of the water; but whenever the centre of gravity is above the water’s surface, the centre of gravity is then the centre of motion.

The longitudinal axis of a ship is an imaginary line, which passes horizontally from head to stern through the centre of gravity.

The transverse axis is an imaginary horizontal line, parallel with the water’s surface; passing through the centre of gravity.

The vertical axis is an imaginary perpendicular line, drawn through the centre of gravity when the vessel is in equilibrium.

It is about these axes that every ship or vessel may be supposed to turn. In rolling, the ship may be supposed to oscillate on the horizontal axis; in pitching, on the transverse axis; and in working, &c., to turn on the vertical axis.

From constantly observing that the performance of ships at sea depends materially on their stability, both naval architects and navigators will, at all times, be desirous of discovering what particular circumstances of construction this property confers, and according to what laws the stability is affected by any varieties that may be given to the forms, dimensions, and disposition of parts; which are determined, partly according to the skill and judgment of the constructor, and partly, in large vessels, as we shall show, by adjustments after the vessel is built.

The form of the immersed body, and the weight of the ship, are the chief terms in the composition of stability, and they are only to be attained, in the requisite degree, by full dimensions near the load-water-line, with sufficient capacity.

At first sight, it is certain that all the weight above the load-water-line helps to make the ship crack, and, consequently, the lighter the upper works the lighter the ship.

Constructors may vary the form of a ship chiefly in three dimensions, that is, in the length, breadth, or depth: let us examine how far enriching or shallowing of ships, in any of these particulars, will contribute toward making them carry sail, or, in other words, gain stability; for although the wind may, in one sense, be said to constitute the power by which ships are moved forward in the sea, yet if it acts on a vessel deficient of stability, the effect will be to heel the ship rather than to propel it forward; stability, therefore, is, not less necessary, than the impulses of the wind are to the progressive motion of vessels.

If the length only, without altering the other dimensions, be enlarged, the centre of gravity and the meta-centre will continue the same height, and her liability in respect of inclination to one side will increase in proportion to the weight of the ship; and as the weight generally increases or diminishes in proportion to the length, we may say that in ships that differ only in length, their stability will be in proportion to their length.

Yet although an increase of length would enable a ship to carry the most sail, consequentely fail faster, it must not be extended to an extreme; because if so constructed, a ship would neither tack nor veer so quickly; neither would the hitt or rife in a sea like one shorter; she would strain more, and be very liable to have the sea break over her. The influence of the rudder may be weakened, and may even be totally lost. The greatest judgment is therefore required in proportioning the length, which may be proportionally greater in those ships that generally navigate in the smoother seas, or are not intended to be deeply laden.

By altering the breadth, the stability is materially affected; for by enlarging it we gain, and by diminishing the breadth we lose a great deal of the stability. M. Bouguer has proved, that the stability increases in proportion to the cubes of the breadths; for, supposing the bottom homogeneous, then, if the increase of weight, and of consequence stability, will be double the increase of the breadth; and zely, the additional weight will act with so much the greater force, as the length of the lever is increased, or as the meta-centre is raised, and the height of that point is augmented in proportion to the square of the breadth; hence the stability 

...
SHIP-BUILDING.

will be increased in proportion to the cube of the breadth; for example, without altering the other dimensions, let the breadth be doubled, we thereby double the weight, which, by acting upon the arm of a lever, double the length will be quadruple, to the ship will acquire eight times the stability.

Thus we see an increase of breadth will produce an increase of stability; for a ship that is broad and shallow has much more stability than one that is narrow and deep; but the sinking of the ship may be much retarded, as the certainly would be leewardly under little sail, which ought to be particularly guarded against, especially in constructing large ships of war. The expense in the building would also be materially increased, according to the usual mode of computing the tonnage, as may be readily seen in the next section.

If the depth only is increased, without enhancing either the length or breadth, all the stability that can be gained will be in the bowage. To increase the depth or draught of water would lower the centre of gravity, and increase the weight; this would operate against stability, because the rest is as the quantity of water to be removed; or nearly as the area of the thwartship section of the imersed part of the body at the midship-bend. It would act at the extremity of the immersed body of a figure less proper to separate the line of support from the centre of gravity, so that the effect on one side would be in some measure destroyed on the other; and, by lowering the centre of gravity too much, the ship would labour excessively, and endanger the masts, too large a draught of water being both dangerous and inexpedient.

Ships having a sufficient degree of stability arising from their construction, will certainly fail faster than others, which, in order to carry the same quantity of sail, require to be ballasted with a much greater weight; for the latter, if ballasted, will be much more liable to roll than the former.

The following circumstance will prove, that instability in the construction cannot be rectified to any considerable degree by the bowage, although, on the contrary, that the stability of many ships, however perfect in construction, may be materially injured by improper trim, or an injudicious mode of bowage.

And, first, as there is nothing of more importance to the well-being of a ship than its stability, it will not be improper to mention an opinion which prevails with seamen in general, that the stability depends chiefly on the bowage of the hold; and at the same time, in order to shew that a very great change in that respect will produce a very trifling difference in the instability, we shall quote a professional author of great merit, M. de Romme, in his book, L'Art de la Marine page 105.

"As to the position of the centre of gravity, no doubt it may vary, but the limits to which it is confined are very strict, especially in ships of war. An example in the Scipio, of 74 guns, armed for the first time in 1779, was hardly in the road before she was suspected of instability. It was important in time of war to clear up those doubts, and to make the necessary experiments to prove this dangerous defect, if it existed. First, the lower-deck guns were run out on one side, while hosed on the other, which heeled the ship thirteen inches; the ship's company were then ordered to their quarters at the side the guns were out, which increased the inclination to twenty-four inches. After these eays the fails were let, and in fine weather the ship was found to crank, as to render the use of the lower-deck guns difficult and dangerous: thus, her instability being proved, she was ordered to port to be remedied.

"Opinions were divided as to the cause of the defect; some imagining it to proceed from the form of the hull; others from the ill arrangement of the charge. The first engineer was ordered to attend at Rochfort, and direct the choice of measures to give the Scipio, as well as two other ships, the Pluto and Hercules, built from the same plan, the stability they wanted. He judged that new bowage would remedy the defect, and his opinion was adopted by the marine council. The Scipio was unloaded, and charged anew, under the direction of the chief engineer. In the first charge she had 84 tons of iron, and 100 tons of stone ballast, and was reloaded with 198 tons of iron, and 122 tons of stone ballast; and as her draught of water, or displacement, could not be altered, it was necessary to diminish 130 tons of water to preserve the same line of floatation; by this means 136 tons were placed, in the second loading, eight feet lower than in the first; yet when the ship was completed with the new distribution of her charge, she was found precisely as deficient as before, inclining twenty-four inches, with the men at quarters, and the guns out. She was afterwards doubled with light wood, a foot thick at the extreme breadth, and ten feet under water, decreasing to four inches length and depthways."
SHIP-BUILDING.

The above operation gives 14 feet 9½ inches, the height of the meta-centre above the centre of gravity of the immersed part of the bottom of the 74-gun ship, Plate 11.

Now let us see how the above calculations in determining the height of the meta-centre above the centre of gravity agrees with actual experiment; for theory (particularly in the constructing of ships) that agrees with experiment is only to be regarded. We are in this particular indebted to the late admiral Leveson Gower, who directed several experiments to be made to try the relative instability of the following ships of war, by heeling them with their lower-deck guns out on one side, and hove up on the other; and afterwards with their men at quarters, the guns remaining as above.

As the inclinations of the Brunswick and Bedford are omitted in the first experiment, we shall only compare the relative stability of the other three ships, which are quite sufficient to explain everything necessary to be remarked on the subject. It is to be regretted that the first inclination of the Brunswick was omitted, as it comes the nearest to Plate I.

The estimated weight of the Formidable was 3150 Tons.

The centre of gravity of the immersed part of the bottom was above the under side of the keel.

The keel

Centre of gravity below the meta-centre

5 0

Which we find exceeds the Bombay Caffle’s; and the ports in Plate I. are five feet eight inches above the water.

By the above experiment we observe, that the guns being run out on one side and hove out on the other, inclined the ship to a certain point, and at the same time there was an exact equilibrium between the moment of the guns, and the whole weight of the ship on each side the line of support in the direction of the vertical effort of the water. The centre of gravity of the ship is in the same vertical line with the meta-centre when the ship is in an horizontal position; and the more the ship inclines, the more will the centre of gravity of the ship be removed from the vertical line of the meta-centre, or line of support. Hence it is plain, that the distance of the centre of gravity from the line of support is always in proportion to the line of the inclination; at least when the inclination is but small, as before observed. Now, if that distance, and also the whole weight of the ship, be known, we have also its momentum, or the relative force with which that weight acts in endeavouring to right the ship, and bring her again into an horizontal position, and which is the measure of her stability; but since both the situation, and likewise the weight that produces the inclination, are known, we may thence know if the momentum of one be equal to that of the other, and thereby easily discover if the centre of gravity is in that very point we propone.

The success of the above experiment (which might be rendered very useful if more frequently tried) depends on the nicety to be observed in taking the exact quantity of the angle of inclination; to attain this, a level line for the sensible horizon of the sea may be used, or, what is much better, a plum-line fastened to the head of the mast, taking its distance from the heel of the mast, both when the ship is up-right, and likewise when she is inclined. The plum-line seems to be the most convenient, because we have thereby immediately the proportion in which the centre of gravity recedes from the vertical line of the meta-centre, which will always be in proportion to the distance of the plum-line from the heel of the mast. During the whole time of the operation, it is necessary to be very careful to render all the circumstances absolutely the same, so as to be well assured the inclination is produced only by the momentum of the guns, &c.

We may in this manner prove the centre of gravity of the 74-gun ship, Plate I., knowing the height of the meta-centre, for, having the quantity of the weight producing the inclination, (which is the same as the above), and examining the distance of the centre of gravity from the line of support in which the effort of the water exerts itself, we have also its momentum, or its relative force, which is equal to the whole ship, since these two exactly balance one another; so that it is only dividing this momentum by the whole weight of the ship, and the quotient will give us the distance of the centre of gravity of the ship from the line of support, or vertical line of the meta-centre.

For the Bombay Caffle of 74 guns and 2700 tons in eliminating...
SHIP-BUILDING.

Estimating the weight or displacement, it was found, that 36
hundreds of an inch balanced 42 tons at three feet; and it
will be found by the following ratios, that 53,445
hundreds of an inch in Plate 1, will balance 42 tons at
three feet. Plate 1, displacement 28,401 tons 175lbs.
= 3859.75 x 53,445 = 151200.5 = 1200 = 126.

We now find that the distance of the centre of gravity is
removed from the line of support 3.445 hundreds of an
inch. After this, it will be easy to discover how far the
centre of gravity is below the meta-centre, since there will
be the same proportion between the distance of the plan-
cline from the heel of the mast, and the height of the mast,
that there is between the distance of the centre of gravity
from the line of support. Thus, the length of the mast is
112 feet, which multiplied by 3.445 = 5985.8 = 1200 =
4 ft. 11 in., the distance of the centre of gravity below the
meta-centre nearly agrees with the calculation above given.

Tonnage or Burthen.

By the tonnage of a ship, is meant to convey the idea of
the weight of the cargo she is intended to carry from her light
to her load water-line, or sea in the water, when bell
equipped for sea. It may also be called the ship's real bur-
then. Therefore, to ascertain the true burthen or tonnage
by calculation, is a question of equal importance and dif-
culty, as preceding displacement, &c.

It is of importance, because it is by this that the mer-
chant or freighiter judges of the fitness of the ship for his
purpose; and although customary rules are given for com-
puting the tonnages of ships, the bare inspection of them
will prove how futile they are. It would be very difficult
to fix upon any general rule which shall be very exact, be-
cause it depends not only on the cubical dimensions of the
ship's bottom, but also on the scantling of her whole frame;
and, in short, on the weight of every article to complete the
said ship ready to receive on board her cargo. The weight of
 timber is variable; the scantling of the frame being no less
so.

The following rules for computing the tonnage of a ship
are commonly adopted and made use of between the contrac-
tor and the builder, at a certain rate per ton for the building,
and will be found to be quite unconnected with the above
definition of a ship's tonnage; for as the depth is out of
the question, the contractor finds a saving in less breadth
and great depth, which make against stability, and conse-
quently injure the velocity; on the contrary, great breadth
and less depth will be found more advantageous to the
builder; thus are the interests of the two parties oppositely
concerned in the result, and both, when carried to the ex-
treme, are exceedingly injurious to the construction of ve-
nels.

The general Rules adopted for measuring the Tonnage of Ships
in the Royal Navy and the Merchants' Service.

Let fall a perpendicular from the fore-side of the item,
at the height of the upper deck, or middle deck, in three-
deck ships, and a shorter perpendicular from the aft-side of
the main-pot, at the height of the wing-transom. In mer-
chant-ships, the fore perpendicular is let fall from the
fore-side of the item, at the height of the wing-transom.
From the length between these perpendiculars, deduct three-
fifths of the extreme breadth, (that is the thickness of the
bottom-plank on each side added to the moulded-breadth),
and likewise as many 24 inches as the wing-transom is above
the upper edge of the keel, and the remainder is reckoned
the length of the keel for tonnage.

The breadth of the keel for tonnage is measured by the
extreme breadth, and that is taken half the extreme
breadth; the breadth by 3.445, with the breadth, is what
may be said, the true tonnage of the ship.

Calculation of the tonnage of the 74-gun ship:
Plate 1, according to the calculation above:

| Length from the fore-side of the ship, at the height of the upper, or 4 ft. 11 in., on the upper side of the wing-transom | 192 | 94 |
| The height of the wing-transom is 26 ft. 10 in., which produces for every 2½ inches | 5 | 61 |
| Three-fifths of the extreme breadth is | 72 | 71 |
| Height of the wing-transom | 137 | 138 |
| Burthen in tons, according to the common rule | 186414 |
| Estimation, showing the real burthen of the ship | 74-gun ship, Plate 1. |
| The weight of the ship at the launching | 1457 | 1198 |
| Draught of water | 1264 | 1040 |
| Weight of the furniture, including the教练 | - | - |
| Weight of the ship at her light water-mark | 1582 | 998 |
| Weight of the ship at the load water-mark | 2829 | 275 |
| From which deduct the weight at the light water-mark | 1582 | 998 |
| Real burthen | 1246 | 1417 |
| Burthen in tons, according to the common rule | 186414 |
| Difference | 617 | 1585 |

By the above it may be readily seen, that the 74
gun ship (Plate 1) will not carry the number of tons the
rated for, by 617 tons 1585 lbs., and hence the inpro-
priety of such a rule being made general, as it will always
be found greatly to increase the tonnage of sharp-built
vefls, while those that are full-built, as ships in the East
India Company's service, will carry a great deal more.
We shall, therefore, calculate the tonnage of the East India
ship (Plate XII) both ways as above, in order to prove
the great inaccuracy of the rules with respect to these ve-
fls, as well as to ships of war.

3 Y 2 Calculation
SHIP-BUILDING.

Calculation of the burthen in tons of the East India ship, (Plate XII.) according to the common rule.

Length from the fore-side of the stem, at the height of the upper side of the wing-transom, to the after-side of the main-poll, at the said height of wing-transom, is 

Feet. 159

Three-fifths of the extreme breadth is 22.6998

The height of the wing-transom is 24 feet, which produces for every $2\frac{1}{2}$ inches 5.

27.6998 27.6998

Length of the keel for tonnage 

Multiplied by the extreme breadth 131.3 37.3333

Multiplied by half the extreme breadth 4367.5122 15.9166

Divided by 94 93968.

Burthen in tons, according to the common rule 999\frac{3}{4}

Estimate, shewing the real burthen of the East India ship, Plate XII.

The weight of the ship at the launching? 

draught of water 748 1071

The weight of the furniture, including the sheathing 62 1782

The weight of the ship at her light water-mark 811 613

The weight of the ship at her load water-mark 2029 597

From which deduct her weight at the light water-mark 811 613

Real burthen 1217 2224

Burthen in tons, according to the common rule, as above 999 1477

Difference 218 747

We now find that the East India ship will carry 218 tons 747 lbs. more than she is rated for by the common rule; which, it plainly appears, is in confederation with the weight of her body being formed fo full; and the greater the contrast between full and sharp bodies, the greater will be the error in the tonnage cast by this rule; which shews the impriopriety of the erroneous method practised for casting a ship's tonnage.

Hence it is obvious, that no dependence can be placed on the common rules for ascertaining the true tonnage of vessels. Indeed we neither have, nor expect to have, any rule that shall be quite exact; because the tonnage depends not only upon the cubical dimensions of the ship's bottom, but also on the weight and scantling of her whole frame. For instance, a ship built at Archangel of fir, will carry considerably more than another of the same plan in every respect, built at the Havannah of live oak; nor is there a greater difference in some ships, when the weight of every thing which properly makes a part of the ship, as to the fastening, &c. &c. is considered. We must, therefore, be contented with a rule that approximates nearer to the truth; and such is the following, proposed by the late Mr. Parkyns, of Chatham-yard.

Rule 1. For sharp ships, particularly those of the royal navy.

1st. Take the length on the gun-deck, from the rabat of the stem to the rabat of the stern-poll, or between the perpendiculars. Then take $\frac{3}{4}$ths of this length, and call it the keel for tonnage.

2dly. To the extreme breadth add the length of the gun-deck, or length between the perpendiculars. Then take $\frac{3}{4}$d of this sum, and call it the depth for tonnage.

3dly. Set up this depth from the limber-frake; and, at that height, take a breadth also from out to out-side of the plank at dead-flat, and another breadth between that and the limber-frake: add together the extreme breadth and these two breadths. Take one-third of the sum, and call it the breadth for tonnage.

Lastly. Multiply the length for tonnage by the depth for tonnage, and the product by the breadth for tonnage, and divide by 49. The quotient will be the burthen in tons nearly.

The following trials have been made, to prove the accuracy of this rule.

Rule 2. For ships of burthen, or commercial ships in general.

1st. Take the length of the lower deck, from the rabat of the stem to the rabat of the stern-poll. Then take $\frac{3}{4}$ds of this length, and call it the keel for tonnage.

2dly. To the extreme breadth add the length of the lower deck. Then take $\frac{3}{4}$ths of the sum, and call it the depth for tonnage.

3dly. Set up this depth from the limber-frake; and, at that height, take a breadth also from out to out-side of the plank at dead-flat; take another at two-thirds of this height, and another at one-third of the height; add the extreme breadth and these three breadths together, and take one-fourth of the sum for the breadth for tonnage.

Lastly. Multiply the length for tonnage by the depth for tonnage, and the product by the breadth for tonnage, and divide by 36.6666 or 36; and the quotient will be the burthen in tons.

The following trials, among many others, shew that this rule does not deviate much from the truth.

Granby,
The general rule for calculating the heading of colliers is as follows:

From the length of the keel subtract 6 or 7 feet for the dead flowage fore and aft; multiply the remainder by the breadth at the midship-frame, and that product by the depth of water the ship draws when loaded; divide this by 96, and you will have the number of London chaldrons the ship will carry.

A method of constructing a scale of solidity, by which may be ascertained the quantity of water displaced at any given draught, and the weight required to bring the ship down to any draught of water proposed.

In order to construct the scale for any ship, it is requisite, in the first instance, to calculate the quantity of water displaced by the bottom, below each water-line, and by the keel, in the same manner that we have already done for the 74-gun fluyt (Plate I.); for which ship, as the areas of the several water-lines are already calculated, a scale of solidity may be readily constructed as follows:

Construct a scale of equal parts, to represent tons, as the scale is marked in Plate XIV.; and another to represent feet and inches, as that below it. The larger these scales, the more exact will be the performance.

</table>

Now set off the tonnages from the above table upon the corresponding water-lines, &c. in Plate XIV., fig. 1, thus: upon C, representing the upper side of the keel, set off, from the perpendicular A H, 15 tons 615 lbs., taken from the scale of tons, equal to C. Upon the line D, or lower water-line, set off 233 tons, 1728 lbs. equal to D D. Upon the line E, or second water-line, set off 083 tons 823 lbs. equal to E E. In like manner, set off the other tonnages upon their corresponding water-lines; then through the points C, D, E, F, G, H, draw the curve A S, which will represent the solidity of displacement at any given height.

For example, the 74 (Plate I.) draught of water, when launched, was 13 feet forward and 17 feet abaft which gives 14 feet 3 inches at dead-flat, or midships, the ship's chief support in this light fluyt. Take, therefore, 14 feet 3 inches from the scale of feet, and set it up parallel from the line A B, or lower side of the keel, to intersect the curve of displacement, as at 1. Take the nearest distance from the intersection of the curve to the perpendicular A H, and apply it on the scale of tons, and it gives 1550 tons 1120 lbs. But by the estimate, the weight of the fluyt, at her launching draught of water, was 1577 tons 2908 lbs., which exceeds the above by 172 tons 1162 lbs.; but that may
may be easily accounted for, by the weight of anchors, cables, men, ballast, &c. as additional weight in the ship at that time. Take 1377 tons 2198 lbs., the weight of the hull exclusively, from the scale of tons, and set it off from the perpendicular line A H, along the line A B, or bafe; whence square up the perpendicular K k, to intersect the curve of displacement. That depth we find by the scale of feet to be 13 feet 4 inches, a difference of 11 inches, accounted for as above.

Now to prove the real burden of the ship by this scale of displacement, we have found, by the ultimate, that the ship, with her furniture, &c. displaces 1582 tons 998 lbs. at her light water-mark. Take 1582 tons 998 lbs. from the scale of tons, set it off as before, and raise the perpendicular L L to intersect the curve of displacement; and another perpendicular at 2829 tons 175 lbs., taken from the scale of tons, which is the weight of the ship at her load water-line, as L L. Then take the distance between the two perpendiculars last drawn, and apply it on the tonnage scale, and we have 1247 tons nearly, the real burden, as before shown by calculation.

Again, take the height where the perpendicular L L intersects the curve of displacement, and apply it on the scale of feet, and we have 20 feet 6 inches, the medium height of the load draught of water, which was 20 feet forward, and 21 feet aft.

Now the perpendicular L being the utmost limit of the quantity of water, expressed in tons, displaced by the bottom of the ship, when she is brought down to her load water-line, it is evident, from what has been already said, that if the number of cubic feet of water which the ship displaces, when light, or, which is the fame, the number of cubic feet below the light water-line, be subtracted from the number of cubic feet contained in the bottom, below the load water-line, the quotient will be the real burden or tonnage.

Any other case to which this scale may be applied is obvious, particularly to merchant-ships. Let it be required to find the number of cubic feet displaced, when the draught of water is 17 feet 7 inches, and the additional number of tons required to bring the ship down to her load water-line.

Take 17 feet 7 inches from the scale of feet, and set it up upon the perpendiculars A N and L L, above the base line A B, and draw an horizontal line through those spots, intersecting the curve of displacement at a; from thence drop the perpendicular O a. Take the distance o a in the horizontal line, to the perpendicular A N, and apply it on the tonnage scale, it will measure 2205 tons 1706 lbs., the displacement answerable to that draught of water; and the measurement from a, taken to the perpendicular L L, applied on the tonnage scale, will give 623 tons 708 lbs., the additional weight necessary to bring the ship down to the load water-line. Again, 623 tons 708 lbs. added to 1582 tons 998 lbs., give 2205 tons 1706 lbs., as above, and thus it is proved that the perpendicular O a is equally distant from the perpendiculars M m and L L.

The measurement of the tonnage might be facilitated, by drawing the tonnage scale revere on the base line A B, and at the load water-line, as in the plate.

Now if the draught of water be required, corresponding to any weight intended to be put on board, it may be readily known as follows.

Find the given number of tons, supposing 928, in the scale on the line m l, through which drop a perpendicular to intersect the curve of displacement, as at P P; and at P draw an horizontal line. Now the perpendicular distance between the base line A B, and intersection of P, being applied on the scale of feet, will give 19 feet, the draught of water required.

Many useful discoveries may be made by blocks or models of ships, and with as great certainty as by the nicest calculations; for it must be allowed, as before observed, that in calculating from a draught drawn from a quarter of an inch scale, it will be liable to some inaccuracies, which cannot be obviated in practice, by reason of various little alterations which may be made in laying off the ship in the mould-loft; consequently the draught and the ship will, in those points, disagree. And likewise, upon strict examination, we shall be enabled to find, that there are not many ships that have both their sides exactly equal in every respect.

Let the block, or model, be constructed to a scale of one-quarter of an inch to a foot of the corresponding parts on the ship; and care should be taken to provide the wood as light and dry as possible.

The model being accurately constructed, it may be also proved by suspending it by a line, fastened to a hook in any part of the straight line, drawn from the middle line of the stem to that of the flen-pot. This hook may be moved forward and aft to different places in the middle line, and a weight may be suspended from the upper part of the middle line, on the pole. If the two sides be exactly of equal dimensions, and homogeneous, they will then be of equal weight.

A plane passing through these three lines, whatever part of the middle line the hook is in, will likewise pass through the middle line of the keel, stem, and poft: therefore, if the model stands this proof, it will be as true to work from as the nicest calculations.

The model, having stood this test, may be suspended by the same line, or filk, in different positions, until it points out the centre of gravity, which will be found, when the block hangs in a state of equilibrium. This practice is, doubtless, very simple; but it will be found very convenient. Further, the model being suspended by the hook, the lines hanging at the stem and poft corresponding to their middle lines, and to that which suspends the block, we may hold a batten out of winding with the line that suspends it, and, with a pencil, draw a line upon it. A plane passing through this pencil line, at right angles to the keel, and passing likewise through the line that suspends the block, will likewise pass through the centre of gravity, which, therefore, must be somewhere in this plane. Again, move the hook to some other part of the middle line, and let the block be suspended from that point; draw also another pencil line, out of winding with this last line of suspension, and the intersection of the two lines will give the height of the centre of gravity above the keel, and likewise its distance from the poft and stem; and if the hook be moved to any other part of the middle line, and a pencil line be drawn as before, it will likewise intersect in the same point; or, let there be ever so many points assumed in the middle line, and the block suspended by each, and pencil lines drawn, they will all intersect in the same point; and as the centre of gravity will always be in that plane which passes through the middle line of the keel, stem, and poft, it may with certainty be marked on the draught.

This will certainly require the greatest nicety; but, if well executed, it will agree with that found by calculation, provided the dimensions be taken very exactly, and likewise from a true scale of equal parts.

By the same model may be found the true tonnage of a ship, thus: Let the light and load water-lines be marked on it; then put the model in water, and load it until the surface
The water is exactly at the light water-line; and let it be loaded until the water drains off, and then weighed. Now, if the weights of similar bodies are in a duplicate ratio, or as the cubes of their linear dimensions, the weight of the ship, when light, is, therefore, equal to the product of the cube of the number of times the ship exceeds its model by the weight of the model, which is to be reduced to tons. Hence, if the model is constructed to a quarter of an inch scale, multiply the weight of the model by the cube of 48, (one-fourth of an inch being equal to 8th of a foot,) or 110592, which will give the weight of the ship if the multiplier be 1, or, as pounds, if pounds, it will be pounds; and it is to be reduced to tons accordingly.

L. Suppose the weight of a model of the 74 (Plate 1.) to be 32 lbs. 13 drachms, when brought down to the light water-line.

The cube of 48 = 110592

Multiplied by = 32 lbs. 13 drachms

Produces = 3545960 lbs. = 1582 tons 816 lbs.

The weight of the ship at her light water-mark, within 118 lbs.

Again, let the model be loaded, until the surface of the water is exactly at the load water-line. Now the model being weighed, the weight of the ship is to be found by the preceding rule; then the difference between the weights of the ship, when light and loaded, is the tonnage required.

Upon the Forces of the Water to bend the Vessel.

Here we can do no better than quote Watton's translation of Euler upon the Theorem, &c. of Des Vaisseaux; to which book we refer our readers for a further illustration of the foregoing particulars, and to Atwood on the Stability of Vessels.

"When we say, that the pressure of the water upon the immersed part of a vessel counterbalances its weight; we suppose that the different parts of a vessel are so closely connected together, that the forces which act upon its surface are not capable of producing any change; for we easily conceive, if the connection of the parts was not sufficiently strong, the vessel would run the risk either of being broken in pieces, or of suffering some alteration in its figure.

"The vessel is in a situation similar to that of a rod A B (Plate XIV. fig. 2.), which, being acted upon by the forces A a, C c, D d, B b, may be maintained in equilibrium, provided it has a sufficient degree of stiffness; but as soon as it begins to give way, we see that it must bend in a convex manner, since its middle would obey the forces C c and D d, whilst its extremities would be actually drawn downwards by the forces A a and B b.

"The vessel is generally found in such a situation; and since similar effects continually act, whilst the vessel is immersed in the water, it happens but too often that the keel experiences the bad effect of a flaw. It is, therefore, very important to inquire into the true cause of the accident.

"For the purpose, let us conceive the vessel divided into parts, by a transverse section through the vertical axis of the vessel, in which both the centre of gravity, G, of the whole vessel, and that of the immersed part O, are situated; so that one of them will represent the head part, and the other that of the stern; each of which we shall consider separately. Let g be, therefore, the centre of gravity of the entire weight of the first, and o that of the immersed part corresponding. In the same manner, let y be the centre of gravity of the whole stern part, and so that of its upper portion.

"Now it is plain that the load will be found by the two forces g m and o n, of which the first will press at g, and the latter at n. In the same manner, the load will be pressed down by the force y u, and may be represented by the force e i; but these four forces will not in general be in equilibrium, as well as the tidal forces produced in the spaces G and O, which are equivalent to them; but whilst the forces before are those shaft fall in the latter together, the vessel will evidently feel effects tending to bend the keel upwards" (called flogging) "if the two points g and y, are nearer the middle than the two other forces g m and y u. A contrary effect would happen if the points were more distant from the middle than from the points g and y, called flogging.

"But the first of thefse two cases usually takes place in almost all vessels; since their hollow has a greater breadth towards the middle, and becomes more and more narrow towards the extremities; whilst the weight of the vessel is, in proportion, much more considerable towards the extremities than at the middle. From whence we see, that the greater this difference becomes, the more also will the vessel be subject to the forces which tend to bend its keel upwards; it is, therefore, from thence, that we must judge how much strength it is necessary to give to this part of the vessel, in order to avoid such a consequence.

"If other circumstances would permit, either to load the vessel more in the middle, or to give to the part in necessary a greater hollow towards the head and stern, such an effect would no longer be feared; but the limitation of most vessels is entirely opposite to such an arrangement; by which means we are obliged to strengthen the keel as much as may be necessary, in order to avoid such a disaster."

Having now investigated the centre of gravity of the displacement, meta-centre, and center of gravity of the whole ship, with other particulars, and laid down all that is requisite to be attended to, in that respect, for the construction of a ship's body under water, we shall, in the next section, proceed to complete the remainder of the sheer-draught.

To complete the Construction of the sheer-draught. Plate 1.

Having found that the displacement of the ship at the load-water line gives the ship sufficient stability to keep the lower ports 5 feet 10 inches above the water, we may proceed to draw all the decks in the sheer plan, beginning with the lower, or gun-deck. The height of the lower fills of the gun-deck ports should be 2 feet 4 inches above the gun-deck plank, which is four inches thick; consequently the upper side of the beam along the side must be 2 feet 8 inches below the fills; add six inches to that for the round-up of the beam; and the under side of the gun-deck at the middle line in midships will be 22 feet 2 inches above the upper edge of the keel; at the forecastle perpendicular let up 24 feet, and at the after-perpendicular 24 feet 8 inches; then a segment of a circle drawn through these three heights will represent the under side of the gun-deck at the middle line. These kinds of sweeps are drawn by thin veneers of pear tree wood, called shee-poulds, struck from a log radius purpose, or by a drawing-bow.) Now let up four inches, the thickness of the gun-deck plank, above the line last drawn, and let another line be drawn parallel thereto, and the gun-deck will be deter-mined at the middle line in the sheer-plan.

Next proceed to draw the upper deck; set up 7 feet 2 inches, being the height from the upper side of the gun-deck plank to the under side of the upper deck plank, along the
the middle line, through which heights draw a curve parallel to the gun-deck, and another curve three inches parallel above it, and the upper deck will be represented at the middle line of the sheer-plan.

The stern-timbers should be next drawn, to shew the boundaries of the sheer-plan above the wing-transom. Set up above an horizontal line drawn at the upper side of the wing-transom at the middle line four feet, upon a perpendicular 6 feet 10 inches abaft the aft-side of the wing-transom, which will be the height and knuckle of the lower counter at the middle line; from thence draw a curve, about six inches hollow, to the upper side of the wing-transom, where the fore part of the rabbet of the stern-post intersects it; and that curve will represent the lower counter at the middle line.

In the same manner, set up the height of the upper counter 7 feet 5 inches, upon a perpendicular nine feet abaft the aft-side of the wing-transom, which will be the height and knuckle of the upper counter at the middle line; then drawing a curve about one inch hollow from thence to the knuckle of the lower counter, the upper counter will likewise be described at the middle line.

Having the upper and lower counters drawn at the middle line, the upper part of the stern-timber is straight above the upper counter, and must be drawn as follows:

1. Set up 23 feet 8 inches, upon a perpendicular 14 feet abaft the aft-side of the wing-transom, as before, and then drawing a straight line from the knuckle of the upper counter, to pass through the said spot, the upper part of the stern-timber will be thrown at the middle line, by which the rake of the stern will be described.

As the stern rounds two ways, both up and ait, (or forward from the timber already drawn,) the stern-timber at the side must alter so much from that at the middle line, and therefore remains to be represented. Set down from the knuckle of the upper counter on its perpendicular 9 inches, and draw an horizontal line before it at that place, and set off thereon 15 inches from the said perpendicular, which will be the knuckle of the upper counter at the side the 9 inches is the round-up, and the 16 inches the round-aft at the upper counter. Then proceed in like manner for the lower counter, if setting down 9 inches, and forward 15 inches, and the knuckle for the lower counter at the side will be produced; then, by drawing a curve from the knuckles on the side (similar to the curve or hollow at the middle line), observing the lower counter at the side is drawn to intersect the touch of the wing-transom at the side, the side stern-timber only wants the upper part to complete it. But as the straight line, which remains to be drawn for the upper part of the side-timber, should not be parallel to that at the middle line, the following method will determine the exact rake thereof.

Draw a straight line at pleasure, as the ticked line under the body-plan, on which set off the breadth of the stern at, the upper counter, or 13 feet 4 inches, equally on each side of the middle line; and there square up a perpendicular on each side: set up from the straight line 16 inches, the round-aft of the upper counter on each perpendicular, and draw a segment of a circle that shall intersect those spots and the straight line at the middle, and the round-aft of the stern will be described at any part of the breadth above the upper counter: thus, take the breadth of the stern at the top timber-line, which is 24 feet 8 inches above the wing-transom, which is 24 feet, and set it off equally on each side the middle, where it shall intersect the round-aft under the body-plan; thence draw a line parallel to that first drawn, and the distance between the two lines, 13½ inches, is the distance that the side-timber will be from the middle timber; on an horizontal line, at the height of the top timber-line, draw a straight line through the last spot set off to intersect the knuckle of the upper counter at this side, and that will be the rake of this counter-timber, as shewn by the ticked lines in the sheer-plan, Plate I.

The rake of the stern-timbers being determined, proceed to finish the decks. Set up from the upper side of the upper deck 6 feet 10 inches at the middle stern-timber, and 6 feet 8 inches fore part at frame 8, and above that 3 inches, drawing curves as before, and the quarter-deck at the middle line will be reprented.

Proceed in the same manner with the round-house abaft. Set up from the upper side of the quarter-deck 6 feet 8 inches at the middle stern-timber, and 6 feet 6 inches at fore part or frame 24, and above that 2¼ inches. The forecastle forward is represented in the same way, by drawing curves, one parallel to the upper side of the upper deck 6 feet 7 inches above it, and another at 3 inches from the beak-head to frame D.

All the decks having been drawn, representing their heights at the middle line, their heights at the sides differ from the former, agreeable to the round of the beam in the breadth of the ship: to do which correctly, take the round-up of the beam of its respective deck, say the gun-deck, 6 inches, and set it up in the middle of any straight line, so that the half-breadth in midship at the height of the gun-deck may be set off on each side. Then raise the segment of a circle that shall intersect the round-up at the middle, with the spots at the breadth, and the round-up of the deck will be described at any part of its breadth. Thus, take the half-breadth at the height of the deck at any timber in the body-plan, and set it off equally from the middle of the round-up till it intersects the curve; whence draw a line parallel to that first drawn, and the distance between the fork line to the round-up in the middle is what the beam round at that place: thus may the round-up be taken at as many timbers as may be found necessary, and below the under side of the deck, at its respective timber in the sheer-plan; then a curved line passing through these spots, will represent the deck at the side; but observe, that the decks are to have a sufficient round abaft, to correspond with the round-up of the stern above the lights, and that the additional round wanted to be set down at the side line.

The sheer or top timber-line may be next drawn, by setting up its height in the sheer-plan aforesaid in midship, and abaft: thus, at timber X forwards, 37 feet 8 inches; at 9 in midships, 35 feet 4 inches; and at the side stern-timber abaft, 41 feet 6 inches: then, by drawing a curve through these spots, as in Plate I, the sheer of the ship, or top-timber line, will be represented.

The ports may now be drawn in the sheer-plan, thus: draw two curves in pencil parallel to the deck at the side, fore and aft, adding the thickest of the deck to that already drawn, as that represents the under side of the deck, or upper side of the beam. The gun-deck ports are to be 2 feet 4 inches from the upper side of the gun-deck planks to the upper side of the lower fills, 2 feet 8 inches deep, and 3 feet 5 inches fore and ait, or from the fore to the after sides, which may now be squared up between the lines last drawn; placing the fore-side of the foremost above 6 feet 5 inches abaft timber X, and 3 feet 1 inch only on athwartship line; the aft-side of the after-port to he 14 inches abaft timber 32, and the fore-side 3 feet 5 inches aforesaid, or in the clear; and the remaining 13 to be 7 feet 7 inches aforesaid. In the same manner draw in the upper deck ports, which
which are from the plank to the port-side 1 foot 11 inches, a
feet 8 inches deep, and fore and aft 3 feet, and are to be placed
equally between the gun-deck ports, as is shown in the plan,
Plate 1. The parts on the quarter-deck, round houses, and fore-
castles, must be placed hereafter where there is a space between the dead-
eyes to admit of them, always to place them as nearly as
possible at equal distances.

To know the heights, round-up, &c. &c. of the other
decks, take them with compasses, in like manner as the gun-
deck was set off from the given dimensions; and by applying
them to the scale of feet, much repetition will be avoided.

The round-house deck being drawn, draw all a parallel to the top
timber-line, and another line three inches above it, which is of the thickesses of the plank-floors, correspond-
ing with the fore part of the round-house, so as to make both
plank-floors and water-way; so will the extreme height of the
top-side be described above the plank-floors, which com-
pletes the height of the side to the fore part of the quarter-
deck, is four feet four inches to the under side above the
top timber-line, and parallel thereto. The fore part abreast
the main-mast hances down eleven inches for seven feet abaft
the gangway or fore part of the quarter-deck.

The drift-rail may now be drawn, the under side of which is
two feet ten inches above the top timber-line, and parallel
thereto from the hance of the plank-floors at the main-
 Pour the quarter-gallery. The drift-rail is four and a
half inches deep, and drawn parallel to the under side of it, drawn
hances as the plank-floors abreast the main-mast, and
flops with a scroll upon the shear-rail at the gangway. The
Shear-rail may next be drawn; it is six inches deep, and
parallel to the top timber-line from the cat-head to the
quarter-gallery. The plank-floors and shear-rail at the fore
part of the ship delineate the height of the top-side here:
the under side of the plank-floors is two feet nine inches
above the top timber-line, and the under side of the drift-
rail one foot eight inches, and turns off with scrolls at the
after part of the fo'c'sle, but in other respects the fame as tho
at the quarter-deck.

It is the practice in the navy of late years, to have square
drills instead of scrolls or hances of any kind.
The upper part of the ship being thus far complete, we have
at one view the utmost extent of the sheer, as seen on a
plane.

It now remains to be drawn in the finishing parts, as the
wales, flern, head, rails, &c.

Proceed to represent the main wales by setting up their
lower edge, at the rabbot of the item or fore part, above
the upper edge of the keel 22 feet 6 inches, in midship or dead-
flat 1 feet 8 inches, and at timber 34½ feet, 23 feet, and draw
the curve as in shear-plan, Plate 1. Above that, and parallel
thereto, draw another curve at 4 feet 4 inches, the breadth
of the main wales.

Next draw in the channel wales, set up as before, at the
rabbet of the item 30 feet 2 inches, in midships 27 feet
3 inches, and at timber 34½ feet 6 inches. Set up their breadth 3 feet, and draw curves as in shear-plan, Plate 1.

The waist-rail may be next drawn; its distance below the
top timber-line is one foot ten inches, the upper side and its
depth six inches, and it is drawn parallel to the top timber-
line all fore and aft.

Now, before the channels and dead-eyes can be drawn, the
centres and raking of the masts must be determined; their
centres on the gun-deck being fixed upon in proportion to the
length of the gun-deck, thus: the centre of the fore-
mast is 2½ feet 4 inches abaft the after-side of the item, or
half its diameter before the one-ninth of the length on the
gun-deck, the centre of the main-mast 10½ feet 4 inches
abaft the after-side of the item, or half its diameter be

SHIP-BUILDING.

Vol. XXXII.
by the timber-heads there shewn, having also a timber-head between. But the practice now is to have a rail upon the heads of the timbers, and the sides birthed up on each side to the under side of the rail between the ports, and only three or four timber-heads run up, one in particular before the bill-board for the shank-painter. On the quarter-deck are seven ports of a side, and four on the round-houfe, placed as clear as possible of the shrouds, as shewn in the figure, Plate I.

The chett-tree for hauling home the main-tack must be placed near the after-end of the fore channel, or half the length of the main-yard before the centre of the main-mall, and drawn from the top of the side down to the upper edge of the channel-wale. The flaps on the side may next be drawn: they must be placed to the fore part of the main drift or gangway, about three feet in length, six inches thinner in the clear, and five inches deep: the upper flap to be eleven inches from the top of the side, continuing the others to the upper edge of the wale.

To complete the fore-plan, the head and item only remain to be drawn, which are as useful as ornamental. Therefore we will proceed with the head, thus: draw the head-foot or its boundary aft, by raising a perpendicular fix feet abaft the aft-side of the item, at one foot eleven inches above the deck at the side, or draw an horizontal line at the same height as the upper deck port-fills: the horizontal is the flat of the beam-head, and the perpendicular continued up to the rail above the forecastle, represents the fore part of the beam-head, and will likewise determine the foremost end of the forecastle. Since Plate I. has been engraved, the beam-head in the navy seems to be done away, and the bow continued to the top of the side, as in the East India ship, Plate XII. It may be stronger thus, but the beam-head was very useful. Let 15 feet 6 inches, the length of the head, be set off from the fore part of the item, and there draw a perpendicular which will determine the fore part of the block or figure; draw another perpendicular at 3 feet 10 inches abaft the former, which is the moulded breadth of the figure, and boundary of the hair-bracket at the upper part. Before the height of the figure can be ascertained, the bow-sprit must be drawn, thus; let up 4 feet 6 inches at the aft-side of the item, above the upper deck, for its middle line, and five or six feet that line 5 inches or 5½ inches above an horizontal in every foot forward; then set off 1 foot 5½ inches above and below this middle line, and draw lines parallel thereeto, and the bow-sprit will be represented in the figure-plan, Plate I. Now the upper part of the block for the figure can be determined, as that should be at least six inches clear of the under side of the bow-sprit, which should pass the under side of the foremost upper deck beam, and lie in the partners on the gun-deck a convenient height for the after part of the manger, as in the inboard works, Plate IV. of Ship-building.

The cheeks are next to be drawn: set up the height of the lower cheek at the item, which is 25 feet at its under side, above the rabbit of the keel, and draw the after-end to the sheer, and the fore part with a handfome flight, fo as to break in with the perpendicular at the fore part of the figure; then set up from the under side of the lower cheek, 3 feet 5 inches at the item for the under side of the upper cheek; draw the after-end rather more than the sheer, and the fore part with more flight than the lower cheek, fo as to make a handfome curve line with the fore part of the hair-bracket. From the under side of the lower cheek, set up at the fore part of the item 7 feet 11 inches, which is the under side of the upper rail, and draw the bag of it, or the part immediately before the item, nearly horizontal, or to the sheer of the flat of the beam-head, it agreeing to that height. The fore-end should curve upwards, fo as to appear parallel with the upper cheek, or nearly fo; and to form the after-end, draw a curve from the bag to break in fair with the beam-head line.

Now the moulding of the upper rail and siding of the cheeks may be drawn, and as they taper all their length regularly, let off 1 foot above the lower side at the after-end of the cheeks, which is 5 feet abaft the fore-side of the item on the sheer, and 7 inches at the fore-end, or about 8 feet 6 inches before the item. Then the moulding of the upper head-rail, which is 1 foot, must be set off abaft the beam-head line, or fore-side of the rail, and drawn parallel thereto from about 5 feet below its head, (which must range with the under side of the rail above the forecastle, or fix inches higher than the range of the other timber-heads,) and from thence to taper to fix inches at the fore-end, which comes to the hair-bracket, which is a continuation of the upper cheeks, and runs in a handfome ferpentine line up the back of the figure, as high as where the shoulder of the figure is supposed to come; at which place it terminates with a scroll. The upper part of the figure or block is formed, by continuing the line from the breast or fore part of the figure to the top of the hair-bracket, observing to keep the upper part fix inches clear of the under side of the bow-sprit, as before observed.

The head-timbers may now be drawn, placing the item-timber its thickefs, which is 7 inches, before the item, and to stand perpendicular from the upper side of the lower cheek to the under side of the upper rail. The foremost timber to be 8 feet before the item, and to stand parallel to the item-timber, or rake half its thickefs at least, which is 2½ inches, which will produce a lighter appearance in the head: the middle timber is placed equally between the two former, and is fix inches thick. Another timber is sometimes placed abaft the item-timber, at the same distance as the one before it, the heel of it stepping on the upper edge of the lower rail. The length of the block for the figure sometimes terminates by a perpendicular line at the heel of the foremost head-timber; the lower cheek ends thereon, or is continued higher up the figure, and finishes with a scroll. The hair-bracket also continues down to the heel of the figure.

The head-timbers being drawn, the middle and lower rails may be drawn by dividing the space between the upper side of the upper cheek and under side of the upper rail equally at every head-timber; then drawing curves to pass through the moulding depth of each rail, equally set off from the above spaces, which moulding depth is 6½ inches at the item, and 4½ inches at the hair-bracket. The after-end of the lower rail may terminate where it touches the side. Before the rail above it can be finished, the cat-head must be drawn, letting it project from the aft-side of the upper part of the main or upper rail to rake forward, fo as to stand square with the bow, or nearly so, and to rise upwards 5½ inches in every foot of its length, which is 8 feet 6 inches without the bow; observing that the under side is to lay on the plane of the forecastle at the side; the upper side may be drawn parallel to the under side at 1 foot 4½ inches, its depth: the knee or supporter under the cat-head forms a fair curve to the after-end of the upper middle rail, as in figure-draught, Plate I. The knee or supporter under the cat-head latterly hangs perpendicularly, or nearly fo, and the rail ends against the side.

The knee of the head may next be drawn; it is to project from the breast of the figure about four inches; thence draw
SHIP-BUILDING.

draw the fore part of the line, with an agreeable figured line to its breadth from the item, which should not exceed two feet in a square at the load-water-line, then, by continuing the same line downwards, narrowing more and more till it approaches the grime, and drawing it more distant from the item, to about four feet in the breadth of place, the lower part break is fair with the side of the tail keel, where it terminates with the fore foot or fore part of the keel, which will be next described. The gams tho'holes come between the head-timbers, and the bob-ray-holes at the fore part of the keel, and the hawseholes between the checks are to be 2 feet 6 inches up from the deck, and 1 foot 3 inches in diameter, as shown in the plan, Plate 1. See Head-hole, hereafter described.

From the line representing the upper edge of the keel, let down 1 foot 6 inches, its depth, and draw a line parallel to its upper edge the whole length, which is 1 foot 2 feet before timber, to the inboard of the flnpl-potl, and the lower edge of the keel will be represented; but to complete the fore foot, which must be of a sufficient depth to receive the lower part of the item, called the boxing, square up the fore end of the keel from the under side to the fore-side of the item, and from thence square up the upper side of the item from its curve. The boxing, or lower part of the item, may now be drawn: set off from the line laid squared 6 feet 6 inches, and draw a perpendicular to half the depth of the keel, and from thence continue a line forward, parallel to the lower edge of the keel, one-third the length of the scarf, which will meet the fore-side of the item and complete it.

The tail keel, which is six inches deep, may be drawn by a line parallel to the under edge of the main-keel; the fore end of it may continue about three inches before the main-keel, or run through to the fore part of the grime.

The sheer-draught being thus far completed forward, the stern and quarters may be finisht, and first draw a line which shall represent the aft-side of the quarter-piece, agreeable to the round-forward of the stern, which is 1 foot before the side timber-timber, on a square, and nearly parallel thereto, continuing this line from the plank sheer to the lower gallery rim, the upper side of which is at, in the line laid down 6 feet 5 inches above an horizontal line, at the upper side of the wing-tranom at the middle. (Observe, all the heights of the stern will be set up above this line, for the manner of obtaining which, with every particular relative to the item, the reader is referred to the section Laying off the Stern, and Plate X.) At the height last set off, draw the upper side of the rim forward parallel to the sheer or top timber-line to 16 feet 6 inches, its length; then draw another line parallel under it at 10 feet 4 inches, its depth. The height of the upper side of the rail at the middle (foo] is 11 feet 9 inches at the quarter-piece, which must also be drawn forward parallel to the sheer to 16 feet 8 inches, its length; its depth, which is 94 inches, drawn in as the middle rim.

The height of the upper side of the rail at the middle (foo] is 11 feet 9 inches at the quarter-piece, which must also be drawn forward parallel to the sheer to 16 feet 8 inches, its length; its depth, which is 94 inches, drawn in as the middle rim. The core part of the quarter-piece may next be drawn, as the heel of it stops on the after end of the middle deck, by drawing a line parallel to the aft-side at 14 inches, its riding. Draw the middle rim-rail, as before directed, at 15 feet 3 inches, the height of the upper side at the fore-side of the quarter-piece, to 12 feet 2 inches, its length. In the same manner draw the upper floor-rail, its upper side being 11 feet 5 inches up at the quarter-piece, and its length forward 12 feet 8 inches. Above this rail is the upper finishing, the upper rail of which ranges with the height of the plank-shear, with another rail below it at 9 inches in the clear; the upper rail may be about 3/8 inches, and the other 4 inches. The upper rail of the finishing is 2 feet 8 inches thunt of the upper floor-rail, and finishes at the fore part, as in the sheer draught, Plate 1. The boundary, or fore part of the upper gallery, is 11 feet 7 inches on the run of the middle rim; from thence a line is drawn upwards, parallel to the quarter-piece. Between the middle floor-rail and the rail above it, the fore part is completed by a curve. The length of boundary of the lower gallery is 15 feet 6 inches on the lower rim; from thence a line is drawn upwards, parallel to the rake of the side timber-timber. Now the lights and quarter, which are three in each gallery, may be equally spaced; the lights in the lower gallery to be 2 feet 7 inches in the clear on a square, and the munitions about 11 inches each; the lights in the upper gallery 2 feet 4 inches in the clear on a square, and the munitions about 91 inches each; observing to keep their lower sides up from the rail, about 5 inches the lower ones and 4 inches the upper ones for the water-table, and their upper sides about 4 inches clear of the under sides of the floor-rails above. Draw the lower floor-rail along the quarter, which is a continuation of the lower counter-rail, as the middle rim is of the upper counter-rail, at the outside of the quarter-piece, from whence they are to be continued their length parallel to the floor, and that will be the height of these rails, as viewed on a level. The height of the lower counter-rail, at the side abait, is 5 feet 4 inches, and from thence continued parallel to the rim-rail above: to its length, which is 7 feet, set down 10 feet inches, its depth, and draw it parallel to the upper side.

The lower finisht is 2 feet 3 inches deep below the lower floor, and its boundary formed by curves, so as to have a light airy appearance, with a floor nearly in the middle of its depth.

The foot-space rail may be 95 inches deep, and rabbets on the ends of the flat of the quarter-deck. The breast-rail is 95 inches deep, and its upper side is 3 feet 2 inches above and parallel to the other, both projecting 2 feet 6 inches on a square to the aft-side at the middle line from the midhip timber-timber. But to complete the balcony, quarter-piece, and taffrail, as shown in the plan, the reader is again referred to laying-off the item, and Plate X.

The boarding of the lower counter may be represented by drawing a curve 4 inches parallel abait the aft-side of the counter-timbers, from the knuckle to the tuck-rail, which covers the margin on the wing-tranom, and projects its thickets 94 inches. Draw likewise the boarding of the upper counter, which is 4 inches thick, and parallel to the timber-timber. Above the upper counter-rail draw in the thickets of the middle run-rail, which is 3 inches, and parallel to the middle timber-timber, and continued upwards to the arch-board over the lights, which is about 48 inches deep.

The rudder may now be represented in the sheer-plan, observing that the head is continued above the upper deck, high enough to receive a tiller about four inches above the deck; then allow for two hoops above the hole, making the upper part of the head 2 feet 6 inches above the deck. Continue upwards the aft-side of the flnpl-potl, which represents the fore-side of the rudder, from whence its breadth or aft-side is set off; and as this should not be more nor less than sufficient to direct the course of the vessel, the common practice is to make the breadth at the heel, or lower end, one-eighth of the main breadth, which will be fix feet for ships having a clean run abait; but for merchant-ships, or those constructed chiefly for burthen, it may be one-fourth. The height of the lower hance may be fixed at the load-water-line, or about six inches above it, and its breadth there should be five-sevenths of the breadth at the heel,
Amongst the several angles that the rudder makes with the keel, there is always one position more favourable than any of the others, as it more readily produces the desired effect of turning the ship, in order to change her course.

If the angle of the rudder with the keel is greater than 45 degrees, the action of the water upon the rudder will increase, and at the same time oppose the course of the ship in a greater degree; because the angle of incidence will be more open, so as to prevent a greater surface to the shock of the water, by opposing its passage more perpendicularly.

If, on the contrary, the angle is lessened to 30 degrees, the rudder will receive the impression of the wave too obliquely, for the angle of incidence will be more acute, so that it will only prevent a small portion of its breadth to the shock of the water, and by consequence will only receive a feeble effort. Thus it appears, that between the effects which result from the water's absolute effort, there is one which always opposes the ship's course, and contributes less to her motion of turning, whilst the other produces only this movement of rotation, without operating to retard her velocity.

Hence we may conclude, that when the water either strikes the rudder too directly, or too obliquely, it loses a great deal of the effect it ought to produce. Between the two extremes there is, therefore, a mean position, which is the most favourable to its operation, viz. the angle 45°, or between that and 42 degrees. See Watson's Euler, p. 130. See also RUDDER.

It is evident, that the fore part of the rudder, as high up as the head of the poll, must be trimmed on each side, to the middle of its thickness, (which is the same thickness as on the gun-deck trim.) When the helm is hard over, the greatest angle the rudder is projected to make with the keel; however, the common method is to force off two-fifths the thickness of the rudder from the fore part on each side, and from thence trim it straight through to the middle of its thickness, or, what is better, to leave the middle to the convexity of the pintles, rather than a sharp edge. By this method the rudder may be put over to the angle of 50 degrees, which is more than is necessary, and it is very seldom that the tiller, owing to its length, can be put over so far to the side as to allow of the rudder making an angle of more than 45 degrees, which angle is quite sufficient.

When the above angle, or what is technically called the trim, is wholly taken from the fore part of the rudder, the main piece is very much wounded by letting on the upper pintle; but this of late years has been greatly remedied, by taking half the bearding from the aft-side of the stern-pole at the head, and from one to two inches on the heel; of course the rudder is bearded so much the less. This also, will greatly assist the conversion of the stern-pole.

The bearding on the rudder is represented by the shading on the fore part of the rudder, and the bearding on the poll by the ticked line in the above plan, Plate I.

The rudder, which is represented in the after-draft, Plate I., and is as at present used in the navy, having its axis of rotation in the centre of its pintles, which are parallel to the aft-side of the stern-pole, causes a space, considerably greater than that transverse section, to be cut in the counter for the rudder to revolve in, which would be impervious to the waves, were it not defended by a coating of tarred canvas, nailed in such a manner to the rudder and counter, as to cover the whole space required. But the ill effects of having so large a space fo ill guarded, have proved very dangerous.

It was to remedy this defect that round-headed rudders of late years have been adopted in many merchant-ships, particularly
particularly that in the service of the East India Company.

The round-headed rudder is represented in the sheer-plan of the East India ship, Plate XII., which consists in making the upper part of the rudder above, and some inches below the hole in the counter, cylindrical, and giving that part, at the same time, a call forward above the upper brace, so that the axis of rotation may be that means be the line passing, as usual, from the heel of the rudder to the upper brace, or that next below the counter, and from thence upwards through the axis of the cylindrical part, or head, in order that the transverse section at the counter may be a circle revolving upon its centre: in which case the space of half an inch is more than sufficient between the rudder and the counter, and consequently the necessity of a rudder-cost entirely done away. But as it was foreshadowed, that if the rudder was by any accident unlipped, this alteration might endanger the turning away of the counter, the hole is made from two to four inches larger all round, according to the size of the ship, than the transverse section of the cylindrical part of the rudder, but that space is easily covered over with a wooden rim, about two inches thick, and of sufficient breadth to nail to the counter clear of the hole: this rim is fitted nearly close to the rudder, and is capable of refixing the shock of the sea, but easily carried away with the rudder, leaving the counter, under such circumstances, in as safe a state as it would be, agreeable to the present form of making rudders in the navy.

It is easy to conceive that the braces cannot be carried up so high on the stern-poll with a round-headed rudder, as in Plate I. But then the head is better treaded, as it has a large bolt driven down through the centre, that traverses in a thick brass plate confined in a strong oaken frame, fixed over the head.

It may also be readily seen, that to bring the axis of rotation through the centre of the rudder-head, it must call so much forward, as was before observed, which requires a sudden lance between the upper brace and the counter; but to avoid this lance cutting away the main poll too much at the head, a false poll, sufficiently thick, is tacked or coaked to the aft-side of the main poll, as in Plate XII.

The body and half-breath plans may now be completed, as it remains to add the superparticular part, or top-side.

Transfer the heights of the top timber-line from the sheer-plan, Plate I., to the body-plan, and draw an horizontal line, at each height, across each respective body. Now the breadth of the ship at this height determines the tumbling-home of the top-side, which should not be too much, as formerly, as it creates an unecessary consumption of crooked or compass-timber, or an extravagant waste of large timber, which must be much weakened by being cut across the grain. Again, great advantages would be derived from having little or no tumbling-home to the sides, as it gives more room upon deck, a greater spread to the sprouds. Additional security to the masts, makes the ship flatter, a much better sea-boat, and in every respect safer, stronger, and better. On the contrary, it may be argued, that by the top-side tumbling-home, particularly in ships of war, all the weight of guns, &c. lying above the low-water-line, may thereby be brought nearer to the middle line, when of course the ship will be left trained by the working of her guns also; but others have endeavoured to prove, that by the weights being equal on both sides, they counterpoise each other, and do not throw the ship, whatever distance they may be removed from the middle line. Again, the top-side narrowing or tumbling-home, as it approaches the top of the side, particularly in ships having two or three guns deck, the forward of the bow guns in action lets away those on the slack above.

In Plate I., the top timber breadth in mih up is four feet below the main breadth, consequently the top timber home two feet each side, and may be brought to the half-breath plan parallel to the main breadth, in frame 22 shaft to 11 forward; then from the middle line at K it is 21 feet 11 inches, at M, 21 feet 8 inches; at O, 21 feet 6 inches; at Q, 21 feet 2 inches; at S, 2 feet 4 inches; at U, 19 feet; and at the break head, 17 feet; at V, 16 feet; at W, 20 feet; at X, 17 feet; at Y, 15 feet; at Z, 12 feet; at A, 10 feet 5 inches; at B, 8 feet; at C, 6 feet 6 inches; at D, 4 feet 6 inches; at E, 2 feet; then to end shaft, square down to the half-breath plan the intersection of the top timber at the side count to timber in the fluer-plan, and set up, as before, 12 feet. Then a fair curve drawn through these points represent the top-timber half-breath.

Transfer the top-timber half-breaths from the half-breath plan to their corresponding horizontal lines at the top timber-line from the middle line in the body-plan. Now the timbers may be laid in the breadth of the half-breath in the body-plan, thus: transfer the upper height of half-breath from the sheer-plan to the body-plan, drawing thereon horizontal lines; then square up the timber already drawn to intersect the upper height of breadth respectively; open the compacts to 11 feet, the length of the upper-breadth sweeps, and fix one foot on each line thus drawn; then from the lines, as squared up, describe an arc of a circle upwards at each timber; then draw at a curve to the hollow of the top-side, touching the back of the upper-breadth sweep, and the breadth at the top timber-line, thus: the timber at the top-side is formed in moldings, to which let a mould be made from the upper height of breadth upwards, continuing the same hollow of top-side lines; then above the top timber-line at 1 foot above the top timber-line at 1 foot, by which would all the timbers of the top-side, except two or three quite aft and forward, may be drawn, and both bodies completed to the top of the side, by moving the mould at each timber gradually upwards, so as to make a fair line with the upper breadth sweep, touching the breadth at the top timber-line.

The foremost frames, as X, U, and S, towards the top of the side, curve outwards, or the contrary way to those abait them; because the breadth at the top timber-line projects the main breadth below, by which the anchor is hove up clear of the bow. From their breadth at the top timber-line, square up a perpendicular line to the top of the side, which produces a sudden angle or knuckle at the top timber-line, from whence they are called knuck-l-timbers.

From the sheer-plan transfer the heights of the top-side to their respective timbers in the body-plan, and draw a curve line through those heights, and the top of the side will be represented in the body-plan. Then, to prove that the heads of the timbers makes a fair longitudinal curve, transfer their half-breathds at the height of the top-side in the body-plan to their respective timbers in the half-breath plan; that is, from frame D forward, and from 10 shaft; if they produce fair curves, the top of the side is correct.

Now the side stern-timber may be drawn in the body-plan, thus: transfer the height of the wing-tram, lower counter, upper counter-knuckles, top timber-line, and top-side, from the side stern-timber in the sheer-plan to the after body-plan, and draw an horizontal line at each height; draw likewise two horizontal lines, equally spaced, between the wing-tram and lower counter-knuckle, and one equally between the upper counter-knuckle and the top timber-line. Transfer the half-breathds of the fix stern-side, where they are intersected by the above horizontal lines, to their corre
corresponding timbers in the half-breath plan, and draw curves through the above half-breaths, some distance abaft the after-frame; then square down where the several heights intersect the side stiff-timber in the sheer-plant, to the half-breath plan on their corresponding lines, and from thence transfer the several half-breaths to their corresponding heights on the body-plan; then, by drawing curves through those half-breaths, the side stiff-timber will be represented.

The main half-breath and top-timber half-breath lines may now be ended abaft in the half-breath plan: thus, square down from the sheer-plan, where they intersect the side stiff-timber, to their corresponding lines in the half-breath plan; also, where they intersect the middle stiff-timber in the sheer-plan, square them down to the middle line in the half-breath plan; then, with a radius in the said middle line, sweep an arc of a circle to intersect the spots half squared down, which will represent the round-oft of the stern at the main half-breath and top-timber lines in that direction.

In a similar manner may be drawn the round-oft of the stern at the knuckles of the lower and upper counter in the body-plan, by transferring the heights of the lower and upper knuckles, at the middle stiff-timber in the sheer-plan, to the middle line in the body-plan; their height at the side being set up before; then, with a radius from the middle line in the body-plan, sweep a segment of a circle to pass through each height, and the round-oft of the stern, at each counter, will be represented as in the body-plan, Plate I.

**Apron, or Inner Stem, &c.**

The apron may now be drawn in the sheer-plan, by continuing a line parallel to the aft-side of the stern, at twelve inches, its moulding from the head of the stern, to about seven feet abaft the boxing, by which it will give thift to the scarts of the stern, as represented by the ticked line in the sheer-plan, Plate I.

The cutting-down, or height of the upper side of the floors in the middle fore and aft, is represented by the ticked line at the following heights: viz., at $\frac{1}{2}$, and from frame D to S, 1 foot 10$\frac{1}{2}$ inches; at F, 1 foot 10$\frac{1}{2}$ inches; at H, 2 feet $\frac{1}{2}$ an inch; at K, 2 feet 2 inches; at M, 2 feet 5$\frac{1}{2}$ inches; at O, 2 feet 11$\frac{1}{2}$ inches; at S, 4 feet 6 inches; at U, 6 feet 6 inches; at T, 1 foot 10$\frac{1}{2}$ inches; at 12, 1 foot 11 inches; at 14, 2 feet; at 16, 2 feet 1$\frac{1}{2}$ inches; at 18, 2 feet 2 inches; at 20, 2 feet 6 inches; at 22, 2 feet 10 inches; at 24, 3 feet 2 inches; at 26, 3 feet 10 inches; at 28, 4 feet 7$\frac{1}{2}$ inches; at 30, 4 feet 11 inches; at 32, 7 feet 7 inches; at 34, 10 feet 1$\frac{1}{2}$ inch, above the upper side of the keel; then a curve line drawn through those heights, will shew the cutting-down.

The depth of the keel-fon is also represented by a line eighteen inches above, and parallel to the cutting-down, into which forward is scared the keel-fon, which is continued upwards to the under side of the gun-deck hook, and nearly parallel to the apron, it being ten inches moulded at the head. The after-end of the keel-fon is completed by the sternon-knee, which forms into the keel-fon, and runs up the fore side of the transom to the under side of the carling under the gun-deck beams, as shown in the sheer-plan, Plate I.

Sometimes a knee is introduced in the dead-wood, as shewn in the sheer-plan, which is drawn against the inner part, which is fifteen inches moulded at the heel, and one foot at the head under the side of the gun-deck transom.

**Nature and Use of the Timbers, when canted.**

Hitherto we have considered the timbers as having their planes athwartships, or at right angles, square to the keel, and have consequently called them square timbers. But the cant-timbers have their planes inclined forward from the keel in the fore-body, and the contrary way, or aft, in the after-body, or canted, as shipwrights term it.

That the reader may clearly understand the nature of the cant-timbers, observe in the half-breath plan, Plate I., where the joint of cant-timber U intersects the middle line; at which place suppose it hung on a hinge, moving fore and aft; and also imagine the line drawn for the cant-timbers on the half-breath plan to represent the upper edge of a surface, of a sufficient breadth to form the shape of the said cant-timber from the middle line in the body-plan; supposing the horizontal view of that surface to be represented by that line. It immediately follows, that the surface must stand perpendicular to the upper edge of the keel, similar to a door swinging on its hinges; and, if we draw the moulding shape of the cant-timber, according to what is laid off in Plate VII. fig. 3., upon this surface, from the keel to the top of the side (not moving its position), and then cut it out, we shall have the true position of the cant-timber, as in its place on the ship, which will stand in a perpendicular direction; we may also, supposing it to be hung, swinging it or cant it either forward or aft, and it will still maintain its perpendicularity with respect to the keel.

The canting of the timbers is of great utility, as it affords the conversion of the timber, and likewise greatly contributes to the strength of the ship in the fore and after parts. For in the first place, were all the timbers of the bow and buttock to be continued square, as those of the square body, though the scantlings of the square timbers on a square should be equal to the scantlings of the timbers, if canted, yet the bevelling of the bow and buttock-timbers would be so great, that the consumption, in some places, in order to get the timbers clear of fap, would be greater by one half than that in the timbers when canted. And, secondly, by canting the timbers gradually from athwartship line, we thereby bring each timber nearer to a square with the planks of the bottom, which is not only the best position to receive the failenings of the planks, &c. But the timbers are also better able to bear those failenings.

We may now proceed to cant the timbers of the fore-body, so that they may stand as square to the curvature of the bow as possible, which will not only greatly lessen the bevelling, but will very much straighten the moulding shape of the timbers; by which means they will be much stronger, not so liable to be grain cut, and having less compass, the conversion will be greatly assisted.

Therefore determine on the cant of the forecrom timber, which is $y$, by setting forward two feet one inch on the run of the main half-breath line before the perpendicular of $X$, and its heel nine inches abaft the perpendicular of $U$, on the stepline, which is three inches nearer the middle line than the bearding, or half-thickens of the dead-wood, and draw the ticked line marked $xy$ in the half-breath plan, Plate I. The after-cant-timber of the fore-body may be before the foremoll square timber $O$ two feet nine inches on the main half-breath line, and the heel on the steplinge two feet five inches before $O$, on the ticked line marked $xy$, drawn as before; then may the intermediate cant-timbers $q$, $r$, $s$, $t$, $i$, $o$, $e$, $x$, $v$, $g$, be drawn, with their joints to intersect their respective perpendiculars as far as $U$, at the main-breath line; then $e$, $o$, and $x$ equally between $e$ and $x$; draw the ticked lines representing each cant-timber from thence to their heels, which are all equally spaced on the steplinge, between $e$ and $x$.

The Hereafter pieces can now be determined on and drawn in the
SHIP-BUILDING.

The half-breath plan, the hole, which may stand parallel with the mould line, or casted square with the bow, which will hold the list and bead, and also their connection, as before observed, by the cast timbers; their number may be two, before the height-head, which comes next the item, unless the apron is wider than the item, which cannot be the case when the cabin is in the middle; as that has now become general, a filling about six inches fided, fayed next the item, which makes it unnecessary to call the height-head above the item to receive the bowprit. In the half-breath plan, Plate 1, the height-head is drawn next the item, then, set off from the item, ten foot four inches, its fiding at the topstring line or bide; before cast y. is inserted a short timber, which shorten the heel of the height-head and hawse-pieces, yet that the heels are expected to be gotten low down as to lay against it, for if the height-head runs down low enough to take a bolt through the gun-deck hook, it is reckoned sufficient; the remainder being made good with a check. From the item, at the timber or timbers before cast y., set up the fiding of the heel, which is thirteen inches. In the same manner set off the fiding of the hawse-pieces, four in number, from each other, as they laye-co together, in wake of the hawse-holes, that is, 18 inches at the head for the first hawse-piece, 17 inches for the head of the second and third, and 18 inches for the fourth; and the fiding at the heels to beal alike 13 inches, as in the half-breath plan, Plate 1.

The hawse-holes may now be drawn, which should be to flatsome as to wound the hawse-pieces as little as possible; they may therefore be placed, so that the middle or centre of the mitred-hole may come in the joint of the first and second hawse-pieces, and that of the outer hole in the joint of the third and fourth hawse-pieces. The holes to be in diameter, after the pipes are let out, 15 inches, and in distance from each other on a square 18 inches, to which lines may be drawn in the half-breath plan to extend from the thickest of the outside to the inside plank, and in a fore and aft direction, so as to cross the middle line of the gun-deck at the main-mast. Sometimes, to avoid wounding the hawse-pieces too much, middle pieces are introduced in wake of the holes fided, about six inches less than the diameter of the holes; then, by cutting three inches on the fides of the hawse-pieces between the holes, those hawse-pieces become consequently more fided, and are wound proportionally, but little.

The hawse-holes may now be repreented in the sheer-plan, thus; set up their height above the gun-deck, which is two feet eight inches, to their under fides, then their diameter above that, which will be clear of the clamps above; then, with a proper five outwards, we shall find them about six inches above the upper side of the lower cheek, which will leave a sufficient habitation of bolt under the hole for the wear of the cable. Square up, from the half-breath plan, where the holes intersect the inside and outside plank at the main half-breath line, that being very near their height, then by drawing lines to their five parallel to their depth, they will be represented as the dotted lines in the sheer-plan, Plate 1; but to continue them to the outside of the boltier, as the fladed holes in the sheer-plan are, square up from the half-breath plan, where they intersect the fore part of the cheek.

The cast-timbers in the after-body may now be drawn, and every part depending on them; in order to which we must here determine on the cant of the faision-piece; therefore, having the round-end of the wing-tranfom represented in the half-breath plan, and likewise an horizontal line at the height of the wing-tranfom, set off sixteen inches, its

bounded breadth, the line is to be continued, where it is the flattest of the after side of the faision-piece, to the termine of the case of the transom, for the purpose to cover the timbers, and square with the track of the back, in which case the pieces will be determined. Then, having the height-head between the after-end and the middle; at the after-end, let the height-head be raised or inclined to the extent of its breadth pieces, before perpendicular 34, and drawn a line from the feet, and therefore a perpendicular 44, which is the centre of the faision-piece, will be described, and be for the foot, in which they will be fixed situated in the half-breath plan, as to answer the former described parts.

The cant of the faision-piece is represented, the cant of the timbers being it is true, better determined, let as be the foremost cast-timber in the after-body, which, the main half-breath line, may be equally divided between the after square-timber 28, and the perpendicular 35, and its heel on the stepping-line be one foot one inches about 28, drawing a straight line, as before; the other cast-timbers between 29 and the faision-piece, which are 30, 31, 32, 33, 34, 35, and 36, may be equally spaced on the stepping-line at the heel, likewise the main half-breath line, drawing straight lines as before, which will interfet their perpendiculars as far as 34 on the main half-breath line; thus the cast-timbers in the after-body will be represented as in the half-breath plan, Plate 1.

The line drawn for the cant of the faision-plan represents the after-side of it, as before observed, which let us to the ends of the transom; but, in order to afflit the conversion with regard to the lower transom, there may be two more faision-pieces about the former; therefore the foremost faision-piece, or that which is already drawn in the half-breath plan, only takes the ends of the three upper transom, which are the wing, filling, and deck-transom; the middle faision-piece takes the three next, and the after faision-piece the three lower ones; therefore let off in the height the fiding of the middle and after faision-pieces, which is 12 inches each; then draw lines parallel to the foremost faision-piece at the fiding, and the middle and after faision-pieces will be represented in the half-breath plan.

The faision-pieces and transom may now be represented in the sheer-plan, as the thwarts-thickness appearance of the faision-pieces limits the length of the transom as they appear therein; square up from the half-breath plan, where the faision-pieces there interfet the stepping, the horizontal or water-lines to their respective water or horizontal lines, and stepping-line, in the sheer-plan; but as the foremost faision-piece runs up three or more feet, if to be gotten above the wing-transom, an horizontal line at the head, and three more between that and the load-water-line, should be drawn from the body to the half-breath plan, in pencil, as they may be rubbed out afterwards, and the interfetion of the faision-pieces squared as before; then curves drawn through the spots as squared will represent the thwarts-thickness appearance of the faision-pieces in the sheer-plan, as in Plate 1.

The height and fiding of all the transoms may now be drawn in the sheer-plan, thus; set down 13 inches below the horizontal line representing the upper side of the wing-transom already drawn, and draw a line parallel thereto, which will show the fiding or under side of the wing-transom as far forward as the faision-piece.

The filling-transom is the next, which nearly fills up the vacancy between the under side of the wing-transom and upper side of the gun-deck plank, and may be represented by drawing two parallel lines under the wing-transom to its height, which may be ten inches, if it will allow two inches between
between its upper side and the lower side of the wing-tranfom, and four inches from its lower side and the gun-deck plank. The deck-tranfom muft be governed by the gun-deck, letting the under side of the gun-deck plank reprefent the upper side of it; draw another line at fourteen inches, its fiding parallel to the upper side, which will complete the gun-deck tranfom. The tranfoms below the gun-deck, which are fix in number, are all eleven inches fixted, and are represented by drawing horizontal lines from the fore-side of the rabbit of the fern-plan; the three upper ones to the middle fashion-piece, and the lower three to the after fashion-piece, keeping each of them about three inches afunder for a free circulation of air. Every means should be taken to preferve them, as they are more difficult to shift than any timbers in the ship.

The fern-polt may now be completed, by drawing the fore-side thus: set forward upon the upper side of the keel three feet from the line, representing its aft-side, and likewise twenty inches at the head, which may be three feet above the wing-tranfom, which will admit of the tiller to be three inches clear of the helm-port tranfom, and two inches from the under side of the beams above; then a ftraight line drawn from the heel to the head in the dimensions fett off, will represent the fore-polt, obferving not to draw the fore-side of the polt through the tranfoms.

The inner pott may be drawn by fettting off before the main pott fifteen inches, its fize at the upper edge of the keel, and thirteen inches at the head, which comes no higher than the under side of the gun-deck tranfom; then, by drawing a line, as before, for the fore-side of the main pott, the inner pott will be reprefented as in the fern-plan, Plate I.

To Draw the Perpendicular View of the Stern.

In deigning the perpendicular view of the fern, there will be an opportunity of feeing whether the fafticles of the counfers are fo disposed, that the lower and fected counfers are in proportion to the reft of the fern: at the fame time, whether the heights of the decks, which, in the prefent draught, Plate I. are fpring aboft fufficiently to give depth to the lights, as well as for other conveniences to make a well-proportioned fern.

Draw an horizontal line at the upper side of the wing-tranfom at the middle line, in the fern-plan, body-plan, and likewise for the fern underneath the body-plan, as the basis of the fern, from which, all the heights will be fett up or transferred. Continue down thereon the middle line of the fern from the body-plan, and drop perpendiculars from the fafticles of the fide counfer-tranfom in the body-plan, to the bafe line in the plan of the fern, and then draw the fide counfer-tranfom on each fide the middle line, the fame as in the body-plan above, and the round-up of the upper and lower counter at the fafticles of each timber. Having the form of the fide counfer-tranfoms in the plan of the fern, fet within them the feafathing of the timber, and draw their fafticles.

The lower and upper counfer-trains being drawn in fern-plan, try if the under sides at the midhip-timber project enough to bury their refpective counfer-planks, thus; square aft a line from each counfer at the fafticle, and on thofe lines fet aft from the fafticle the thickenes of the counfer-plank, fay three inches at the lower counter, and one quarter more, that the moulding may not come to a sharp edge. The lower counfer-plank may be increafed to four inches, its general fize, the three upper ones the fame manner with the under counter, its birthing being two and half inches thick. This will fhow how much the light-part of the trains will be on a leval view below the fafticles of the timbers. Then transfer their height to the plan of the fern at the middle, and keep them parallel to the fafticles to the outide, fufficient for the projection of the quarter-galleries, as in plan of the fern, Plate I.

Take the height of the under side of the quarter-deck at the aft part of the middle fern-timber in the fern-plan, and fet it up in the plan of the fern at the middle line; then round the quarter-deck in the fern, agreeable to the upper counfer-train, in the following manner: take the height from the upper counfer-train, in the plan of the fern, to the quarter-deck at the middle line, and fet it off in the direHon of the fide timbers at the infide. This makes the quarter-deck round more than the upper counfer-train, and adds life to the fern; for the upper part of the lights in the fern should be parallel to the tranfom. As, if they were to round by the fame mould as the upper counfer-train, the bars in the fakes next the fide would be longer than thofe in the middle line, and would appear as if the top of the lights rounded less than the upper counfer-train. Draw in the upper part of the lights about an inch and half below the under side of the quarter-deck tranfom, and their lower part about fix inches above, and parallel to the upper counfer-train, which will allow fufficient depth for the water-table. Set off within the fide fern-timbers, in the plan of the fern, the thickenes of the clamps, and the projection of the cornice in the cabin, and let that be the fide of the lights.

Then determine on the breadth of the mummies, allowing fufficient for the weights and pulley-pieces, and divide the fakes, fix in number, equally.

Now, as well-proportioned lights are great ornaments in ferns, having the breadth of the lower part of the lights in the clear, let their depth be at leaft one-third more than the faid breadth; fet off upon the rake of the fern-timbers, in the fern-plan, and transfer that to the plan of the fern, which makes a good proportioned light. Set off likewise the mock-light in the aft part of the quarter-gallery the fame fize as the ref.

Then to rake the fakes regularly from the middle to the fides, continue upwards the middle line and the outside of the fide fern-timbers in the plan of the fern, till they interfet at the faid middle line; then from their fpaceings at the lower part, the fides of the lights may be drawn to their heads, or upper part, with a ftraight batten fixed at the interfetion of the middle line. In the fame manner may all the intermediate fern-timbers be drawn to their fiding in the middle of each munion from the wing-tranfom to the under side of the quarter-deck, likewise the fhorter ones that make the fide of the counfer-ports, and thofe under the middle of the lights to the upper counfer-train. At about half the breadth of the mummies from the mock-light, place the infide of the quarter-piece, then fet foff at the heel fixteen inches, its moulded breadth, and continue upwards the outside of the quarter-piece, as before, for the lights. In the middle of the quarter-piece, or nearly fo, place the outside of the gallery, which determines the projection of the gallery from the fide.

Draw in the plan of the fern the foot-space rail, its under fide to be about an inch and a half below the aft part of the quarter-deck, and parallel thereto to the outside of the quarter-piece; likewise draw the breach-rail, transferring its height from the fern-plan at the after-part, and fet it up at the middle line as in the plan of the fern, and rounding it, as defcribed for the quarter-deck, to the infide of the quarter-piece. Then let the round-houfe deck be drawn in the plan of the fern as directed for the quarter-deck, which will determine the lower part of the taftrail, as the necking-moulding should be kept an inch and a quarter below the round-houfe tranfom. Then may the boundary, or upper part of the taftrain and quarter-pieces, be finifhed as in the plan of the fern,
SHIP-BUILDING.

In the starboard quarter-piece is designed the aft part of the gallery, which is at the middle of the quarter-piece in the flash-plan; therefore it will be proper to draw the form of the middle of the quarter-piece, and the foreside of the taffrail, upon the flash-plan. Thus, take the heights from the level line at the upper side of the wing-transom in the plan of the stern, to the lower part of the quarter-piece, or upper side of the upper counter-rail, and likewise in as many places as may be found necessary, to get the exact form, and let them up in the flash-plan, drawing level lines. Square up the spots on the quarter-piece and taffrail to the round-side of the stern on a level; then take what the round gives at each spot squared up, and set it off from the mudship flannel-timber on their corresponding level lines in the flash-plan. This produces the ticked line that was drawn in pencil in the flash-plan, shewing the middle of the quarter-piece and fore-side of the taffrail. Take the fiding of the taffrail, and draw the aft-side of the taffrail and quarter-piece parallel to the middle line of the quarter-piece, and fore-side of the taffrail, and draw likewise the fore-side of the quarter-piece parallel to the middle. By the same method, prove the thwartship view in the flash-plan of the lower side of the taffrail, and inside of the quarter-piece.

Take the height in the plan of the stern of the upper counter-rail at the outer part, and set it up in the flash-plan, drawing a level line. But to find how much the after-end of the rail will be before the knuckle of the upper counter at the side-timber, the round-side of the upper counter must be laid down on a level, as in the half-breath plan; transfer the outer end of the said rail square from the middle line in the plan of the stern, on to the round-side square from the middle line in the half-breath plan; then square it up to the flash-plan, on the level line laid down. Design the lower gallery rim, with the lights and munion, as in the half-breath plan, which is a continuation of the upper counter-rail, and this will determine the length of the gallery in the flash-plan. Take the height in the plan of the stern to the foot-space rail, at the outer side of the quarter-piece, and transfer it to the aft-side of the quarter-piece in the flash-plan. Take likewise the upper and lower part of the lights in the plan of the stern, at the birthing of the outside of the gallery, and set them up in the flash-plan, at the ticked line, for the middle of the quarter-piece. Design the lower finishing as in the plan of the stern, and transfer the height and round-forward of the lower counter-rail, as before described, at its outer end, and then add to the rails and lights as set up in the flash-plan, from thence forward, agreeable to the fiding of the ship, to their boundary, or fore part of the quarter-gallery.

Lastly, the upper finishing being designed in the flash-plan, transfer their heights, and complete the quarter-gallery, as drawn in the starboard quarter-piece in the plan of the stern, Plate I.: the aft-side of the rudder, counter-ports, and helm-port transom, may also be drawn.

To Design the Plan of the Head.

Continue forward the middle line of the half-breath plan. Upon it square down the fore-side and aft-side of the figure from the flash-plan, and upon those lines set off the half-fiding of the figure.

Then draw the main rail to its half-breath appearance, thus: set off the fiding of the after-end of the main rail from the outside of the plank at the top-timber half-breath, to the fore-side of the back-head in the half-breath plan; and the fiding of the front-end from the outside of the figure, the fore-end being square down from the fore-part of the hair-bracket in the flash-plan; otherwise, however, to add to the fiding the thickness of the long timber, by drawing straight lines to those spots, the half-breath plan of the main rail will be represented as in Plate I.

Square down from the flash-plan the head-timber, where they intersect the under side of the main rail, to the middle line of the half-breath plan: likewise square down the fore and after side of the knight-head, and draw the half-breath line at the upper side of the back-head flat, and the thickness of the outside plank.

Square up from the middle line in the half-breath plan the head beam, in a to let aft about two inches upon the fore, and square up likewise the cross-piece close to the aft-side of the foremost head-timber, to which and the head-beam the main rail is secured by knees on the aft-side.

Draw the moulding fize of the upper check as you see the ticked lines in the half-breath plan, then the half diameter of the bow-sprit parallel to the middle line; and also the fore and aft carling as much without the bow-sprit as the drawing may lead down clear of the bow-sprit, and outside of the upper cheek.

The feats of ease, no less than two double ones, should be placed the most conveniently, as shewn in the plan. The remaining space of the flat of the head may be composed of ledges; and, lastly, may be drawn the boomkins, which spread the fore-tack, thus: square down from the centre of the fore-mast from the flash-plan to the middle line of the half-breath plan, and from that intersection draw a line forward, to form an angle of thirty-six degrees with the said middle line; and upon it set off half the length of the fore-yard; then draw in the boomkin parallel to the line representing the fore-yard braced up sharp, and it will come nearly over the middle head-timber on the main rail, its heel resting against the knight-head; the length may be ascertained by a line drawn from the fore yard-arm at the outer end.

The round-houses, or feats of ease for the officers, are clearer shewn in the plans of the upper deck and forecastle; which plans and draught of the inboard works will be designed hereafter, the flash-draught plate being completed.

To Design the Disposition of the Frame. Plate II.

The utility of a plan of this description requires but little explanation; as it is evident, upon inspection, that it exhibits the disposition and shift of every timber, that consequently affords the means of disposing of every piece to the greatest advantage, both with respect to the strength of the ship, and to the conversion of the timber; and, moreover, of preparing every piece for its proper situation, before the ship comes on the stocks, with the greatest facility.

The frame-timbers are formed into bends, as before observed, by the union of first futtocks, second or middle futtocks, third and fourth futtocks, with top-timbers, which are severally scarfed together and bolted. Sometimes the frames are scarfed close together, or separated, for air; those that are separated have dry pieces of oak fayed between them in wake of the bolts; these should all be split out before the planking is brought on, that a free passage may be given for the circulation of air.

By the disposition of the frames in their several stations, they stand respectively one on each side of every gun-deck port, by which the sides of every middle and upper deck port are likewise provided for. Thus, one fourth futtock and one long top timber will form the side of every gun-deck port in two-decked ships, and the side of every upper deck port in three-decked ships. A long top-timber and a fourth

Vol. XXXII.
fourth futtock will, in like manner, make the sides of the middle deck ports in three-decked ships, and the sides of upper deck ports in those of two decks.

With respect to the frame-timbers, it is, in the first instance, of the greatest consequence to the strength of a ship, that they should be cut as little as possible by the ports on each deck, bevels, scuppers, &c.; and, secondly, that all the timbers designed to make the sides of ports, are, or should be, continued, if possible, without scarring, up to the top of the side. Tho' timbers, however, in the sudden turn of the body, having so much compass in their lengths, and other which run up to receive the rough-tree rail having too great a length to be otherwise obtained, must be admitted to scarfs, as shown in the disposition, Plate II.

Tho' timbers that run up to make the sides of quarter-deck ports, forecastle ports, or to the rough-tree rail, should, if possible, be made of timbers standing up on the upper deck fills, over the upper deck ports. The side along the waist, between the ports, may be filled in with fir timber, laid fore and aft, and dove-tailed into the frames.

All timbers in the range of the fore and main channels should run up to the top of the side; and the filling-timbers between each frame are all to be equally spaced between the frames; and all the openings between the range of the chain and preventer-bolts are to be filled in solidly with dry oak fillings, as are also those over every gun-deck and middle deck port, that there may be solid boring in wake of the port-ropes-pipes, and muzzles-lashing eye-bolts; also behind iron knees and steams. But as fillings of this kind interrupt the free passage of the air, let a hole, one inch and upwards, be bored throughout their length. All fillings should be charred, or burnt.

All ships should be as light as possible in their upper works, consistently with the services for which they are intended; and, as the frame should not be incumbanted with more short timbers than are absolutely necessary, two timbers over each point are sufficient. The frame will be adequately full, and every purpose answered, when timbers are provided to form the gallery doors, and to fill in the quarters from the after-frame to the side of timbers; and forward, from the foremost frame to the hawse-pieces.

Having considered the several subjects above-mentioned, transfer from the sheer-draught, Plate I., the keel, likewise the stem and stern-post, with the transoms, and stepping-line for the heels of the cant-timbers, the under-side of the decks at the side, also the ports, the plank-keers, rough-tree rails, and beak-head; then the side of timber.

Square up from the half-breadth plan, Plate I., the joints and fillings of the cant-timbers, where they intersect the water-lines, main and top-breathths, and plank-keer, to their respective lines in the sheer-plan, as Plate I. at $c_1 u$, in the fore-body, and at $c_2 s$ in the after-body. Thus may their thwartship appearance be transferred to the disposition, Plate II. In the same manner may be squared up the thwartship appearance of the knight-head and hawse-pieces, which may likewise be transferred as the rest, and also the hawse-holes.

The height of the heads of all the timbers may now be taken above the base line in the body-plan, Plate I., and transferred to their respective timbers above the upper edge of the keel, in Plate II. Curves being drawn through those heights, will give the head of each timber on a perpendicular view in the disposition.

Now square up in the disposition the fillings of all the timbers between the cant-bodies; and as the upper deck ports are left fore and aft than those of the gun-deck, the upper part of the frame-timbers must be opened so much from the joint. The frame-timbers may now be marked with their respective names, likewise the finge timber dead-flat, where the body turns to shift the floors, as they are always under-bevelled.

The fore-fide, or moulding of the side fterntimbers, may be drawn, and the gallery doors from the sheer-plan, Plate I. Then the fills, and all the timbers necessary to frame the quarters abaft frame 36. The ports being drawn, their fills may all be represented; making the upper fills in wake of the chain-bolts much deeper. Then the blocks through the side should be drawn, that the long timbers may not be provided, and afterwards cut afunder by those blocks; namely, the main tack-block between D and B, the fore sheet-block between 4 and 6, and the main sheet-block between 24 and 26.

The fourth futtocks being the longest timbers in the ship, and, from their shape, very difficult to be gotten of the whole length, especially for ships which have much tumble-home, or even long enough to run up fo as to make the side of the upper deck ports, particularly forward and aft, the sides of such ports should have their fourth futtocks scarfed together with a hook and butt, as at fourth futtock 26 in the disposition, Plate II., giving shift to the port and each other: or, if preferred, the scarf sideways, as represented at fourth futtock O.

The third futtock that come under the gun-deck ports, are to be continued upwards to the under side of the fill, as at D. But when the third futtocks, owing to their great compass, cannot be gotten fo long, they may be scarfed, as at 4, obsevering always to get them longer than the regular shift.

The design of Plate II. is to have at one view every timber on one side the ship, that the utmost care may be taken to reduce every timber to the shortest length admissible; as, in a disposition of this kind there is every opportunity of so doing; and likewise of pointing out and converting to the best advantage the most scarce and valuable timber.

The design of expanding the bottom and top-side, Plate III. is to have the lengths and breadths of all the planks at one view, that the planking may be shifted agreeable to the lengths to be obtained, so as to run no hazard of beginning with a shift of planking that could not afterwards be continued. For the planking of a ship is a branch very material; that, unless it be judiciously performed, it will unavoidably be very injurious to, or subverive of, those good qualities that might be expected from the superior construction of the ship. The planking ought, therefore, to be particularly well performed: as, in the proper shifting, fastening, and caulking, the goodness of every part of the materials for that purpose should, consequently, be very carefully inspected.

The length of plank is a very great object to be considered; and, in the shifting, it is principally to be observed. For English plank it is allowed; and hath generally been found to answer, that if three whole planks be wrought between every two butts on the same timber, and all the butts to have a fix-feet shift, or be in distance from each other fix feet, the planks will only be twenty-four feet long; this shift is generally followed, excepting for the wales, &c. for ships of every clafs in the royal navy. But as English oak-plank, having sufficient breadth at the tops in that length, has become exceedingly scarce, merchant-ships have the planks...
SHIP-BUILDING.

Planks divided of various lengths, according to the thickness, as two small and three large planks, in feet and half feet, and two planks between, and four plank ed upwards, to have five feet, and three planks between every two butts in the half. In general, however, to have every butts in the half, and three planks between every two butts in the last. For this purpose, the butts may be divided in a regular manner, for there is no regularity in the work, but the workmen must be instructed, and the planks be twenty-four feet long.

The planks must be wrought of such length, and the butts fluted, in order to give the planked off to the ports and each other. To do this, the planks in midship should have a three-part butts; that is, should allow three butts to each port; being careful, in large ships, to make one butt answer for the pump-half and fore. To affix the conversion, the planks may be wrought top and butt. When the edges of four planks, they have a fair beam in the middle; but if wrought in three planks, let the two lower planks be wrought top and butt, and the upper flake of a parallel breadth.

The thick-stripe, or demulcifying planks, from the lower edge of the water to the thickest part of the bottom plank, being of English oak, is wrought top and butt, and should be fluted from the butts of the water to the regular lengths of the bottom plank as soon as possible.

The plank of the bottom is English oak-plank, as low as the light water-mark, and below that, may be East Country plank of the best quality. The English plank is wrought top and butt, to twenty-four feet lengths at least. Now to break the butts, so as to work East Country plank to advantage, requires care; for, as just observed, the general length of English plank is twenty-four feet, whereas East country plank is from thirty to fifty feet; consecutively, the best way to work a double butts at birth, or one of forty-eight feet in length. It rarely happens that the birth is broken from English plank to East country plank, without introducing two planks between two butts on the same timber in some places; and, it may be admitted, owing to the superior length. Be careful, in fluting the East country plank, to keep the birth as nearly equal as possible, not being confined to butt on one timber, but to make an advantage of drawing the butts having no less than a six-feet flake.

East country plank is wrought of a parallel breadth from ten to eleven inches, excepting forward and aft; for the fore and after-half, that come into the racket should be English oak-plank. Four or six flake near the keel may be in the timbers, adding to the flake clear of the lower part of the keel; and, likewise, that no butt is placed under the pumps, and work them very broad at the poll. The edge of the flake of the fix or eight flake next the keel in East country plank, are rabbetted close: and the flange, dept in tar, is laid between the planks and timbers.

In flaking the fore part of the butts, the breadth of the flake should be doubled, and also the flange of the bow, that every flake of plank may be wrought into the racket; and every flake should be kept from flaying as much as possible. But, in full-bowed ships, it would be impossible to bring every flake to the item without too much waste. It is, therefore, a general custom to have a flake of planks, and two flake ed in the middle, and three flake ed at the fore of the ship, and four flake ed in the middle, and two flake ed at the stern.

The feet of the flake, thickest at the butts, thinnest at the middle, and thinnest at the ends, to afford the water to the ports; and there are two flake ed in the half, with two flake ed in the lower, and two flake ed in the fore. As it is four feet between the ports, it may be allowed sufficient to have a flake of three flake ed, where a plank comes between; or five feet, where two cents between. But that this will not be less than to flake butts, where no plank comes between. The channel and the areas, in large ships, should work down to the flaps at the ports of midships; and, where the flaps work, and are, should work down to as many ports as may have flaps cut, and afford wood to receive the port-hooks, by which the wood to work down be continued in inches each way by it, and the flaps of the ports; hence to have one foot to the regular breadth; but, by all means, let planks run through, if they hold but five inches after the flaps are cut, so that the port-hooks will clear the beam; for planks, however broad, working down to the ports, make that part no stronger than any other.

Forward in wake of the hawse-holes, the planks should be wrought as to have the beam to cut the planks as little as possible by the holes; and care must be taken that no beams come behind the cheeks.

The sheer-plies, as they are the greatest strengtheners of the upper part of the top-side, should have their butts divided with the utmost care, in order to produce the greatest strength between the drifts, and give the flanged flake to each other. They are wrought of parallel breadths, with hook and butts cleared about four feet long between the drifts. The butts afore and abaft may be square, especially behind the channels, which should be of English oak. The others, owing to their great length, must be of East country plank.

Observe, if the channel or sheer-wales are in three flake ed, two of them may be wrought top and butt, to affix the conversion.

In flanking the infinite, attention must be paid that the butts of the planks, sprikitings, and striggings in the wind, should give flake to the butts outside.

Clamps, when wrought of a single flake, should have hook and butt flaked about four feet long.

Gun-deck clamp and sprikitting should have a three-part flake in midships, as should likewise those of the middle and upper deck. Clamps and sprikitings, when wrought in two flake ed, may work top and butt, and on the latter is to come in wake of the pump-half runner.

The clamps of the lower deck can be wrought towards the after part of the ship, free from the beam off the deck, as to clear of the after-half, come to the timber, as it was wrought in the middle, to produce a great flake; but these clamps are lit to produce an easy entry, and some of the after-beams, or course, must face on the clamps.

4 A
SHIP-BUILDING.

However desirable a three-port shift may be with regard to strength, planks of that length are hard to be gotten; therefore, to add security to a two-port shift, let the plank below or above the butt be dovetailed into each timber next the butt, and likewise edgeways, keeping the douls clear of each other.

To design on a plan the body of the ship, shewing the lengths and breadths of all the planks as near as is required for practice, will be found by experience to be necessary; for when the ship is planking, without a plan of this fort to affist, it is requisite to girt the body in several places, to know the number of strakes the bottom will require, in order to work the planks of each quality of an equal breadth, and likewise to know the diminishing of the breadth of the planks forward and aft. To do this satisfactorily, without a plan, is attended with much inconvenience and trouble. It also affords an opportunity of not only shifting the work before it be immediately wanted; but by having the whole height of the bottom and top-side before you at one view, you have a better opportunity of seeing whether the planks are sufficiently clear of each other, which is better than seeing them on the ship's side. And when the ship is planking, if there should be any lengths which may prove difficult, you may, by referring to the plan, see if the butt can conveniently be altered, without prejudicing the shift that is not wrought; some part of which it is likely may be altered to conform thereto.

The bottom may be expanded by the horizontal or water-lines, also by the ribband-lines; therefore, from the sheer-plan, Plate I., may be taken the section of all the timbers, and the lower edge of the rabat of the keel, from the after-fid of the Iftern-port, to as far forward as the rabat of the keel continues straight, that is to timber M; likewise the fear of the keel; all of which are to be let off on the plan of expansion, as in Plate III. Then to expand the square body, transfer the heights of the upper and lower edge of the main-wale, channel-wale, sheer-strake, upper and lower fides of all the ports, the height of the decks at the side, and under side of the plank-strake, from the sheer-plan, Plate I., to the body-plan. Transfer from the body-plan the half-breadth of the timbers at the upper and lower edge of the main-wale, channel-wale, sheer-strake, and under side of plank-strake, to the half-breadth plan, and draw in the lines to their half breadth; which being done, apply to those lines, and also to the horizontal or water-lines, narrow slips of paper, confining them thereto by needles or small pins, from dead-flat forward to square timber O, and from thence abaft to 28; marking upon each slip of paper the elevation of every timber, and its respective water-line, &c. as girted.

In the same manner, girt the timber dead-flat in the body-plan, Plate I., from the inside of the rabat of the keel to the under side of the plan-strake or gun-wale; then mark upon it the heads of the timbers, water-lines, upper and lower edges of the wales, and ports; likewise the decks at the side and under side of the plank-strake. Then square up the elevation of dead-flat, as shown on Plate III.; and upon that line let up the middle of the rabat, to which spot fix, with a needle, the spot corresponding thereto on the slip of paper that girted dead-flat; then upon the line mark off from the said slip the water-lines, heads of the timbers, upper and lower edges of the wales, ports, &c. In the same manner proceed to girt every square timber in the body-plan, Plate I., marking thereon the name of its respective timber. Then fix the spot marked for the middle of the rabat of each girt, to the middle of the rabat of its respective timber in Plate III.
SHIP-BUILDING.

which will represent the moulding edges of the cant-timbers, the water-lines, wales, &c. Likewise mark the heads of the timbers, as taken from the body-plan, as the slips now lie, which heads may be drawn when the slips of paper are taken up.

The mouldings of all the timbers may then be drawn from their moulding edges, and the openings therein where required for air, or to make the slips of ports, observing to taper the heads of the cant-timbers on the flying-line.

The operation of expanding the after cant-body is so similar to the above as not to need repetition; therefore, supposing the after cant-body to be expanded as far aft as the fashion-pieces and stern-timber, there only remains to be explained the expanding of the transoms.

The buttck-lines being drawn in the further plans of Plate 1., proceed to draw in pencil the moulding edges of the transoms in the half-breadth plan, thus: lay a slip of paper in the direction of the upper edge of each transom in the sheer-plan, and mark thereon where they cut each buttck-line fore-side of the rabbet of the stern-post, and the after perpendicular.

Square down the after perpendicular to the half-breadth plan, and therefrom set off each transom on its corresponding buttck-line, and the rabbet on the half thickness of the post. Then draw curves through those spots, till they intersect the aft-side of the fashion-pieces, and the moulding edges of the transoms will be represented in the half-breadth plan.

Now draw in pencil the transoms and buttck-lines, where they cross the aft-sides of the fashion-pieces in the body-plan, by transferring their heights from the sheer-plan, where they intersect the thwartship view of the fashion-pieces on the aft-side.

Provide narrow slips of paper, as before, and extend one round the aft-side of each fashion-piece in the body-plan, Plate 1.; and mark thereon where the upper sides of the transoms and buttck-lines cross them. Then place other slips round the moulding edges of the transoms, below the wing-transom in the half-breadth plan, marking the aft-sides of the fashion-pieces against which the transoms cut off, and the several buttck-lines, as also the side of the stern-post, or inside of the rabbet, which is the extreme length of the planks when worked. Then extend other slips of paper round the several buttck-lines in the sheer-plan, Plate 1. and mark on them the aft-sides of the fashion-pieces, and the moulding or upper edges of all the transoms below the wing, and likewise the margin-line of the wing-transom, which is the end of the buttck-lines and planks also.

Then place the slips of paper as on Plate 11., tho' for the heights of the transom and buttock-lines to the aft-sides of the fashion-pieces respectively marking their heights, to which fix tho' for the buttck-lines and moulding edges of the transoms to correspond; then move both the latter, till their corresponding spots agree together, and so confine them with pins; then mark the proper edges of the slips of paper, which will give the expanded form of the moulding edges of the transoms, and likewise the buttck-lines as they properly interrelate the transoms. The farthest spots on the papers of the transoms give the boundary of the stern-frame at the inside of the rabbet, and the farthest spots on the papers of the buttck-lines and the margin, of the wing-transom.

In the same manner may be taken off the lower edges of all the transoms, and draw the upper part of the wing-transom, which makes the stern-frame complete.

Take a slip of paper, and place it up the rabbet of the stern-post, in the sheer-plan, Plate 1., and mark on the paper the lower edge of the rabbet of the keel, the three lower water-lines, and the lower edge of the lower transom; then place the slips of paper as in Plate 11., keeping the spot for the lower edge of the rabbet well and the corresponding spots on the keel; and above the slips of paper, till the marks for the water-lines on the lower edge of the transom agree with the spots stated; then, by marking the edge of the plot, the whole will be described, and the boundary of the planks below the transom.

The operation may be performed by the rigid rules, as well as by the way above, as before observed; but in the latter, the cant-timbers, as it has been drawn in the body-plan, Plate 1., in the figure as well as in the text, to level through their proper lengths, which was omitted, to prevent confusion. All the lower planks are represented in Plate 11.

The whole side being now expanded, the planks of the bottom and wales may all be represented, agreeable to the foregoing directions. Likewise, on the top-side we have an opportunity of knowing the distance of every beam from the port-holes, whereby you may judge whether it is better to cut down upon the strakes for the ports, or to work the strakes somewhat broader, to correspond with the slips of the ports. This should be carefully considered, otherwise you will be under the necessity of making a bad shift in the top-side; or be forced to cut down upon the lower strake, that the bolts, which are driven through the lower fills, will be of little use; and also to cut up too much for the upper part of the ports, that there will not be left sufficient wood for the port-holes to bear the weight of the ports; inconveniences which ought to be well considered, before it is too late to alter them.

The strength of the ship, with respect to keeping her from breaking her sheer, chiefly depends on the shift of the planks from the water to the gun-wale, of which the greatest care should be taken to make the best possible, agreeable to the usual lengths of the planks; and likewise that the inboard planks, especially the strake above and below the ports, should be shifted as clear as possible of the outside strakes.

The longer the planks in the top-side are wrought, the stronger must the work be; but then it would be imprudent to work longer than the usual length of the planks, because when the ship wanted repair, you would be forced to cut plank on purpose, and thereby work green plank instead of seasoned. The breadth of the planks should be consulted, before you determine on the number of strakes in the top-side, as before observed; for if the planks are rather narrow, the top-side will look the nearer, and be equally as strong, if not bored too much.

To explain the Profiles, or inboard Works of the 74-Gun Ship, with Observations on the inboard Works of Ships in general, Plate IV.

Sometimes the inboard works are drawn in the sheer-plan of Plate 1.; but when so drawn, they appear so confused, that the best and readiest method is to appropriate a draught for that purpose, as Plate IV., in which every particular will be more clear and conspicuous.

To construct this draught, it will be necessary to take from the sheer-plan of Plate 1. the keel, keel and fairs, stern, stern-post, rudder, counter-timbers, fashion-pieces, transoms, cutting-down line, keel-flom, stern-post, all the decks, and centres of the masts; also the drifft, plank-sheer all fore and aft, the joints of the frame-timbers, and the ports.

The flations of the beams are next to be considered, and should be so disposed as to come one under, and one between, each port, or as nearly so as possible, to answer the other
other works of the ship, as the hatchways, ladder-ways, mail-rooms, &c.; but where a beam cannot possibly be placed under a port, or too wide apart, then a beam-arm, or half-beam, should be introduced to make good the deficiency.

To dispose of the beams, as in the profile, Plate IV., draw a fine pencil line under the deck-line at the side, and parallel thereto, to the mounding of the beams, which is for the gun-deck, 16 inches; upper-deck, 12 inches; quarter-deck and forecastle, 8½ inches; and round-houle, 6 inches. Then place the first beam of the gun-deck under the middle of the first port, or nearly so; the second between that and the third, which takes the heels of the bowspirit-rip; the aft-side of the latter to be 3 feet 10 inches before the centre of the fore-mast; the fore-side of the ninth to be 2 feet 6 inches abaft it; the aft-side of the fifth to be 10 feet 9 inches abaft the centre of the fore-mast, against which are the fore riding-bitts; the aft-side of the seventeenth to be 21 feet 10 inches abaft the said centre, which takes the after riding-bitts; the sixthth comes equally between; the aft-side of the tenth beam plumbs the after-part of the forecastle, or nearly so, and makes the fore-side of the fore-hatchway, which is 4 feet 10 inches fore and aft, and is made by the eleventh beam; the ladder-way between the ninth and tenth beam is 3 feet 2 inches in the clear; the aft-side of the twelfth beam is 5 feet 8 inches abaft the fore-hatchway; and the fore-side of the thirteenth 11 feet; between these two beams are let down the fore-jer capitan-rip. The fore-side of the seventeenth beam is 5 feet 8 inches before the centre of the main-mast, and makes the aft-side of the main-hatchway, which is 8 feet fore and aft, and is made by the sixteenth beam; the eighteenth beam is 9 feet 9 inches in the clear abaft the seventeenth; and the nineteenth 4 feet 10 inches in the clear, which makes the after-hatch; the aft-side of the twenty-first beam is 12 feet abaft the after-hatch; and the twenty-second 5 feet 6 inches in the clear abaft it, which takes the rip of the main-jeer-capitan; from the twenty-third to the thirtieth are about 4 feet in the clear alder. Between the twenty-third and twenty-fifth is the ladder-way to the cock-pit, and hatch to spirit-room; and the twenty-sixth beam should be placed exactly under the centre of the mizen-mast, all the beams having any thing attached to them being particularized. The intermediate ones may be equally spaced between them; and their fiding, which are 16 inches, may now be set off, and each beam be drawn. But as beams are seldom made of less than two pieces, the limber, which are four inches, had better be added to the fiding.

On the upper deck the first beam is placed under the beak-head, to receive the tenons of the beak-head fittations; the second beam must be so fixed, as not to be too much wounded by the bowspirit; the third and fourth about 2 feet 6 inches in the clear on each side the centre of the fore-mast; the others, particularly those that have pillars under them, should be fitioned on to the gun-deck; from the fifth beam to the tenth is let up in the middle 2 inches of the fore-hearth carling, which is 12 inches square; between the tenth and the eleventh beam is the fore-hatch over the gun-deck, abaft which is a ladder-way, and next abaft it the capitan; the seventeenth beam takes the topfiall-fleet-bitts on the afd-side; and the next beam before makes the fore-side of the main-hole, before which is a ladder-way about 4 feet 6 inches in the clear. The eighteenth beam on the fore-side takes the main-jeer-bitts, and the next abaft makes the after-hatchway; between the twenty-fifth and twenty-second is the capitan-room, which should be at least 5 feet 8 inches in the clear, to admit the capitan. From the twenty-second to the twenty-fifth are gratings, and a ladder-way to the gun-room, &c. The transom abaft scores in to the flem-timbers.

The quarter-deck beams having no framing of carlings and ledges as the others below, require nearly twice the number in the same length, and a greater round-up, otherwise they would be apt to bend with their own weight.

The length of the quarter-deck is determined by having the aft-side of the foremost beam about four feet before the centre of the main-mast, and in general receives the tenon at the head of the main-topfiall-fleet-bitts; the second beam is about 4 feet 6 inches abaft the centre of the main-mast, and receives the tenon at the heads of the main-jeer-bitts; of late these bits are clear of the beams above the riding bitts; the other beams, in general as far aft as the mizen-mast, are kept about 2 feet 8 inches in the clear alder. Between the third and fourth beams is a ficit on each side for the top-tackle; from the seventeenth to the twelfth are gratings; and between the eleventh and twelfth a ladder-way for the officers. Fourteen and fifteen are placed about 1 foot 10 inches on each side the centre of the mizen-mast; and the thirteenth 3 feet 6 inches before fourteen, so as to receive the tenons of the fleering-wheel fittations in the middle; the twenty-fourth beam is placed as to receive the tenons of the munion of the screen-bulk-head, and sometimes rounds aft for the bulk-head to follow the round-aft of the stern, or nearly so. Again it the fore-side of the flem-timbers, and scored aft into them, is a tranfome like the deck below, but having a balcony; the deals run aft to form the fame.

The forecastle beams should be four more in number than there are in the upper deck, in the length of the forecastle; and where a wide opening occurs, such as the mail-room, a half-beam should be introduced, to make good the deficiency. The cat-beam is so placed that the fittations of the beakhead-bulk-head may face on the fore-side 1½ inch; and when the cat's-tail comes in upon the forecastle, and is secured thereon, it must be three-feet fided, as it requires a rabat of five inches on the afd-side to receive the ends of the deals; but of late years the cat's-tail now is under the beams, which greatly assists the conversion of the cat-heads, and makes more room on the forecastle, and consequently the beam need be no larger than the others, whereby a great weight is taken off this part of the ship. Between the first and second beam is a ladder-way about three feet in the clear. The third beam is two feet before the centre of the fore-mast; the main-topfiall-fleet-bitts come on the fore-side, and the heels upon the upper deck. The fore-side of the fourth beam is three feet abaft the centre of the fore-mast, which allows for the fore-jer bitts to come on the fore-side of the beam; and their heels should cut outwards sufficient to lead the fore-tack ast clear of the galley. From the sixth to the eighth beams are the gratings over the galley; on the fore-side of the ninth beam is the ficit for the fire-hearth funnel; between that and the tenth, the fream-grating over the boiler; and on the after-beams was a cupola, or belfry for the bell, but that of late has been removed to the fore-part of the quarter-deck, between the main-topfiall-fleet-bitts, in the royal navy.

The round-houle beams are smaller than those of the quarter-deck; therefore, let the number of beams on the round- houle be two, or more, in number than in the same length of the quarter-deck. The round-houle should always have a great round-up, both for strength and convenience.

With regard to placing the round-houle beams, we have only to attend to the foremost fitation of the fleering-wheel, so as to receive the tenon at the head: the mizen-mast must also have a beam about 20 inches on each side the centre.
centre. Before the mast is a small pair of huts for the marine-capitalists; and over the ridge of the captain’s lobby is a companion with glass-stairs; but lately all-natives of glass are let into the deck, which are found more convenient. The intermediate huts may be placed on either deck under, letting the beams over the deck, bulk-heads have a proper round-arch, agreeably to the quarter-deck beam underneath.

The beams of the several decks, as taken from the floor-plan, Plate I., being determined, those of the ship only remain to be fixed, that is, from the upper side of the gun-deck beams 7 feet 1 inch, for the lower side of the arch, but at the plate-room forward and abaft are laid with three-inch deal or planks. They may be kept as much below the range of the other beams, that is, from forward to member number six, and in the twelfth to the after-beam, which is immediately under the twenty-seventh beam of the gun-deck.

The beams of the orlop-round-up 24 or 2 inches thick, and should be placed directly under the middle of the gun-deck, except the second beam from forward, which may be equally spaced between the first and third. Between the tenth and the eleventh beams is shown the capstan-flop, &c., for lowering the fore-carpet down on the orlop occasionally; but this has been left in the new yard. The fifteenth and sixteenth beams take the well-bulk-heads, and till of late years was enclosed by a lower-board bulk-head from the orlop to the gun-deck, but is now only laid over with gratings. Between the twelfth and twenty-first is a hatch to the spirit-room, and between the twenty-second and twenty-third, a hatch to the coal-hole.

Below the orlop are the works in the hold: such are the breast-hooks from number one to six, the floor of the orlop being made by the fifth and sixth hooks, and framed by carlings. These looks stand square with the body, but the looks under the gun-deck and upper deck lay with the floor of the deck; there is likewise a look under the after-beam. The magazine and large room extend from the after-side of the first beam of the orlop to the after-side of the sixth, which takes the head of the after-rigger-bins. Next abaft the magazine, the bulk-head are fire-rooms to the fifth-side of the eighth beam, and under those a blow-locker. Close abaft the main-hatchway is the pump-well, included with a bulk-head of three-inch plank, about five feet fore and aft, and eight feet athwartships in the clear. No well in the ship, the best for the mast-male, and the pumps on each side; and adjoining the well, on the fore and after-riders, are blow-lockers about two feet in the clear. On the fore-side of the twenty beam is the bulk-head of the spirit-room, which extends to the after-side of the twenty-second beam, and on the fore-side of the twenty-third beam is the bulk-head of the coal-hole, and part of the powder-room, which extends to the after-side of the twenty-fourth or after-well, from the orlop cannot extend further aft, but sufficient space would not be left for the bread-room. On the fore-side of the after-beam of the gun-deck is a bulk-head, which terminates the breadroom, and all space abaft its the true called lady’s-hole. Close before the powder-room, bulk-heads are a crutch; and two more crutches are spaced abaft the powder-room.

In the profile, Plate IV., is represented the method of connecting the sides and beams together by knees and adzes, as used when that plate was engraved; but owing to the great rarity of knee-timber face, that time, other methods of connecting the sides and beams together have been adopted, which will be more noticed hereafter, under the head of arrangements and profiting in the building of ships.

In the hold it is customary to place the orlop under the beam at the deck of the orlop, and the after-beam under the beam. In the middle, the beam under the beam before the main-male, and the main-hatchway between the lower and the lower-deck-hatchway. The beams extend about twelve feet on each side beyond the hold, and about one foot four inches square.

First orlop-riders are from six to eight feet, on the side of each floor-deck, and are in the form of the lower orlop-riders. Observe, in shifting the riders, that they come clear of the pump, and of each other, otherwise they will cast shoreways, as at the nineteenth beam of the orlop.

A long carling 14 inches deep and 12 inches broad, is nailed up two inches on the outer side of the first floor-deck beam, or to the beam before the main-timber, and connected to the hawse-see by an iron plate on each side of the after-end, the bolts being driven through, and clinched on each plate alternately.

The inboard wall being described in profile on the several decks, it is necessary also to represent them on each plan of deck.

Instruments for describing the Plans of the Decks. Plates V. and VI.

Transfer from the floor-plan, Plate I., the heights of each deck at the side, at every timber, to its corresponding timber in the body-plan; then upon each plan draw the deck line, and therefore square up the heights of all the timbers, as taken from the floor-plan. Next transfer from the body-plan the breadth of each timber, and the height of the deck is to be drawn, and let them on each side the middle line, at its corresponding timber and plate; but in Plates VI. and VII., half the deck only is represented; then transfer from the floor-plan, where the deck intersects the side of the stem and fore-foot at the rudder, in Plate VI., and the last line set of half the extra of the 44th beam line off. A curve drawn through the breadth, as set off, ending in the rudder face and abaft, will represent the side of the timbers; the breadth, in the fore-foot of the 44th beam, and drawing another curve thereon, gives the boundary of the deck at the side, and determines the length of the beam.
Upon each plan square down the sides of the ports and beams, and centres of the masts and capstans, from the profile, Plate IV.

Thus far the plans of the decks are general; but as each deck is very differently fitted, it is necessary to have a half-plan of all at least, and what little difference there may be on the opposite side, let the explanation suffice.

In the plan of gun-deck, Plate V., is shown not only the upper sides of all the beams, and the method of tabling them together in two or more pieces, as then customary, but now douelled instead of tabled; those in middhips, being the longest, are made of three pieces; and those where they are shorter, as at the twenty-sixth beam, are in two pieces; those in three pieces have the middle piece feared to each arm. The method of connecting the fides with hanging and lodging-knees is likewise shown in this plan, with the iron lodging-knee behind the rider, (engraved hanging by mistake,) as at the fifteenth and sixteenth beams. The beam-arms at the main-hatchway and mail-rooms are represented as tabled into their adjoining beams, the seventeenth and eighteenth. The framing of the deck to receive the flat having three tier of carlings, nearly all fore and aft, with a sufficient number of ledges let into them parallel with the sides of the beams, is also represented here. The framings in the middle are the main-partners; those for the fore-masts to be formed by the standard against the fore-side of the fore-riding-bitts, the inside of which must be kept half the diameter of the mast, and five inches more for the wedging, and to extend from the bitts to the top of the bow-sprit; the cross-chocks, which frame the mast-hole athwartships, are to be eight inches thick, and kept at the main distance on each side the centre of the mast, and rabbet into the partners: the main-hole is made eight square, but now circular, by corner-pieces rabbed to half their thickness into the partners and cross-chocks: on the fore-side of the fifth beam is a cap-scuttle about two feet square, and another abaft the sixth beam for handing up cartridges, &c. from the magazine. The fore-riding-bitts are 1 foot 8 inches square, and placed four feet afunder, or two feet each side the middle line: the after-riding-bitts are of the same size, and placed 4 feet 6 inches afunder, and the standard against their fore-sides extends to the fore-riding-bitts: the cross-pieces abaft the riding-bitts are 1 foot 6 inches fore and aft, and two inches less deep, and the face-pieces on their aft-sides are of six inches thick. The framing on the main-hatchway and ladder-way consists of coamings 1 foot 6 inches above the beam, that is, the lower piece to be 9 inches deep and 10 inches thick, and the upper piece 9 inches deep and 7 inches thick, douelled together, and spread in the clear 4 feet 8 inches; and the head-ledges to be 7 inches thick, scored and tailed into the coamings, and to round-up above the latter, after the rate of 2½ inches in six feet of length. The capstan-partners are here framed as on the upper deck; but as this method of lowering the fore-jer capstan is discontinued, let it be framed as the main-jer capstan. The main-mast partners are framed similar to the fore partners, the carling being 1 foot 5 inches broad, and 1 foot 6 inches deep. The chain-pumps are represented on the plan as fitting the pump-cafes through the main-partners, and the back-cafes without; the fprocket-wheel and spindle-work in boss rhodins or gudgeons, let into the top-fall-feet and jeer-bitts, and the winches also in the pump-pillars. The main-hatchway is 6 feet 4 inches athwartships, and fitted with coamings and head-ledge as the fore-hatchway. The after-hatchway is the same as the fore-hatchway. The flap for the main-jeer capstan is 1 foot 10 inches broad, and 1 foot 5 inches deep, to be scored down between beams 21 and 22, and lap thereon 8 inches above the beam, with broad carlings on each side to receive the bolts of the pall-rim: in the middle of the step is an iron cap to receive the spindle. The hatch to the Spirit-room, and ladder-way to the cock-pit, are framed as the fore-hatchway. The mizen step to be 1 foot 8 inches broad, and 1 foot 4 inches deep, and beared down between beams 25, 26, and 27, two inches. The bread-room scuttle, which is 2 feet 4 inches square, is on the larboard-side, and is framed with coamings and head-ledge, with a cap or top as high above the deck as at the hatchways: on the starboard-side abaft is a scuttle about two feet square over lady's-hole, and another 1 foot 8 inches square over the scuttle to the magazine. On the gun-deck, in the middle of the three or four after-beams, is a standard, fitted 12 inches, the upper end to say against the transoms, as high as the helm-port transom.

A 'skate without the coamings at the main-hatch is represented, the binding-'skates all fore and aft, which are to strengthen the deck, as they are weakened by the hatchways, therefore the butts should be shifted clear of them: in the inner 'skate are driven the flopper-bolts. Forward is shown the moulded fize of the deck-hook and raking, also the plan of the half-way-plates and manger, with the flanions.

On the same plate is drawn the plan of the orlop, with its several conveniences. On the fore-platform, which extends from the fore-peak to the fore-hatchway, is the boatswain's cabin on the larboard-side, with such another for the carpenter directly opposite; and before each is a flour-room, to hold their respective flores; before the boatswain's flour-room is a flour-room: between the fore-riding-bitts are two doors, one leading to the light-room passage on the larboard-side, and that on the starboard-side to the magazine and gunner's flour-room. Cloae before the heel of the larboard foremost riding-bitts is a cap-scuttle, inclosed, to hand up filled cartridges; and on the opposite side a flat scuttle to the magazine, likewise inclosed; at the end of the light-room passage is a scuttle to the light-room: abaft the riding-bitts are scuttles to the boatswain's, gunner's, and carpenter's flour-rooms under the orlop. The fore-hatchway is of the same size, and immediately under that on the gun-deck, but has only a flat framing round it, to take the hatches that cover it. The beams of the orlop are rabbed on eacg edge to receive the flat, which is only oak boards ½ inch thick as far as the after-platform. The midship flour-room now extends from the main-hatchway to the fore-hatchway, and is framed round with pillars upon a carling ten inches deep; and as the capstan-room is not used, the gunner's cabin is made at the fore-part. The main-hatchway is of the same size as that over it, and is framed round as the fore-hatchway. The well is not inclosed, as shown on the plan, but at present is laid over with gratings. The after-hatchway is of the same size as the hatch over it, and framed like the others. Between the beams 21 and 22 is a double hatch to the Spirit-room, and one next abaft it to the coal-hole. On the fore-side of beam 23 is the bulk-head of the cock-pit, and abaft it inclosed are two fultons, one to the powder-room the other to the light-room.

On the larboard-side abaft is the steward's room, abaft which is the bread-room; and the interval between the steward's room and light-room bulk-head is the steward's bed-place and racks for flowing cheese: next before the steward's room is the purfer's cabin, before that the flop-room, and next to that a compartment for the marines' clothing. From the steward's room, to nearly forward on each side, are the wings, or an open space about 4 feet 6 inches from the side, sufficient to swing a mall, if necessary, to plug up shot-holes in the time of action. From the steward's room to the marines' clothing
is built up with a bulk head of 14-inch deal, and the top of the forecastle's cabin forward, and between these, with its rooms and whole deck battens or lattice work. On the forward side, opposite the forecastle's cabin, and first lieutenant's room, and between the captain's cabin, is the fore- and main-mat, and it is fitted up for the doctor's and forecastle's cabin. On this plan it is customary with a different colour to mark the places of the work in the hold; and to distinguish them on the plate, they are represented by fine-tinted lines.

Under beam 1 is a bulk head for the boundary of the light-room, together with its plan, and also the magazine lights, jambers, and planks, (to show the layers of light more into the magazine). The magazine is surrounded by a strong bulk head of three-inch planks, the edges rabbeted together, the inside of which is doubled with flat deal, so as to cover each joint, and on the outside with flat deal, and a thick coat of mortar under it. The flat of the magazine is first laid with three-inch planks, caulked on beams underneath, upon which are fastened, with copper planks, the pallating beams, framed together at right angles, about three feet distant: the upper edges are rabbed to receive the flat, which is 14-inch deal, lined on the under side. The bulk head at the side, which forms the webbing, is contrived with panels, and rabbed flanneaux to receive the panels: in the fore part of the magazine are midship the filling-room, which is lower than the surface of the flat about twelve inches: this is lined with head, as it is the place where the carriages are fitted, (hence its name,) for greater security: as it is close abaft the lights, glass fashes extend across, guarded with a copper wire-net work; in the sides of the filling-room are racks for filled carriages, and a compartment behind them for flaves of empty barrels. The powder barrels are flowed upon durance battens, over the pallating flat, which is parted off from the filling by an open bulk head of flanneaux and battens. Magazines are now only fitted up to receive barrels with carriages already filled.

Abaft the magazine are a store room for the boat, on the forecastle side, in midship, a store room for the gunner, and under that a shot locker; and on the forward side a store room for the carpenter.

Next abaft the main hatchway is the plan of the well, and shot locker abreast and abaft it. Under the fore side of the beam is the bulk head of the magazine, and under the aft side of the beam is the bulk head of the coal hole: its after bulk head is under the fore side of the beam, which also makes the fore bulk head of the powder room, which is lined both round with a bulk head similar to that at the magazine forward; likewise the light room, and pallage to the powder room, which is fitted up with racks for flowing filled carriages, as represented in the plan: abaft the powder room bulk head is occupied for the bread room, to the bulk head for lady's scullery.

On Plate VI. is represented the half plan of the quarter deck, well, and forecastle, likewise the half plan of the upper deck. On the plan of the upper deck is shewn the beak head flanneaux, whose sides are rabbed to receive the bulk head: the midship flanneaux to be about 2 feet 6 inches each side, and 12 inches square as high as the flat of the beak head: they tenon at the heel into the foremost beam of the upper deck, and receive into their outsides the tenon of the collar carling, which is of the same size as the flanneaux, having its upper side well with the flat of the beak head, which is of the same height as the lower fills of the ports. The midship flanneaux to be 68 inches square above the
cells, and the other flanneaux, which are about a foot on each side, are all 66 inches square, and all fitted into the cast beam. The two side flanneaux are placed either to the spread of the main- and fore-mast, as far as may be kept far enough out that the fore head can readily be abaft to make the head of the port: the next flanneaux makes the head down: on the midship side of the beak head is a skate, with a flap below it to lead in the fore deck. The heels of all these flanneaux to enter into the collar carling with a double step.

The framing of the fore- and main partners are shown, as directed, for the main partners on the gun-deck, on the outside of which are the heels of the fore sheet and jib-battens; the heel of the former to spread sufficiently from the middle line to lead the fore deck clear of the gally, having a flare fitting into the frame for that purpose. Abaft the fore main partners are the cants for the gally, which is included abaft by two doors.

The fore hatch and ladder way to be framed, as directed, for the main partners on the gun-deck, on the outside of which are the heels of the fow deck, and main-battens: the heel of the former to spread sufficiently from the middle line to lead the fore deck clear of the gally, having a flare fitting into the frame for that purpose. The heels of all these flanneaux to enter into the collar carling with a double step.

The framing of the fore- and main partners are shown, as directed, for the main partners on the gun-deck, on the outside of which are the heels of the fore sheet and jib-battens; the heel of the former to spread sufficiently from the middle line to lead the fore deck clear of the gally, having a flare fitting into the frame for that purpose. The heels of all these flanneaux to enter into the collar carling with a double step.

The framing of the fore- and main partners are shown, as directed, for the main partners on the gun-deck, on the outside of which are the heels of the fore sheet and jib-battens; the heel of the former to spread sufficiently from the middle line to lead the fore deck clear of the gally, having a flare fitting into the frame for that purpose. The heels of all these flanneaux to enter into the collar carling with a double step.

On this plan the flat of the deck is represented, and the several butts shifted: close to the side are the water ways, five inches thick, and the first stroke of oak, which is cut off between the riders: the next 4 strokes are also English oak in the water of the guns, shifted in short lengths, and anchor locks, or top and butt, to affix the conversion. The rest of the deck is three-inch Prussia deal, except the binding

flanneaux, which are the second and third, without the main hatch-coamings, and under the forecastle: the decks must be so shifted as to work their whole length, or great waste will occur, that is, 30, 36, and 40 feet lengths. The mizen partners are framed with a carling on each side, and corner pieces as high as the beams, and the flat round them 8 oak, five inches thick.

Close up under the beams is represented the tiller, as fitted with the horn loop over the end, for keeping up the tiller rope in the sweep, and a loop abaft it, with eyes in it, through which the rope is recoiled, to be set up by tackle or to the eye bolts: further aft, at the end, are iron rods, which are bored through the beam, to keep the tiller afloat. At the fore end, on the upper side, is an iron gooseneck, which traverses the sweep, and keeps up the fore end; the rope traverses the sweep in a groove, and is led up to the wheel on the deck above by flannels fitting at the end of the sweep, and the blocks after the mast represented by the ticked line.

Sometimes abaft, where the side is to round to have riders, iron standards are fitted, as on beams 26 and 27.

On the beam, before the mizen-mast, is the bulk head of the ward-room fitted with double doors on each side.

The knee of the mizen mast prevents the hanging of a door at the side of the round houses forward; they are therefore included with a bulk head, and a door on the aft side.

On the plan of the forecastle is shewn (as was the practice when the plate was engraved), the construction of the life rail, as let over the heads of the beak head flanneaux,
SHIP-BUILDING.

with the chafe-port and upper part of the round-houses; also the plan of the cat-head, cat’s-tail, and the knee abaft the cat-head. Between the cat’s-tail and the fore-mast is framed in midhips a ladder-way, and round the fore-mast are the fore-top-fail-fleet and jear-bitts, with their cross-pieces; on the sides of the masts the check-blocks, or they must be provided very large, to receive all the staves necessary for sheets, braces, &c. Abaft the fore-mast, on each side, is a scuttle for the top-tackles to lead through to hook on an eye-bolt on the upper deck. Over the galley, in midhips, are framed the steeam-gratings; and between them coamings for the chimney-funnel. At the aft-part of the forecastle are represented the belfry-bitts, with the knees to support them; and over the breast-beam are shown the foot-rail and flanions, as then used, but now discontinued.

Along the waist into the side, instead of gang-boards, as formerly, the deck is continued from forward to about seven feet three inches from the side; likewise the flat is continued along the midhips, five feet three inches on each side the middle line, except an opening over the main-hatchway.

Upon the plan of the quarter-deck is shown the plan of the breast and foot-rail over the breast-beam, with their flanions, now rendered unnecessary by continuing so much of the deck along. On each side of the main-mast is a flat scuttle for the pumps to be passed through; and on the after-side of the beam abaft the mast are the brace-bitts. Abaft the brace-bitts, on each side, is a flat scuttle, for leading through the main top-tackles to an eye-bolt driven in the upper deck. From the seventh beam to the twelfth the space is framed for gratings, and a ladder-way, as before directed, five feet four inches in the clear. Between the fourteenth and fifteenth beams are fixed the steering-wheel and its flanions; in the next opening is the mizen-mast: the partners are formed with thick-stuff, as at the upper deck. On the beam abaft the mast is the bulk-head of the lobby and bed-place; and on the twenty-first beam the bulk-head of the captain’s cabin: between these bulk-heads are a fore and aft bulk-head that part the lobby and bed-place; and on the twenty-fourth beam is the screen-bulk-head. The latter is unnecessary when there is no walk or balcony abaft.

A plan of the round-house is not wanted, as, besides its beams and ports, there are only the mizen-top-fail-fleet-bitts on the fore-side of the beam before the mast, and taffrail-knees abaft: when an open stern, illuminators instead of a companion are let into the deck.

Explanation of the Methods of Laying-off all the Parts of a Ship on the Mould-loft Floor, preparatory to the actual Building of the Ship.

The sheer-draught, Plate I., being completely drawn upon paper, mostly to a scale of a quarter of an inch to a foot, as before observed, or forty-eight times less than the real size of the ship, it remains to expand it to that size on the mould-loft-floor; but the latter is seldom long enough to admit the laying-off of any large vessel in one length; in small mould-lofts they must of course lay-off in three or four lengths. Indeed, to lay-off in one length would cause unnecessary waste of time; for many of the joints of the timbers, or perpendiculars of the fore-body, answer alike for the after-body.

Laying-off. Plate VII.

Plate A may be said to represent the mould-loft-floor in miniature, by the same scale as Plate I.; but here, to prevent confusion, the different plans are shown separate, but on the floor in the groups: the several plans are laid off one over the other, which, to the practitioner, is perfectly clear.

The mould-loft-floor being cleared, begin by striking a straight line from one end to the other, as A A in the above plate, in distance from the side of the loft as much as the keel is deep. This line will represent the upper edge of the rabbet of the keel in the sheer-plan, fig. 1, above which all the heights are to be set up, and it will represent also the middle line of the half-breadth plan, fig. 2.

Proceed now to lay-off the fore-body, by transferring from the sheer-plan, Plate I., and erecting from the line A A, to the right-hand, the several perpendiculars or joints of the frames (Q, B, D, F, H, K, M, O, Q, S, U, X; and the fore-mast-perpendicular, and likewise frames 2 and 4 abaft Q). This must be accurately done, so as not to exceed the room and space.

Now describe the stem, as in Plate VII., fig. 1, supposing it of the full size, by setting up from the line A A the height of the centres from Plate I., and the nearest distance thereon from the adjoining perpendicular, as at Q, Q; by which radius the fore and after sides are swept, likewise the rabbet in the middle, from the keel upwards to S. Then set up the height of the head, or upper part, and its distance forward from the nearest perpendicular; then, by pinning a batten to the flots laid off, and to the curves already swept, the item will be formed likewise.

Transfer from the sheer-plan, Plate I., the heights of the lower and upper height of breadth-lines from the line A A, as in Plate VII., from the perpendicular 4 to the item; then, by pinning a batten to those heights, produce the fair curves E and F.

Let the outlines of the fore-body-plan, Plate VII., fig. 3, be represented, that is to say, the middle line by the line A A; the base line, or upper edge of the keel, by one of the perpendiculars; then will the outside line, R, be parallel to the line A A: at the moulded breadth at dead-flat (as few mould-lofts are broad enough to admit the height of the timbers as in the plate,) strike in the half-fiding of the item S from the middle line.

The main half-breadth line may now be laid off, by transferring it from the half-breadth plan, Plate I., to its corresponding timbers on the floor, from the line A A; and to end this line at the item, take the height in the sheer-plan, fig. 1, where the lower height of breadth-line intersects the aft-side of the rabbet of the item, and transfer it to the middle line of the body-plan, fig. 3; and from thence take the half-thickness of the item, and set it up from the middle line of the half-breadth plan upon a line squared down from the aft-side of the rabbet of the item, at the lower height of breadth in the sheer-plan. Then, by pinning a batten to the several half-breadths set off, and to its ending at the item, we form the fair curve D, as in Plate VII., fig. 2, or main half-breadth line.

Observe, when the batten is pinned, to look along it strictly, and see that its edge produces a fair line: this must be always understood, and therefore need not be repeated.

Transfer from the sheer-plan, Plate I., the heights of the centres for the radius of the floor-sweeps of the fore-body to the floor, and by pinning a batten thereto, produce the line B in fig. 1.

Transfer from the half-breadth plan, Plate I., the rising half-breadth, or narrowing of the floor-sweeps of the fore-body, and by pinning a batten thereto, produce the line B, in fig. 2.

Transfer from the sheer-plan, Plate I., the heights of the top-timber-line to the floor; and should the floor not be broad enough to admit the whole heights, set them up their
their respective timbers from time straight line, A A A.

Then, having marked the several lines laid off with their respective names, proceed to lay off the fore-body, fixing on some convenient part of the floor, marks the line A A A.

Plate VII. fig. 1, serves for the middle line M, Plate VII. fig. 3, and one of the projected lines for the bale line, or upper part of the keel, as before observed. The diagonal lines in the body-plan are not used in laying off the body on the floor, and taking the bevellings of the several timbers, but are of very principal use in the actual building; for at their flatters the ribs and harpins, which keep the whole frame of the ship together until the planking is brought on, their situation with regard to the heads of the timbers must be determined; it consequently follows, that a particular explanation of them is necessary.

The floor-head diagonal marked C in Plate VII. figs. 3 and 5, terminates the length of the floors, hence its name. The placing of this diagonal is of the utmost consequence to the strength of the ship, it being near the bridge, or that part which takes the ground, that it consequently is always liable to the greatest strain. It should, therefore, be placed as much above the bearing of the body in midships as can be conveniently allowed by conversion of the timber; but, afore and abaft, it is not of so much consequence. Bevellings are taken at this diagonal as far forward and aft as the floor extends.

The diagonal marked B in Plate VII. figs. 3 and 5, is placed in midships eighteen inches to two feet, according to the size of the ship, below the head C; it is the situation where the floor-ribband is placed in midships, and likewise the floor-harpin forward. Bevellings are also taken at this diagonal, all fore and aft, from which it is termed the floor-ribband.

The lower diagonal, marked A in Plate VII. figs. 3 and 5, is situated generally in the middle between the keel and floor-ribband; at which place the lowest bevellings of the timbers are taken.

The diagonal marked D in Plate VII. figs. 3 and 5, is situated in the middle, between the floor-ribband and first footlock-head, at which place a ribband and harpin are necessary for the security of the first or lower footlocks, and hence called the first footlock-ribband.

There are also bevellings taken at this diagonal, all fore and aft; which, being the part of the body where the timbers most vary, occasion them to be the greatest bevellings in the whole body.

The diagonal marked E in Plate VII. figs. 3 and 5, terminates the heads of the first footlocks, and is therefore called the first footlock-head; it should be spaced about seven feet above the floor-head, in order to give sufficient scarf or shift to the lower part of the second footlocks. Bevellings are likewise taken at this diagonal, all fore and aft.

The diagonal marked F in Plate VII. figs. 3 and 5, is situated in the middle, between the first footlock-head and the second footlock-head, at which place a ribband and harpin are necessary for the security of the second footlocks, and hence called the second footlock-ribband. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked G in Plate VII. figs. 3 and 5, terminates the heads of the second footlocks, also the heads of the third footlocks.

The diagonal marked H in Plate VII. figs. 3 and 5, is situated in midships in the middle, I mean the tack-head and the third footlock head, at which place the ribbands and harpins are necessary for the security of the third footlock, and hence called the third footlock-ribband.

Observe, when the harpin is placed low enough at the keel, that the wales may be worked before it is taken down, or it may fly up like the other, and not come home to the timbers. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked I in Plate VII. figs. 3 and 5, terms the heads of the third footlocks, and is therefore called the third footlock-head, and should be spaced about seven feet above the second footlock-head, to allow giving the same shift to the fourth footlocks as the other footlocks have. Observe, such third footlocks are sometimes taken under the gun-deck ports, must be continued upwards to the upper part of the ports, if possible to be gotten. Bevellings are also taken at this diagonal, fore and aft.

It must be observed, that the diagonals for the ribbands, as above described, must all be drawn in pencil on the body-plan, Plate I.

A ribband and harpin are also placed all fore and aft below the gun-deck and upper deck ports, and one likewise at the top timber-line, as at M, N, and O, Plate VII. figs. 3 and 5, which, with the ribbands and harpins before mentioned, keep the whole framing of the ship together to its true model.

Having described the diagonals, and struck them across the fore-body on the floor, as in Plate VII. fig. 3, the several timbers may be completed, by first transferring the lower height of breadth-line E from the sheer-plan, Plate VII. fig. 1, from G to X, to the fore body-plan, fig. 3, and striking horizontal lines at each of those heights across the body-plan, as at K; then transfer the main breadth of each timber from the half-breadth plan, fig. 2, upon their corresponding heights from the middle line of the body-plan, fig. 3. Then by taking the radius or length of the lower height of breadth-line E from the fore body-plan, Plate I., of timber dead-diet, set it off upon its lower height of breadth-line, and it will sweep downwards nearly as low as the lecued footlock-head; in the same manner, proceed with all the timbers to Y.

Take off the half-breadths of each timber in the fore body-plan, Plate I., from the middle line on the diagonal floor-ribband, as far forward as X, and set them up from the middle line of the half-breadth plan, fig. 2, upon their respective timbers; then, to end it at the stem, transfer the height where it intercepts the half-thickness of the stem in the body-plan, fig. 3, to the fore part of the rabbet of the stem in the sheer-plan, fig. I.; from thence square it down to the middle line of the half-breadth plan, fig. 2. Take the half-thickness of the stem in the body-plan, fig. 3, on the diagonal, and set it up from the middle line of the half-breadth plan, fig. 2, upon the line last squared down; and from thence sweep an arc the thicknesses of the bottom plank taken on the diagonal, the after part of which arc is the ending of the fore part of the floor-ribs. Then, by pinning a batten to the several half-breadths, and to the back of the arc or ending, the floor-ribband will be laid off.

In the same manner proceed with the ribs or diagonals.
D, E, and H, fig. 3, as you find ticked from @ to the item in the half-breadth plan, fig. 2, to their respective diagonals in the body-plan, fig. 3.

Set up 11 feet from the base line in the body-plan, fig. 3 and 4, and strike a line parallel thereto, which is the height of the centre of the floor-sweep at dead-flat. Then take the heights in the sheer-plan, fig. 1, for the centre of the floor-sweeps B, from B to K, and let them up in the body-plan, fig. 3, above the centre at dead-flat, and at each height strike level lines. Then take the half-breathths in the half-breadth plan, fig. 2, of the centres of the floor-sweeps B, and let them off on their corresponding heights from the middle line in the fore body-plan, fig. 3. Then, with a radius at the centre in the body-plan, to its corresponding half-breadth on the diagonal floor-ribband, sweep the curves of the several timbers at the floor-head, from @ to K.

Having swept in the various curves below the lower height of breadth, and at the floor-heads, pin a batten to the half-breathths, as set off on the diagonals for dead-flat, and the back of the above sweeps; continue it with a small curve or hollow from the sweep at the floor-head to the rabbet of the keel, which completes that timber from the lower height of breadth to the keel. The fame proceed will complete all the timbers. With regard to the heeling of the timbers exactly, set off the half-thicknes of the keel from the middle line in the body-plan, fig. 3, on the base line, and parallel thereto to its depth; then with compasses, opened to the thicknes of the bottom planks, sweep two arcs, so as to form the triangle at the outside on the upper edge, and it will be readily seen that the timbers along the midships will end at the outside of the rabbet; but as they approach forward, they will end on the inside of the rabbet; and as the keel tapers at the fore-end, they must be heeled sufficiently within the keel to admit the thicknes of the plank; then to heel the timbers that rise on the item, transfer their heights where they cut the outside of the rabbet of the item in the sheer-plan, fig. 1, to the half-thicknes of the item in the body-plan, fig. 3; from thence, with compasses opened to the thicknes of the bottom plank, sweep an arc inwards, the back of which is the ending of the timber, and a line squared from the timber to the height set off on the outside of the item represents the rabbet in that direction.

The fore-body being completed below the lower height of breadth, the upper part, or top-side, may be laid off by transferring the upper height of breadth line F from the sheer-plan, fig. 1, at each timber from dead-flat to X, to the body-plan, fig. 3, and striking level lines across at each height. Continue upwards each timber parallel to the middle line, from the lower to the upper height of breadth. Then, with the radius of the upper-breadth sweep taken from the body-plan, Plate I., sweep upwards every timber from its respective upper-breadth line, from dead-flat to O.

Transfer the height of the top timber-line I, from the sheer-plan, fig. 1, at every timber, to the fore body-plan, fig. 3, and strike in level lines at every height; then take the top-timber half-breadth from the half-breadth plan, fig. 2, at every timber, from dead-flat to X, and set them off from the middle line of the body-plan, fig. 3, upon their respective heights. Then, by a mould made to the hollow or tumbling-home of the top-side, and upper-breadth sweep at dead-flat, and a few feet above the top-timber-line, every timber from dead-flat to O may be formed on the floor by lowering or raising the mould as to agree with the upper-breadth sweep, and the half-breadth, as set off on the top timber-line. But the timbers before O must gradually par-

take of the hollow of top-timber X, which falls outwards considerably from a perpendicular at its main-breadth, though parallel to the middle line above the height of the top timber-line to the top of the side, which must be transferred from the sheer-plan, fig. 1, to each timber respectively in the body-plan, Plate VII. fig. 3. Pin a batten to those several heights, which will form the curves O and P, as in fig. 3. Take square from the middle line in the body-plan, fig. 3, the half-breathths of all the timbers at the top of the side, and set them up on their corresponding timbers from the middle line in the half-breadth plan, fig. 2; seeing that it makes a fair curve. The fore-body may now be laid off above the main-breadth, which completes the whole of the square fore-body, fig. 3.

The correct height of the knuckles of the timbers at the beak-head requires some attention; for if they were carried too high, the sheer of the ship must be lifted; or, if kept too low for the sheer, the timbers must be reduced to raise the knuckles; therefore determine what part of the sheer-trakes shall come well with the knuckles; for if the knuckle was to come in the middle of either sheer-trake, the foreship of it must then be wrought, taking a large piece of timber and much labour. In Plate VII. the upper edge of the sheer-trake is well with the knuckle. Another consideration to be taken into this account is the lifting the sheer forward, that it may have the same appearance on the ship as is designed on the draught; for if not lifted gradually some inches higher towards the stem, the curvature of the bow will make it appear to drop below a fair curve.

To know how much the sheer of the ship requires to be lifted forward has sometimes been resolved in this manner. Prolong the sheer of the wale before the stem in the sheer-plan, fig. 1, at pleasure; then pin a batten to the round of the bow at the main half-breadth, in the half-breadth-plan, fig. 2, and mark on the batten the flat planes of the sheer timbers and the side of the item; then pin the batten to the sheer of the wale in fig. 1, keeping the flat planes of the timbers, as marked on the batten, well with those near dead-flat, where they will not alter; then mark the other timbers, and the item on the sheer of the wale line prolonged, and level them as, to intersect their corresponding timbers and the item; then a batten pinned to those intersections will give the curve for lifting the sheer of the ships round the bow. Thus as the forepart of the bows of ships are so very different, it cannot be recommended as an undeviating rule, and therefore must be referred to practice; however, it is requisite to make an allowance for it in the laying-off of all ships, as the decks, sheer-trakes, and consequently the knuckles of the timbers, all partake of the necessary additional height.

The sheer body afore dead-flat being now laid-off, proceed to lay-off the after-body abaft dead-flat; but it is only necessary to point out such differences as occur at the extremes of the ship, the midship part being similar in both bodies.

On the mould-loft-floor it is customary to fet off as many of the perpendiculars abaft the fore-body already laid off, as to have sufficient room for the stern-poel, using as many of those in the fore-body as will answer to the regular room and space of the timbers, which will be as far as B, which will extend in the after-body as far as C, conseqently from 14.3. F. 24. strike up from the line A, A all the remaining perpendiculars to 96.

Strike in the aft-side of the stern-poel on the floor from the sheer-plan, Plate I., and the aft-side of the rabbet; and strike a line parallel thereto, on the fore-side, to the thicknes of the bottom plank.

Transfer
SHIP-BUILDING.

Transfer from the sheer-plan, Plate 1, the heights of the centres of the floor-tweeps, lower and upper breadth of breadth, top-timber-line, and top of the sheer, are all here.

Transfer from the half-breadth plan, Plate 2, the half-breadths of the floor-tweeps, made half breadth, and top-timber half breadth, but to the end the main-deck, and likewise the top-timber half breadth in the half-breadth plan, fig. 2, the side-counter-timbers will be laid off as the sheer-plan and body-plan, and where this intersect the side-counter-timber in the sheer-plan, shall be squared down to the half-breadth plan.

In the plan of the after-body on the mould-board, its middle line is marked by the sides of the laterals, consequently the bodies at the lower part can each other. This would have appeared very evident in the plate, but it is always a maxim to lay off on the floor to true as few lines as possible.

The lower height of breadth and tweeps, and the centres of the floor-tweeps in the after-body, fig. 5, may all be obtained in the same manner as directed for the forebody. The diagonals struck in, and the several half-breadths of the timbers let off thereon, form the after-body-plan, Plate 1. These timbers which come near the after-end of the heel, must be ended by cutting off the half-thickens of the keel, as far as it tapers from the stern-post in the half-breadth plan, fig. 2; and within the half-thickens of the keel, let off the thickens of the bottom plank. Then take off the half breadth of each timber to the inside of the rabbit, and let it off on the base line from the middle line of the body-plan, fig. 5, which is the true ending of every timber at the upper edge of the keel.

The top-side of the after-body, fig. 6, is laid off in the same manner as directed for the fore-body at dead-flat, even to the after-timber.

When the bodies are thus far laid off on the floor, it is usual to make the moulds, and then to work and的情形 all the timbers in the square body; that is, from O forward to 28 abaft.

Moulds for the Timbers in the Square Body.

The moulds for the midship floors are generally made first in the following manner: take fir-board, about three-quarters of an inch thick, and lay the outer edge to the floor-timber dead-flat, in the body-plan, fig. 3, from the keel to the floor-head, and make it of a parallel width, about four inches. Provide another board, and lay it to the foremost square floor O, from the head to the sides of the keel, and make it of the same width. Then tack them both down in their places, and nail a piece of board made parallel to the half-breadth of the keel, its middle edge well with the middle line, and lower edge cut square, and be well with the base line, or upper edge of the keel: the upper end is to extend a few inches above the cutting-down of O. Now nail a straight batten, about four inches wide, at the floor-head, from dead-flat to O; the upper edge well with the direction of the floor-head C. Let batten of the same width be nailed across, with their upper edges kept well with the floor-rabbet B, and one at the lower diagonal A, and as many between as may be thought necessary. Let these battens be one inch narrower than the others, which will distinguish them, as the former show the proper flations of the diagonals, and likewise the direction of the floor-heads. Then, upon the crofs battens must be marked the intermediate floors from dead-flat to O. There must be outside pieces and battens put together, exactly in the same manner, for the other side; and the lines for the moulding edges of the floors correctly transferred to the other side.

These two moulds may then be laid together at the middle line by lengths, for the rest of the frames, and

The cutting-down line being to be first transferred to the sheer-plan, fig. 1, to the floor, as at M, Plate II, take its half to the upper edge of the keel at every fourth foot above the quarter, and draw the proper length of the mould in one line, as before. Here, each body-plan, by laying off the two transverse lines, or transverse moulds, from the upright board, is brought to the former of floor, to brace, to prove the moulds running. The moulds will then be adding the form of the forebody thus.

Now lay the blank side of the mould upward in the after-body, fig. 5, and mark from thereon, as before, the moulding edges of any of the floors from dead-flat at the mould will continue, and the heights of their cutting-down, which will be needed to 27 to 21.

Then to the floor from 22 to the after-square floor 28, another similar mould may be made.

The lower futtock-moulds are laid made off the framed board of the above thick, the edge of the fore-laid to the frame-futtock, and the inside edge to the edge of the rib, from a few inches within the side of the keel to the first futtock-head. Thus when the mould is in its place, mark thereon the whole of the side of the keel, lower diagonal A, floor-rabbet B, first futtock-rabbet D, and first futtock-head E; or a shorter way, the diagonals numerically, as 1st diag. 2nd diag.

But if saving of stuff and time be considered as an object, make the edges of the mould lay to the two adjoining frames, and set down flats to the corresponding lines at every diagonal, and all at the head and heel.

The second futtock-moulds may be next made similar to the above, from the floor-head to the second futtock-head, marking thereon the heel C, first futtock-rabbet D, first futtock-head E, second futtock-rabbet F, and second futtock-head G.

The third futtock-moulds may be next made in the same manner from the first futtock-head to the second futtock-head, marking thereon the heel E, second futtock-rabbet F, second futtock-head G, third futtock-rabbet H, and third futtock-head I.

The fourth futtock-moulds differing in their shape, and being much longer than the others, the bent and readied method is to lay this mould to dead-flat, from the second futtock-head to the top of the side, and two or three feet longer, as the heads run higher above and abaft dead-flat. The inside of the mould towards the upper part may be made to the canting line, but at the heel, and a few feet above it, should be made as broad as possible; so that the mould may be moulded nearly all the fourth futtock in the forebody. Lay the mould in its place at dead-flat, and mark thereon the heel G, third futtock-rabbet H, third futtock-head I, lower and upper heights of breadth K and L, gun-deck port-fillet M, upper deck port-fillet N, top timbers O, and top-side P.

Next place the upper part of this mould to the former fourth futtock, O, of the square body, and it will be found to lay to the main-breadth upwards (as it will likewise lay to all the timbers between O and dead-flat, on consequence of the radius of the upper-breadth swept being all of one length); then, when the mould is in this position, it is found that part of the timber from the main-breadth downwards to the fourth futtock-head, the fourth futtock of this timber may be moulded by this mould, as it may then be conveniently marked on it; but if not, then the mould

mailed
Must be moved to the next timbers aft, placing it after the same manner, until the mould is found to which it will mould, as described above; while the mould lies well to the timber above the bevel, take its corresponding fifth buttock-mould, keeping the heel of the fifth buttock-mould well with the heel of its timber, then rake or mark its moulding edge on the fourth buttock-mould. In the same manner place it to the other timbers, marking thereon its corresponding third buttock, at the same time marking all the respective heights of the ribbands, &c. as at dead-flat. Observe, should the mould not lay towards the head of some of the foremost timbers, (as the tumble-home is less forward abaft than in midships,) measure the distance from the mould to the line of the timber on a square, and mark it on the mould; this being done to all the intermediate timbers, they may be laid to be complete on that side; and when so done, it will be necessary to have a small hole bored through the mould at every firmark, or height, upon every timber, by which means the true shape of the timbers, and places of the firmarks, may be transferred to the other side of the mould, and likewise upon the timbers when moulding.

In the same manner must be formed another mould to dead-flat for the timbers in the after-body, marking thereon all the timbers it will take. Those timbers of the square body afore or abaft the timbers already marked on the mould made to dead-flat, on account of there being more compas at the heel, may be marked upon one mould to each body, proceeding as before, only making the lower end of the mould sufficiently broad to take the most compas timbers thereon. But should the heelers do so much as to cause the lower end of the mould to be cumberfome; in that case, make moulds to each timber, as described above.

The top-timber moulds may be made in the same manner as those for the fourth buttocks, from the top of the side to the heel I, or third buttock-head.

*Method of taking the Bevellings of the Timbers in the Square Body.*

The moulds for the timbers of the square body being made, it is necessary to show in what manner their bevellings may be taken; for, until then, the timbers which have bevellings cannot be cut out.

Provide a bevel-boarding for the floors, in breadth as much as the floors are fided; and, in length, sufficient to take all the floor-bevellings thereon, as Plate VII. fig. 8. The fifth bevelling to be taken is from the cutting-down line for trimming the throat of the floors; but from dead-flat to floor E, they will be found to be fquare, or as far forward and aft as the cutting-down is parallel with the keel. They will be all represented by a square line on the board. Then, for the throating of floor F, apply the flock of the bevel to the perpendicular, or joint below the cutting-down line, and the tongue well with the cutting-down line M, as at N, Plate VII. fig. 1, and that will give the beveling for the throat of floor F. Proceed in the same manner with every floor, till all those bevellings be taken and marked on the board, as a, fig. 8, distinguishing them by writing their respective names, as ϕ to E, F, G, H, &c. to O. These will be all standing bevellings, both in the fore and after-bodies. In the next place, the bevellings for the outsides of the floors must be taken, which are always under-bevellings in both bodies, in consequence of the floors being always placed on that side of the joint from which the body declines; these bevellings are taken at the lower diagonal b, fig. 8, the second diagonal, or floor-ribband, c, fig. 8, and floor-head d, fig. 8. To take these bevellings, let off the fiding of each floor from its joint, or perpendicular, on each diagonal in the half-breadth plan, Plate VII. fig. 2, (offering, as before, that the floors in the fore-body are before the joint, and those in the after-body abaft it,) the diagonal formed by the heads of the timbers being laid off in the half-breadth plan, as far as the square bodies, for that purpose, as at M, fig. 2; then take the distance of each diagonal on the fiding line square from the middle line of the half-breadth plan, and let them down on their corresponding diagonals from the middle line in the body-plan, making spots in *Plate VII.* fig. 3. Then fix one leg of a pair of compasses on tho: spots of the lower diagonal, beginning with the first floor before dead-flat that has any bevelling, which is A, and, with the other leg, sweep the nearrest distance to the line of its corresponding timber. That will determine when it is within a square in the breadth of the bevelling-board; and so proceed with every floor alternately to O, as at b, fig. 8; thus the bevellings may be taken for every floor at each diagonal, and be thence marked on the board, as *Plate VII.* fig. 8.

In the next place provide bevelling-boards, one for each buttock, and one for the top-timbers, offering that the breadth of each board corresponds with the fiding of its respective fputtock bevel and top-timber; then, to take the bevelling, each, as before explained for the floors; only observing which futtocks are standing bevellings, and which are under: for fputtocks that have standing bevellings, the fiding of the timber must be cut off upon each diagonal, abaft the joint of its respective timber in the fore-body half-breadth plan, and before the joint in the after-body, and so contrarywise for those which are under-bevellings.

Therefore observe, that floors have under-bevellings, lower or frit buttocks standing bevellings, second fputtocks under, third fputtocks standing, fourth fputtocks under, and top-timbers standing bevellings. The bevellings of each may now be taken at every diagonal for every timber, and marked on their respective boards, the fore-body on one side, and the after-body on the other.

The bevellings to be taken for each buttock and top-timber are as follows: for the lower or first buttocks, lower diagonal a, second diagonal or floor-ribband b, third diagonal or first buttock-ribband c, and first buttock-head d, *Plate VII.* fig. 7. For second fputtocks, floor-head, which is second fputtock-head, third diagonal or first fputtock-ribband, first fputtock-head, fourth diagonal or second fputtock-ribband, and second fputtock-head. For the third fputtocks, first fputtock-head, which is the third fputtock-head, fourth diagonal or second fputtock-ribband, second fputtock-head, fifth diagonal or third fputtock-ribband, and third fputtock-head. For the fourth fputtocks, second fputtock-head, which is fourth fputtock-head, fifth diagonal or third fputtock-ribband, third fputtock-head, main-breadth, port-fill-line, top-timber-line, and top-side. For the top-timbers, third fputtock-head, which is the top-timber-head, main-breadth, port-fill-line, top-timber-line, and top-side. The bevelling for the main-breadth, and all above, may be taken from the half-breadth plan, by fixing the flock of the bevel to the joint of the timber, and moving the tongue to the respective half-breadth lines.

It is necessary, in the practical application of the moulds, to have the size of the timbers the moulding-way; this must be either set off on the bevelling-boards, or on the moulds. As the latter may be reckoned the belt way, first set off the fenting of the timbers the moulding-way at every head, &c. at dead-flat; thus, at the top of the sides, 6 inches, *Plate VII.* fig. 3; at the upper deck ports, N., 10½ inches; at the gun-deck ports, M., 11½ inches; at the third fputtock-heads, I., 11½; at the second fputtock-heads, G., 12½ inches; at the
SHIP-BUILDING.

When making a batten to all these parts, make it square to the cutting-down of the dead-flats at the middle line, will give the footstock-riband, or outer edge of the timber dead-flat, then, take the face or moulding at the head or heel of every timber, and let off on their respective moulds.

Then to mould the inner, the mould is laid on the timber, and the mould edge of the intended floor is brought to the cutting-down of the piece; then, if there is cutting-down in the piece sufficient for bevelling, and sufficient below it for seating, which should be no less than six inches, increasing forward and aft, as the strength may require. Where that is more, if there remains sufficient wood to mould the floor agreeably to its line on the mould, which is readily seen by marking spots on the piece corresponding with the line of the battens, and the observer deciding whether there was wood sufficient to mould the line agreeably to the scantlings marked on the mould. The above mentioned spots may be made conspicuous on the piece, and the cutting-down also marked from the mould; then, its corresponding full footstock-mould will finish its cutting edge, or a phable batten may be joined to the spots, and the moulding edge formed as low as the piece will admit (to that it is not within the given subsidence below the cutting-down), the batten being fair raked by its edge; then rule up the marks for the diagonals to apply the bevellings. Set off on a square from the outside the given scantlings, and pin the batten thereto, as also to the cutting down, and rake by the edge; the inside of the floor then will be completed, and the deficiency, if any, below the seating is made good by chocks.

To mould all the footstocks except the fourth, the mould need only be laid off to the outer edge of the piece; and if the piece comes near enough to the mould to allow for the scantlings and bevellings outside and inside, rake by the edge of the mould likewise the firmarks, head, and heel; then from the moulding edge set off the scantlings square from their respective places, and try if the edge of the mould will not form the line by moving up or down; if not, it must be finished by a phable batten, as before directed. Observe, should any of the timbers-be a few inches short in the length, let them be made good by the next timber upon it, as through chocks are not to be admitted.

The fourth footstock-moulds are laid upon the piece, and should be in an horizontal position (as indeed all moulds should to try the bevelings); then see that the piece forms agreeably to the line on the mould of the timber intended to be moulded, by making a hole with a gimlet through the holes at the various firmarks belonging to the main-breadth; observing, at the same time, that the piece is strictly conformable to the head of the mould above. When both are found to agree, and is wood in the piece sufficient for the bevelings, rake by the side of the mould in like manner and cut as low as the main-breadth; below that it may be completed by the upper part of the corresponding third footstock-mould, keeping it well to the holes made by the gimlet at the heel and third footstock-ribbon, which firmarks must also be raked up on the piece, likewise the heights of breadth, port-fall lines, top-timber line, and top-side. The inside towards the head is finished by the scantlings given, and a batten as before described. But when fourth footstock-moulds have firings at their heads, owing to the difference in the tumbling-home of the side, then, as the mould lies upon the piece, and the heel is found to answer, it must be seen that the upper part of the piece answers to the firing marked upon the mould; then, towards the heel may be finished as before, but the upper part above the upper part of the deep mould be completed by a mould to the other head. The fourth bevel edge marked there, and placed at two by the footstock mould, and at two by the upper part of the deep mould, its edge may be considered, and the footstock mould formed up to the line of the beading line, then let off the piece at the line making the upper, and at the line that points to the lower edge of the footstock, and I will the other be completed.

Upper moulds are moulded in much like the fourth footstocks, to render a further account unnecessary.

The mould for the shelf is badly being formed, proceed to make mould for the stem, stern-post, &c. The mould for the shelf is made to the lines representing the fore and after-floor, or moulded breadth, from the head to the heel; last in piece, according to the number the stem is to be completed of. The rabbit is detached on the mould, or represented by the battons that forms the aft-side being made parallel to the thickness of the bottom planks; but if the rabbit comes in the mould, a batten of the depth must be raked on the mould, agreeably to the rabbit. Plate VII. Upon this mould must be marked the lengths of all the decks, likewise of the harpins and chocks, by a horizontal line at each height across the mould. Some mark every two feet above the upper edge of the rabbit of the heel upon the mould. There should be a perpendicular line, &c. in other words, a square line to set the item by, which may be the perpendicular of the gun-deck.

The stern-post mould is made to the lines representing the fore and after sides of the stern-post, from the head to the heel, and a batten to the rabbit; then, across its mould may be marked the height of the upper side of the wing, filling, and deck-transtoms at the middle line, into the heights of the harpins. Another mould is also made for the beading-line on the poit, the side of which must be fayed to the beading-line from the upper side of the wing-transtom down to where the beading-line intersects the fore-side of the inner poit, and the fore-side of the mould to the fore-side of the inner poit; then upon the mould must be marked the flations of the upper sides of all the transtoms, marking their respective names thereon. By many, the line of this mould is superceded by marking the whole of the heights, &c. upon the stern-post mould.

Another mould may be made to the thwartship bearding of the stern-post, thus: square down the intersection of each water-line, with the fore-side of the inner poit in the sheer-plan, to its corresponding water-line in the half-breadth plan; then take the several half-breathths from the middle line in the half-breadth plan, and let them off from a straight line at their corresponding heights in the sheer-plan; and a curve made to pass through these spots will be the thwartsship bearding of the poit, at the fore-side of the inner poit, from the middle line, to which the mould is to be made; the same may be done, and a mould made to the fore-side of the stern-post.

A mould should be made to the dead-caud abait, which is limited on the upper part by the cutting-down line, on the lower part by the upper edge of the heel, the after-end by the fore-side of the inner poit, and the fore-end by the aft-side of the after-floor. The mould for the dead-caud line is represented on it; and to likewise are the several pieces that compose the whole, as they can be gotten to as to give flux to each other. Upon this mould are the shed batten with one edge straight to the middle line; they correspond with the flations of the square timbers; and the other edge
is hollowed to the moulding of the timbers, which gives the half-thickneys of the dead-wood below the flapping or bearding-line, as marked on the mould, as all above that line the dead-wood is trimmed perpendicular to the fiding of the keel. To make this mould more conveniently, it may be made in two parts, separating lengthways at about half its depth.

To Lay-off the Cant-timbers, Plate VII. Laying-off, Plate A.

The necessity and utility of canting the timbers forward and aft, have been already explained in constructing the sheer-draught, Plate I. But that the reader may have as clear an idea as possible of the design of the cant-timbers, and their disposition when canted, observe then in the half-breath plan, Plate VII. fig. 4, where the lines representing the joints of the cant-timbers, as transferred from the sheer-draught, Plate I, interfeét the middle line, there may be suppolèd the hinge of a door; and the lines for the cant-timbers may be suppolèd to present the door, which may be fwinged forward at pleafure; fo that if the ship was on an even keel, the fides of the cant-timbers (though trimmed to their proper form) would become perpendicular, fince the hinge of the door; or suppolèd the form of the cant-timber was drawn on the door and fawed out, it would be perpendicular as before. The diagonal ribbands are similar to the cant-timbers in this refpect: and as the cant-timbers at the middle line become perpendicular, making one ftraight fection in the direction of the cant-timbers; fo the cant-ribbands at their interfeétion of the middle line in the body-plan, fig. 3, become horizontal, that is, parallel to the keel at the middle line all fore and aft, provided that the ribbands for the fore and after bodies meet at the middle line, as the floor-ribbands do in fig 3. Or otherwise, as the cant-timbers are reprefented by a door that is hung perpendicular, fo may the cant-ribbands be reprefented by any plain surface, like the flap of a table, that may be hung horizontal to the fide of a room; then will the fide of the room become the middle line of the ship, equal to the middle line in the half-breath plan, fig. 2, and the flap of the table may be canted down to the direction of the diagonal lines in the body-plan, fig. 3. To understand it clearly, suppolè the edge of the flap of the table to be cut in the form of one of the diagonal ribbands laid off in the half-breath plan, fig. 2; let it be the floor-ribband; then within the floor-cant-ribband in the half-breath plan, fig. 4, is the square or horizontal ribband B, which is the form or diftance from the middle line which the flap of the table makes when canted down, as in fig 3. The cant-ribband in the half-breath plan, fig. 4, is the fame as the flap of the table, if lifted up till its level, fhewing the extreme half-breath of the ship, were it cut in the direction of the cant-line in the body-plan, fig. 3. The cant-ribband in the half-breath plan, fig. 4, is the proper line to make the mould to for the harpin. But the interfeétion of the cant-timbers in fig. 4, with the cant-ribband, is not the proper flation of the timbers; because the cant-ribband is now raised from its proper place, and the timbers remain as before. Therefore, when the cant-timbers crofs the square ribbands, square them up to their corresponding cant-ribbands, as may be readily seen in fig. 4, which are the proper ftations of the cant-timbers on the harpin-moulds. For if the flap of the table, which is the cant-ribband-line, and hinged at the middle line, was to fall down in its proper place, it would then be exaftly underneath the long tacked line B, which is the square ribband. The ftations of the square timbers on the harpin-mould will make no alteration, because the mould falls in the direction of the square timbers. Strike a ftraight line from the interfeétion of the cant-timber with the middle line, to their correspondong ftations on the harpin-mould; as at cant-timber S, fig. 4. This will give the direction as the cant-timbers fland on the harpin-mould.

Before we proceed any further in laying-off the cant-timbers, the fore cant-body, that is figs. 3 and 4, should be proved by the square timbers and water-lines, as far aft as timber M at leaft; fo it is poiffible that the ribband-lines may have a fair appearance on the floor, and yet not produce a fair body in the ship; but if the water-lines and ribband-lines agree, there need be no fear of producing a fair bow, as the lines cannot be altered after the cant-timbers are laid off.

Therefore, transfer the water-lines from the body-plan, Plate I., to the body-plan on the floor, and then they may be all run from timber M, and ended forward, as directed in the constructing the sheer-draught, Plate I. These lines laying with a more acute angle with the timbers, any unfairness in the body is more readily seen; but when the ribband-lines and water-lines produce fair curves in fig. 4, and likewife fair timbers in fig. 3, we may proceed to lay-off the square ribband-lines, which may be done in the following manner: mark on the edge of a batten the di{tances taken square from the middle line of the fore body-plan, fig. 3, to where the floor-ribband interfeets each of the square timbers O, Q, S, U, X and Y. Then fet them off from the middle line on their corresponding timbers in the half-breath plan, fig. 4. The ending of it may be performed as the ending of its corresponding diagonal or cant-line, with only this difference, that, instead of taking the half-breath of the item in the direction of the diagonal line, it must be taken square from the middle line in the body-plan, fig. 3, to where the floor-ribband interfeets the half-breath of the item. Then, by pinning a batten to the spots on the timbers and to the ending, is produced the curve B, or square ribband No. 2, marked on the floor S 2, and its corresponding ribband C 2, meaning square 2 and cant 2, which give a multiplicity of words; and it may be understood more clearly as we proceed, than by expressing the ribbands by their proper names, as floor-ribband, &c. Then, by proceeding in the fame way with the refi of the diagonal or cant and square ribband-lines, they may be all defcribed on the floor, as at A 1, B 2, C 3, D 4, and E 5; Plate VII., fig. 4.

Now proceed to the operation, where the cant-timbers in fig. 4, interfeét the square ribbands A, B, C, D, and E, or ends 2, 3, 4, and 5. Take the nearest distance or square from the middle line, and fet them off square from the middle line to interfeét their corresponding ribbands in the body-plan, fig. 3, and from thence level out lines at pleafure, as may be seen in fig. 3. Then take the distance from the middle line in fig. 4, in the direction of the cant-timbers, to the interfeétions of the square ribband with the cant-timbers, and carry them to their corresponding timbers in the body-plan, fig. 3, setting them off square from the middle line on the lines before levelled out. This will give the spots for the timbers, and likewife the proper ftations of the harpins to be crofied on the timbers.

Square up from the half-breath plan, fig. 4, where the cant-timbers crofs the half-thickneys of the dead-wood H, to the bearding-line R in the sheer-plan. Likewife from fig. 4, where the cant-timbers crofs the main half-breath line, port-fill line, top-timber half-breath, and half-breath at top-fide, let them be squared to their corresponding lines in the sheer-plan.

Take the heights in the sheer-plan, where the cant-timbers crofs the bearding-line, likewife the lower and upper main-breaths.
breadths, the port-side line, the top timber-line, and top of
the fide, and let them in up the body-plan, fig. 3. Striking
lines thereto parallel to the base line; then take the distance
from the middle line in the half-breadth plan, fig. 4, in the
direction of the cant-timbers, to the line for the half-breadth
of the dead-wood at each timber, and let them off from the
middle line in the body plan, fig. 3, on the heights set up for
the bearding. This will give the ending of the cant-timbers
on the bearding-line.
Take the distance from the middle line in the half-breadth
plan, fig. 4, in the direction of the cant-timbers, to the main
half-breadth, port-side half-breadth, top-breadth, and to
finite, and let them off in the body-plan, fig. 3, square from
the middle line, on their corresponding heights. This will
give the spots through which the curves of the timbers are
to pass by pinning a batten, and likewise the proper heights
of the havrins on the timbers.
To Lay off the Bevellings of the Cant-Timbers.
Let the bevelling of cant-timber $w$ be required, and this
will suffice for all, as the processes are alike. Strike a line
afore and likewise abaft the joint of cant $w$, in the half-
breadth plan, fig. 4, to the scantling of the timber, which
should be the breadth of the bevelling-board. Square a line
from the intersection of the joint with the middle line,
to the edges or fiding of the timber $w$ in the half-
breadth plan, as at L, fig. 4; then take the nearest distance
or square to the middle line, from where the ticked line
afore crosses the square ribbands $A$, $B$, $C$, &c. and set it
down from the middle line in the body-plan, fig. 3, on
each corresponding ribband, in the same manner as was done
for the joint of the timber, and level them out on each side
of the diagonal ribbands, because the distance taken off in
the direction of the bevelling edge in fig. 4, will sometimes
be without and sometimes within the diagonal. Then take
the distance from the square line, which crosses the middle
line at the joint in fig. 4, to the square ribbands $A$, $B$, $C$, &c.
in the direction of the ticked line, before the joint or fore
edge of $w$, and set them off square from the middle line
in the body-plan, fig. 3, on their corresponding spots before
levelled out. Where the same ticked line, in fig. 4, inter-
sects the half-breadth of the dead-wood, square it up to the
bearding-line in the sheer-plan, and transfer that height to
the body-plan, fig. 3. Then take the distance in fig. 4,
from the squared line, as before, to the line for the half-
breadth of the dead-wood, in the direction of the ticked
line; and set it off square from the middle line in the body-
plan, fig. 3, on the height of the bearding-line, which gives
a spot to finish the lower end. Where the same ticked line,
in fig. 4, intersects the main half-breadth-line, square it up
to the lower height of breadth in the sheer-plan, and transfer
that height to the body-plan, fig. 3. Then take the distance
in fig. 4, from the square line, as before, to the main
half-breadth, in the direction of the ticked line, and set it
off square from the middle line in the body-plan, fig. 3,
on the height last set up. Then, by pinning a batten through
those spots, the fore edge is produced in the body-
plan from the heel to the lower height of breadth.
Proceed exactly the same with the edge abaft the joint of
$w$, and the two edges will be run in the body-plan, fig. 3,
as the ticked lines there represent, the nearest distance of
which, taken with compasses, to the joint at every ribband,
shows how much bevelling the timber requires at each place
in the breadth of the bevelling-board; that is, if the ticked
line, which is the bevelling edge of the timber, come within
the joint of the timber (or nearer the middle line), then the
bevelling of the timber would be so much within (or under
from) a square, consequently the ticked line without the
joint will be so much without (or bevelling from) a square.
Figs. 5 and 6, exhibit the form of the halves pieces and
cant-timbers of the after-body, which being laid off and
bevelled in the same manner as cant-timber $u$ in the fore-
body, it is useless to explain them; nevertheless, cant-tim-
ber $w$, is completely laid off, that it may be referred to at
leisure. It may be necessary to add, that the greatest pains
are required to prove the correctness of the after-body, not
only by the water-lines, but by the vertical sections or but-
tock-lines, and by introducing one or more square timbers
abat 56, to prove the buttock quite ast, and lower-called
proof-timbers. When these are all found to agree, it will
not only produce a fair cant-ribband, but likewise a fit head-
frame. See Plate IX. Laying off C.
Observe, the diagonal $H$, fig. 5, or third futtock-
ribband, ends upon the aft side of the wing-tranom, which
requires the following method to end it. Transfer the
height from the line $AA$, or upper edge of the keel,
where the diagonal $H$ intersects the margin-line of the
transom in the body-plan, fig. 5, to cross the margin-line in
the sheer-plan; and where it crosses, square it down to the
margin-line in the half-breadth-plan, fig. 6; then take the
distance from the middle line in the body-plan, fig. 5, in the
direction of the diagonal $H$, to where it intersects the
margin-line of the wing-tranom, and set it off from the
middle line in the half-breadth-plan, fig. 6, on the line
squared down from the margin-line, which ends the diagonal
$H$, or third futtock-ribband. To end it as a square rib-
band, take the nearest distance, or square, from the middle
line in the body-plan, fig. 5, to where the diagonal $H$ inter-
sects the margin-line, and let it off square from the middle
line, fig. 6, to intersect the margin-line there; and if truly
squared down for ending the cant-ribband, the ending of the
square ribband will also intersect the margin-line at the
same place in fig. 6.
Moulds are generally made to each timber, or futtock, in
the cant-boadies; and in croffing or marking them, it must
be observed, that the flations of the beams and ribbands are
where the lines levelled out intersect the lines of the cant-
timbers. On the heels of the double futtock and half-
timber moulds, nail on a batten to the fleping and side of
the dead-wood, by which the heel is to be cut off. To
perform this, set off on the half-breadth plan, fig. 6, the
thickness of the fleping, or dead-wood, above the fleping-
line, which may be the half-thickness of the keelson, from
and parallel to the middle line, as there ticked; then from
the middle line in the half-breadth plan, fig. 6, take the
distance in the direction of the cant-line to the ticked line,
and let it off in the middle line in the body-plan upon the
line levelled out for the heel of the same cant-timber; and
from that spot square up a line to the upper side of the
cutting-down, which will give the height of the inside of
the timber, and will represent the side of the dead-wood
to which the batten is to be nailed. A firmark, croffed on this
batten at any certain height above the keel, and carefully
croffed on the side of the timber, when trimmed to corre-
pond to a line gotten upon the dead-wood at that same
height above the keel, will be the surest and best method
of keeping the cant-timbers to their exact height on the
ship.

Bewellings.—To take the bevellings, provide a board as
broad as the scantling of the timber, and long enough to
take all the bevellings of the fore-side of the joint, and like-
wise abaft it, as Plate VIII. fig. 9. Begin with the fore-
side of cant-timber $w$, fig. 4: the heel-bevelling is the first
to be taken, which gives the direction to trim the heel of
Vol. XXXII.
the futtock the fore and aft-way, or faying to the dead-wood; therefore, the outside of the dead-wood being parallel to the middle line, apply the flock of a bevel in the direc-
tion of the joint of cant-timber $u$ in the half-breadth plan, and place the tongue well with the middle line, or at the half-thickness of the dead-wood, as at $E$, fig. 4, letting the tongue teach forward, which will be an under-
bevelling, and may be thence marked on the board. The 
bevelling of the heel, to trim it to the beveling or boarding-
line, is next taken. Thus, where the joint of cant-timber $u$
intersects the half-thickness of the dead-wood, in fig. 4, 
figure it up to cross the bearding-line in the sheer-plan; 
and, at that place, let the tongue of the bevel be placed to
the bearding-line, teaching forward, and move the flock
till it is perpendicular, as at $O$ in the sheer-plan, which
will give the above bevelling, which may be the next marked
on the board.

The outside bevelling of the heel is best obtained by
trimming the heel parallel to the inside, where it fays to the
side of the dead-wood, to the thickness of the beveling.
Then, to take the bevelling at the lower diagonal, fix one
leg of a pair of compasses in the line of the cant-timber $u$
in the body-plan, fig. 3, where the level line interfefts, and
extend the other leg to the ticked line, representing the fore
dge of the timber $u$. Sweeping it till you get the nearest
distance, and that will shew how much the bevelling is
within or without a square in the breadth of the bevelling-
board; if the former, the ticked line must be towards the
middle line of the joint, and of course the latter without it;
then do the same with the diagonal lines, and the bevellings
of each, so taken, may be marked on the board.

To take the bevellings at the main and top-breadths, and
at the port-fill line between them, apply the flock of the
bevel to the joint of the cant-timber $u$, in the half-breadth
plan, fig. 4, as at $G$, and place the tongue in the direction of
the respective half-breadth lines, as at top-breadth, ob-
ferving to let the tongue teach forward; these bevellings
are fet off on the board, as taken, and the whole kept at
a regular distance of about three-quarters of an inch on the
left-hand side of the board; and, to complete them, mark
their respective names and fore-side of cant $u$, as $a$, fig. 9.

The bevellings may now be taken for the aft-side of
cant $u$; but the operation is performed like the former, only
oberving that the square line at the heel comes within side
of the middle line of the half-breadth plan, and likewise
when the bevel is applied to take the bevellings at main-
breadth and above, the tongue of it must teach aft; these bevellings may then be marked on the fame side of the
board below the others, and the board for cant-timber $u$
will be complete, as $b$, Plate VII. fig. 9.

In like manner the bevellings may be taken for cant-
timber 35 at the aft-side, and marked on another board, as $a$, fig. 10; likewise for the fore-side, as $b$, fig. 10; and
so on for all the other cant-timbers, both on the fore and
after cant-bodies, and also for the fashion-pieces, and marked
on their respective boards.

Making the Moulds, and taking the Bevellings of the Harpins,
Plate VII. Laying-off, Plate A.

The ribbands to which the harpins are connected reach
along the ship fore and aft; but in the wake of the cant-
bodies, or at the fore and aft parts of the ship, they are
termed harpins, and are trimmed to the shape of the ship's
body by moulds and bevellings from the mould- loft. The
reader, in the foregoing fection, being made acquainted
with the nature of canting the ribbands, it may only be
necessary to obferve, that the ribbands at the port-fill line
would be placed better about eight inches below the upper
side of the lower fill, fo that they may be let out above the
ribband; and likewise the ribband at the top timber-line
should be fo placed, that one of the sheer-frakes should be
wrought before it is diifurbed. This is commonly a larger
ribband, like that at the floor-head, to keep the top-side
fair.

The harpin-moulds are made of fir-board, to the dia-
gonal or cant-ribband lines in the cant-bodies, figs. 4 and 6;
from the item or flemn-poll, to the adjoining square timber,
as at $O$, fig. 28, to be about seven inches broad; and as they
lie in their places on the floor, mark the flations of the
cant-timbers upon them thus. Where the cant-timbers
interfect the square ribbands, square them up to their cor-
responding cant-ribbands; then striking a ftraight line from
the interference of each cant-timber, at the middle line of
the half-breadth plan, to the corresponding flations left
squared up, will give the direction of the cant-timbers as
they fland with the harpin-mould, as at cant-timber $u$, fig. 4.
The method of taking the bevellings is at every square
timber, which must be likewise marked on the harpin-mould
before it is diifurbed. The flations of the square timbers
make no alterations, because the harpin is lowered to its
cant in a perpendicular direcion. Fix the flock of a bevel
in the direction of the diagonal, fay the upper one, or third
futtock-ribband $H$, in the body-plan, fig. 3, and the tongue
against the outside of the square timber $O$; then mark it
on a board (the board to be as broad as the harpin is deep
or fided), and fo on with the other square timbers before
$O$, marking each of them, and its respective timber, as
before; then fix the flock of the bevel upon the fame
harpin-line in the body-plan, fig. 3, and the tongue against
the flide of the item, and mark that likewise upon the board;
and by that bevelling the foremost end of the harpin must
be trimmed, to fay against the flim. The fore and aft
part of the harpin against the item is obtained by the foot,
or fwell on the fore-end of the harpin-mould, which is cut
off well with the half-thickness of the item, taken
diagonally, and parallel to the middle line, in the half-breadth
plan, fig. 4. Another bevelling is taken and applied over
the end, after it is cut off to the fore and aft-line, and be-
velled against the item, thus; fix the flock of a bevel upon
the horizontal line of the harpin upon the item, and teach
the tongue down the aft-side of the rabbet; then mark it
on the board, and the bevellings are completed. To com-
plete the harpin-mould, square down from the bevel-plan,
where the fore-side of the rabbet of the item crofes the
upper fide of the harpin, to the mould on the half-breadth
plan, and make a fmark, which being kept to the fore-
side of the rabbet of the item on the ship, is the guide to
fix the harpin to.

To Lay-off the Hawse-Pieces, Plate VIII. Laying-off B.

This plate represents the lines on the floor, as before
oberved, but made separate here for clearness. The hawf-
pieces, in figs. 1 and 2, are fuppofed to fland perpendicular
when in their places, and their fides to look fore and aft.
They may be called square timbers, only they look fore
and aft, instead of athwartships. This being the firft
method of laying-off the hawfe-pieces, will be called under-
flood.

Strike in ftraight lines as much aftarnder, and parallel to
the middle line in the half-breadth plan, fig. 3, as the
knight-head and hawfe-pieces are to be fided, marking them
$K$, $H$, i, 2, 3, and 4.

Where the edges of the foremost cant-timbers, marked
$E$ in the half-breadth plan, fig. 3, crofs the water-lines,
main-
SHIP-BUILDING.

main breadth, and level line, at their heads A, B, C, D, E, F, G, and likewise do the same with the breadth lines, which will give the sides of the tamarisk or the beam-ends. Thus, by putting a battens to all these points, you will have the ship's view of the tamarisk, as in fig. 1.

Where the lines be called knight-head and hawfe-pieces, in the half-breadth plan, F, fig. 6, is the water line, main breadth, and alike, but be likewise squared up to these corresponding lines in the sheersplan, fig. 1; a battens are laid in to the main trim, as in the line, and the edge raised or cleared up, with the line of the knight-head and hawfe-pieces, and so on in their proper places; and where the lines for the knight-head, and 1, 2, and 3 hawfe-pieces, mark the true edge of the short cant-timber, before cant y, in the half-breadth plan F, fig. 3, let them be squared up to the knee-edge, G, of the same timber, in the sheers-plan, fig. 1; likewise the heel of hawfe-piece 4, calling the fore edge of cant y, which gives the height of the knight-head and hawfe-pieces.

The midship side of the knight-head connecting well with the side of the stem, the rabbet being in the middle of it, makes the ends of the rabbet the fore-sides of the knight-head. But when the rabbet is not in the middle of the stem, it connects well with the side of the apron and dead-wood, consequently the boarding-line represents the fore-side.

Before the moulds for the knight-head and hawfe-pieces can be crossed, if made, the hanging of the hawps must be described in the sheers-plan, fig. 1. Thus, take their heights perpendicularly from the line, where they intersect the square timbers, and at the side of the stem, in the body-plan, fig. 2, and transfer them respectively to the sheers-plan, fig. 1; then, by putting a batten to those heights, we have the lines A, B, C, D, and E, or hanging of the hawps in the sheers-plan, fig. 1.

The heels of the knight-head and hawfe-pieces, where they intersect the cant-timber in the sheers-plan, fig. 1, are lined up perpendicularly, in which direction they must be cut off, to lay against the side of the cant-timbers F and G.

The moulds may now be made of inch-beards to the lines marked K, or knight-head, and 1, 2, 3, and 4 hawfe-pieces in the sheers-plan, fig. 1, from the heads to the heels, and the moulds at the heels to be cut off in the direction of the perpendicular line thereat, and while in their places mark a firm mark on the moulds, wherever the hawps intersect the moulding edge of the knight-head and hawfe-pieces, also the main-breadth and head, and as many between as it may be thought necessary to apply bevellings, as may be seen at the hawfe-piece 4. Thefirmarks at the hawps also show the height to keep the hawps to on the ship.

The beveling may be next taken, and marked on a board, which should be as broad as the hanging of the hawfe-piece, having a board to the knight-head, and each hawfe-piece, or all on one board, if not thought unhandy, as fig. 4. The first beveling taken from the knight-head or hawfe-pieces to the side of the cant-timber in the half-breadth plan, fig. 3, as G, for the knight-head, and H for the hawfe-piece 4, is the inner beveling. To cut off the heels to lay against the cant-timber at the hawfe-pieces, the bevel should be applied square from the heel, as cut off, to the perpendicular lines at the heels in the sheers-plan, fig. 1. But to get the beveling at the heel to counter-mould them, when the heel is cut off and trimmed to the above beveling, the foremost edge of can y must be laid off on the square, as i, and on the cant, as k, in the body-plan, fig. 2, as the junct of any of the cant-timbers were in Plate VII; and is much like the bevel edge of the cant. And, before y, the latter has a bevel edge to form the heel of the knight-head and hawfe-piece. The strike in the body-plan, fig. 2, on the line of the knight-head and hawfe-pieces parallel to the middle line, and where the moulding edge at the heel intersects the face-edge, on line and side view of the cant-timber, in the half-plan, fig. 1, level it out to intersect the line k.

To the three lines, i, j, k, of the height, fig. 1, of the heels of the knight-head and hawfe-pieces at the interline of the sheers-plan of the fore edge of the cant-timbers, as F and G, and let them up to the body-plan, in their respective edges, marking them up from there, then place the block of the heel against the perpendicular line, and the plumb line to the edge of the timber, as G, for the knight-head, and I, for hawfe-piece 4, which will give the exact beveling to be applied on the heel when cut off for the counter-moulding of the knight-head or hawfe-pieces.

The side of the knight-head and hawfe-piece being parallel to each other, they will have, in the sheers-plan, fig. 1, for the beveling, of each other, similar to parallel lines laid down for the cant-timbers; i.e., as much as the moulding edge of the hawfe-piece, 1, is within or abate the moulding edge of the knight-head, from the head to the heel, so much is the beveling of the knight-head within or under a square, in the distance between the knight-head and the hawfe-piece, in the half-breadth plan, fig. 3; therefore with compasses sweep the nearest distance at each haunch, &c. from the moulding edge to the outer edge of the knight-head, and each hawfe-piece, as may be seen at haunch-piece 4, in the sheers-plan, fig. 1, and set it within a square upon the board, as e, f, g, and so on for the others.

The bevelings of the knight-head and hawfe-pieces, if taken from the water-lines, main-breadth, &c. in the half-breadth plan, fig. 3, would be found to alter but little; yet they are not to true in their application as when taken on a square.

But was the counter-moulding beveling at the heel correctly set off, and another at the head for the knight-head, then the mould for hawfe-piece 4, being kept well at the head and heel, and to its proper height, must consequently counter-mould the knight-head exactly, if the knight-head could be gotten long enough to reach to the heel, or if the crack was fayed before it was moulded, and the knight-head properly fixed.

In the same manner, the mould that is made to the moulding edge of the hawfe-piece 2, would counter-mould the hawfe-piece 1, and so on of the rest.

There is no necessity to run the water-lines in the half-breadth plan, fig. 3, on purpose to lay off the hawfe-pieces, because they have a sufficient number of square haunches already run; for in the half-breadth plan, fig. 3, where the knight-head and hawfe-pieces cut the square haunches, let them be squared up to their corresponding haunches in the sheers-plan, fig. 1, which will give the exact form of the knight-head and hawfe-pieces; and, if the work is correct, will agree with the former by the water-lines.

To Lay off the Haufe-Pieces, where the Sides are required to look fore and aft, and likewise to be field off at the Heels.

Every timber in the ship which is fided straight, must appear, either in plan or elevation, as a straight line; therefore it is necessary, before any operation can be performed, to have a clear idea of the disposition of the timber when in its place. The hawfe-pieces are intended to look fore and aft, that is, at any particular height the sides of...
SHIP-BUILDING.

them are to be parallel to the middle line; but as the heels of them are to be fixed less than the heads, they will consequently be nearer the middle line; therefore they will not appear in a straight line in the half-breadth plan, fig. 7, as they did in fig. 3, and cannot be viewed in a straight line, unless by supposing them really in their places in the body-plan, fig. 6.

Proceed to dispose of the knight-head and hawse-pieces as in the body-plan, fig. 6, where they will appear straight lines. The moulding edges are the thin lines, except the outside of hawse-piece 4, which is intended to be laid off, in order to get the bevellings of No. 4 hawse-piece.

The thwartship view of the foremost edge of cant-timber y, and the cant-filling before it in the half-breadth plan, fig. 7, which the knight-head and hawse-pieces end against, must be squared up and represented in the sheer-plan, fig. 5, as in the proceeding operation.

The fore and aft view of the foremost edge of cant-timber y, and the cant-filling before it, both on the cant and main, must be laid off as b, i, in the body-plan, fig. 6, as before explained.

Now proceed to lay off the hawse-pieces, or to draw the form in which they will appear in the half-breadth plan, fig. 7. The knight-head is already laid off, because it is the same as the half-thicknesses of the stem in the half-breadth plan, fig. 7. Therefore take the distance square from the middle line to the heels of the hawse-pieces, where they intersect the fore and aft view of the cant-timbers i and G in the body-plan, fig. 6, and set them off square from the middle line in the half-breadth plan, fig. 7, on the edges of the cant-timbers F and E; which gives the heels of the hawse-pieces in fig. 7. Take the distance square from the middle line in the body-plan, fig. 6, to where the hawse-pieces cross the harpins, A, B, C, D, and E; and set them off square from the middle line, on their corresponding square harpins in the half-breadth plan, fig. 7. Likewise, in the same manner take the half-breadths in the body-plan, fig. 6, for the main breadth and the harpin at the head; and set them off in the same manner as before in the half-breadth plan, fig. 7. Then pin a batten to those spots, and mark the curves in the half-breadth plan, fig. 7, which gives the form they will appear in, were you right over them, and looking down upon them; occasioned by the different curves of the body when cut by these sections.

The next operation will be to draw the form of the body, supposing it to be cut by the different sections of the hawse-pieces, to which form the moulds are to be made to trace the hawse-pieces. Proceed in the following manner:

Where the hawse-pieces 1, 2, 3, and 4, in the half-breadth plan, fig. 7, cross the square harpins c, b, a, f, and g; and likewise the main-breadth B, and harpin above A; let them be squared up to their corresponding harpins in the sheer-plan, fig. 5, where they end against the edge of the cant-timbers F and E in the half-breadth plan, fig. 7; they may be likewise squared up to intersect the thwartship view F and G of those cant-timbers in the sheer-plan, fig. 5, to give the heels of the hawse-pieces. But this is not so true, as to take the heights of the heels where they intersect the fore and aft view of the cant-timbers i and G, in the body-plan, fig. 6, and transfer them to the sheer-plan, fig. 5, on the thwartship view of the said timbers F and G; this is the proper height of the heels; yet if both ways agree, it shews the truth of the work. Then pin a batten to those spots squared up, and mark the curves 1, 2, 3, and 4, which gives the moulding edges of the hawse-pieces, and shews them as they appear when in their places. This method is usually practised when required to be laid off in this manner, and will suffice for practice; but by explaining the situation of those at present laid off, it will sufficiently shew they are not exact, therefore we shall point out a method the most accurate.

Consider the hawse-pieces as they are now laid off, and as they appear in the sheer-plan, fig. 5; you there see the exact form of them, supposing them to be in their places, and that you are looking level at them. You may therefore observe the exact form of the harpins, when you are looking level at them, where they appear at their proper heights: consequently, then, you have the exact length and form of the hawse-pieces only as they appear in a level view. And because they do not stand perpendicular, you cannot have the exact length nor form properly to mould them.

In order to draw the proper method that may be depended on, lay-off the moulding edge of hawse-piece 4 or the outside of No. 3, which will make the most difference, because it stands most from a perpendicular.

There must be supposing one given point to work from; therefore, it being the most proper, let it be the heel. Strike the level line from the heel in the body-plan, fig. 6, to the heel in the sheer-plan, fig. 5, as f. If the hawse-piece 4 was not laid off in the sheer-plan, fig. 5, the moulding edge must be gotten up, as before, from the half-breadth plan, fig. 7. Therefore, as it is, strike lines upwards, perpendicular from the separate harpins in the sheer-plan, fig. 5, where the moulding edge of hawse-piece 4 intersects them. Then take the distance from the heel of No. 4 hawse-piece, in the body-plan, fig. 6, to each harpin, main-breadth, &c. taken in the direction of the moulding edge of hawse-piece 4; and set them up perpendicular from the heel of hawse-piece 4, in the sheer-plan, fig. 5, on the lines before squared up, at their corresponding harpins: then pinning a batten to those spots, mark the curve in fig. 5, which will give the exact moulding of the hawse-piece, and the heights for the stations of the harpins to be crossed on the hawse-piece moulds.

Though the exact and proper method to lay-off the hawse-pieces is described by laying off No. 4, the explanation must suffice for this, being too minute to be drawn on the plate. Yet the first method is not entirely to be condemned, as they are seen in the sheer-plan, fig. 5, because it makes no little difference in the moulding, that the error is not to be regarded in the practice. The greatest difference it makes is in the length, which, in No. 4, does not make it two inches longer. But the certainty of the latter method being the most correct, must be proved by working at extremes; that is, supposing the head of hawse-piece 4 to stand where it is in the body-plan, fig. 6, and the heel to be fixed at the middle line, then, if laid off by both methods, the difference would be readily seen, which method is best to be depended on.

The moulds for the knight-head and hawse-pieces are made to the lines in the sheer-plan, fig. 5, as before directed.

The bevellings, supposing the hawse-pieces to be properly laid off in the sheer-plan, fig. 5, are taken in the same manner as was shewn in fig. 1; for though they do not appear in the same manner in the half-breadth plan, fig. 7, yet in the sheer-plan, fig. 5, (their sides looking fore and aft,) you there see the form of them square from the plans of their respective sides: therefore the distance, as they appear from each other in the sheer-plan, fig. 5, at each harpin, is the proper bevelling of them, agreeable to their distance from each other taken at their corresponding harpins in the body-plan, fig. 6.

Where the heels of the hawse-pieces lie on the thwartship view of the cant-timbers in the sheer-plan, fig. 5, line them
them up perpendicular, which gives the disposition of the heels of the hawfe-pieces to say against the fore-side of each cant timber.

The bevelling of the heels of the hawfe-pieces must likewise be done the same as in fig. 3; for though in the half-breadth plan, fig. 7, the form of the moulding edges of the hawfe-pieces appear in this view, yet the sides of them, at level heights, are exactly fore and aft; therefore the bevelling to trim the heels to say against the side of the cant-timber, is the same for all the hawfe-pieces, and must be taken with the flock of the bevel looking fore and aft, or parallel to the middle line, as is expressed by the bevel G, which is applied in the half-breadth plan, fig. 7, to take the bevelling of the No. 4 hawfe-piece.

To take the bevelling of the heel, to be applied when the heel is trimmed by the half bevelling, in order to counter-mould the hawfe-pieces, transfer the heels of the hawfe-pieces from the sheer-plan, fig. 5, to the cant-timber in the body-plan, fig. 6, as for taking the bevelling of the hawfe-piece 4, and strike up a perpendicular line, to which apply the flock of the bevel, and the tongue to the fore cant-edge, as at k, fig. 6. This gives the bevelling of the heel, in order to counter-mould the hawfe-pieces.

As the most accurate method of moulding the hawfe-pieces has been treated of, it is requisite it should be so respecting the disposition of the heels, and the bevelling of the heels. As the bevelling of the heel is shown for No. 4 hawfe-piece, the following will explain the difference that may be expected, if the hawfe-pieces were required to be laid off on extremes, or if a section of the body were required in such direction.

Set up any particular height on the hawfe-piece 4, in the body-plan, fig. 6, and suppose it to be the height where the harpin C intersects it; then take that height from the heel of the hawfe-piece No. 4, in the direction of the line of the hawfe-piece, and let it up perpendicular from the heel of No. 4 hawfe-piece, in the sheer-plan, fig. 5. Take the distance square from the middle line at the proposed height in the body-plan, fig. 6, and set it off square from the middle line in the half-breadth plan, fig. 7, on the cant edge E; there make a spot, and carry it square up to the ticked level line in the sheer-plan, fig. 5, and strike the line from thence to the heel of No. 4 hawfe-piece, which gives the exact form of the heel to say against the fore-side of cant-timber 3.

From the spot before mentioned in the half-breadth plan, fig. 7, take the distance to the middle line in the direction of the cant-timber, as E, and set it off from the middle line in the body-plan, fig. 6, on the ticked level line, and draw it down to the heel of the timber; which is the proper line to which the flock of the heel should be applied to take the bevelling of the heel, in order to counter-mould the hawfe-pieces. The explanation of the above must suffice, as it would not only interfere with the method laid off, but also be too minute to be described on the plate.

Where the hawfe-pieces in the half-breadth plan, fig. 7, cross the square harpins e, d, c, f, and g, square them up to their corresponding cant-harpins, as at h, which gives the proper stations of the hawfe-pieces on the cant-harpins; but the direction of the hawfe-pieces to be marked on the harpin-moulds will be fore and aft, as well on the cant-harpins as on those which lie level: such are the harpins at the port-fill and head; for where the hawfe-pieces cross those harpins in the half-breadth plan, fig. 7, is the proper station of the hawfe-pieces on the aforesaid harpins; or otherwise it is the proper distance from the middle line which the hawfe-pieces will be on each harpin, when the harpins are in their places; because these harpins are shown in the half-breadth plan, fig. 7, as they really appear when they are in their places.

The method of laying off and disposing of the hawfe-pieces when casted, is the most complete of any, as it is the bell for the strength of the ship, and will likewise affect the conversion of the timber: for by casting them, they will not only be diminished at the heels, whereby a hawfe-piece of timber will make them, as in the foregoing method, but the bevellings will be lost acute; and as the casting and diminishing of them at the heels are performed by one operation, they consequently must appear as straight lines when viewed in the half-breadth plan; and, as before observed, that all timbers, when casted nearer to a square with the body, add more to the security of the plan, and the timbers are not wounded so much by that security. The casting of the hawfe-pieces is also some advantage to the hawfe-holes; for although the hawfe-holes are generally cut nearly parallel to the middle line, yet casting of them leaves wood at the outside of the hawfe-hole, which is the thickest from the middle line, as it is the wearing side of the hawfe-hole.

Dispose of the hawfe-pieces in the half-breadth plans as in fig. 11, on which plan they will be straight lines, similar to the cant-timbers. Strike in likewise the fore-side of the cant-timbers marked E, F, as before, against which the heels of the hawfe-pieces are to be cut off.

Lay off the thwartship view of the hawfe-pieces and fore-side of the above cant-timbers E, F, in the sheer-plan, fig. 9, in the following manner. Where the fore-side of the cant-timbers E and F in the half-breadth plan, fig. 11, crosses the half-thickness of the dead-wood C, square them up to the hearding-line in the sheer-plan, fig. 9, and in the same manner proceed at every water-line, 1, 2, 3, 4, 5, and 6; likewise with the main-breadth and harpin at the head: then pin a batten to those spots, and mark the curves, as F, G, which gives the thwartship view of the fore-side of the cant-timbers the hawfe-pieces heel against.

In the same manner proceed with the hawfe-pieces: where, in the half-breadth plan, fig. 11, they interface the water-lines, main-breadth, and harpin above, square them up to their corresponding lines in the sheer-plan, fig. 9; and where they intersect the fore-edges of cant-timbers E and F in the half-breadth plan, fig. 11, square them up to interface the thwartship view of the said cant-timbers, as E and F in the sheer-plan, fig. 9. This gives the exact height of the heels of the hawfe-pieces, where they step against the cant-timber, when they are in their places. Then by pinning batten to all the spots squared up, mark the curves 1, 2, 3, and 4, which will give the exact thwartship view of the hawfe-pieces, supposing they were in their places; but as the sides do not look fore and aft, these are not the proper lines to make the moulds to; but will be serviceable hereafter, to get the proper height of the harpins to be croffed upon the hawfe-piece moulds. The moulding edge of the knight-head is the aft-side of the rabbot of the hem.

Where the knight-head and hawfe-pieces interface the fore-side of the cant-timber, marked E in the half-breadth plan, fig. 11, fit a batten in the direction of the line of the knight-head, or hawfe-pieces; mark thence the points where they are intersected by the water-lines; and set them off from the middle line in the body-plan, fig. 10, on their corresponding water-lines. Then take the heights, where the heels of the knight-head and hawfe-pieces intersect the thwartship view of cant-timber F in the sheer-plan, fig. 9, and transfer them to the middle line in the body-plan, fig. 10.

Having
Having the lower height of breadth and harpin at the beak-head laid off in the sheer-plan, fig. 9, take the heights where they intersect the thwartship view of the knight-head and hawfe-pieces, and transfer them to the body-plan, fig. 10. Then take the distances in the half-breadth plan, fig. 11, from the intersection of the knight-head and hawfe-pieces, with the cant-timber marked E, to the main-breadth and harpin at the beak-head, taken in the direction of the line, and set them off from the middle line in the body-plan, fig. 10, on their corresponding heights, marking spots. Then by pinning a batten to those spots, mark the curves K, H, 1, 2, 3, and 4, which are the proper moulding edges of the knight-head and hawfe-pieces, and consequently those to which the moulds are to be made. Now to give the direction for cutting off the heels to lay against the side of the cant-timber, the mould of No. 4 hawfe-piece must be cut off well with the middle line in the body-plan, fig. 10; but as the knight-head and the other hawfe-pieces cut off against the timber, before that which No. 4 heels against, take the height in the sheer-plan, fig. 9, where the heels of the knight-head, and 1, 2, 3 hawfe-pieces intersect the thwartship view of the foremost cant-timber at G, and transfer them to the body-plan, fig. 10; and where they intersect their respective hawfe-pieces, there strike up a perpendicular line, as at No. 3 hawfe-piece, which will also give the direction to cut off their heels against the said cant-timber.

But now since they are laid off by the water-lines, the proper flations of the hawfe-pieces below the main-breadth cannot be marked on the moulds. Therefore the level thwartship view of the hawfe-pieces must be laid-off in the sheer-plan, fig. 9, as before, which is the exact height of them when they are in their places; consequently, then, the points where they intersect the thwartship view of the knight-head and hawfe-pieces, shew the exact height to be transferred from the sheer-plan, fig. 9, to their corresponding lines in the body-plan, fig. 10, which gives the exact flations of the hawfe-pieces to be crossed on the knight-head and hawfe-piece moulds.

The bevellings are to be taken thus: Strike a line in the half-breadth plan, fig. 11, to the siding of the knight-head and hawfe-pieces, as was done for bevelling the cant-timbers, as the ticked line at No. 4 hawfe-piece, it being the clearest to be understood. Then square a line at the heel, where the moulding edge of No. 4 hawfe-piece crosses the cant-timber marked E. Then take the distance from the squared line in the direction of the siding or ticked line to the separate water-lines, where they intersect the ticked line, and fet them off from the middle line in the body-plan, fig. 10, on their corresponding water-lines. Where the ticked line in the half-breadth plan, fig. 11, intersects the cant-line E, square it up to intersect the thwartship view F, in the sheer-plan, fig. 9, as marked with a star, and from whence transfer it to the body-plan, fig. 10, as far as the middle line. Then take the distance from the forward line at the heel in the half-breadth plan, fig. 11, to the cant-line E, in the direction of the ticked line, and let them off from the middle line in the body-plan, fig. 10, at the height last mentioned. Continue the ticked line or sidding of the hawfe-piece to intersect the water-lines 1, 2, and 3, in the half-breadth plan, fig. 11; then take the distance from the squared line at the heel to those water-lines in the direction of the siding or ticked line, and set them off from the middle line in the body-plan, fig. 10, on their corresponding water-lines to the left hand, which serves to prove the spot at the heel by continuing the bevelling edge to the lowest water-line. Where the ticked line or sidding of the hawfe-piece 4, in the half-breadth plan, fig. 11, intersects the main half-breadth and beak-head harpin, square them up to their corresponding lines in the sheer-plan, fig. 9, and transfer them to the body-plan, fig. 10, striking level lines. Then take the distance from the squared line at the heel in the half-breadth plan, fig. 11, to the main half-breadth and beak-head harpin in the direction of the siding or ticked line, and let them off from the middle line in the body-plan, fig. 10, on their corresponding heights, which gives the spots to which a batten must be pinned, and the curve marked out thereby will be the bevelling edge of the hawfe-piece 4; and at whatever distance the bevelling edge in the body-plan, fig. 10, is from the moulding edge of the hawfe-piece 4, so much is the hawfe-piece under from a square in the distance from the siding or ticked line, to the joint of the hawfe-piece in the half-breadth plan, fig. 11.

The bevel G, as shewn in the half-breadth plan, fig. 11, gives the direction to cut off the heel. When the heel is cut off, in order to find the bevelling of the heel to counter-mould the hawfe-pieces, the fore-sides of the cant-timbers, as E and F, in the half-breadth plan, fig. 11, must be laid off in the body-plan, fig. 10, which may be done by the water-lines. Then transfer the height of the heel of the hawfe-piece No. 4, from the sheer-plan, fig. 9, where it cuts the thwartship view of the cant-timber marked F, to its corresponding cant-timber in the body-plan, fig. 10, and strike a perpendicular line to which apply the flock of a bevel, and the tongue, to the cant-timbers, as at M; the fame likewise for hawfe-piece No. 1, as at L, and so on for the others. This gives the exact bevelling to be applied when the heel is cut off, in order to counter-mould the hawfe-piece, if it should be so required. The bevellings of No. 4 hawfe-piece are all taken at their heights, as may be seen in the body-plan, fig. 10, and marked on the bevelling-board, as at a in fig. 12; the laid heights to be all crossed upon the hawfe-piece mould.

To Lay-off the Hawfe-pieces by the Square Harpins when canted.

The square and cant-harpins being of necessity laid off in the half-breadth plan, fig. 11, it is necessary to explain the method of laying off the cant-hawfe-pieces by the square harpins, which are marked c, d, e, f, g, in the half-breadth plan, fig. 11. The point where the knight-head and hawfe-pieces intersect the fore-side of the cant-timber marked E in the half-breadth plan, fig. 11, is supposed to be in the middle line in the body-plan, fig. 10, which middle line will serve for laying off the knight-head and hawfe-pieces, as it did for the foregoing operation by the water-lines. By being laid off in the fame body-plan, fig. 10, it will be a convincing proof that both methods may be depended upon, because they will be found to agree, as near as can be expected on so small a scale as the plate.

To explain the laying off the knight-head and all the hawfe-pieces would be too tedious; (though they are all laid off in the middle line) for by laying off and bevelling the hawfe-piece No. 4, the ticked lines (which are transferred from the sheer-plan, fig. 9, to the body-plan, fig. 10, in order to give the proper flations of the hawfe-pieces on the hawfe-piece moulds, when laid off by the water-lines) will now be proved to agree with the operation by the hawfe-pieces.

Now the knight-head and hawfe-pieces are intended to be laid off together by the harpin-lines. There is no necessity to lay-off the thwartship view of them in the sheer-plan, fig. 9; but the thwartship view of the fore-side of the cant-timber they heel against will be wanted, to find the height of the heels. Having the level height of the hawfe-pieces laid off before in the sheer-plan, fig. 9, where the fore-sides of the cant-timbers, marked E, F, intersect the square.
square harpins, $d, e, f, g$, in the half-breadth plan, fig. 11, square them up to the correspondent harpins in the sheer-plan, fig. 9. This gives the thwarts view of the centre-line, and if the work be true, it will lie per the lines by the water-lines. The exact height of the body should be found, in order to prove the rest of the work, and as the lines of the half-breadth plan, fig. 11, continued above the foot of the cant-timbers, $E, F, G$, to intersect the figure in the figure in the sheer-plan, then by harpips in the body-plan, fig. 12, and the middle line (in this manner, when the bottom is continued in the snake beyond the middle line of the-harpins, it would intersect the middle line at the proper heights). This gives the level of the half-breadth plan.

To get the half-breadth plan, No. 4, as laid out by the water-lines, let it be laid off by the level or square harpins: thus, when the middle line intersects the fore-edge of the cant-timbers, marked $E$, in the body-plan, fig. 12, square it up to intersect the thwart view $F$, in the sheer-plan, fig. 9: and so to the height to the middle line in the body-plan, fig. 11. This gives the level of the half-breadth piece No. 4, exactly similar to the method by the water-lines.

Observe in the half-breadth plan, fig. 11, where the half-breadth piece No. 4 crosses the square harpins, and from thence take the nearest distance to the middle line; and let them off on their respective harpins square from the middle line in the body-plan, fig. 12, there flanking a level line, in the same manner as was done for the cant-timbers. Then take the distances in the half-breadth plan, fig. 12, from the intersection of the harpins piece No. 4, with the cant-edges marked $E$, to where it intersects each of the square harpins, in the direction of the line for the laid half-breadth piece; and let them off square from the middle line in the body-plan, fig. 12, on their respective level lines before mentioned; observing to set off the distance to the left hand of those which were taken about the cant-line $E$. This gives the spots for the moulding edges of the half-breadth piece No. 4; and is likewise the exact station of the harpins to be cored on the moulings.

Proceed in the same manner to find the spots for the moulding edges of the other half-pieces; as those for the main-breadth and beak-head harpins are found in the very same manner as by the water-lines.

The beveling-edge is laid off in the same way as the moulding edge; only the distance taken in the direction of the ticked or budding-line is taken from the squared line at the heel, instead of its intersection at the cant-edge $E$, in the half-breadth plan, fig. 11. The plate will shew the difference of laying-off, between the water-lines and harpins, is in the performance only.

To find the proper stations of the knight-head and haufw-sizes on the harpin-moulds, we need only square up the intersections of them with the square harpins to the cant-harpins, in the same manner as was done for the cant-timbers. And the points where the knight-head and haufw-pieces, in the half-breadth-plan, fig. 11, cross the harpins at the port-fills and beak-head, shew the proper stations of them, as they appear when the harpins are in their places, they lying level in a thwart or direction of the direction of the ship, fore and aft-way. The main breadth is only used as a beveling spot; for was it required to place a harpin to that height, its great sheer would require a very different operation to form the line to make the mould to.

To Lay-off the Transoms, Plate 1X. Lay-off C.

The transoms and fashion-pieces compose the stern-frame. The upper ones are the wing, filling, and deck-transoms; and there may be as many under the deck-transoms as the form of the body will admit, or is readily possible. The upper part is called the water transom, which is the face of the frame.

This may be admitted the easiest and best method of laying off the after part of the ship given in the large, because every transom composed of the body, running through the bottom, they may be considered finished in the breadth; for when the planks are wrought on the bottom, and the water transoms, beak, and foops and deck are laid off, it may be allowed to be a matter of the foot or bow in with the breadth-books, because the bow part of the ship has no other allowance to keep the bowas together.

As there are several operations required to lay-off the stern-frame, Plate IX. Lay-off C., it is made separate plate for that purpose; though it represents the lines on the floor, before observed. The fashion-pieces being struck in the half-breadth plan on the floor, and the water-line runs as in Plate I, square up the intersection of the fashion-pieces with the bearding-line, water-lines, the end of the wing-tranoms, and main breadth line in the half-breadth plan, to their corresponding bearding-line, water-line, wing-tranom, and height of breadth line in the first-plan; thus a battened piece to those spots will represent the thwartview of the after-side of the fashion-pieces, which are marked $S, F, P$, Plate IX. fig. 1.

Where the half-breadth pieces next at the foremost-moulded lines in the half-breadth plan, take the distances square from those to the middle line; and let them off square from the middle line, on their corresponding lines in the body-plan. A battened piece to those spots will give the fore and aft view of the fashion-pieces, generally called the square fashion-pieces, which are marked $S, F, P$, Plate IX. fig. 2.

Transfer from the sheer-plan of Plate I, the heights of all the transoms to the sheer-plan on the floor; likewise the flying or depth of each tranom, as W, E, D; 1, 2, 3, 4, 5, and 6, Plate IX. fig. 1.

In the body-plan, fig. 2, describe the upper side of the wing-tranom $a$, by a segment of an arc to its round-up, till it intersects the aft-side of the foremost square fashion-piece $S$; and below that a parallel curve $b$, where the ends of the planks of the buttocock are intended to be cut off, which is called the margin-line. Square down from the sheer-plan the after-side of the wing-tranom to the middle line of the half-breadth plan; and from these draw the after-side of the wing-tranom at its upper side, by a segment of an arc to its round-up, which shews the line to which the mould is to be made. Take the height of the margin-line $d$, at the middle line in the body-plan, fig. 2, and transfer it to the fore-part of the rabat of the stern-post, in the sheer-plan, fig. 1; and from thence square it down to the middle line in the half-breadth plan, marking a parallel arc between the after-side of the wing-tranom, which is likewise called the margin-line. Continue to draw the level view of the moulding edges of all the transoms in the body-plan, fig. 2, in the following manner; take the wing-tranom and the filling under it lying level, then form the transom and the filling under its round-up, as above. This is the proper curve to which the round-up mould is made for fitting those transoms. The next is the deck-tranom, which is generally laid off to the round-up of the gudgeon beam; the other transoms below the deck lying straight and level, are represented by level lines ly.

Transfer from Plate I, the buttocock-lines 1, 2, 3, 4, 5,
SHIP-BUILDING.

and let them be struck on the floor in the body-plan and half-breadth plan. Then proceed to run the buttock-lines in the sheer-plan, fig. 1, as directed in the construction of the sheer-draught, Plate I. The buttock-lines, the square timbers, and likewise the water and ribband-lines, should be made to agree to the greatest exactness.

The moulding edges of the other transoms may now be laid off from the buttock-lines in the sheer-plan, fig. 1; but if they are laid off in the half-breadth plan, then only half or one side can be represented. The best method, therefore, will be to lay them off in some convenient place on the floor by themselves, whereby both sides may be represented, and there will not be then such confusion in the lines. This, for distinction, may be termed plan of the transoms, as Plate IX. fig. 3.

The moulding edge of the wing-tranfom is already described to which the mould is to be made; the filling-tranfom is next, which lies between the wing and deck; and as it lies horizontally, the description of it will suffice for all the other transoms that come under the deck, which also lie horizontally.

As there is no more trouble in laying-off a tranfom which is fided straight, and lies level, than there is in laying-off a water-line, strike on each side of the middle line M, in the plan of the transoms, Plate IX. fig. 3, the half-thickness of the dead-wood or boarding-line, and taking it from the body-plan, fig. 2, (and as low down as the deck-tranfom the inner point is fided the fame); likewise the buttock-lines. Take from the half-breadth plan the square timbers 32, 33, 34, 35, 36, and the proof timbers 1 and 2, and strike them in the plan of the transoms, fig. 3, at right angles with the middle line; also strike in the cast of the fashions-pieces F, M, A. Then strike a perpendicular line, P, in the sheer-plan, fig. 1, at the interfeftion of the upper edge of the wing-tranfom, at the fore-part of the rabbit; likewise another at right angles with the middle line, at the aft-fide of the wing-tranfom, as P, in the plan of the tranfoms, fig. 3.

Now from the perpendicular P, above mentioned, called perpendicular of the tranfoms, take the distance in the shear-plan, fig. 1, to where the upper fide of the filling-tranfom, P, interfefts the fore-fide of the rabbit of the poft or boarding-line B, and let it off from the fame line P P, in the plan of the tranfoms, fig. 3, at the middle line, squaring a line across to each boarding-line; which line will be the after-part of the filling-tranfom at the middle line. Observe where the boarding-line, C, of the poft, in the sheer-plan, fig. 1, comes before the fore-fide of the rabbit, to take the aforefaid distance to the boarding-line of the poft, as that terminates the after-part of all the tranfoms; then take the distances in the sheer-plan, fig. 1, from the perpendicular line P, to where the line representing the upper fide of the filling-tranfom interfefts the different buttock-lines 1, 2, 3, 4, and 5, and let them off from the fame line P P, in the plan of the tranfoms, fig. 3, on their corresponding buttock-lines on each fide of the middle line. Then take the distances in the body-plan, fig. 2, from the middle line, to where the upper fide of the filling-tranfom, C, interfefts the square timbers, and let them off on both fides of the middle line on their corresponding timbers, in the plan of the tranfoms, fig. 3; then by pinning a batten through the spots on the buttock-lines and square timbers, to its after-part at the fide of the boarding C, the moulding edge or upper fide of the filling-tranfom will be defcribed on one fide the middle line; the mould may then be made to that fide, and canted over, and the opposite fide marked thereby, being sure thus to have both fides alike. This filling-tranfom having been laid off horizontally, of course, when moulding the filling-tranfom, the mould must lie in an horizontal position; but having no little room between the wing and deck-tranfoms, it becomes neceffary to give the filling-tranfom a round-up between both. Those who would be more correct in laying-off tranfoms, that have a round upwards, may see the subjedt farther explained in the following methods.

To lay-off the deck-tranfom, strike a ftraight line in the sheer-plan, fig. 1, at the under-fide of the deck, at the middle line, to take that part of the hang of the deck only, which is terminated between the rabbeft of the fem-poft and the fashions-piece, as H, fig. 1. Then take the round of the deck R, at every buttock-line, as under the body-plan, fig. 2, and let them off below and fquare to the ftraight line H, in the sheer-plan, fig. 1, marking parallel lines thereto, to interfeft their corresponding buttock-lines, which gives the moulding edge of the tranfom. Proceed in the fame manner with the lower edge, by striking a line for the lower fide of the tranfom at the middle line parallel to the former; and let the round down, as before, upon any buttock-line.

The upper and lower fides of the deck-tranfom being obtained on the buttock-lines, in the sheer-plan, fig. 1, transfer their heights from the sheer-plan, fig. 1, to the body-plan, fig. 2, repectively; then by pinning a batten to those heights, the upper and lower fides of the deck-tranfom, d d, may be represented in the body-plan, fig. 2.

The lines above mentioned, in the sheer-plan, fig. 1, parallel to the fheer of the deck, at the interfeftion of the buttock lines and fashions-piece, should be continued aft to the perpendicular P; then take the distances from that line, in the direction of the parallel lines, to the buttock-lines and fashions-piece, and let them off fquare from the fide line P P, in the plan of the tranfoms, fig. 3, on their corresponding buttock-lines and fashions-piece. Next take the half-breadth from the body-plan, fig. 2, at the interfeftion of the deck, at the fide, with the square timbers, and let them off on their corresponding timbers from the middle line, in the plan of the tranfoms, fig. 3; then by pinning a batten to thofe spots, this forms the moulding edge of the deck-tranfom D D.

The tranfoms under the deck, all lying horizontally, may be laid off by taking the distances of the buttock-lines and boarding-line from the perpendicular P, in the sheer-plan, fig. 1, on the upper edge of each tranfom, and putting them off on their corresponding buttock-lines from the fame perpendicular P, in the plan of the tranfoms, fig. 3, and also at the timbers from the middle line in the body-plan, fig. 2; and let them off from the middle line on their corresponding timbers in the plan of the tranfoms, fig. 3; a batten pinned to thofe spots will represent the moulding edges of all the tranfoms.

To prove the interfeftion of the tranfoms with the fide of the fashions-piece, which is the end of each tranfom, as already laid off in the plan of the tranfoms, fig. 3. Thus, where the upper fide of the wing-tranfom in the body-plan, fig. 2, interfefts the foremoft square fashions-piece S, level it out to interfeft the cant-fashions-piece e. Then take the nearest diance from the cant-fashions-piece at that place to the middle line, and let it off from the middle line in the plan of the tranfoms, fig. 3, in the direction of the line of the foremoft fashions-piece F. In the fame manner prove the filling and deck-tranfoms. Take the distances from the middle cant-fashions-piece to the middle line along the upper fide of Nos. 1, 2, and 3 tranfoms in the body-plan, fig. 2, and let them off on the middle cant-fashions-piece M, from the middle line in the plan of the tranfoms, fig. 3, as before. Take likewise
the distances from the aftermost cant-fashion-piece to the middle line for the transoms 4, 5, and 6, and let them be b, as before, on the line for the aftermost cant-fashion-piece A, in the plan of the transoms, fig. 3, to which spots the transoms in fig. 3, must agree.

Cut out the ends of the wing, filling, and deck-transoms, at the after or a side of the first half-fashion-piece P, and transoms Nos. 1, 2, 3, 5, under the deck at the after-side of the middle fashion-piece M, and Nos. 4, 5, 6, at the after-side of the after-fashion-piece A, as is clearly shown in the plan of the transoms, fig. 3, where the middle fashion-piece is represented as kept at the under side of the deck-transom, and the after-fashion-piece at the under side of the transom No. 3.

To make the Moulds and build the Transoms.

The moulds are made of fir battens laid to the line already laid off in the plan of the transoms, fig. 3, for their after-sides; and another to their fore-side, at their moulding or breadth at the upper side; which are confined together by battens at each buttoc-line, and one at each end to the direction of the fashion-piece, allowing what they are intended to be let into the fashion-pieces; and a broad piece in the middle, to the fire of its seating c c, with the middle line correctly marked thereon.

The bevelling of the transoms are frequently taken from the buttoc-lines in the fier-plan, fig. 1, in the following manner. Apply the flock of the bevel E to the upper side of the transoms, in the fier-plan, fig. 1, and the tongue to the buttoc-line; but let the tongue be off at the upper and lower sides of the transom, as at the filling-transom in the fier-plan, fig. 1, which gives the exact bevelling of the transoms at their corresponding buttoc-lines.

The bevellings for the wing-transom are taken from the margin-line to the under side of the wing-transom, as above. The under side of the wing-transom is transferred from the body-plan, fig. 2, to the fier-plan, fig. 1, by the buttoc-lines.

The bevells for the deck-transom may be taken by applying the flock of the bevel parallel to the hang of the deck, at the middle line, and the tongue to each buttoc-line; keeping the tongue well at the upper and lower sides of the transom, as before observed, and so must be applied on the transom, by placing the bevel at each corresponding buttoc-line, and keeping the flock out of winding with the upper side of the transom at the middle line.

The transoms under the deck may be bevelled by the buttoc-lines in the fier-plan, fig. 1, and the bevellers may be taken very exact; but it requires to be very particular in applying the bevel on the transom; to do which, the flock of the bevel must be kept in the direction of the buttoc-lines, at the upper side of the transom, and the tongue teaching to the buttoc-line below, which ought to be marked at the lower side of the transom, and not treading to the bevel's casting promiscuously, for then the bevel may not be exactly square.

When this trouble is taken to bevel the tranoms, then they may, when trimmed, be depended upon.

This is a method not to be recommended to those who would be particularly exact, because there can be no more bevellings on the transoms than the number of buttoc-lines which intersect the transoms; as for instance, there are only two buttoc-lines which cross the lower-transom in fig. 3, and one of them is close to the end, which is not sufficient to get the exact form of the lower side of the transom. Therefore, the best way to find the bevellings of these transoms is to lay-off their lower sides, which is very easy to be

the distances from the aftermost cant-fashion-piece to the middle line for the transoms 4, 5, and 6, and let them be b, as before, on the line for the aftermost cant-fashion-piece A, in the plan of the transoms, fig. 3, to which spots the transoms in fig. 3, must agree.

Cut out the ends of the wing, filling, and deck-transoms, at the after or a side of the first half-fashion-piece P, and transoms Nos. 1, 2, 3, 5, under the deck at the after-side of the middle fashion-piece M, and Nos. 4, 5, 6, at the after-side of the after-fashion-piece A, as is clearly shown in the plan of the transoms, fig. 3, where the middle fashion-piece is represented as kept at the under side of the deck-transom, and the after-fashion-piece at the under side of the transom No. 3.

To make the Moulds and build the Transoms.

The moulds are made of fir battens laid to the line already laid off in the plan of the transoms, fig. 3, for their after-sides; and another to their fore-side, at their moulding or breadth at the upper side; which are confined together by battens at each buttoc-line, and one at each end to the direction of the fashion-piece, allowing what they are intended to be let into the fashion-pieces; and a broad piece in the middle, to the fire of its seating c c, with the middle line correctly marked thereon.

The bevelling of the transoms are frequently taken from the buttoc-lines in the fier-plan, fig. 1, in the following manner. Apply the flock of the bevel E to the upper side of the transoms, in the fier-plan, fig. 1, and the tongue to the buttoc-line; but let the tongue be off at the upper and lower sides of the transom, as at the filling-transom in the fier-plan, fig. 1, which gives the exact bevelling of the transoms at their corresponding buttoc-lines.

The bevellings for the wing-transom are taken from the margin-line to the under side of the wing-transom, as above. The under side of the wing-transom is transferred from the body-plan, fig. 2, to the fier-plan, fig. 1, by the buttoc-lines.

The bevells for the deck-transom may be taken by applying the flock of the bevel parallel to the hang of the deck, at the middle line, and the tongue to each buttoc-line; keeping the tongue well at the upper and lower sides of the transom, as before observed, and so must be applied on the transom, by placing the bevel at each corresponding buttoc-line, and keeping the flock out of winding with the upper side of the transom at the middle line.

The transoms under the deck may be bevelled by the buttoc-lines in the fier-plan, fig. 1, and the bevellers may be taken very exact; but it requires to be very particular in applying the bevel on the transom; to do which, the flock of the bevel must be kept in the direction of the buttoc-lines, at the upper side of the transom, and the tongue teaching to the buttoc-line below, which ought to be marked at the lower side of the transom, and not treading to the bevel's casting promiscuously, for then the bevel may not be exactly square.

When this trouble is taken to bevel the tranoms, then they may, when trimmed, be depended upon.

This is a method not to be recommended to those who would be particularly exact, because there can be no more bevellings on the transoms than the number of buttoc-lines which intersect the transoms; as for instance, there are only two buttoc-lines which cross the lower-transom in fig. 3, and one of them is close to the end, which is not sufficient to get the exact form of the lower side of the transom. Therefore, the best way to find the bevellings of these transoms is to lay-off their lower sides, which is very easy to be
SHIP-BUILDING.

where the lines (before mentioned) levelled out intersect the cant-line-piece, is the proper station of the wing, filling, and deck-tranforms on the fashion-piece mould for the moulding edge, but not for the direction in which those tranforms strike the fashion-piece, because of the round of those tranforms; which will be more explained in the following method.

When the latter sides of the tranforms are laid off, it is but little trouble to make a slight mould to counter-mould the under sides of all the tranforms, by making it only to one arm of the tranform, and then canting it over, to mould the opposite arm. Then, when the breach of the tranform is trimmed to the bearding-line, set off the distance from the middle line each way, as far as the bearding-line e is from the middle line in the plan of the tranforms, fig. 2, to which the tranform-mould is made. Then trim the end of the tranform square, and set off the bevelling for the end of the tranform; then cant the tranform over, and applying the mould made for the under side to the breach and bevelling at the end, you have the tranform counter-mould, without the affliction of any other bevelling; or they may be set off, to see if they agree with the mould; and if they do, you may be sure the work is correct.

To Lay-off the Tranforms when laid.

The utility of canting the tranforms is, that it greatly affists the conversion of timber, is better for faffening the plank of the bottom, and bolts square to the stern-post. When the tranforms have a very great bevelling, it is difficult at the upper edge to get sufficient faffening for the planks, which sufficiently points out the utility of canting them: proceed therefore to the operation, which will require the reader's particular attention; as those minute particulars which cannot so conveniently be displayed on the plate, can only be explained in words.

Dipofe of the tranforms in the sheer-plan, fig. 4; let the wing and filling-tranforms be placed level, and the upper side of the deck-tranform to the proper hang of the deck; and the other tranforms below at the fashion-piece, as much above a level as represented in the sheer-plan, fig. 4; so as to make them nearly of an equal opening at the stern-post, and likewise at the fashion-piece. There shew the disposition of the tranforms at the middle line.

Now proceed to shew the level view of the moulding edges of all the tranforms in the body-plan in the following manner: the wing-tranform a, and the filling e, lying level, they form a segment of a circle in the body-plan, fig. 5, to their given round-up. This is the proper curve to which the round-up mould is made for faffing these tranforms, as before oberved. The next is the deck-tranform d, which being confined to the hang of the deck, and the round of the beam, is the most difficult of all, if executed in a proper manner: it ought to undergo the following operation. The ticked line H, in the sheer-plan, fig. 4, is the under side of the deck at the middle line, and is intended to be the upper side of the deck-tranform at the middle line. Transfer the heights of the ticked line H, or upper side of the deck-tranform, in the sheer-plan, fig. 4, at every square timber, to their corresponding timbers in the body-plan, fig. 5; and where the deck at the middle line in the sheer-plan, fig. 4, intersects the button-lines, transfer them to their corresponding button-lines in the body-plan, fig. 5; a batten pinned to these spots shews the interfection of the deck at the square timbers, as H, in the body-plan, fig. 5, supposing the deck had no round-down at the side. Under the line A A, for the upper side of the keel, in the body-plan, fig. 5, marks the round-up of the gun-deck beam K; and where the ticked line H for the deck, at the middle line, in the body-plan, fig. 5, intersects the square timbers, square them down to the round of the deck R, under the body-plan. The timbers and the buttocck-lines are there marked and numbered in the same manner with those from which they were cut off, in which they were placed, and from which they were faffed down. Take the distance at each place on the round of the deck, under the body-plan, fig. 5; square up to the line A A, or upper side of the keel (which is the round of the deck at each timber), and set them down below their corresponding timbers, in a perpendicular direction, from the interfection of the deck at the middle line with the square timbers H, in the body-plan, fig. 5; and from those spots direct them towards the middle line M, parallel to the round of the deck under the body-plan, till they intersect the square timbers, which are the proper stations on the square timbers the curve I of the deck will make, supposing it to be continued to the outside of the timbers; which is required, in order to find the exact form of the moulding edge of the deck-tranform.

Let the buttocck-lines in the body-plan, fig. 5, be continued down to the round of the deck R, under the body-plan; then take the round of the deck at each buttocck-line, and set it down below the deck at the middle line H, in the sheer-plan, fig. 4, on their corresponding buttocck-lines, and transfer those spots to the buttocck-lines in the body-plan, fig. 5; then to those spots on the buttocck-lines, and those on the timbers, pin a batten, and it will shew the curve the deck-line at the side will make, if continued to the outside of the timbers, as I, in the body-plan, fig. 5.

To find the deck at the side in the sheer-plan, fig. 4, take the heights at every square timber in the body-plan, fig. 5, where they intersect the deck at the side, and transfer those heights to their corresponding timbers in the sheer-plan, fig. 4, by pinning a batten to those spots, with those made before on the buttocck-lines, you have the deck at the side, as I, in the sheer-plan, fig. 4, which is the level view of the moulding edge of the deck-tranform.

To find the lower side of the deck-tranform in the sheer-plan, fig. 4, and likewise in the body-plan, fig. 5; this should be done in the same manner as the upper side. If it is intended to be very correct, run the ribband-lines, which will be a proof to the rest of the work, in laying-off the tranforms.

To find the level view of the tranforms below the deck, in the body-plan, fig. 5, observe where the lower and upper sides of the tranforms in the sheer-plan, fig. 4, intersect the buttocck-lines, square timbers, and fashion-pieces; transfer those heights to the body-plan, fig. 5, on their corresponding lines, which give the level view of the tranforms in the body-plan, fig. 5.

To lay-off the cant-tranforms, proceed, as before, to make a separate plan, as fig. 6. The moulding edges of the wing, filling, and deck-tranforms, are laid off so familiar to the former, as not to need repeating here. But should the deck-tranform have much sheer, and a great round, it would be a further proof of correctness, to take the distance from the perpendicular line P, in the sheer-plan, fig. 4, to timber 32, in the direction of the sheer of the deck I, and set it off square from the line P P, in the plan of the tranforms, fig. 6, which will be further forward than the said timber, as before laid off; then pin a batten to the round of the deck under the body-plan, fig. 5, marking the middle line, and the spot that was squared down from the deck at the side, at timber 32, to the round of the deck, and set it off on the new timber 32, in the plan of the tranforms, fig. 6. This would give the exact spot on timber 32, if the deck was required to hang and round to extremes, in the same manner.
by placing a batten to the round of the wing and filling-tranoms in the body-plan, fig. 5, and marking the square timbers, buttck-lines, and square fashion-pieces on the batten; then let the batten be drawn, and it will be the exact half-breadth at every square timber, buttck-line, and fashion-piece, and will give the exact length of the wing-tranoms.

To lay off the tranoms under the deck, take the distance from the line P, in the shee-plan, fig. 4, to the buttck-lines in the direction of the tranoms, and set them off from the line P P, in the plan of the tranoms, fig. 6, on their corresponding buttck-lines. Take the half-breadths in the body-plan, fig. 5, square from the middle line to the intersection of the tranoms Nos. 1, 2, 3, 4, 5, and 6, with the square fashion-piece, and set them off square from the middle line in the plan of the tranoms, fig. 6, to intersect the fashion-piece, marking a line parallel to the middle line, as No. 6. Then take the distances from the line P, in the shee-plan, fig. 4, in the direction of the tranoms, to the fashion-piece, and set them off square from the line P P, in the plan of the tranoms, fig. 6, on the lines a, a, at the intersection of the fashion-piece. Take the half-breadths square from the middle line in the body-plan, fig. 5, where the tranoms intersect square timber 36, and set them off square from the middle line, in the plan of the tranoms, fig. 6. Then take the distances from the line P, in the shee-plan, fig. 4, to square timber 36, in the direction of the lines of the tranoms, and set them off square from the line P P, in the plan of the tranoms, fig. 6, to intersect their several half-breadths, as at k, c, d, c. In the same manner proceed to find all the spots for the square timbers, in order to prove the buttck-lines. This will give the exact form of the moulding edge of all the tranoms below the deck, and the flating of the fashion-piece on the tranom, with the length of the tranom at the moulding edge.

To find the direction of the end of the tranom, to lie against the side of the fashion-piece, observe in the half-breadth plan where the fashion-pieces intersect the middle line, and square them up to the shee-plan, as may be seen ticked, and marked K, M, L, calling them the fashion-pieces at the middle line in the shee-plan, fig. 4. Take the distance from the line P, in the shee-plan, fig. 4, to the middle line of the aftermost fashion-piece K, in the direction of the tranoms No. 6, and set it off from the line P P, in the plan of the tranom, fig. 6, on the middle line, and mark the ticked line g g, from the spot on the middle line, to the spot on No. 6 tranom. This will give the direction to cut off the end of the tranom, in order to lie against the side of the fashion-piece.

To bevel the tranoms when canted.

Those tranoms which are not fided straight, as the wing, filling, and the deck, are generally bevelled by the buttck-lines, as before observed; but rather than trufl to the bevellings only (it being rather difficult to apply them to trv as they should be), lay-off the under sides of all the tranoms, and make a light mould to them. This will correct the bevellings, and make greater dispatch in trimming the tranoms. Then there need only (except for proof sake) be taken the bevelling at the bearding-line, and the bevelling at the end; for the mould will give the rest. But observe to be careful in the bevellings at the ends of the tranoms; for instance, the ends of the wing and filling-tranoms, when they be level, are to be cut off square; but keep the square as much above the end of the wing and filling-tranoms, as they round in their length, and let the square look out of winding with the middle of the tranom. Also the bevel (when applied on the outside it is cut off, in order to bevel the end for canting) must be kept as much above the end of the tranom, and look out of winding with the middle of the tranom.

As the bevelling for the end of the deck-tranom is taken against the cant-fashion-piece by a level line in the body-plan, fig. 5, it must be observed how much the tranom at the middle line in the shee-plan, fig. 4, is below a level (suppose one foot). Then place a batten at the middle line on the tranom, and lift the foremost end of the batten up till it becomes level, as supposing the tranom to be in its place; then proceed with the square and the bevel for the end of the tranom, in the same manner as for the wing and filling, looking out of winding with the batten at the middle line.

To bevel the tranoms, which are canted in the shee-plan, fig. 4, proceed in the same manner as in bevelling the cant-timbers, by making a parallel line to the moulding edge. Therefore lay-off the bevellings of the tranoms, by squaring a line from the upper side, where it intersects the line P, in the shee-plan, fig. 4, to the under side, as the ticked line a at the lower tranom. Take the distances from where the squared line, a, crosses the lower edge in its cant direction, to the bearding-line c, and to all the buttck-lines, and set them off square from the line P P, on their corresponding lines, in the plan of the tranoms, fig. 6. Where the bearding-line c, in the shee-plan, fig. 4, proves to be square from the direction of the tranom, as it is, or very nearly so, at the lower tranom, then the bevelling for the moulding edge, and likewise for the bevellings, will come as near together in the plan of the tranoms, fig. 6. This may sufficiently prove that the method of bevelling is correct.

Where the under side of the lower tranom intersects the square timbers and square fashion-piece in the body-plan, fig. 5, take the nearest distances from thence to the middle line, and set them off square from the middle line, in the plan of the tranoms, fig. 6, striking lines parallel to the middle line, as at ii. Then take the distances from the squared line a, in the shee-plan, fig. 4, in the direction of the under side of the lower tranom, to the square timbers and fashion-piece T, and set them off square from the line P P, on their corresponding lines laid off, in the plan of the tranoms, fig. 6. To these spots, and those on the buttck-lines, pin a batten, and it will represent the ticked line b k, within the lower tranom, which will shew how much the lower tranom is under from a square, agreeable to the depth of the tranom. Take the distance from the squared line a, in the shee-plan, fig. 4, to the ticked perpendicular K, which is the after-fashion-piece at the middle line; and set it off from the line P P, on the middle line, in the plan of the tranoms, fig. 6, and mark the ticked line m, from thence to the spot on the fashion-piece, which will be a line parallel to the ticked line g, before marked to cut off the end of the tranom; and the distance between the two ticked lines shews how much the end of the tranom is under from a square, agreeable to the depth of the tranom.

The ticked line b k, in the plan of the tranoms, fig. 6, which is for the bevellings, is the line to make the temporary mould to, in order to cut the outer mould the tranom, and beveling off one end of the mould to the bearding-line for the breech of the tranom, and cutting off the others to the ticked line m for the end of the tranom, when the mould is applied to the under side of the tranom, it will be easily perceived it the work be true.

To find the exact bevelling to be applied over the end.
of the tranfom, after the end is cut off, in order to counter-
mould the tranfom, proceed in the following manner.
Where the upper and lower fides of the lower tranfom inter-
fect the after-cant-fashion-piece P, in the body-plan,
fig. 5, level them out to interfect the after-cant-fashion-
piece O. Where the upper fide of the lower tranfom inter-
fects the perpendicular ticked line K (which is the af-
ter-fashion-piece in the fheer-plan, fig. 4), transfer that
height to the middle line, in the body-plan; fig. 5; and
from there draw a straight line to the upper fide of
the lower tranfom, on the cant-fashion-piece, as the ticked
line e, to which line fix the flock of a bevel, as at B,
and the tongue to the cant-fashion-piece O, as low down
as the spot for the lower fide of the tranfom. This is
the proper bevelling to be applied on the end of the
tranfom, after the end is cut off, in order to counter-mould
the tranfom. The ticked line e, to which the flock of the
bevel is placed, is the direction of the tranfom to be croffed
on the fashion-piece mould. The bevel B, which is repre-
sented in the body-plan, fig. 5, fhewing the bevelling of
the end of the lower tranfom, fufficiently proves the utility
of canting the tranfoms; for, by having fo little bevelling,
it greatly afifts the converfion of timber, as well as that it
muff certainly be better for the security of the plank of the
buttock.

To Lay-off a Square-Tuck, Plate IX. Laying-off C.

We have already explained the utility of the tranfoms in
composing the ftern-frame, by which method most ships are
inclined abaft. But yachts and cutter-built veffels are
owing to their clearerms of run abaft, inclined by a square
tuck, by which room is gained; and, when properly put
together, this mode of conftuction is, perhaps, stronger
than tranfoms would be in veffels of this defcription.

The tuck propofed to be laid off is that of the royal
yacht, Plate XIII. But that the reader may be led pro-
gressively on from the eafieft to the moft difficult part of
the operation, we fhall firt propofe a square tuck, the
fides of which are to be out of winding, or in the fame
direction as the rabbit of the poft, in confequence of which
the wing-tranfom muft be ftraight athwarthips, and the
whole will be one flat furface (fimilar to the tranfoms of
boats), or a fection of the veffel cut athwarthips, but not
in a perpendicular direction, which is the only difference
between it and the fquare timbers; and as the fection is
agreeable to the rake of the ftern-poft, it confequently
follows, that the laying it off must differ from the fquare
timbers in the operation.

The horizontal view of the tuck muft firt be reprefented
in the body-plan, fig. 8, which is done in the following
manner: ftrike a horizontal line in the fheer-plan, fig. 7,
at the height of the wing-tranfom at the fide, as at 5; and
likewise as many horizontal lines below that as may be
thought fufficient; and where they interfeft the aft-part of
the rabbit of the poft a, square them down to the half-
breadth plan, fig. 9; then transfer their heights to the
body-plan, fig. 8; and where they interfeft the fquare
timbers 21, 22, 23, 24, 25, and P, in a horizontal di-
rection, take those difiances from the middle line, and let
them off upon their correffponding timbers from the middle
line, in the half-breadth plan, fig. 9; then by pinnnig a
batten to those spots, the horizontal view of the tuck, as
will be reprefented in the body-plan, fig. 8, as high as the
wing-tranfom at the fide. But was the head of the fashion-
piece required to run up, to take a bolt or two through the
heel of the fide, a counter-timber, proceed in the fame manner
for a horizontal line or two above that at the fide of the
wing-tranfom; lay, one at the upper fide of the wing-
tranfom at the middle line; then run the main half-breadth
line in the half-breadth plan, fig. 9; then, where the half
horizontal line and main height of breadth line interfect the
aft-side of the rabbit a, in the fheer-plan, fig. 7; square
them down to the half-breadth plan, fig. 9, and take their
difiances from the middle line in the half-breadth plan, fig. 9,
to where they interfect the horizontal line 6, and the main
half-breadth line, and fet them off from the middle line on
their correffponding horizontal lines, in the body-plan,
fig. 8; then by continuing the curve, a, upwards through
those spots, the horizontal view of the tuck will be con-
tinued up to the height of breadth.

Now, where the horizontal view of the tuck in the body-
plan a, fig. 8, interfects the bearding-line b, take that height;
and transfer it to the fheer-plan, fig. 7, ftriking there the
horizontal line S, which repreffes the feting of the tuck;
then take the diftance from the feting of the tuck, in the
fheer-plan, fig. 7, on the rake, in (the direftion of the rab-
bet of the poft a), to the repective horizontal lines and height
of breadth, and fet them up the middle line, from the hori-
ontal line S, at the feting of the tuck, in the body-plan,
fig. 8; ftriking a horizontal line to the rake, at every
height, as fhewn by the fine-ticked lines; then, where the
horizontal view of the tuck, a, interfects the horizontal
lines firft ftuck, carry it up parallel to the middle line, to
their correffponding horizontal lines on the rake; which will
give the spots through which the fine-ticked curve is to
pafs, that will repreff the proper shape of the tuck,
agreeably to the rake, as e; and the line to which the
fashion-piece mould muft be made.

The bevellings for the fashion-piece may next be taken,
by proceeding as follows. The aft-side of the rabbit of
the poft a, in the fheer-plan, fig. 7, repreffes the aft-side
of the fashion-piece of the tuck; therefore, take the fiding
of the fashion-piece, and fet it off afore the rabbit, and
square thereto; then, by ftriking a parallel line to the aft-
side a, the fore-side of the tuck b will also be repreffed;
next, from the feting of the tuck S, on the aft-side, square
the line C from the rabbit to the fore-side; and from its
interfeftion at e, take the heights of the horizontal lines up
the fore-side, and fet them up on the middle line from the
horizontal line S, at the feting of the tuck, in the body-
plan, fig. 8; ftrike horizontal lines for the fore-side of the
fashion-piece, as diftinguifhed by the long-ticked lines;
then, where the fore-side of the fashion-piece b, in the fheer-
plan, fig. 7, interfects the horizontal lines and height of
breadth, square it down to their correffponding horizontal
line and main half-breadth, in the half-breadth plan, fig. 9;
at which interfeftions take the difances fquare to the middle
line, and fet them off from the middle line on their corre-
ffponding horizontal lines, for the fore-side of the fahion-
piece, in the body-plan, fig. 9. Continue the fore-side
of the fashion-piece down to the bearding-line d, as you fee
ticked in the fheer-plan, fig. 7; then take the diftance from
the interfeftions of the fquared line at the feting e, down
the fore-side of the fashion-piece to the horizontal line 1,
and where it interfects the bearding-line d, and fet it off in
the body-plan, fig. 8. Below the horizontal line S, at the feting
of the tuck down the bearding-line, ftrike a horizontal line
for No. 1, and proceed as before directed to obtain the half-
breadth
breadth spot on the half-breadth and body-planes, figs. 9 and 8; then stick a stick to a batter, and mark the curve which will intersect the beaver-line, and the fore-side or lower face, d, of the fashion-piece will be represented in the body-plan, fig. 8.

The attitude and fore-side appear now in their proper shape, as in the body-plan, fig. 8, and of the same form as the fashion-piece, when turned and laid flat with the attitude upwards, as thus both edges will be seen, in consequence of its having a bending bevelling; therefore, the distance from the line represents the attitude to the line of the fore-side, taking the greatest distance, at a, which will show how much the bevellings are tending, or without a square, in the breadth of the bevelling-board, which should be equal to the thickness of the fashion-piece.

When the mould is made to the ticked line, c, of the attitude, the heel of it must be cut off well with the line for the seating of the tack, and likewise well with the middle line, in order that it may dovetail and bolt into the fore-poll. Mark also on the mould the beading-line, or side of the inner poll. The different firmarks for the ribbands must be marked on the moulds, but, in order that the firmarks of the ribbands may be correctly marked, observe where the diagonal lines intersect the horizontal view of the tack a, in the body-plan, fig. 8, and carry them up parallel to the middle line, to the line for the side of the fashion-piece c, to which the mould is made. This will be their proper flatness or upper sides, and may thence be marked on the mould.

The bevellings may be taken at the different firmarks or ribbands, and set off where taken, as the bevel at the fourth riband, which will show it more clearly. The ticked line c, drawn parallel to the black of the bevel in the same distance from the outside of the bevel, as the fashion-piece is fised. Then draw a line square from the black of the bevel to the ticked line c; and where it intersects the ticked line g, as at b, set off from b to i, the same distance as the fore-side t, from the side of that place, as before directed, and open the tongue of the bevel to i. This will show the bevelling of the fashion-piece at that place. The bevel is to be applied square from the moulding edge.

Run in the half-breadth plan, fig. 9, the diagonal 7, although the ending of it only differs from those explained before, and need only be described. Transfer the height from the body-plan, fig. 8, where the diagonal 7 intersects the horizontal view of the fashion-piece a, and set it up in the beaver-plan, fig. 7, at the side of the fashion-piece; and from its intersection there, square it down to the half-breadth-plan, fig. 9; then take its distance in the body-plan, fig. 8, from the middle line to the horizontal view of the fashion-piece a, its diagonal direction, and set it off from the middle line, in the half-breadth-plan, on the line squared down, which gives its ending at the fashion-piece. In the same manner transfer its height where it intersects the upper side of the wing-tranom, in the body-plan, fig. 8, and set it up in the beaver-plan, fig. 7; and where it intersects the side of the fashion-piece, square it down to the half-breadth-plan, fig. 9; then take the distance from the middle line, in the body-plan, fig. 8, as before, to the upper side of the wing-tranom, and set it off from the middle line, in the half-breadth-plan, fig. 9, on the line squared down; then mark a line through those spots, as the long-ticked line c, is the half-breadth-plan, fig. 9, which will be the true ending of the diagonal 7, or any diagonal crossing the wing-tranom and fashion-piece.

Square tucks of lighters are like those above described, and the lines are laid off at a similar manner, but composed of only one piece between tucks, and their upper line is bounded by the upper side of the beaver. But the tucks of lighters (or legeras), is best of the parts of the body, i.e. the tucks of the wing-tranom, which makes the side of the fashion-piece to take a part of it also the whole or at least its length, which makes them rather more difficult to be laid off. But, supposing the former to be clearly understood, we shall give a description of a tuck, the outside of which is to be finished forward, in its finished state.

Suppose a flat surface, of such a level (as longer from the head of the fashion-piece or height of breadth to the seating of the tuck, and in breadth to the outside of the tranom) as was placed upon one side to the rabbet of the poll, and the other edge bent round to a curve, as much as the outside of the tuck in intended to be round forward, in which position suppose it to be confined; then draw the shape of the outside of the tuck or fashion-piece down to the poll, and cut it out. The true shape of the tuck or fashion-piece is now shown as it is to be trimmed, and it will appear in its finished state. Then take it from its position, and lay it flat, letting the round be uncorked; and it will then appear, as it is required to be laid off in the body-plan, in order to make the mould therefrom.

The fashion-pieces for the square tuck being already laid off, the same horizontal lines, &c. may be transferred to the beaver and body-planes, figs. 10 and 11; then proceed to lay it off upon the flat, agreeable to the help of the rabbet of the fore-poll, as before directed, with this difference, having no round-aft pedals, but one straight line in the half-breadth view, in the beaver-plan, fig. 7, which was the side of the rabbet of the fore-poll; but, in the present square tuck, when the head of the fashion-piece is carried forward, to connect with the end of the wing-tranom, the moulding edge of the fashion-piece forms a serpentine line.

Therefore, where each horizontal line intersects the side part of the rabbet of the poll a, in the beaver-plan, fig. 10, square down the distances to the middle line of the half-breadth-plan, fig. 12, making of spots; then upon the horizontal line, No. 5, at the height of the wing-tranom, at the side, let off from the side of the rabbet of the poll a, the round-forward of the wing-tranom, in the beaver-plan, fig. 10, and square it down to the half-breadth-plan, fig. 12; upon which let off the half-breadth of the wing-tranom, and thence sweep a curve, the centre of which radius being in the middle line, shall cut the spot for the said horizontal line, in the middle line of the half-breadth plan, fig. 12, which will represent the side of the wing-tranom a, at the height of the horizontal line at the side. Now, from the other spots squared down on the middle line of the half-breadth-plan, sweep curves with the same radius, and they will be parallel to the curve of the wing-tranom a. The horizontal lines being transferred from the half-breadth plan, figs. 9, 10, to fig. 12, take the distances from the middle line in the half-breadth-plan, fig. 12, where the horizontal lines intersect their respective curves for the side of the tuck, and let them off from the middle line on their corresponding horizontal lines, in the beaver-plan, fig. 11; a batter pinned to these spots will show the horizontal view of the tuck a, in the body-plan, fig. 11. Also, where the horizontal lines in the half-breadth-plan, fig. 12, intersect their respective curves, square the distances up to their corresponding horizontal lines in the beaver-plan, fig. 12; and by drawing a curve to pass through those spots, the horizontal view of the side of the fashion-piece, a, will be represented in the beaver-plan, fig. 10; and what the thwart-
thwartship view of the aft-side of the fashion-piece leaves
the rabbe't of the stern-post, in order to be conformable to
the wing-tranform at the side, is easily perceived by the
shaded lines.

Till this thwartship view of the aft-side of the fashion-
piece, b, be shewn in the sheer-plan, fig. 10, the ribband
lines cannot be truly ended, although the operation is the
same as before described.

Though the aft-side of the fashion-piece b, in the sheer-
plan, fig. 10, leaves the rabbe't of the stern-post at the
head conformable to the end of the wing-tranform, yet a square
line at the footing must be drawn as before, to lay-off the
tuck on the flat; therefore, take the nearest distances from the
square line a, in the sheer-plan, fig. 10, to where each
horizontal line crosses the aft-side of the fashion-piece b, and
let them up from the horizontal line S, in the body-plan,
fig. 11, striking horizontal lines, as distinguished by a fine
tick.

Then take the half-breadth of the wing-tranform, in the
body-plan, fig. 11, square from the middle line, and let it
off from the middle line, on the line A A. Next, fix one
leg of the compasses at the end of the wing-tranform, in the
sheer-plan, fig. 10, and take the nearest distance to the aft-
part of the rabbe't of the stern-post a, which is square from
the rabbe't, as the line e; and let it off square from the line
A A, at each end of the tranform b b; and sweep the arc
e e, which gives the round-aft of the tuck at any height,
square from the rabbe't of the stern-post. Square down the
fine-ticked lines, or horizontal lines, 2, 3, 4, 5, 6, and 7; on
the rake where they intersect the horizontal view, a, of the
fashion-piece in the body-plan, fig. 11, to the round-aft
line, on a square under the body-plan. Then take their
distances from the middle line, on the curve e e, or round-
aft, on a square, and let them off from the middle line of the
body-plan, fig. 11, on their corresponding horizontal lines;
then pin a batten to these spots, and to where the footing
intersects the post, and it will give the form of the aft-side
of the fashion-piece d, to which the mould is to be made,
that will agree with the other timbers, when in their
places.

To be correct with the length of the wing-tranform on the
flat, take the half-breadth from the body-plan, fig. 11, on the
round for the upper side of the tranform; then continue the
end of the tranform in the half-breadth plan, fig. 12,
square out from the middle line, as at c; on which (square
from the middle line) let off the half-breadth taken on the round
from the body-plan, fig. 11, and from that spot sweep an arc to break into the middle of the tranform, at the middle line, as represented by the dotted line a; then from the before mentioned spot, or end of the wing-tranform at b, take the half-breadth round the dotted curve to the middle
line, and let it off from the middle line in the body-plan,
fig. 11, round the curve, for the upper side of the tranform.
This will give the exact length of the tranform on the
round-aft of the tuck.

Previous to the laying-off of the fore-side of the fashion-
piece, it will be proper to understand in what manner the
fashion-piece is to be moulded and trimmed, particularly on the
fore and after-sides.

Make a mould to the moulding, or outer edge of the
fashion-piece laid off on the flat, as the fine ticked line d in
the body-plan, fig. 11. The upper end may be made as
high as the height of breadth, or horizontal line 7, and the
lower end may or ch to the footing on the post. Let the
upper end of the mould be cut off well with the direction
of the horizontal line 7, and let the heel be exactly perpen-
dicular at the side of the inner post. Make another mould
to the round-aft, on a square c c, as shewn under the body-
plan, fig. 11, and of a parallel breadth, like part of a beam-
mould. Make it as broad as the fashion-pieces are intended
to be fitted, and let the midship-end be well with the side of
the inner post, and cut off parallel to the middle line. Let
the side-end correspond well with the moulding edge of the
fashion-piece, and cut off agreeable to the round of the side
when the mould lies in its proper place, underneath the
body-plan, fig. 11. Let the fashion-piece be fided suffi-
ciently for the wing-tranform to dovetail into the aft-side
of it, and let the fore-side of the fashion-piece, that runs
above the wing-tranform, be of sufficient length to receive
the bolts of the side stern-timber, and long enough at the
heel to meet at the middle line.

When the fashion-piece is roughly fided on the aft-side, so
as to lay the mould on the aft-side, to mark the upper and
lower end nearly, then cut off the head by the mould for
the thwartship-way, and the fore and aft-way, square. Then
fatten the round-aft mould, that is made to the fiding, on
the head of the fashion-piece, by which may be trimmed the
fore and after-sides of the fashion-piece out of winding,
by lines parallel to the middle line. Thus will you have
the best opportunity of seeing how to convert the piece, by
seeing both sides at once. Then will the fashion-piece be of a parallel thickens from one end to the other,
by all lines that are parallel, whether perpendicular or
horizontal.

To Lay-off the Fore-side of the Fashion-Piece.

Having the fiding of the fashion-piece on a square, set it
off in the sheer-plan, fig. 11, square from the rabbe't of the
stern-post a; then with compasses take the fiding of the
fashion-piece in the direction of the horizontal lines, and
set it off square from all the aft-sides of the horizontal lines,
prolonged in the half-breadth plan, fig. 12, on each horizontal
line, and square them up on their corresponding lines in the
sheer-plan, fig. 10. Then pin a batten to those spots,
and the fore-side of the fashion-piece e will be represented.
Take the heights above and below the squared line d, in the
sheer-plan, fig. 10, to the intersection of each horizontal line
with the fore-side of the fashion-piece e, in the same manner
as the aft-side was done; and set off above and below the
ticked line S, in the body-plan, fig. 11, and strike horizontal
lines, as there distinguished by long-tick. Then take the
half-breadths in the half-breadth plan, fig. 12, to the fore-side
of the fashion-piece on the horizontal lines, square from the
middle line; and set them off square from the middle line
on to the line for the round-aft, on a square e e, under the
body-plan, fig. 11. Then take them off again on the round-
aft line, and set them off from the middle line, on their
Corresponding horizontal lines in the body-plan, fig. 11.
Then pin a batten to those spots, and the form of the fore-
side of the fashion-piece e will be agreeable to the fiding
proposed.

The aft-side of the fashion-piece not being straight, will
render it more troublesome than neful, to run lines in order
to trim the outside of the fashion-piece by bevellings;
therefore it would be better to make a mould to the fore-side, e,
and trim a spot to lay to the side of the inner post or dead-
wood; and set off a bevelling for the outside at the main-
breath, as at B, fig. 12.

Mark the line at the footing S, in the body-plan, fig. 11,
on the mould for the aft-side, and on the mould for the fore-
side, and when the aft-side is moulded, and the side trimmed
to lay to the inner post, mark the spot b square from the
aft-side
SHIP-BUILDING.

affines to the fore-side, to which place the lappet $b$, on the mould for the fore-side, must properly correspond; and the head of the mould must be kept well with the lappet to the bevelling at the main-breath. The mould lies then in its proper place to mould the fore-side of the fainion-piece.

It is customary, in boats, for the planks of the bottom to run through to the aft-side of the transom, and sometimes to the aft-side of the fainion-piece of lighter; but in larger vessels it is better to rabbot the fainion-piece; for when the planks of the bottom are rabbotted into the fainion-piece, and the inside of the butts left longer than the outer, the planks are apt to be pelled to the timbers on caulk {ing their ends; while, on the contrary, when the planks run through the fainion-piece, they are not able to bear the force that is required to be made by caulk{ing their ends sufficiently. In vellets of this class, likewise, the ends of the planks would be liable to be startled off by accident.

The fainion-piece, as it is laid off, both fore and aft-fines, is conformable to the timbers of the body, being for that reason easier understood; but when the fainion-piece is moulding, be careful to leave enough without the lines for the thickness of the plank; which may be found exactly by holding a batten at the out{side of the fainion-piece, at several places, parallel to the lines for the fore and aft-fines of the fainion-piece, and square from the lines.

Then extend the compas{es to the thickest of the bottom plank, or otherwise run as many fictitious diagonal lines as shall be necessary, and square from the moulding edge of the fainion-piece. Then set off the thickness of the plank of the bottom, and lay off the extreme out{side of the fainion-piece, likewise the aft-side, observing the round in the direction of the diagonal line, whereby a mould may be made to the aft-side, at the extreme breadth, and the outside may be trimmed by bevellings from the diagonal lines. But great care must be taken to place each diagonal line square from the moulding edge of the fainion-piece; and then, as the fainion-piece at the aft-side will wind or twist in the direction of the diagonal lines, the tongue of the bevel may not cast at all the bevelling spots, exactly in the direction wherein the diagonal lines were laid off; for the diagonal lines at the middle line (suppose in the floor-plan) are parallel to the upper side of the keel; and are cut down similar to the flap of a table, as before observed; in which direction the tongue of the bevel ought to cast, when the bevellings are taken from the diagonal lines.

The fainion-pieces are rabbotted on their aft-fines, to receive the planks of the tuck; but do not take the rabbot too low down as where it intersects the poll, but leave it square some inches above it, that the midthip piece may be gotten in its length as it rabbot{ts into the poll, and it will also leave a better butt for caulk{ing, as shewn in the body-plan, fig. 11.

The wing-tran{on mould must be made to the fine ticked curve $a$, in the half-breath-plan, fig. 12. The bevelling of the wing-tran{on will be the fame arrow{head on the aft-side, which bevelling is the rake of the rabbot of the poll $a$; and the wing-tran{on is rabbotted at the aft-side at the lower edge for the planks of the tuck, and at the upper edge for the planks of the lower counter, (if thought proper,) therefore the breadths of the fainion-timbers should be placed as much before the aft-side of the wing-tran{on as the thicknesses of the planks of the lower counter allow.

To prevent any error in the true height of the fainion-pieces, let the finmark $c$, in the body-plan, fig. 11, be correctly marked on the mould and side of the fainion-poll, so that when the heels of the fainion-pieces are letting on the poll, these finmarks must exactly agree.

To lay off the several Parts of the Head, Plate X. Layning-off $D$.

The knee, cheeks, rails of the head, and block for the figure, must be laid off to their full size on the floor from Plate I., which is the horizontal and thwarting view, when the cheeks, rails, &c., are fixed in their places.

To make the Mould to the Knee of the Head.—The lower part of the knee at the fore, as at X, Plate X., fig. 1. Layning-off $D$, may be made by the board about an inch thick, and up the fore-part of the knee and them, as high as the cutting-down and beveling of the figure; but these need be no broader than about five inches for lighter, as at 39, 39, fig. 1. Then across the mould are slaters, batters, which not only keep the mould togeth{er, but the manner of sliding the knee is expressed thereby. Thus, take any perpendicular, as at 24, fig. 1, and level out the several heights 13, 14, 15, 16, and 17; and at 13 and 17 let off the half-fining of the flem, striking a line thereto. Then let fall a perpendicular from the fore-side of the knee at the upper part, as at 25, fig. 1, and let off the half-fining of the knee at 4, and at 12, and strike a line. Strike the lines across the knee of the head, where it is intended to have the upper side of the battens, as at 1, 2, 3, &c. Then apply the batten to the perpendicular 25, fig. 1, keeping it fall at the upper end, and mark on the perpendicular the spots 1, 2, 3, &c. Then from the perpendicular 25, fig. 1, take the half-fining at each spot, and let them off on their corresponding lines at the fore-side of the knee: proceed in the same manner for the half-fining of the flem at 24, fig. 1, and strike in the lines as ticked across the knee. Then batten the lines, being made to those lines, and nailed across the mould, the half-fining of the knee may be readily let off at the upper side of each batten, and the knee, when put together, may be trimmed straight from the fore-side to the flem or aft-side of the knee: the cutting-down, as at 1, 2, 3, &c, and 4, fig. 1, is fided in the same manner.

To make the Mould to the Gripe, G, fig. 1.—The gripe is only the completion of the knee to the keel, and the mould is made so similar to the knee above as to need no further description.

To make the Moulds to the Cheeks.—The cheeks must be laid off to their moulded size on the half-breath-plan, fig. 2, at $C$, $C_1$ to the main half-breath line, allowing the thickness of the plank, as at $R$, and against the side of the knee. Another mould must be made to the flight of each cheek, in the floor-plan, fig. 1, at $C$, or upper cheek; and $L$, $C$, the lower cheek, from the heel of the figure $Z$, to reach as far as the cheeks are there fewn, marking a finmark at the fore-side of the item. Then, to mould the cheeks to their proper flight, draw off the knee-arm to the mould made in the half-breath-plan, marking on the piece the fore-side of the item from that mould: then fullening the flight-mould to the knee-arm of the cheek, observing to keep the finmark well at the fore-side of the item, and keeping the mould parallel to the middle line, let the cheek be trimmed out of winding by the thwart{ing lines, or lines which are square from the mould. Then there is a certainty, when the cheek is bevelled, no angle will appear in the throat, as there will be sometimes by the usual method, particularly in full-bowed ships, where the beav sprins more than the flight of the cheeks. When the side-arm of the cheek is trimmed
SHIP-BUILDING.

Determine the fore-and-aft arms by the flight of the cheeks laid off on the floor, there will sometimes be a very disagreeable throat, which cannot happen when trimmed by the above method. Although the side-arm may not hang so much as the sheer of the ship, yet it will not look disagreeable, because the throat of the cheek is the only part that takes the flight.

To find the Head-Rails.—Strike in the perpendiculars Z and Y from the fore-side of the figure, and perpendicular to the half-breadth of the in the queer-plan, fig. 1, down to the half-breadth-plan, fig. 2. Determine on the half-breadth of the lacing, as at 1, 2, 3, &c., as shown in fig. 1. Set off the flight lines from perpendicular Y, on the middle line in the half-breadth plan, fig. 2, and square them out to the line P, or outside of the mainrail, numbering them, as before, at the middle line; then square them out from the line P. Take the distances from the line 32 in the queer-plan, fig. 1, to the upper and lower parts of the main-rail at each perpendicular line, and set them off on their corresponding numbers in the half-breadth plan, fig. 2, which was squared out from the line P; and then, by pinning a batten to these spots, it will give the form of the main-rail, and it will shew the same form, when in its place, as that in the queer-plan, fig. 1. Where the lines squared out from the middle line in the half-breadth plan intersect the inside of the main-rail, strike them from thence square from the line P to the rail already laid off, and take the distances on these lines from the line P to the upper part of the rail, and set them down from the line 32 in the queer-plan, fig. 1, on their corresponding perpendiculars; which will give the inside of the main-rail in the queer-plan, fig. 1, as the ticked line, which rises above the middle of the rail forward, being the upper line, and below towards the after end as the after part, falls below the outside. The inside of the rail at the lower edge must be set off in the same manner in the queer-plan, in order to lay off the timbers exactly.

Strike the ticked line in the plan of the rail in the half-breadth plan, fig. 2, which is the line to which the chamfer at the under side of the rail the mouldings are intended to be wrought to. This must likewise be laid off in the queer-plan, because in a thwartship view this is the proper sight of the lower edge of the rail: for the lower part of the rail in the queer-plan (which was first laid off in order to lay off the rail to its proper cant in the half-breadth plan) may now be rubbed out, when the rail is supposed to be chamfered or wrought.

In the half-breadth plan, fig. 2, where the lines squared out from the middle line intersect the ticked line before-mentioned by the front edge of the rail, then take the distance of those lines from the line P to the lower part of the rail-laid off, and set them off from the line 32 in the queer-plan, fig. 1, on their corresponding perpendiculars. This gives the lower part of the rail in the queer-plan, at the chamfer, being the fight part of the rail when trimmed and in its place.

Before the main-rail is cant, as in the half-breadth plan, fig. 2, the proper form of it cannot be ascertained in the queer-plan, fig. 1; for the rail, when canted in order to make the mould, must be gradually diminished from one end to the other, and from thence transferred to the queer-plan; for instance, the middle line at the after-part of the rail in the queer-plan, is the aft-part of the rail at the outside; so that from thence to the fore-side of the rail shews less than the rail in the middle; also, at the foremost end the rail will not shew so much as it does in the half-breadth plan; whereas in the middle it shews the same.

Before the middle rails can be cant in the half-breadth plan, fig. 2, to their proper spread, proceed in the following manner: Strike an horizontal line from where the aft-side of the stem-timber 20, in the queer-plan, fig. 1, intersects the upper side of the upper cheek, as the line 27, in fig. 3. Take the heights from the upper side of the upper cheek, at the perpendicular line 7, in the queer-plan, fig. 1, to the upper and lower parts of the three rails L, M, and N, and set them up from the horizontal line before-mentioned in fig. 3, as you fee ticked at L, M, and N. Then take the distances from the middle line in the half-breadth plan, fig. 2, at the line 7, to the outside of the main-rail; likewise to the inside, and the ticked line for the chamfer of the rail at the under side; and set them off on their corresponding lines in fig. 3, and draw the thwartship section of the main-rail. Set off in the half-breadth plan the half-thickness of the knee S Y of the head, and the moulding of the upper cheek C C; then take the half-thicknesses of the knee at 7, or aft-side of the stem-timber in the half-breadth plan, fig. 2, and set it off from the middle line u in the plan of the timbers, fig. 3, on the line 27. Then determine the breadth of the timber at the upper side of the cheek, and pin a batten to the curve for the outside of the timber. Then in the plan of the timber, fig. 3, determine on the half-breadths of the middle rails L and M; and transfer them from thence to the half-breadth plan, fig. 2, at the aft-side of the stem-timber. Then set off the distance of the foremost end of the rails from the middle line, and strike in the two lower or middle rails N, O, in the half-breadth plan, fig. 2.

The middle and lower rails being determined in the half-breadth plan, fig. 2, the outsides of them, being the fight-sides, are the proper end to be laid off. The outside of the middle rail is marked O, and the outside of the lower rail N. Where the upper sides of the middle rail M, and lower rail L, in the queer-plan, fig. 1, intersect the aft-side of the hair-bracket H, strike the horizontal lines 33 and 34, answerable to thec in the half-breadth plan, fig. 2.

Where the lines 1, 2, 3, &c. which are square from the middle line in the half-breadth plan, fig. 2, intersect the lines O and N, let them be squared out from the lines O and N, in the same manner as was performed for P. Then take the distances from the lines 33 and 34, in the queer-plan, fig. 1, (at the same perpendiculars as before,) to the upper side of the middle and lower rails, and set them off in the half-breadth plan, fig. 2, from their corresponding lines O and N, on the lines squared out. This gives the form of the upper sides of the middle and lower rails, which is sufficient to shew the method of laying off each rail, agreeable to their different cant or spread. The lower side of the rails may be determined by the diminishing line to the moulding or depth of the rail at each end.

It is very seldom that the middle and lower rails are laid off on the floor only; the main or upper rail, when trimmed, is gotten up into its place, and moulds are there made to the head-timbers, and then the middle and lower rails are spread and equally divided thereon between the upper rail.
rail and upper check, and the moulds made to them when their situation is determined on.

But in order to shew what may be performed on the floor, the timbers of the head may not only be laid off, but the bevellings taken, and the very foars for the rails be cut out thus:

"Take the heights in the sheer-plan, fig. 1, at the side of each head-timber, from the upper side of the upper check in the upper and lower sides of each rail, for the outside of the rail, and let them up from the base line of their corresponding timber, fig. 3, striking the horizontal lines as there ticked. Then take the distances from the middle line to the half-breath plan, fig. 2, at the side of each timber to the outside of each rail, and set them off on their corresponding ticked lines, fig. 3. Where the aft-sides of the timbers, in the half-breath plan, fig. 2, intersect the inside of the middle and lower rails, let them be drawn square from the lines N and O, to intersect the lines of the rails laid off. Then take the distances from the lines N and O, on the lines squared out, to the lines of the rails laid off, and set them down from the lines 33 and 34, at the asf-sides of their respective timbers in the sheer-plan, fig. 1, making spots which form the upper side of the rails at theinside, the same as was performed for the upper rail. Take the distances from the upper side of the check in the sheer-plan, fig. 1, at the asf-sides of the timbers, to the spots last mentioned, and likewise to the line for the upper side of the upper rail at the inside, and set them up from the base line of each respective timber in fig. 3, and strike a faint line. Then take the distances from the middle line in the halff-breath plan, fig. 2, at the asf-sides of each timber, to the inside of the before-mentioned rails, and set them off from the middle line \(u\), in the plan of the timbers, fig. 3, on their corresponding faint lines. This gives the upper part of the rails at the inside. The same operation may be performed to find the lower part of the rails at theinside; or you may draw the inside of the rails perpendicular, and set down the depth of the rails agreeable to what they measure on the moulds, taken in the direction of the timber. This may determine the under side of the rails at theinside.

As the line of the chamfer of the upper rail \(N\) (being the sight-side of the rail when it is trimmed, and in its place) is before represented in the sheer-plan, fig. 1, take the height from the upper side of the check to the chamfer of the rail, at the asf-sides of each timber, and set it up from the base line of each corresponding timber, fig. 3, striking faint lines parallel to the base line. Then take the half-breaths at the asf-sides of each timber in the half-breath plan, fig. 2, to the ticked line of the upper rail, (which is supposed to be where the rail is also to be chamfered,) and set them off from the middle line \(u\), in fig. 3, on their corresponding lines last struck, and from thence draw the under side of the rail to theinside.

Having the upper side of all the rails, inside and outide, in the plan of the timbers, fig. 3, set off, draw the line for the upper side of the rails, which shews how much the inside of the half-breath is higher than the outside, if cut off in the direction of the asf-side of the timber. Then having the spots, as before mentioned, for the outside of the rails, (being on the ticked lines first drawn,) the under side of the rails may be drawn parallel to the upper, or to intersect the spot before-mentioned for the inside, which was set down agreeable to what it measured in the mould, taken in the direction of the rail, as it is marked on the mould.

Having the scores for the timbers, the half-thickness of the knee of the head at the asf-side of each timber, set it off from the middle line \(u\) on the base line of its corre-

**SHIP-BUILDING.**

loping timber in fig. 1. Likewise take the height from the upper side of the upper check in the sheer-plan, fig. 1, to the ticked curve, representing the centre line of the knee, and let it up from the base line of each timber in fig. 3. Thus will give the score to be cut off, in order to let the timber meet its opposite at the mould. Then set off the distance at the upper side of the upper check, and draw the inside and outside of the timber as described in the plan. This will be the exact form of the timbers, or more particularly, of the scores of the middle and lower rails, and laid off in the groin, might be performed to the greatest number.

To brewh the Timbers in the Head.—In the sheer-plan, fig. 1, set off the side of the timbers, and strike in their fore-side. Then figure a line from the asf-side to the fore-side, from where the asf-side intersects the upper side of the check, as at 18, 19, 20, in the same manner as was done to find the bevellings of the east-timbers.

Take the heights at the fore-side of each timber from its heel, as squared, to the upper and lower sides of the rails, in the same manner as directed for the asf-side, and set them up on the plan of each respective timber, fig. 3; then set off the fore-side of each timber in the half-breath plan, fig. 2, and take the distances from the middle line to the outside of each rail at the fore-side of each timber, and set them off on the plan of each respective timber, fig. 3, on their corresponding horizontal lines last mentioned. Where the fore-side of each timber in the half-breath plan, fig. 2, intersects the inside of the middle and lower rail, let them be squared out from the lines N and O, to intersect the lines of their corresponding rails laid off. Then take the distances from the lines N and O, in the half-breath plan, fig. 2, agreeable to the lines squared out, to the lines of the rails laid off, and set down below their corresponding lines 33, 34, 35, 1, at the fore-side of each corresponding timber in the sheer-plan, fig. 1, making spots. Then take the heights from the square line at the heel up the fore-side of each timber in the sheer-plan, fig. 1, to the spots last mentioned, and set them up in the plan of their respective timbers, fig. 3, striking new horizontal lines. Then take the distances from the middle line in the half-breath plan, fig. 2, at the fore-side of each timber to the inside of the rails, and set them off on their corresponding horizontal lines last struck, in the plan of each respective timber, fig. 3. This will give the direction of the upper side of the rails, and, if rightly performed, will be parallel to the upper side of the rails laid off for the asf-side.

In the same manner every operation performed for the fore-side as was directed for the asf-side, the heights being taken from the heel as squared in the sheer-plan, fig. 1, instead of the upper side of the check, which shews how much the rails lift at the fore-side from a square; and the half-breaths being taken at the fore-side of the timbers in the half-breath plan, fig. 2, shew how much the scores at the fore-side of the timbers are under from a square with the asf-side, because the timbers in the half-breath plan are square from the middle line.

Having the disposition of the rails for the fore-side of the timbers, let off the same distance from the rails as it is from the rails of the asf-side, both inside and outside, and mark the curves as ticked for the inside and outside of each timber, in the plan of the timbers, fig. 3. Then whatever distance the ticked lines of the fore-side are from the lines of the asf-side, so much is the outside of the timber under, and the inside flanging from a square, agreeable to the fore-side of the timber. Or, having the asf-side of the timbers laid off exactly, the fore and asf bevellings might be taken more cor-

Vou. XXXII.
rect from the half-breadth plan, fig. 2. The bevelling for the
heel of the timbers may be taken agreeable to the flight of
the upper check, because the check stands fore and aft; but
it will not answer exactly to the other bevellings agreeable
to the flight of the rails in the sheer-plan, fig. 1, unless they
are taken to the lines of the rails when laid off in the sheer-
plan; and then the bevellings must be applied close to the
fores that are trimmed for the cant of the rails.

To Lay-off the Rails to the Cant in the Sheer-Plan.—The
perpendicular lines must be drawn in the sheer-plan, fig. 1,
the same as before, and likewise those in the half-breadth plan,
fig. 3, anfwerable to them. Let fall a perpendicular from
the interfection of the upper part of the upper rail N, with
the aft-side of the hair-bracket H, in the sheer-plan, fig. 1,
down to the upper rail P, as before canted in the half-breadth
plan, fig. 2, to which point the rail mufl be suppfed fixed.
Then place a batten to the inside of the rail, as canted in
the half-breadth plan, fig. 2, and mark on the batten the
perpendiculars as at 12, and the interfection of the lines
1, 2, 3, &c.

Then in the sheer-plan, fig. 1, where the perpendiculars
1, 2, 3, &c. interfept the upper fide of the upper rail, level
aft-lines at pleafure, as you there fee ticked; then place the
batten to each level line, marking thereon its correpofponding
perpendiculars, obferving always to keep the fooniorm
perpendicular marked on the batten to the perpendicular Y.
This gives the spots to which a batten pinned will form the
upper fide of the upper rail O, and is exaftly anfwerable in
form to the upper fide of the rail N, in the half-breadth
plan, fig. 2. While the batten is pinned to the form of the
rail, mark thereon the interfections 1, 2, 3, &c.; and when it is
straight, place it to any perpendicular line, and mark the
exteriors of the rail, and the ferveral interfections, as at 26, fig. 1;
then fet off the moulded fize at each end, and strike a
ftraight line, which will give the tapering at every perpen-
dicular, and a batten pinned thereeto will form the under-side
of the rail.

In the fame manner are the other rails to be performed
in the sheer-plan. The aft-side of the after-timber being
already laid off, and the cant of the middle and lower rails
being determined on the half-breadth plan, fig. 2; let fall
the perpendiculars 35, 36, where the lines 33, 34, interfept the
aft-part of the hair-bracket H, in the sheer-plan, fig. 1,
down to the half-breadth plan, fig. 2, and proceed as
above.

It may be neceffary to notice here, that when Plate 1.
was engraved, all veffels above a frigate in the royal navy
had beak-heads, which mode has lately been discontinued:
but fuch of our readers as may be defirous of knowing the
belt method of laying-off the beak-head timbers, are referred to
the "Elements and Practice of Naval Architecture," by
Steel.

To Lay-off the several Parts of the Stern.

To Lay-off the Side Stern-Timber.—The fide stern-timber
mufl be laid off on the floor, and a mould made to it, fo that
when trimmed and put up in its place on the ship, that is, to
the tumbling-home of the fide, it fhould appear as its ticked
line in the fl eer-plan, Plate 1. from whence it is transferred
to the floor.

Strike the horizontal lines from the ftern-timber in the
sheer-plan, Plate VII. fig. 11. Laying-off A, to square-
timber 36, at the wing-tranfom, at the fide, at the knuckles
of the upper and lower counters, at the top-breadth, and at
the top-fide. Likewise strike as many between the wing-
tranfom and lower counter as may be thought neceffary,
that part being the moft critical to obtain the exact form
of the timber. Then transfer these horizontal lines to the
aft-body plan, fig. 5, as you fee ticked in the plate, and
number them accordingly. Then take off the half-breadth
of each horizontal line in the body-plan, fig. 5, at every
square timber, as far forward as timber 28, and transfer them
to their correpofponding square timbers in the half-breadth
plan, fig. 6. To these spots pin a batten, and mark the
curves, or half-breadths, and continue them as far aft as the
ftern-timber in the fl eer-plan, fig. 11, and number them in
the half-breadth plan, fig. 6, as in the plate.

Where the horizontal lines in the sheer-plan, fig. 11, in-
terfept the aft-part of the ftern-timber, square them down,
or let fall perpendiculars to their correpofponding lines in
the half-breadth plan, fig. 6, as fhewn in the plate. This
gives the ending of the after-part of the half-breadth lines.
Then take off the half-breadths of the horizontal lines in the
half-breadth plan, fig. 6, at their ending, as above-mentioned,
and fet them off on their correpofponding horizontal lines in
the body-plan, fig. 5. A batten pinned to thefe spots forms
the aft-side of the ftern-timber A, agreeable to the form in
the sheer-plan. But if these half-breadths, when fet off in
the body-plan, fhould not make a fair line, then in the half-
breadth plan, fig. 6, which seem moft to require it, mufl
be altered at the after-end, till they all correpfond to make
a fair line in the body-plan.

Now let off the moulded fize of the ftern-timber upon
each horizontal line, in fig. 11, to which pin a batten, and
the fore-side of the timber will be repreffented, and from the
mould is to be made broad enough to be anfwerable to the
fore-side of the timber.

Then, where the horizontal lines in the sheer-plan, fig. 11,
interfept the fore-side of the timber, tranfer them to their
correpfponding lines in the half-breadth plan, fig. 6, parallel
to the other lines, which are ticked down from the aft-side,
and on the half-breadth lines make the fots as you see fere
in the plate. Then take the half-breadth of each horizontal
line in the half-breadth plan, fig. 6, at the spots laft-men-
tioned, and fet them off on their correpfponding horizontal
lines in the body-plan, fig. 5. Pin a batten to thefe spots,
and mark the line B, which is the fore-side of the timber,
agreeable to the line for the fore-side in the sheer-plan.

Having in the body-plan, fig. 11, the form of the aft-side
and fore-side of the ftern-timber, as it appears upon an
horizontal view when in its place, it follows next to point
out a method to make a mould, in order to mould the
ftern, fof that it fhall have the fame appearance when it is in
its place upon a horizontal view, as it now fhews in the
sheer and body-plans. Unles there be a method which may
be depended upon for the exact heights of the counters,
it can be to no purpofe to design a view of the stern, in order
to difplay of the decks, the lights, and all other heights,
in fuch a manner, that each part may bear a juft proportion to
the rest.

Strike the line C in the body-plan, fig. 11, the thicknefs
of the mould from the fide of the timber, to which place
a batten, and keep one end well with the horizontal line at
the end of the wing-tranfom, and mark on the batten all the
horizontal lines in the body-plan. Then carry the batten
to the sheer-plan, fig. 11, and keeping the end of the batten
well with the horizontal line A of the wing-tranfom at the
fide, fet up all the heights on the batten perpendicular, and
strike them through the ftern-timber parallel to the hori-
izontal lines first struck, as you see in the plate. Where
the ticked horizontal lines in the sheer-plan, fig. 11, first
struck interfept the fore-side and aft-side of the ftern-timber,
square them up to the horizontal lines last struck. This
will give the spots, to which a batten pinned will give the
ticked
ticked lines 1 and 11, to which the mould is to be made. The last heights which were set up are the proper heights of the knuckles and horizontal lines to be marked on the mould.

The ticked lines 1, 11, in the sheer-plan, fig. 11, to which the mould is to be made, are supposed to be the straight line C in the body-plan, fig. 11, having fall at the wing-tranform, and the head lifted up till it stands perpendicular; which, if lowered again to the direction of the straight line C, in the body-plan, fig. 11, will appear exactly the same as the stern-timber itself laid off in the sheer-plan, fig. 11, which is the form of the timber required when trimmed and in its place.

In the next place, the mould should be so made, that the stern-timber shall be trimmed both ways by this one mould; that is, to the shape as it appears in the sheer-plan, fig. 11; and likewise to the fore-side and aft-side thwartship appearance in the body-plan, fig. 11.

Proceed to make the mould of dry seasoned inch-deal to the ticked lines 1, 11, in the sheer-plan, from the upper side of the wing-tranform at the side to the head G; then, when the mould is in its place, mark on it the upper horizontal lines, in the same direction as they are laid off, distinguishing them by their proper names on the mould, as the lower counter at D; upper counter at E, heel at A, No. 1 at B, No. 2 at C, No. 5 at F, and head at G. Then take the distances from the straight line C, in the body-plan, fig. 11, to the fore-side of the stern-timber B, at every horizontal line, and in the direction of the horizontal lines, and let them down in figures at the fore-side of the mould on their corresponding horizontal lines: then proceed in the same manner, and let down the distances or spilings on the aft-side of the mould from the lines C and A. But to mould the timber from those spilings requires much trouble, and without great care taken, the stern-timber will not be exactly moulded.

Therefore, the most correct method of finishing the mould, and the easiest in application when moulding the piece, is, instead of having the spilings marked on the mould, to have brackets made of 2-inch deal, agreeable to the spilings (deducting the thickness of the mould) at each horizontal line, having their ends at the fore-side and aft-side cut exactly square from the mould, or their aft-sides may reach to the round-ast; then fasten those brackets to the under side of the mould, keeping the middle of their thickens very well with their respective horizontal lines, as they appear haded in the sheer-plan, fig. 11, observing to keep the side of every bracket in the same direction from the mould as the bevel at F, fig. 11, in the body-plan, that is, to the inclination which the straight line C has from an horizontal plane in representing the tumbling-home of the stern-timber.

To be more exact, let the half-thickness of the brackets be gauged down to their ends, and the sides clamped away thereto, which will direct upon the timber, when trimmed, the exact flations of the knuckles, and also of the horizontal lines.

The brackets may be so fixed on either side, as to mould the timber for both sides of the ship.

The mould, thus made, may be applied in any direction in moulding the timber, provided its upper side is kept straight, and out of winding. Then examine where the timber, in its rough state, deviates most from the under side of the brackets, and make that the general spiling to be applied from the under side of the brackets. Wherever this spiling must be applied beyond the brackets, owing to the inequalities of the piece, let a straight-edged batton, of sufficient length, be kept well to the under side of the brackets, from which let down the spiling required, whatever it may touch the piece. Then by boring holes with a small gimlet, exactly in the direction of the gauge-line, at the ends of the brackets, and full as much below the brackets as the general spiling, you will preserve the exact moulding of the timber, after the rough wood is sawn off, agreeable to the mould.

To take the bevelling of the ast-side of the timber, the round-ast of the stern at the counters, and top-timber line, must be laid off thus in the half-breadth plan. Take the distance from the midship to the side stern-timber, on a square in the sheer-plan, Plate 1., and set it off upon the mid-line, Plate VII. fig. 6, abaft its corresponding perpendicular, as squared down from the counters, &c. at the side, sweeping curves towards the laid round-ast on a square; then fix the tongue of a bevel to the different round-ast lines, and the flock parallel to the middle line will be the bevelling of the round-ast at each place, to be applied square from the mould.

Take the bevelling to cut off the heel from the body-plan, Plate VII. fig. 11, thus: fix the flock of a bevel to the line C, and the tongue to the round-up of the wing-tranform, as at D; and apply it over the heel of the mould, when it lies in its proper place, to where the lower bracket strikes the timber.

Supposing the heel of the timber to be carefully trimmed, as above directed, a thin mould may be made to the section of the heel on the wing-tranform, and the bevellings taken to pay it to the fashion-piece from the stern-frame, as that is generally in its place before the stern-timbers are trimmed.

The bevellings for the round-up of the knuckles of the lower and upper counters may be taken from the body-plan, Plate VII. fig. 11, by fixing the flock of a bevel to the ast-side of stern-timber A, and the tongue to the round-up, as at E, and so applied from the timber when it is trimmed.

To Lay-off the Stern and Quarter-Galleries, Plate X. Laying off D.

In Plate VII. Laying-off A, the laying-off of the side stern-timber to make the mould to, is represented in its proper situation, that the reader might have a clearer idea of the operation. But we are not to suppose that any mould loft is broad enough to admit of the stern to be laid off in that manner; neither would it appear clear enough, if laid off in the body-plan.

Therefore, in some convenient part of the floor, lay off the horizontal (or level) view of the stern, as Plate X. fig. 6, from Plate 1.; and likewise the quarter, as far forward as timber 32, as fig. 4.

Strike an horizontal line at the upper side of the wing-tranform at the middle line, which will be a base line to the stern; likewise the lines 17 and 18 parallel to the bafe line, to intersect the knuckles of the lower and upper counters, at the side stern-timber 33, in fig. 4; continuing them through their respective timbers in fig. 6. Then take the heights from the base line, in fig. 4, to the knuckles of the lower and upper counters at the midship stern-timber 32, and set them up the midship line above the base line, in fig. 6. Then spring the arc of a circle through those heights in fig. 6, and as far as the quarters project, as B, B, which will be the knuckles of the timbers. Design the lower and upper counter-rails in fig. 4, and set off the projection of the plank of each counter, thus: square out a line from the knuckle of each counter at the midship stern-timber 32, as a and t, and draw the thickens of the plank of each counter parallel.
SHIP-BUILDING.

parallel to the timber, which gives the under side of the rails; then transfer the upper and under sides of those rails from fig. 4, to the middle line, fig. 6, and describe parallel curves to the knuckles 42 and 43; and the upper counter-rail B, and lower counter-rail A, will also be represented in the plan of the ftern, fig. 6, and that will shew how much the flight-part of the rails will be on a level view below the knuckles of the timbers.

But the round-up and round-aft of the counter-rails, to make the moulds to for trimming the rails, must be laid off on a square, thus: from the fore-side of the rails at the midship-timber 34, in fig. 4, square in a line from the knuckle to touch the side-timber 33; then take the distance from the knuckle of the upper counter from the midship-timber 32, to the side-timber 33, in the direction of the above square line, and let it off from any straight line, as AA, at CC, fig. 9, which is the knuckle or breadth of the upper counter, squared down from fig. 6. Then spring the arc BB, which is the round-aft of the upper counter, on a square.

Next take the distance from the knuckle of the upper counter, at the side-timber 33, to the line squared in from the knuckle of the midship-timber, and let it off as before at CC; above the line AA, fig. 9, and spring another arc, which will be the round-up of the upper counter, on a square. Proceed in the same manner with the lower counter, and we shall have both rails laid off to the round-up and round-aft on a square.

This is the best way to make the moulds for the round of the rails; because if the rails were cut out of a faying plank, or piece of thick-fluff, the round-up would be the same; that when in put in the boiler, and let to the round-aft, they would then have their proper round-up on a level view; or, were they cut out of a small piece of timber, it would answer the same purpose, and be most expeditions and exact.

The counter-rails may be cut out of a straight piece of timber, without kilning them, as they are apt to fly after that proceeds, thus: take the round-up and round-aft together, that is, from the knuckle of the side-timber to the knuckle of the midship-timber, and spring an arc thereto, as before; then when the rails are trimmed to the sheer, and the fore-side fanted to the timber, they will exactly conform to the round-up and round-aft, when put in their places.

Having the round-up of the lower and upper counter-rails in fig. 6, and continued them far enough out for the projection of the quarter-galleries, round up the quarter-deck in the stern, agreeable to the upper counter-rail, in the following manner: take the height from the upper counter-rail, in fig. 6, to the quarter-deck, in the direction of the side-timber at the inside; and let it up the middle line of the stern. This makes the quarter-deck round more than the upper counter-rail, and adds life to the stern; for the upper part of the lights in the stern should be parallel to the tranfon. And if they were to round by the fame mould as the upper counter-rail, the bars in the fables next the fide would be longer than thofe in the middle line, and would appear as if the top of the lights rounded less than the upper counter-rail. In the fame manner difpofe of the round of the poop, or round-house.

This shoud determine the round of the decks abat; and the beams of thofe decks, as they approach aft in fig. 4, must be gradually increafed in their round-up, to correspond with the tranfon.

Obferve that the above lines, in fig. 6, for the quarter-deck, fhow the round of the deck at the ftern-timbers, without confidering at prefent the projection of the balco-

Set off withinfe of the ftern-timber, in fig. 6, the thickens of the clamp, and the projection of the cornice in the cabin, and let that be the fide of the light. Then detemine on the breadth of the muctions, allowing fufficient for the weights and pulley-pieces, and divide the other lights equally. Set off likewise the mock-light in the aft-part of the quarter-galley, the fame fize as the rell. About half the breadth of the muctions from the mock-light, place the inside of the quarter-piece; then determine on the breadth of the quarter-piece at the heel. About the middle of the quarter-piece place the outside of the gallery, which determines the outside of the gallery on the quarters, fig. 4. Having the breadth of the lower part of the lights in the clear, let the depth be one-third more than the breadth at the lower part; set off upon the rake of the ftern-timbers, in fig. 4, and transfer that to fig. 6, which makes a good proportional light. But obferve, between the upper counter-rail and the lights must be room allowed for the faii-fills, and about one inch and a half between their heads and the tranfon above. Then determine on the out-bounds of the taifrail and quarter-pieces, and lower finifhing.

Next difpofe of the quarter-galley in fig. 4, fhowing the out-lines of the quarter-piece and taifrail, thus: let fall a perpendicular from the knuckles of the lower and upper counters of the midship-timbers, in fig. 4, as you fee ticked and numbered 14 and 15; then where the horizontal line 17 and 18, from the knuckles of the fide-timber, intersect the perpendiculars 14 and 15, take the diftances, and let them off from the knuckles of the side-timber, in fig. 6, down the perpendiculars, c, c, c; from thence prating the arcs 24, 24, and 26, 26, to touch the horizontal lines 17 and 18, at the middle line, which are called round forward on a level. Then will the ticked curves 24, 24, and 26, 26, be answerable to the ticked perpendiculars 14, 15, which fall from the knuckles of the midship-timber in fig. 4.

Take the heights from the bafl-line, in fig. 6, to the knuckles of each counter, at the outside of the gallery, at the ticked perpendiculars d and e, and let them up from the bafline in fig. 4, striking the ticked horizontal lines c and d. Then from the horizontal ticked lines 17 and 18, in fig. 6, take the length of the perpendiculars d and e, to where they intersect the ticked curves 24 and 26, or round forward on a level, and let them off forward from the perpendiculars 14 and 15, in fig. 4, on the horizontal lines c and d respectively, which will give the exact knuckles at the timbers, in fig. 4, at the outside of the gallery. Then take the heights of the ends of the rails from the bafl line at A and B, fig. 6, and let them off from the bafl line in fig. 4, at the knuckles of the timbers laft mentioned, and continue them forward, agreeable to the sheer of the fhip. This will give the exact heights of the lower and fecord-counter-rails, as they will appear on the fhip, if the work be conformable to the floor.

To Lay-off the Foot-Rail of the Balcony.

Here we may again repeat the obfervation, which was made about laying-off the beak-head timber, that since Plate I. was engraved, the sterns of all fhips of the line are now continued upwards to the round-aft of the second counter-rail, without any balcony, as they are much stronger so, and more useful, if guns are wanted to be used right-aft occa-

Neverthelefs, fhips of 50 guns have at prefent a balcony or walk in the stern.

To understand the exact form of the balcony-rails, as they appear in the sheer-plan, and likewife in the plan of the stern,
SHIP-BUILDING.

dern, will require much attention, and some pains taken to be made correct.

Where the quarter-deck line at the side intersects the side-dern timber, as in fig. 4, let fall the tailed perpendicular 13 to the half-breadth plan, fig. 5; and from that perpendicular set off the half-breadth of the quarter-deck at the stern-timber, from the middle line in fig. 5, as taken from fig. 6. Then square down from the last perpendicular, where the under side of the deck at the middle line intersects the midship-timber, in fig. 4, to the middle line in fig. 5; and spring an arc, as the tailed curve 1, having the round aft of the fleet, at the under side of the quarter-deck, and also at the aft part of the timbers, the heads of which run up to the under side of the quarter-deck. But items having no balcony, the timbers are continued upwards as much above the taffrail as they may be wanted, which certainly must add strength to the stern.

In fig. 5, draw the side stern-timber, which requires to project aft, about ten inches farther than the midship-timbers, as at 2, for the convenience of the necessities in the quarter-gallery, and abaft that allow three or four inches for the ballusters in the aft part of the quarter-gallery, and let that be the aft part of the quarter-deck at the side. Then design, in fig. 5, the midship part of the ends of the deck. That part, from the side-timber to the outside of the gallery, (being the aft part of the floor,) must be parallel to the tailed line 1.

Strike the perpendicular line 43 abaft fig. 4, and 5, and where the tailed line 1, which is the round aft at the heads of the timbers in fig. 5, intersects the outside of the timbers, take that half-breadth, and let it off on the perpendicular 43 from the middle line. Then take the round-up of the quarter-deck on a perpendicular, in fig. 4, at the side-timber, and set it off on the half-breadth laid taken from the perpendicular 43, and spring the arc H, which is the round-up of the quarter-deck, on a perpendicular.

Let the quarter-deck, at the middle line in fig. 4, be continued as far aft as the ends of the deck c, in fig. 5; then from the line for the under side of the deck, drop as many perpendiculars as may be thought sufficient to find the true form of the under side of the deck, from the side to the midship, as may be seen numbered 23, 3, &c. in fig. 4. Carry down these perpendiculars parallel to the line 43, to intersect the ends of the deck c, in fig. 5, and from thence carry them at parallel to the middle line, to intersect the round-up of the deck H. Then take the distance from the line 43, to the curve H, for the round of the deck at 14, fig. 5, and let it down the perpendicular 3, from the under side of the deck, fig. 4. (for pers. 2 was too small a round to be perceived in the plate); continue the same regular to 29, fig. 5, which answer to pers. 9, in fig. 4. Take the half-breadth in fig. 6, to the outside of the quarter-deck floor, and set it off square from the middle line to intersect the ends of the deck c, in fig. 5. Then carry that as before, to the curve H, the intermediate lines 21, 22, with 23, at the outside of the floor, and also carry them up to the under side of the deck in fig. 4, as 11, 12, 13.

Then take the distances from the line 43 to the round of the deck H, in fig. 5, at 21, 22, 23, and let them off below the under side of the deck, on the perpendiculars 10, 11, 12. Then through these spots, and those before set off, draw the tailed curve to the aft part of the quarter-deck at the middle line. This will be the exact form of the under side of the quarter-deck, if cut off agreeable to the plans, fig. 5, from the outside of the floor in fig. 4. Draw the tailed line 45, in fig. 4, agreeable to the lines of the hump, and set off below the line 40 about one inch and a half, or as much as the joiners require for the penilling which is at the under side of the balcony, and forms that set up the depth of the rail. This will give the exact height of the taffrail in the figure, fig. 4.

To find the proper height of the aft part of the quarter-deck at the under side of the taffrail, in fig. 4, take the half-breadth at the side of the deck to the under side of the taffrail in fig. 5, and let it off from the middle line on the base line, as in fig. 6, and exact perpendiculars far back to the under side of the deck. Then take the heights from the base line, in fig. 4, to the under side of the deck, as Nos. 2, 3, &c., set them in on their corresponding perpendiculars, in fig. 6. Through these points 1 get in a tailed line, which will give the under side of the deck in fig. 6; then set off the tailed lines of the deck, and get in the parallel lines above it. 1, 4, to the side of the taffrail, as before described, in fig. 4. This will give the exact form of the taffrail, in fig. 6, agreeable to the round-off in the plan of the quarter-deck, fig. 5.

To Lay-off the Breast-Rail of the Balcony.

It has been customary to mould the breast-rail of the balcony with the same mould as the first-space-rail is done with. But to complete the range of balconies in the balcony, so as to make them have an agreeable rake in the figure, fig. 4, and likewise a proper diminution of moulding, in the plan of the stern, fig. 6, the following method only can be relied on.

In the plan of the stern, fig. 6, let the side-timber be produced upwards till it intersects the middle line; and from that point to the above-mentioned distances at the under side of the quarter-deck, in fig. 6, make ticked lines as high as the breast-rail. Whatever height the upper side of the breast-rail is intended to be at the middle line, in fig. 6, take that height from the deck at the middle line, and let it up from the deck at the several ticked lines in the direction of the said lines, as well as at the side-timber. Through these points get in the upper side of the breast-rail, D, in fig. 6. Supposing these ticked lines to be ballusters, they should all be of an equal length. Where the perpendicular ticked lines 2, 3, &c. in fig. 4, intersect the ticked line for the deck at the side, draw them upwards parallel to the side stern-timber; then take perpendicularly the heights of each of the ticked lines at the upper side of the breast-rail from the base line in fig. 6, and set them, as taken from the base line, fig. 4, to intersect their corresponding lines last-mentioned. Through these points draw the curve K, which is the upper side of the breast-rail, as it will appear in the figure, fig. 4.

Drop the ticked perpendicular 1, from the side of the breast-rail, fig. 4, to the middle line, fig. 5, and parallel to that the ticked perpendiculars 2 to 13, which will be found to intersect the ticked lines at the upper side of the breast-rail in fig. 4. Then take the distances (or breadths) from the ticked lines above-mentioned at the upper side of the breast-rail in fig. 6, to the middle line, and set them off on their corresponding perpendiculars 2, 3, &c. from the middle line in fig. 5; a batten passed through these half-breaths forms the line G, at the upper side of the breast-rail. But observe, it only gives the form of the breadth corresponding with the side part of the deck; therefore, if the ballusters are laid off in this manner, the form of the half of the rail to the reader to apply on the deck, in order to cut off the deal, and what is intended to rebate on the ends of the deals must be added the side, and as much wood as is necessary to raise the members of the rail must be left on the mould abaté the line.
line 5. Whatever is left abaft the foot-rail mould must be also left abaft the line G for the mould of the breast-rail, upon a supposition that both moulds are made to suit the aft part of the ballusters. The half-breath of the rails only being laid off is the most correct, for then the moulds will be made in two halves exactly alike, and may be scarfed and nailed together in the middle from any straight line. The middle line and outside of the timber should be marked on each mould.

To Lay-off the Taffrail and Quarter-Piece.

The form of the taffrail and quarter-piece, in fig. 6, being laid off from the plan of the stern, Plate I., square up from fig. 5. what the taffrail projects at 24, to the quarter-deck in fig. 4, and continue it upwards parallel to the taffrail, as you see ticked; then set off the half-breath of the stern at the quarter-deck, and likewise at the top of the taffrail on the tier line 25, fig. 6, taking the round-aft at each place, and set it at the corresponding height from the above ticked line in fig. 4. This will give the ticked line T being the midship-timber at the upper part of the stern, or the fore-side of the taffrail at the middle line. Let this ticked line T be answerable to the line A A, fig. 9.

Drop as many perpendiculars from the top of the taffrail and outside of the quarter-piece, as in the left-hand of fig. 6, as may be thought necessary. Take the perpendicular heights from the base line in fig. 6, to the several perpendiculars last mentioned on the taffrail and quarter-piece, and set them up from the base line in fig. 4, and strike in the horizontal lines 22 to 31, the half being the height of the taffrail at the middle line. Take square from the middle line in fig. 6, where each perpendicular intersects the upper part of the taffrail and outside of the quarter-piece, and let them off from the middle line on the ticked line 25, fig. 6; then take the distances from the ticked line 25, to the round of the stern on a level 26, 26, at each line squared down, and let them off on their corresponding lines laid ticked in fig. 4, from the ticked line T, forward in the direction of the ticked lines. A batten pinned to those spots will give the ticked curve Q in the middle of the quarter-piece (which, in a thwartship view, is the aft part of the timbers, supposed to be continued to the heel of the quarter-piece); then abaft this ticked line set off the aft-side of the taffrail, and continue it to the heel of the quarter-piece; that will determine the aft-side of the quarter-piece, from which set forward the fiding of the quarter-piece, and that gives its fore-side, as it will appear when in its place.

The rims and fiddles might be all laid off on the floor; but it would appear confused on the plate, and perplex the reader. And, indeed, the making of a handsome quarter-galley depends chiefly on the performance on the ship; therefore an explanation may give more useful information than a drawing.

The length of the rims and fiddles being determined in fig. 4, the breadth abaft need only be taken from fig. 6, and let the fiddle at the quarter-deck serve for all the rims and fiddles in the quarter-galley, keeping the foremoist end well. At least, the same mould that moulds the fiddle at the upper parts of the lights, may mould the rim at the lower part of the lights, because the mullions in the quarter-galley should be all out of winding; and in order to make them so, the fiddle at the quarter-deck will require to be longer than the rim at the lower part of the lights, more or less, according to the winding of the top-fide. This might be allowed for exactly in laying-off the fiddles; but it is better to leave the fiddle at the quarter-deck long enough, and proceed in the following manner.

Suppose the rim at the second counter-rail to be trimmed agreeable to the form of the fiddle at the quarter-deck, and to be in its place on the ship; and suppose the fiddle at the quarter-deck to be fayed to the tide: then set off the breadth of the fiddle at the aft part, and nail a batten from thence to the rim. Then let off the mullions on the rim, and at every mullion on the rim hold a straight batten from thence to the under side of the fiddle, and look them out of winding with the batten at the aft part, or with each other, observing to set off the same distances at the under side of the fiddle from as they are on the rim. Then the wood may be dubbed away, or the fiddle taken down, and mould the under side (which will nearly agree) to every spot, with the fame mould as the rim was moulded with. Then you may be certain the fiddles will be out of winding, and, if required, would slide from one end of the gallery to the other. Then, when the mullions are let off, you may find a greater distance from the foremost mullion to the fide of the fiddle, than there will be on the rim; but this cannot be avoided, and is of but little consequence; because the canting-livre, or confole-bracket, is introduced on purpose to intercept the finishing of the gallery with the flipp-fide: for if the fiddle at the quarter-deck was to be no longer than the rim at the second counter, it would fall into the hollow of the top-side at the foremost end, and the foremost mullions in the view of the flippers, fig. 4, would appear to take more than the after ones; and when looking from before the gallery, the mullions in the lower and upper gallery would not appear out of winding, but the whole gallery would seem in confusion; therefore the upper gallery must undergo the same operation, and then it will bear to be viewed in any direction.

It is requisite, at least, to lay off the fiddle and rim of the lower gallery, and allow for the winding of the top-side, in order to mould them nearly; but by following the above method in the performance of the work, any little error that may happen will be corrected.

To lay off the lower rim B, and middle fiddle C, fig. 4, to make the moulds to, transfer the height of the upper side of the lower rim B, and upper fiddle C, in fig. 4, continued forward to square timber 32, to the body-plan, Plate VII. fig. 5, upon its corresponding square timbers. Then take the half-breaths as far forward as square timber 32, and set them off from the middle line on their corresponding timbers in Plate X. fig. 5, and produce the half-breaths, and thickness of the planks A and B without it, as far aft as in the plan, fig. 5.

Then square down the knuckles of the upper counter from fig. 4 to fig. 5, and spring an arc to the round-aft, which will be the fore-side of the upper counter-rail. Next sweep another arc to the thickness of the upper counter-rail, parallel to and abaft the ticked curve, and the upper counter-rail will be shown in the plan, fig. 5. Then take the half-breath of the upper side of the upper counter-rail to the outside, B, in fig. 6, and set it off from the middle line in fig. 5, on the ticked perpendicular 13, as squared down from the outside knuckle. Thence form the curve F, or outside of the lower rim. The ticked parallel line within is the outside of the mullions, upon which set off the flations of the lights, making them all alike, and the mullions 44, 45, 46, 47, between. Square up the mullions to the upper side of the lower rim in fig. 4; and from the spots squared up strike lines parallel to the side stern-timber, to the under side of the middle fiddle. The aft part of the middle fiddle is already laid off in fig. 5, and the form of the outside may be
be determined by the inside of the mould of the lower rim, keeping the fore and after, and allowing the additional length required by the wading of the top-side, &c. Then to prove that the outer-edge of the rim and floor are out of winding, square down the sides of the munsions from the under side of the middle floor in fig. 4, to the outside of the middle floor in fig. 5; and at the sides of the munsions, take their half-breadths from the middle line, and let them off square from the middle line in fig. 6, upon the under side of the middle floor. In the same manner take off the half-breadths of the munsions on the rim, and let them off on the upper side of the upper counter-rail. Then strike lines to these spots in fig. 6, and they will be parallel to the side timber and each other, consequently out of winding. The upper gallery rim and floors may be laid off in the same manner, and the moulds all made; observing to take the munsions of the upper lights agreeably to those below, which may be set off as follows. Determine on the far part of the upper gallery, and continue it upwards as the ticked line H, in fig. 4; then with a batten, fitted as square as possible from the fore-side of the foremost munion, mark on it the sides of all the munsions. Then fit the frame end of the batten to the ticked line H, and move it diagonally, till the side of the after-munion touches the fore-side of the quarter-piece, and mark all the sides of the munion as on the ticked line 41; then striking lines through those spots parallel to the rake of the lower munsions, the lights and munsions will be represented in the upper gallery.

The upper and lower fillings may be formed at pleasure, making them as light as possible, to please the eye, and containing sufficient room in the upper filling to hold a cuttern.

To Lay-off the Stern upon the Rake.

The horizontal plan of the stern being laid off, proceed to lay off the stern upon the rake; or, at least, the taffrail and quarter-pieces. For, were moulds made to them as already laid off, it is easy to conceive that they would be too low and too narrow, when fixed upon the stern, to its round-alt and rake; which must be the case upon the ship. In the plan of the stern, fig. 6, strike up lines in the middle of each munion, one in the middle of the side timber, one up the inside of the quarter-piece, and one between, to raise upwards to the centre of the stern, in the middle line, as marked 35, 36, 37, and 38, as on the right hand.

Draw the horizontal line B B through fig. 7 and 8, which will correspond with the ticked lines 26, 27, at the upper counter in fig. 6. Take the perpendicular heights of all the timbers, from 35 to 38, and at the inside of the quarter-piece in fig. 6, from the lines 25, 26, to the ticked curve for the knuckle of the upper counter, and set them up from the line B B in fig. 8, and draw parallel lines thereto, as you fee ticked, and numbered 9, 10, &c. Take likewise the perpendicular heights from the lines 25, 26, 27, in the intersections of all the timbers, with the under and upper sides of the taffrail and quarter-piece; and set them up from the line B B, in fig. 8, where they are ticked and numbered as before. Strike lines to the rake of the midship and side counter-timbers above the upper counter-rail, taken from fig. 4, and transferred to fig. 8, as the ticked lines 32 and 33. Draw a line square from the midship stern-timber 33, in fig. 8, to intersect the knuckle at the upper counter at the taffrail-timber, as the ticked line 30; then continue the midship-timber 32 down to the line 30; then take the distance from the midship to the side-timber in the direction of the ticked line 32, and set it off from the line B B, in fig. 7, on the ticked lines C, C, and raise the are B B, which shows how much the stern rounds off on a square, agreeable to the breadth of the upper counter, which round off gives the stern above, as before observed.

Where the timbers 35, 36, 37, 38, and inside of the quarter-piece, fig. 6, lie on the ticked line 42, or knuckle of the upper counter, square them down to fig. 7; then take the round-off of each timber from the line A A, in fig. 7, and set them off square from the midship timber 32, fig. 8, to intersect their corresponding level lines in fig. 8. Where the above timbers in fig. 6, intersect the upper part of the taffrail and quarter-piece, let them be squared down as before; and transfer the round-offs to their corresponding level lines in fig. 8, letting them off square from the midship-timber, as before. Then from these spots, down to the spots on the level lines of the knuckle of the upper counter, strike the lines of the intermediate timbers, and mark them 1, 2, 3, &c. which shews the thwartship view of the timbers, as hatched in fig. 6.

If the side-timber 33, and midship-timber 32, were prolonged in fig. 8, till they intercet each other, that would be the centre for the intermediate timbers, as disposed in fig. 6, and prove the work.

It will be necessary to have one spot at the outside of the quarter-piece, as 39, fig. 6, and squared down, as before, to the round-alt, fig. 9; then take its round-alt at 11, fig. 9, from the line A A, and set it off square from the midship-timber, fig. 8, on its corresponding level line 16, as transferred from fig. 6.

Square down the heel of the quarter-piece where it intersects the knuckle-line, 42, fig. 6, to fig. 9, to the round-alt B B. Then pin a batten to the round-alt on a square B B, in fig. 9, and keeping it fast at the middle line, mark spots on the batten, where the ticked lines 2, 4, 7, 10, 12, and outside of quarter-piece, are squared down from the knuckle-line 42, fig. 6. Then fit the same end of the batten well to the middle line, fig. 7, keeping it straight along the line B B, and thereon mark the several spots on the right hand, and leeward, as before. Then, if the floor will admit of it, continue upwards the spots in the middle of the side counter-timber, at 33, at 12, 13, fig. 7, till they intersect the middle line, and from thence, as a centre, may all the other spots be continued upwards, as in the plate. But if this cannot be performed, the heights of the timbers 35, 36, &c. must be taken up their perpendicular lines, from the line 25, 26, 27, fig. 6, where they intersect the upper side of the taffrail and quarter-pieces, and set them up from its corresponding line 28, the middle line in fig. 7, striking horizontal lines; then pin a batten, as above, to the round-alt B B, in fig. 9, and mark spots thereon at the middle line, and perpendicular lines 1, 2, 3, 5, &c. squared down from their heads; and set them off upon their corresponding heights last set off in fig. 7; then lines struck through those spots to the spots before set off on the line 25, or B B, the timbers will have their regular tumble-home, as from the centre in the plate. Then take the distance square from the line 30 in fig. 8, up each separate timber, to the spots on the level lines for the upper part of the taffrail and quarter-pieces; and set them up square from the line B B, in fig. 7, to intersect their respective timbers, and in like manner the spot at the outside of the quarter-piece; then a batten pinned to those spots will represent the boundary of the stern of taffrail T, and quarter-pieces Q, Q, on the rake, fig. 7. Then take the heights square from the line 30, fig. 8, up the separate timbers, to the heights for the lower part of the taffrail and inside of the quarter-pieces, and set them up, as before, on their corresponding timbers in fig. 7; then by pinning a batten
SHIP-BUILDING.

batten to those spots, the under side of the taffrail I, and inside of the quarter-pieces, will be completed to make the moulds to. The cove-rail D may be also marked on the taffrail mould, and likewise upon the quarter-piece mould.

Practical Directions for the actual Building.

Having now explained the usual methods of forming the draughts, and laying off the several parts of the ship, it remains only to describe the progressive manner of its actual building, or putting together the several parts.

A flap being provided, the blocks on which the keel is laid are usually about five feet asunder. Each block is laid upon a ground-way in the middle of the flap, unless a smaller vessel is intended to be built where the launch has been laid for a large ship. In this case, by keeping the blocks towards one side, the sliding-planks may be preferred for that side.

The blocks, being the foundation of the whole, must be very carefully fixed, and their upper surface to a declivity of five-eighths of an inch to every foot in the length, observing that there may be water enough to launch the ship into, and keeping them high enough at the fore-part to clear the fore-foot of the ground-ways in launching, and to admit of the sliding-planks to be laid with a declivity of about seven-eighths of an inch to a foot.

The caps or upper blocks should be more in depth than the false keel; and they should be clear-grained oak, that they may split out the easier when the false keel is put under.

The upper sides of the blocks are made straightforward and aft, and level athwartships; sometimes the after-blocks are raised above a straight line, as the great weight of the stern and overhanging generally fettle in building.

Keel is generally elm, fawn straight and square, and is scarf ed together with coaks, with tarred flannel between each scarf, which are firmly bolted together and caulked.

The rabbert for receiving the plank of the bottom may be trimmed out, leaving about a foot at each end of the scarf, for the better caulking the butts. In the navy, the rabbert is lined parallel to the upper side of the keel to the thickness of the bottom plank; but, in most merchant-ships, the rabbert is taken out of the middle of the keel, to prevent its canting, should the ship take the ground. The keel is fast fair and straight along the middle of the blocks; and, to keep it in that position, tree-nails are driven along its sides into the blocks.

Dead or rising-wood is of oak timber, and fayed upon the upper side of the keel. The pieces along the midships are of a parallel thickness, and in breadth to overhang the keel about two inches on each side. The dead-wood above and abaft, for the security of the half-timbers, is as high as the cutting-down. This part of the dead-wood below the fairing-line is trimmed to the shape of the body, and above the fairing, perpendicular to the fize of the keel. The scarefs or butts of the dead-wood should give scarf to the butts of the keel, and to each other.

Stern is composed of two or more pieces of oak timber, of the belt quality, as shifting it is very expensive. It is fawn to its fiding and moulding, and trimmed and scarfed together as the keel, and the rabbert taken out likewise.

On the stem should be marked, from the mould, the heights of the harpins, decks, cheeks, &c. and a line square from the keel, and a middle line as a guide to let it by.

Apron is also oak fawn to its fiding and moulding, and fayed to the aft-side of the stem, to secure it at the fcares, which are bolted through the apron, observing to place the bolts within the rabbets.

Bollard-timbers are oak fawn to their fiding and moulding, their heads in wake of the bowspirt to be left the thickness of the plank inside and out; they are fayed and scarfed to the sides of the stem and apron, and bolted through, where practicable, observing to place the bolts clear of the deck-hooks. Sometimes oak fillings are fayed between the stem and bollard-timbers, to keep them more open in wake of the bowspirt.

Hawse-pieces are oak fawn to their fiding and moulding, and are fayed to the bollard-timbers, and to each other, in wake of the hawse-holes; and are opened above and below the hawse-holes, for the admission of air, to about one inch and a half. When in their places, they are to be bolted to the bollard-timbers and each other, clear of the hawse-holes and breast-hooks. Let it be observed, that the hawse-pieces should be so disposed as to be equally cut by the hawse-holes.

Stern-post is oak fawn to the fiding and moulding, and should be provided for the top, and to work upwards, if to be got. The rabbert is trimmed out on each side, to receive the plank of the bottom, to the shape of the body; and a tenon left on the heel, one-third the depth of the keel.

Inner-post is oak fawn to a parallel breadth, and fided, as the shape of the body may require, below the heel; it is fayed to the fore-side of the stern-post, and a tenon is made on the heel as on the main-post, and the head left long enough to tenon an inch into the tranfort next above it.

Tranffoms are oak fawn to their fiding, whether rounding upwards or square; and to the moulding by their respective moulds. The wing-tranffom, if faved only to the margin bevelling, may be brought in for other uffes, if found defective; for tranffoms require much trouble and expense to shift them; the quality of the timber ought, therefore, to be of the best, and quite free from any defect whatever. In converting the tranffoms, let care be taken to work them top and butt alternately.

The tranffoms are to be trimmed with the greatest nicety, and then let on the post, with fcores on each side of about an inch; observing the greatest exactness in letting them down, and that they stand at right angles with the middle line on the post. The ends, when cut off to the mould, are left one inch and a half longer, to tenon and face on to the aft-sides of the fashion-piece. The ends may be opened or mouthed, to admit the air.

Fashion-pieces are oak fawn to their fiding, then to the mouldings and bevellings; and, when trimmed, let on to the ends of the tranffoms, in the manner already described.

Frame-timbers are oak fawn to their fiding, straight, and out of winding, then moulded and fawn to their respective bevellings, except the cant-floors, which are fided to their proper cant.

The frame-timbers should be converted of found well-grown timber, without fap or vein appearing in wake of the ports, and fawn full to their fidings, so that their fcatting may remain after the ports are trimmed out. Every timber should also be provided to its length, consequently each should stand upon its proper head; or if one timber happens to be short, provide the next long enough to make good the deficient length, as through-chocks should always be rejected, or only admitted on extraordinary occasions. The heads and heels of all the timbers to have one-third of the subflance left the moulding way, when trimmed; and the feats of the chocks should not exceed once and a half the fiding of the timber.

In providing the floors, care should be taken to reverse the butt end of each preceding floor, because the tops may sometimes
sometimes be scanty; and, when short of the floor-head, may be admitted, if the second futtock runs down and meets upon its respective floor.

All floors are required to have sufficient wood to seat themselves on the dead-wood, and the beams to run up to the cutting-down on the under side of the keel; then any wood wasting below the seating may be made good by a chock.

The floors, when correctly trimmed, are let down into scots cut in the dead-wood, to the exact height of the cutting-down from the upper edge of the rabat of the keel, in their respective situations; set precisely level, and at right angles with the middle line of the keel. The floors are then ribbanded and floored, securing the floors at the head and heel to prevent any alteration; for the truth and precision of the whole fabric may be said to depend upon the accuracy of the floors, when set into the ribbands.

Futtocks.—The several futtocks are trimmed straight, and out of winding on the joint side; and the lower futtocks in the navy run down to the side of the dead-wood, but in merchant-ships they are from nine to twelve inches short of the keel, that water may not lie above the ceiling. The wood wasting on the inside of the lower futtocks, in the navy, is made good by cross-chocks up to the cutting-down.

The timbers that compose a frame, or bend, are bolted together, either close or opened, as required: the joint-side of the second futtock to the joint-side of the lower futtock, to the middle of its length or paying, and bolts thereto with three bolts of square iron. The heel of the third futtock joins the head of the lower futtock, and bolts, as the former, to the second futtock; the heel of the fourth futtock joins the head of the second futtock, and bolts to the third; and the heel of the top-timber shears on the head of the third futtock, and is bolted or fastened with tree-nails to the fourth futtock, taking care that no bolts are driven in wake of the ports or port-fills.

They are raised into their places by sheers and tackles, and great care should be taken that the frame be not strained in hoisting, as its form would be altered, and of consequence the true shape of the body lost; to prevent which, the joints of the sheers and heads are secured by nailing quarter over them, and a shore fitted on the inside or bag of the frame.

The frames, as hoisted, are kept to their true breadth, and equally distant from the middle line, by the cross pales, which are nailed at the main height of breadth, or in the ports: the latter is preferable, if not thought too high, because the ends need not be cut, and they may remain till the ship is planked, and the beams in and kneeled.

The frames are next ribbanded thus: the cant-frames may be gotten near to their flating by the harpin-moulds, then the harpins gotten up; and, if the frames come fair, may be nailed and floored to their timbers.

The square frames, corresponding at the floor-farmark or guide, must be levelled, and the joints set at right angles with the middle line, observing that the spacing of the ports agrees. The ribbands may then be nailed and floored, and the lower futtocks bolted to the floors.

Filling-timbers, or the timbers between the frames, are trimmed and hoisted into their place separately; then equally spaced asunder, and nailed to the ribbands; then chocked at their heads and heels, and the whole frame dubbed fair inside and out to its scantling for planking.

Keelson is oak fawn to its fiding and depth, or moulding, then fayed along the middle of the floors, and bolted through every floor and the keel, with three or more dows on each leaf, which should give as much fast as possible to the leaft of the keel. In from 3 feet to 4 feet of the keel planks have been fayed upon the upper side of the keel, and the bolts driven through that keel planks.

Stemens is oak fawn to its fiding and moulding, then trimmed and fayed to the orphan, and fainted with lower or double into the first part of the keel. The bolts through the fird planks of stem will be considered, and the two bolts may then be driven through between them.

Stemmen, or keeves, is oak fawn to its fiding and moulding, then trimmed and fayed against the transoms and supports of the dead-wood, and shears with a hook, or double into the after-piece of the keel. It is bolted to the frame, and then joint as the keel planks, of which it is a continuation.

Wales are next wrought, and the thickest fluff below them: they should be fainted with a stuffing for the frame, as the tree-nail holes, which are double and square alternately in every timber, and should be left open as long as possible, for the admission of air. A douil is the timber next each butt in the wales, in the hark above and below it, has been lately introduced in the navy, as an additional security. The wales and diminishing harkes are then doubled down fair, and large cleats nailed at the first part of every port, to which the hark is subliminally floored.

Planking.—The bottom is next planked down sufficiently low to work the orlop-clamps. See Planking expanded, Plate V. II.

Inboard Clamps, Thick-fluff, &c.—These are wrought similar to the outisde fluff above. The clamps to the floor of the deck, and their upper sides to the round-up of the beam, and the lower edge, square to the timbers, unless they work down to the ports; then, in wake of the ports, the lower sides are trimmed level, and between the ports square to the timbers. Clamps over ports are bearded from half their depth to one inch less in thickness on the under side, excepting over the ports, where the wood is left on, for the muzzles of the guns to have to; and the douils are doubled as the wales.

The thick-fluff is to be wrought with a square close edge over the joints of the timbers; and the sprikings are to have a beam allowed, agreeable to the thickens in the outisde fluff, which should be a full sixteenth to every inch in the thickens.

Beams are fawn to their fiding, and to the moulded depth square to the fiding. Beams of two, three, or four pieces are scarfed together; and if in three or four pieces, the middle pieces may be fit, excepting in the hatchways.

Beams in two pieces have a scarf one-third the whole length of the beam. Beams in three pieces have the middle pieces and the end pieces each half the length of the whole beam, the middle piece having a scarf each way to take the arms. Beams made of four pieces have two middle pieces, each similar to the former: the arms and middle pieces are each to be in length three-sevenths of the whole length of the beam. See Gun-deck, Plate V. I.

Beams are either tabled or douelled, and bolted together at the scarfis: if tabled, the lengths of the tables are once and a half the moulded depth in length, and divided at the middle of the depth; and where the wood is taken out on the upper side, it is left on the lower side, and so alternately; taking the wood out on the upper side at the table next the butt, as it will the better hang and support the lip. At each lip, beyond the tables, is a coak about six inches long; and next to that is a straight lap, about the same length.

The beams, when cut off to their length, have their ends mouthed and charred, and then are let down about one inch into
into the clamps, at their several stations, at right angles with the middle line; keeping their upper sides out of windings with the beam line.

Knees.—The beams, at their ends, are connected to the sides by knees, or other substitutes for knees. The knees are fawn or trimmed to their fiding, and fayed to the fide, taking as little wood as possible out of the throat the moulding way, as the greatest strength of the knee is there. Each knee tapeyers towards the toe to which it is fided; and the subflance in the throat should be about twice and a half the fiding, and not to admit of any chock that would reduce the knee at any part less than the fiding.

Each knee should have two douls in the beam-arm, and from three to four bolts; and the two upper bolts in the fide-arm of the hanging-knees should be kept up as high as possible, and the others equally spaced to the toe, and bored as square to the fide as the frame outsife will allow.

In those parts of the ship afore and aft, where wooden knees cannot be procured of kindly growth, (for upon that depends the strength,) knees of iron are generally placed. These, although much used, particularly in merchant-ships, cannot be so fully depended upon as those of wood, because they cover less surface, are noT wise flexible, nor can the bolts be driven so tight in iron as in wood. If, therefore, the ships strain, they must inevitably work loose. Again, the holes must be bored in the direction in which the knees are placed, so that the iron knees are intended to be placed, oak fillings should be driven between the timbers; otherwise the bolts may come in the openings, which is inadmissible. Besides this, the bolts may come in the fames of the outside plank; when it so happens, the belt way is to cut out a piece, and clenche the bolt upon the timbers.

Bolts in wooden knees are mostly driven from the outside, and clenche upon the knees inside; but bolts in iron knees are driven from the inside, with collar or stout heads, because upon the head depends its fastening; or if the bolts be of copper, they must havc a ring under the head, and the head spread or made large in driving. All bolts driven from the inside should be carefully clenched upon a ring, let fiush into the plank, by means of a machine or centre-bitt for that purpose, and the points under water carefully caulked after the ring is let in.

Wooden knees having becom scarce for some years past, many substitutes have been attempted; and iron knees, or rather knees formed of iron and wood conjointly, are certainly best when properly applied. See Substitute.

Standards, either on the deck or to the fides of orlop beams, are fo familiar to knees, as to require no further description.

Breast-hooks, steps, and crutches, are oak, fawn to their fiding, then moulded. The deck-hooks are fayed to the timbers, the others to the inside fluff. The holes for the bolts are bored alternately, near the edges, equally aluncifer, and square with the body. Breast-hooks, steps, and crutches, are affixed in the moulding by chocks; and the deck-hooks may be affixed by large eakings, worked behind them. All the chocks, &c. are douelled or tabled, and ought on no account to have less wood or substance than their fiding, clear of the chock.

Riders are oak fawn to their fiding, moulding, and bevelings; then fayed to their respective places, as follows.

Floor-riders in two pieces have a crofs-chock fayed over the heels, with a hook and but scarf; their heels run down to the limber-flate, and the heads run upwards between the joints of the floor-heads and firft futtock-heads.

First futtock-riders fay close to the fides of the foor-riders, and their heels extend downwards within four feet of the keel; their heads run upwards between the joint of the firft futtock-head and under side of the orlop-beams, with a crofs-chock fayed over the heels as the floor-rider.

Second futtock-riders fay close to the fides of the firft futtock-riders, and scarf with a hook-scarf under the head of the floor-riders, or connect thereto with a chock. Their heads run up within two inches of the under side of the gun-deck beam, and are fawn with a swell at the orlop-beam, to which they fayl sideways; and they bolt through the beam and the adjoining riders fore and aft.

Third futtock-riders fay bolt and fay to the fides of the second futtock-riders, and are fawn with a swell, as the above, at the gun-deck beam. The heads run up within two inches of the under side of the upper deck beam, or middle deck, in three-deck ships; and the heels come within two inches of the upper side of the orlop-beam.

Ships in the navy at present have no inside fluff below the clamps, but have their timbers filled in between with dry flakes of oak, driven in tight and caulked; and the riders are fayed over the timbers, and fland diagonally at the angle of forty-five degrees.

The knee of the head is oak, each piece fawn to its fiding, agreeable to the tapered batters, where they interact. The main piece should make the lower part of the knee, and run up to the fore part of the elem, to which it fays high enough for a hole to be cut in it to receive the main-flay collar. The front piece runs up to feature the figure, and should be broad enough to take the hoefay holes and the Venk end flay in the main piece about one foot below the load draught of water. Another piece must be provided to make the facing to secure the figure. The other pieces between may then be provided, as most convenient, marking on the mould the shape of each piece, as provided; the surface of each piece is then fayed close together, and douelled. The knee is hoisted up into its place, and then bolted with seven or more bolts through the flen and apron, and some times through the deck-hooks.

Cat-heads are now fawn straight, fideaways, and plumb, moulded to fliight, in ships of the line, to five inches in a foot above a level line without the bow; and in frigates and smaller vessels, to the angle of forty-five degrees. The inner end fays up to the under side of two or more of the forecattle beams, so as to fland square with the bow.

Supporters of the cat-heads are knees of oak fayed to the under side of the cat-head, and the arm to the flde to fland perpendicular; the upper arm bolted through the cat-head, and the other through the flde.

Rudder.—The main piece to be oak fawn to its fiding, and the upper part to the given dimensions, and the lower part to be moulded as broad as the piece will admit. Whatever the main piece may require to complete its f Sid^-may be elm, fayed close to the main piece, and douelled. The other pieces to complete the surface of the rudder may be fir, fayed close to the main piece and each other, and douelled. The whole is then trimmed fithrough to its thickners, and bolted together between the straps of the pintles. The back is then fayed on, and fastened to the aft-side, and the fole at the heel; when cut off to its length, which is nine inches short of the under side of the keel. The fore-side may be then bearded from the middle to two-fifths the thickners, lined down on each edge; but this has been found to cut or wound the main piece so much at the upper pintle, that, lately, the aft-side of the stern-poit is likewise bearded at the upper end; and consequently the fore-side of the rudder so much the less. The pintles may next be let on thus: the braces being let on to the stern-poit, and square from the ast-side, a staff of the whole length.
material

The head, if not round-headed, is thirded and bearded back about three-quarters of an inch, and the edges taken off to a hold round. The 1 lbs. for the tillers may now be cut through the lower half three inches clear of each frame, and the higher part of the upper half three inches clear of the deck; latey, the head-hoops may be driven on.

Amongst all other useful machines for drawing bolts out of flats (the Boleris), the following was invented by Mr. William Hall. See Transactins of the Society for the Encouragement of Arts, &c. vol. x.

"First, The use of this machine is to draw the keelson and dead-wood bolts out, and to draw the knee of the head bolts. Secondly, The head of the keelson bolts here before were all obliged to be drawn through the knee, floor-lumbers, and knee, to get them out: by this means the keelson is entirely ruined, and a large hole the head makes materially wounds the floors; and frequently, when the bolt is much corroded, it works loose and the bolt comes out of the side of the keelson. Thirdly, The dead-wood bolts that are driven with two drifts, or 1 lb. dam or new, out, by which means the dead-wood is condemned, so some of it is easily serviceable. Fourthly, In driving the knee of the head bolts, sometimes the keelson flares off, and it must be got to again, but is furred up; but with this machine it may be drawn away again."

In Plate XIV. Ship-buildings, fig. 3. A represents two strong male fresws, working in female fresws, near the extremities of the cheeks, against plates of iron, E. E. C C is the bolt to be drawn, which, being held between the chaps of the machine at D D, by turning the fresws by the lever B, forced out of its hold. F F are two dogs, with hooks at their lower extremities, which, being driven into the plank, serve to support the machine till the chaps have got a full hold of the bolt. At the upper part of the dog, are two pins passing through holes in it, and in the head of the bolt. Fig. 4, is a view of the upper side of the machine, where A, the hole is which the bolt passes out of work; B, the chaps, which is has no fresw over it, the head of the bolt is more by the two pins, V 6, of the chaps, apart from the sides, the letter is &

SHIPLUND, or Shippond, in Camden, a large weight: Hill, Derby, Warwick, and Shropshire, contain, each, one, or two, none in the other places. At London the shippond contains 3 cents, 20 lyndons, 371 lbs. 14 oz., and 320 lbs. A lyndon is 15 lbs., and 3 oz. At Ipswich, a shippond contains 12 shipponds, each of 20 lyndons, or 240 lbs.; and all shipponds are half a lyndon in 320 lbs. At Hamburg, a shippond contains 23 cents, 20 lyndons, or 25 lbs., a lyndon is 14 lbs, and a centner 15 lbs. Hamburg weight. At Copenhagen the shippond contains 3 cents, 20 lyndons, or 320 lbs.; a lyndon is 16 lbs., and a centner 161 lbs.

SHIPLEY, Jonathan, in Geography, an English poet, was born in the year 1714, and was educated at Christ Church, Oxford, where he wrote some verses upon the death of queen Caroline; and in 1736 he took his degree of M.A. Soon after this he entered into holy orders, and obtained a living. In the year 1744 he was imlisted prebendar of Winchelsea, and in 1748 appointed chaplain to the Duke of Cumberland, whom he accompanied abroad. In 1749 he became canon of Christ church, and in 1760 dean of Winchelsea. In 1756 he was advanced to the bulk of St. Asaph. He died in 1788. He was author of poems, and sermons on public occasion.

SHIP-MONEY, an imposition which was most heavily charged upon the ports, towns, cities, boroughs, and counties of the realm; by virtue commonly called ship money, under the great seal of England, for the provising and furnishing certain ships for the king's service. This imposition was revived by king Charles I. in the years 1635 and 1636; but by Act 17 Car. I. it was declared to be contrary to the laws and statutes of the realm, claim of right, liberty of the subject, &c.

SHIPPANDSTOWN, in Geography, a town of Virginia, on the south side of the Patsowack; 40 or 50 miles from Alexandria.

SHIPPENSBURGH, a town of Pennsylvania, in Cumberland county, on branch of Conadium, west creek, which divides itself into the Shenquebbagh; containing about 200 houses, chiefly built of stone, 1750 of years, and three meeting-houses, one for Quakers, one for Gospellers, and one Methodist. It derives its name from its proprietor John Shippen, esq., of Philadelphia, who leased out the land in small lots to the crown, except from two to four acres a year; 120 miles W. of Philadelphia.

SHIPPER, or Shipper, a Dutch term, signifying the master of a ship. We also use the word, properly, for our countrymen.

SHIPPIGAN, or Shipigian, in Geography, is the cult of St. Lawrence, on the south side of Canada, S.W. of, and separated by a narrow chanel from Moscow island.

SHIPPING, denotes a multitude of vessels.

SHIP-SHAPE, in Salt Lake, is the state of a ship, or the manner of an expert lake; as, they
fay, the maff is not rigged ship-shape, and trim your fails ship-shape.

SHIPSTON-UPON-STOUR, in Geography, a market-town in the upper division of the hundred of Ofwald-flow, and county of Worcestershire, England, is situated in a district entirely detached from the body of the county, and close to the left bank of the river Stour, whence is derived the latter part of its name. The houses here are chiefly built of flone; but notwithstanding this advantage, the town cannot boast much of its appearance, many of them being small, and thatched with straw. Several attempts have been made to establish manufactures here, but without any permanent success. The market-day is Friday, weekly; and there are two annual fairs, one on the 22d of June, and the other on the first Tuesday after the 10th of October; both of them for horses, cows, and sheep. The manor of Shipston formerly belonged to the priory of Worcester, and is now part of the possessions of the dean and chapter. The church is only a chapel of ease to the mother church of the parish of Tredington, which extends about nine miles in length and two in breadth. According to the population returns of 1811, the parish contains 297 houses, and 1377 inhabitants, of whom about 1000 reside within the township of Shipston-upon-Stour. Nash's Survey of Worcestershire, 2 vols. fol. Beauties of England and Wales, vol. vi.

by Mr. Loud, 8vo. 1813.

SHIPTON, a flourishing township, of excellent land, in Lower Canada, on the east bank of the St. Francis; 20 miles N.W. of Acot, and containing about 356 inhabitants.

SHIPWRECK. See Wreck.

SHIRAVERD, in Geography, a town of Peria, in the province of Ghilan; 30 miles S. of Altara.

SHIREBURY, a town of Syria, the residence of a sheik; 15 miles E. of Aleppo.

SHIRBORN, a river of England, in the county of Warwick, which runs into the Sow.

SHIRE, Scyrin, originally Saxon, shir, or shires, formed from scriran, to divide; a part or portion of the land, called also a county; which fee.

SHIRE-Clerk, he that keeps the county court; and his office is so incident to that of the sheriff, that the king cannot grant it away.

SHIRE-Man, was anciently the judge of the shire, by whom trials for land, &c. were determined.

SHIRE-Mote, in our Old Writers, an assembly of the county or shire at the aules, &c. See Scyregemot.

SHIRE-REVE. See Sheriff.

SHIRE, Knights of the. See Knight.

SHIREWOOD or SHERWOOD FOREST, in Geography, is an ancient and extensive forest, comprehending a large portion of the county of Nottingham, England. Thoroton, in his History of Nottinghamshire, says that it stretches into the hundreds of Broxton, Thurgarton, and Bassetlaw; and measures about twenty-five miles in length, by from seven to nine in breadth, an extent which seems to agree with its ancient boundaries, as stated in a perambulation made in the sixteenth year of Henry III. The period when this district was originally constituted a forest is unknown, but that event must have occurred previous to the time of Henry II., as in the first year of that monarch's reign, it appears from official records, that William Peverel was called upon to answer "De Placitis Foretarum in Comitate Nottingham." At that time Peverel had the whole profit and command of this forest; but it must soon afterwards have reverted to the crown, for in 1161 the sheriff of the county prays to be discharged of "f. in valto forestae," and in 1163 he prays for a similar discharge, and for the discharge of "40l. paid to the canons of Shirewood for alms." In the Forell books is inserted a copy of a charter by king John, granting to Matilda de Caux, and Ralph Fitzlephem her husband, and their heirs, all the liberties and free customs which any of the antecedents of the said Matilda, lords of Laxton, had held in Nottinghamshire, including the forest of Shirewood. The same rights afterwards fell to John Barking, as heir-general to Matilda de Caux; and in 1226 the forest is mentioned as being then in possession of his son; but this line failing, it descended to the family of the Everinghams, in whom having lost their possessions by forfeiture in the reign of Edward I., it reverted to the crown. Since that event, its civil jurisdiction has been generally vested in the sheriffs of the county, and its forest jurisdiction only granted to various individuals among the nobility and gentry, as special marks of royal favour. An inquisition taken before Geoffrey de Langley, in the reign last mentioned, illustrates the customs of this forest. By it the chief keeper appears to have been obliged to have three deputy keepers for a like number of districts, in order to attach all trespasses, and prevent them at the attachment before the verderers. In the first keeping, which lay between the rivers Lene and Doverbeck, he was to have one forester riding with a page, and two foresters on foot; two verderers, and two agisters. This keeping contained the three hundreds of Baskwood, Lindeby, and Willey. The High Forest, including the hundreds of Birkland and Bilbigh, and the park of Cliffton, formed the second keeping; and here were two foresters riding, with two pages and two agisters. The third keeping, Runnwoode, had one forester on foot; two woodwards, one at Carburton, and the other at Budby; and the same number of verderers and agisters. The chief keeper was further bound to have a page bearing his bow, whose duty it was to gather "chimineage," which is usually supposed to have been a tax for the formation and preservation of roads. By the last survey made of this forest in 1609, it was parcelled out into three walks, called the north, middle, and south walks. The forest officers, under the superintendence of the chief justice in eyre north of Trent, are a lord warden, a bow-bearer and ranger, four verderers, a feward, and nine keepers, besides two sworn woodwards for Sutton and Carleton. The surveyor-general of the woods has likewise a jurisdiction over this forest, as far as regards the wood and timber of the crown. He has a deputy in the forest, who has a fee-tree yearly, and a salary of 20l. Thorneyc-wood Chace, though a branch of this forest, is distinct from it in jurisdiction, having been granted by queen Elizabeth to John Stanhope, esq. and his heirs, as hereditary keepers. This chase comprehends a large portion of the south walk, and was formerly well stocked with fallow deer; but these, of late years, have greatly diminished in number.

Of the ancient woodland in this extensive tract, little remains except in the hundreds of Birkland and Bilbigh, which form an open wood of large old oaks, covering about 1500 acres of ground; but modern plantations have lately increased rapidly, and there are, in different districts and parks, a few trees, remarkable alike for their great age and magnitude. In Cliffton park is an immense oak, called the Parliament Oak, from a tradition that a parliament was assembled here by Edward I.; and in the same park is another tree, styled the Broad oak, the bole of which measures 27 feet in circumference. Many of these venerable oaks may likewise be seen in Welbeck park, on the skirts of the forest, where some of them are upwards of 44 feet round. Rookes, in his "Sketch of the Forest," mentions a recent discovery of a very curious mode of ascertaining the great antiquity of some of these trees. He tells us, that in cutting down some timber in

Birkland
Burkland and Billagh, letters were found cut or damp'd in the body of the trees, dotting the king's reign in which they were so marked. The cyphers were of King John, James I., and William and Mary. The mark of John was eighteen inches within the tree, and about a foot from the centre; it was cut down in 1509; but the middle of John's reign was 1529, from which, if we subtract 120, the number of years requisite for a tree of two feet diameter to arrive at that growth, it will make the date of planting 1387.

The forest of Shirwood was, in ancient times, frequently the scene of royal molend. As early as the reign of Henry II., Maudfield was the general residence of the court upon these occasions, and it was in this vicinity, according to tradition, that Henry made acquaintance with the miller of famous memory, John Cokele. This forell was likewise the retreat of another personage, equally celebrated in the chronicle of L Ballard, the illustrious Robin Hood, who, with little John, and the rest of his associates, making the woody yew of its thyme, laid the whole county under contribution. Thoroton's History of Nottinghamshire, republished, with additions, by John Thirkell, 3 vols. 4to. 1590. Beauty of England and Wales, vol. xii. by Mr. Lord, 8vo. 1813.

SHIRKING, one of the Kurile islands, about 26 versts from Pomoruzh'th. It rises a round mountain top; and about it, on the coast, walks of rock and loose brittle stone, but it has no sandy bay, nor any safe inlet for shipping. The island is nearly as broad as it is long, and may be about 40 versts in circumference. It is only inhabited by fea-huns and other marine animals, with some red foxes and sea-fowls that have been carried thither with the ice. There is no wood on the island, except a few flocks of the mountain pine and some elder bushes; and it has neither a stream nor a spring of water. The rocks are very much disjointed and fall in fragments. N. lat. 50° 40'. E. long. 138° 5'.

SHIRLEY, Anthony, in Biography, second son of Thomas Shirley of Welton, in Sudley, a celebrated traveller, was born in 1565. He studied at Oxford, where he took his bachelor's degree in 1581, after which he joined the English troops, which, at that time, were serving in Holland. In 1596 he was one of the adventurers who went to annoy the Spaniards in their settlements in the West Indies, and on his return he was knighted. After this he was sent by the queen into Italy, in order to affright the people of Ferrara in their contest with the pope; but, however, he arrived, all the disputes were accommodated, and peace was signed; he accordingly proceeded to Venice, and travelled from thence to Perse, where he came in great favour with Shah Abbas, by whom he was sent ambassage to England in 1612. By the emperor of Germany he was raised to the dignity of count, and by the king of Spain he was appointed admiral of the Levant seas. He died in Spain about the year 1630. There is an account of his life in his own Expedition in the third volume of Huet's Collection, under the following title: "A True Relation of the Expedition undertaken by Sir Anthony Shirley, Knight, in 1596, intended for the Island San Tome, but performed to St. Jago, Dominica, Margarita, along the Coast of Tierra Firma to the Isle of Jamaica, the Bay of Honduras, Thirty Leagues up River Dolee, and homewards by Newfoundland, with the memorable Exploits achieved in all this Voyage." His travels into Perse are printed separately, and were published in London in 1613; and his travels over the Cappan sea, and through Russia, were printed by Pococke's Parmenius, 1727.

SHIRLEY, James, a poet and dramatic writer, was born in London about the year 1594. He received the early part of his education at Merchant Taylors' School, from which place he was removed to Oxford. He was, on account of his talents, patronized by Dr. L'Estrange, who, however, would not consent to his utter orders, by reason of his being disqualified by a large rent on his pious estate, which, in his estimation, according to the rules of the church, rendered him unfit to officiate in clerical duties. Shirley therefore left Oxford, without a degree, but he afterwards removed to Cambridge, and, writing with such facility, he took orders, and delivered a curacy. His religious creed was not sufficiently settled, and he went over to the church of Rome, where he joined his orders, and opened a grammar-school at St. Albans. After some time he deserted this employment, and became a writer for the stage. His productions were successful, and he acquired a reputation which enabled him to be taken into the service of Queen Henrietta-Maria. When the civil war broke out, he accompanied the earl of Newcastle in his campaigns, and also assisted him in the composition of several of his plays. On the ruin of the king's castle he came to London, and assumed his occupation of a school-master, in which he met with considerable encouragement, and he showed his attention to the duties of his office, by publishing some works on grammar.

During the Commonwealth, theatrical amusements were suppressed, Shirley had no room in which he could display his dramatic talents; but after the Restoration several of his pieces appeared on the stage. The death of this author is thus described: his house in Fleet-street being burnt in the great fire of London, in the year 1666, he was forced with his wife to retire to the suburbs; the consequence of the fire and the alarm which this occasioned, both himself and wife died within a few hours of each other, and they were buried in the same grave.

Mr. Shirley was author of thirty-seven plays, consisting of tragedies and comedies, and of a volume of poems, published in 1646. He had the reputation of being the chief among the second-rate poets of his time, but his works have long since disappeared from the stage, and they are scarcely ever referred to by modern authors; yet there have been critics who thought highly of them. Dr. Farmer, in his Essay on the Learning of Shakspere, favours the imagination of Shirley is sometimes fine to an extraordinary degree. He alludes Mr. Ogilvie in his translation of Homer and Virgil, with pleasing notes on them.

SHIRON, or Shorison, a town of Thibet; 120 miles N. of Catmandu. N. lat. 30° 10'. E. long. 85° 5'.

SHIRVAN. See Shirvan.

SHISNIEZ, a town of Poland, in Volhyna; 12 miles N. of Conflantina.

SHITAKOONTHA, a name of the Hindu deity Siva. It means the blue-throated; and the fable accounting for the name is often alluded to in the writings of that fanciful people. It relates, that when the ocean was churned, in the manner described under our article KURMATAVARA, poison was produced among the fourteen precious articles resulting from that marvellous operation. The word, as well as poison, means medicinal drugs. This was swallowed by Siva.

"To soften human ills, dread Siva drank
The poisonous flood that flowed his azure neck."

In the songs of Jayadeva, translated by Sir W. Jones, in praise of Vishnu and Lakshmi, under their names of Kritika and Radha, the following passage occurs, which we are in
duced to extract as an instance of the playful gaiety of Hindoostane poetry, and the prevalence of mythological allusions, in all their writings. Heri and Narayana, we may premise, are names of Vilhun; and Padma, or the Lotos, of Lakshmi.

"Whatever is delightful in the modes of mufic; whatever is divine in meditations on Vilhun; whatever is exquisite in the sweet art of love; whatever is graceful in the fine branches of poetry,—all that let the happy and wise learn from the songs of Jayadeva, whose soul is united to the foot of Narayana. May that Heri be your support, who expanded himself into an infinity of bright forms, when eager to gaze with myriads of eyes on the daughter of the ocean, he displayed his great character of the all-pervading deity, by the multiplied reflections of his divine perfon in the numberless gems on the many heads of the king of serpents, whom he chose for his couch: that Heri, who, removing the lucid veil from the bofon of Padma, and fixing his eyes on the delicious buds that grew on it, diverted her attention by declaring, that when she had chosen him as her bridegroom, near the sea of milk, the disappointed husband of Parvati drank in despair the venom which dyed his neck azure."—Jones's Works, vol. x. Af. Ref. vol. iii.

The many-headed king of serpents is named Sehha, a frequent subject of poetical exuberance. See Seshā.

Of the blue-necked Siva, Íntikanatha is another name, of similar meaning as that at the head of this article; and which indeed occurs oftener than Síntakantha, or Íntakanatha.

SHITTAT, in Geography, a town of Arabia Deserta; 50 miles W.N.W. of Melched Ali.

SHITTEN BAY, a bay on the W. coast of the island of St. Christopher.

SHIVAL, a town of Hindoostan, in Viflapour; 25 miles E. of Baddamny.

SHIVERAPILLY, a town of Hindoostan, in the cir-
car of Cicacole; 20 miles W. of Cicacole.

SHIVERS, in a Ship, the seamen's term for those little round wheels in which the rope of a pulley or block runs. They turn with the rope, and have pieces of brass in their centres, which they call the cock, with holes in them, into which the pin of the block goes, and on which they turn.

These shivers are usually of wood, but some are of brass, as those in the heads of the top-masts. See Sheave.

SHIVERS, in Rope-making, the foul particles taken from the hemp, when hatchelling.

SHIVERING, the flute of a sail when the wind is too oblique to fill it, so that it flutters about. This must be the case when a vessel is put about, till the sails are filled again with the wind.

SHIVERY SALT, a name given by the salt-workers to a fort of salt, very little different from the brine-salt. See Salt.

SHIUMLA, in Geography, a town of Bulgaria, in the fanjacat of Dridra. In this place, thought by the Turks to be impregnable, they were defeated by the Russians with terrible slaughter; 62 miles E. of Varna. N. lat. 43° 10'. E. long. 26° 27'.

SHIZAR, a town of Syria, in the pachalie of Aleppo; 15 miles S. of Famieh.

SHOAD, in Mining, a term for a train of metallic stones mixed with earth, sometimes lying near the surface, sometimes at considerable depths, but always serving to the miners as a proof that the load or vein of the metal is thereabout. The deeper the shoad lies, the nearer is the vein.

SHOAD-Stones, a term used by the miners of Cornual, and other parts of this kingdom, to express such loose mafles of stone, as are usually found about the entrances into mines, sometimes running in a straight course, from the load or vein of ore to the surface of the earth.

There are shoads of the common kinds, appearing to have been pieces broken from the flata, or larger mafles, but they usually contain munde or maccaric matter, and more or less of the ore to be found in the mine. They appear to have been at some time rolled about in water; their corners being broken off, and their surface polished and rounded.

The antimony mines in Cornwall are always easily discovered by the shoad-stones, these usually lying upon the surface, or very nearly so; and the matter of the stone being a white spar, or deabed crytal, in which the native colour of the ore, which is a shining blueis-black, easily discovers itself in streaks and threads.

Shoad-stones are of so many kinds, and of such various appearances, that it is not easy to describe or know them: but the miners, to whom they are of greatest use in the tracing, or searching after new mines, distinguish them from other stones by their weight; for if very ponderous, though they look ever so much like common shoads, there is great reason to suspect that they contain some metal. Another mark of them is their being spungy and porous; this is a sign of especial use in the tin countries, for the tin shoad-stones are often so porous and spungy, that they resemble large bodies thoroughly calcined. There are many other appearances of tin shoads, the very hardset and firmest stones often containing this metal.

When the miners, in tracing a shoad up hill, meet with such odd shoads and earths, that they know not well what to make of them, they have recourse to vanning, that is, they calcine and powder the shoad, clay, or whatever else is supposed to contain the metal; and then valling it in an instrument, prepared for that purpose, and called a vanning box, they find the earthy matter washed away, and of the remainder, the shoad, or gravelly matter lies behind, and the metallic matter at the point of the shovel. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoad, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore. Phil. Trans. No. 69. Price's Mineralogy, p. 124, &c.

SHOAL, in Sea-Language, is the fame as shoal, and is applied to flats in the water.

They say it is good floating, when a ship sailing towards shore, they find by her founding it grows shallower and shallower by degrees, and not too suddenly; for then the ship goes in safety.

SHOAL INLET, in Geography, a channel between two small islands on the coast of North Carolina. N. lat. 34° 5'. W. long. 77° 58'.

SHOALNESS, a low cape on the west coast of North America. Captain Cook met with some Indians on the coast, near this cape, who came off to the ships in canoes, expressing, as he conceived, their pacific intentions by hallowing and opening their arms, as they cautiously advanced. At length some of them approached near enough to receive some trifles that were thrown to them. This broucht on, says Captain Cook, "a traffic between them and our people, who got dresse of skins, bows, arrows, darts, wooden vesels, &c.; our visitors taking in exchange whatever was offered them. They seemed to be the fame kind of people that we had lately met with along this coast; wore the same ornaments in their lips and noses, but were far more dirty, and not so well clothed. They appeared to be wholly unacquainted with people like us;
SHOA, or Shoal, a prop, or counter-feet, set up to support any thing of weight which leans on one side. See Buttress.

SHOALS, or Shores, in Ship-building, are ship-banks, spars, or pieces of timber, fixed under the rabbards, or against the sides and bottom of the ship, to prop or support her while building or repairing.

SHOBA, or Shoët, in Geography, a town of some note in Africa, in the kingdom of Dah: 42 miles or 42 days' journey W.S.W. of Cobe. The place is said to be well supplied with water, and has not one chalk-pits, which, when Mr. Browne visited them, were almost exhausted for the purpose of adorning the royal residence, and for others, with a kind of white-wash. In Shoba reside some babals; the rest of the people are Persians, and occupied in other pursuits.

SHOCK, or Schlock, in Commerce, a German word expressive 6 c. pieces.

SHOE, in Geography, a small island in the Pacific Ocean, near the coast of New Guinea. S. lat. 6° 11'. E. long. 179° 53'.

Shoën Indians, Indians of North America, on the island of Lake Mülloren. N. lat. 48° 15'. E. long. 127° 45'.

Shoes, a covering for the foot, usually of leather. Its structure, though the object of a particular art, is too popular to need explaining.

Its history is more obscure. Berd. Baudouin, a shoe-maker by profession, has learned the treatment of the ancient shoe, De Solea Veterem, where the tongs, matter, form, &c. thereof, are particularly defined.

Baudouin maintains, that God, in giving Adam flax of beards to clothe him, did not leave him to go bare-footed, but gave him shoes of the same matter; that, after raw flax, men came to make their shoes of raffia, broom, paper, flax, shoe, wood, iron, leather, etc. In America there is a tree, the Sapelo Tree, which produces a tree, the sapel, which is used in making shoes.

Now, to make the two sides of the upper-leathers, let us place all round the edges of the sole, and half round the insole, which are of the same length to penetrate through the sole and the tarsus of the upper-leather, and also through the inner sole, to reach the metal face of the heel, and being forcibly driven, they will be turned by the iron, so as to cleat with the sole, or rivet through the leather, and firms instead of the wire or stitching commonly employed to unite the sole to the upper-leathers.
SHOES.

Shoes, Machines for making. These are the invention of Mr. Brunel, of whose mechanical genius we have had frequent occasion to speak in this work. He has lately established at Battersea an extensive manufactory of shoes, chiefly intended to supply the army, where all the operations are performed by the aid of machines, which act with such facility, that they can be managed by the invalid soldiers of Chelsea Hospital, who are the only workmen employed, and most of them disabled by wounds, or the loss of their legs, from any other employment.

The shoes made by these machines are different from the common shoes, in the circumstance of the sole being united to the upper-leathers by a number of small rivets instead of sewing, in the same manner as those we have mentioned in the preceding article. To facilitate the description we intend to give of the machines, we shall first describe the structure of one of these shoes. Its upper-leathers are the same as any other shoes, and consist of three pieces; viz. the vamp, or part which covers the upper part of the foot, and the two quarters which surround the heel, and are fewed together behind it; they are also sewed to the vamp at about the middle of the length of the shoe. The sole part of the shoe is composed of the real or lower sole, with its welt, the heel, and the inner or upper sole.

The lower sole has an additional border, which is called the turner, or semi-flute, fixed upon its upper side, all round the edge, by a row of rivets, so that it makes a double thickness to the sole towards the edge; but this additional piece is only of small width from the outside of the sole inwards, and gradually diminishes away in thickness to nothing, as it recedes from the edge of the sole, so that the middle part of the sole is only of the same thickness as the single leather.

The upper-leathers are made sufficiently large to turn in, all round, beneath the foot, under the edge of the inner sole, for about three-quarters of an inch wide, and the outer sole, reinforced by the welt, is applied beneath, so that the turning-in is included between the two soles; that is, it is included between the edge of the inner sole and the welt, or extra thickness which surrounds the lower sole.

To hold the shoe together, a row of rivets is put through the sole, all round the edge, and they are of sufficient length to pass through all the four thicknesses, viz. the lower sole, the welt, the upper-leathers, (where they are turned in,) and also through the inner sole; and these rivets being made fall, unite the parts of the shoe together in a much firmer manner than sewing. The rivets have no heads, but are made tapering, and the largest ends are on the outside of the sole, which prevents them from drawing through; and at the same time, the strength of the rivetting will not be materially impaired by the gradual wearing away of the sole leather.

The rivets prevent the wear in a very great degree, and for this reason there is a greater number of rivets put into the sole than merely those which hold the shoe together. The different nails are, first, the short nails, or rivets, which only penetrate through the single thickness of the lower sole; these are arranged in parallel rows across the tread of the foot, that is, about two-thirds of the length from the heel; there is likewise a double row of short nails, which is carried round parallel to the outline of the toe, at about three-quarters of an inch from the edge, and extends as far as the middle of the foot. Next, the tacking nails, which are of a sufficient length to reach through both the sole and the welt, and thus fix the two together; of these, there is a row all round the edge of the foot, nearer to the edge than the row of short nails before mentioned. Lastly, the long nails, which, as before described, fasten the shoe together; these form also a complete row round the edge of the whole shoe, and nearer to the edge than any of the preceding rows. The heel is also fastened on by a row of long nails round its circumference. The heads or thick ends of all these nails appear on the lower surface of the sole, and all contribute to preserve the leather from wearing. We shall now proceed to a description of the ingenious instruments and machines used in this manufactory, beginning with those for Cutting out the Leather.—This is performed by stamps, each of which is an iron frame or ring, bent to the faze and figure of the sole, or other part to be cut out by it; one edge of the frame is edged with file, and ground sharp, so that it will cut the leather: the sharp edge of this frame being placed upon the skin, and struck with a mallet, will cut out a piece from the skin, which is exactly of the same fize as the interior opening of the frame. The leather for the soles is first softened, by soaking it in water; the skin is then spread out on a block or table of lead about two feet long and eighteen inches wide, and the stamp or knife for the soles is placed upon the skin in the most advantageous position to cut out the piece; then two or three blows upon the top of the knife with a beetle or large wooden mallet, forces its edge through the leather, and cuts out the piece, which remains in the opening of the knife, but being taken out another is cut in a similar manner.

A knife of this kind is provided for all the pieces which are used to form the shoe, and they are called after the names of the respective pieces, which are as follows: 1. The sole, which is not cut out the full faze for the sole of the shoe, but wants a piece at the heel. 2. The piece-piece is a semi-circle, to be joined to the sole to make up the heel. 3. The heel: these two last pieces are cut out of the small pieces, or scraps of leather. 4. The runner, or welt, which is applied upon the sole, all round the edge, to make the extra thickness where the upper-leather is to be joined to the sole. All these parts are cut out from the strong hides. 5. The inner sole. The upper-leathers are, 6, the vamp, or part which covers the toes and upper part of the foot; and 7 and 8, the right and felt quarters, which surround the heel, and are fewed to the vamp, being also fewed together behind the heel.

All these parts, except the welts, are cut out by knives of the above description, there being a lot of knives for every different-sized shoe which is made in the manufactory. For cutting out the inner soles, the knife is fixed horizontally, with its edge upwards, beneath a heavy cast-iron lever, which moves on a centre pin, supported in the frame which supports the knife. The lever has a plate of lead attached to it near the centre, so that when it is brought down horizontally the lead will descend upon the knife, the edge of which being imprinted into the lead, will cut through the leather which is previously spread upon the knife. To use this cutting-out machine, the sole is first cut out roughly from the skin by a common cutting-knife round a wooden pattern, and the lever being lifted up nearly to a vertical position, the rough sole is laid fairly upon the edge of the knife; then, by letting fall the lever, its weight, and the leverage upon the plate of lead, causes a sufficient pressure upon the leather to force it upon the edge of the knife, and cut it to the exact shape required. The lever is guided in its descent, to ensure that its lead shall fall precisely upon the knife.

Immediately after the soles are cut out, they are stamped on the grain-fize of the leather with a number which denotes the fize of the shoe to which they belong. The stamp is engraved on the face of a small hammer, so that one blow makes the desired mark. The heels and other parts are also marked,
SHOES.

marked, that the workman may make no mistake in putting the shoe together.

The leather for the soles is cut into strips of about an inch wide; for this purpose, the piece is spread on a flat table about two feet square, the surface of which is covered with a flat iron ruled in the width of the desired strips, and forced down upon the wooden table, leaving between these divisions spaces to admit the point of a knife. Several small pins project up from the iron rulers to penetrate the leather and hold it fast. To form the leather down which it is cut, a frame of iron is fixed to the table by hinges at one end; so as to fold down horizontally upon the leather; and the frame is moved over all with similar rulers, the intervals between them corresponding exactly with those between the rulers on the table. The cutting is performed by a hooked knife, fixed into a long handle. The workman holds down the frame upon the leather, and introducing the hooked point of the knife between the bars, draws it towards him; this cuts through the leather, and he repeats it at every interval between the rulers, and thus divides the whole leather into strips of the same breadth as the rulers.

To prepare these strips for use, each one is split lengthways into two other strips, by an oblique cut along the middle of it; thus producing two strips, which have bevelled or feathered edges, similar to a ruler for drawing. The splitting of the strips is performed by a very complete machine, consisting of a pair of brass rollers, one of which is turned by a lever, and the other receives its motion from it by means of a pair of equal cog-wheels, one wheel being fixed upon the ends of each of the rollers. The rollers are mounted above the other in an iron frame, in a similar manner to those used for lamination: the lower one has a groove formed round it, which is of a proper size to receive the strip of leather before it is divided, and the pressure of the upper roller compresses it into the groove. A guide, consisting of an iron frame, with a square hole through it, is fixed up before or in front of the rollers, to conduct the leather into the groove; and on the opposite side, or behind the rollers, is a stem, or stand, which receives a cylindrical steel pin, and holds it fast in an horizontal position, in the direction in which the strip of leather will move when it comes through the rollers. The end of this steel pin is flattened and ground to a sharp edge, like that of a chisel, and preventing itself to the end of the strip of leather as it is passed through the rollers, will evidently divide the strip longitudinally into two pieces, when the leather is forced forwards at an angle of the cutter by the motion of the rollers. This edge is placed obliquely to the axis of the rollers (or to the surface of the leather which passes between them), and therefore will divide it by an oblique cut, so as to produce two narrow feather-edged pieces from each strip. The pressure of the rollers upon the leather tends to consolidate its texture, and supply the place of hammering.

Preparation of the Soles.—The leather is hardened by palling it between rollers, to produce the same effect as hammering does in the ordinary method of shoe-making. The rollers used for this purpose are made of brass, about five inches diameter, and as much in length; they are mounted in the usual kind of frame, except that instead of screws to hold down the upper roller, and regulate its distance from the lower one, two plain cylindrical pins are inserted into the holes which usually receive the screws, and these pins have a strong lever bearing upon their upper ends, to press the upper roller down upon the lower, by the action of a weight at the extremity of the lever. These pins are only about four inches distant from the centre or fulcrum of the lever, and the weight (of about 100 pounds) is at a distance of four feet from the centre, it therefore presses down the upper roller upon the lower, with a force of nearly 1200 pounds. The lower roller has a cog-wheel upon the extremity of its spindle, which is attached by a pin, upon the end of an arm turned by a hand-wheel; the upper roller is moved from this wheel, and another pin the links between the rollers. Two holes are provided together, being had one upon the other, with the fifth hole of the latter towards each other, and a plate is placed between them, which is made thick in the middle, and dimpled every way to the edges, where it is thin. The foot of the wheel of the two latter is outside, so as to be in contact with the roller when the holes are transferred to the machine which draws them up; and when they have nearly pulled through, the man who turns the wheel reverses the motion, and rolls them back again, then forwards, and so on for four or five times, in the same manner as the action of many linens. After this operation the leather becomes hard and fold, and much reduced in thickness, partly at the middle part.

The heel being so small cannot conveniently be rolled; but to produce the same effect they are flapped in a fly-pref; for this purpose, a heel-piece is put into a small box or cell of cast-iron, of a proper shape to receive it, and a thick plate, which is fitted to the box, being laid upon it, the whole is put beneath the screw of the press, one blow of which is sufficient to press the iron plate upon the leather, with a force which will render it hard and fold.

The sole is made complete by joining to it the small semicircular piece at the heel; for this purpose, the parts which are to be joined together are cut bevelled, so that they will overlap without increasing the thickness, and then three or four nails are driven through the bevelled parts, to hold them together. To cut the joints bevelled, a simple press is used; the sole is laid flat upon the edge of the bench, and a piece of iron is pressed down upon it by a lever, upon which the workman leans his elbow. The edge of the bench is bevelled, and faced with iron, and this, together with the upper piece of iron, guides the knife, so that it will cut the joint bevelled: the heel-piece is then cut in the same manner, but reversed.

Application of the Short Nails.—The leather for the sole is next inlaid with short copper or iron nails, which are put through holes in the leather, in the broad part of the foot, where the greatest wear will take place; and there is also a double row of similar rivets, inlaid round the toe part, at about three-quarters of an inch within the edge of the sole. The holes for these nails are first punched in the leather of the sole by a punching machine, and then a second machine cuts the nails, and inserts them into the holes.

The punching machine is moved by the foot of the workman, who is seated before a small semicircular table of cast-iron, on which he places the leather. This table is supported by a strong column, rising from the floor to a height of about two feet above the table, which is joined to the column by a projecting bracket, so that the column is on the opposite side to that where the workman is seated. The upper part of the column has two arms, projecting forwards from it towards the workman, and extending over the table; at their extremities they are formed into sockets, to fulfil a square iron rod or perpendicular rudder, which at the lower end has the piercer or awl screwed into it; one of the sockets guides the upper part of the slider, and the other the lower part, so that it has a freedom of motion in a perpendicular direction, but no other. The slider is caused to descend by means of a treadle moving on a centre pin, attached to the foot of the iron column, beneath the bench, from this treadle an iron rod ascends through a hole in the

Vox. XXXII.
bench (and also through holes in the arms, which project from the column to fulfill the slider), and at the upper end this rod is connected with a lever, which moves on a joint at the upper end of the iron column, whilst the extreme end of the lever is connected with the top of the perpendicular slider. By this arrangement it is clear, that the foot, being prefixed upon the treadle, will communicate motion by the iron rod and upper lever to the slider and piercer, and force its point through the leather, which is placed upon the small iron table. A short lever and counterpoise are provided to raise up the slider again the instant the pressure is removed. To prevent the piercer striking upon the iron of the table, and breaking the point, a ferow is inserted in a piece projecting from the slider, and its point in descending comes to rest upon the upper of the two arms which fulfill the slider, and thus stops the descent of the slider at the proper place.

The piece of leather for the sole is fixed upon a pattern made of iron plate, cut to the same size and shape as the sole, which is united to it by two sharp gauge pins, which are fixed in the pattern, one at the middle of the tread, and the other in the centre of the heel; and these pins project so far, that they will just penetrate through the leather, to hold it fast against the pattern, which is perforated with all the holes which are intended to be pierced in the sole. The leather is applied upon the pattern, and struck with a mallet, so as to force the gauge pins into the leather, and unite the sole and the pattern together; the pattern is then laid flat upon the table of the machine, with the leather uppermost, and is brought beneath the joint of the piercer, so that it will penetrate in the defined place. To ascertain this place, a small fluid or pin is inserted into a hole in the table, in the exact spot where the point of the piercer descends; the fluid projects a little above the surface of the table, but is only held up by a spring, so that it can easily be pierced down. The pattern being placed so that any of the holes therein receive the point of the fluid, it is evident that when the pressure of the foot makes the piercer descend, its point will make a puncture in the leather which is fastened upon the pattern, which puncture will be opposite to the hole in the pattern; and though it perforates the leather quite through the thickness, the point of the piercer cannot be blunted against the iron, because it is received in the hole in the pattern, and the fluid descends by the pressure, so that the pattern will lie quite flat upon the surface of the table. In this manner the workman pieces any number of holes in the leather, placing it beneath the point of the piercer by the aid of the pattern, and then piercing the foot to bring the point down and pierce the hole. As soon as the piercer rises, he removes the pattern to another hole, and so on. A small piece of iron is fixed jut above the leather, which prevents its being lifted up, and following the piercer when it rises. The piercer pierces through a hole in this piece.

Nailing Machine for short Nails.—The sole being thus pierced with holes, the short nails are put into it by a very curious machine, which at the same time forms the nails, by cutting them off from the end of a strip of iron or copper, of the same breadth as the length of the intended nails. The sole is pretreated to the machine by laying it upon a small table, similar to the last machine, and is directed by means of the same pattern; so that each of the holes in the leather will be successively brought beneath the point of a blunt piercer, which descends by the action of a treadle. In the upper part of the machine is a pair of shears, to cut the nails: they consist of a lever, loaded at the extremity with a weight, and connected with the treadle, so that the end of the lever is lifted up when the treadle is depressed by the foot. Near the centre of this lever is a cutter, which is fixed to it, and moves with it. Another cutter is supported by the frame, so as to be stationary, and in the proper situation to come in contact with the edge of the moving cutter, when the end of the lever is lifted up. The cutters act in a manner similar to a pair of shears, to cut off a small piece from across the end of a strip of iron, which is introduced between the cutters. This piece forms the nail or rivet, which is to be put into the hole in the leather; and immediately after it is cut, it falls into a tube, by which it is conducted down to a small cell or tube, situated immediately over the leather. In this the nail stands perpendicular, and ready, when the piercer descends, to be forced down into the hole in the leather; because the cell which receives the nail is exactly beneath the point of the piercer, so as to hold it perpendicularly in the proper situation. The workman is seated before the machine, and with his right hand directs the sole, with its pattern beneath the piercer, in the same manner as before described. In his left hand he holds the strip of iron or copper which is to make the nails; and he introduces the end of it through a small hole, which communicates to the cutters, pushing it forward with a gentle force: this causes the end of the strip to enter between the cutters, when the shears are open. Then adjusting the sole by the pattern, so that one of the holes in the leather will be beneath the nail contained in the cell, he presses down the treadle: this forces the nail down from the cell into the leather, by the descent of the piercer, and at the same time closes the shears, and cuts off a nail across the end of the strip. The nail immediately descends by the tube into the cell, where it places itself perpendicularly, and ready to be put in its place in its turn. Thus the machine, at every stroke, cuts a fresh nail to supply the place of that which it puts in the leather by the fame stroke. The strip of copper is turned over every time, to form the nails alternately head and point.

When all the nails are put in, they are battered down with a hammer; and as they are but very little longer than the thickness of the sole, this reduces them to an even surface.

Application of the Welt to the Sole.—The welt, or runner, is a narrow strip of leather applied upon the sole, round its edge, to make the sole of a double thickness round the edge, where the upper leather joins to the sole, although the sole is only fingle within. The welt is made from the leather, the thicknesses of which we have before mentioned, and is fastened to the sole by tacking nails of sufficient length to pass through both the sole and the welt. These nails are arranged round all the circumference of the sole, and the holes are first pierced through the sole by the punching machine, which we have before described, but by a different pattern of iron, which is attached to the sole by its two gauge pins entering the fame holes which were made through the leather in the first operation. This pattern is pierced with a row of holes all round the circumference, which are arranged within the former row of rivets, or farther from the edge of the sole; but around the toe and tread of the foot, for half its length, the holes are in double number, or at half the distance that they are in the heel part. This pattern being used in the dance manner as before depicted, the punching machine pierces the sole with holes, exactly corresponding to it; which holes are filled with tacking nails in a separate machine, something similar to the nailing machine before described. But as the nails are longer, it would be too laborious to cut them by the fame motion; the nails are, therefore, cut by a machine made on purpose, and applied to the leather by
SHOES.

The nailing Machine for Long Nails.—This is made exactly the same as the punching machine before described, but with additional apparatus to supply the nails, and put them into the holes. Thus it has a vertical column, with a table and two projecting arms to support the perpendicular divider, which in the former case was applied to the table, and to rest against the earth, and the weight. The piercer at the lower end is sharpened, and is intended to penetrate the leather, but only to stop the nails, into the holes previously placed by the punching machine. The additional parts are as follows: a wheel or wheel of nails, also a wheel of punches, which thence, having been placed, are forced with a great number of nails, the number of which, the holes are really made in reference, as shown in the figure, consisting of only four circles, one within the other. The inner space within the circle is filled with nails, like a wheel; and in the centre is a hole, which is barely large enough for the centre pin, which, as before mentioned, is placed from the vertical column of the machine, and fulfills the upper end of the perpendicular divider. Upon this circular table the wheel is supported in a horizontal position, at the height of 18 or 20 inches above the table on which the leather is placed, and by a lever to turn upon its centre pin. The wheel is filled with nails when it is used, one being put into every hole of its circumference, with the points downwards; and the holes are sufficiently large to let the nails drop through the wheel, except when their points rest upon the circular table which supports the wheel. At one part of the circumference of this table an opening is cut through it, and a small tube descends from it, to conduct a nail down to the point of the piercer. The motion of the wheel upon its centre brings the nails successively over the opening or mouth of the tube; and therefore each nail, in its turn, drops by its weight through the hole in the tube into the tube itself, which is made so small, that the nail nail remains with its point downwards, and fall into a small cell, so situated that the nail will fall exactly beneath the point of the piercer, when the same is in its highest position. But when the piercer is depressed by the action of the treadle, its point will act upon the head of the nail, and force it down through the cell into the leather, placed upon the table of the machine; the hole in the leather having been previously pierced by the punching machine. The cell which receives the nail is very ingeniously contrived to hold it in a perpendicular direction, beneath the end of the piercer. It is situated immediately above the leather, and is conical within, so that the nail drops down into it until it becomes fixed fast; but when the nail is to be forced down by the piercer, the cell opens in two halves, being formed by notches in two pieces of steel, which are held together by being screwed together at one end, and are made so thin as to spring together, and form a cell for the reception of the nail, although they will readily separate when the piercer forces down the nail. It is during the ascent of the piercer that another nail is dropped down from the wheel through the tube; and received into the cell, whilst its two halves are still kept open by the piercer, or rather as the piercer at this moment occupies the interior of the cell, the nail is received into the space, or open joint, at which the two halves of the cell meet, so that the nail lies close by the side of the piercer. But when the piercer has risen up completely out of the cell, its two halves spring together, and the joint in which the nail is placed being formed with a notch inclining inward, they throw the nail into the cell, while the piercer is sunk in. Back on the lever, and the wheel is brought back into its position on the opening of the cell, the wheel is turned over, and contained in the wheel of punches, and the wheel of nails, and the holes are thus filled in their places. A small lever is placed by the balance of the weights, which will turn it, when the machine has finished its work. The action of this mechanism is to the following effect:—when the lever descends, it forces the end of the short lever to move forward; this motion is communicated by the small upper lever to the wheel, which slips over the flaps, to the teeth of the wheel; but as the wheel is turned by the hand of a person, and the back of the wheel, having contact with the teeth of the wheel, will turn the wheel round the face of the tooth. In this manner, at every descent of the lever the wheel engages a fresh tooth of the wheel; and at every ascent, the wheel turns round upon its centre pin; the weight of the wheel, resting upon the flat circular table, being sufficient to retain as it is placed.

The nailing machine sets with the same rapidity as the other machines, to put a nail into every one of the holes previously made; and for this purpose the leather is kept upon the fame pattern by which those holes were pierced, not only for the purpose of placing the leather so that the nails shall be inserted into those holes, but that the thickness of the pattern may allow the nails to penetrate and project through the leather on the under side. When the nails are all put in, they are bent down, with a mallet, to drive all the heads to a level with the surface. The leather is then separated from the pattern, and put into a frame called

The swelling Stand.—This machine is a small square table of cell-iron, fixed on the top of a pedestal, in which it is capable of turning round, for the convenience of the workman, and to enable him to work at the different sides, as he remains seated before the table. An iron frame is connected with the table by hinges at one side, so that it can be lifted up or turned down, to lie flat upon the surface of the table; and in this position it can be fastened down by means of a simple clamp. This frame is intended to hold the leather which is placed beneath the frame; the interior opening of the iron frame is nearly of the same size and shape as the hole of the shoe. The sole is placed flat upon the table, in the proper position, which is determined by two gauge pins fixed into the table, and entering the holes made in the sole; then the iron frame being turned down upon the leather, will include the sole as it were with an iron hoop, or nailed border, all round the edge; and the frame being clamped down, the sole is confined, as if lying in the bottom of a cell of iron, of the same figure as itself, and with the nail points projecting upwards from the sole. In this frame the skin is applied, by laying the flaps of leather upon the edge of the sole, in contact with the inside of the iron frame, and bending it to follow the curve of the outline of the sole. As fall as any part of the length of the
SHOES.

If rip is settled to its position, it is attached to the sole by striking it down with a mallet upon the points of the nails. The thin or feathered edge of the ifrip of leather is put inside, so that the edge of the sole, for about the breadth of half an inch, is of a double thickness; but within this, the extra thickness diminishes away to nothing, leaving only the thickness of the sole. The ends of the ifrip of leather which comprise the welt, where they join and complete the circuit of the sole, are cut sloping, so as to lap over each other, and make a joint, without any increase of thickness, or apparent division. When the sole is taken out of this frame, the welt and sole are beat down well together, to make a good joint; it is then carried to the cutting press, in which the edge or outline of the sole and welt are cut smooth, and to the fame fize; because, as the frame of the wetling machine must be rather less than the sole, in order that the frame may bear upon the edges of the sole all round, and thus hold it fast, the welt, which is moulded or bent round within the frame, will be a small quantity less all round than the sole. To guide the knife in cutting round the edge of the sole, it is confined between two iron patterns, which are made exactly to the size to which the edge is to be pared. They are attached to the sole by two gauge pins, fixed into one of the plates, and passing through the holes in the sole, project far enough on the opposite side for the other plate to be fastened on, in its required position, by two holes which receive the ends of the pins.

The cutting-press very much resembles a common lathe: a horizontal spindle is supported in a frame, confining of two standards, erected from a horizontal plate, to fulfil the spindle, which paffes through a collar in one of the standards, and projects some inches beyond it, having at the extremity a piece of wood flat on the surface, and of the fame shape as the sole. Against this flat surface the two iron plates, with the sole between, are placed, and they are forcibly pressed together by the action of a screw, fitted into a third iron fandard, erected from the fame horizontal plate, and pressing by means of a lever upon the iron plates exactly opposite the end of the spindle. This pressure causes the spindle to retreat a small quantity in the direction of its length, and then a flat circular plate, fixed upon the spindle, (in the fame situation as the pulley of a common lathe,) is made to press against a fimilar flat plate, which is frafted to the frame, and therefore cannot turn round. By the friction between these two surfaces, the spindle becomes immovable, and the press holds the sole firmly, whilft the workman, who is seated before the machine, cuts all round the edge with a drawing-knife, which is made sharp in the middle, and is worked with both hands by having a handle at each end. When he has with this tool pared down that part of the edge which is uppermost, he releases the screw of the press, and a spring then causes the spindle to advance so far as to relieve the flat circular plate, which is fixed upon the spindle, from its contact with the fixed plate. This leaves the spindle at liberty to be turned round, and the sole turns with it, so as to bring up a new part of the edge of the leather to a convenient situation to be pared or cut; and the screw is then turned to fallen the spindle as before decribed, and at the fame time to prefs the sole between the two patterns.

When the edge of the sole is thus cut, it is carried to a grindstone, and ground smooth: the ifone is turned with a quick motion, by means of a band and large wheel; the leather is afterwards polished by applying it to the edge of a wooden wheel, on which a little bees-wax is spread.

Application of the long Nails.—The sole, thus re-inforced by the welt, is returned to the punching machine, and being attached to another pattern, a range of holes is pierced all round the outer edge, through both, jilt within the former row of tapping nails; after which, by the nailing machine, these holes are filled with nails which project through the upper side of the welt, being longer than any of the former, and being also intended to penetrate through the upper-leather and inner soles, and thus fasten the shoe together. In this state the sole is ready to be put to the upper-leather.

The upper-leathers are prepared for applying to the sole, in the fame manner as the ordinary shoe, viz., by leaving the vamp, or piece which covers the upper part of the foot, to the two quarters which go round the heel, and also fewing these two quarters together behind the heel. The workmen do not hold the work upon their knees to few it, but four men work at a square table, the corners of which are cut off, and a small piece of wood projects from each angle: the two pieces of leather which are to be fewed together are laid upon one of these pieces of wood in the proper poifition to be fewed, and are held falt by an endless ftrap, which is laid over them; and the workman binds it falt down, by pressinf his foot in the ftrap, like a ftripp. This method of fewing, which is far fuperior to the common mode, might, from its simplicity, be used by all fhoe-makers, and would render their business less unhealthy; whereas at present they are fubject to many difeafe from fitting in the awkward and unnatural poifition which is neceffary to reach their work, when they hold it upon their knees.

Operation of lathing or revolving the Shoe together.—The upper-leathers are put upon a lathe, and held right thereupon whilst the sole is applied. This is done in

The Clamping Machine.—It is a small oval table, supported on a column, but capable of turning round upon the column, to enable the workman to work at any fide. In the centre of the table a lathe is fixed, with the sole upwards; it is supported at a height of about five inches from the table. The sole is made of cast-iron, in a folid piece, with the stem or part by which the lathe is supported; but the under part, upon which the upper-leathers are to be moulded, is made of wood, for the convenience of altering the figure when neceffary. The lathe is fixed upon the table by means of two leaves pins; and a strong pin, which projects from the lower part of the lathe, and paffes through the table, is bound falt by a wedge, which confines the lathe firmly upon the table, in the fame manner as if it was made in a piece therewith. The table has a number of pieces of braces attached to it by hinges, and arranged all round the lathe in fuch a manner, that they can be turned up against the lower part of the lathe, and then form clamps, which are exactly adapted to the figure of the lower part of the lathe, and will therefore clamp or bind the leather firm upon the lathe at the toe, heel, and every part thereof, except at the flat part of the sole. The braces clamps are of fuch dimenfions, that they will touch each other when turned upon each other, and thus form a complete cell or box, in which the lower part of the lathe will be contained, and the leather confined upon it; but the cell being made in several pieces, or clamps, they can be removed one by one, as found neceffary. The clamps are forced up to their fitution by means of an independent screw for each, which is tapped in an oblique direction through the edge of the table, and the point forces up the end of a small rod, which is jointed to the clamp near the part where it acts upon the leather; by this means the force of the screw acts to turn the clamp up upon its hinge, and at the fame time prefs it againfl the leather. When the preffure is released by displacing the end of the small rod from the point of the screw, the clamp will be suffered to fall back upon the table; and this being done
done to all the clamps, the last stands insolated in the middle of the table, from which it can be detached by withdrawing the wedge which closes it. The inner sole of the shoe is now put upon the sole of the last, being lightly fastened thereto by two short pins, one of which is driven through the gauge hole in the toe of the sole, and enters a hole made in the last; and the other pin is fitted in the heel part of the last, and enters the hole in the sole. The upper-leathers are now put upon the last in the true position. In this state, the last is taken to the clamping machine, and fastened to its place in the centre of the table; the clamps are then turned up, one by one, beginning at the heel, and the upper-leathers being pulled up all round by a pair of pinces, so as to make them fit tight upon the last, the clamps are screwed tight. In this state, the upper-leathers are made to take the form of the last, being firmly attached thereto, except at the joint part; at this part the leather stands up all round about three-quarters of an inch, which quantity is turned down flat upon the edge of the inner sole (previously fastened upon the sole of the last), and a small quantity of paste is put in to make it stick fast: four or five notches are cut out in the leather at the toe and at the heel, to make the part which is turned down be flat upon the sole, and without folds or overlappings, and to make a close contact, the leather is beaten down. Patches of leather are likewise pulled, and bucked flat upon the inner sole for leveling, to make up the sole to the same thickness in the centre as it acquired towards the edges all round by the turning-in of the upper-leathers. In this state, the nail which fastened the inner sole to the last is withdrawn, being now unnecessary, and the real sole is applied, an iron frame, or saddle, being employed to determine its proper position upon the last. This frame is made of thin iron, and its figure is similar, and of the same size as the row of nails which project through the sole, and by which the sole is to be riveted into its place: it is made in two halves, which are united by a joint or hinge at the heel part; and at the toe part are two holes, through which a pin can be put to hold the frame together. This pin, as well as the joint pin of the hinge at the heel, projects downwards sufficiently to enter into a hole made in each of the two clamps at the toe and heel, in such a position as to guide the frame, so that it will apply the sole exactly in the proper position.

The sole, when prepared as before described, by inferring all the long nails in the holes, so that the points project through the leather, is put into an iron box or mould, and a plate being laid upon it, is put into the fly-press, and by a single blow the sole is rendered congruous without, so as to adapt itself to the last. When it is taken out of the mould, the iron frame before-mentioned is put together round the row of nails, the size of the side of the frame being made exactly of the proper size to receive the projecting points of the nails, and retain them perpendicular to the leather, and prevent them from spreading out. The sole is then applied in its place by the two guide pins of the frame, and by striking upon the heads of the nails, their points penetrate through the turning-in of the upper-leather, and also through the inner sole. When they are well entered the iron frame is taken away, by withdrawing its pins, and opening its two halves on their joint, and the nails are driven down into their places. This causes them to project through the inner sole into the sole, and the points meeting the iron sole are turned back, and thus clenched into their places. To render the motion more certain, the sole of the last is made with a flight groove all round, where the points of the nails will fall, and the groove

observable points, the points are more readily turned together, and are all turned in the same way, so that they may not interfere.

The shoe is now put together, and the clamps being released and turned down, the sole it is taken off the last, for which purpose the heel of the last is made in a separate piece, and joined to the sole by a single hook or spring catch; but the last being released, the sole draws off the last with the greater ease, the heel part remaining within the shoe, and is taken out afterwards. The shoe is now carried to the evening last, where it is put upon a last exactly similar to that of the clamping machine, but fastened down upon a bench, and the sole is fixed without the groove, which caused the points of the nail to turn up. Upon the last the nails are beaten down, to meet all last, and make the sole fast with the sole: the heel is then put on by laying it in its place, and driving down the large nails which have been put through it by the moving up-hinge, in the same manner as for the sole.

The sole of the shoe is now fitted with a suitable toe, to level all the nail heads, and render the leather smooth; the shoes are then carried to the grindstone, by which they are polished, and finished up in every part, the soles blacked, and polished by the wheel with a composition of bees-wax and ivory black, which renders them glossy: the upper-leathers are then rubbed by a circular brush, which is turned by the lathe, and the shoes arerendered fit for sale, except those which require binding and lining, with a lining of thin leather, in which case they are finished in the same manner as common shoes.

Nail Machine.—This is equally deserving of notice with any other part of this ingenious mechanism. In our article Nail we have described the nail machine; but we consider this as a much better machine for cutting brads or nails without heads. The nails are cut from sheet-iron, the plates being first reduced into strips, of a breadth equal to the length of the intended nails, by a large pair of shears, acting in the same manner as those described in the article Canine; but are constructed in a different manner, by employing cast-iron for the frame and for the lever. The iron plate is presented to the machine by one man, whilst another works the handle, and at a single stroke cuts off the desired strip of iron; the first of iron is cut so that the section of the strip, or the form a piece which the iron acquires by rolling, will be across the length of the strip. From this it follows, that when the nails are formed by cutting off narrow pieces from the end of the strip, the grain of the iron will be the lengthwise of the nail.

The cutting of the nails is readily performed by the machine, which is turned by the foot of the worker, whilst he supplies the iron by his hands. The motion of the treads turns a crank and heavy fly-wheel, similar to the wheel of a lathe; from the same crank a rod proceeds to the longer end of a flat lever, the axis of which is supported by pivots in the upper part of the frame, so as to be above the wheel and crank. At a small distance from the centre of the lever, and at the opposite side of the axis to the long lever, a heel cutter is fixed, which acts as a fixed cutter supported by the frame; the fixed cutter has an edge on the upper sole, and the moving cutter, which is fixed to the lever, is made sharp on the lower sole. The revolution of the wheel and crank causes the lever to rise and fall, and the edges of the two cutters in the moving path as a whole together as possible, without touching. At the most elevated position of the moving cutter, its edge rides above the edge of
of the fixed cutter so far, that the thickness of the strip of plate can be admitted between them; the end of the strip is pushed back, so that a small portion of the end of it overhangs the edge of the fixed cutter; therefore the edge of the fixed cutter, when it descends, meets this overhanging piece, and prevailing down upon the edge of the fixed cutter, cuts it off, and the piece so separated forms a nail. When the moving cutter re-alcends, the iron is pushed forwards again to overhang the fixed cutter, and another nail is thus cut off. The nails are narrow at one end to form the point, but at the other end are about as broad as the thickness of the plate, so as to be of a square figure; but at the point they are, in one direction, as broad as at the head; this is the direction of the thickness of the plate, so that in reality the nail is the figure of a small wedge instead of a pyramid, the point being in fact a sharp edge. To effects this, the cut which the machine makes across the end of the strip of iron is not perpendicular to the length of the strip, but rather inclined thereto; and at every successive nail which is cut, the inclination of the cut is reversed, so that the head of one nail is cut from the same side as the point of the next, and so on alternately of the whole length of the strip of iron. The thickness of the nail is regulated by the quantity which the end of the strip is allowed to project over the edge of the fixed cutter, and the angle of inclination by two stops, against which the edge of the strip is always brought to bear, when the workman places it ready for the cut. To flop the end of the iron, a part projects from the lever beneath the edge of the moving cutter, and is curved to the arc of a circle described from the axis: this stop is as far removed behind the edge of the cutter as the thickness of the nail intended to be cut off by the defcent of the moving cutter. In working the machine, the workman keeps the wheel constantly revolving by the motion of the treadle; and holding the strip with his edge in contact with the two stops, so as to give it the proper inclination, he pushes it forwards, with a gradual pressure, against the moving cutter: then the instant the cutter is sufficiently raised to admit the strip, it will advance forwards, until the end of the strip touches the stop which is beneath the cutter; on the descent of the cutter, the nail is cut off, and the workman immediately turns the strip with the other side upwards, which has the effect of reversing the inclination of the cut; and pushing it forwards, another nail is cut as the former, and thus the operation continues with the utmost rapidity.

There are several sorts of machines in this manufactory, so that a great number of shoes are proceeding at the same time through the different stages of their fabrication; and the rapidity of the execution is such, that a given number of workmen will here make a far greater number of shoes than by the common method, and they are more durable, particularly for the strong shoes which are desirable for soldiers. Several of the machines were constructed by Mr. Maudslay, with his usual accuracy of execution.

Shoe-makers' Machine.—This is a simple contrivance, to enable those artizans to perform their work in a standing posture; by which means they will avoid the deformities incident to those who follow sedentary employments.

In the common method of working, the shoemaker is obliged to sit and slop in the most awkward posture imaginable, sometimes in order to hold the shoe and nail between his knee and thigh, whant he sews the sole to the upper leather; at other times he must hold the last between his knees; and to few the leathers together whilst he holds them upon his knees, he must lean very much forwards. In all these operations he sits as it were doubled up, so as to impede the action of his lungs, and ultimately produce many diseases. The machine is a kind of vice, to hold the shoe in any position whilst it is fewed.

The Society of Arts have thrown a laudable desire to recommend these machines to the trade; and to induce their general adoption, they have given several rewards to those who have produced machines. The first of these was Mr. Holden, then Mr. Parker, and next Mr. Stafes, whose machine, being more improved than the preceding, demands some description. A small bench, or table, is firmly supported on four legs, at about four feet from the ground; a circular cushion is affixed upon the bench, having a hollow or bason in the centre of it, with a hole from the bottom of the hollow, quite through the cushion, and also through the centre of the bench. This hole receives a strap, which is doubled, and the two ends fewed together. The nail is put into the double of the strap, and it is drawn down by a treadle, so as to hold the last firmly in the hollow of the cushion, which is stuffed soft withfinside; and as the hole through the cushion is too small for the shoe to pass down, the last can be set in any direction which is most convenient for the sewing; but by reviving the treadle, it can be removed in an infant, turned round, and fixed again to few another part. A foot can be applied in front of the machine, for the workman to rest himself occasionally: this foot is supported by only two legs, and a piece of wood, which projects horizontally from beneath the foot, and enters into a mortice, made in a part of the frame. Upon this the workman fits a shoe, as if upon a saddle; and as his work is held before him at a proper height, he fits in an upright posture, which is not attended with the same prejudicial effects as sloping to work upon the knee. The machine is provided with a small tray, or box, behind the cushion, to contain all the small articles which the work requires; also a drawer beneath it for tools, &c.; a whetstone fixed up at a convenient height; and an anvil, which sits into the hollow of the cushion, so as to lie firmly, to hammer the leather upon instead of a lapstone.

Shoe-makers are to make their shoes of sufficient leather, or forfeit 3s. 4d. (1 Jac. I. c. 22.) and journeymen shoe-makers embossing leather shall make satisfaction for damage, or be ordered by justices to be whipped, &c. Persons buying or receiving such leather, are to make reasonable recompense, to be levied by diftraits, &c., and search is to be made after the fame: also leaving their work undertaken, or neglecting it, to be sent to the house of correction for a month. 9 Geo. I. cap. 27. 13 Geo. II. c. 8. See Leather.

Shop, in the Mange. A horfe-shoe is a piece of flat iron, with two branches or wings, which being commonly forged according to the form of the hoof for which it is designed, is made round at the toe, and open at the heel.

A shoe for all feet, is one that is cut at the toe into two equal parts, which is joined by a rivetted nail, upon which they are moveable in such a manner, that the shoe is enlarged or contracted less or more at pleasure, in order to make it, fit all forts and fizes of feet.

To shoe a horfe after the form of a lunette, a patin, &c. see Lunette; Patin, &c. See also Shoeing of Horfes, &c.

Berenger observes, that the ancients did not shoe their horses, that is to say, they did not nail upon their hoofs any pieces of iron, or of other metal, in the form of the modern horse-shoe; but when they intended to defend them from any thing that might annoy them in travelling, they fastened upon their feet, by means of straps and ligatures, a sort of sandal, stocking, or what we call boots. Thefe
SHO

The were made of felts twisted together like a mat, or else of threads, and were notched this thread with plate of metal, and covered by the iron and other matter with silver and gold, as in the habits of Nero and Peppers.

It does not appear in what era, or in what country, the modern art of shoes was first used. The earliest proof which the above account sobre, is to be found in the shoe found to have belonged to the horse of Child, who lived near the year 491, and is preserved in Montagu's Antiquities of France. It perfectly resembles the shoe now in use.

Shoes of the Horse. As the crooked pieces of iron attached to these shoes on the horse or other beasts, by means of nails, there are various forms and shapes of iron, as common, and others which are adapted and accommodated to the particular purposes and circumstances of the horses. Different parts of animals, his wits, require different forms in their shoes. In speaking of the shoe which it occurs on its lower surface, it has been remarked by some, that there are certain proportions to be observed in its different parts. Its breadth should be considerably less than the breadth of the common shoe; it is totally unnecessary to cover any part of the fore, especially when care to preserve it natural hardens. The breadth of the shoe at the heels should be one-half of its breadth at the toe. Its thickness should decrease gradually from the toe, so as to be reduced one-half at the extremity of the heels. As to the distribution of the flamp-holes, every person acquainted with the subject knows, that in shoes for the forefeet, they should be at the toe and quarters, because the wall, or crust, of the forefeet is stronger at the toe than at the heels. The reverse of this is to be observed in the hind shoes, because the heels and quarters of the hindfeet are commonly stronger than the toe. It is impossible to lay down any general rule for filling of these holes in bad feet; it must be the business of the farrier to distribute them in such a manner, as to be able to fix the nails in those parts of the crust where the horn is found and firm. Farriers generally multiply their flamp-holes too much, which brings the nails too close together, occasions the horn to break in splinters, and at length destroys the crust.

The following number is recommended for good feet; viz.: for race-horse's fix, that is three on each side; for saddles-horses, four, on the outside and three within, the quarter on this side being weaker than on the other; the number for coach-horses of the middling size; for large coach-horses four on each side; and for cart-horses, five on the out and four on the in. It is also of principal importance to determine the weight of the horse, for it is matter of all importance, to fix some horse with shoes weighing each five pounds, making together a burden of twenty pounds of iron attached to the fore feet. It is obvious to common sense, this such an additional weight, fixed to the extremity of the leg, must be productive of some inconvenience or other; and, in fact, the muscles are thereby compelled to greater exertion; the ligaments are stretched, and the articulations continually fatigued; and, besides all these evil consequences, the horse by its weight forces out the nails, and entirely spoils the texture of the wall or crust, that it becomes often extremely difficult to fix the shoe to the hoof. Why then, it is asked, do not practitioners of the present day, who are daily witnesess of these facts, and indeed are the principal authors of them, apply themselves to the correction of their own errors? Their answer, it is feared, is obvious; because he who is unacquainted and delinquent of sound principles in his art, cannot turn to real profit the experience he has acquired, nor shall he in the path of knowledge, as he has formerly, be at a loss to determine to introduce, and put the horse to a proper use.

The weights which are prescribed, for the different kinds, are exactly as follows:

For the fore feet of cart horses [n],

<table>
<thead>
<tr>
<th>Weight</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1/2</td>
<td>For the harder parts of the kind</td>
</tr>
<tr>
<td>1 1/2</td>
<td>For the larger coach-horses</td>
</tr>
<tr>
<td>1 1/2</td>
<td>For the smaller coach-horses</td>
</tr>
<tr>
<td>1 1/4</td>
<td>For the smaller cart-horses</td>
</tr>
<tr>
<td>1 1/2</td>
<td>For the larger cart-horses</td>
</tr>
</tbody>
</table>

And by reducing the breadth and length of those shoes, their thickness may, it is supposed, be increased without making any addition to their weight.

Shoes of the horse, of iron, are fastened upon the feet of ox, or other cattle, in the field or read labour. Shoes of the feet, to which is given a piece of flat iron, with some fit at the side on the outward edge, to receive the nail: at the toe is a projection of some inches, which pulling up the cart, is bent over the bow, to keep the shoe in its proper place. This projection is flat, however, employed in the general practice of making the shoe, nor can it be of common use; see Shoving of Cows.

Shoe of Gold, in Commerce, 21 lb. is used at Venice in China. Gold is here considered as merchandise; it is held in regular import of a determined weight, which the English call fines of gold; the largest of their weight is 10 parts, and the gold is reckoned 93 touch that is 94 parts in 100, though it is really only 92 or 93. Formerly, 10 singles of silver were given for one tale of gold of the same degree of fineness; but of late, from 100 to 110 tales of silver of 94 touch have been given for 10 tales of gold of 92 or 93 touch; and sometimes from 110 to 120 tales, or even more, of Spanish dollars, reckoned at 92 touch, have been paid for 10 tales of gold. It must be observed, that when gold is exchanged for silver, its price is always valued by the tale weight; and it is held either above or below touch, as follows: if the gold be 96 touch, and sold at 5 under touch, subtract 5 from 96, and 91 remains: then 91 tales of silver are paid for 10 of gold; if gold be sold at 10 above touch, the merchandise being full 96, add 10 to 96; and 106 tales of silver are paid for 10 tales of gold.

We shall here observe, that there is but one kind of money made in China, called , which is not coined but cast, and which is only used for small payments; it is composed of six parts of copper and four parts of lead, it is round, marked on one side, and rather raised at the edge, with a square hole in the middle. These pieces are commonly earned, like beans, on a string or wire. A tale of five silver should be worth 1000 call; but on account of their convenience for common use, their price is somewhat much raised, that only 750 call are given for the tale. See Tae.

SHOE, Huf, in Farriery, Mining, Sc. See HORSE-HOOF.

SHOE, Huf, Head. See HORSE-HOE HEAD.

SHOE, Huf, Head. See Horse-shoe Head.

SHOE, OF THE ANKLE, in Sea Language, a small block of wood, convex on the back, and having a small hole fitted to contain the point of the anchor shrouds in the fore-side. It is used to prevent the rope or taut peev or wounding the plank, or upper till, bow, when the day, or during the day, for which purpose they say, and are used, the bow, between the flues of the anchor and the plank, as being proved to the latter by the weight of the former. Falconer.
SHOE

SHOE, To, an Anchor. See Shoeing the Anchor.

SHOE-Blocks, are two single blocks, cut in a solid piece transversely to each other. They are used for legs and falls of the bunt-line, but are seldom employed.

SHOE-Hoofing. See Housing.

SHOEBURY Ness, in Geography, a cape of England, on the south coast of the county of Essex, at the mouth of the Thames. Here king Alfred erected a fortress against the Danes. There are two villages near North and South Shoebury, both containing together about 200 inhabitants; 5 miles N.E. from the Nore. N. lat. 51° 32'. E. long. 0° 35'.

SHOEING of Horses, a term applied to the operation of softening the pieces of iron on the bottom parts of the hoofs, or that of fixing shoes to the feet. These, and some other animals destined to labour, are shod with iron, in order to defend and preserve their hoofs. The shoes of horses should differ according to the feet, as has been already seen. The common form of shoes, and the method of shoeing, are wholly condemned by some, as Mr. Clark, and a new method recommended, which appears founded on just principles, and to have been sanctioned by much experience. It is remarked, that in preparing the foot for the shoe, according to the common method, the frog, the sole, and the bars or binders, are pared so much that the blood frequently appears. The common shoe by its form (being thick on the inside of the rim, and thin upon the outside), must of consequence be made concave or hollow on that side which is placed immediately next the foot, in order to prevent its reeling upon the sole. The shoes are generally of an immoderate weight and length, and every means is used to prevent the frog from reeling upon the ground, by making the shoe-heel thick, broad, and strong, or raising cramps or caulkers on them. From this form of the shoe, and from this method of treating the hoof, the frog is raised to a considerable height above the ground, the heels are deprived of that fulness which was provided by nature to keep the crust extended at a proper width, and the foot is fixed as it were in a vice. And by the preasure from the weight of the body, and resistence from the outer edges of the shoe, the heels are forced together, and retain that shape impressed upon them, which it is impossible ever afterwards to remove; hence a contraction of the heels, and of course lameness. But farther, the heels, as has been observed, being forced together, the crust prys upon the processess of the coffin and extremities of the nut-bone: the frog is confused, and raised so far from the ground, that it cannot have that support upon it which it ought to have: the circulation of the blood is impeded, and a wafting of the frog, and frequently of the whole foot, ensues. Hence, it is contended, proceed all those difficulties of the feet known by the names of founder, hoof-bound, narrow-heels, thrushes, corns, high foles, &c.

And it has likewise been frequently observed, that there arises from this compreension of the internal parts of the foot, a swelling of the legs immediately above the hoof, attended with great pain and inflammation, with a discharge of thin, ichorous, fetid matter; from which symptoms, it is often concluded that the horse is in a bad habit of body (or what is termed a gase falling down), and must therefore undergo a course of medicine, &c. The bad effects of this practice are still more obvious upon the external parts of the hoof.

The crust towards the toe, being the only part of the hoof free from compreession, enjoys a free circulation of that fluid necessary for its nourishment, and grows broader and longer; from which extraordinary length of toe, the horse stumbles in his going, and cuts his legs. The smaller particles of sand infininate themselves between the shoe and the heels, which grind them away, and thereby produce lameness. All this is entirely owing to the great spring the heels of the horse must unavoidably have upon the heels of a shoe made in this form. This concave shoe in time wears thin at the toe, and, yielding to the preasure made upon it, is forced wider, and of consequence breaks off that part of the crust on the outside of the nails. Inflamations of this kind daily occur, infomuch that there hardly remains crust sufficient to fix a shoe upon. And further, it is generally thought, that the broader a shoe is, and the more it covers the sole and frog, a horse will travel the better. But, as it has been remarked, the broader a shoe is of this form, it must be made the more concave; and, of consequence, the contracting power upon the heels must be the greater. It is likewise to be observed, that, by using strong broad-ridged concave shoes in the summer season, when the weather is hot and the roads very dry and hard, if a horse is obliged to go fast, the shoes, by repeated strokes (or friction) against the ground, acquire a great degree of heat, which is communicated to the internal parts of the foot; and, together with the contraction upon the heels, occasioned by the form of the shoe, must certainly cause exquisite pain. This is frequently succeeded by a violent inflammation in the internal parts of the hoof, and is the cause of that difafe in the feet so fatal to the very best of our horses, commonly termed a founder. This is also the reason why horses, after a journey or a hard ride, are observed to shift their feet to frequently, and to lie down much. And if we attend further to the convex surface of this shoe, and the convexity of the pavement upon which horses walk, it will then be evident that it is impossible for them to keep their feet from slipping in this form of shoe, especially upon declivities of the streets. It is also a common practice, especially in this place, (Edinburgh,) to turn up the heels of the shoes, into what are called cramps or caulkers, by which means the weight of the horse is confined to a very narrow surface, viz. the inner round edge of the shoe-rim and the points or caulkers of each heel, which soon wear round and blunt; besides, they for the most part are made by far too thick and long. The consequence is, that it throws the horse forward upon the toes, and is apt to make him slip and stumble. To this cause we must likewise ascribe the frequent and sudden lamenesses horses are subject to in the legs, by twilling the ligaments of the joints, tendons, &c. It is not affirmed that caulkers are always hurtful, and ought to be laid aside; on the contrary, it is granted that they, or some such-like contrivance, are extremely necessary, and may be used with advantage upon flat shoes where the ground is slippery; but they should be made thinner and sharper than those commonly used, so as to sink into the ground, otherwise they will rather be hurtful than of any advantage.

It is suggested that the Chinese are said to account a small foot an ornament in their women; and for that purpose, when young, their feet are confined in small shoes. This no doubt produces the defired effect; but must necessarily be very prejudicial to them in walking, and apt to render them entirely lame. This practice, however, very much resembles our manner of shoeing horses; for, if we looked upon it as an advantage to them to have long feet, with narrow low heels, and supposing we observed no inconvenience to attend it, or bad consequence to follow it, we could not possibly use a more effectual means to bring it about than by following the method already described. It is supposed that in shoeing a horse, therefore, we should in this, as in every other case, study to follow nature: and certainly that shoe which is made of such a form as to rememble as nearly as possible
SHOEING.

While the natural tread and shape of the foot, must be preferable to any other. But, as it is extremely difficult to lay down fixed rules with respect to the proportions to be observed in treating the heels of different kinds of horses, it is equally difficult to lay down any and rules for determining the precise form to be given to the hoof. It will be obvious to every judicious practicer, from the various constrictions of their feet, from nature, and other causes that may occur, that a great deal must depend upon the discretion and judgment of the operator, in proportioning the shoe to the foot, by imitating the natural tread, to prevent the hoof from contracting a bad shape. In order, therefore, to give some general idea of what may be thought most necessary in this matter, it is endeavored to describe that form of shoe, and method of treating the heels of horses, which, from experience, has been found most beneficial. And in this it is to be remembered, that a horse's shoe ought by no means to rest upon the foal, otherwise it will occasion lameness; therefore it must rest entirely upon the crust; and, in order that we may imitate the natural tread of the foot, the shoe must be made flat; if the height of the sole does not forbid it; it must be of an equal thickness all around the outside of the rim; and on that part of it which is to be placed immediately next the foot, a narrow rim or margin is to be formed, not exceeding the breadth of the crust upon which it is to rest, with the nail-holes placed exactly in the middle, and from this narrow rim the shoe is to be made gradually thinner towards its inner edge. And that the breadth of the shoe is to be regulated by the size of the foot, and the work to which the horse is accustomed; but in general, it should be made rather broad at the toe, and narrow towards the extremity of each heel, in order that the frog may rest with freedom upon the ground. The necessity of this has been already shown. The shoe being thus formed and shaped like the foot, the surface of the crust is to be made smooth, and the shoe fixed on with eight or at most ten nails, the heads of which should be sunk into the holes, so as to be equal with the surface of the shoe. The frog, frog, and bars, as has been already observed, should never be pared, farther than taking off what is ragged from the frog, and any excrescences or inequalities from the sole. Mr. Ofmer has remarked, that the shoe should be made so as to land a little wider at the extremity of each heel, than the foot itself; otherwise, as the foot grows in length, the heel of the shoe in a short time gets within the heel of the horse; which pressures often breaks the crust, and produces a temporary lameness, perhaps a corn. But this method of shoeing horses has been followed long before Mr. Ofmer's treatise on that subject was published; and for these several years past it has been endeavored to introduce it into practice. But so much are farriers, grooms, &c., prejudiced in favor of the common method of shoeing and paring out the feet, that it is with difficulty they can even be prevailed upon to make a proper trial of it. They cannot be satisfied unless the frog be finely shaped, the sole pared, and the bars cut out, in order to make the heels appear wide. This practice gives them a show of wideness for the time; yet that, together with the concave form of the shoe, forwards the contraction of the heels, which, when confirmed, renders the animal lame for life.

It is contended, that in this flat form of shoe, its thickest part is upon the outside of the rim, which is most exposed to be worn; and being made gradually thinner towards its inner edge, it is therefore much lighter than the common concave shoe; yet it will last equally as long, and with more advantage to the horse; and as the frog or heel is allowed to rest upon the ground, the foot enjoys the same points of support as its natural state. It must therefore, it is supposed, be much easier for the horse in his way of going, and a means of making him fore-footed. It is likewise evident, that, from this the hoof cannot acquire any bad form; where, at the same time, it receives every advantage that possibly could be expected from shoes. In this respect it may very properly be said, that we make the shoe to the foot, and not the foot to the shoe; as is but too much the case in the common shoes, where the foot very much resembles that of a cat, fixed into a walk-at-hell. But it is to be observed, that the heels of young horses, before they are shod, for the most part are wide and open at the heels, and that the crust is sufficiently thick and strong to admit of the nail's being fixed very near the extremities of each. But, as has been formerly remarked, from the constant use of concave shoes, the crust of this part of the foot grows thinner and weaker, and when the nails are fixed too far back, especially upon the inside, the horse begins to walk; to avoid this, they are placed more towards the fore part of the hoof. Thus causes the heels of the horse to have the greater spring upon the heels of the shoe, which is so very detrimental to occasion lameness; whereas by using this flat form of shoe, all these inconveniences are avoided; and if the heels of young horses from the first time that they were shod, were continued to be conically treated according to the method here recommended, the heels would always retain their natural strength and shape. By following this flat method of shoeing, and manner of treating the heels, several horses now under this management, that were formerly tender-footed, and frequently lame, while shod with broad concave shoes, are now quite sound, and their hoofs in as good condition as when the first shoes were put upon them. It is thought that if farriers considered attentively the design of shoeing horses, and would take pains to make themselves acquainted with the anatomical structure of the foot, they would then be convinced, that this method of treating the heels, and this form of shoe, is preferable to that which is so generally practiced. But it has been alleged, that in this form of shoe, horses do not go so well as in that commonly used. This objection will easily be set aside, by attending to the following particulars. There are but few farriers that can or will endeavour to make the flat shoes, in which these objections operate. The reason, in forming it, does not so easily turn into the circular shape necessary, as in the common shoe; and perhaps this is the principal reason why they object to it, especially where they work much by the piece. And as many horses that are commonly shod with concave shoes, have their foals considerably higher than the crust, if the shoe is not properly formed, or if it is made too flat, it must unavoidably rest upon the sole, and occasion lameness. Further, that the practice of paring the sole and frog is also so prevalent, and thought so absolutely necessary, that it is indiscriminately practiced, even to excess, on all kinds of feet; and while this method continues to be followed, it cannot be expected that horses can go upon hard ground, on this open shoe, with that freedom they would do if their foals and frogs were allowed to remain in their full natural strength. Experience teaches us, that in very thin-hoofed horses, we feel an acute pain from every sharp-pointed bone we happen to tread upon. Horses are sensible of the same thing in their feet, when their foals, &c., were pared too thin. Hence they who are prejudiced against this method, without ever reflecting upon the thin state of the sole, &c., are apt to condemn it, and draw their conclusions more from outward appearances than from any reasoning or knowledge of the structure of the parts. From a due attention likewise to

Vol. XXXII.
SHOEING.

the structure of a horfe's foot in a natural state, it will be obvious, that paring away the foie, frog, &c. must be hurtful, and in reality is destroying that substance provided by nature for the defence of the internal parts of the foot; from which practice it must be more liable to accidents from hard bodies, such as sharp stones, nails, glass, &c. From this consideration we shall likewise find, that a narrow piece of iron, adapted to the shape and size of the foot, is the only thing necessary to protect the crust from breaking or wearing away; the sole, &c. requiring no defence if never pared. But there is one observation farther necessary to be made; which is, that the shoe should be made of good iron, well worked, or what smiths call hammer-hardened, that is, beaten all over lightly with a hammer when almost cold. It is well known, that heating of iron till it is red softens it greatly; and when the shoes thus softened are put upon horses' feet, they wear away like lead. But when the shoes are well hammered, the iron becomes more compact, firm, and hard; so that a well-hammered shoe, though made considerably lighter, yet will last as long as one that is made heavier; the advantage of which is obvious, as the horse will move his feet with more activity, and be in less danger of cutting his legs. The common concrete shoes are very faulty in this respect; for, in fitting or shaping them to the foot, they require to be frequently heated, in order to make them bend to the unequal surface which the hoof requires from the conical use of the shoes; they thereby become soft, and to attempt to harden them by beating or hammering when they are shaped to the foot would undo the whole. But flat shoes, by making them when heated a little narrower than the foot, will, by means of hammering, become wider, and acquire a degree of elasticity and firmness which it is necessary they should have, but impossible to be given to them by any other means whatever; so that any farrier from practice will soon be able to judge, from the quality of the iron, how much a shoe, in fitting it to the circumference of the hoof, will stretch by hammering when it is almost cold; this operation in fitting flat shoes will be the less difficult, especially when it is considered, that as there are no inequalities on the surface of the hoof (or, at least, ought not to be) which require to be bended thereto, shoes of this kind only require to be made smooth and flat; hence they will press equally upon the circumference or crust of the hoof, which is the natural tread of a horse. And a preference has lately been given by the best hands to this description of shoe, which he calls the "feated shoe," and which he has formed in a die, in the fame manner as money is struck in coinage. The upper surface of this shoe consists of two parts; an outer part, which is a perfect plane near the rim, corresponding with the breadth of the crust, and called the crat; and an inner part, sloping from the flat, and distinguished by the name of the bevel. The crat is obviously intended to support the crust in its whole extent, the bevel to lie off the sole; and this latter being more or less broad, according to the kind of work proposed to be done, will give the requisite strength to the shoe. As the whole of the crust bears on the crat, it is liable to be broken than when only a small part of it rests on the shoe. In consequence, likewise, of the crust resting on the flat crat, the weight of the body has a tendency to spread the foot wider in every direction, rather than to contract it, as has been observed to happen with the common shoe, and when afterwards filled with the felted one, it has become wider without the horfe having been taken from his usual work; and again, it is observed, that a foot being of a full size and proper form when first filled with the felted shoe, has retained the same size and form without the slightest alteration, as long as the felted shoe was used. By the crat or bevel in the shoe, a cavity is formed between it and the sole, sufficient to admit a pick, and to prevent preasure on this part, without the sole itself being hollowed, and consequently weakened. For if it be one of the functions of the horny sole to defend the sensitive sole, of which, from its situation and nature, no one can doubt, it must be evident that the more perfect it is left, the stronger it must necessarily be, and of course the more competent to perform its office. And though he cannot be fanguine enough to suppose that this shoe will prevent lamens in every cafe, there is nevertheless sufficient proof from experience to assert, that it will diminish its frequency. Some strong objections have however been made to this form of shoe by Mr. Coleman. If it should be found, where the shoe is applied, that the sole very frequently receives preasure, then we shall demonstrate that the practice is incompatible with the principle. If it be good practice for the sole to receive preasure, then the principle must be erroneous that attempts to make the shoe rest totally on the crust; and if the principle be well founded for the crust only to support the shoe, then, if the shoe be in contact with the crust, the practice must be imperfect. Except a model is taken to every horse's foot, it is impossible for the reeding-place of the shoe precisely to fit the crust; for the crust not only varies exceedingly in different horses, but in the same hoof at different parts. The flat surface, therefore, that is only broad enough for the toe, is frequently too broad for the quarters and heels. And in all the shoes he has ever seen of this description, the flat part of the shoe is made of the same breadth at the quarters as at the toe. It is farther to be observed, that this surface very generally exceeds the crust at every part. In the same proportion as the seat of the shoe exceeds the breadth of crust, exactly so much of a flat surface is opposed to an equal quantity of sole. The principle of this shoe is therefore defeated by the practice; for, instead of the seat resting on the crust, it projects over the edge of the sole. It is therefore a fact, that while great pains have been taken to make a flat seat on the shoe, in order to support the crust only, and the web concave, in order to remove preasure from every part of the sole, that the seat has nevertheless very rarely fitted the crust; and consequently the foles of all flat feet, at their connection with the crust, must receive more or less of preasure from the seat of the shoe. Where the sole is concave, this shoe will only rest on the Wulst, but a shoe that is flat on its whole internal surface would answer the same purpose; for the concave part of the sole opposite to the concavity of the web of the shoe would receive no preasure, even from a shoe wholly flat. He therefore recommends a shoe which has been found free from these and other objections, and which indeed bids fair to supercede the use of every other kind. But before this is noticed, it may be necessary to mention curiously the shoes proposed by Mr. St. Bel, and Mr. Taplin; but in fact the changes they have introduced are rather novelties than improvements. Mr. St. Bel has indeed committed a great error, that of promoting the arched form of the horfe's foot, and thus raising the frog out of the way of preasure, a practice highly injurious to the animal.

It is indeed observed, in respect to Mr. St. Bel's mode of shoeing, by Mr. Coleman, that he employed a shoe with a flat upper surface; but, from not attending to the very important operation of removing the sole under the heels of the shoe, to every kind of hoof, it frequently failed of success. But that the best form of the external surface of the shoe is a regular concavity, that is, the common shoe reversed. This shoe leaves the hoof of the same figure when stood, as before its application. And it is evident, that a concavity has more points of contact with pavement and other
SHOEING.

In shoeing, it is to be noted that there are two circumstances naturally to be attended to, viz., to cut the hoof and apply the shoe. Before the hoof is protected by iron, four parts require to be removed, and others preserved. This is even more important than the form of the shoe. But many have attended chiefly to the shoe, and not to its application or to the hoof; and this error has produced much mischief and more expense to the Veterinary College, than all the prejudices and calamities of grocers and farmers. The first thing to be attended to, is to take away a portion of the sole between the whole length of the bars and crulh with a drawing-knife; for the heels of the sole cannot receive pressure without corns. To avoid this the shoe should be made concave, so as not to be in contact with the shoe. If there be any one part of the practice being more important than the reef, it is this removal of the sole between the bars and crulh. When this is done, the horse will always be free from corns, whatever may be the form of the shoe. Besides this, the heels of the shoe should be made to rest on the junction of the bars with the crulh; whereas, if the bars are removed, the shoe is supported by the crulh only, and not by the solid bases of the crulh and bars united.

And it is added, that it is necessary that the sole be cut before any other part of the hoof be removed. If the heels have been first lowered by the butterers, then possibly there may not be sufficient sole left to enable a drawing-knife to be applied without reaching the sensitive sole; whereas, by cutting the sole in the first instance, we can determine on the propriety of lowering the heels and shortening the toe. The sole can then defend, without the motion being obstructed by the shoe; and any foreign bodies that may have got into this cavity are always forced out when the sole defends, without producing any mischief. When the shoe is applied, the cavity between the sole and shoe should be sufficiently large, at every part, to admit a large horse-pickcr, and particularly between the bars and crulh. If the sole is naturally concave, a shoe with a flat surface applied to the crulh, will not touch any part of the sole; and if the sole be flat, or even convex in the middle, or towards the toe, the quarters and heels of the sole will generally admit of being made concave with a drawing-knife, so as not to receive any pressure from a flat shoe. If a shoe with a flat upper surface does not leave ample space for a pickcr between the sole and shoe, then it is requisite to make either the shoe or the sole concave. When the sole appears in flakes, and thick in substance, it will be better to make the whole of the sole concave by a drawing-knife; and this operation should always be performed before the toe is shortened or the heels lowered. When we have made the sole hollow, then a shoe with a flat surface will rest only on the crulh: but if the shoe be flat, or convex, and thin towards the toe and middle of the hoof, so as to prevent the possibility of removing the sole at these parts, to form a concavity, then it is necessary to employ a shoe sufficiently concave to avoid pressure, and to admit a pickcr. In this case, however, the shoe at the heels and quarters, even in convex feet, will generally allow of removal with a drawing-knife, and then the quarters and heels of the shoe may be flat. It therefore follows, that where the sole can be made concave, a shoe with a flat surface may with safety be applied, but where parts of the sole, from diseased or bad shoeing, become flat, a shoe with a convex surface is required. An added tooth is always a staple, and as the horse perfects it from the tips, three of the crulh requires to be cut off at least twenty-eight days. In these cases we can remove this tooth, the horse will be proper to apply a shoe that is thickened at the quarters, and reduced to the navel and toe, and the horse will be less liable to sprain.

And it is stated that the bars and frog should never be removed. What is rugged and detached had better be cut off with a knife by the groom than left to the farmer, who will perhaps remove two of the four parts. Where the frog is not large and projecting, the heels may be lowered by a rafh, or the butterer, for in every case we are to endeavour to bring the frog into contact with the ground. The frog must have pressure, or be deterred. Nevertheless, when the frog has been diffused for a considerable period, and become soft, it must be accustomd to pressure by degrees. If the quarters are high, and much exceed the convexity of the frog, we should gradually lower the heels, and endeavour to bring the frog and heels of the shoe on the same parallel line. Where work is required of the horse, while the frog is not long enough, it may be gradually used to pressure, by lowering the hoof about the tenth of an inch every time of shoeing, until the frog be hard, and equally prominent with the heels; or if the horse is not wanted, great advantage would be derived from his standing without shoes on a hard pavement. But the feet of horses are so variously deformed by bad management, it will be requisite in shoeing to attend to each particular kind of hoof. If any form of shoe be indiscriminately applied for all kinds of feet, it must frequently fail of success: but by proper attention to the different hoofs, we can generally improve the whole foot, so as to employ the shoe recommended at the Veterinary College. And, after the hoof has been properly prepared, then it is requisite to apply a shoe, and to vary its length, breadth, and thickness at the heel, surfaces, &c., according to the hoof. If the heels of the fore-feet are two inches and a half, or more, in depth, the frog found and prominent, and the ground dry, then only the toe of the hoof requires to be shortened, and afterwards protected by a short shoe made of the usual thickens at the toe, but gradually thinner towards the heel. For a common fixed saddle-horse, it may be about three-eighths of an inch thick at the toe, and one-eighth at the heel. The intention is, to bring the frog completely into contact with the ground, to expand the heels, prevent corns, thrushes, and canker. If applied in May or June, when the ground is dry, it may be continued all the summer; and in warm climates, where this is the case, no other protection for the hoof is requisite. And he adds, that to long as the wear of the hoof is not greater than the supply afforded by nature from the coroet, so long may the short shoes be worn; but in wet weather this is not the case: he has known some light horses to wear them the whole year; but such instances are not common. Nevertheless, the short shoe can be employed on most horses with advantage in summer, when the heels are from two and a half to three inches in depth, and the frog equally prominent; but, unless the hoof has been properly performed, the heels and frog are generally too low for the short shoe. The toe of the horse requires to be shortened as much as possible; but if the frog touches the ground, no part of the heel should be cut; and, by pursuing this practice, the heels will frequently grow sufficiently high to receive the short shoe. After speaking of the application of the short shoe to running horses, it is stated, that during the wet months, we must protect the whole crust by a long shoe; and if the heels of the hoof are low, we employ the same shoe in summer. In winter, when the heels are too high,
high, it is better to lower them moderately with a rasp, than to wear them down with a short file, as the wet may cause more horn to be destroyed than is necessary to be removed; but it cannot be too often repeated, that the sole between the bars and crust should be taken out before the heels are cut. If the heels are first removed, then possibly the horn left will be insufficient to afford a proper degree of concavity between the bars and crust. Where very high-heeled shoes have been worn, the frog would be liable to injury, as well as the mufcles and tendons that bend the leg, from the sudden application of a shoe made thin at the heels. Indeed, whether the shoe or hoof be the caufe that elevates the frog, the attention is required to bring it gradually into contact with the ground. We therefore thin the heel of the shoe by degrees, that the frog may become accustomed to hard preſsure. The thickness of the laft shoe at the heel will always furnish a proper criterion for that to be next applied. If only a small portion of the hoof can be taken from the toe, the heel of the new shoe should be about one-tenth of an inch thinner than the shoe removed; and the growth of the crust will generally be equal to this diminution of iron. By reducing the heels of the shoe in the same proportion as the hoof grows, a thin-heeled shoe may, in a few months, be employed; and yet the horn being preserved at the heels, and cut at the toe, every time of feeding, the heels (shoe and hoof together) will be as high, and frequently higher, than when the former thick-heeled shoes were employed. The crust that depends at the heels we allow to remain; but subtraft an equal quantity of iron from the heels of the shoe, and as much horn as possible from the toe of the hoof. This system should be continued till the heels of the shoe are about one-third the thickness of the toe. In proportion as the crust from the coronet to the toe increafes, and the heels decrease in depth, the back finews and mufcles will be put on the stretch. And the converfe of this must be equally true, that as the heels are high and the toe short, the mufcles and finews are relieved. It therefore follows, that every atom of horn or iron taken from the toe of the crust, or shoe, tends to relax the parts behind, and that the removal of horn or iron from the heels produces the opposite effect. If thefe sim̂ple facts are kept in view, there can be no difficulty in ascertaining the quantity of iron that may be removed with safety from the heels of any hoof, without danger of mischief to the mufcles and tendons.

But in the shoeing of horses that are liable to cut, the following useful direĉtions have been given by Mr. Moorcroft. It is contended, that in order to prevent a horse from striking the foot or shoe against the opposite leg, by which it is often bruised or wounded, is an important point; inasmuch as this accident occurs very frequently, and it not only blemishes and disfigures the leg, but also endangers the safety of the rider. The parts frick in the hind-leg, are the infele of the fetlock-joint, and the coronet; in the fore-leg, the infele of the fetlock-joint, and immediately under the kneee; which latter is called the freely cut, from its happening only when a horse goes fall. Young horses, when first backed, generally cut their fore-legs, although naturally they may be good goers. This arises from their placing the foot on the ground too much under the middle of the breast, in order the better to support the burtien to which they are unacĉustomed; but by degrees they acquire the method of balancing the weight, with the foot in the same direĉtion it would naturally have were they without it. It may, therefore, he thinks, be laid down as a general rule with such horses, that, till they regain their natural method of going, the edge of the inner quarter of the shoe should follow exactly the outline of the crust, but should not be fet within the crust, nor should the crust itself be reduced in thickness; as both these practices tend to weaken the inner quarter, and to deform the hoof. And here it must be oberved, that the outer edge of the shoe should, in all cases of bound feet, follow exactly the outer edge of the crust, except just at the heel, where it should project a little beyond the line of the hoof. Also, that horsees with narrow caufes, having their legs placed near together, are apt to cut when they begin to tire; and with thele the practice just mentioned should always be employed. Horsees that turn their toes much outwards are, of all others, most subject to cut. But in reply to the aflertions of some, that this accident also happens to such horsees as turn the toes much inwards, he denies having met with a single instance of the kind. In horsees of the firft description, it has been long oberved, that the inner quarters of the hoof were lower than the outer, and that the fetlock-joints were nearer each other than in horsees whose feet pointed straight forwards. These two facts probably led to a conclusion, that if the inner quarters were raised to a level with the outer, and so much the more as they were made proportionally higher, that the fetlock-joints would be thrown farther apart, so as to admit of the foot palling by the supporting leg without striking the joint. Accordingly, for the two laft centuries, at leaft, it has been usual to make the inner quarter of the shoe higher than the outer; and not only has this been the general practice, but it has been regularly recommended by almost every writer from that time to the present. And notwithstanding this method has very frequently failed of success, yet repeated disappointment appears never to have led to the circumstance of quizzing the truth of the principle. Nay, indeed, the reliance placed upon it has been so strong, probably from the simplicitie of the reasoning on which it was founded, that in the cafes where it most particularly disappointed expectation, its failure was generally attributed to the practice not being carried sufficiently far; and accordingly the shoe has been still more raised on the inner quarter, and the edges of the crust and shoe have been filed away. When these expedients likewise failed, the laft resource has been, a circular piece of leather placed round the joint to receive the blow of the foot.

It is noticed, that about four years ago, a shoe, with the outer quarter thick and the inner one thin, was applied in a cafe which had baffled many attempts on the old plan. On the first trial the horse ceased to cut, nor has he ever done it since; which can only be attributed to his having confantly worn the fame kind of shoe. And other bad cafes, which have occurred occasionally since that period, have been treated in the fame way, and with the fame success, although for a long time it was at a loss how to explain them. If the action of cutting principally depends on the faulty position of the fetlock-joints, and of the feet with respect to each other, and it seems generally agreed that such is the fact, it should seem that a means which, by raising the outer quarters, much throw the fetlock-joints still nearer to each other, would necessarily increase the defect in question; but as the reverse of this actually takes place, it might induce a suspicion that there exists some other caufe of cutting which has been hitherto overlooked. For horsees which cut their hind-legs, the shoe, at the outer heel, should be from half an inch to an inch in thickness, according to the kind of horse, and to the degree in which he may cut. The web of the shoe should gradually become thinner till it reaches the toe, which should be of the ordinary thickness, and from which it should slope off, and end like a tip in the middle of the inner quarter. For horsees which cut only in a flight degree, a shoe of the fame thicknesses throughout, but reaching on the inner quarter only as far as the middle of the foot, will
will in most instances be found sufficient. This shoe, in point of effect, would be equally proper for the fore-foot, were it not that in such horses as are used for the saddle, the fore-feet, being more charged with weight than the hind feet, are more particularly liable to be injured, and a horse thus shod on the fore-feet ought not to be used; therefore, it is expedient to let the inner quarter of the shoe be, and reach to the heel; but the outer edge should be bevelled off, to allow hope towards. The same kind of shoe is equally well calculated to prevent the speedy cut, offering to bevel off more freely the part which chance, and not to put in any nails thereabouts. And here it may be proper to remark, that in bound feet, the heel of the shoe should reach as far on the heel as the end of the angle formed by the crush, and the lustre being fully untied; but it should not be carried quite so far as the end of the heel of the hoof. But in order to ascertain what would happen to a horse thus shod with different kinds of shoes, the following trials were made.

Experiment 1. A horse with a narrow chest, who had never cut, and having parallel shoes on his fore-feet, was trotted at about the rate of eight miles an hour, in a straight line, over ground sufficiently soft to retain chiefly the impressions of the shoes, but not to admit the feet to sink into it. These parallel shoes were drawn along the track, including between them the prints of the shoes. By these it was found, that there was regularly a distance of nine inches and a half between the outer edge of the near fore-shoe and that of the off fore-shoe.

2. Shoes thick in their inner quarter, and like a tip, reaching only half way on the outer quarter, were then used; and it appeared that the distance between the outer edges of the prints of the shoes, taken as before, was regularly reduced to eight inches and a half.

3. The same shoes were afterwards placed on the opposite foot, so that the thick heel was on the outer quarter; and the result, under circumstances exactly the same as in the foregoing experiments, was, that the distance between the outer edges of the prints of the shoes was regularly increased to eleven inches. To account for these results, it is necessary to attend closely to the different effects produced by the weight of the fore part of the body acting upon the two fore-feet, when raised on the inner or outer quarters, during the opposite states of rest and action. And first, with regard to shoes raised on the inner quarter: whill a horse fo shod is standing full, the fetlock-joints are certainly thrown farther apart than when any other kind of shoe is used. Hence it was concluded, that the limb which supported the body would have its fetlock-joint thrown so much outwards, as to keep it completely out of the way of the foot in motion. But it appears that the impressions made on the ground by such shoes are much nearer together, than those made by parallel shoes, and two inches nearer together than those made by shoes raised on the outer quarter. And this may be thus explained: when the horse is at rest, the weight is supported equally by the two fore-feet; but the infant one foot quite the ground, the weight is suddenly transferred to the other; and by the outer quarter being lower than the opposite one, the fore part of the horse has a tendency to fall over to the outside. To prevent this, the moving foot is suddenly brought close to the fetlock of the supporting foot, in order to relieve it by catching the weight; and the foot itself is placed on the ground too much under the middle of the breadth. The same circumstance occurs to both feet in their turn: and the horse, being thus in constant danger of falling to one side or to the other, is constrained to bring his feet near together to preserve his balance; and in doing this, it presses the foot against the opposite fetlock. And it is generally happens, that the more the two are turned outwards, the nearer the falkon points are brought together, and the more the horse is disposed to cut. However, this is true only to a certain extent; for if the faulty position of the lower part of the leg be carried and study beyond a given point, till of producing an incised degree of cutting, it will enable it remedies the defect altogether. The reason of this is the reverse of what takes place when the inner quarter is raised; that is to say, when the weight of the fore part of the body is only upon one leg, it bears too much upon the inner quarter, from its being lower than the outer quarter; and thus the horse has a tendency to fall over to the inside of the supporting leg. To prevent this, the moving foot is thrown a little farther from the supporting leg, in order to maintain the balance: and thus the foot makes the fetlock joint.

In cafes where the roads are covered with ice, it becomes necessary to have the heels of horses' shoes turned up, and frequently sharpened, in order to prevent them from slipping and falling; but this cannot be done without the frequent moving of the shoes, which breaks and destroys the crush of the hoof where the nails enter. To prevent this, it has been recommended to those who are willing to be at the expense, to have foil points screwed into the heels or quarters of each shoe, which might be taken out and put in occasionally. And the method of doing this properly, as laid down by Mr. Clark, is first to have the shoes fitted to the shape of the hoof, then to make a small round hole in the extremity of each heel, or in the quarters, about three-eights of an inch diameter, or more, in proportion to the breadth and size of the shoe; in each of these holes a screw is to be made. The foil points are likewise to have a screw on them, exactly fitted to that in the shoes. Care must be taken that the screw on the points is no longer, when they are screwed into the shoe, than the thickness of the latter. The foil points are to be made sharp: they may either be made square, triangular, or chisel-pointed, as may be most agreeable. The height of the point above the shoe should not exceed a quarter of an inch, for a faddle-horse; they may be made higher for a draught-horse. The foot handle, that is necessary to screw them in and out occasionally, is made in the shape of the capital letter T, and of a sufficient size and strength. At the bottom of the handle a socket or cavity must be made, properly adapted to the shape of the foil point, and so deep as to receive the whole head of the point that is above the shoe. In order to prevent the screw from breaking at the neck, it will be necessary to make it of a gradual taper. The same is likewise to be observed of the female screw that receives it; that is, the hole must be wider on the upper part of the shoe than the under part. The sharp points may be tempered or hardened, in order to prevent them from growing too soon blunt; but when they become blunt, they may be sharpened as at first. These points should be sharpened, when the horse is put into the stable; as the foals will do them more injury in a few minutes than a day's riding on ice. A draught-horse should have one on the point of each shoe, as that gives him a firmer footing in drawing on ice; but for a faddle-horse, when points are put there, they are apt to make him trip and stumble. And when the shoes are provided with these points, a horse will travel on ice with the greatest security and headways, much more so than on carriage-way or turnpike roads, as the weight of the horse presses them into the ice at every step. And in addition to the common shoe for horses that have found feet, there are also others.
others of various shapes, determined by the necessity of the cafe, as by the different derangements and diseases to which the horfe's foot is liable. See Shoe.

Shoeing of the Afs and Mules. With respect to what concerns the shoeing of other animals, Mr. Clark thinks that the mule, being an animal uncommon in this country, the afs of no great value, and the ox not generally employed in labour, it is needless to lay much on the subjéct. The shoe for the fore-feet of the mule is very similar to that which the farriers call the bar-foot. It is very wide and large, especially at the toe, where it sometimes projects four inches and upwards beyond the hoof. This excess is given it with a view to enlarge the base of the foot, which is in general exceedingly narrow in this animal. The shoe for the hind-feet is open at the heels, like the horfe's shoe; but it is lengthened at the toe, like the preceding one. And it is added, that the foot of the afs, having the fame shape as that of the mule, requires the fame kind of shoe, with this only difference, that the shoe of the fore-foot is not closed at the heels, and that its edges do not project so much beyond the hoof. The fame form of shoe is used for the hind-feet of this animal.

Shoeing of Oxen, the buisines of fixing shoes upon animals of this kind, and which is constantly necessary wherever they do any fort of field or road labour; but it is a practice which is yet far from being performed in a perfect manner. Mr. Clark remarks, that in many parts of France, where the ox is used for draught, it is sometimes necessary to employ eight shoes, one under each nail; or four, one under each external nail; and sometimes only two, one under the external nail of each fore-foot. In this country two pieces, or shoes, to each foot are generally, however, made alike of; being mofiily fixed on, especially in the northern districts, with three or four large-headed nails to each shoe. They are fitted on in a similar manner to those of the horfe. But from the shoes of these animals being, from the smallness of the pieces, so liable to break, it has been suggested to have them shod with whole shoes, in the manner of the horfe; but how far this is a practice that will answer, must depend upon future trials. It is probable, that in this way the foot will be too much confined to succeed in any very perfect manner. Where oxen are left without shoeing, they are continually liable to become lame, and to be incapable of going on with their work. As there is much trouble in the shoeing these animals, from its being necessary to call them each time, it has been found requisite to have recourse to contrivances for shoeing them standing. See Ox-shoeing Machine.

Shoemakers' Chips, in Agriculture, the refuse cuttings pared off in making shoes, which, when collected in sufficient quantity, are found useful as a manure. See Manure.

Shoenech, in Geography, a Moravian settlement in Pennsylvania, near Nazareth, begun in 1757.

Shoesharo, a town of Little Baharia; 60 miles S.W. of Acfu.

Shogle. See Chou.

Shoket, a town of Syria, in the pachalic of Damascus, on the Oronte; 22 miles S. of Antakia.

Sholavenden, a town of Hindooftan, in Madura; 14 miles W.N.W. of Madura.

Sholaveram, a town of Hindooftan, in the Mawar; 14 miles S. of Triptore.

Sholingur, a town of Hindooftan, in the Carnatic; 20 miles S. of Bomraotezolam.

Shocampetty, a town of Hindooftan, in Coimbatore; 5 miles S.S.W. of Caroor.

Shoolds, in Rural Economy, a provincial term applied to holls.

Shoolarumboo, in Geography, a town of Hindooftan, in the province of Dindigul; 17 miles N.N.W. of Dindigul.

Shooleramcotta, a town of Hindooftan, in the province of Dindigul; 7 miles N. of Dindigul.

Shoomtsha, one of the Kurile islands, the nearest to Kamtuchaka. The channel between the Lopatka and this island is 15 versts broad. The length of the island from N.E. to S.W. is 50, and the breadth 30 versts. The land is low, with moderate ridges of hills. The eastern coasts, about the middle of the island, form steep shores and rocky shelves, and are for some way into the sea fringed with rocks. Here is one, and it is said that a vein of silver has been formerly worked. In the centre of the island is a lake, five versts in circuit, which flows by a streamlet into the sea. In this are caught fine salmon, and several other kinds of fish. There are no flat-trees upon the island, but merely bushes of alder, willow, and an fuphale kind of poplar, or Siberian cedar, on which grow little cedar-nuts. The inhabitants are not genuine Kuriles, but of Kamtuchakan dale decent; of these 46 perons pay tribute. N. lat. 51° 25' to 53°. E. long. 156° 14'.

Shoor, a town of Hindooftan, in Lahore; 15 miles S.E. of Koohab.

Shoot, in Agriculture, the young branch of any fort of plant, which is afforded in one feedon. It also signifies a young animal of the cattle kind, in some districts.

Shoot, in the Sea Language. They lay the ballast shoots, when it runs over from one side to another.

Shoote, among neat cattle, an affectation of the bowell kind, with which calves are often attacked a few days after calving. The usual symptoms are, first, a colic or pain that is more or less violent, and is frequently very feverous and dangerous, especially when it is contagious. This colic is terminated, and the calf relieved, by a discharge taking place from the bowells; though this sometimes proves fatal before the shoote appears. Secondly, a loathing and refucing of food, even previous to the discharge; which decreases and increases according to the duration and violence of the disorder. Where the disafe prevails, the best medicine which can be administered is that of eggs and flour properly blended with oil, melted butter, and anised, linseed, or similar mucilaginous vegetable matters; and milk simply mulled with eggs may be often given with much advantage.

Shooter's Hill, in Geography, a hill in the county of Kent, between London and Dartford.

Shooting. See Gunner and Projectile.

Shooting of Bombs. See Bomb.

Shooting with Air. See Wind-gun.

Shooting, Malicious, in Law. See Mahim.

Shooting of Salt. It is to be observed, that the figures arising from the shooting of dissolv'd salts are not constantly the fame, but vary according to different circumstances, such as when they happen to shoot more or less hastily, or in different proportions of liquor. See Salt.

Shooting Point, in Geography, a cape of Scotland, on the south coast of the county of Fife, and east side of Largo bay.

Shoots, Hot. See Hot.

Shoot, Water. See Water.

Shop-lifter, a person who, on pretence of buying goods or otherwife, takes an opportunity to steal them; and if the goods amount to the value of five shillings, though
though so person be in the shop, he is guilty of felony without benefit of clergy, by 1 W. III. c. 22.

SHORAB, in G. (sp.), a town of Perak, in the province of Perak; 8 miles W. of Merlimau.

SHORAY, a town of Hindustan, in the circuit of Chas-river; 21 miles N. of Kumilla.

SHORE, Jane, in Biograph., the concubine of king Edward IV., was the wife of Mr. Matthew Shore, a goldsmith in Lombard-street, London. Historians represent her as extremely beautiful, cheerful, and generous. The king, it is said, was so captivated with her temper than her person; he never made use of her influence over him to the prejudice of any one; her importunities were always in favour of the unfortunate. After the death of Edward, she attached herself to the lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the accusation of witchcraft. For this she was doomed to a public penance, and to the loss of her property. She was alive, but probably in a very wretched state, under the reign of Henry VIII., when she was seen by Sir Thomas More, poor and old, and without the smallpox trace of her former beauty. Mr. Rowe, in his tragedy of Jane Shore, has adopted the popular story, related in the ballad, of her perishing with hunger in a place where Shore-ditch now stands. But Stow assures us, that this place had its name long before her time.

SHORE, John, a famous performer on the trumpet. Matthias Shore, the father of John, and Colley Cibber's wife, was sergeant-trumpeter, in which office he was succeeded, first by his brother William Shore, and afterwards by his son John. His daughter, Mrs. Cibber, had been a scholar of Purcell in singing and playing on the harpsichord; in the exercise of that talent at home, her con- quest over the heart of Colley Cibber first began. Purcell, from his connexion with the family, and his admiration of John's performance on the trumpet, took every opportunity in his power to employ him in the accompaniment of his songs and other theatrical compositions; and this accounts for the frequent use he made of that martial and field instrument, even when the subject of the poetry was pacific. John Shore lived till the year 1753, when he was succeeded as sergeant-trumpeter, by that admirable performer the late Mr. Valentine Shaw, whose exquisite tone and fine shake must be still remembered by many persons living, who have heard him at Vauxhall, and in Mr. Handel's oratorios.

SHORE, among Builders, &c. See SHOAN.

SHORE, or Common Shore, a corruption of sewer. See Sewers.

SHORE, in Agriculture, a sort of artificial drain or course, formed in low flat lands for the purpose of freeing and relieving them from the collected surface-water. The want of shores is now most common in waste and unreclaimed lands; but it occasionally occurs in those of other kinds, as wet meadows, to the great injury and prejudice of the prevailing crops, and the future productiveness of the land, as the letting surface-water can get off in no other way. There are very great extents of even appropriated lands, in some cases, that are greatly damaged and inconvenience by water lodging and stagnating in the furrows of the ridges and the ditches, for want of having sufficient proper shores, or public drains, for drawing it off; and of public proper laws and regulations for enforcing the re-opening and the clearing, from time to time, of those which have been formed in former periods; as well as for the preferring of the whole always in a suitably open state.

It is extremely probable, that a large proportion of the low flat lands of the country, which are now in slide, what dry conditions were, in their natural state, liable to at times be covered with water. This appears to have been the case, from the compact glory of moorland of the field, and the flat covering of black vegetable earth which is silted over the surface of them, where the work of drainage has not been performed upon them. And, from many of such low flat lands being now lying in a tolerably dry state, from large tracts of that of the marsh kind, which is now barely out of the reach of water, which, if wetted by till their drains and ditches to the brim, as well as from the humid fogs and mists of the low lying districts,—it would seem, it is laid, to be equally probable, that much industry and exertion have at former periods been employed, to free the lands of this sort in the country from the slates in which water and time had placed them.

The feudal system is supposed to have been particularly favourable to undertakings of this useful kind, and that since its decline, the courts of the manorial description, which succeeded and survived it, have contributed to enforce its beneficial regulations. But that they have now for the most part lost their power, existence, and authority, or where they are still continued and retained, what relates to the buxoms of public drains and water-courses, in their maintenance, is too oft neglected and overthrown. Hence it is noticed by a late writer, that, "relater to this important department of rural economy and internal policy, the country may be said to have been moving, and in a general view of it, still continues to move, in a retrograde direction."

In a great number of situations, vast injury and inconvenience are at present sustained from the want of the shores, drains, ditches, and other outlets for drawing off the water being kept properly open and free for its discharge into the adjoining rivers, brooks, or seas.

Some sufficient power and authority for the regulation of all matters of this nature should certainly exist in every district of the kingdom; which is not now the case, at least to any full and effectual extent, as many most important and advantageous would necessarily result from it, in the management and improvement of lands, as well as in the increase of the produce of it.

It has been suggested, that a great deal may be effected in this way, by the having recourse to the appointment of justices for the conducting of the business of shores and water-courses, wherever there are the slightest remains of the existence of manorial courts. And that, even where there is nothing of this sort to be met with, it would not fail to have a good effect, in many cases, where the lands are considerable, to have fences in the name, chosen from among the neighbouring tenantry in an annual or other manner, for the purpose of directing the proper regulation of the public shores, drains, water-courses, and other modes of conveying away the superabundant water from the land.

SHORE, S. A., is a general name for the sea-coast of any country. A bold shore is a coast which is steep and abrupt, so as to admit the closest approach of shipping without exposing them to the danger of being stranded. The shores of the sea are divided, by coast Marstigh, into three portions, according to which, all his descriptions, in his account of the botan of the sea, are given. The first part of the shore is that tract of land to which the sea first reaches in stornes and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the district from this, which is always covered with water.

The
The first part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the growth of some plants, and wholly unfit for that of others, by the saline fumes and impregnations: and it is fearlessly to be conceived by any but those who have observed it, how far inland the effects of the sea reach, so as to make the earth proper for plants, which will not grow without this influence, there being several plants frequently found on high hills and dry places, at three, four, and more miles from the sea, which yet would not grow, unless in the neighbourhood of it, nor will ever be found elsewhere.

The second part or portion of the shores is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered faint by the water, and it is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartaceous matter deposited from the water, and the colour of this whole extent of ground is usually dusky and dull, especially where there are rocks and flanes, and these are covered with a flamy matter.

The third part of the shores is more affected by the sea than either of the others, and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of these alter it a little.

Shore of Muchtol, in Geography, a cape of Scotland, on the E. coast of the county of Kincardine, so called from a village near the coast; 3 miles N. of Stonehaven.

Shoreditch, St. Leonard, a parish in the hundred of Osflnpton, and county of Middlesex, England, is situated in the northern suburbs of London, and forms one of the twenty-three out-parishes of Middlesex and Surrey, which are mentioned in the bills of mortality. This parish is of great extent, and is divided into four liberties, called the liberties of Churchend, Hoxton, Honywell, and Moorfields. The church, a modern edifice, was opened for divine service in August, 1740, having been erected in place of a very old church, which Ellis, author of the "History and Antiquities of Shoreditch," states to have been of Saxan origin. The afcent to the church is by a double flight of steps leading under a portico, supported by four Doric columns. The body is plain in its architecture, but is well lighted by spacious windows. The fleape, which rises to a very considerable height, has rather a handfme appearance. In the old church were a variety of monuments and brasses in memory of persons of distinguished rank; among whom were the countets of Wellmorland (daughter to Edward, duke of Buckingham), who died in 1553; Eleanor, countess of Rutland, who died in 1551; and two sons of the said countets of Rutland; but none of those in the new church possess any interest. This parish abounds with alms-houses, established either by public city companies or by private individuals. In Holywell was anciently a priory for nuns of the Benedictine order, which was founded early in the twelfth century, and possessed a revenue of 293l. per annum at the time of the dissolution. According to the parliamentary returns of 1811, this parish contained 5658 houses and 43,930 inhabitants. The History and Antiquities of the Parish of St. Leonard-Shoreditch, by Henry Ellis, quarto, 1797.

Shoreham, New, a borough and market-town in the half hundred of Fihergate, rape of Bramer, and county of Suffex, England, is situated upon the coast of the English Channel, at the distance of about 6 miles W. from Brighthelmstone, and 55 miles S. by W. from London. This town is indebted for its origin to the decay of Old Shoreham, which is now a very trifling village, and appears to have been a place of considerable importance in ancient times. New Shoreham is a borough by prescription, and has sent members to parliament since the year 1295, the 23d year of the reign of Edward I. In 1771 it became conspicuous in the annals of electioneering, by the development of a remarkable scene of corruption practised in the election of members for the parliament then assembled. The returning officer having returned a candidate with only 37 votes, in prejudice to another who had 87, of which he had rejected 76, without assigning any satisfactory reason for so doing, was called upon to account for his conduct at the bar of the house of commons; when he defended himself, by stating that those whom he had quired formed part of a society, called the Christian club, the offensive object of which was only a.malk to cover its real one, the setting the borough to.ale to the highest bidder. In consequence of these aflerions, the house resolved itself into a committee to inquire into the truth; and being fully satisfied on that head, after a patient investigation, it was resolved to incapacitate the members of the club from voting at elections in future.

The church of New Shoreham is a curious and interesting specimen of ancient Norman architecture. At present only the east end is fitted up and appropriated to divine service, as the nave, or part westward of the tower, has been entirely destroyed. It consists of a nave, transept, tower, and choir; and by its style of architecture, appears to have been built near the end of the twelfth century. See a beautiful engraving of it in Cooke's "Southern Coast of England."

New Shoreham is governed by two constables, annually elected, who are the returning officers. The market-day is Saturday, weekly; and there is a fair on the 25th of July. It was formerly a town of more relative note than at present, and had a priory of Carmelites or White Friars, founded by Sir John Mowbray, knt.; as also an hospital dedicated to St. James. It is chiefly remarkable, however, for being built upon the spot where Ella, the Saxon, landed, with supplies from Germany in aid of his countrymen, Hengist and Horda. According to the parliamentary returns of 1811, the parish contains 165 houses, and 770 inhabitants. History of the Boroughs of Great Britain, and the Cinque Ports, 3 vols. 8vo. 1792. Beauties of England and Wales, vol. xiv. by F. Shoberl, 1813.

Shoreham, a township of America, in the state of Vermont, and county of Addison, on the E. side of lake Champlain; containing 2033 inhabitants.

Shorehaven, a sea-port on the south coast of the island of Stromfoe, with a good harbour, called Tros. N. lat. 61° 40'. E. long. 11° 7'.

Shorl, in Mineralogy. See Shorl.

Shorl and Morling, in our Old Writers, words used to distinguish fells of heep; forling being the fells after the fleaves are shorn off the heep's back; and morling the fells head off after they die or are killed. In some parts of England they understand by a forling, a heep whole
SHORN VELVET. See Velvet.

SHORTH, THOMAS, in biography, a physician of the early part of the last century, and the author of many works relating to chemistry, meteorology, and medicine. Few particulars are recorded of his life, which seems to have been spent more in the pursuit of science, than in the exercise of his profession. He was a member of the Royal Society. The following are the principal works which he left.

SHORTH, JAMES, an eminent optical, was born at Edinburgh in the year 1710. At the age of ten he left his parents, and being left in a state of indigence, he was admitted into Heriot's Hospital, where he soon showed a fine mechanical genius, by constructing for himself a number of curious articles with common knives, or such other instruments as he could procure. At the age of twelve he was removed from the hospital to the High-school, where he showed a considerable taste for classical learning, and he soon became at the head of his forms. He was intended for the church, but after attending a course of theological lectures, he gave up all thoughts of a profession, which he found little suited to his talents, and from this period he devoted his whole time to mathematical and mechanical pursuits. He was pupil to the celebrated Maclaurin, who perceiving the bent of his genius, encouraged him to prosecute those particular studies for which he seemed best qualified by nature. Under the eye of his preceptor he began, in 1732, to construct Gregorian telescopes; and, as the preceptor observed, by attending to the figure of his specula, he was enabled to give them larger apertures, and to carry them to a greater perfection, than had ever been done before him.

In 1736 Mr. Shorth was invited to London by queen Caroline, to instruct William, duke of Cumberland, in the mathematics; and on his appointment to this office, he was elected a member of the Royal Society, and patronized by the earls of Macclesfield and Morton. In the year 1739 he accompanied the former to the O'key islands, where he was employed in making a survey of that part of Scotland. On his return to London he established himself as an optical, and in 1743, he was commissioned by lord Thomas Spencer to make a reflector of twelve-feet focus, for which he received 600 guineas. He afterwards made several other telescopes of the same focal distance, with improvements and higher magnifiers; and in 1752 he completed one for the king of Spain, for which, with the whole apparatus, he received 1250l. This was the noblest instrument of the kind that had ever been contrived, and has probably not been surpassed, made by the grand telescopes manufactured by Dr. Herchel.

Mr. Shorth was commissioned to visit the place of his nativity once every two or three years during his residence in London, and in the year 1760 he paid his last visit to Scotland. He died in June 1760, after a very short illness, when he was in the 80th year of his age. His eminence as an artist is universally admitted, and he is spoken of by those who knew him from his youth upwards, as a man of virtue and very amiable manners.

SHORT ACCOUNTS. See Account.

SHORT CROCKS, in Agriculture, are a sort of crocks, which are formed of best pieces of wood of the oak or elm kind, and so contrived as to be fixed on the handle, such that the ends or crooks turning up, for to bear the loads on them. They are in use in the counties of Devon and Cornwall, in the latter of which they have both short and long crooks, as they term them, which are made use of for carrying sawdust, hay, faggot, bale wood, flake, and flagstones. They are a relic of the old mode of carrying loads in hilly districts. Single-horse cart loads would probably answer the purpose in a far better way. See Cart.

SHORT GRAFTS, in Gardening, a term applied to the pieces or grafts which are kept in a continually mown, short, close state, as on lawns, and in pleasure-grounds, or other situations about country residences. The portions of mown or short grafts about seats and houses of the above sort in the modern improved modes of laying out pleasure-grounds, are mostly much more confined in their limits than was formerly the case; as they are not only troublesome, but very expensive in keeping in that proper order and neatness which is necessary for the purpose of ornamental effect, and the utility of walking upon them as occasion may require; and because a much better and more natural effect is found capable of being produced without them; while at the same time the lands can be rendered useful in supporting animals, and of course no loss be sustained.

Where pieces of short grafts are, however, formed, and to be kept in order, it will be necessary to roll, mow, and sweep up the grafts litter in a clean neat manner from them once or oftener in the course of the week during the spring season, and frequently at other times. The refuse litter, thus procured, may be employed for different garden purposes, where it cannot be converted to better uses. See Lawns and Pleasure-Ground.

It is mostly in too dirty a state to be applied as food for any sort of cattle flock.

SHORT-GRAFT SYLPHS, that sort of tool of this kind which is employed in mowing short grafts. Sylphs for this use should be rather short, and laid in the shaft with the edges low, in order that the grafts may be cut in a close neat manner, without leaving any scythe ridges or bulks, as they are usually termed. The scythe or sythe, in performing this sort of mowing, are commonly made narrow, in the intention, that the grafts may be well and levelly cut out of the bulks or parts under the scythe, and by such means have a more neat and even appearance. See Scythe.

SHORT SMILLS, in Agriculture, a sort of oat, which is famed on account of its remarkable flouriness. It is much grown in the county of Essex, and is a thick, full, weighty kind, which succeeds well on most lands of the more dry kind. See Oats.

SHORT SAILS, in a Man of War, are the same with fighting sails, being the fore-sail, main-sail, and fore-top-sail, which are all that are used in fight, lest the sail should be fired and spoiled: besides the trouble of managing them when a wind gives chase to another.

A chaise is a disposition to fight, they say the chaise flung into her short sail, i.e. puts out her colours in the poop, her flag at the main-tops, and her streamers or pennants at the yard's arms; at which time, her short-sail, peeks her nizen, and rides her main-yard.
SHORTFORD, q. d. fore-clf, an ancient cullom in the city of Exeter, when the lord of the fees cannot be answered rent due to him out of his tenement, and no dilrefes can be levied for the fame. The lord is then to come to the tenement, and there take a phone, or some other dead thing, off the tenement, and bring it before the mayor and bailiff, and thus he must do seven quarter-days successively, and if on the seventh quarter-day the lord is not satisfied his rent and arcars, then the tenement shall be adjudged to the lord to hold the fame a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the said tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arcars; but if no appearance be made, and the rent not paid, the lord comes again to the court, and prays that, according to the custom, the said tenement be adjudged to him in his demesne as of fee, which is done accordingly, so that the lord hath from henceforth the said tenement, with the appurtenances, to him and his heirs.

SHORT-JOINTED, in the Manage. A horfe is faid to be short-jointed, that has a short pattern; when this joint, or the pattern, is too short, the horfe is subfected to have his fore-legs from the knee to the cornet all in a straight line. Commonly short-jointed horfes do not manage so well as the long-jointed; but out of the manage, the short-jointed are the fittest for labour or fatigue, efpecially those of the farm breed.

SHORT-SIGHTEDNESS, Myopia, a defect in the conformation of the eye, wherein the cry Stalline, &c. being too convex, the rays reflected from different objects are refracted too much, and made to converge too far, fo as not to unite before they reach the retina, by which means vision is rendered dim and confused. See Myops.

A learned author thinks it probable, that out of fo great a number of short-sighted persons as are daily to be met with, few are born fo, for it generally grows upon young people at the age of twenty or twenty-five, and therefore might possibly be prevented by using their eyes, while young, to all farts of conformations, that is, by often looking through glafes of all farts of figures, and by reading, writing, or working with fpectacles of feveral degrees of convexity; for whatever be the powers by which the eye conforms itself to effent vision, they may possibly grow weak, or lose their extent one way or other, for want of variety of exercife. It feems an opinion without foundation, to think that fuch an exercife of the eyes can anywife injure them, provided due care be taken to avoid looking at objects that are too bright.

Short-sightedness may come by accident; of this we have a remarkable instance, mentioned by Dr. Briggs in his Ophtalmographia, of a perfon upwards of seventy years old, who had used fpectacles for ten years, and yet by catching cold, he suddenly became fo short-sighted, that he could not diftinguish objects three feet off, and after the cold and defluxion were cured, he continued to read the smallest print without fpectacles for many years.

Dr. Smith mentions a young gentleman, who became short-sighted immediately after coming out of a cold bath, in which he did not totally immerfe himfelf, and has ever since used a concave glafs for many years.

It is commonly thought that short-sighted persons wears off in old age, on account of the eye becoming flatter; but the learned doctor queftions whether this be matter of fact, or hypothesis only.

It is remarkable, that short-sighted persons commonly write a small hand, and love a small print, becaufe they can fee more of it at a view. That it is cultumary with them to look at the perfon they converse with, because they cannot well fee the motion of his eyes and features, and are therefore attentive to his words only. That they fee more distinctly, and somewhat farther off, by a strong light than by a weak one; because a strong light caufes a contraction of the pupil, and consequently of the pencils, both here and at the retina, which lefens their mixture, and consequently the apparent confundion; and, therefore, to fee more distinctly, they almost close their eye-lids, for which reafon they were anciently called myopes.

Dr. Jurin observes, that perfons who are much and long accustomed to view objects at small distances, as fludents in general, watch-makers, gravers, painters in miniature, &c. fee better at small distances, and not fo well at great distances, as the reft of mankind. The reafon is, that in the eye, as well as in other parts, the muscles, by conjent exercife, are enabled to contract themselves with more ftrength, and by difufe are brought to lefs ftrength. Hence, in the perfon before-mentioned, the greater muscular ring of the uvea contracts more easily and strongly, and the cornea more readily obeys the contraction of the ring, whence they fee better at small distances. And the cornea, by being thus often and long bent into a greater convexity, does by degrees lose fomething of its elafcity, fo as not to return to its natural elafcity when the muscular ring ceafes to act upon it. This is one caufe of their not feeing fo well at great distances; also the ligamentum ciliarum, being feldom employed to leffen the convexity of the capsule, by degrees becomes lefs capable of performing that office; and the capsule being feldom drawn out, and put into tension, mult befeome fomething of its diſtleſſe quality, fo as lefs easily to comply with the action of the ligament. And this is another caufe of their not feeing fo well at great distances. Jurin, Elafy on dift. and infid. Vifion.

The ordinary remedy for short-sightednefs is a concave lens, held before the eye, which making the rays diverge, or at leaft diminishing much of their convergency, makes amends for the too great convexity of the cry Stalline.

Dr. Hook fuggets another remedy. Finding that many short-sighted perfon are but little helped by concaves, he recommends a convex glafs, placed between the object and the eye, by means of which the object may be made to appear at any distance from the eye: and consequently, all objects may be thereby made to appear at any distance from the eye, so that the short-sighted eye fhall contemplate the picture of the object in the fame manner as if the object itself were in the place. It is true, the image will appear inverted, but we have expedients to remedy this too; for, in reading, there needs nothing but to hold the book upside down. To write, the belt way, in this cafe, will be, for the perfon to learn to do it upside down. For diftant objects, the doctor afferts, from his own experience, that with a little practice in contemplating inverted objects, one gets as good an idea of them as if feen in their natural posture.

SHOSTACK, in Commerce, a money of account in Poland and Hungary. In Hungary, a hoflack is 2 imperial grofchen, or 6 creutzers; an imperial grofche, or kayfer grofche, is 2 polutarus, 3 creutzers, or 12 pfenings; a polutar is 6 pfenings, and a creutzar 4 pfenings. A Hungarian grofche is worth 2 creutzers in Upper Hungary, but 27 creutzers in Lower Hungary: thus, 5 grofchen in Upper Hungary, or 6 grofchen in Lower Hungary, = 1 kayfer grofche. A rixdollar of account is worth 12 imperial florin, 1½ Hungarian florin, 15 hoflacks, 30 imperial grofchen, or 90 creutzers. An imperial florin is 10 hoflacks, or 20 imperial grofchen, and a Hungarian florin, 8½ flol-
SHOT. 1/3 or 1/4 lira; or 1/3 or 1/4 imperial groschen; thus, 7 shillings of the crown of the Empire of the Austrian States.

In Poland, the form of 30 groschen or groszt, each of which is divided into 18 pfennigs, contains 24 shillings, or 2 florins, or 24 pfennings. A shilling is worth 12 groschen, or 16 pfennigs; a Groschen, 2 pfennings; a pfennig, 3 pfennings. Kelly's Cambit.

SHOT, Indian, or Burdekin. See CANNA.

SHOT, in the Military Art, includes all sorts of ball or bullets for firearms, from the cannon to the pistol. See BULLET, CANNON, &c.

That for cannon are of iron; those for muskets and pistols are of lead.

SHOT, for ordnance, especially in the sea service, are of several sorts: as,

SHOT, Round, balls or globes of iron fitted to the bore of the piece.

SHOT, Bar, is formed of two bullets, or rather half bullets, joined together by an iron bar, serving to cut down mails, lails, &c.

SHOT, Cape, Chain, Grape, Langlet, Random, Star, and Tournament, see the respective articles. See also FIRE-ARMS.

SHOT, for fowling, is otherwise called ball, by reason of its figure and size.

The method of making it is as follows: the lead being melted, stirred, and skimmed, a quantity of powdered yellow powder is thrown in it, as much as will lie on a fowling, to twelve or fifteen pounds of lead; the whole being well stirred, the ornament will be.

To judge whether there be ornament enough in, a little of the lead is dropped into a glass of water, and if the drops prove round, and without tails, there is ornament enough, and the degree of heat is as it should be.

This done, a copper plate, hollow in the middle, and three inches in diameter, bored through with thirty or forty small holes, according to the size of the shot, is placed on an iron frame, over a tub of water, four inches above the water; the hollow part is to be very thin; on this plate are laid burning coals, to keep the melted lead in fusion. The lead is now poured gently, with a ladle, on the middle of the plate, and it will make its way through the holes in the bottom of the plate into the water in round drops.

Great care is taken to keep the lead on the plate in its proper degree of heat: if too cold, it will float the holes; and if too hot, the drops will crack and fly.

The shot, thus made, are dried over a gentle fire, always stirring them that they do not melt; this done, the greater are separated from the smaller by passing them through sieves for that purpose.

SHOT, From, See Fresh Shot.

SHOT, Hip, See Hip Shot.

SHOT, Water. See Water Shot.

SHOT, of a Cable, on Shipboard, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads, for a ship will ride easier by one shot of a cable, than by three short cables out a-head.

SHOT-FLAGON, a sort of flagon somewhat bigger than ordinary, which, in some counties, particularly Derbyshire, it is the custom for the host to serve his guests with, after they have drank above a shilling.

SHOTS, in Agriculture, a term provincially applied to young flour-bwne.

SHOTT, in Geography, a town of Egypt; 3 miles S. of Siut.

SHOTT, a large valley or plain of Africa, in the country of Sahara, on the borders of Algiers; 5 miles in length, and about 12 in breadth. To work near by itself is the feature, or the banks of some like river, but the coasting here is somewhat varied, and scarce the borders of a rather of large plain, as accidents in the season of the year, is either covered with salt, or overflowed with water. Several parts of the Shot contain a light very bad, which, after sudden rains, or the overflowing of the adjacent rivers, are changed into many quicksands, and occasion no small danger to the unwary traveller. La Croix was badly informed, in affirming that all the rivers of this kingdom run from south to north; since, besides several others in a contrary direction, we have no fewer than five, and these very considerable streams, which empty themselves from the northward into the Shot; seven miles S.W. of Conflantia.

SHOTTON, Exh. See HERMAG.

SHOTTON, Blood. See Blood-Shotten.

SHOTSWOOD, in Geography, a town of America, in New Jersey, on the Ramapo, 4 miles E. of Brunswick.

SHOVEL, Sir Cloudesley, in Biography, a British naval hero, was born about the year 1652, of parents in rather humble circumstances, but who had expectations from a relation, whose name was Cloudesley, they thought fit to bellow that name on their son, as a probable means of recommending him to his relation's notice. Nevertheless, being perhaps disappointed in their plans, they put out their son apprentice to a shoe-maker, to which business he applied some years, when he betook himself to the sea, under the protection of Sir John Narborough, with whom he went out in no higher capacity than that of cabin-boy. He soon, by talents and steady application to the art of navigation, became an able seaman, and obtained preferment, through the favour of Sir Christopher Myngs. After the close of what is called, in history, the second Dutch war, Shovel went out with Sir John Narborough, who was deputed to check the piratical state of Tripoli. In the spring of 1674 Sir John arrived before Tripoli, and being ordered to try negotiation rather than force, he sent Shovel with a message to the Dey, deferring preparation for the evils already suffocated, and security for the time to come. The Dey, defying his youth, treated him with disrespect, and refused to back with an honorable answer. Mr. Shovel, on his return, proved that he had not been an obsequurious spectator on shore; and the admiral, pleased with his remarks, sent him again with a second message. He was treated with more rudeness than before, which bore with apparent submission, and made use of it as an excuse for remaining longer on shore; and on his return he assured the admiral, that it was very practicable to burn all the ships in the harbour. Sir John immediately appointed him to the enterprise, which he executed with the most complete success. The account which the admiral sent home respecting the conduct of this young man was so honourable to his talents and courage, that in the course of a few months he had the command of the Sapphire, a fifth-rate, given him; and soon after was raised still higher in the service, by being appointed to the James Galley, a fourth-rate, in which he continued to the death of king Charles II., by whom he had been raised.

By James II. captain Shovel was preferred to the command of the Dover, a fourth-rate, in which he was at the time of the revolution. This event was fortunate for the captain Shovel, as well as very agreeable to his way of thinking; for being in almost entire engagement during the reign of William, he became confidante, and made his way in the service as quick as it was possible to be effected. He was in the battle of Battle-Bay, in the Edger, a third-rate, and
SHO

Agriculture, visiting the

Gibraltar, performing bombardment, arriving at Portsmouth, the Holland, as a remarkable event. He performed all the duties of the admiral, and delivered to him the commission with his own hands.

In the following year, Sir Cloudesley Shovel attended the king to Holland; and in 1692, he was declared admiral of the red, and again accompanied his majesty to Holland; and on his return, he joined admiral Rooke with the grand fleet, and had a large share in the danger and glory of the celebrated battle of La Hogue. When it was thought requisite that the fleet should be put under command of joint admirals in the succeeding year, he was one; and, says the judicious and cautious Campbell, "if there had been nothing more than this joint commission, we might well enough account for the misfortunes which happened in our affairs at sea, during the year 1693." The joint admirals were of different parties; but as they were all good seamen, and probably meant well to their country, though they did not agree in the manner of serving it, it is most likely that, upon mature consideration of the posture things were then in, the order they had received from court, and the condition of the fleet, which was not either half manned or half victualled, the admirals might agree that a cautious execution of the instructions which they had received was a method safe for the nation, and more so for themselves, than any other they could take." On this occasion, Sir Cloudesley Shovel was at first an object of popular odium; but when the affair came to be strictly investigated in parliament, he gave so clear and satisfactory an account of the matter, that it satisfied the people that the commanders were not to blame; and that if there was treachery, it must have originated in persons in office at home. The character of Sir Cloudesley remaining unimpeached, we find him again at sea, in 1694, under Lord Berkley, in the expedition to Camaret-bay, in which he distinguished himself by his dextrous embarkation of the land forces, when they failed on that unfortunate expedition; as also when, on their return to England, it was deemed necessary to send the fleet again upon the coast of France, to attack Dieppe, and other places. From this time till 1702, Shovel was not engaged in any expedition of moment, when he was sent to Vigo, after the capture of that place by Sir George Rooke, to bring home the spoils of the Spanish and French fleet. He arrived on the 16th of October, and carried off whatever could possibly be brought home, burnt the rest, and arrived safely in the Downs on the 7th of November; which was considered as so remarkable a service by the court, that, though he was no favourite at court, it was resolved to employ him in affairs of the greatest consequence; and he so effectually crushed the power of the French at sea, that they did not afterwards dare to meet the British fleet; and on account of the great share which he had in the victory obtained the 13th of August, 1704, he was appointed rear-admiral of the fleet of England in the January following. He performed many other acts, which were useful to his country, and important to the cause in which it was then engaged. His last act was the defence of the coasts of Italy, of which, when he had taken due care, he left a sufficient force at Gibraltar for the purpose, and left with ten ships of the line, five frigates, four fire-ships, a troop, and a yacht, for England. On the 2nd of October, 1707, he came to foundings, and in the following morning he had ninety fathom water. About noon he lay by, but at six in the evening he made sail again, and float away under course, believing that he saw the light on St. Agnes, one of the islands of Scilly. Soon after this several of his ships made signal of distress, as he himself did. It was with difficulty that Sir George Byng, in the Royal Anne, saved himself, having one of the rocks under her main chains. Several others ran the most imminent risks; but the admiral's ship, and some more, perished with all aboard. How this accident happened has never been properly accounted for. The body of Sir Cloudesley Shovel was thrown afloat the next day upon the island of Scilly, where, falling into the hands of some fishermen, he was filleted and buried. Among their plunder was an emerald ring of great value, which, being thrown about, made a great noife all over the island, and led to the discovery of the body. This was now taken up, and conveyed to London, where it was interred with great solemnity in Westminster Abbey. To his memory an expensive monument of white marble was erected, by direction of her majesty, on which was the following inscription: "Sir Cloudesley Shovel, knight, rear-admiral of Great Britain, admiral and commander-in-chief of the fleet; the just rewards of long and faithful services, he was deftently beloved of his country, and esteemed, though dreaded, by the enemy, who had often experienced his conduct and courage. Being shipwrecked on the coasts of Scilly, in his voyage from Toulon, on the 22d of October 1707, at night, in the 57th year of his age. His fate was lamented by all, but especially the sea-faring part of the nation, to whom he was a very worthy example. His body was flung on the shore, and buried with others in the sands; but being soon after taken up, was placed under this monument, which his royal mistress has caused to be erected, to commemorate steady loyalty and extraordinary virtues." See Stockdale's edition of Campbell's Lives of the Admirals.

SHOVEL, in Agriculture, a well-known implement, consisting of a long handle, and a broad blade, with raised edges.

SHOVEL, Cafting, a tool somewhat of the wooden shovel kind, which is sometimes employed in cleaning or dressing corn. It is very useful in this mode, where the wind is truffled for managing the buffalo.

SHOVEL, Driving, a form of tool of this nature, frequently employed for the purpose of clearing out the lofe crumbly earthy materials from the bottom parts of drains. It is formed with a crooked handle, the edges of the shovel being turned up on the sides, in order to prevent the materials which are scraped up from falling off. In consequence of the crookedness of the handle, the workman is prevented from floating so much as would otherwise be the case, in performing the work. There are different constructions of this implement made use of, in managing buffets of this fort.

A scoop is likewise sometimes made ufe of, both with and without this implement, for the purpose of scooping up and clearing out all the crumbs, loofe mould, and other similar materials, from the bottom parts of drains, before they are laid or filled with spray, bruft-wood, or any other subfance, in order that they may be quite clear and free of any fort of obftruction. The tool is formed in a crooked scoop-like manner at the head, and of different shapes, sizes, and breadth, according to the nature of the drains and openings in which it is to be employed; being, in working, drawn or pulled along the bottoms of the cuts or drains.

The
The handle has also occasionally a hooked form, in order to ease the workman in using it.

**SHOVEL**. Parrying, that fork of tool of this kind, which is employed in some places for parrying off the sword or surd from the surface of ground, in order to burn it. The shovel which is used in Devonshire for this purpose has a hollow heart-shaped form in the wheel part, with a long handle, which makes it a very powerful implement. The plate of the mouth part is from nine to ten inches in width, where the handle is inserted, which is made with a considerable curve upwards; the blade is about twelve inches in length, terminating with a bread angular point, which, with its fides, are constantly kept very sharp and keen for cutting; on the left hand, or leafside of the tool, a sharp wing, comb, or couter, rises up in an oblique manner, to cut and divide the fice part from the whole ground. Thus, however, in consequence of the toughness of the surface, and the impediments presented by the roots of furze, flags, heather, and other similar matter, is not unfrequently dispelled with, the fice being rent or torn off by the workman from the side of the whole ground, whilst it is cut up and separated from the earth below. When a foot or fifteen inches of the fice rises upon the handle of the shovel, it is separated from the uncle part of the surface by a sudden effort or exertion with the tool, and by a turn of it is whelmed or laid over the mould side upwards. Where the state and circumstances of the surface will permit, as by not being too much loaded and encumbered with the above goes of plants, the effort of separating the cut from the uncle fward may in all cafes be much assisted, by having the fice, which is next to be pared, cut or nicked in such lengths as may be most convenient to the workmen. And in some particular places and situations of land, the regular nicking of the fice to be pared from the ground is indeed found indispensably necessary, as where the ground is of such a money quality as to render the operation impracticable without it. In all such instances it is, however, probably much better, as being more convenient and expeditious, to have the shovel formed with a cutting wing, by which the whole may be done at once, without any sort of delay in the bullwells. This sort of shovel may be seen at fig. 9, in the plate of paring ploughs.

**SHOVELS**, an useful tool for some small purposes. It is that fport which is often employed in ferating small roots or plants, as those of the cultivated faffron, and some others of a fimilar nature.

**SHOVELER**, in Ornithology. See Bread-beaked Duck.

**SHOVELING**, in Agriculture, a term used in Ireland to signify the throwing the mould of furrows, in cleaning them out, over the ridge.

**SHOULDER**. Humers, in Anatomy. See Extremities.

**SHOULDER**, Luxation of. See Luxation.

**SHOULDER-Blade**, in Anatomy, a bone of the shoulder, of a triangular form, covering the hind part of the ribs, called by anatomists the scapula and omolata. See Extremities.

**SHOULDER-Beak**, See Extremities.

**SHOULDER**, in the Mane, is the joint of a horse's fore-quarters, that joins the end of the shoulder-blade with the extremity of the fore-thigh.

**SHOULDER of a Branch**, is that part of it which begins at the lower part of the arch of the banquet, over-against the middle of the fonceau or chaperon, and forms another arch under the banquet. The shoulder of a branch casts a greater or less curve. Hence, according as it is to bulge or flow, or weaken the branch. See Branch, Branchlet.

**SHOULDER Pierced Houts**, called in France, pierres, such as have their fides poudry, thin, and hard without cut in it. A horse charged with shoulder-pierce that has thick, flabby, and heavy shoulder.

**SHOULDER of a Branch in Fortification**, is where the face and the back meet.

**SHOULDER-Drop**, in Agriculture, a sort of order drawn, connected with a flider on each side of the cut or opening, so that these sort of fides may be laid over it, and form an opening or drain for the water below. See Drain.

**SHOULDER**, in Black Making, a part only made upon the surface of blocks, posts, &c. by reducing one part to a less substance.

**SHOULDER-Block**, a large single block, lust nearly square at the lower end, or side of the block, and cut feping in the direction of the theave. Should-blocks are used on the lower yard-arms, to lead in the top-sail-fore-top, and on the top-sail-fores, to lead in the top-gallant-fores; and by means of the shoulder they are kept upright, and prevent the sails jamming between the block and the yard, they are also used at the lower outer end of the boomkin, to lead in the fore-stacks.

**SHOULDER-OF-MUTTON Sell**, a triangular sell, similar to the late sell, but attached to a mall instead of a yard.

**SHOULDERING**, in Fortification. See Epaulment.

**SHOULDERING-Piece**, in Building. See BracKet.

**SHOULDER-KNOTS**, See Epaullettes.

**SHOULDER-PITCH**, in Farriery, is a disease in a horse, when the pitch or point of the shoulder is displaced, which makes the horse halt downright.

**SHOULDER-PLAINT**, or SHOULDER-TORN, is a hurt which befalls a horse by some dangerous slip, by which the shoulder is parted from the breast.

**SHOULDER-WRENCH** is a strain in the shoulder.

**SHOUT, CLAMOR**, in Antiquity, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation. Thus as Cicer, in an assemblage of the people, was expounding the arrogation of L. Antony, who had had the impudence to cause himself to be inscribed the patron of the Romans, the people, on hearing this, raised a shout to show their indignation.

In the ancient military discipline shouts were used, 1. upon occasion of the general's making a speech, or harangue, to the army from his tribunal: this they did in token of their approving what had been proposed. 2. Before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread.

This is a practice of great antiquity, besides which, it wants not the authority of reason to support it, for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose.

Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. See Acclamation.

It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name before they let fire to the pile. See Burial.
SHOWEL, in Agriculture, a term applied to a blind for a cow's eyes.

SHOWER, a cloud resolved into rain, and discharged on a certain tract of ground.

In Natural History we meet with abundance of instances of extraordinary and preternatural flowers; as flower of blood, mentioned by Gallendus and others; a brimstone flower, mentioned by Pliny; flower of frogs, mentioned by Wormius; flower of milk-fed, in Sicily, mentioned in the Ephemer. German; flowers of ashes, frequent in the Archipelago; a flower of osier, in Wiltshire; a flower of whittlings, mentioned in Philosoph. Trans. There are the natural reasons of many of which may be seen under Rain.

SHOWOR, in Geography, a town of Hindooftan, in Myore, where, in 1790, a bloody battle was fought between the British and Tippoo, and in which the latter was defeated; 15 miles S. of Satimungulam.

SHOWS, or SHAWS, in Agriculture, a term applied to the haulm or tops of potatoes. See POTATO and SOLANUM.

SHRAHEEN, in Geography, a mountain of Ireland, in the county of Mayo; 11 miles N.E. of Cafflebar.

SHRAVEY LAND, in Agriculture, a term used in some districts, as those of Suffolk, and some others, to signify that of a strong, gravelly, or flinty nature. The fears or holes on the sides of steep hills, where the turf or sward has flipped away, and laid bare the foil on the South Down, are sometimes called thraives. See Soil.

SHREW, or SHREW-MOUSE, in Zoology, the common name of the creature called by authors Mus araneus, and Sorex araneus of Linnaeus. It is an animal of a mixed brown and reddish tawny colour; the belly is white; its tail is about one inch and a half long, and covered with short hairs; its body is about two inches and a half in length; and its eyes black and very small; they are indeed little larger than those of the mole, and do not exceed the size of the head of the smallest pin; it is no wonder, therefore, that the creature is almost blind; the nose long and slender; the ears short and rounded; the teeth are very small, and differ in their shape and situation from those of all other creatures in the world; and seem as if nature had in one creature made a sort of mixture of the teeth of the mouse and the fnaek kind.

It has two long fore-teeth, as all the mouse kind have; but these are not tingle, as in mice, but have two or three other small and sharp teeth growing out of them: these, to an accurate observer, might either be wholly unseen, or taken for dimint teeth; and the anterior long teeth are not separated from the root by any gap or space, as in the mouse kind, but make one continued feries with the others. The upper jaw in this creature is longer than the under, and the teeth are sharp and ferrated, fome with two, fome with three points, and these fo small, that they might caufily not be feen, but that the tips of them are reddish. Their whole number is twenty-eight.

It is very common in many parts of the world, and is met with in almost all our dry grounds, in old walls and holes in the earth; near hay-ricks, dung-hills, and necessfly houfes; it lives on corn, infects, and any filth; the cats will kill it, but never attempt to eat it. It brings four or five young at a time.

Its whole body has a fetid and offensive smell. The ancients erroneously believed it was injurious to the cattle. There seems to be an annual mortality of these animals in the month of August, numbers being then found dead in the paths.

It is distinguished at first fight from the common mouse, in that it is smaller; its nose longer, and like a hog's; it has five toes on the hinder as well as the fore-feet; its eyes are extremely small; its ears very fhort; its claws are long and whithit, and its feet fhort. Ray and Pennant.

SHREW-MOUSE, Water, Sorex fodiens of Pallas, is much larger than the common shrew; its length from nose to tail being 32 inches; its tail two inches; the upper part of the body and the head are of a black colour; the throat, breast, and belly, of a light ash-colour; and beneath the tail there is a triangular dusky spot.

This animal inhabits Europe and Siberia; was left in England till the year 1766, when it was discovered in the Shropshire forest, it burrows near the water, and is said to swim under water; it is called in some places the blind mouse, on account of the smallneds of its eyes; and its chirrups like a grafsopper. Pennant.

SHREWSBURY, in Geography, an ancient borough and market-town in the hundred of the same name, and county of Salop, or Shropshire, England, is situated on two hills, peninfulated by the river Severn, at the distance of 112 miles from Bath, and 162 miles from London. It is the chief town, or capital, of the county, and, from its historical importance, is particularly deserving of an extended description, even in a work like the present. According to the parliamentary returns of 1811, it is divided into the fix parishes of St. Giles and Holy Crofs, St. Chad, St. Mary, St. Julian, St. Alkmund, and Meole-Brace, which united, contain 3292 houses, and 16,066 inhabitants. It must be remarked, however, that some of these parishes extend a fhort way into the country. The liberties of Shrewsbury comprifte fix other parishes, four townhips, and two chappelies.

Origin and Hiftorical Events.—Although no doubt can be entertained of the high antiquity of Shrewsbury, it being frequently mentioned by our earlieft historians, there is no authentic record of its origin. Probable conjecture, however, has affigned that event to the fifth century, when the Britons were forced by the Saxons to abandon all the country to the eftward of the river Severn. It is fuppofed that, after the deftruction of the Roman Uriconium, the fortifications of which enabled the po leurs for a time to check the progress of their enemies, that they eftablifhed themselves on the fite of Shrewsbury, on account of the natural security afforded by its lofty and peninfular position. At that period this spot was called the Pengwere hill, whence the town received the appellation of Pengwere, to which Powis was fubfently added, when it had become the capital of Powifland, and the feat of its princes, whole palace occupied the fame ground with the old church of St. Chad. Here the Britons maintained themselves for feveral centuries, notwithstanding the repeated efforts of the Mercur Saxons to defpoif them; but at length the arms of the warlike Offa proved too powerful for further resistance, and they were compelled to retire to Mathrafael, among the mountains of Montgomeryshire, where they preferred their ancient dignity and independence, till finally fubdued by Edward I. of England.

The Saxons, having obtained poifile of this ancient capital, changed its name from Pengwere to Scrobblebyrig, or Scrobblebyri, which words have nearly the fame signification, viz. "the head of the alder groves." Instead of levelling it with the ground, as was their custom when they feized upon any Britifh town, they seem to have proteeted it with care, and probably even increafed its opulence and extenfion. In the reign of Alfred it was numbered among the principal cities in his dominions: and in that of Edward the Elder.
In 1096, King Ethelred kept Christmas in Shrewsbury; but in about ten years thereafter, the inhabitants having declared against that prince, in favour of his rival Canute the Dane, his son, prince Edmund, afterwards King Edmund Ironside, attacked and took the town after a short siege. On this occasion Shrewsbury seems to have fallen greatly, as in the reign of Edward the Confessor, its lieutenants amounted to 252 in number. Poltrew to the Conquest, it was bequeathed upon Roger de Montgomery, who was created earl of Shrewsbury, Arundel, and Chepstow; and appears from Domaird book to have then paid 15s. in tax to the king and sheriff. Earl Roger, on acquiring possession of this city, (for in it was ryled in his time,) fixed his residence in it, and founded both a castle and an abbey. He did not, however, long possess them undisturbed; for in 1266, Owen Gwynedd, prince of Wales, assaulted it with his formidable force, that the conqueror deemed it advisable to repel the invasion in person. He accordingly marched hither from York, raised the siege, and overthrew the Welsh with prodigious slaughter. Shrewsbury was again besieged in the reign of Henry I., in consequence of its then possession, Robert, son to earl Roger, having united his forces to those of the rebellious barons; and it was probably only saved from the horrors of an assault by the submission of the earl, who was banished to Normandy, and had all his immense estates forfeited to the crown.

Shrewsbury being esteemed the most important town and fortress on the marches of Wales, continued, during several centuries, to be one of the principal places of rendezvous for the English armies, and hence was often visited by its monarchs. Numerous conflicts took place in its immediate vicinity, and its inhabitants frequently suffered the evils incident to sieges. During the wars between Stephen and the empress Maud for the succession to the crown, William Fitz-Alan, a powerful baron, then governor of Shrewsbury castle, supported the claims of the latter. Stephen, however, early obtained possession of it, and ungenerously put to death many of the brave knights by whom it was defended. Fitz-Alan fled to the continent, where he remained an exile till the accession of Henry II., who restored him to all his honours and privileges. In the reign of King John, the royal council assembled here to consider of important affairs; and among the measures adopted was the checking the incursions of the Welsh; when the prince of Poitou came, and frankly offered terms of accommodation; but to the disgrace of the English lords, instead of receiving him with respect, they threw him into prison. Soon afterwards, however, he was released, and a treaty with the Welsh was concluded, for the performance of which twenty-nine children were delivered as hostages, all of whom were most inhumanly hanged by King John, in consequence of some infringement of its terms by the prince of Wales. But this barbarous massacre did not long remain unpunished; for in 1215, the Welsh having dispersed all the armies of the lords marcher, suddenly appeared before Shrewsbury, which submitted without resistance. How long the Welsh held their conquest, or how they lost it, is uncertain; but in 1221 Shrewsbury had again passed into the possession of the English. In the seventeenth year of Henry III. it was plundered and burnt by the earl of Pembroke and other furious barons, who had joined their arms to those of prince Llewellyn. The rebel Simon de Montfort, earl of Leicester, likewise feigned upon this town; but it soon reverted to the king; and in 1267, Henry assembled a large army here, with the design of crushing the Welsh power, but the interference of the pope prevented the execution of his views. Edward I., who, during his father’s life-time, had been invested with the government of Shrewsbury, made it, in 1277, the principal seat of his court, and removed thither the court of exchequer and king’s bench, in order that he might the more easily accomplish his favourite project, the subjugation of Wales.

During the rebellion which immediately preceded the accessions of Edward II. to the throne, he gave to his forces, the king was received at Shrewsbury with great military parade, and a tournament was held here, attended by the marcher lords and principal persons of the council. Afterwards, when Edward was deserted by his enemies and courtiers, he sailed for Gascony, and his patron, Roger Mortimer, earl of Arundel, who had been banished to his allegiance, was seized by the inhabitants, and put to death; for which service Mortimer, in the name of the king, granted to the burgesses of Shrewsbury, whom he calls "the good men of Salop," all the goods and chattels found upon the earl. Richard II. held a parliament here in the 14th year of his reign, on which occasion he gave a sumptuous feast to the members in the abbey of St. Peter and St. Paul. The next event of importance which occurred at this town was the famous battle of Shrewsbury, in which Henry V., then prince of Wales, first distinguished himself in the field, and the impious Hotspur fell, after performing, in conjunction with the rival Douglas, the most brilliant acts of prowess.

Throughout the whole of that eventful period, marked by the contentions of the rival houses of York and Lancaster, the inhabitants of Shrewsbury steadily adhered to the interests of the former. The learned author of the "Account of the ancient and present State of Shrewsbury," contends that it was here, and not at Salisbury, as commonly supposed, that Henry Stafford, duke of Buckingham, was executed by order of Richard III., who was chiefly indebted to him for his usurped crown. When Henry VII. landed in Wales, he marched directly towards Shrewsbury, where he was received with raptures of joy by all except the "head bailey," who for a time refused him admittance. Here he was first proclaimed king of England, and here he collected and organized the greater part of those forces with which he achieved the signal and decisive victory of Bosworth Field. In conformance of these circumstances, Shrewsbury was greatly favoured by that monarch, and was frequently visited by royal persons of his reign.

From this period till the reign of Charles I. no event of historical importance happened here. When the parliamentary war broke out, however, the town came into the hands of the king, and was cordially welcomed by the inhabitants, though they had been strongly prejudiced against him by the commissioners for the parliament. The greater part of the army with which he first took the field was composed of persons resident in this town and the adjoining counties. After the king left Shrewsbury, it was garrisoned in his cause; but the bad health of the governor having prevented him from enforcing the discipline of the garrison with sufficient vigour, they became negligent and debauched. The parliamentary officers, colonels Mitton and Bowyer, being informed of the state of the garrison, made several attempts to surprise the town, and at length succeeded in their object, in February 1645. By this event the parliament gained the important advantage of cutting off the king’s communication with North Wales, and a formidable association, which was on the point of being formed between the loyal inhabitants of the counties of Salop, Worcester, Chester, and Flint, was destroyed in the bud.

In Cromwell’s life-time, and also immediately after his death, two attempts were made to gain possession of Shrewsbury in favour of Charles II.; but both of them were frustrated. The last circumstance which history records worthy of notice, occurred
SHREWSBURY.

occurred in August 1687, when James II. held his court here. On this occasion, the "sentiments of loyal attachment, for which Shrewsbury has ever been conspicuous, burst forth with chivalrous enthusiasm."

**General Appearance of the Town.**—Shrewsbury, from its lofty and picturesque situation, presents, at every approach, a pleasing variety of views; and the noble sweep of the river, which seems to embrace it, heightens at every turn the charms of the scene.**"** Except on the north and west sides, where the streets approach close to its banks, a narrow margin of meadows, or of garden ground, interposes between the houses and the river. The exterior circle of the town is lined with an unbroken range of well-built houses, most of which command beautiful views over the adjacent country. On its western side is a public field, called the Quarry, which occupies about twenty acres of ground, and is adorned with avenues of trees. At one extremity of this field are the remains of a rural amphitheatre, where the Augustine friars of the adjoining convent were probably wont to exhibit those ancient sacred dramas called mysteries, or Whitfun plays; which were certainly acted here in the reign of queen Elizabeth.

Such is the exterior aspect of Shrewsbury; but it is to be regretted that its interior appearance is far from corresponding with the external aspect. The streets are ill arranged, and some of them narrow and steep, and often differently paved. The houses are extremely mixed in their architectural character, exhibiting a strange contrast of ancient and modern buildings. This circumstance is in part to be attributed to the happy freedom which Shrewsbury has enjoyed, from those general confonnations which have occasioned the devastation of other towns within the last two centuries.

**Civil Government and Corporation.**—Shrewsbury is a corporation, both by charter and prescription. The first charter was granted by Henry I.; but other princes have since altered and extended the privileges it conferred. By the charter now in force, granted by king Charles I., the corporation consists of a mayor, recorder, steward, town-clerk, 24 aldermen, 48 burgesses, or common councilmen, two chamberlains, a sword-bearer, journeymen at mace, &c. Four general quarter-seisions are held in the course of the year, and the mayor and some of the aldermen, who are magistrates, hold a court every Tuesday. The chartered companies, besides the general corporations, are sixteen in number, of which those of the drapers and mercers are the most considerable.

Shrewsbury sent members to parliament from their earliest establishment. They are chosen by the inhabitants burgesses, who have been legally ascertained to the parish rates. The mayor is the returning officer. The markets are on Wednesday and Saturday, weekly; and there are eight annual fairs.

**Public Buildings and Institutions.**—The public structures of Shrewsbury are, the castle, the town-hall, the churches, the charitable institutions, the town and county gaol and Bridewell, the market-house and cross, the theatre, and the bridges.

The Castle stands on a narrow neck of land, about five hundred yards in breadth, which is formed by the windings of the Severn. It was founded by Roger de Montgomery, as before mentioned, and became the chief seat of his baronial powers. As all the transactions of interest connected with this edifice have been noticed under the head Historical Events, &c., it is unnecessary to repeat them. This structure has evidently undergone so many alterations, and is so greatly dilapidated, that it is difficult to form any probable idea of its ancient state. The buildings of it now remaining consist of the keep, the walls of the inner court, and the great arch of the interior gate-way. The keep, which is converted into a handsome dwelling-house, consists of two round towers of equal size, embattled and pierced, and connected by a square building, about one hundred feet long, and nearly of the same height. The inner court is now a garden, "on a circular plat in which, the newly elected knights of the Shire have been greeted by the sheriff, from perhaps the first foundation of our invaluable constitution." The arch of the gateway is clearly part of the original castle. It is eighteen feet high, massive, and semi-circular, and appears to have supported a tower, from which hung the portcullis. On the opposite side of the court is a small pollern, probably built in the time of Charles I.; and on its south side is a lofty mound, the summit of which is surrounded by a ruined wall, at one part of which rises a small watch-tower, now a beautiful summer room, much referred to on account of the fine views which it commands. This castle was defended by ramparts of stone thrown across the peninsula, from the castle to the river, on each side. One of them was formed by Robert de Belleme, and the other by order of Oliver Cromwell. Ramparts and walls with towers likewise defended the town on its northern and eastern sides, but few traces of these remain. The principal gates were three in number, and called the Castle, or North-gate, the East or Abbey-gate, and the Welsh-gate, the latter of which stood on the Welsh bridge.

The *Town-ball* is a modern structure, finished in 1786. It was designed by Mr. Haycock, a native of the town, and exhibits a handsome front. Here are held all meetings of the corporation, and grand juries, likewise the courts of justice for the town and county. The grand jury room is decorated with portraits of George I. and II., and of admiral Benbow; and another room is appropriated to the reception of a valuable collection of books.

The *established churches* are St. Giles's, St. Chad's, St. Mary's, St. Alkmund, and St. Julian's. St. Giles's is a small plain building, and appears, from some remains of masque square piers, and a semi-circular arch, to have been partly built in the Norman era, and probably on a larger scale than it is at present. Most of the other piers are round, and support pointed arches. St. Chad's church is of modern erection, having been built between 1790 and 1792, in lieu of the old collegiate church, which fell down in the first mentioned year, in consequence of its repair having been too long neglected. It is, "upon the whole, a splendid, and, in many respects, an elegantly ornamented structure." In this church the mayor and corporation are accustomed to sit on festival and other public days. Here are but few monuments, and none of note; but in the church-yard is a chapel, in which many of the tombs and inscriptions rescued from the ruins of the old church are deposited: the principal of them, however, were removed to the respective parish-churches of the families to which they belonged. St. Mary's church was likewise collegiate, and had the privileges of a royal chapel, of which advantages it was deprived in the reign of King Edward VI. It is a venerable pile, in the form of a cross, and comprises a nave, side-aisles, transept, choir, and chapels, with a tower at the west end. Its architecture embraces almost every style prevalent from the Norman conquest to the reign of Henry VIII. The nave is divided from the side-aisles by semi-circular arches; but those separating it from the choir are lofty and pointed. The ceiling here is of oak, and rises in an extremely flat arch, divided by its principal beams into square panels, including circles richly adorned with quatrefoils and foliage; the ribs and bosses being carved into double rosettes, with devices and knots at their termination.
The chancel, chair, &c. display chiefly the pointed style. At the extremity of the former is a spacious window, in the later pointed style, which is nearly filled with stained glass, brought from the ruins of old St. Chad's church. The principal piece represents Jeoff in a deep sleep. The spire of this church rises 275 feet above the summit of the tower, upon which it rests. The monuments are numerous, and some of them curious: but we shall only notice one inscription, which is remarkable, from the circumstance of its commemorating a person named Cadman, who was killed in defending from the summit of the spire, by arape of lightning from thence to the opposite side of the river from that on which the church stands. The parish-church of St. Alkmund's, like the two last mentioned, was formerly collegiate, but its college was dissolved as early as the reign of King Stephen. The old church was taken down about the year 1793, and the present building raised in its stead, which is a clumsy imitation of our ancient architecture. St. Julian's church, which closes the list, is a plain substantial edifice, rebuilt in 1750, on account of the ruined condition of the former edifice.

In addition to the above-established churches, there are in Shrewsbury several dissenting places of worship, viz. a Roman Catholic chapel, a Presbyterian meeting-house, also one for Methodists, and another for Quakers.

The Charitable Institutions belonging to Shrewsbury are, a small hospital, formerly dedicated to St. Giles, another called Millington's hospital, several almshouses, an infirmary, a house of industry, and the free and charity-schools. The infirmary is among the earliest provincial institutions of the kind in England, having been opened in 1747. It is supported by voluntary subscriptions, and by benefactions. The house is a plain but respectable building of brick, with a stone portico in front. The house of industry was originally a founding hospital, connected with that in London, and was only converted to its present purposes in 1784. It is governed by directors chosen from among the inhabitants of Shrewsbury, and maintains, on an average, about 275 poor, including children, partly by a rate levied on the fix parishes, and partly by the produce of the labour of the paupers. The free grammar-school was founded and endowed by King Edward VI. at the request of Henry Edwards and Richard Whitaker, and was afterwards augmented by Queen Elizabeth, at the instance of Thomas Aiton. The school-house is a large and lofty structure, forming two sides of a square court. The government of this school is vested in the bishop of Lichfield, and the corporation, who appoint two schoolmasters, one of whom is superior to the other. Several of them have been men of great talents and erudition, and have cherished the seeds of knowledge in many individuals afterwards distinguished in society. Among the latter, were Sir Philip Sydney; lord Brook, lord chief justice; lord chief justice Price; Dr. Bowers, bishop of Chichester; Dr. John Thomas, bishop of Salisbury; and the learned Dr. John Taylor. The learned Dr. Butler is the present head master. The other public schools in this town are Bowdler's charity-school, founded in 1724, by Mr. Thomas Bowdler, alderman, for the education and clothing of poor children of St. Julian's parish; Allart's charity-school, founded in 1798, under a bequest by Mr. John Allart, one of the chamberlains of the corporation; and a subscription charity-school, instituted in 1708, for instructing poor children of the town at large.

The Town and County Gaol and Bridewell, which now form one building, stands near the castle, where the sheriffs probably had his gaol in former times. Its situation is at once beautiful and fabulous, and though it cannot boast much elegance of exterior appearance, it is spacious and airy, and posses the every convenience requisite for its domestic purposes. In front is a free-tone arched gateway, containing a bust of Howard, by Bacon.

The Market-house is one of the largest and most magnificent buildings of its kind in England. It is of the age of Queen Elizabeth, whose arms, sculptured in high relief, decorate the portal, on each side of which is an open arcade, consisting of three large circular arches, supported by columns. The north and south ends of the building are likewise ornamented with large open arches, over one of which stands a statue of Richard, Duke of York, removed hither from the Wells bridge in 1791. Adjoining this building is a conduit, which supplies a great part of the town with water. The Market-craft is a strong structure of brick and stone, having a reversion over it. The old cross was destroyed in 1705. The Theatre, according to Phillips, the old historian of the town, is part of the palace formerly belonging to one of the latter princes of Powis, but though evidently an ancient structure, it seems improbable that its date should be so remote as such a fact would necessarily imply. It is fitted up in the interior in an appropriate manner.

The Bridges over the Severn at this town are called the Welsh bridge, and the English, or East, bridge. Both of them are new structures, erected in place of older ones, which had gone to decay, and were, from their narrowness, unsuitable to the traffic of commercial advancement Shrewsbury and the county at large now enjoy. The Welsh bridge consists of five elegant arches, about 206 feet in aggregate length, 30 feet high, and 30 broad. Adjoining to it is a quay, faced with stone, and accommodated with warehouses. The English bridge extends 400 feet in length, and consists of seven semi-circular arches, built of fine freestone. The central arch is 60 feet span and 40 high from the lowest water mark; and the two on each side 35 feet wide and 20 high. The breadth between the balufrades is 25 feet; and the ornaments are at once light and graceful.

Monastic Institutions.—The principal monastic establishment in Shrewsbury was the abbey of St. Peter and St. Paul, which flourished in the suburb that still bears its name. It was founded, or, as some will have it, refounded and endowed by Roger de Montgomery, and a nobleman named Warine, who filled it with monks of the Benedictine order. These having subsequently obtained possession of the relics of St. Winefrid, their abbey became the constant resort of various classes of people from all parts of the kingdom, who, according to their circumstances, offered donations on the shrine of the saint. This society, at its dissolution, consisted of an abbess, fourteen monks, and three novices, whose annual revenues, according to Dugdale, amounted to 532l. 4s. 10d. but Speed rates them as high as 656l. 4s. 3d. The remains of the abbey are very inconsiderable, the ground which it occupied being in great part converted into a garden. There is, however, a very curious little structure, which has puzzled the learned in antiquities as to its use: by some it is regarded as a pulpit for preaching. Its plan is an octagon, six feet in diameter, but considerably higher. Over it is an obtuse dome of stone, supported by six narrow pointed arches. The roof within is vaulted on eight ribs, which spring from the side walls, and form a belfry at their crossing in the centre, bearing a representation of the crucifixion. The arches on the south side are without ornament, but three of them on the north side are filled with stone panels, adorned with different figures of angels and saints. The abbey church was built in the form of a cross, and was a spacious and magnificent edifice; but at present is in a state of dilapidation, except the western aisle, which is now used as a parish-church, instead of St. Giles'. The other religious
gious houses here were, a convent of Augustinian friars, founded about the year 1256; a second of Franciscan or Grey friars, the date of which is unknown; and a third of Dominicans, founded by lady Genevile in the reign of Henry III. The queen of Edward IV. twice lay in at this monastery. Beside these, there were chapels dedicated respectively to St. Michael, St. Nicholas, St. Catherine, St. Blaïfe, and St. Mary Magdalen.

Shrewsbury contains several ancient private structures, which would claim notice, did the limits of our article permit of a commenurate extension. One of them, still called the Council-House, was formerly the residence of the court of the marches of Wales, on their annual visits to this town. For some account of this court, see Ludlow.

The eminent notices of Shrewsbury, besides Dr. Thomas and Dr. Taylor, before-mentioned, were Thomas Churchyard, a poet of some note, admiral Benbow, and the Rev. Hugh Farmer, author of several learned and critical works.

The objects in the vicinity of Shrewsbury, most worthy of notice, are the Shelton oak, which is remarkable from a tradition, that Owen Glyndwr ascended it to reconnoitre, previous to the battle of Shrewsbury, and for its great size; Battlefield, where the battle was fought; and Haughmond Abbey, which stands about four miles to the eastward of Shrewsbury. It is situated on a rising ground, which commands beautiful and extensive views, and owed its foundation and endowment to William Fitz-Alan, in the year 1100. The inhabitants were canons regular of St. Augustine, who enjoyed at the dissolution a yearly revenue, rated by Dugdale at 250l. 13s. 7d. and by Speed at 294l. 12s. 9d. Of the abbey-church, scarcely a vestige remains, but considerable portions of the other buildings are yet standing. Phillips' History and Antiquities of Shrewsbury, 4to. Some Account of the ancient and present State of Shrewsbury, 12mo. 1808, an interesting and judicious topographical work. Beauties of England and Wales, vol. xiii. by J. Nightingale and R. Ryland.

Shrewsbury, a town of America, in the state of New Jersey, and county of Monmouth, on the sea board, having Middletown on the N., Freehold W., and Dover S.W. It is divided from Middletown by North river, which is navigable for a few miles. The compact part of the town is pleasant, and contains an Episcopal and Presbyterian church, and a meeting-house for Friends. The number of inhabitants is 3773. This place is frequented by genteele company from Philadelphia and New York, for health and pleasure; 79 miles E.N.E. of Philadelphia. — Allo, a township of America, in Rutland county, Vermont, between Clarendon on the W. and Saltash on the E., containing 990 inhabitants. — Allo, a township of York county, Pennsylvania, containing 1702 inhabitants. — Allo, a township in Worcester county, Massachusetts, incorporated in 1727, and containing 1210 inhabitants; 6 miles E. of Worcester. — Allo, a town of Pennsylvania, in Codorus creek; 10 miles S. of York.

Shrewsbury, a river of New Jersey, which runs into the Atlantic, N. lat. 40° 22'. W. long. 74° 2'.

SHRIEK, in Ornithology, an English name for several species of the Lanius; which fee.

SHULLA, in Geography, a town of Africa, in Lunda-mar; 48 miles E.S.E. of Benown.

SHRIMP, in Natural History, is the Cancer Crangon of Linnaeus; which fee.

This shell-fish inhabits the sandy shores of Britain in vast quantities, and is reckoned the most delicious of the genus. Some writers have classed it under the genus of Squilla.

The white shrimp, or cancer squilla, is the prawn. (See Cancer Squilla). It inhabits the coast of Kent. By 30 Geo. II. c. 21, white shrimps in the river Thames and Medway are only to be taken from Bartholomew day to Good Friday; and red shrimps in the river Medway only from April 25 to July 1.

SHRINE, formed from ferinum, a defh, or cabinet, a cafe to hold the relics of some saint.

SHRINT, in Ornithology. See Missel-Bird.

SHUFF, a sort of banker or money-broker in the East Indies. See RUPEE.

SHRONDO, in Geography, a town of Africa, in the kingdom of Dentila, in which are considerable gold mines.

SHROPSHIRE, one of the midland counties of England, is situated between 52 and 53 degrees N. latitude, and 2 and 3 degrees W. longitude, from London. It is bounded on the S. by the counties of Worcester and Hereford; on the E. by Staffordshire; on the N. by Cheshire, a detached part of Flintshire, and Denbighshire; and on the W. by the same county, and those of Radnor and Montgomery. According to archdeacon Plymley's "General View of the Agriculture of Shropshire," it extends about 44 miles in length, 28 in breadth, and 134 in circumference, comprising an area of 900,000 acres, or about a 45th part of England and Wales united. It is a flat soil, and is separated into two almost equal divisions by the river Severn. The parliamentary returns of 1811, state the number of houses it contains at 35,875, and its population at 194,298 persons, of whom 95,842 were males, and 98,456 females.

Historical Events.—When the Romans invaded this island in the reign of the emperor Claudian, this county was inhabited by two British tribes, called the Ordovices and Cornavi, whose respective territories were bounded by the Severn. The Ordovices, who appear to have been a more warlike and enterprising people, joined with the Silures, under the renowned Caractacus, to defend their country. Among the hills of Shropshire, that great chieftain for a time successfully strove against the overwhelming tide of Roman conquest; and here, several antiquaries contend, was fought the unfortunate conflict which terminated his military career, and led to his captivity. After that event, Shropshire formed part of the province called Flavia Caesaris, and seems to have been held in undisputed tranquillity so long as the Romans remained in Britain; but when they withdrew their forces to the continent, it again became the theatre of war between the Britons and the Saxons. For some centuries it condescended part of the kingdom of Powiand, of which Pengwern, now Shrewsbury, was the capital (see Shrewsbury); but in the reign of the great Offa it fell under the dominion of the Saxons, when the British princes retired to Mathrafael, in Montgomeryshire. To secure his conquests, Offa formed an immense rampart of earth, extending about 100 miles in length along the confines of Wales; but the utility of this work, for the purposes of defence, seems to have been very inconsiderable, as we find the Welsh constantly making inroads into the Mercian territories.

In the ninth century, when the Danes invaded this island, Shropshire shared in the calamities which their ferocity brought upon the kingdom, but in a much lefs degree than most other counties. During the reign of Edward the Con¬fessor, Gruffydd, prince of North Wales, became the terror of the English by his incursions into this county. Harold undertook an expedition against him, in which he was so successful, that the Welsh were glad to purchase peace by
the massacre of their chief. After the conquest, nearly the whole of Shropshire was bestowed on Roger de Montgomery, a relation of the conqueror's; but the invasions of the Welsh frequently disturbed him in the enjoyment of his splendid acquisitions. In 1067 they laid siege to Shrewsbury, the feast of his 30th power, with so formidable a force, that the king found it necessary to march against them in person, when they were defeated with great slaughter. This discouragement, however, only served to increase the warlike spirit of the Welsh; and William finding himself failed in his repeated attempts to reduce those high-spirited foes to submission by open combat, adopted a more politic mode of warfare. He filled grants to certain of his favorites of all the lands they should be able to conquer from the Welsh; and endeavored to divide and weaken the Welsh border chieftains themselves, by promising a confirmation of all the rights and privileges to such of them as would simply acknowledge the sovereignty of the English crown. 

Hence appears to have originated the seignories and jurisdictions of the lord marchers, whose power was even more arbitrary and despotic than that of the monarch himself. They constructed and restored castles at their pleasure, and garrisoned them with soldiers of their own. They likewise built towns, and exercised the most absolute authority, both civil and military, within their respective territories. In later times, however, this power was considerably controlled by a chief court of the marches of North Wales, which was generally held at Ludlow, but sometimes also at Shrewsbury and other towns; and was still more limited after the union of Wales with England, from which period no lord marcher could exercise any prerogative not confirmed to him by charter, without a special licence from the crown. During the various revolts which occurred subsequent to the death of Edward I., and also during the contentions for the crown between the houses of York and Lancaster, Shropshire was occasionally the scene of military contests, of which the most celebrated was the battle of Shrewsbury. When the civil war broke out in the 15th century, this county was peculiarly distinguished for its loyalty; but except the taking of the county-town by the parliamentary forces, no transgression of peculiar interest happened within its limits throughout that unfortunate era.

General Aspect, Soil, and Climate.—Shropshire possesses within its boundaries almost every variety of natural charm; the bold and lofty mountain; the woody and secluded valley; the fertile and widely cultivated plain; the majestic river, and the sequestered lake. The soil is no less various. In the hundred of Oswestry, a deep loam and gravelly soil prevail; and in those of North Bromfield and East Bramyley, a light or sandy loam. Pimhill hundred contains a mixture of boggy land, and of sandy soil, with a greater proportion of found wheat land. In the other hundreds, clays of different consistence form the most general soil; but there are numerous patches and extensive tracts both of deep and sandy loam, gravel, &c. The climate of coarse partakes of the character of its surface and soil. On the eastern side of the county, where the land is warm and flat, likewise frequently consumes a fortnight sooner than near the middle of the county, where the vales are extensive, but the surface less light, and the bottom often clayey, and hay and grain are both gathered earlier there than on the western side, where the vales are narrow, and the high lands frequent and extensive, although the soil is not in general so light. The easterly winds prevail in winter, and those from the west in autumn; but the easterly winds are most regular; those from the west blowing for a series of months (five

or six perhaps) strong and frequent, and the same wind, a similar period lasts often and his fullest. The land may be said of the wet and dry features in the county, but the periods of both appear to be much shorter.

Rivers and Lakes. — Shropshire abounds with rivers as much as any county in England. The principal among them is the Severn, which enters the county in the Vale of Muckley, and runs an irregular serpentine channel to Shrewsbury, where it at last encircles. At this town it turns towards the north, but soon again sweeps to the southward, passing by Wem, Mawceley, Madeley, and Bridgworth, to Bewdley, where it enters Worcestershire. Its course with a Shropshire is estimated at nearly seventy miles in length, throughout the whole of which space it is navigable for barges, tows, wheelers, and boats, and is abundantly supplied with fish of various denominations. The contributive streams to this great river, belonging to the county, are the Camel, the Vyrnwy, the Morda-Brook, the Perry, the Meole-Brook, the Rea, the Teme, the Bell-Brook, the Cund-Brook, the Wolt, the Marbrook, and the Bore-Brook, all of them considerable waters. Those of most importance, which do not join the Severn, are the Merles, which falls into the Dee, the Teme, the Shelbrook, the Elly-Brook, the Weever, the Chut, the Towy, which discharges itself into the Teme, in Herefordshire, and the Corve; but besides these, there are nearly a hundred streams of minor extent, which our limits will not permit us to mention. The lakes here are numerous, but none of them are very extensive. That of Ellesmere, which is the largest, covers about 115 acres of ground.

Minerals.—Shropshire is well supplied with minerals. The mines of lead ore, on the western side of the county, are extremely productive, and their product is reckoned to be of excellent quality. Copper and calamine are likewise found here in great quantities, but neither of them has hitherto been mined with any degree of success. Coal of a superior kind is wrought on the eastern side of the county, particularly in the parishes of Wellington, Lilleshall, Wrockwardine, Wombridge, Stichley, Dawley, Little Wenlock, Madeley, Barrow, Benthall, and Broughley. It is likewise found in the hundred of Stottesden, and to the southward of the Clee hills; also on the north and north-west confines of the county. Ironstone, as is usually the case, accompanies the coal flints, as well as lime-flints, which is quarried in various places, but particularly at Lilleshall, Porth-y-Wain, and Llanymynach, and in the parishes of Cardington and Alberbury. This county further contains abundance of building-stone, and slates for covering roofs. At Pitchford, about seven miles S.E. from Shrewsbury, is a red sandstone, approaching the surface in many places, which exudes a mineral pitch. From this rock is extracted an oil, known by the name of Betton's British oil. Mr. Arthur Akin is preparing an interesting publication on the mineralogical stratification of this county.

State of Property, &c.—The extent of estates in this county is very various. While the possessions of a few noblemen and gentlemen include from 10,000 to 25,000 acres each, there is an infinite number of freeholders and yeomen's estates of all inferior sizes. The number of freeholders entitled to vote amount to above 5000, and the total extent of the county, either inclusive or exclusive of 900 acres. They cannot hold tenure, but of cooler custom than in most of the neighbouring counties. The lords of some customary manors have enfranchised the copyholders, upon receiving an equivalent in money; but the customs of the greater number are still preferred and acted upon. In the manors of Ford, Cudoror, Wem, and Lop-
pington, the lands descend to the youngest son; and in the manors of Cardigan and Stretton, (where the eldest son succeeds,) in default of sons, the daughters are co-heiresses.

Agriculture.—The extent of farms is nearly as various as that of estates; but in general they are of a large size, and are, in some instances, held on leases for life; in others, for seven, ten, or twenty-one years; and, in many cases, from year to year only. The crops commonly cultivated are wheat, barley, oats, peas, turnips, and potatoes; hops, hemp, flax, and cabbages, are only reaped in small quantities. The growth of hay and the improvement of pasture lands are rather neglected branches of Shropshire agriculture; but on the borders of the Severn, and in the vicinity of several of the larger streams, there are many excellent tracts of meadow land, which produce grass in great luxuriance, without the aid of any other manure than what is deposited by the floods. The grasses most common in the county are the sweet-scented vernal grass, Timothy grass, meadow fox-tail, and some species of the agrostis; but the latter flower too late to be of much use for cultivation. Several varieties of the pea and fultica are likewise common.

Woods and Plantations.—Notwithstanding large yearly falls of timber, there still remain in Shropshire some fine woods of oak, and a vast number of good hedge-row trees, chiefly ash and oak. Birches, both as trees and as fences, are common in the south-west district. There are beeches, in this county, many large tracts of coppice-wood, and several extensive modern plantations; but the former suffer much by the demand for charcoal, which the numerous iron works in this and the adjoining counties occasion.

Of wooded lands, Shropshire is comparatively free. Almost all the lands in cultivation are inclosed; and the commons are every day decreasing, so that few of any great extent remain, except that of Morf, near Bridgenorth, which measures five miles in length, and nearly three in breadth; and the great lands between Church-Stretton and Bishops-Castle, and from Clun to the borders of Radnorshire, which are solely occupied as sheep-walks, and perhaps could not be better employed. There are several large moors, and many smaller ones, in Shropshire. The chief district of moor-land is that in the vicinity of the village of Kinnerley.

Roads and Canals.—The turnpike-roads of this county are excellent; but the parish roads are in general bad, and the repair of them much neglected, from the want of proper surveyors. Canals, though late of introduction into Shropshire, are now frequent. The chief cuts are the Shropshire canal, which commences at Donnington wood, and terminates at Coal Port on the Severn, running through an extensive alluvial of coal and iron works; the Ketley canal, which joins that of the Shropshire; the Shrewsbury canal; and the Ellesmere Navigation, which forms in itself a system of canals, extending through that large and fertile tract of country which lies between the Severn on the south and the Mersey on the north, and between the confines of North Wales on the west and the borders of Staffordshire on the east, a space of 50 miles in length, and upwards of 20 in breadth, exclusive of the valleys which open into North Wales. Its grand object is to unite the Severn, the Dee, and the Mersey, and by that means open a communication between the districts above mentioned and the ports of Liverpool and Bristol.

Manufactures and Commerce.—Among the manufactures of Shropshire, those of Ketley and other places in the iron district are the most considerable. Garden-pots, and other earthen vellums, are made at Broseley, which is likewise noted for the manufacture of excellent tobacco-pipes. At Caughley, in the same neighbourhood, is a china manufacture of great excellence, and at Coal Port is another of the same kind; besides one of that species of earthenware called the Queen's or Wedgewood ware. Shropshire also contains several mills for dyeing woollen cloths, and some cotton and linen manufactories. These various products of course form a considerable share in the commercial means of Shropshire, but its principal traffic is probably the staple trade of Shrewsbury, in flannels and Welsh wools, which are bought in large quantities at the markets of Pool and Oswestry, and are not only sent to every part of the kingdom, but are exported to different quarters of the world, particularly to the West Indies and to South America.

Civil and Ecclesiastical Divisions and Government.—Shropshire, like every other county in England, is governed by a lord lieutenant and two Justices of the Peace, or the sub_extended.

Parliamentary Representation and Chief Towns.—Shropshire sends twelve members to parliament, two knights of the shire, and two baronets for each of the boroughs of Shrewsbury, Ludlow, Bridgenorth, Wenlock, and Bishop's-Castle. The principal landed proprietors who have an influence in the representation are the Earl of Powis, the Lord Bradford and Berwick, the Hills, the Corbet, and Colonel Forester. The market-towns in the county are, Church-Stretton, Cleobury-Mortimer, Ellesmere, Hales-Owen, Madeley, Newport, Wem, Great-Wenlock, Oswestry, Whitchurch, and Wellington.

Antiquities.—Shropshire contains a great many objects of antiquarian interest. The chief Roman stations within its limits were Uriconium, now Wroxeter, Medulum, near Drayton, and Rutnumere, near Wem. Antiquaries differ respecting the precise position of the two last, but with regard to the former, there is little doubt but it was a chief city of the Cornovii, founded and fortified by the Romans. Watling-street enters the county on the east, between Crackle-wood and Welson, and passes through it in a bending line to Luntwood, in Herefordshire, on the southern borders. Of the Saxon period no certain remains exist; but of the Norman era, and of subsequent times, there are many; as the castles of Shrewsbury, Ludlow, Bridgenorth, Clun, and Red Castle, and the abbeys of Shrewsbury, Haughtmond, Buildwas, Wenlock, and Hales-Owen, several priories, and a great number of curious churches. The most remarkable encampments are those of Bury Ditches and the Walls, and at Purflew, Basford Gate, and Hawkstone. A General View of the Agriculture of Shropshire, by Joseph Pymley, M.A. Archdeacon of Salop, 8vo. 1803. Beauties of England and Wales, vol. xiii. by J. Nightingale and Ralph Rylance, 8vo. 1811.

SHROUD, from the Saxon Florid, a biller, or cover, is used to denote the drefs of the dead. This is required by statute to be made of sheep's wool only. See Burial.

If any one, in taking up a dead body, reals the hrend, the property of which remains in the executor, or the person who was at the charge of the funeral, it is felony.

SHROUDS, in Sea Language. See Shrouds.

SHROVE-
SHROVE-TIDE, the time immediately before Lent; thus called by our ancestors, because employed in ferreous, that is, in conferring their fines to the priest, in order to a more devout keeping of the ensuing Lent fast.

SHROWDING of Trees, the cutting or lopping off the top branches: this is only practised to trees that are not fit for timber, but designed for fuel, or some other present use.

Such trees the husbandmen find much preferable to coppice, as they need no fence to secure them; because they stand in no danger from the breakings and rubbings of cattle, which too have the benefit of grazing under them.

As for the time of shrowing, it is not to be practised till the trees have stood three or four years; and then it must be done either at the beginning of the spring, or the end of autumn.

Those of the harder sort are not to be lopped above once in ten or twelve years, and that at any time in the winter. The pithy and soft woods are bell shrowded in the spring. The flumps left should always be cut aloft, and smooth, in order to call the water off, and prevent its sinking in, and rotting the tree.

SHROWDS, or Stunns, in Sea Language, are great ropes in a ship, which go up on both fides of all masts, except the bowspirit.

The throns are always divided into pairs, i.e., one piece of rope is doubled, and the two parts fastened together at a small distance from the middle, so as to leave a fort of node or collar to fix upon the mast-head.

They are fastened below by chains to the ship's fides, and aloft, over the head of the mast; their pennants, fore-tackles, and twisters, being first put under them: and they are served there, to prevent their galling the mast. The top-mast throns are fastened to the puttocks, by plates of iron, and by what they call dead-men's eyes, and laniers also, as the others are. See Pattocks.

The throns, as well as the fails, are denominated from the mast to which they belong. Thus they are the main, fore, and mizen throns, the main-topmast, fore-topmast, or mizen-topmast throns, and main-top-gallant, fore-top-gallant, or mizen-top-gallant throns.

The number of throns by which a mast is fulllained, as well as the fize of the rope of which they are formed, is always in proportion to the fize of the mast, and the weight of the fail it is intended to carry. The two fore-mast throns, on the larboard and starboard fide of the ship, are always fitted first upon the mast-head; and then the second on the larboard, and the second on the starboard, and so on till the whole number is fixed.

The intention of this arrangement is to brace the masts with greater facility, when the fails are close-hauled, which could not be performed without great difficulty, if the fore-mast throns were latt fitted on the mast-head, because the angle which they would make with the mast would then be greatly increas'd. Falconnier.

Rowboat throns are those which support the howspirit. Bumkin throns are those which support the bumkin. Futtock throns are those which connect the efforts of the top-mast throns with the lower throns. Bentneck throns are additional throns to support the masts in heavy gales. Preventor throns are similar to Bentneck throns, and are used in bad weather to ease the lower rigging.

The terms are, fage the throns; that is, slacken them. Sotake the throns; that is, set them fatter.

SHROWD Trucks. See Trucks.

SHROWD Stoppers. See Stoppers.

SHRUBS, in Botany and Vegetable Physiologoy, are commonly understood to be plants with a perishable woody stem, of a more humble or slender form of growth than trees. Linnaeus once attempted to define the limits between trees and shrubs, by the former having leaf-buds, the latter none; but this distinction was soon found to be of no avail. Trees of hot countries have generally no buds, while many very humble shrubs of cold ones are furnished with this protection. This is so obvious, in Willows for example, that Linnaeus probably only meant to apply the rule generally. Thus the whole genus of Salix having buds, and being mostly arboreous, every species of that genus, however diminutive, must be deemed a tree. Accordingly, S. babara, hardly an inch high, is termed in the Flora Lapponica, the leaf of all trees. But the shrubby genus Lonicera has full more elaborate buds than Salix.

Shrub, in Gardening, a low woody plant of branching growth and ornamental appearance; it is sometimes, however, of a large growth and stature. Shrubs are commonly divided into the evergreen and deciduous kinds; and they may be subdivided still farther into the exotic or tender and the hardy sorts, as well as into such as are rarely seen or met with, and such as are well known and in common cultivation. In the former as well as latter of these great divisions, the plants may likewise be separated and arranged according to their size, forms, modes of growth, colours, and other particulars: in the last of which, it has been observed, there is every shade between the rufus, which is among the least, and the Bermudian juniper, which is nearly the largest;—from the holly, which is slightingly tinged with red, to the box, which is of a golden yellow,—in shape, from the cypress, which grows in the form of a spire, to the daphne tartan aura, which forms a globular tuft upon the surface of the ground;—from the hedges, which falls itself to the wall, to the adromeda and vince, which recline themselves upon the surface.

In the latter, the plants are said to be diversified in each of these particulars, being capable of division, as they may be cultivated principally for the beauty of their flowers, as the rhododendron, erica, and many others:—for the smell, as the sweet briar, abinchthoids, chriodendron, jasminum, and some others;—for both these qualities, as the rose, Cape jasmine, and a few more:—or as being grown, in a great measure, for the beauty of the leaves, as the acuba, variegated holly, elder, and some others;—for the purpose and appearance of the fruit, as the meyphus pyracea and the orange;—for the beauty of the whole plant, as the arctelia, and several others;—and, lastly, the great proportion for all these properties together, as the myrtle, laurus, tinus, laurel, and some others. Some of these, however, belong to the former of the above general divisions or classes.

Shrubs are of very great importance in forming all sorts of collections in gardens, and other places; and in ornamental pleasure-ground works they constitute a class of materials of the most interesting kind, which cannot be done without.

In such situations and works they are arranged, varied, and placed out, in many different ways, so as to produce the most pleasing effect and variety in the particular intentions with which they are planted or set out. See Shrubs.

It has been observed by Mr. Loudon, in his work on Ornamental Gardening, that the evergreen class of shrubs are deficient in moss situations, as well as trees of the same sort; but that they deserve to be very generally planted, equally on account of their uncommon beauty in the
the winter season, as for their contrast with the yellow and russet tints of the deciduous kind, and trees of the same nature, in the autumnal and spring seasons. They ought, generally, according to him, to be the prevailing sorts planted near the houses and buildings of country-folks, not only for the reasons suggested above, but because they are capable of concealing some part or parts of the edifices, disguising their real extents, and thus blending them at all seasons with the surrounding scenery. There is also another circumstance in their favor, which is the superiority of their foliage and shade.

It is thought, also, that the cyphus is too seldom planted in such situations, as it has the capability and power of giving a rich classical appearance and effect to them; as is seen in some cafes, as at Foxley and Yoxal Lodge.

And the holly, it is suggested, should be planted still more than any other shrub, in particular cafes; as no other is capable of affording and producing such an excellent and diversified effect in woody scenery, as is exemplified in some forest situations.

The ivy is capable, it is said, of answering three important uses, and of course deferring of more frequent growth. There are the varying of the leaves of single trees, and small groups of them, the giving of effect to old decaying trees, and the rendering of ugly trees interesting, as well as other familiar rural purposes; the producing of variety in different sorts of buildings; and the giving of ornament and utility to works of the country kind.

In the first of these intentions, in different cafes, where the number of trees of the same kind are considerable, and very much alike, which are in the fore-ground, one or several of them may be varied and diversified by the ivy shrub, in probably as happy a manner, and with as good an effect, as in any other way, and better than by the use of any fort of deciduous climbing plant. Single trees can always be rendered interestingly different by the same means, as well as old and ugly trees of different sorts.

In the second use, where cottages, ruins, irregularly formed buildings, old hovels, and other familiar structures, are to be varied, partially concealed, and rendered different in their external appearance, but which cannot be cheaply done in other ways, they may be highly and richly diversified and decorated by the simple planting of the ivy shrub, and directing it so as to cover in different places or parts. The expense of such works would also be less, in many instances, it is remarked, if the external appearance of them were contrived so as to admit this plant; which would not only vary and alter them generally; but might occasionally be substituted for, and supply the place of, particular parts, as is exemplified in many instances.

The last of these intentions is that of planting the ivy shrub against walls of the stone kind, dike, and sunk fences between fields, and other similar purposes, in the view of rendering them more ornamental and durable. The chequering of them in this way, on their sides, with shades of green, and little ribs or columns, and richly mantling their tops, have, it is said, much effect in producing variety, and at the same time in rendering them more lasting. Mortured and unmortured walls are likewise preferred and secured by it. This creeping shrubby plant may consequently be of extensive utility in various ways; as, besides affording beauty, shelter, and durability, it may be beneficial in thickening hedges in the vicinity of the sea-coal, when joined with the elder. It should, in all cafes, be carefully planted, either by jets or young seedlings, which last is by much the readiest mode of raising and providing it. Nothing more is wanting, as it succeeds well in moist foils, situations, and exposures. Where tall plants are wanted for particular uses, they must be provided with good roots.

In the deciduous kind of shrubs, the modes of varying and planting are very different, according to their nature, habits, size, and other qualities and circumstances. For the most part, however, the larger sorts are put more out of the way, in order that the smaller and more curious kinds may be more fully exposed to view. The peculiar properties in some of this description of shrubs also direct the modes and manners of planting them, as that of the time of flowering, and several others. They are varied and planted differently, likewise, for a great variety of other different reasons.

In planting the laburnum, as there are two sorts, which differ greatly in their spray or small twigs and foliage, that with the smaller and more delicate branches and flowers should confinately be chooset for putting out with other shrubs; the other, which is of much larger growth, is well suited for rough gravelly soils, rocky banks, and the rocky margins of water, where, in the two latter situations, the plants may sometimes be seen in great perfection.

Shrubs of these different kinds are raised and produced in many different ways, as may be seen under their different particular proper heads.

Some sorts of shrubs, particularly in the early state of their growth, stand in need of not merely a foil and situation, but a mode of cultivation which is adapted to their different natures and habits. And though most shrubs require to have the earth or soil about them either frequently stirred, or kept clean and free from all plants of the weed kind, there are some that succeed best when the surface of the ground is overrun with low plants of the mops kind.

In all cafes, shrubs are to be preferred in a neat and perfect order, by the removal of the decayed and withered parts, and the proper cutting in of particular shoots and branches where necessary, especially in some of the deciduous kinds. In the evergreen clafs, the knife or shears, however, are very seldom to be applied, except for the removal of the destroyed parts, which are constantly to be carefully taken away.

SHRUB, Fruit, that fort of low shrubby plant which bears fruit of some kind or other. Shrubs of this kind are mostly very useful, and not few in number. The forts are various, as the gooseberry, the currant, the raspberry, and some others, cultivated in garden situations; and the barberry or harberry, and a few other kinds, in thofe of the shrubbery. Shrubs of this description, in most cafes, require carefull attention in cutting, managing, and keeping the ground in proper order, by due cultivation, and the proper ufe of suitable manure. See SMALL FRUITS, and Standard Fruit Trees.

In planting them, those of the garden fort are most properly planted, either by jets or young seedlings, in the view of rendering them more ornamental, and not in the usual mode, on the sides or borders of the different cultivated compartments of the garden ground. Those which produce ornament, as well as fruit, are to be placed out in variety with other shrubs, in the more open parts of shrubberies, or alone in particular cafes.

SHRUBS, Stealing of: See LARCENY.

Wilfully spoiling or destroying them is a species of that malicious mischief, which subjected the offender to pecuniary penalties for the first two offences, and for the third, if he be committed in the day-time, and even be the first at night, to the guilt of felony, and transportation for seven years. 6 Geo. III. cap. 36. and 48.

SHRUBBERY, in Gardening, a tract, portion, or space of ground, which is planted with shrubs, trees, and flower plants,
plants, for the purpose of ornament. The term is, however, perhaps the most properly applied to narrow belts and strips of ground, planted with shrubs and flowers, which are sometimes the principal ornaments of small feuds, and other similar constructions and conveniences. They are contrived in different forms and modes, for the purpose of giving the desired effect; and the notion of such schemes of planting shrubs and flowers, is considered by Mr. Loudon as good and proper, as when executed according to the principles of nature and good taste, they must produce effects of the interesting as well as the pleasing kind; but that from the reverie having been so frequently the café, their tawdry insipidity has been justly reprobated by some; as Mr. Knight, in the following line, &c.

"Curle on the shrubbery's infipid scene."

It is suppos'd that shrubberies are, in general, made and contrived with the intention of procuring walks, which may either conduct or direct to some particular place or scene, such as the kitchen garden, the farm, a wood, or any other similar object; or they may lead and extend merely through the shrubberies, for their own sakes, and such views of external objects as can be produced from them, or are deserving of attention. In designing and forming shrubberies, therefore, keeping the above in view, three points will, it is thought, require to be particularly attended to: first, the arrangement, distribution, and grouping of the shrubs, which ought to be that of general nature; in the second, the intermixing of the glades and pastures, which, in most cases, is an essentially requisite consideration; and in the third or last, the judicious introduction of the views of the more distant scenery, which is generally definable, unless in such parts as, by way of utility or contrariety, are preferred in a state of umbritrility.

The two latter requisites are, it is said, naturally connected with picturesque improvements, the general principles of which are blended and intermixed with this branch of ornamental gardening.

The directions which this able designer of rural works of this nature has given for the forming of shrubberies with proper taste, in different cases, situations, and circumstances, are, that when such groups of shrubs and flower plants are small and placed upon lawns, they should always be of very irregular shapes; but that, when upon gravel, their forms must depend upon circumstances. In cafes where they are in a part in which art is avowed and ought to prevail, then the more artificial the forms are, so much the better; but that if merely a group for separating, dividing, or varying a road, walk, or natural path at a distance from artificial scenes, then the shape should be as irregular as in those upon lawns. Whether such shrubbery groups are made in a regular or irregular manner, they almost in every cafe require to be cultivated or wrought over for some years afterwards. This, in the mode of digging and working them which has been usually had recourse to, produces, it is said, a harsh and disagreeable boundary line; which, in addition to the means of proper arrangement, suitable grouping, and the natural connection of surface, may be improved principally, it is suppos'd, by the destruction of such lines of separation in as complete a manner, as high a degree, and as extensively as possible. Nothing, it is thought, can be more readily or more easily accomplished, as it is only requisite to keep the earth on the margins or borders of such groups of the same level as the surfaces of the lawns or pastures, and to suffer both to unite and blend harmoniously together, or with each other. And as all groups of this shrubbery kind are only dug or wrought over during a certain period of time, as until the shrubs become so large as to render further culture unnecessary; the paths should be allowed to gradually encroach and spread itself across the shrubs and flower plants, until at last it wholly covers the surface. After this, the shrubbery group becomes rough and picturesque; the flower plants, full to increase the growth among the shrubs, will, it is suppos'd, be productive of exactly what is seen to happen in natural groves; with this elegant difference, that in place of settle, thistles, and low coarse weeds, which, however, it is remarked, are as good to the passer by as the flower plants, there will be the narcissus, tulipings, lilies, and others, which are quite in character with the rest of the pleasure-ground, and thrive well among the paths. It is figg'd, that in placing the shrubs in such groups, the great art consists in putting them in irregularly; but though the outline of the ground to be cultivated must, even under the best taste, be somewhat formal, yet the shrubs can always be planted as irregularly as if no outline or form of group existed. This is, however, said to be a plan of manner of distribution, which has never been put in practice; as whether the frame of the ground may be which is to be dug and planted, the shrubs are distributed in a regular manner over every part of it; even where digging is no longer attended to, till some of the shrubs are thinned out, but the whole left a formal unconnected clump of vegetation; in appearance, it is observed, as different from the irregular group-thickets of nature, as a green hillock is from a rocky precipice. It is fatigued, however, that the groups of this nature, or rather those masses of formal shapes which are placed in particular situations, such as oval in the fronts of small villas, or basket-work patches upon the lawns in the fronts of residences of the mansion kind, should always have determinate outlines; as being devoted, in a great measure, to tender flower plants and flowering shrubs, they will require to be constantly in a cultivated state. Their outlines or boundaries may, it is suppos'd, be properly formed, according to circumstances, either of elegant masonry, wood, baskel-work, or of plants of the flower kind, such as thist, the daisy, and some others, and not unfrequently, when surrounded by gravel, by a broad margin of turf. In regard to the general forms of such shrubbery planted masses, it is said that they may be oval, circular, pentagonal, or fanciful, according to pleasure; and that their surfaces may either be kept level with the lawns or other parts, or be gradually raised from the margins to their centres. It is however noticed, that when raised in this way, the sides should always be made to present a concave slope, and not that of a convex one, as is most commonly the case, and which has a very bad effect in different instances, as in the public squares of the metropolis, &c. Basket-work shrubbery groups have not unfrequently, it is remarked, a very pretty effect when covered with mosses. Other groups which are unconnected among themselves, and which have shapes that are rather unsuitable to the nature of the situations in which they are formed, are likewise productive of variety. In all cafes, some sort of agreeable effect ought to be afforded in as striking a manner as possible.

It is conclusively remarked, that though the connection of surface in such shrubbery groups is always of importance, neither those of the irregular or regular shapes ought ever to be placed in any situation, except where they have a proper relation and union with what surrounds them.

In the larger and more extensive works of the shrubbery kind, the same rules and principles will be requisite to be had recourse to, but with a greater attention to the production of variety and effect. These are to be accomplished by such
such means as have been already suggested, and by giving them a more natural conformity, as well as by the introduction of greater diversity in the shrubs, trees, and other sorts of plants that are made use of in the formation of them. It is indeed observed, that one of the most effectual means of rendering rural scenes still more interesting than they commonly are, is by introducing a more extensive variety of shrubs than is usually employed, a vast number of which are capable of answering the purpose. They are not, however, to be planted in such situations in the common indiscriminate manner, but with much regard to the effect which they are to produce. In short, it is concluded, that it is in the shrubbery, or those places of pleasure-grounds which contain flower plants, shrubs, and trees,—which occupy considerable space,—exhibit views of the country or of other parts of the ground, that ornamental gardening and picturesque improvement blend themselves together in producing those happy effects which so much interest the feelings and fancy.

SHRUBBY-Hoak-Weed, in Agriculture, a plant of the flabby weedy kind, which is often troublesome and injurious in woods and plantations. See Hieracium, and Weeds.

SHRULE, in Geography, a river of the county of Tyrone, Ireland, which joins the Moyle near New Town Stewart. There are also several parishes of this name in Ireland, but none called from a town now existing, except Shrule in the county of Mayo, on the borders of the county of Galway; 106 miles N. by W. from Dublin.

SHTUKA, a powerful tribe or kabyle in the province of Sufe, in the southern division of the empire of Morocco, inhabited by Shelluka, amounting in number to 380,000.

SHARIF, a small low island in the Red Sea, near the coast of Africa. N. lat. 24° 22'.

SHUBENACADIE, a river of Nova Scotia, which rises within a mile of the town of Dartmouth, on the E. side of Halifax harbour, and discharges itself into Cobaquid bay, receiving in its course the Slewinick and Guys rivers. The large lake of the same name lies on the E. side of the land that leads from Halifax to Windsor, and about 7 miles from it, and 121 from Halifax.

SHUCK, in Agriculture, provincially a flouk, or twelve sheaves of corn set up together in the harvest field.

SHUD, in Rural Economy, a word sometimes provincially used to signify flaked.

SHUG, in Agriculture, a term used to imply the flaking of any thing, as hay, &c.

SHUGGINGS, a word signifying that which is flaked or scattered, as grain at harvest, &c.

SHUHUSHU, in Geography, a village of the pachalic of Bagdad, one day's sail from Korra, and situated on the bank of the Euphrates. It is as large as Samarat (which see), but much more flourishing; for the Euphrates, which is navigable, even in the driest season, for boats of considerable burthen as far up as this place (where the effects of the tide are also felt), enables the inhabitants to carry on a trifling traffic with Bassora. Shuushu is a great mart for horese, and is famed for the riches of the cloves raised in its vicinity.

SHUK, in Agriculture, a term sometimes provincially applied to a hulk or shell.

SHUKERA, in Geography, a town of Thibet; 42 miles S. of Gangote.

SHULA, or SHULI, in Mythology. See Sula.

SHUMAN, in Geography, a town of Grand Bucharia; 30 miles W. of Vahngierd.

SHUMBERG, a town of Illria; 5 miles N. N. E. of Pedena.

SHUME, or ASSUME, a violent hot wind of Africa, or, as they are called, Oncas, which, in the intermediate journeys between several parts of the Defart or Sahara, occasions great inconvenience and difficulties to travellers. It sometimes wholly exshales the water carried in skins by the camels for the use of the passengers and drivers: on which occasions the Arabs and people of Soudan affirm, that 900 dollars have been given for a draught of water, and that 10 or 20 are customarily given, when a partial exhalation has occurred. In 1805, a caravan proceeding from Tombuctoo to Tafilet was disappointed in not finding water at one of the usual watering-places, when, as it is said, all the perfons belonging to it, 2,000 in number, besides 1,800 camels, perished by thirst. The intense heat of the sun, aided by the vehement and parching wind that drives the loofe sand along the boundles plains, gives to the Defart the appearance of a sea, the drifting sands resembiling exactly the waves of the sea, and hence aptly denominated by the Arabs "el Bahar billa maâ," a sea without water. During the prevalence of this wind, it is impossible to live in the upper rooms of the houses; so that the inhabitants retire to subterraneous apartments, cellars, or warehouses on the ground-floor, eating only fruits, as the water-melon or prickly pear, as the animal food at this time is loathsome whilst hot, and has scarcely time to cool before it becomes tainted. The walls of the bed-chambers, being of stone, are moistened by throwing upon them buckets of water, in order to render the rooms habitable towards the night; and so great is their heat, that in doing this, the effect is similar to that which is produced by cating water on hot iron. Mr. Jackson says that he has felt the thume 20 leagues out at sea. When in N. lat. 30°, W. long. 11° 30', a quantity of sand fell on the deck. He adds, that he never found any extreme inconvenience from the thume N. of the province of Sufe, although at Mogodor it is sometimes felt, but not so severely, during three days.

The Akkaabahs, or accumulated caravans, which cross the great defart of Sahara, and consist of several hundred loaded camels, accompanied by the Arabs who let them to the merchants for transporting their merchandise to Fez, Morocco, &c. are sometimes obliged suddenly to strike their tents, and proceed on their journey, when the thume rises and drives the loofe sand along the plains, which attaches to them and forms a fixed object in its course, and soon buries it. We shall here add, that the guides of these accumulated caravans, being enabled by the two pointers to ascertain the polor star, steer their course with considerabe precision, and that they often prefer travelling in the night to enduring the suffocating heat of the fcorching meridiano heat. When the Akkaabah reaches Akka, the first station on this side of the Defart, and situated on its confines, in Lower Sufe, which is a part of Biledulgerid, the camels and guides are discharged, and others are there hired to proceed to Fez, Morocco, Taroudant, Tafilet, and other places. The Akkaabahs perform the traverse of the Defart, including their jouruements at El-wahs, or Oafes, in about 150 days. Proceeding from the city of Fez, they go at the rate of 34 miles an hour, and travel seven hours a day; they reach Wedinnoom, Tatta, or Akka, in 18 days, where they remain a month, as a great accumulated Akkaabah proceeds from the latter place. In going from Akka to Tagallia, they employ 16 days, journeying here 15 days more to replenish their camels; they then proceed to the Oafes and well of Taouden, which they reach in seven days, and after lying there 15 days, they proceed to Tombuctoo, which they reach the fifth day, making a journey of 54 days actual travelling, and of 75 days repose; being altogether, from Fez...
Rennell in favour of his opinion in the 'Geographical Memoir on the Persian Empire,' has examined with critical skill and great candour the objections of Dr. Vincent, and the principles on which they are founded; and the result is, that he inclines to favour the opinion of major Rennell, in support of which he cites the authority of Strabo, who says, that the Persian capital was entirely built of brick, there not being a stone in the province; whereas the quarries of Shutter are very celebrated, and almost the whole of the town is built of stone, but there is no such thing in the environs of Shus, which was anciently formed of brick, as appears from our author's description of the pyramids that still remain. However the question concerning the site of the city of Shus be determined, it is now a gloomy wilderness, infested by lions, hyenas, and other beasts of prey.

SHUSJIMIAN, a town of Persia, in Khurasan; 6 miles N. of Maru.

SHUSTER, a province or district of the Persian empire, constituting one division of Kuzzistan, or Chufistan, the other being formed by the territories of the Sheik, the latter extend from the banks of the Taw to the confines of the Karoon and Abzal, and from the shore of the Persian gulf to a range of hills which skirt the valley of Ram Hormuz to the south. The most fertile spots in this district are those in the environs of Darsk, the capital of the Abzal prince, and on the banks of the Hafar and Shat-ul-Arab. Here dates and rice are produced; and hence the Sheikh Mahomed derives his principal revenues. The wheat and barley that are grown are scarcely sufficient for the supply of the inhabitants. The rice harvest is in August and September, and that of other grains in April and May. The northern and western parts of the country afford tolerable pasturage; and here the wandering tribes, which compose the principal part of the population, pitch their tents. Both banks of the Karoon, from its junction with the Abzal, eight furlongs below Shuster, to the ruins of Shus.
SABA, are uninhabited, and consequently almost wholly uncultivated, and covered with brash-wood, the resort of hons, wild bears, and other animals. Moraines are common. The Chab country is watered by three rivers, viz. 11th, the Karoon, suppos'd by some geographers to be the ancient Choafpes, but Kinneir disputes their identity; it rises 22 furlongs S.W. of Ipahan, and after receiving many tributary streams in the mountains of Lauritian, flows through the city of Shutter to the village of Bandekeel, eight furlongs to the S. of that city, where it meets the Abzal: puruing thence a fotherly course, as far as Sabla, N. lat. 30° 32', and 30 miles E. of Baffora, it divides itself into two branches, one of which discharges itself into the sea at Goban, and the other, assuming the name of Hafar, separates, after a course of 14 miles, into two branches, one of which paves through an artificial canal, three miles in length, into the Shat-ul-Arab, and the other enters the sea by the name of the Baniheir. 2dly. The Tad, which see; and the 3d is the Jerahi, or ancient Pafhtigiris, which descends from the mountains behind Behaban, in the province of Fars, and passing within a few miles of the walls of that city, runs through the vale of Ram Hormuz to old Dorak, in the territory of the Chab Sheikh. Here it is difpersed in various directions for the purpose of agriculture; and the water afterwards is 10d, or occasions the salt moraines in the vicinity of modern Dorak. The principal towns in the district of Chab Sheikh are, Dorak or Pelahi, Ahwaz, Indanic, Mathoor, Goban, and Jerahi, whence the river, fo called, derives its name. The revenues of the Chab Sheikh amount to five lacs of piastras, or about 50,000 l. sterling a-year; and he can bring into the field 5000 horse, and 20,000 foot.

The territories attached to the government of Shutter constitute the fairest portion of Sullana. It derives its fertility from four noble rivers, and from a multitude of smaller streams. This wealthy province, which, according to Strabo, yielded to the husbandman 100 or even 200 fold, and was rich in its productions of cotton, fugar, rice, and grain, is now, for the greatest part, a forfaken waife. The only indications to the contrary occur between Bandekeel, Daphshoul, the vicinity of Haueeza, and the vale of Ram Hormuz. From the Abzal to the Tigris, and the river Gyndes, on the western side, and from the banks of the Karoon to thofe of the Shat-ul-Arab, all is dreary and defolate; and on the E. side of Shutter a lonely wild, upwards of 60 miles in length, extends from that city to the entrance of the valley of Ram Hormuz. Although the inhabitants of the towns and villages groan under the arbitrary fway of the governor of Shutter, his authority is hardly acknowledged by the wandering tribes, both Pefian and Araban, of Kuzitiam. Of the four great rivers which embellish and fertilize the district of Shutter, Karoon deferves the firft mention. Next in magnitude is the Abzal, which has two fources, one in the Shutter Koh, near Boorojord, and the other in the mountains of Lauritian: thefe form a junction N. of Daphshoul, and after passing under the walls of that city, empty themfelves, after a winding course, into the Karoon, at Bandekeel. The third river is the Kerah, or Haueeza river, called by the Turks the Karafa, which is formed by the junction of many streams in the province of Ardelan, in Kuriditan: it runs through the plains of Kermanhow, meeting the Kazawur and the Ga-

mafs. The Karafa, increafed in magnitude by tributary streams, flows with a furious course towards Kuzitiam, and supplied with an acception of water, it paifes on the W. of the ruins of Shus to the city of Haueeza, and enters the Shat-ul-Arab, about twenty miles below Korna. The fourth river is that suppos'd by Mr. Kinneir to be the ancient Gyndes, which proceeds from an unknown fource in the mountains of Lauritian, and joins the Tigris between Koot and Korna.

Shutter, the capital of Kuzitiam, and the residence of a Begolbeg, is situated in N. lat 32°. E. long. 48° 50', at the foot of the mountains of Bucakiari, on an eminence commanding the rapid course of the Karoon, acros which is a bridge of one arch, upwards of eighty feet high, from the summit of which the Persians often throw themselves into the water, without the flight of a fishy. On the western side it is defended by the river, and on the other side by the old stone wall, now fallen into decay. The houses are good, being principally built of stone, but the streets are narrow and dirty. The population, confifting of Persians and Arabians, exceeds 15,000 souls; and it has a confiderable manufacture of woollen stuffs, which are exported to Baffora, in return for the Indian commodities brought from thence. This city is generally believed to be the ancient Sufa; but some approved geographers entertain a different opinion. (See SHUS.) Shus, in the old Pefian language, means pleasing, or delightful, and Shutter ill more delightful; and the name is said to be given to this city by Sapor, the fon of Artaxerxes Babegan, by whom it was founded, and caufed to be built under the inspection of his prifoner, the Roman emperor Valerian. It was once, without question, a place of vall extant, and no inconfiderable magnitude. The castle, dyke, and bridge, are moft worthy of notice. The castle occupies a small hill at the western extremity of the town, commanding a fine view of the river, mountains, and adjoining country. This fortrefs is, on two fides, defended by a ditch, now almost choked up with fand, and on the other two fides by a branch of the Karoon. It has one gate-way, formerly entered by a draw-bridge. The hill is almost entirely excavated, and formed into furdahs and fubterraneous aqueducts, through which the water still continues to flow. Near the castle is the dyke, or "bund," built by Sapor across the Karoon, with a view of turning a large proportion of the water into a channel more favourable for agriculture, than that which nature had affigned it. This dyke is constructed of cut stone, bound together by clamps of iron, about 20 feet broad, and 400 yards long, with two small arches in the middle. It has lately been rebuilt by Mahomet Ali Meera, governor of Kermanhow, and its beneficial effects are already experienced. The artificial canal, occafioned by the conftuction of this dyke, fiumebogues, after a long winding course, into the Daphshoul, half a mile from Bandekeel. Near the canal is a bridge, built of hewn stone, conftituting of 32 arches, 28 of which are yet entire. The city of Shutter is fo remarkable for its fulbility, as to be the continual refort of invalids from the surrounding territories. In summer the heats are exceafive from nine in the morning to the fame hour at night, when the air is refreathed by a gentle breeze from the N.W. During the day the inhabitants take refuge in fubterraneous chambers, and pafs the night on the flat roofs of their houses. The winters are mild, and the fprings temperate and delightful. Shutter affords excellent fprings, Kinneir's Geog. Mem. of the Pefian Empire.

SHUT in Land. See LAND.

SHUTESBURY, in Geography, a township of America, in Hampshire county, Maffachusetts, on the E. side of Connecticut river: 90 miles W. by N. from Boston, containing 930 inhabitants.

SHUTTING, in Anchor-Making, denotes joining or welding one piece of iron to another.
SHUTTLE, in Manufactures, an instrument used by the weavers, which, with a thread it contains, either of woollen, silk, flax, or other matter, serves to form the woofs of stuffs, cloths, linens, ribbands, &c. by throwing the shuttle alternately from left to right, and from right to left, across between the threads of the warp, which are stretched out lengthways on the loom.

In the middle of the shuttle is a kind of cavity, called the eye or chamber of the shuttle; in which is included the thread, which is a part of the thread defined for the woof; and this is wound on a little tube of paper, rush, or other matter.

The ribband-weaver's shuttle is very different from that of most other weavers, though it serves for the same purpose: it is of box, six or seven inches long, one broad, and as much deep; it has iron at both ends, which terminate in points, and here is a little crooked, the one towards the right, and the other towards the left, representing the figure of an S horizontally placed.

SHUTTLE, in Inland Navigation, a term expressing a small flue, paddle, &c.

SHUTTLEWORTH, Obadiah, in Biography, organist of St. Michael's church, Cornwall, was elected, on the resignation of Harte, for St. Donne's Back-church, who was succeeded by Burney in 1749. Shuttleworth, soon after his election at St. Michael's, was appointed one of the organists of the Temple church. He was the son of Shuttleworth of Spitalfields, the father of a remarkable musical family, and had acquired a small fortune by teaching the harpsichord, and transcribing the compositions of Corelli, before they were printed in England. He had three sons and a daughter, all good musicians; and had frequent concerts at his house for the amusement of his friends, in which the sons played the violin and tenor, the daughter the harpsichord, and the old gentleman the viol da gamba. His son Obadiah, particularly, was so admired a performer on the violin, as to be ranked among the first masters of his time. He led the band at the Swan concert, from its first institution to the time of his death, about the year 1735, when he was succeeded by Feoffing. His brothers were excellent performers on the violin, and employed in all the city concerts. But Obadiah is almost a single instance of the same musician being equally admired for his performance on two different instruments. He was such a favourite player on the Temple organ, that great crowds went thither to hear him of a Sunday evening, when, after service, he frequently played near an hour, giving a movement to each of the solo groups previous to his final fugue on the full organ.

SHWAN-PAN, the name of a Chinese instrument, composed of a number of wires, with beads upon them, which they move backwards and forwards, and which serves to affix them in their computations. See ABACUS.

SHWAYEDONG, in Geography, a small but neat town of the Burma empire, on the Irrawaddy, containing about 100 houses, ranged in a regular street; each dwelling has a small garden, fenced with a bamboo railing. In two Masonries and a few small temples did not encourage the particular notice of Col. Symmes and his companions; but the tall and wide-spreading tree that overawed them were objects of pleasing contemplation. Symmes's Embassy to Ava, vol. ii. p. 174.

SHY, in Agriculture, a provincial term, signifying high-milled or head-dry, is the manner of wild oats, &c.

SHYAMULA, in Metaphy, a name of Parvati, the comfort of the Hindu deity Siva. It means with a blue body; and is, with many other names of similar derivation, given to that goddess, and to Vishnu, Krishna, and Rama, who are described and represented of blue. Among these names are Swayam, Shyamala, &c.

SI, in Geography, a town of China, of the third rank, in Hoo-nan; 50 miles N.W. of Kowang.

SI, or STA, a town of China, of the second rank, in Ch'ang-fi. N. lat. 36° 40'. Long. 110° 31'.

SI, in Music, a name in fuguing, given by the French to the sharp 7th of the key of C, to preclude the embarrassment of the mutations in foliation. (See Heurachord, and Mutation.) A similar expedient had been often attempted by various authors; but none had been so generally adopted as this, which however was long solely confined to France; nor is it yet general all over Europe. And we think that the manner in which the French syllabize not only vocal but instrumental music, is subject to very material objections; it only provides for one key. If the new syllable fi had been used for the sharp 7th of every key, as well as that of ut or C natural, and la for every key-note or tonique in minor keys, it would have exempted the princeps in fuguing from much perplexity. There is no certain name for any note, except in the key of C, ut, re, mi, fa, sol, la, fi, ut; and whether B is flat, natural, or sharp, it is equally denominated fi, as C, whether natural, flat, or sharp, is always called ut. When D is the key note, it is named re; when it is the 3d of the key of Bb, or 4th of A, it still retains the name of re.

Malcolm, in the year 1721, was the first who openly censured the hexachords; which Dr. Pepusch, in 1731, defended with some warmth, by giving the bell and clear explanation of their use and importance, not only in fuguing but composing, in regulating the answers to fugues. Fouehl, Padre Martini, Salis, and the most respectable Italian and German theorists, still adhere to the foliation which has produced so many great composers and singers during the two last centuries. We have given our opinion fully on the subject in the article SEHRA, a Roman maister, who proposed a new method of naming the intervals in cultivating the voice. See SEHRA.

The original introduction of this syllable is attributed by Merennes and other writers to one Le Maire, a French musician, who laboured for thirty years to bring it into practice; but he was no sooner dead than all the musicians of his country made use of it. However, it has been the more general opinion, that the syllable fi was introduced into the scale by Eriicus Putenius of Dort, who lived about the year 1580. M. Bourdelot ascribes the introduction of this syllable into the scale to a Cordelier, about the year 1675; and he adds, on the testimony of the abbé de la Louette, that it was invented, or a second time brought into practice, by one Metru, a famous fuguing-maister at Paris, about the year 1676; and Bonet inclines to think, that the honour of the invention might be due to the Cordelier, but that the merit of reviving it is to be ascribed to Metru. Bourdelot attributes, that though the use of the syllable fi is much approved
proved of by the French musicians, yet in Italy they disdain to make use of it, as being the invention of a Frenchman.

The French are not yet agreed to whom they are obliged for the syllable fi; some say it was Nevers, some Le Maire, and other claimants are mentioned by Roucoux; but not being quite satisfied with its utility, we shall befall no pains in verifying the claims of an imperfect invention.

St Action, in Law, the conclusion of a plea to the action, when the defendant demands judgment, if the plaintiff ought to have his action, &c.

SIABE', in Geography, a town of Peria, in the province of Segeltan, or Seifan.

SIABISCH, a river of Russia, which runs into the Abakan, near Bankalov, in the government of Kolyvan.

SIADY, a town of Samogitia, feated on a lake; 33 miles N.N.W. of Miedniki.

SIAINE, a river of France, which runs into the Mediterranean, N. lat. 43° 31'. E. long. 7°.

SIAGONAGRA, a name given by some medical writers to the gout in the jaws.

SIAKA, in Geography, a town of Japan, in the island of Ximo; 12 miles W. of Taifero.

SIAKOH, a mountain of Peria, in the province of Irak; 50 miles E.N.E. of Kom.

SIAL, a small island near the coast of Egypt, which forms a harbour in the Red sea. N. lat. 24° 30'. E. long. 35° 2'.

SIALACOORY, a town of Hindooftan, in Cochin; 30 miles N.E. of Cranganore.

SIALISMUS, formed from σαλεως, salivae, a word used by the ancients to express a discharge of salivae, brought on by the holding hot things in the mouth; and by us for a salivation by mercury.

SIALO, in Geography, a town on the E. coast of the island of Sibu. N. lat. 9° 53'. E. long. 123° 30'.

SIALOCHI, a term used by the ancients to express such person as had a plentiful discharge of salivae, by whatever means. Hippocrates uses it for a person having a quinsey, who discharges a very large quantity of salivae. Others express by it person, whose mouths naturally abound with a bitter salivae; and others, such persons as, having a very large tongue, spit into people's faces while talking with them.

SIALOGOGUES, in Medicine, from σαλεως, salivae, and αγαθος, I exsile, comprehend all such medicines as increase the flow of salivae.

The substances which operate upon the salivary glands, so as to excite them to pour out their fluid in increased quantities, are of two kinds; namely, those which may be called external, and which, when applied within the mouth, stimulate the excretories of salivae and mucus, opening thereby their acrid qualities; and those which are administered internally, and operate through the medium of the circulation.

It seems to be a falutary provision of nature, that when any acrid matter is applied to the sensible parts of the tongue and internal surface of the mouth, a quantity of salivae and mucus should be poured out to wash it off, or to defend those parts from its irritating effects. Whence, by the continued application of acrid substances, a considerable evacuation of the vessels of those parts is produced. By emptying the salivary glands and mucous follicles, they produce an afflux of fluids from all the neighbouring vessels to a considerable extent. Whence it will be readily understood, that these malacitactors may relieve rheumatic congections, not only in the neighbouring parts, as in the case of tooth-ache, but also congections or inflammatory dispositions in any part of the head, supplied by the branches of the external carotid.

Many substances are resort to for this purpose, and chiefly the warm and acrid vegetables; indeed every substance that proves sharp and heating to the tongue, or internal surface of the mouth, will answer the end. The angelica is a mild and agreeable salagogue; the impregnatoria more acrid; and the pyrethrum more acrid still, and therefore more commonly employed. Other substances might be enumerated, but it may be enough to add, that a bit of fresh horse-radish root, held in the mouth, and chewed a little there, is as effectual as any.

The only medicine which we possess, that is capable of exciting a flow of salivae when taken internally, is mercury. In its crude and simple state of quicksilver, however, it is perfectly inert, and exerts no influence whatever upon the living body, until it is oxidated, or combined with other materials. Its operation then, as Dr. Cullen has ably demonstrated, is not, as was formerly suppos'd, by any chemical action on the fluids of the body, by which they are attenuated, and thus made to pass off more readily through the excretory ducts; but by a general inflamatory effect on the vascular system, and especially upon the various excretories of it. When blood is drawn from a person under the full influence of mercury, it exhibits no appearance of any diminution of confidence; but, on the contrary, it is always found in the same condition as in inflammatory diseases.

It will not be necessary to enter into detail in this place respecting the mode of administering mercury as a salagogue, since that has already been done under the head of Lues Venerea, for which disease principally it is so exhibited. In this disease, indeed, as well as in other diseases of the liver, in hydrocephalus, and some other maladies, it is not administered with a view to the evacuation from the salivary glands; its operation as a salagogue is rather looked upon as the object of its full influence on the constitution, than as the means of its remedial power. See Cullen, Materia Medica, part ii. chap. 17.

During the prevalence of a chemical theory, to which the discovery of the importance of oxygen in the animal economy gave rise, and when it was suppos'd that the nitric acid had been found to be a substitute for mercury in the cure of syphilis, it was even maintained that this acid acted in a similar manner upon the salivary glands, and was, in fact, a powerful salagogue. Further experience, however, while it disproved the antinoueral power of this acid, disproved also its virtues as a salagogue, except indeed it might influence the excretory ducts of the glands externally, that is by its acrid qualities in the act of being swallowed.

SIALUSSIEB, in Geography, a town of the Arabian Trak, on the Euphrates; 8 miles E. of Sura.

SIAM, a country of Asia, the name of which is of uncertain origin; but probably derived from the Portuguese, in whose orthography Siam and Siaô are the same; so that Sian, or Siang, might be preferable, as Loubere has suggested, to Siam; and the Portuguese writers in Latin call the natives "Sioues," The Siamese style themselves "Ta," or freemen, and their country "Meuang Ta," or the kingdom of freemen. The Portuguese might possibly derive the name Siam from intercoure with the Peguene. "Shan," however, is the oriental term. Before the recent extension and encroachments of the Burman empire, the rich and flourishing monarchy of Siam was regarded as the chief state of exterior India; but some of its limits are not now easily ascertained. On the west of the Malayan peninsula some few pollinations may remain to the south of Taimeir; and on the easterly side of that Cherefonee, Ligor may
Siam.

In 1771, the capital of Siam was Bangkok, which was later renamed Ayutthaya and then Bangkok again.

Our principal sources of information with regard to Siam are the publications of L. Loubere, who acted as ambassador from Louis XIV to the king of Siam, and those of the French missionaries, of which, that from the paper of the bishop of Toulouse by Tuiras, in 1771, is the most important.

According to Loubere's account, the first king of the Siamese was crowned in the year 1500 of his epoch, or about 575 years after the Christian era. Since the Portuguese discovery, their wars with Pegu, and occasional forays of the thre, constitute the principal topics of their history. In 1569 the Pegu king declared war on account of two white elephants, which the Siamese refused to surrender; and after prodigious slaughter on both sides, Siam became tributary to Pegu; but about the year 1620, raja Hapi delivered his crown from this servitude. In 1680, Philon, a Greek adventurer, being highly favoured by the king of Siam, opened an intercourse with France, for the purpose of supporting his ambitious designs; but they were punished by his execution in 1689, and the French connection was thus terminated. From Turpin, who has extended the history of Siam to the year 1770, we learn, that the first king began to reign about 1444 years before Christ, and that he had forty succedors before the epoch of the Portuguese discovery, or the year 1546, many of whom were precipitated from the throne on account of their depotsin. Nevertheless, these forty kings cannot be supposed to have reigned more than ten years each, at a mean computation, the first historical date cannot ascend beyond the year 1100 after Christ, instead of 1444 years B.C. One of the most remarkable events, after the French had evacuated Siam, is the war against the kingdom of Cambodia, which was reduced to the necessity of seeking the protection of Cochin-China. The Siamese army, having advanced too far into the country, was destroyed by famine; and their fleet, though it destroyed the town of Ponteams, with 200 tons of elephants' teeth, had little success. In 1760 a signal revolution happened in Siam, preceded by violent civil wars between two rival princes. According to Turpin's statement, the Birmans, a people of the kingdom of Ava, had, in 1754, languished five years under the Peguese domination. Having lost by death their
their king, queen, and most of their princes, they lamented their humiliation and servitude, and anxiously sought for a deliverer. With this view they selected one of their companions, named Manlong, a gardener, who, singularly qualified for the office they devolved upon him, by corporeal and mental endowments, undertook to rescue them from the yoke of tyrants, on condition of their cutting off the heads of all the little fabulent tyrants whom the Peguese had sent to oppress them. They readily submitted to his terms; and after the massacre, Manlong was proclaimed king. Having prepared a force, and established a discipline which rendered the Birmans almost invincible, he began by the capture and complete ruin of the city and port of Siriam, which took place about the year 1759; and advancing to Martavan and Tavil, the new monarch received information of the riches of Siam, and formed the desir of its conquest. He began by sending 30 ships to pillage the cities of Mergui and Tanaferim, and this success led him to flatter himself that he should be able, with great ease, to subdue the whole kingdom of Siam. The court of Siam, hearing of this irruption, sent to the bishop of Tabraca, to request that he would arm the Christians, who amounted only to the number of 100, and yet acquitted themselves with greater honour than the puffedimalious multitude. The Birman sovereign, being at the distance of three days' march from Yuthia, the capital, died in consequence of an abeyce. The subhurs, however, on the Dutch quarter were ravaged and burnt; and the surrounding country was exposed to a thousand cruelties. The death of Manlong delivered the Siamee capital; the young efl of his sons having assumed the sceptre, found himself under the necessity of regaining his own kingdom, in order to stifle any revolt. The Siamee sovereign, however, having rashly pronounced a sentence of death against the faoujeur of his brother, was forced to abdicate the throne, and in consequence of this event he became a Talapoin, or monk, in May 1762, and many of his nobles followed his example. Siam remained in a state of security, upon the report that the new prince of the Birmans had been dethroned upon his return to A v a; and that his elder brother, who had succeeded, had no wish to make conquests. This pacific monarch dying suddenly, a pretence of war was afforded by the affiance which the Siamee had given to a rebel Birman governor. In January 1765, the Birmans attacked Mergui and took it; and then proceeded to Tanaferim, which they reduced to ashes. Flushcd with success, the general of the Birmans marched against Yuthia, not doubting that the conquest of the capital would induce other cities to submit. The provinces on the north-west of the royal city were ravaged; and the inhabitants saved themselves from death or slavery by dijperion into forests, where they participated the food of wild beasts. The Siamee, threatened with speedy and total destruction, reunited their forces; but though they fought with ardour, their languid defeat subjected their country to the power of their conqueror. The fields, ravaged by the confuming flames, preferred nothing to them but ashes, and famine became more terrible than war. The victorious Birmans built, at the confluence of two rivers, a town, or rather a fortified station, which they called Michoug. The Siamee, on their part, attempted to fortify the capital, and earnestly solicited the affiance of two English vessels which happened to arrive. The captain of one of them contented to defend the capital, on condition of being supplied with cannon and ammunition: but the jealous Siamee infaith that he should first lodge his merchandizes in the public magazine. With this condition he complied, and going on board his ship, harased the enemy, and destroyed their forts, so that every day was marked either by their defeat or flight. But demanding more ammunition, the daftardly court became afraid, that the English captain, with his single ship, would conquer this ancient monarchy. Its indignant captain withdrew, after feizing six Chinese vessels, whose officers received from him orders upon the king of Siam to the amount of the merchandizes which had been lodged in the public treasury. Upon his retreat, the Birmans, finding no opposition, spread universal desolation, and configned even their temples to the flames. Instead of recurring to arms, the superfluous monarch and his minions repented their whole confidence in their magicians. A Siamee prince, indeed, who had been banished to Ceylon, raised a little army, and returned to the affiance of his country; but the disunited court of Siam sent forces to oppose their deliverer. Many of the Siamee, justly provoked by this conduct, joined the Birmans, who in March 1766 again advanced, after having been repulsed by the English captain, to within two leagues of the capital. In September 1766, the Birmans feized a high tower, at the distance of about a quarter of a mile from the city, and raised a battery of cannon, which gave them an absolute command of the river. In this state of urgent danger, 6000 Chinese were charged with the defence of the Dutch factory, and of a large adjacent temple. The Birmans, in consequence of previous skirmishes and a subsequent assault, feized on five considerable temples, which they converted into fortresses; but in another assault they were compelled to retire. The Siamee officers, eager to secure the magazines of grain, as a future resource, produced an immediate famine which, followed by a contagious disorder or pestilence, occasioned the most dreadful devilation. The Dutch factory was in vain defended by the Portuguese and Chinese; and after a siege of eight days, it was taken and reduced to ashes. The whole Christian quarter of the city shared the same fate; and the virgins were obliged to marry the first young men that presented themselves, in order to be protected by the matrimonial tie, which the Birmans reverence. The Birmans, demanding an unconditional surrender, assaulted the city, and captured it on the 28th of April 1767. The wealth of the palaces and temples was consumed by the flames, or abandoned to the soldiery. The golden idols were melted; and the victors, finding that their avarice had been sacrificed to their fury, recurcd to acts of violation and cruelty. The great officers of the kingdom were loaded with irons, and condemned to the galleries. The king, attempting to escape, was massacred at the gate of his palace. When nothing remained for these conquerors to destroy, they refumed their march to Pegu, accompanied, among other captives, with the remaining princes and princesse of the royal blood of Siam. In June the Birmans quit Siam, after having burnt the town of Michoug, soon after its construction.

When the Birmans evacuated their conquest, the Siamee fled from their forraits, and superfluously directed their first rage against their gods, for having abandoned them to a destructive enemy. Availing themselves of the wealth which accrued from the statues, filled by superfluous perfons with gold and silver, who expected to find them when they revisited this world, they proceeded to elect a leader; and Phai-Thai, an officer of acknowledged ability, was the object of their choice. This new prince displayed considerable bravery and talents; and in the year 1768 suppressed a rebellion that was infligated against him. The Birmans in vain attempted to renew their incursions into the Siamee territory: they were repulsed, and afterwards obliged to turn their arms against the Chinese, who were defeated in their turn. For further particulars with regard to the history of Siam, see Birman Empire. Indeed, if the Birman empire maintains
maintains its present extent. Siam, we can have little doubt, will ere long be deprived of its independence. But it is an event not, perhaps, less probable, that the Burman empire itself will fall into confusion, and be disemboweled.

Everything we are told respecting the government, the laws, the literature, the arts, and personal qualities of the Siamese, indicates a corresponding state of advancement with that of the Burmans. That the religion of the Siamese is the same with that of the Burmans, and derived from the same origin as that of the Hindus, there seems to be sufficient evidence. Somonnodaen, mentioned by Loubere as the chief idol of Siam, is interpreted by competent judges to be the same with the Buddha of Hindoostan. The sacred language called Pali is of the same origin: the most esteemed book seems to be the Vina, and the precepts of morality are chiefly five: one, not to kill, not to steal, not to commit uncleanliness, not to lie, and not to drink any intoxicating liquor. Loubere has given a translation of a more minute code of morals, chiefly compiled for the use of persons dedicated to religion, whom he calls Talapoons. Their laws are said to be in high reputation all over the East; and it is not certain, whether, like those of the Burmans, they are of Hindu, or of indigenous birth. Their system of legislation is represented by all writers on this country, as extremely severe in its sanctions; death or mutilation being punishments of unspeakable of offences. The Siamese imitate the Chinese in their festival of the dead; and in some other of their rites. The government of Siam is despotic, and the sovereignty, as among the Burmans, is revered with honours almost divine. The succession to the crown is hereditary in the male line. The population has not been accurately ascertained, nor have we any documents for this purpose. Allowing to the Burman empire more than fourteen millions, as some have estimated, the Siamese dominions may probably be peopled by about eight millions. However, Loubere assures us, in his time, that from actual enumeration, there were only found, of men, women, and children, 1,000,000. Loubere says that the Siamese had no army, except a few royal guards; but Mandello estimated the army, which may be occasionally raised, at 60,000, with no less than 3000 or 4000 elephants. The navy is composed of a number of vessels of various sizes, which display a singular fantastic elegance, like those of the Burmans; and naval engagements frequently occur. The revenues of this sovereignty are of uncertain computation. Mandello describes several races arising from the third of all inheritances, from trade, conducted by royal agents, annual presents from the governors of provinces, duties imposed on commerce, and the discovery of gold, which seems to be a royal claim. Tin is also a royal metal, except that found in Junjkelyon, which is abandoned to the adventurers. Loubere adds a kind of land-tax, and other particulars, among which is the royal domain.

Siam appeared to the French, in the reign of Louis XIV., to be of considerable political importance; for this monarch was ambitious of forming permanent settlements, by rendering it a rich mart of Indian commerce. If we had any apprehension that the Burmans would become dangerous to our pollexions in Bengal, our alliance with Siam might be highly serviceable. In a merely commercial point of view, as it may be difficult to preserve the friendship of both the Burmans and the Siamese, it is not easy to determine from which state superior advantages might be derived. If directed by European policy, Siam would form frict alliances with the more easterly states of exterior India, as a common defence against the growing preponderance of the Burmans.

As to the manners and customs of the Siamese, as they have embraced a branch of Hindu belief, they are rather Hinduistic than Chinese; though its formation is centred between the vast countries of China and Hindoostan. Loubere has given a detailed account of the Siamese ceremonies. The females are under few restraints, and marry at an early age, and are paid parturition at forty. Marriages are conducted by female mediation, and a priest or magnetist is usually consulted concerning the propriety of an alliance. On the third visit the parties are considered as wedded, after the exchange of a few presents, without any further ceremony, civil or religious. Polygamy is allowed, more from embellishment than any other motive; and one wife is always acknowledged as proper. Royal marriages, from considerations of pride, are sometimes ineffectual; nor does a king hesitate to espouse his own sister. Divorce is seldom practised; but the rich may chuse a more compliant wife without dismaying the former. Few women become nuns, till they are advanced in years. The Siamese funerals resemble those of the Chinese. On this occasion, the Talapoons sing hymns in the Pali tongue. After a solemn procession, the body is burnt on a funeral pile of precious woods, erected near some temple; and the magnificence of the spectacle is enhanced by theatrical exhibitions, in which the Siamese are said to excel. The tombs are pyramidal, and those of the kings are large and lofty. The common food of the Siamese consists of rice and fish; they also eat lizards, rats, and several kinds of insects. The buffaloes yield rich milk; but butter would melt and become rancid; and cheese is unknown.

In Siam little animal food is used; the mutton and beef being very bad. The doctrine of Buddhism inspires the Siamese with horror at the effusion of blood. The houses are small, and constructed of bamboo, upon pillars, in order to guard against inundations, which are common. The palaces only exceed common habitations by occupying a wider space, and being constructed of timber, with a few ornaments. They are also more elevated, but have never more than one floor. With regard to their persons, the Siamese are rather small, but well made. The figure of the countenance, says Kempter, both of men and women, has less of the oval than of the lozenge form, being broad, and raised at the top of the cheek; and the forehead suddenly contracts, and is almost as pointed as the chin. Their eyes, rising towards the temples, are small and dull; and the white is commonly completely yellow. Their cheeks are hollow; mouth very large, with thick pale lips, and teeth blackened by art; the complexion coarse, brown mixed with red, to which the climate greatly contributes. From this description the Siamese appear to be much inferior in personal appearance to the Burmans; and to approach rather to the Tartarie or Chinese features.

The dress of the Siamese is light, clothes being rendered almost unnecessary by the warmth of the climate. A mufflin shirt, with wide sleeves, and a kind of loose drawers, are almost the only garments of the rich, a mantle being added in winter, and a high conic cap upon the head. The women use a scarf instead of the shirt, and the petticotes of painted canvas; but with this light dress they are extremely modest.

The Siamese are said to excel in theatrical amusements; the subjects being taken from their mythology, and from traditions concerning their ancient heroes. Their ordinary amusements consist of races of oxen, and those of boats, the combats of elephants, cock-fighting, tumbling, wrestling, and rope-dancing, religious processions, illuminations, and beautiful exhibitions of fire-works. The men are generally very indolent, and fond of games of chance; while the
the women are employed in works of industry. Although the Siamese are industrious, they are ingenious, and some of their manufactures deserve praise; nevertheless, the ruinous and depopulating war of the government crushes industry by the uncertainty of property. They are little skilled in the manufacture of iron or steel, but excel in that of gold, and sometimes in miniature painting. The common people are mostly occupied in procuring fish for their daily food, while the superior classes are engaged in a thriving traffic.

The language of the Siamese, called "Thay," according to Dr. Leyden's account of it (Asiatic Researches, vol. x. p. 244.), appears to be in a great measure original; but there is reason to conjecture, that it is not different from that of the Burmans. To this purpose it is alleged, that Siamese dramatis personae used to perform in the Burman dominions, which is not probable, unless the language were common. Dr. Leyden says, that it is more purely monosyllabic, and more powerfully accented, than any of the Indo-Chinese languages. It certainly is connected, in some degree, with some of the Chinese dialects; especially the Mandarin or Court language, with which its analogies, as well as some other terms, coincide, but these are not very numerous. It borrows words freely from the Balis, but contrasts and disguises more the terms it adopts, than either the Rukheng or the Burman. It is a very defective original, and the mode of expressing esteem and adulation, this language resembles the Chinese dialects, with which also it coincides more nearly in construction than either Burman or Rukheng. Its construction is simple and inartificial, depending almost solely on the principle of juxta-position. Relative pronouns are not in the language; the nominative regularly precedes the verb, and the verb precedes the subject which it governs. When two sublative verbs come together, the last of them is for the most part suppos'd to be in the genitive. This idiom is confonnant to the Malayu, though not to the Burman or Rukheng, in which, as in English, the first sublative has a possessive signification. Thus, the phrase, a man's head, is expressed in Burman and Rukheng, by bu-la-huang, which is literally man-head; but, in Siamese, it is kua-khon, and in Malayu, kapala orang, both of which are literally head-man. A similar difference occurs in the position of the accented with an active verb, which can be in Burman and Malayu generally precedes the verb, as tumming cha, literally rice eat; but in Siamese follows it, as keng kaw, literally eat rice, which corresponds to the Malayu, makan-nafi. The adjective generally follows the sublative, and the adverb the word which it modifies, whether adjective or verb. Whenever the name of an animal, and, in general, when that of a species or class, is mentioned, the generic, or more general name of the genus to which it belongs, is expressed with it, as often happens in the other monosyllabic languages, as well as in the Malayu. In the position of the adverbial particle, the Malayu often differs from the Siamese; as Mana pargi, literally where go, but in Siamese, pai bhei, go where. The Siamese composition is also, like that of the Burman, a species of measured prose, regulated solely by the accent and the parallelism of the members of the sentence; but in the recitative the Siamese approximates more nearly to the Chinese mode of recitation, and becomes a kind of chant, which different Brahmins admired. Dr. Leyden is very similar to the mode of chanting the Samaveda.

The Thay coincides occasionally, even in simple terms, both with the Burman and Malayu; but these terms bear so small a proportion to the mass of the language, that they seem rather the effect of accident or mixture, than of original connection.

The Thay or Siamese alphabet differs considerably in the power of its characters from the Balis; though it not only has a general resemblance to it in point of form, but also in the arrangement of the character. The vowels, which are twenty in number, are not represented by separate characters, but by the character corresponding to the short akar, variously accented; excepting the vocalic ru and lu, which are only variations of the r and l consonants. The consonants are thirty-seven in number, and are not arranged by the series of five, like the Deva-nagar and Balis, but the first series, ka, consists of seven letters; the second series, cha, of six; the third series, ta or da, of five; the fourth series, ba or pa, of eight; the fifth series, ja, of four; and the last series, ja, of six, including the vocalic akar, though two of them are not in common use. Each of these letters is varied by sixteen simple accentuations, and by thirty-fix complex ones. The letters ka, nga, ta, or da, na, ma, ba or pa, are also final consonants. Hence it is easy to perceive the near approximation of the Siamese to the delicacy of the Chineze accentuation; while in other respects, the alphabet is considerably more perfect, than in the Burman or Court language of the Chineze, which has neither the same variety of consonants, nor admits so many, in the close of a syllable. The Siamese pronunciation, even of consonants, corresponds very imperfectly to the European mode: r and l are generally pronounced n in the close of a syllable; b is often prefixed to a consonant; but from the total suppression of the voice in pronouncing syllables which terminate in a consonant, no aspiration can be pronounced after them; ma and ba, sa and sby, are often difficult to be distinguished in pronunciation, as are ja and ja, kye and chye, with other combinations. From this circumstance, many combinations of letters are pronounced in a manner somewhat different from that in which they are written.

The first European who attempted the study of the Siamese literature, was the learned German, but his labors have never been published. The learned and indefatigable Hyde procured from the Siamese ambassador at London, an imperfect copy of the Siamese alphabet, which has been published by Greg. Sharpe, in the "Syntagma Dissertatioum," 1767. It is inferior to La Loubere's alphabet in accuracy, though it contains a greater number of compound characters. La Loubere's alphabet contains three forms of the qa, corresponding to the Nagari; but the bha and bha, being diffused in common pronunciation, are commonly omitted both in the alphabet and in modern MSS.

The Siamese or Thay language contains a great variety of compositions of every species. Their poems and songs are very numerous, as are their Chetiras, or historical and mythological fables. Many of the Siamese princes have been celebrated for their poetical powers, and several of their historical and moral compositions are still preferred. In all their compositions, they either affect a plain simple narrative, or an unconnected and abrupt style of short, pithy sentences, of much meaning. The books of medicine are reckoned of considerable antiquity. Both in science and poetry, those who affect learning and elegance of composition, sprinkle their style copiously with Bali. The laws of Siam are celebrated all over the East, and La Loubere has mentioned three works of superior reputation, the Pra-Tam-non, the Pra-Tam-Ra, and the Pra-Raja-Kam-manot. Of these, the first is a collection of the institutions of the ancient kings of Siam; the second is the constitutional code of...
of the kingdom, and contains the names, functions, and privileges of all the officers; the third, which is about 150 years old, contains additional regulations. Of these, the first is the most celebrated and the most deserving the attention of Europeans.

The Thay exhibits considerable variety of measures in conjunction, and frequently introduces several of them in the same manner as is frequently done in Bithynia, Parthia, and Sikkim competitions. The most frequent measure, however, among the Thay, as among the Rukhsang and Barma, seems to be that described in Raj, which consists of four long syllables, but admits occasionally of one or more intercalary short ones: the Jam, which consists of five syllables, the Chod-hang of six, the Lhathamang of seven, the Jelurata of eight, are also frequently employed. The Siamese are not deficient in literature, and their modes of education are well explained by Loubere.

From Mandello we learn, that the commerce of the capital of Siam consists in cloths imported from Hindostan, and various articles from China; in exports of jewels, gold, benjoin, lacca, wax, tin, lead, &c. and particularly dear-flax, of which more than 150,000 were sold annually to the Japanese. Rice was also exported in great quantities to the Asiatic Isles. The king was, by a rumious policy, the chief merchant, and had factors in most of the neighbouring countries. The royal trade consisted in cotton cloths, tin, ivory, faltpetre, rack, and skins sold to the Dutch. A late writer informs us, that the productions of this country are prodigious quantities of grain, cotton, bennjamin; fandal, akindig, and Japan woods; antimony, tin, lead, iron, load-flax, gold, and silver; saphires, emeralds, agates, crystal, marble, and tambac. Siam, in respect of fertility, loco-position, and productive labour, possesses commercial advantages of the fame nature with those of the Birman empire; but on the coast at least, the climate is far from being healthy.

The two first months of the Siamese year, corresponding with our December and January, form their whole winter; the third, fourth, and fifth, belong to that portion which is called their little summer; and the seven others to their great summer. As they lie north of the line, their winter corresponds with ours, but it is almost as warm as a French summer. Their little summer commences their winter; autumn is unknown in their calendar; the winter is dry, and is distinguished by the course of the wind, which almost constantly blows from the north, and is refreshed with cold from the snowy mountains of Thibet, and the bleak wastes of Mongolia.

We have already described this country as a wide vale between two high ridges of mountains; but compared with the Birman empire, the cultivated land is not above half the extent either in breadth or length. Lays indistinct more than the Birman, the agriculture of the Siamese does not extend far from the banks of the river, or its branches; so that towards the mountains there are vast aboriginal forests filled with wild animals, whence they obtain the skins which are exported. The rocky and variegated shores of the noble gulf of Siam, and the fire and magnificence of the Melan, confpire with the rich and picturesque vegetation of the forests, illuminated at night with crowds of brilliant fire-flies, to inspire strangers with admiration and delight.

The soil towards the mountains is parched and infertile; but on the shores of the river consists, like that of Egypt, of a very rich and pure mould, in which a pebble can fearfully be found; and the country would be a terrereal paradise, if its government were not so despotic as to be reckoned far inferior to that of their neighbours the Birman. Rice of excellent quality is the chief product of their agriculture; wheat is not unknown, pulse and other vegetables abound, and man is supplied in their gardens.

The fertility of Siam depends in a great degree, like that of Egypt on the Nile, on their great river Menam, and its contributory streams; for an account of which, see MEIUMAN.

Of the lakes of this country little is known. A small one, however, lies in the east of the kingdom, which is the source of a river that flows into that of Cambodia. It possesses extensive ranges of mountains, including the kingdom on the east and west, and we have already referred. A small ridge also extends from east to west, not far north of Yenam, called by Loubere Tarananum. The forests of the country are large and numerous, and produce many valuable woods. Its chief animals are elephants, buffaloes, and deer. The elephants in particular are distinguished for their sagacity and beauty; and those of a white colour are treated by the Siamese with a kind of adoration, as they believe the soul of each is royal. Wild beasts, tigers, and monkeys, are numerous. The reports of the mineralogy of Siam are various. Mandello, or rather his translator Wegequart, who added, about the year 1670, the accounts of Pegu, Siam, Japan, &c. informs us, that Siam contains mines of gold, silver, tin, and copper; and Loubere suggests, that they were anciently more diligently wrought, as the ancient pits indicate; not to mention the great quantity of gold, which must have been employed in richly gilding the idols, pillars, cedings, and even roofs of their temples. In his time no mine of gold or silver, worth the labour of being wrought, could be found. The mines chiefy wrought by the Siamese were those of tin and lead. The tin, called "calin" by the Portuguese, was sold throughout the Indies; but it was soft and ill refined. Near Louvo was a mountain of lead-stone, and another of inferior quality in Junkfiiion; which, see Pinkerton's Geog. vol. ii.

The Siamese, though of a melancholy turn, have no objection to lively music. They have often parties on the water, which they render very pleasant by a number of voices, and the clapping of hands, with which they beat time.

The instrument in the highest favour with them produces a sound similar to two violins perfectly in tune, played at the same time. But there is nothing more disagreeable than its diminutive, the kit of this instrument, which is a kind of rebec, or violin with three brahs flings.

Their copper trumpets very much resemble, in tone, the cornets with which the peasants of France call their cows. Their flutes are not much sweeter. They make likewise a kind of carillon with small bells, which are lively, and not disagreeable, when not accompanied by their iron drum, which flaps every one that is not accustomed to its noisy harpsheas. They have drums made of terra-cotta, a baked clay, with a long and very narrow neck, but open at the bottom: they cover the drum with a buffalo's hide, and beat it with the hand in such a manner, that it serves for a bass in their concerts. Their voices are not disagreeable, and if we were to hear them sing some of their airs, we should not be displeased. Laborde.

Siam, a name sometimes given to the country above described. See JUTHA, and the preceding article.

Siam, Gulf of; a large bay of the East Indian sea, between Cambodia and the peninsula of Malacca, having to the north Siam.

SIAMOILE, a town of Hindooftan, in the Carnatic; 13 miles N. of Nellore.

SIAMAPA. See CHAMPA.
SIAN, Sceio, or Cio, a town of Africa, in Melinda.

SIANCAS, a town of South America, in the province of Tucuman; 30 miles E.S.E. of St. Salvador de Jujui.

SIANDUPADA, a town of Hindoostan, in Myfore; 13 miles S.W. of Bangalore.

SIANELLY, a town of Hindoostan, in Myfore; 13 miles S.W. of Bangalore.

SIANG, a city of China, of the second rank, in Quang-fi. N. lat. 27° 58'. E. long. 109° 41'.

SIANG-CHAN, a town of China, of the third rank, in Tche-kiang; 25 miles S.E. of Ning-po.

SIANG-HIAN, a town of China, of the third rank, in Hou-quang; 40 miles S.W. of Tchang-tcha.

SIANG-TAN, a town of China, of the third rank, in Chan-f; 20 miles S.E. of Ting.

SIANG-YANG, a town of Corea; 28 miles N.N.W. of San-pou.

SIANG-YN, a town of China, of the third rank, in Hou-quang, on the Heng river; 27 miles N.N.W. of Tchang-tcha.

SIANKE, or SYNKE, in Natural History, a name given by the people of some parts of the East Indies to the caryophyllus, or clove-ipece. The people of the Moluccas, according to Garcias, call it "chanque," which is only a small difference of pronunciation. The Turks and Persians call the same ipice "calafur."

SIAO, in Geography, a town of China, of the third rank, in Kiang-nan; 22 miles W. of Pefu.

SIAO, an island in the East Indian sea, about 30 miles in circuit, which belongs to the sultan of Ternate. The Dutch maintain in this island a corporal, a few soldiers, and a school-master for the instruction of the children of the natives. It abounds with provisions. N. lat. 2° 44'. E. long. 123° 5'.

SIAO-CHAN, a town of China, of the third rank, in Tche-kiang; 17 miles N.W. of Chao-king.

SIAO-HE-CHAN, a town of Chinefe Tartary. N. lat. 37° 54'. E. long. 120° 34'.

SIAO-HO-TCHAN, a town of Chinese Tartary. N. lat. 41° 43'. E. long. 121° 42'.

SIAO-NON-HOTUN, a town of Chinese Tartary. N. lat. 41° 24'. E. long. 126° 50'.

SIAO-PI-HOTUN, a town of Corea. N. lat. 40° 24'. E. long. 125° 26'.

SIAO-TEIN, a river of China, which runs into the Eastern sea, N. lat. 37° 21'. E. long. 118° 44'.

SIARA, a small town of Brasil, and capital of a district or captnicity of the same name, so called from a river which rives in the mountains, and discharges itself into the ocean in S. lat. 3° 30'. The captnicity is small, not being above 54 miles in compass. It has two fortresses, one on the north, joining to the town of Siara, and situated on a small hill on the right side of the fave of the river, which is so shallow as to admit only small vessels; and the other, called Fort St. Luke, situated on the coast, at the mouth of a small river, navigable only by barks. This district abounds in cotton, fugar, tobacco, and Brasil wood, the usual staples of the country. The trade of the town, consisting chiefly of fugar and tobacco, is considerable. S. lat. 3° 15'. W. long. 58° 40'.

SIABREHUI, a town of Hindoostan, in the Carnatic; 3 miles N.E. of Udegherry.

SIARMAN, a town of Persia, in the province of Ma-

zanderan, on the Calpian fea; 12 miles E.S.E. of Ferra-

bad, or Farahat; which see.

SIAS, a river of Russia, which runs into lake Ladoga, near Sialkoi.

SIASKOI, a town of Russia, in the government of Peterburg, near lake Ladoga; 24 miles N.E. of Nova Ladoga.

SIATGONG, a town of Hindoostan, in Bahr; 20 miles S. of Bahar.

SIATON, a town on the south coast of the island of

Negroes. N. lat. 6° 21'. E. long. 125° 3'.

SIH, a town of Arabia, in the province of Mafcat; 30 miles W.N.W. of Mafcat.

SIABA, a small island in the East Indian sea, near the south coast of Mindanao. N. lat. 6° 36'. E. long. 125° 25'.

SIÉ, or SOB, called also Ibe or Sohe, in Ancient Geography, a people of India, on this fide of the Ganges, and one of the firft nations that encountered Alexander on the banks of the Acmeines.

SIBALD DE WERT, in Geography. See Falkland Islands.

SIBALDES, a cluster of islands near the coast of Patagonia. S. lat. 50° 53'. W. long. 59° 35'.

SIBATTA, a town of Japan, in the island of Niphon; 15 miles S.E. of Nambu.

SIBAU. See SEBO.

SIBB, a diftric of the Perfian empire, in the province of Mekran, governed by a chief, who resides in a small town of the fame name. It confists of a very extreme plain, through the centre of which flows a river, nearly dry, in the bed of which are several groves of date-trees; but the country, generally speaking, is quite barren.

SIBBA. See SEBBA.

Gen. Ch. Cal. Perianth inferior, of one leaf, cut half way down into ten segments; its bafe erect; segments spreading, half-lanceolate, equal in length, permanent, the intermediate ones narrowefl. Cor. Petals five, ovate, inserted into the calyx. Stam. Filaments five, capillary, shorter than the corolla, inserted into the calyx; anthers small, obtuse. Fil. Germans five, ovate, very short, in the bottom of the calyx; styles from the middle of one fide of each germen, the length of the flamen; stigmas capitulate. Peric. none, the closed calyx sheltering the Seds, which are five, somewhat oblone.

Obi. The ptils were found by LINNAEUS to be fometimes, though very rarely, doubled in number, on the fame plant with other flowers that had only five. They appear to vary from five to ten.

Elf. Ch. Calyx in ten segments. Petals five, standing on the calyx. Styles from the bafe of each germen. Seeds five, in the bottom of the calyx.

25. t. 6. f. 1. Scotch Cinquefoil; Pet. herb. Brit. t. 41. f. 71.—Leaflets wedge-shaped, three-toothed. Native of the summits of the highest mountains of Lapland, Scotland, Switzerland, Siberia, and North America. Tournefort gathered it also in Cappadocia. The plant thrives best in a moauldering mucous soil, flowering in June and July. The root is perennial and woody, throwing out many short, spreading, leathy, herbaceous, round, downy flods, which are slightly branched, and procumbent, except sometimes at their flowering extremities. Leaves on long stalks, whose base bears a pair of oblong, acute fiped, like thole of a rose; their leaflets three, on short, flat parts, wedge-shaped, inclining to ovate, green, hairy, entire, except their three large terminal teeth. Flowers in small terminal leafy corymbs, inconspicuous, with minute yellow petals and filaments, inserted into the thickened rim of the green leafy calyx. Seeds dry, hairy. We have noticed in Fl. Lapp. (C Knutsen's t. 242. f. 3. cited by Linnaeus, and recently copied by Pursh, belongs rather to the Petasitf puberula; nor does this figure, in essential points, resemble Sibbaldia.

3. S. altaeae. Large-flowered Sibbaldia. Linn. Suppl. 131. Willd. n. 3. "Pall. Act. Petrop. for 1773; 526. t. 18. f. 2." (S. n. 42, var. J; Gmel. Sib. v. 3. 187.)—Leaves in numerous linear segments. Stems slightly branched. Petals roundish-heart-shaped. Found by Pallas very abundantly on the rocks of Dauria. The stems are cut, and about three inches high, slender, often simple, and slightly leafy. Flowers, especially their petals, three or four times the size of the leaf, of which nevertheless Gmelin, and at one time Pallas himself, thought this plant a variety. SIBBENS, or STEVENS, in Medicine, and in particular diseases, of a chronic nature, somewhat resembling phyllyps, prevalent in the western parts of Scotland. It is said to denote from the appearance of a fungous exu-erhence from some of the cutaneous spots, not unlike a raspberry; the word fibres, or flised, being the Highland appellation for a wild raspberry. Whence it has also been sometimes confounded with pea, a disease of tropical climates, brought from Africa, and so denominated by the Negroes from the same fruit. See Framboeia and Yaws.

This malady is not of ancient date in Scotland. The first writer on the subject was Dr. Gilchrist, who, in the year 1765, distributed a short description of the fibres among the people of Ayshire, which was afterwards published by the Philosophical Society of Edinburgh. (See Essays and Observations Physical and Literary, vol. ii. art. 11.) According to tradition in the Highlands, the disease was introduced there by the soldiers of Oliver Cromwell, who laboured under the venereal disease, when garrisoned in that country. From thence it is said to have been carried to Dumfries by a party of soldiers, who had been stationed in the north Highlands; and it is perfectly as-terned, according to Dr. Paterson, that it was introduced into Ayshire, about the year 1745, by people who went thither from Dumfries to buy cattle. Since that period it has constantly prevailed in different places in that district, at different times; sometimes abating so much, that even in some instances, as to give hopes that it would entirely disappear; then breaking out again with greater violence, generally in the harvest season, and spreading over several parishes. (See Dr. Paterson's Letter, in Beddoes's Contributions to Physical and Medical Knowledge, p. 408.) At its first appearance, it occasioned little uneasiness or apprehension to those affected with it; but it was found discovered to be a formidable disease, resembling in character the venereal disease, and to be propagated extensively by its contagion. In such a manner, as Dr. Gilchrist expressed it, 'great are the perplexity and distress, the ful- pision and terror, caused by it, wherever it comes; and hitherto nothing has been able to prevent the spreading of it.' The disease differs, however, materially from lues venera, though it is cured by the same remedy; the poison being introduced into the system not through the medium of the organs of generation, but commonly by the mouth and throat, in which the primary ulcerations occur.

The fibres almost always begins with an inflammation of the throat, first on the uvula and velum postcum of the palate, and afterwards on the tonsils, of a dark red colour, which is succeeded in one or two days, and sometimes more quickly, by small pimples, or vesicles, which terminate in ulcers, with a white surface, and red abrupt edges. There is often also an aphthous appearance, or a series of white specks and sloughs, upon the roof of the mouth, and inside of the cheeks and lips, which commonly figs itself also at the corners of the mouth, in a small rising of the skin, of a pear or whey-colour; upon which part also a small fungous excrescence often appears, not unlike a raspberry, which changes to a scab, and is a pretty sure sign of the disease, although there be no aphtha or sore throat. The uvula is sometimes destroyed by the ulceration; and children at the breast, when thus affected in the mouth and throat, have perished from hunger, not being able to suck or swallow.

In a little time the constitution is contaminated by the absolutions of the poison, and a series of secondary symptoms appears. In some, and especially in adult persons, dark red spots, or sometimes fungous excrescences, arise about the anus and perineum, which gradually increase and ulcerate. But the most common appearances are eruptions of a pulular character on the skin, containing, however, little fluid, and soon terminating in a dry scab, surrounded by a livid margin, and ultimately in ulceration. In some, and especially in children, these eruptions occupy chiefly the belly, groins, and sides, and are sometimes seen on the face. The ulcers, into which they pass, usually make but small progress, not exceeding in general the point of the finger in fume, and being irregular in their forms, and pretty clean, with slightly inflamed edges. In some instances, however, they have been seen to become confluent, and to unite into one large foul ulcer over a great part of the abdomen, ex- haling a most intolerable and peculiar fume. In some children, indeed, the whole scalp has gangrened, and the ears have nearly fallen off. Smaller ulcers have also formed on the breast and face, covered with a purulent flough, remaining inert, without pain or inflammation, and seldom increasing in size.

In other cases, where the primary symptoms have been moderat,
SIBBENS.

moderate, and have subided, the secondary symptoms, affecting the skin superficially, assume different shapes. The whole surface of the body, Dr. Gilchrist says, has been observed to be mottled, of a dusky copper colour, or a dirty hue, as the discolourings of the skin in this distemper commonly are. Infants of the month have had a redness in the lower part of the belly, buttocks, thighs, and part of the legs, where sometimes it terminates abruptly in a ring. In some of these there was an inflammation, and a watery shining swelling of the pudenda. A more certain appearance in such subjects somewhat older are broad red patches, as large as the palm of the hand, over all the trunk, as well as the limbs, attended with inflammation. A clatter, or clutters, of small pustules come out; the skin grows dry, and peels off, leaving a new tender skin beneath; and this will happen a great many times, sometimes in one place, sometimes in another. Scabby eruptions are often met with on the scalp, fore-head, inside of the thighs, groins, and parts contiguous; where frequently small hardnefles, rifing just within the skin, excite a very troublesome itching. Besides the inflammation and excrections about the fundament already noticed, other appearances of the distemper present themselves on the breast, shoulders, and elsewhere, especially a fort of herpes excedens, or spreading tetter, healing in one part, while it breaks out in another adjoining, and leaving a great deformity of the skin, after it cicatriz. In a few cafes, an eruption of tubercles occurs upon the face, rather numerous, and in figure and figure resembling the small-pox at the height, but being of a reddish colour. These are attended with great heat and tumour of the face, so as sometimes to close up the eyes. In some cafes they have spread thickly over the whole body, and suppurated, not unlike the confluent small-pox, and have even proved fatal, as the swelling subided; but in others, where not so numerous, they gradually decay, without coming to suppuration. In some persons there is a swellling of the surface, without any appearance of tubercles; in which cafe, the cuticle exfoliates from time to time in fine white reticulated flakes, as often as it is renewed. In other cafes, tubercles arise from small bright red spots, of a more intense redness than those just mentioned, which in some places become confluent, and form a flat smooth elevation, which soon becomes of the usual colour of the skin, and sometimes slightly ulcerates. The face, too, is often affected with different kinds of eruption, sometimes alone, and sometimes together with the rest of the body.

Where the distemper attains still greater malignity, larger boils appear difperfed over the arms, shoulders, face, legs, and feet, which suppurate, and form ulcers, which penetrate to the muscular parts, laying them quite bare, and seeming even to corrode them superficially. These ulcerations are of a high florid colour, with scarcely any discharge upon their surface, except a little ichor, which renders them exquisitely tender and painful, and fiercely bearing the mildest applications. Their edges are hard and ragged, their size various, and their appearance very malignant; so that Dr. Gilchrist says, when viewed singly, they might have been mistaken for real cancers, but the number of them, the manner of their coming out, and other circumstances, soon determine the distemper to which they belong.

There is one symptom, not yet particularly described, but from which the distemper takes its name, which remains to be mentioned. An itchy tetter, or a fort of ring-worm, breaks out in a circular form, which either spontaneoufly, or from being scratched, becomes raw and excoriated, and does not cael, but continues to ooze out an ichorous hu-

mour. In a short time a fungous excrecence sprouts up, much like a raspberry or strawbery, elevated one half above the surface, and, when fully formed, appearing as if felt in a pocket cut in the flesh exactly to receive it. Sometimes, however, a black scab forms, crumbling over the fores, except at the edges, where there is a crack or ring, like the line of fracture between a mortified and a sound part, from which the fame fort of ichor constantly oozing. By degrees this crack enlarges towards the centre, and the scab, being pulled off, gives place to the fungus just described. In other cafes, these fungous excrecences are preceded by a dark or grey scurf, resembling the scaly leprosy. These parts are the seat of an intense itching, and when they are excoriated by scratching or rubbing, the fungus has room to sprout up. These fores occupy every part of the body, and many of them are seen in the same subject at the same time; but the excrecences do not always sprout up, and are more commonly produced in the fores which never form a scab, than in the scabby or scaly ones. The fungus is rather indolent than tender to the touch, and its colour is not remarkably different from that of the fungus of other fores.

The fibbens very rarely affects the bones, and then only by extending from the soft parts, and perhaps never attacks the large and more solid bones. In several cafes, the teeth, with their sockets, have been lofl, and fome of the bones of the cheeks and nofe have come away, and a portion of the cartilaginous separafion of the noftrils has been destroyed by the distemper. Several perfons die in a flate of hectic, from the very extensive ulcerations, before the bones could be materially affected.

Cafes of Sibbens.—This distemper has been principally prevalent among the lower ranks of the people in Scotland, though not exclusively; for fome families of good condition have lofl their children by its attacks. The distemper affects the young and adult perfons equally; but perfons advanced in years appear to be lefs liable to the infection. Children, however, and women, from their more irritable frame, are most fitceptible of it.

The distemper is commonly communicated by the direct conveyance of the infectious matter by some species of contact, and generally through the medium of the mouth; whence the primary symptoms appear in the mouth and throat, as before described. "It is propagated," Dr. Gilchrif obferves, "by using the fame fpoons and knives, and wiping with the fame cloth, which the infected have ufed, without cleaning or washing them; drinking out of the fame glaf or cup; fmoaking with the fame pipe; feeping with the infected, or in the fame bed-clothes they have lain in, and handling their fores; by locking or giving fuch, faling, or killing, and fondling children, or feeding them in an uncleanly way." Dr. Gilchrif adds, that it is completely proved, that the fibbens is propagated chiefly by these inattentions to cleanliness, by this circumstance, that "it has never got footing among thofe of better fafhions," nor in towns, where, excefs with the very bowling, greater attention to cleanliness is generally observed; and that it was unknown among the more cleanly inhabitants of the Englih border, while it occurred at Dumfries, and along the Scottish boundary. Another proof was deduced from the more frequent occurrence of the distemper after autumn, which was thus accounted for. "A company of reapers is made up of very different people, brought together from all parts; they eat and drink promiscuously out of the fame cups and dilies; and a few fpoons are made to ferve a good many, by putting them round from one to another. The fame is done with a pipe
pipe in smoking. When the body is warm, and the pores open, the tender tips of the lips and mouth is most exposed to receive the infection, which, the heat, in labours, will render more active and apt to be communicated. A girl, who had the thrush to a great degree, at the tables, read the disease through a whole parish, where it was not formerly seen.

Contagious as this fact are not usually communicable by effusion; but it seems to be believed, by those who have witnessed the progress of fibbens, that it may be propagated without actual contact. Dr. Gilchrist says, "nor is it unlikely, that in certain circumstances, the breath may become contagious;" implying, however, his want of positive evidence on the subject. But Dr. Pateron allers, that "it is a fact so astonishing, that the breath of people, labouring under the sore throat, is loaded with infection, and communicated the disease, without the contact of objects." Beddoes' Contributions, loc. cit.

It will be obvious, from the preceding detail of the symptoms and causes of fibbens, that it is the result of a morbid point, operating felt locally, and afterwards constituting a disease, or producing phenomena, exceedingly analogous to those of the venereal disease. There is also the farther analogy, as we shall see, that the cure is effected principally, if not exclusively, by mercury; whereas several writers, and apparently Dr. Gilchrist among the rest, have deemed it a modification of syphilis. It was found discoverd, says the writer, "to be of the venereal kind, or the foul disease." Dr. Pateron, however, has pointed out several circumstances which mark a difference between the two.

In the first place, he observes, the venereal disease was common in Scotland long before the fibbens appeared; and he had never been able to trace the latter to any person affected with syphilis. Secondly, it is much more infectious than common syphilis, for it seldom gets into a family without infecting every person in it, and frequently spreads rapidly over a village. If the common sense were to spread in a similar manner, its progress in all large towns would be truly dreadful. Thirdly, the fibbens is a more purely cutaneous or superficial affection than the common lues, for it very rarely indeed occasions buboes, and almost never affects the large bones. And, lastly, the fibbens is much more readily cured than the ordinary form of syphilis; for a much less quantity of mercury removes blotches and extensive ulcers, than is required to cure the secondary symptoms of syphilis, contracted in the ordinary manner. Its ordinary commencement in the organs of déglutition, and its never appearing in a primary form on the genitals, nor being propagated by contagion, appear also to establish a distinction between the two maladies.

Cure of Fibbens.—We have partly anticipated this subject in the preceding paragraph, where we have stated that mercury is found to be the specific remedy. It appears that, like syphilis, the disease is perhaps never cured by the unassisted efforts of the constitution; and that mercury, as in the other affection, does not fail to cure it, except in those deplorable cases, where, from the long continuance of the disease, hectic symptoms have come on, and the constitution is so broken down as to be unable to bear the remedy.

It seems to be a well ascertained fact, too, that, of all the preparations of mercury, the corrosive sublimate, or oxyminurate, is the best adapted for the cure of fibbens; that is, it cures it more speedily, and with equal certainty with any other mercurial preparation. This circumstance also constitutes a point of distinction between the two maladies, and may arise, according to Dr. Pateron's suggestion, from the fibbens being a more superficial or cutaneous affection than syphilis. Dr. Gilchrist, however, considers it better to adopt the ordinary dose of mercury, though not carried to the extent of high salivation. For the purposes of forcing regularly by mercury in cold, without which, he finds, it often fails, and the symptoms return, rendering a secondary course of medicine necessary. He frequently says, that the disease is prevented of slight administration of the remedy, that it will sooner or later return with greater force, or in a worse form; and that it is only to be treated by a regular course of medicine, judiciously adapted to the feverish degree and continuance of the malady.

As to the active preparation of the disease in Scotland was held in the ordinary practice which prevailed among the lower classes of the people, I shall mention the last. It is eating and drinking, pulling the hands from the mouth to the mouth, rubbing in the face, using the hand towel, &c.; for the most effectual check to the propagation of the malady was to be expected from a system of prevention, which consisted in adopting a more decent and cleanly proceeding. Dr. Gilchrist recommends the persons employed in harness work, each to carry with him a dith, cup, knife, spou, and a cloth to wipe with, that all the parties to eat not with the same utensils, and transact their consumption to one another. He also strongly urged the improbity of admitting that common familiarity, which every one claims by custom to kids and kindred children, and especially to deny it to strangers, and those of low rank. By attending to these, and similar means of prevention, the disease appears to have been materially controlled, and its prevalence diminished.
flated at 5350, and the breadth at 1960, which extent exceeds that of Europe. The vast country of Siberia, says Mr. Tooke, contains, by calculation, upwards of 105 millions of square versts, comprehending within it several kingdoms, taken by roving Kozaks (Coffacks) on their own account, and then surrendered to the tzar, who completed the conquest; at present this country consists of several of the most extensive governments. The farthest eastern boundary is that of Afia, and the seas of Kamtchatka and Ochotok, and the northern is the Arctic ocean. On the W. the frontiers correspond with those between Afia and Europe, and the southern limits may be rated more at large in the following manner: The river Cuban, part of the Caucasian chain, and an ideal line, divide the Russian territory from Turkey and Persia. The boundary then ascends along the north of the Caspian through the steppe or desert of Isfin, and the eastern shore of the river Ob, to its course in the Altai mountains, where it meets the vast empire of China, and proceeds among that chain to the sources of the Onon, where it includes a considerable region called Daouria, extending about 200 miles in breadth, to the south of the mountains called Yablonnoy; the limit between Russia and Chinefe Tartary being partly an ideal line, and partly the river Argoon, which joined with the Onon constitutes the great river Amur. Thence the boundary returns to the mountainous chain, and follows a branch of it to a promontory on the north of the mouth of the Amur.

The population of Asiatic Russia may be regarded as primitive, except a few Russian colonies recently planted; and the Techaks in that part which is opposite to America, suppos'd to have migrated from that continent, in their persons and customs are different from those of the Asiatic tribes. Next to the Techaks, most remotely north, are the Yukagirs, a branch of the Yaku's, and further west the Samoyedes. South of the Techaks are the Koriaks, and further south the Kamtchadales, who are a different people, and speak a different language. The Lamutes are a branch of the Mandchures or Tungules, who are widely diffus'd between the Yenific and Amur, and the southern tribes, ruled by a khun, conquer'd China in the 17th century. The Ovlaks, and other tribes of Samoyedes, have penetrated considerably to the S. between the Yenific and the Irific, and are followed by various tribes of the Mangusils, as the Kalmucks, Burats, &c. and by those of the Tartars or Huns, as the Tosuts, Kirguses, and others. The radically different languages amount to seven, independently of many dialects and mixtures.

The vast extent of northern Afia was first known by the name of Sibir, or Siberia; but the appellation is gradually passing into diffuse. When the Mangusils establish'd a kingdom in these northern regions, the first residence of the princes was on the river Tura, on the site of the town now called Tumen, about 180 miles S.W. of Tobol'sk; but they afterwards removed to the eastern shore of the Irific, and there founded the city of Ilker near Tobol'sk. This new residence was also called Sibir, of unknown etymology, and the name of the city pass'd to the Mongolia principality.

Although this is doubted by Coxe, Pallass says that the ruins of Sibir are still visible 23 versts from Tobol'sk, and that it gave name to the rivulet Sibirska, and the whole of Siberia. When the Russians began the conquest of the country, they were unappreciated of its extent; and the name of this western province was gradually diffus'd over the half of Afia. The principality establish'd by the Mongusils under Sheibuni in 1242 in the western part of Siberia, around Tobol'sk and the river Tura, from which it has been sometimes called Tura, has been already mention'd. The actual conquest of Siberia commenced in the reign of Ivan Vassilievitch II., who ascended the Russian throne in 1534. Induced by the prospect of establishing a traffic for Siberian furs, he determined to undertake the conquest of the country, and in 1538 added to his titles that of Lord of Sibir, or Siberia. Yarmak, a Collack chief, being driven, by the Russian conquests in the south, to take refuge, with 6000 or 7000 of his followers, near the river Kam, afterwards marched down the Ural chain, defeated the Tartar Kutchun, khan of Sibir, and pressed forwards to the Tobol and the Irific, and also to the Ob, and in this astonishing expedition, subjugated Tartars, Vogules, and Oflaks. Finding it impossible to maintain and complete his conquests with his small army, he surrendered them in 1591, by a formal capitulation, to the tzar Ivan Vassilievitch, who nobly redeemed his magnanimity and exertions. This conqueror of Siberia, however, did not live to witness the full accomplishment of this enterprise. He died in 1584: and after his death the discovery and conquests which he had made were prosecuted by regiments of Donkoi Collacks, sent thither for that purpose, as far as the eastern ocean and the mountains of China; and in the middle of the 17th century this whole part of the world had become a Russian province. A person, whose name was Cyprian, was appointed first archbishop of Siber in 1621, and at Tobol'sk, where he resided, he drew up a narrative of the conquest. About the middle of the 17th century the Russians had extend'd east as far as the river Amur; but Kamtchacta was not finally reduced till the year 1711. Behring and other navigators afterwards proceeded to discover the other extensive parts of Afia. In his first voyage of 1728, Behring coasled the eastern shore of Siberia as high as latitude 67° 18', but his important discoveries were made during his voyage of 1741. The Aleutian isles were visit'd in 1745; and in the reign of the emperors Catharine II. other important discoveries followed, which were completed by captain Cook. In the south the Mongol kingdom of Kazan was subdu'd in 1552, and that of Altakhan in 1554, and the Russian monarchy extended to the Caspian sea. In 1727, after previous conflicts, the Russian limits were continued westward from the source of the Azoton to the mountains Sahambas, near the confluence of two rivers with the Yenifici; the boundary being thus ascertained between the Russians and the Mongols subject to China. The trade with China has been conducted at Zuruchaiou, on the river Argoon, N. lat. 50°, E. long. 137°, and at Kychta, about 90 miles S. of the sea of Baikal, N. lat. 51°, E. long. 160°. This boundary between two states is the most extensive on the globe, reaching from about the 65th to the 145th degree of longitude; 80° (lat. 50°) yielding, by the allowance of 39 geographical miles to a degree, 3120 miles.

The most curious antiquities in Siberia seem to be the stone tombs which abound on some flespe, particularly near the river Yenifici, representing in rude sculpture human faces, camels, horsemen with lances, and other objects. Here are also found, besides human bones, those of horses and oxen, with fragments of pottery and ornaments of drefs. The most singular ancient monument in Siberia is found on the river Abakan, not far from Tobol'sk, being a large tomb with rude figures.

The religion of the Greek church, which is professed by the Russians, has made no great progress in their Asiatic dominions. Many of the Tartar tribes in the S.W. are Mahometans, and others are votaries of the superstition of Dalai Lama. But the religious sentiments of the Schamanists are the most prevalent; particularly among the Tartars, Finns, Samoyedes, Oliaks, Mandchurs, Burats, and Tun.
SIBERIA.

gues; and they have been adopted by the Koriaks, Tchuka, and people of the eastern tribes. On the eastern coast of the sea of Baikal is the rock of the Schamans, an island of a peculiar shape; whilst the Schamanians admit one chief infernal deity and his subalterns, authors of evil, who also believe in one supreme uncreated beneficent being, who commits the management of the universe to inferior deities, and they delegate portions of it to subaltern spirits. See Schamans.

The archipelagic fee of Tobolsk is the metropolis of Russian Asia in the north, and that of Astrakhan in the south. There is another fee, that of Irkutsk and Nertchinsk, and some others of more recent origin.

Siberia is divided into two great governments, those of Tobolsk in the west, and Irkutsk in the east. The smaller provinces are Kolivan, Nertchinsk, Yakutsk, and Ochotchik. In the S.W. is the government of Caucaucus, with one or two other divisions, blending Europe and Asia.

The population of Siberia cannot be computed at above 3½ millions. The political importance and relations of this part of the Russian empire principally relate to China and Japan. The manners and customs of Aiatric Russia vary with the numerous tribes by whom it is peopled. The Tartars are the most numerous: next to their importance are the Mongols, one tribe of whom, viz. the Kalmucks, are found to the W. of the Capan, while the others, called Burats, Tartars, &c. are chiefly round the sea of Baikal. Further to the east are the Mandchous or Tunguses. See these denominations respectively.

The languages of all the original nations of Aiatric Russia are radically different; and among the Tunguses, Monguls, and Tartars, there are some traces of literature, and not a few MSS. in their several languages.

The principal city of Aiatric Russia is Astrakhan, which fee. Azof (which fee) derives its importance chiefly from its being a fortified port. The chief towns on the Aiatric side of the Volga, are Samara and Stauropol. At the mouth of the river Ural, or Jak, stands Gurief; but the chief place after Astrakhan is Orenburgh, founded in the year 1740, and the seat of a considerable trade with the tribes on the E. of the Capan. Beyond the Uralian chain the first city that occurs is Tobolsk; which fee. Kolyvan is a town of some consequence on the river Ob, having in its vicinity some silver mines of considerable produce, and north to this is Tomik. Further to the E. the towns become less of consequence. On the river Yenisey is a small town of the same name, and another called Sayanik. On the river Angara stands Irkutsk, supposed to contain 17,000 inhabitants, the chief mart of the commerce between Russia and China, and the seat of supreme jurisdiction over eastern Siberia. On the wide and frozen Lena stands Yakutsk; which fee.

The chief commerce of this part of the Russian empire consists in fables and other valuable furs; for which the Chinese return tea, silk, and mankeen. That with the Kirguses consists in exchanging Russian woolen cloths, iron, and household articles, for horses, cattle, sheep, and beautiful sheep-skins. On the Black sea there is some commerce with Turkey, the exports being furs, kavior, iron, linen, &c. and the imports wine, fruit, coffee, silks, rice. In the trade on the Capan the exports are the same, and the return chiefly filk. The principal Russian harbours are Astrakhan, Gurief, and Kifir, near the mouth of the Terek, but the chief haven is Baku, belonging to the Persians. The Tartars, on the east of the Capan, bring the products of their country and of Bucharia, as cotton-yarn, furs, fluffs, hides, and rhubarb; but the chief article is raw filk from Shirvan and Ghanan, on the W. of the Capan.

In Aiatric Russia the climate extends from the vine at the bottom of the Caucasus, to the solitary beetle on the shores of the Arctic ocean. Through the greater part of Siberia, the most southern frontier being about 50°, and the temperature according to 78°, the general climate may be considered rather as frigid than temperate; being in three quarters of the country on a level with that of Norway and Lapland, untouched by the gales of the Atlantic. To the S. of Baikal, the climate corresponds to that of Berlin and the N. of Germany. The chains of high mountains, which form the southern boundary of these provinces, contribute also to increase the cold; so that the sea of Baikal is commonly entirely frozen from December till May. The finest climate in these eastern parts is that of Daouria, in the province around Nertchinsk; and the numerous towns on the Amur enjoy the great superintendence of what is called Chinese Tartary, which is comparatively a fertile and temperate region. The change of the seasons is very rapid; the long winter is almost insensibly succeeded by a warm spring; and the quickness and luxuriance of the vegetation exceed description.

The greater part of Siberia, that is, the middle and southern latitudes of it, as far as the river Lena, is extremely fertile, and fit for every kind of produce; but the northern and eastern parts, being encumbered with wood, are destitute of this advantage, being unfit both for pasturage and culture. The whole of this part, as far as the 60th degree of N. latitude, and to the Frozen ocean, is full of bogs and morasses covered with moss, which would be absolutely impassable, if the ice, which never thaws deeper than seven inches, did not remain entire beneath it. In the central parts vegetation is checked by the severe cold of wide a continent. Towards the S. there are vast forests of pine, fir, larch, and other trees, among which is a kind of mulberry, which might thrive in many climates that are now destitute of it. The sublime scenes around the sea of Baikal are agreeably contrasted with the marks of human industry, the cultivated field and the garden. Many parts of Siberia are totally incapable of agriculture; but in the southern and western districts the soil is remarkably fertile. North of Kolyvan barley generally yields more than twelve-fold, and oats commonly twenty-fold. Exclusive of winter wheat, most of the usual European grains prosper in southern Siberia. In some parts flax grows wild, and hemp is prepared from the nettle. Wheat is found in Siberia, and falcon near the Caucasus. The beet rhubarb abounds on the banks of the Ural or Jak, southern districts being watered by the Yenisey, and in the mountains of Daouria. But it is not possible that agriculture should flourish while the peasantry are slaves, and sold with the soil. Nevertheless, an intelligent traveller was surprised at the abundance of buckwheat, rye, barley, oats, and other grain which he observed to the S. of Tobolsk; where the cattle were also very numerous, and in the winter fed with hay. The large garden strawberry, called hautbois, is found wild in the territory of Irkutsk; and on the Altai mountains the red currant attains the size of a common cherry, ripening in large bunches of excellent flavour. Near the Volga and the Ural are excellent melons of various kinds.

Some of the largest rivers of Asia belong to the Russian empire; such as the Ob, of 1900 British miles in course; the Yenisey, about 1750; and Lena, 1570. To these we may add the Irtysh, the Angara, the Schiega, the Yaks, &c. The lakes of this country are numerous. The most considerable in the north of Siberia is that of Pazaik; that of Baikal, derived under that article; a large lake between the rivers Ob and the Irtysh, 170 miles long, divided by an island into two parts, called the lakes of Tchany and Soum.
In this quarter there are many smaller lakes, and others to the N. of the Caspian, some of which are salt, particularly that of Bogdo. To these we may add the Altan Nor, or golden lake, and the lake of Atyn, called by the Russians Telelako. The mountains are the Uralian, the Altai, Bogdo Alim, or the Almighty mountain, Sinai-Sepka, Schlangenberg, which is the richest in minerals, the Sayanik mountains, the mountains of Nerfinka and Russian Daouria, the chain of Stanvooi or mountains of Ochotlik, and Cauca-

tina. For the corners of Russia, see STEPPY.

Siberia has hitherto been found to possess scarcely any genera of plants; and even all the species of any considerable importance, are those trees which are common to it with the north of Europe. Under the head of the zoology of Asiatic Russia, we may enumerate the rein-deer, which performs the offices of the horse, the cow, and the sheep; the dogs of Kamtschatka, which are used for carriage; the horse, which is found wild, a species of afs, the urus or bison, the argali or wild sheep, the ibex or rock-goat, large flags, the mulk or civet, and wild boar; wolves, foxes, and bears; the fable, several kinds of hares, the catlor or beaver, the walrus, and the common seal. But it would be superfluous to enlarge. Siberia is so rich in zoology and botany, that, as Mr. Pennant observes, even the discovery of America has scarcely imparted a greater number of objects to the naturalist. The mineralogy of Siberia is equally fertile, and displays many singular and interesting objects. The chief gold mines of Siberia are those of Catherinburg or Ekatherinburg, on the E. of the Uralian mountains, about N. lat. 57°; the mines of Nerfinka, discovered in 1704, are principally of lead, mixed with silver and gold; and those of Kolyvan, chiefly in the Schlangenberg, or mountain of serpents, so called by the Germans, began to be wrought in 1748. The gold mines of Beredof are the chief in the empire; those of Kolyvan and Nerfinka being denominated silver mines. Besides the copper mines in the Uralian mountains, there are fome in those of Altai. But the iron mines of Russia are of the most solid and lasting importance, particularly those which supply the numerous founderies of the Uralian mountains. Rock-fall is chiefly found near the Ilek, not far from Orenburg. Coal is scarcely known; but sulphur, alum, fa ammoniac, vitriol, nitre and patron, are abundant. Siberia possesses a variety of gems, particularly in the mountain Adunfotto, near the river Argoon, in the province of Nerfinka or Daouria. Common topazes are found here, and also the jacinet. The kind of jade called mother of emerald is a Siberian product; and beryl or aqua marina is found in Adunfotto, and in greater perfection in the gem mines of Mourintfsky, near Catherinburg, along with the chrysolite. Red garnets abound near the sea of Baikal. The rubycoloured fchior has been discovered in the Uralian mountains. The green fespar of Siberia is a beautiful ftone, and carved by the Russians into a variety of ornaments. The Daourian mountains, between the Onon and the Argoon, afford elegant onyx. The beautiful ftones called the hair of Venus and Thetis, being limpid rock crystals containing capillary fchior, red or green, are found near Catherinburg. The alliance ftone consists of a greyish porphyry, united, if gned together, with transparent quartz. Great quantities of malachite have also been found in the Uralian mountains; one piece of which is said to have weighed 107 pounds, or 3852 pounds. Siberia affords the beautiful red and green Jasper; and lapidaries are found near Baikal. The Uralian chain presents fine white marble; and in the numerous primitive ranges there are many varieties of granite and por-
phry. The chief mineral waters of Russia are those of Kamtschatka.

The islands belonging to Asiatic Russia may be distributed into the Alcuitan, Andrenovian, and Kurilian groups, with the Fox islands, which extend to the promontory of Alaska in North America. See these articles respectively. For further particulars respecting Siberia or Asiatic Russia, see RUSSIA. See also Cosse's Russian Discoveries; Tooke's Rufl. Emp.; and Pinkerton's Geog. vol. ii.

SIBERIAN KOZAKS, or COFFACKS, a branch of the Don-
cfki Coffacks, who, inligated by a disposition to roaming and pillage, in the 16th century, abandoned their habitations on the Don, in order to plunder the countries lying eft-
ward. In order to restrain their progrege, Ivan Vasilliefich II., who fat upon the Russian throne, assembled, in the year 1577, a considerable army, and got together a fleet of ships to chaffle these audacious robbes. These hordes, intimidated by these hostile preparations, dispersed and fled into the neighbouring regions. See the preceding article.

SIBERIAN BARLEY, in Agriculture, a hardy fort of grain of the barley kind. See BARLEY.

SIBERIAN OAT, an useful fort of hardy oat brought from that country. See OAT.

It has been found by fome as much superior to the common black oat as the Poland fort is to others. It has the advantages of being capable of being grown with safety in December, and of being fit to cut as foon or sooner than early peas; the produce is greater than the usual forts; and rain, instead of injuring, rather improves the colour, which is of the pied kind. The kernel is plump and large, and the flour to make excellent fodder for live-rock of the next ficle kind.

SIBIDOOLOA, in Geography, a town of Africa, in the flat of Manding, the government of which is a republic, or rather an oligarchy; 40 miles N. of Lilas.

SIBIL-L-MULSIB, a town of Arabia, in the province of Hedjjas; 120 miles N.N.W. of Mecca.

SIBILI, a town of Africa, in the kingdom of Bam-
bara; 25 miles N.E. of Segu.

SIBILI KAOVA, a town of Russia, in the government of Tobolok, on the Irift; 28 miles N. of Tara.

SIBIRIXOA, a town of New Mexico, in the province of Cinaloa; 45 miles N.W. of Cinaloa.

SIBINBAS, a town of Hindootan, in Bengal; 10 miles E.N.E. of Kifhenagur. N. lat. 25° 25'. E. long. 88° 50'.

SIBOCKOO, a town on the E. coast of the island of Borneo. N. lat. 4° 24'. E. long. 119° 12'.

SIBOURNE, a town of France, in the department of the Lower Pyrenees, on a small river opposite to St. Jean de Luz.

SIBRAIM, or SARAHRIM, in Ancient Geography, a place which terminated the land of promise towards the north. Ezekiel says (xlvii. 16.) that this city was between the con-

cesses of Hamoth and Damascus, probably the fame which Abulfeida calls Houverin, a village of the country of Ems, or Hamoth, S.E. of that city.

SIBISIB, in Zoology, an animal of the empire of Moz-
rocco, abounding in the mountains of the province of Sufe; of an intermediate species between the cat and the squirrel, somewhat similar to the ichneumon in form, but not half its size; it inhabits the Atlas, and lives in holes, among the ftones and caverns of the mountains; it has brown hair, and a beautiful tail, resembling that of a squirrel, about the length of its body. The Shelluks and Arabs eat this animal, and consider it a delicacy. This is the only animal which the Mahometans torment before its death, which they do by taking hold of its hind-legs, and rubbing it on a ftone, or flat
flat surface, for a few minutes, which operation causes the animal to scream out. They then cut its throat, according to the Mahometan custom. In take it is laid to resemble a rabbit; but friction, as they pretend, is necessary to render it tender and palatable.

SIBTHORP. John, in Biography, an eminent botanist and traveller, was the youngest son of Dr. Humphrey Sibthorp, professor of botany at Oxford, where the subject of the present article was born, October 28, 1758. He received the first rudiments of his education at Magdalen school, from where he was removed to the school at Lincoln. In due time he entered at Lincoln college, Oxford; but upon obtaining the Redcliffe travelling fellowship, he became a member of University college. Being intended for the medical profession, he was necessarily sent to Edinburgh, to complete that branch of his education; but he took the degree of doctor of physic in his own university. The tale he had early imbued for natural history, especially botany, was cultivated at Edinburgh, and indulged in a tour to the Highlands of Scotland. After his return from thence, he visited France and Switzerland, spending a con siderable time at Montpellier, where he formed an intimacy with the amiable Broussais, (see Paper,) collected many plants of that country, and communicated to the Academie des Sciences of Montpellier, of which he became a member, an account of his numerous botanical discoveries in the neighbourhood. The death of an elder brother of his father, by which a considerable estate devolved on the latter, occasioned Dr. J. Sibthorp to return to England in 1783, when, on his father's resignation, he was appointed to the botanical professorship. For this his Oxford degree of M.D. was necessary. (See Sibthorp, arid Sibthornia.) It was perhaps the last service he expected from it, for he was a favourite son, and had bequest an ample independency of his own in pro sect, from the estate of his mother, who was his father's second wife. These expectations, and his academic appointments, though they releaved him from the calls of his profession, only rivetted more firmly his ardent attachment to botany; his passion for which became, by those appointments, a duty; nor was it ever, to his last hour, dispelled from the task he had undertaken, or to prefer any relaxation, or any indulgence, to this laborious pursuit.

During the stay of professor J. Sibthorp at London, in the winter of 1783, the museum and library of the celebrated Linnaeus were fold, by private contract, to the writer of this article. The professor was commendably defirous of adding to great a treasure to the collections, already famous, at Oxford; but the acquisition depended on a resolute and decisive step, which was already taken, and not on any management or negotiation, to which the person entrusted with the sale was superior. This competition occasioned no interruption in the friendship, but rather then formed, between the parties concerned, which continued increasing during their joint lives.

Dr. Sibthorp passed a portion of the year 1784 at Got tingen, where he projected his first tour to Greece; the botanical investigation of which celebrated country, and especially the determination of the plants mentioned by its classical authors, had, for some time past, become the leading object of his pursuits. He first visited the principal seats of learning in Germany, and surveyed some of its mountains and forests; but it was impossible to quit this part of the world without a considerable stay at Vienna. There he cultivated the friendship of the two professors Jacob, father and son; familiar with peculiar care the celebrated manuscript of Dioscorides, which had so long been preserved in the imperial library; and procured a most excellent draftsmanship of Mr. Ferdinand Bauer, to be the companion of his expedition. On the 6th of March, 1786, they set out for the various ports of Greece, and passed through Carcass to Tripoli, Venice, Pisa, Florence, Rome, and Naples; examining every thing that was curious, and keeping an exact record of their botanical observations. After visiting the celebrated environs of Naples, they let out this city, early in May, and touching at Malta, as well as at the site of Milo, they proceeded to Crete. Here, in the month of June, our botanical expeditions were welcomed by Flora in her gayest attire. The lovely scenery of the Spachicote mountains was withdraw'd, and a tribe of lovely little butterflies were just peeping through the veil.

Having narrowly escaped shipwreck, in returning to Milo by one of the country vessels, Dr. Sibthorp and Mr. Bauer touched successively at several islands of the Archipelago, visited Athens, and remained for a while at Smyrna. Here they traced the steps of Socrates and Hellequin, proceeded, by land to Buria, climbed the Parnassian mountains, and at length reached Constantinople, where they spent the ensuing winter, in the course of which Dr. Sibthorp devoted himself to the study of modern Greek. In a botanical excursion to Belgrad, on the 17th of February, 1787, and another to the jucquerie, March 5, the plants found in flower were entirely the same as are met with, at the same season, in England. Dr. Sibthorp's residence at Constantinople, the neighbouring tribe of Karkis, and his communications with the naturalists of the fishes and birds of those regions, enabled him to throw much light on the writings of naturalists.

On the 14th of March, 1787, having joined our captain with captain Emery and Mr. Hawkins, Dr. Sibthorp and his draughtsman sailed from Constantinople in a Venetian merchant-ship for Cyprus, taking the islands of Mytilene, Scio, Cos, and Rhodes; and touching at the coast of Asia Minor, in their way. A stay of five weeks at Cyprus enabled Dr. Sibthorp to draw up a Flora and Flora of that island. The former consists of 18 Mammalia; 83 Birds, 19 Amphibians, and 100 Fishes; the latter comprehends 616 species of plants. The particular distinctions, domestic and medical uses, and reputed qualities of these last, are amply recorded; and the vernacular names of the animals, as well as of the economical plants, are subjoined. The fame method is pursued, in a subsequent part of this journal, rejecting the plants and animals of Greece, with every thing that could be collected relative to the medicine, agriculture, and domestic economy of that country and the circumjacent islands. The illustration of the writings of Dioscorides, in particular, was Dr. Sibthorp's chief object. The names and reputed virtues of several plants, recorded by that ancient writer, and still traditionally retained by the Athenian shepherds, served occasionally to elucidate, or to confirm, their synonymy. The first sketch of the Flora Greece comprehends about 1200 plants. "Thus," says the author, "may be considered as containing only the plants observed by me in the environs of Athens, on the snowy heights of the Grecian Alp Parnassus, on the steep precipices of Delphi, the empyrean mountain of Hymettus, the Pentele, the lower hills about the Piræus, the olive grounds about Athens, and the fertile plains of Bœotia. The future botanist, who shall examine this country with more leisure, and at a more favourable season of the year, before the summer sun has scorched up the spring plants, may make a considerable addition to this list. My intention was to have travelled by land through Greece; but the disturbed state of this country, the eve of a Russian war, the rebellion of its bailiffs, and the plague at Larissa, rendered my project impracticable." On the Mammalia of Greece,
Greece, 37 are enumerated, with their modern names, 25 reptiles and 82 birds. All these catalogues were greatly augmented by subsequent observations, in so much that the number of species, collected from an investigation of all Dr. Sibthorp's manuscripts and specimens for the materials of the *Prodromus Flore Graece*, amounts to about 3000.

We shall not particularly trace our traveller's steps through Greece, or the various islands of the Archipelago. His health, which suffered from the confinement of a ship, and the heat of the weather, was restored at Athens, where he arrived on the 19th of June, 1787. From thence he proceeded his journeys in various directions, and with various success. The ascent of mount Delphi, or Delphi, in Negropont, in a storm of wind and rain, on the 30th of August, was one of his most laborious, if not perilous, adventures; but his botanical harvest was abundant. With regard to scenery, mount Athos, which he visited a week after, seems to have made most impression on his mind. This spot also greatly enriched his collection of rare plants. From hence he proceeded to Thessalonica, Corinth, and Patras, at which last place he embarked with Mr. Bauer, on board an English vessel, for Bristol, on the 24th of September. After a tedious and stormy voyage, they arrived in England the first week in December.

The constitution of Dr. Sibthorp, never very robust, had suffered materially from the hardships and exertions of his journey. But his native air, and the learned leisure of the univcrsity, gradually recruited his strength. The duties of his professorship were rather a recreation than a toil. The superintendence of his exquisite draughtsman, now engaged in making finished drawings of the Greek animals, as well as plants; and his occasional visits to the Linnean and Bankian herbariums, for the removal of his difficulties; all together filled up his leisure hours. He was every where welcomed and admired for his ardour, his talents, and his acquisitions. His merits procured an augmentation of his stipend, with the rank of a Regius professor; both which advantages were, at the same time, conferred on his brother professor at Cambridge. He became a fellow of the Royal Society in 1789, and was among the first members of the Linnean Society, founded in 1788. In the spring of the year last mentioned, the writer of this, with Sir Joseph Banks and Mr. Dryander, paused a week at Oxford, which was devoted to a critical survey of the professor's Grecian acquisitions; nor was the honey of mount Hymettus, or the wine of Cyprus, wanting at this truly artistic entertainment. But the greater these acquisitions, the less was their poetical satisfacon with them. No one knew, so well as himself, how much was wanting to the perfection of his undertaking, nor could any other person so well remedy these defects. Though lie was placed, a few years after his return, in very affluent circumstancies; and though his necessary attention to his landed property, and to agricultural pursuits, of which he was passionately fond, might well have turned him, in some measure, aside from his botanical labours; he steadily kept in view the great object of his life, to which he finally sacrificed life itself. No name has a fairer claim to botanical immortality, among the martyrs of the science, than that of Sibthorp.

On the 20th of March, 1794, Dr. Sibthorp set out from London, on his second tour to Greece. He travelled to Constantinople in the train of Mr. Lifton, ambassadour to the Porte, and was attended by Francis Borone, of whom an account may be seen at the end of the article Rutaceæ, as a botanical assistant. They reached Constantinople on the 19th of May, not without Dr. Sibthorp's having suffered much from the fatigue of the journey, which had brought on a bilious fever. He soon recovered his health at Constantinople, where he was joined by his friend Mr. Hawkins from Crete. Towards the end of August they made an excursion into Bithynia, and climbed to the summit of Olympus, from whence they brought a fresh botanical harvest. Dr. Sibthorp discovered at Fanar an aged Greek botanist, Dr. Dimitri Argirami, who had known the Danish traveller Forikall, and who was possessed of some works of Linnæus.

Recovered health, and the accession of his friend's company, caused Dr. Sibthorp to set out with alacrity on his voyage to Greece, on the 9th of September. Paffing down the Hellespont, on the 13th, with a light but favourable breeze, they anchored at Kouna Calie, in the Troad, spent two days in examining the plains of Troy, and then proceeded to the isles of Ithmas and Lemnos. On the 25th they anchored at mount Athos, and paffed ten days in examining some of the convents and hermitages, with the romantic scenery, and botanical rarities, of that singular spot, on all which Dr. Sibthorp descend at length, with great delight, in his journal. Their departure was, for some time, prevented, by a few Barbary pirates hovering on the coast, whom these monks, unlike the priests of the Athenian Bacchus, were not potent or valiant enough to defeat, or to turn into dolphins. Our voyagers sailed on the 5th of October, and on the 7th landed at Skiathos. From hence, on the 11th, they proceeded down the strait of Negropont, and on the 15th passed under the bridge of five arches, which connects that island with the main land of Greece. On the 15th, at noon, they entered the harbour of Pyraeus, and proceeded to Athens, where the four succeeding weeks were employed in collecting information relative to the present state of the government, the manufactures, and the domestic economy of that celebrated spot. Here Dr. Sibthorp left his assistant Borone, who perished by an accidental fall from a window, in his sleep, on or about the 20th of October.

November 16th, Dr. Sibthorp and Mr. Hawkins left Athens by the ancient Eleusinian way, while the classical dreams of the Cephalis, the heights of Helicon and Parainis lay before them. They proceeded to Patras and to Zante, where they arrived in the middle of December, enriched with a large collection of seeds, the only botanical tribute that could, at this season, be collected from those famous mountains. An apothecary at Zante furnisdh'd Dr. Sibthorp with an ample and faithful account of the plants of that island, with their modern Greek names; nor did the winter pass unprofitably or unpleasantly in this fequester'd spot; where neither agreeable society, nor copious information relative to our learned travellers' various objects, was wanting. The feast was sufficiently favourable in the middle of February, 1795, to allow them to visit the Morea, of which peninsula they made the complete circuit in some what more than two months. The Violet and Primrose welcomed them in the plains of Arcadia; and the Narcissus *Tazetta*, which Dr. Sibthorp was disposed to think the true poetic Narcissus, decorated in profusion the banks of the Alpheus. The barbarian horde, under whose escort they were obliged to travel, had talle enough to collect nosegays of these flowers. The oaks of the Arcadian mountains presented them with the true ancient Mistletoe, *Loranthus europaeus*, which fill servcs to make birdline; whilst our Mistletoe, *Vifium album*, in Greece grows only on the Silver Fir. May not this circumstance account for the old preference of such Mistletoe as grows on the oak, among the ancient Britons, and consequently help us to trace the origin of their superstitution to Greece? (See Druids.) The Jay, still called by its ancient
SIBThorp.

Secret name _Kiros_, which is generally taken for the Muggle, was swimming among these rocks; and the Water Ouzel, _Sitta vittata_, flying along the rocky sides of the alpine torrents of Arcadia, presented itself to Dr. Sibthorp’s recollection, as probably the White Blackbird, which Aristotle says is peculiar to the neighbourhood of Mount Cyllene. In vain did our classical travellers look for the beauty of Arcadian shepherdesses, or listen for the pipe of the tylban swain. Figures emaciated, and features harrowed, with poverty, labour, and care, were all that they met with. The verdun of the Pachus’s court, with other vermin, who presume to call themselves Christian monks, and whose places are all bought of the Turks, devour the subsistence of these poor people, and drive many of them to a precarious and predatory life among the mountains.

Proceeding to Argos, and thence to Mycenæ, the travellers were highly gratified by finding, on the gate of the latter, those ancient lutes, which Pausanias describes as the work of the Cyclops; and near it the reputed tomb of Agamemnon, a circular building, formed of immense malleus of stone, placed with such geometrical precision, though without mortar, that not one had given way. That which forms the portal is defended by Dr. Sibthorp as the largest stone he ever saw employed in any edifice. A number of fragments of vases, like those commonly called Etruscan, lay among the ruins of Mycenæ. At Hermione, now called Callirhoë, in the Argolic peninsula, famous for the purple dye anciently prepared there, a wall pile of the shell from which that dye was obtained, and still denominated Porphyri, served to ascertain the species, which is _Murex trunculus_ of Linnaeus, figured by Fabius Columba in his rare and learned work, _de Purpurari_, under the name of _Purpuraria nigra violacea_. (See _Purple Fish_.) From this place Dr. Sibthorp and his friend intended to have coasted along the bay of Argos in a boat, but the sea was then infested with pirates, which obliged them to give up that project, and to return by land to Argos, whence they proceeded to Corinth, Patras, and by way of Elis to Pyrgos. Here they obtained another escourt from Said Aga, to whose protection they had before been indebted, and safely reached Calamata, on the gulf of Corone, where they were detained by the celebration of Easter, on the 12th of April, amid a profusion of sky-rockets and crackers. Proceeding in a boat along the barren and raggy shore, covered with bushy and prickly _Euphorbia_, they reached Cardamoula. Here the Greeks are tolerably free from the tyranny of the Turks, and their persons and demeanour exhibit less marks of degen-eracy. Panagiote, a popular character, nephew of the Cherife, came down, with a train of followers, to welcome the strangers, and conducted them to his tower-like castle, where a narrow entrance, and dark winding stair-case, led to a chamber, whose thick walls and narrow loop-holes seemed well prepared for defence. The country of Mishia, though governed by a Bey, is under the control of eight subordinates, but partly independent, native chiefs, who, like our old feudal lords, often make war on each other, when they bring not only men but women into the field. No Turk is allowed to live in this district. The land is extremely hilly, and easily defended. Taygetus, the highest mountain in the Morea, and almost rivalling Parnassus, was ascended by our adventurous travellers; but the quantity of snow, and the great distance, prevented their reaching the summit. Panagiote and fifty of his followers accompanied them, and he displayed his botanical knowledge by shewing Dr. Sibthorp damnel, still called by, among the corn, which he said occasioned dizziness; and a wonderful root, the top of which is used as an emetic, the bottom as a purgative. This proved _Euphorbia Apina_, to which the very same properties are attributed by Dioscorides.

From Cardamoula the travellers were carried by the dependants of this hospitable Greek chief, along a precipitous road, to Mitrea, where they had the unexpected pleasure of meeting a party of their English friends, in the garb of Tartars, with whom they explored the site of ancient Sparta. After returning to Calamata, and returning from the summit of a neighbouring precipice the ruins of Meleager, with the rich plains watered by the Pamisos, and bounded by the hills of Lacoon, Dr. Sibthorp and Mr. Hawkins hastened to Corone, where a Venetian vessel wanted to convey them to Zante, which place they reached on the 25th of April. Here Dr. Sibthorp parted from the faithful companion of his tour, whom he was delineated never to see again, but in whose friendship he safely confided in his last hours. Mr. Hawkins returned to Greece; while the subject of our memoir, leaving Zante on the 11th of May, experienced a most tedious voyage of twenty-four days to Ótranto, though five days are the most usual time for that passage. He touched at the island of Cephalonia, and next at Prevela, on the Greek shore, where being detained by a contrary wind, he employed the 7th of May in visiting the ruins of Neapolis. The weather was unfavourable, and Dr. Sibthorp here caught a fever, and from which he never recovered. It seems to have proved the exciting cause of that disease, which had long been latent in the mesenteric and pulmonary glands, and which terminated in a consumption. Being obliged by the weather to put in at the little island of Panno, May 11th, the violent north-west wind "continued," as he too expressively says in his journal, "to nurse his cough and fever." He was confined to his bed, in a miserable hovel, to which, after frequent attempts to fail, he was driven back fix times by the unfavourable wind. At length, the vessel was enabled to call anchor in the port of Ótranto on the 24th of May. Here he was obliged to submit to a quarantine of three weeks, part of which, indeed, was allowed to be spent in proceeding to Ancona. From thence he sailed through Germany and Holland to England. Of the precise time of his arrival we find no mention. It was in the autumn of 1755, and his few succeeding months were chiefly marked by the progress of an uncoquatable disease, for which the climates of Devonshire and Bath were, as usual, referred to in vain. He died at Bath, February 8th, 1756, in the thirty-eighth year of his age, and lies interred in the abbey church, where his executors have erected a neat monument to his memory.

We have now to record the posthumous benefits which Dr. Sibthorp has rendered to his beloved science, and which are sufficient to rank him amongst its most illustrious patrons. By his will, dated Ashburton, January 12, 1756, he gives a freehold estate in Oxfordshire to the university of Oxford, for the purpose of publishing his _Flora Graeca_, in folio volumes, with 100 coloured plates in each, and a _Prodromus_ of the same work, in 8vo, without plates. His executors, the honourable Thomas Wrausden, John Hawkins and Thomas Platt, esqrs., were to appoint a sufficiently competent editor of these works, to whom the manuscripts, drawings, and specimens, were to be confided. They fixed upon the writer of the preface article, who has now nearly completed the _Prodromus_, and the second volume of the _Flora_. The plan of the former was drawn out by Dr. Sibthorp, but nothing of the latter, except the figures, was prepared, nor any botanical characters or descriptions whatever. The final determination of the species, the distinctions of such as were new, and all critical remarks, have fallen to the lot of the editor, who has also revised the rect.
ferences to Dioecorides, and, with Mr. Hawkins's help, corrected the modern Greek names, which later were unnecessarily taken down but incompletely, from many illiterate and imperfect authorities, on the spot. When these publications are finished, the annual sum of 200l. is to be paid to a professor of rural economy, who is, under certain limitations, to be the Sherardian professor of botany, and who is, very properly, obliged to read lectures, that the appointment may not become a reproach, instead of an advantage, to the university. The remainder of the rents of the estate above mentioned is destined to purchase books for the professor; and the whole of the textator's collections, with his drawings, and books of "Natural History, Botany, and Agriculture," are given to the university. This bequest rivals the munificence of Sherard and of Sloane, in the service of natural science, and has only been exceeded by that of the late Mr. Robertson of Stockwell, whose ill-made will was let aside by the common law of the land.

The only work which professor John Sibthorp published in his life-time is a Flora Oxoniensis, in one volume 8vo, printed in 1794. It has the merit of being entirely founded on his own personal observation. The species enumerated amount to 1200, all gathered by himself, and disposed according to the Linnaean system, with the alterations of Thunberg, which were then new, but which are now not admitted as improvements. The adoption, though imperfect, of Hedwig's genera of Mosses in this Flora, must be esteemed a more fortunate measure. S.

SIBFORPIA, in Botany, was so called by Linnaeus, in compliment to Dr. Humphrey Sibthorp, for about forty years professor of botany at Oxford, and the immediate successor of Dillenius. He is said to have delivered but a single lecture in all that time, which was not a successful one, nor do we know of his having enriched the science with any publication. A short letter from this gentleman, announcing the death of his predecessor, is extant among the Epistolae ad Hollerum. In this he modestly expresses a wish that he were equal to the talk before him. However imperfect his claims to botanical celebrity, his son has conferred more honour on the above name than either of them could derive from it; see the preceding article.—Linn. Gen. 350. Schreb. 418. Wild. Sp. Pl. v. 3. 340. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 667. Prodr. Fl. Grec. Sibth. v. 1. 419. Ait. Hort. Kew. v. 4. 51. Jull. 99. Lam. Illustr. t. 535. Gartn. t. 535—Clas and order. Didymsea Angiosperma. Nat. Ord. Periconae, Linn. Pedicellae, Jull.

Gen. Cal. Cal. Perianth inferior, of one leaf, turbinate, in five deep, ovate, spreading, slightly unequal, permanent segments. Cor. of one petal, bell-shaped, in five deep rounded segments; the uppermost largest, equal to the calyx; two lower ones shorter, and less coloured. Stam. Filaments four, awl-shaped, not half the length of the corolla, scarce visibly unequal, spreading, two at each side, opposite to its lateral stamens; anthers roundish, two-lobed. Pét. Germen superior, roundish, compressed; style cylindrical, very short, thicker than the filaments; stigma peltate. Peric. Capsule compressed, orbicular, notched, swelling at each side, acute at the margin, of two valves and two cells, the partitions from the centre of each valve. Sedis few, roundish-oblong, convex on one side, flat on the other, invested into a globulose central receptacle.

I. S. europae. Sibthorpia, or Cornish Money-wort.

Lim. Sp. Pl. 880. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 639. (S. profrata; Salib. Ilc. 11. t. 6. Allium purpure pulilla repens, folicis Saxifrage aurea; Rall Sym. 352. Pluk. Phyt. t. 7. f. 6. Cornwall Penny-wort; Petiv. Herb. Brit. t. 6. f. 11.)—Ray observed this curious little plant to be plentiful in Cornwall and Devonshire, on moist banks, and about the margins of rivulets, flowering from June to August, being accompanied by the elegant Campanula hederacea. There several succedent botanists have gathered both. Locley found the Sibthorpia in Portugal, and Mr. Hawkins on the mountains of Crete; but we know not of its having been noticed in any other country. We have seen it completely naturalized on the lawn of James Vere, esq. in his curious garden at Knightbridge. The root is fibrous, perennial. Stems prostrate, creeping extensively, branched, slender and delicate, leafy, hairy. Leaves alternate, filiform, horizontal, kidney-shaped, with thallus fistaft notches, hairy, rather fleshy, about half an inch broad; pale and veiny beneath. Flowers axillary, foliaceous, on short hairy filaks. Corolla of a pale greenish-yellow, with a purplish tinge in the three upper foment.

The S. evolvulacea of Linnaeus's Supplement being a very distinct genus, now known by the name of Dichondra, see that article, the above becomes the only species of Sibthorpia.

SIBU, in Geography, one of the Philippine islands, about 240 miles in circumference. The principalproductions are a species of grain called borona, which serves instead of rice; cotton, tobacco, wax, and civet. This island was discovered by Magellan in 1521. N. lat. 10° 41'. E. long. 123° 30'.

SIBU, Sibu, or Sogbu, a town in the above-mentioned island, containing 5000 houses, the see of a bishop, and residence of a governor. In this town, as some say, Magellan, the celebrated circumnavigator, died. N. lat. 10° 35'. E. long. 123° 44'.

SIBUCO, a town on the west coast of Mindanao. N. lat. 7° 3'. E. long. 122° 10'.

SIBULTIQUE, a river of Mexico, which runs into the Pacific ocean, N. lat. 13° 35'. W. long. 89° 16'.

SIBUYAN, one of the Philippine islands, about 36 miles in circumference. N. lat. 12° 36'. E. long. 122° 22'.

SIBYLS, Sibyl, fupposed to be the same with the Sybilline, supposed to be the same with the Sibyls of the ancient world, as the 9th, 0th, 30th, 33th, 35th, Anti-quit, virgin-prophetesses, or maidsupposed to be divinely inspired; and who, in the height of their enthusiasm, gave oracles, and foretold things to come.

Authors do not agree about the number of the Sibyls, though their existence is allowed, as sufficiently established by antiquity. Capella reckons but two; v. Erophyle of Troy, called Sibylla Phrygia; and Sinuachia of Erythe, called Sibylla Erythrea. Solinus mentions three; v. Cumea, Delphica, or the Sibyl of Sardis, and Erythrea; and of this opinion is Aufonius, who thus describes them;

"Et tres fatidice nomen commune Sibylla, Quasar ternegeminata fatalis carmine libri."

Ælian makes their number four, v. the Erythreaen, the Egyptian, the Sibyl born at Samos, and another of Sardis in Lydia; and Varro increases it to ten, denominating them from the places of their birth; the Perian, called Sabetta by the Persians; Libyan, according to Eupidides, the daughter of Jupiter and Latona; Delphi, named Daphne by Diidorus Siculus, who says that she was born at Thebes in Eudoxia; Cimmerian; Erythreaen, who prophesied to the Greeks, that were going to besiege Troy, the happy succses of
of their enterprise, and who lived, according to Livy, in the time of the Tregu war, as Varro believes, but under the reign of Romulus: Samians, called, according to Sosides, Piltho, or Petitionum, and according to Phulius Epiphanius: Cumaean, named with a variety in some authors, and by others Demophile or Hierophylus, who is said to have offered to Tarquin the Elder a collection of Sibyls verses, in nine books; Heliopolis or Troad, born at Miletus, near the town of Gorga, in Trea, who lived, according to Heracleides, in the time of Cyrus and Sother; Phrygiae, who gave her oracles at Assvr, the place of her residence; and Tiburtines named Albans, and honoured a divinity in the vicinity of the river Anio. Of these, the most celebrated are, the Erythraean, Delphic, and Cumaean Sibyls.

Some modern authors, with regard to the authority of Varro, or of that of the other ancient, are for nothing all the Sibyls in one; so that, according to them, different names were given to one and the same Sibyl from the different places where the utterer of her oracles she first published her predictions in the city of Erythrae, the place of her nativity: then roamed about the world; and closed her life at Cumae, in Italy. Dr. Hyde (De Relig. Persar.) shocked at the contradictions and fabulous adventures with which the Pagans filled the history of the Sibyls, accounts for them in the following manner. He observes in the collection Virgo a bright star, which the Persians called Sambula, denoting, in their language, epica, or an ear of corn; and remarks, that the Persians, who were fond of a lucubratory art, looked on the sign of the Virgin as having a greater power than all the other cephalic bodies, for discovering future events. The Greeks, having learnt the sciences of the eastern nations, soon adopted these trifling opinions, and, agreeably to their genius, embellished them with their fictions. Their poets soon invented a Sibyl virgin, in allusion to the term Sambula, carried her into several countries, and made her act the part of a prophetess. So that, according to this eminent writer, whatever has been said both by the ancients and moderns of the Sibyls and their prophecies, is entirely fabulous. This conjecture, though ingenious, is contradicted by the testimony of antiquity, which allows that there were, in different times and countries, such extraordinary personages, who were reputed to have a particular fore-knowledge of futurity, and whose predictions, carefully collected, were confided upon important occasions. The Persian Sibyl might, indeed, owe her original to the circumstance above-mentioned, but that is no sufficient argument against the existence of other Sibyls. The Romans had the highest and possible veneration for the Sibyl; and if they did not always regard them as divinities, they at least regarded them of a middle nature between gods and men; and some of them received divine honours. Lactanius says, with confidence, that the Tiburtine Sibyl was worshipped as a goddess at Tibur. Some of them had temples. Justin Martyr mentions that of the Sibyl of Cumae, in Italy, built over the cave where she delivered her oracles. Virgil mentions this temple, or rather he considers it as a temple the grotto where the Sibyl delivered her oracles, because in after-times there was one actually built there. "Vocat alta in Tempia Sacerdorum," Æn. i. 6. We may here add, that the inhabitants of Gorga, in the Leper Phrygia, had a custom of representing upon their medals the Sibyl who was born in that city, as being their great divinity. As a farther proof of the worship paid to the Sibyls, they had statues erected to them, which were placed in the temples.

The Sibylline oracles were held in great veneration by the more credulous among the ancients; but they were much suspected by many of the more knowing. The books in which they were written were kept by the Romans with great care; and nothing of them was destroyed without consulting them. Tarquin first committed them to the custody of two particular priests, appointed for that purpose. (See Diodorus Siculus.) Now, whether by whom this collection was made, are circumstances which authors have not ascertained. It is not likely that the Sibyl prophesied in verse, far less that they themselves kept their predictions, and delivered them to order. All that we know concerning them is, that a woman came to Tarquin the Elder, as Varro says, or, according to Pliny, to Tarquin the Proud, offering him a collection of their verses in nine books, or three according to Pliny; and that the demand for them 300 pieces of gold; that when the price or refusal to give that sum, the threw three of them into the fire, and asked the same sum for the remaining six, which being refused, the burned three more, and perfidiously asking the same sum for those that were left: at length the king, fearing that would burn the other three, gave her the sum which he had demanded. Although this story has very much the air of a fable, it is related by many authors; and it is certain that the Romans had in their possession a collection of the Sibylline verses.

These books were carefully kept till the civil wars of Sylla and Marius: when the Capitol being accidentally let on fire, and burnt down to the ground, these books were burnt with it. This happened in the year before Christ 83. But the Capitol being again rebuilt about seven years after this period, the senate determined to restore the Sibylline oracles; and having procured many that were said to be of this kind, laid them up in the Capitol, in order to supply the place and office of those that were lost. However, the books thus obtained had been dispersed in the hands of many, and were, therefore, by being thus vulgarly known, unfit for the use which the Romans proposed to make of them. On this account a law was passed, which required the surrender of them, and prohibited any from retaining copies of them, under pain of death. Augustus, when he assumed the high-priesthood of Rome, revived this law, and destroyed a great multitude of copies which were brought in. Tiberius caused many more to be burnt, and preferred only those which were found most worthy of approbation for that service of the state for which they were originally intended; and to these, as long as Rome remained heathen, they had constant recourse; till at length Honorius, the emperor, A. D. 395, issued an order for destroying them, in pursuance of which, Sulpicius burnt all these prophetical writings, and demolished the temple of Apollo, in which they were reputed. Nevertheless, there is still preferred, in eight books of Greek verse, a collection of oracles, pretended to be the Sibylline. Dr. Cave, who is well satisfied that this collection is a forgery, supposes that a large part of it was composed in the time of Adrian, about the year 150; that others were added in the time of the Antonines; and the whole work completed in the reign of Commodus. Dr. Prideaux says, that this collection must have been made between the year of our Lord 138, and the year 167. It could not be earlier, for mention is made of the next successor of Adrian, i.e. Antoninus Pius, who did not succeed him till the year 138; and it could not be later, because Justin Martyr, in his writings, often quotes it, and appeals to it; and he did not outlive the year 167. Fabricius supposes that this collection does not contain all the Sibylline oracles which were used by the ancient fathers; and that the most ancient Christia
Christian writers, who have quoted the Sibylline oracles, had only a part of the collection which is transmitted down to us. Some of the fathers, not apprized of the imposture, have often cited the books of the Sibyls in favour of the Christian religion; and hence Celsus takes occasion to call the Christians Sibyllists. It must be allowed that St. Clement, St. Theophilus, and some other Greek fathers of the second century, had a much greater respect for the Sibyls than they deserved; for Dr. Lardner says, that he is well satisfied that the Sibylline veres quoted by them are the forgeries of some Christian. The ancient Sibylline veres did not recommend the worship of the one God, condemning all manner of idolatry, as though which are cited by Justin, Theophilus, and Clement. It must be owned, however, that Clement calls the Sibyl a prophetess, and seems to quote her veres as Scripture, in the strictest sense of the word, together with the Scriptures of the Old Testament; so that if there be any books improperly advanced by him into the rank of sacred Scripture, they are the Sibylline books; but Dr. Lardner does not think that he esteemed them of equal authority with the books of the Jewish canon. It is a circumstance that deserves to be mentioned, that the Heathen people knew nothing of thefe Sibylline veres till they were found out, or rather forged, by some Christian, and then incautiously and imprudently recommended by others. Justin Martyr seems to have been the first Christian writer who quoted the collection now existing of Sibylline oracles, or any Sibylline veres whatever, containing the peculiar doctrines of Christianity. The more ancient writers preceding him, who have mentioned the Sibyls, have quoted nothing but what might be found in Sibylline writings among the Heathens. In the collection above-mentioned, which appears, for the chief part of it, to have been a work of the second century, we have many unquestionable evidences that the writer, who calls himself a Christian, was acquainted with the New Testament, and that in several places he recites the same facts in the same or familiar language. The pretended prophecies of this collection are undeniably taken from the New Testament. Whatever was the particular view of the author in composing this work, says Dr. Lardner, and however improperly some ancient writers have produced testimonies from it in their defences of the Christian religion, it is now of use to us, as it affords an argument that our gospels were extant, and in much repute, in the author's time. See farther on this subject, Prideaux's Conn. vol. iv. p. 885, &c. Lardner's Credib. of the Gospel Hist. vol. iv. book i. cap. 29, or Works, vol. ii.

SICAB, in Geography, a town on the north-west coast of the island of Negros. N. lat. 11° 26'. E. long. 123° 2'.

SICAE, in Ancient Geography, a town of Thrace, called in the time of Steph. Byz. Justinian.—Alfo, a town of Afa, in Cilicia.—Alfo, the name of a place in the vicinity of the town of Alexandria.

SICAL, or SISAI, in Geography, a town of Mexico, on the north coast of the province of Yucatan; 60 miles N.W. of Merida.

SICAMUMIN, in Ancient Geography. See CAIPHA.

SICAN, in Geography, a town of Peru, in Khorafian; 15 miles S.W. of Zawian.

SICANDERAB, a town of Hindooftan, in Doob; 36 miles W.N.W. of Pattiyan.

SICANE, in Ancient Geography, a town of Spain. Steph. Byz.—Alfo, a river of Sicily, which runs near Agrigentum.

SICANUS, a town of Spain, according to Thucydides.

SICAPHA, a town of Africa Proper, being one of those which were situated between the two Syrtes. Ptol.

SICARD, CLAUDE, in Biography, a Jesuit missionary, was born at Aubergue, near Marillees, in 1677. He entered into the society of Jesus in the year 1699, and for seven years taught the classics and rhetoric in their schools. He was at length sent on a mission to Syria, and thence to Egypt, where he died at Cairo in 1726. He was a man of deep as well as extensive learning, and an exact observer of what was remarkable in the countries he visited. His first publication was "An easy Method of learning Greek," translated into French from the Latin of Peter Gras, with additions. When abroad, he sent home several curious letters, which were published in the "Nouveaux Memoires de l'Academie de Jesus dans le Levant," in which are likewise published his "Plan of a Work on Egypt, ancient and modern," and a "Dissertation on the Psalms of the Red Sea, and Journey of the Israelites."

SICARI, in Ancient History, a Sibyl of Judea, who went about the country for the accomplishment of their nefarious purposes, with short swords concealed under their clothes. Josphus has described them in the most odious colours. Eleazar, he says, the chief man among them, was a descendant of Judas, who had perfidious not a few of the Jews not to enrol themselves, when Cyrenius the censor was sent into Judea. For then the Sicarii confpired against all who were willing to submit to the Romans. They treated all such as public enemies. But other pretences were professed, in order to cover their cruelty and avarice. These hypocritical villains were hired to murder Jonathan, the high priest, at the instigation of Felix. Accordingly, some of the sicarii, coming up to Jerusalem, with an apparent purpose of worshipping God, and having short swords under their coats, mixed themselves with the multitude, and killed Jonathan. This murder palling unpunished, the robbers afterwards attended the feasts without any seeming concern, and carrying, as before, swords under their clothes, and mixing with the multitudes, killed several people, some of whom they reckoned their enemies, and some whom they were hired by others to destroy. This they did, not only in other parts of the city, but within the bounds of the temple itself. Joseph. De Bell. Jud. i. vii. c. 8. § 1. 5.

SICASICA, or CIASICA, in Geography, a town of South America, and chief place of a jurisdiction of the same name, in the government of Buenos Ayres, 240 miles in extent; 40 miles N.N.W. of Oroiro.

SICAYAP Point, a cape on the north-west coast of Mindanao. N. lat. 8°. E. long. 123° 30'.

SICCA, a town on the north coast of the island of Sumatra. N. lat. 1° 32'. E. long. 110° 40'.

SICCA, La, a small island in the Mediterranean, near the coast of Naples. N. lat. 39° 58'. E. long. 13° 52'.

SICACCOLUM, a city of Hindooftan, in the circle of Condapilly, on the Kithna; 35 miles S.S.W. of Ellore.

SICCAPILLYO, a town of Hindooftan, in Myfre; 25 miles N.N.W. of Chinna Balabaram.

SICCA-VENEREA, KEFF, in Ancient Geography, a town of Africa, situated about five leagues S.W. of Laribus Colonia, and 25 leagues W.S.W. of Tunis. It was built upon the declivity of a hill. Valerius Maximus says, that it had a temple of Venus, at which young females prostituted themselves, in order to obtain a portion that might enable them to marry.

SICCHASIA,
SICCHASIA, a word used by some writers to express that unbelief at the fomach, and loathing of food, which women are often affected with in their pregnancy.

SICCHOS, in Geography, a town of South America, in the audience of Quito; 20 miles W. of Latacunga.

SICCINNIS, in Antiquity, a mixed kind of dance.

SICERA, in the Jews Antiquity. The Hellenistic Jews give this name to a very melancholy liquor. St. Chrysostom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the signification and nature of ficera, assure us, that it properly signifies palm-wine.

Pliny acknowledges, that the wine of the palm-tree was very well known throughout all the East, and that it was made by taking a bullet of the dates of the palm-tree, and throwing them into three gallons of water; then squeezing out the juice, it would intoxicate like wine.

The wine of the palm-tree is white; when it is drank new, it has the taste of the cocoa, and is sweet as honey; when it is kept longer, it grows strong, and intoxicates. After long keeping, it becomes vinegar.

SICCHAR, in Ancient Geography. See the next article.

SICHEM, or Sichem, called also Neapolis, Siciar, or Sychar, and Mashartha, a town of Judea, in the tribe of Ephraim, which took up the tenth share of Samaria. This town was situated on the summit of a mountain, and became one of the strongest and most celebrated towns of this tribe. It was at this place that Abraham lodged, on his way to Canaan (Gen. xii. 6.); and it afterwards became the abode of Jacob, who bought a field in its vicinity, which he gave to his son Joseph, who was buried there. (Gen. xlvi. 21.) Near the same city was Jacob's well or fountain, at which Jesus dined with the woman of Samaria. (John. iv. 7.) Joshua gave it to the Levites of the tribe of Ephraim, who belonged to the family of Kishath, the first of the Levites; and it was appointed to be one of the six cities of refuge. (Josh. xxvii.) It was at Sichem that Joshua assembled the tribes of Israel (Josh. xvii. 1.), to renew their engagement of fidelity to God. Sichem was destroyed by Abimelech; but it appears to have been afterwards re-established, because it is said (1 Kings. xii. 2.) that Rehoboam came hither, after the death of Solomon his father; and it was fortified and inhabited by Jeroboam. (1 Kings. xii. 25.) After the ruins of Samaria by Shalmaneser, Sichem was the capital of the Samaritans; and Josephus says (Antiq. lib. xi. cap. 8.), that it was in the time of Alexander the Great. It was dilapidated, according to Eusebius and Jerome, 10 or 12 miles from Shiloah, 40 from Jerusalem, and 52 from Jericho. Jerome says, that Paula visited the church built on Jacob's fountain; and others, who wrote in the eighth century, speak of this building; but it is not mentioned by Plutarch, who wrote in the twelfth century. Sichem or Sichar is now Naplofle, or Nebulus; which see.

SICHES, or Siben, in Geography, a town of France, in the department of the Dyle, on the Dreme; 30 miles N.E. of Brussels.

SICHERFREUTH, a town of Germany, in the principality of Bayreuth; 3 miles S.E. of Bayreuth.

SICHILL. See Schilli.

SICILIAN, a river of Ruffia, which runs into the Ochotkoi sea, N. lat. 52° 28'. E. long. 152° 14'.

SICHOU-LO-HOTUN, a town of Corea, in the sea of Japan. N. lat. 42° 20'. E. long. 130° 27'.

SICHROW, a town of Bohemia, in the circle of Boletlaw; 3 miles N.N.W. of Tarnau.

SICHTELLEN. See Sichtellen.

SICHU, a town of Mexico, in the province of Mexico; 15 miles N.N.E. of Mexico. - Also, a town of Mexico, in the province of Guatemala; 15 miles W. of Panama.

SICIGNANO, a town of Naples, in Provincia Cuma; 10 miles W. of Cagnano.

SICILIAN Mignara, Sic., and Vesper. See the last mention.

SICILIANA, in Exodus, a name given by Deodorus, and some other authors, to the great Archelais, called Tarquin, and part-heirs.

SICILIANA, a pastoral movement in a flow metre of 3; The character of this movement requires a point to the foot note of almost every triplet. Nothing is more pleasing than the Sicilian strains of great masters. Handel hardly ever fails rendering them characteristic, touching, and pleasing; such as, "He shall feed the Flock like a Shepherd;" "Let me wander not unseen," etc.

SICILIANE, or PASTORALI, a kind of simple rural music, refounding in Christmas time through all quarters of Naples, and executed by Abruzzole or Calabrian shepherds, upon 2 species of bag-pipes, called in Abruzze zampogna, and ciamemell in Calabria. The tunes vary, according to the provinces: in the south, they have three different airs; the northern shepherds have only two, to which they add any variations which the bolder of their own genius inspires. The boys learn of their fathers to play upon this instrument, as the means of subsistence. The waits, fill kept up in the pay of some corporations in England, are counterparts of these shepherds.

SICILICUM, the name of a weight in use among the ancients; which, some say, was equal to three drachmas of our weight; others say only to two.

SICILY, in Ancient and Modern Geography, an island in the Mediterranean, the largest of all the islands in this sea, being about 150 British miles in length, and 70 in mediad breadth. Swinburne reckons its greatest length at 340 miles, and breadth 133; and places it between N. lat. 36° 25' and 38° 25', and E. long. 12° 50' and 16° 5'. Sicily is separated from the continent by the straits of Messina, which, in some parts, are about four miles broad. (See CHARYBDIS, MESSINA, and SCYLLA.) At Messina, and at the mouth of the straits from the promontories of Pelorus in Sicily and the Lode di Volpa, or Forest Tail, in Calabria, is nearly a mile. Many of the ancient historians and poets have rated this island as formerly joined to the continent, and severed from it, at an unknown period, by some extraordinary convulsion; nor is this opinion at all improbable. Accordingly Pomponius Mela observes, "Sicilia, ut ferunt, aliquando atra Brutto adnexa." To the same purpose Virgil (Aen. i. v. 414.) says:

"Hae loca vi quondam, et falsa convulsa ruina
Diffiliulis ferunt, cum protinus utraque Tellus
Unea fuerat. Venit medio vi pontus et udis
Hesperium ficto latus abscidit.

"Situs Italicus details this event more at large (lib. xiv.):

"Aurorius pars magna jacet Trinacria Tellus
Ut femel expugnata nata, et vallentibus undis
Acceptit freta carules propulsa tridentes,
Namque per occultum caeca vi turbinis olim
Impactuum Pelagos lacerae vestrae terrae
Difciit, et medio pertussus arva profundo,
Cum populus pariter convulsa transubti urbem.

"Claudian affirms positively,

"Trinacria quondam Italica pars fuit."

Pliny,
Pliny, Strabo, Diodorus, and many others, both historians and philosophers, are of the same sentiments, and pretend that the strata on the opposite sides of the straits agree perfectly; and some imagine, that this separation is recorded in the name given to Rhegium, a town of Bruttium. With regard to the breadth of the strait that separates Sicily from Italy, Silius says, ubi supra:

"Sed fpantium, quod difficiat conforia terre,
Latras fama eft (fic arca intervenit unda),
Et matutinos voluere tranfmittere cantus."

And some persons have even affirmed, that not only the crowing of a cock might be heard from one shore to another, but that a strong voice might be heard through this distance. Mariners have asserted that this canal is not two miles broad.

Sicily, on account of its somewhat triangular form, has been called Trinacria, or Trinacia, and Trinquetra. Its ancient name was Sicania, derived from its inhabitants the Sicani; but when the Siculi took possession of the greatest part of the island, it assumed the name of Sicilia. The interior of Sicily is full of mountains. The ancients, proceeding from the west to the east, enumerated the following: viz. Eryx, near the sea and Drepanum, celebrated for a temple of Venus; Crates, towards the north, in which are the sources of the Eleutherus and Himera, and thofe of Hypsa, which flowed towards the south; the Gemelli collas, more fouthward than the chain of Crates, in which is the source of the Camicus, and of other rivers; the Nebrodes, northwards and efl of the preceding; Maro, still more to the efl; the Herce, from south to north, between the sources of the Himera to the west, and thofe of Simethus to the efl; and also the famous mountain Aetna; which fee. Among the rivers of Sicily noticed by the ancients, we may enumerate, on the eastern coaft, the Simethus, which rifes well of Aetna, and fouth of the town called Engyum, runs towards the fouth-eft, receiving in its course the Chryfas, and ditches itself into the sea near to and north of Murgentium; and the Mela, south of the preceding, and running in a ftraight direction from west to efl; and on the fouthern coaft, the Himera, which had its source in mount Artheinus, in the environs of Enna, and flowed into the sea at Phylilia; and the Hypsa, which proceeding from the interior of the island, flowed into the sea near to and eft of Selinus.

The principal places in ancient Sicily are enumerated and briefly described under their appropriate names in different parts of the Cyclopaedia.

Sicily was celebrated among the ancients for its extraordinary fertility. Its mines of lead, copper, and silver, and its variety of stones and volcanic productions, have been recorded by ancient and modern writers; and it has been observed, that the summits of its highest mountains have furnished a great number of different marine productions.

This island has undergone a variety of revolutions: it has been denominated, in very remote times, the island of the Sun, and the land of the Cyclops, and of the Leprygons. It was afterwards called Sicania and Sicily, from the names of its possessors. The Phoenicians also had establishments in this island, and carried on with it a considerable commerce, in the advantages of which the Trojans are said to have participated. The Greeks established themselves in Sicily for the first time after the siege of Troy, and kept possession of it for a long period, forming different republics, and transporting hither their manners and arts, and different opinions, and erecting temples of stone of the Doric order; and in process of time they shared the government of it with the Carthaginians. These new conquerors, who about 510 years B.C. gained possession of it, brought with them their commerce, their arms, and their gods. They occupied the western and northern shores, whilst the Siculi retained the midland country; and the southern and eastern coasts were inhabited by the Greeks. The Mamertines arriving hither from Italy took possession of Messina, and called over the Romans, who, urged by their ambition, wanted only a pretext of taking up arms against the Carthaginians. After a variety of successive contests, they took possession of the island. The Romans occupied themselves for some years in establishing peace, abundance, and even splendour; and they erected during the time of the republic superb edifices of marble; their power and ambition letting no limits to their magnificence. Under their dominion Sicily became more flourishing than it had been in the time of the Greeks, when it was considered as free. The Sicilians, under the government of the Romans, lost their military genius, and these mutual jealousies which served only to accelerate their own destruction. When the Romans made themselves masters of Sicily, they permitted the inhabitants to retain the temples, the deities, and the forms of worship which the Greeks and other nations had established among them, and till the division of the Roman empire, they maintained a certain character of elegance and refinement. But at this period the monuments of antiquity funk into neglect; the arts were no longer held in estimation; and talents disappeared on the accses of ignorance and barbarism. Towards the end of the fourth century, Syracuse was the first town of Sicily that received Christianity, and soon after other towns and the whole country followed its example; and this event was followed by a neglect of their temples and public monuments. The ignorance of the priests, no less notorious than the fervour of their zeal, induced them to make war against the sciences and the arts, that they might thus the more effectually and speedily destroy Paganism, which cultivated them.

The Sicilians, having relinquished all martial ideas during a long series of generations, turned their attention solely to the arts of peace, and the labours of agriculture. Their position in the centre of the empire preferred them from both civil and foreign foes, except in two instances of a servile war. But the rapacity of their governors was a more constant and insupportable evil. In this state of apathy and opulence, Sicily remained till the seventh century of our era, when the Saracens began to disturb its tranquillity. The barbarous nations of the North had previously invaded and ravaged its coasts, but had not long kept possession. The Saracens, however, were more fortunate. In the year 827 they availed themselves of quarrels among the Sicilians to subdue the country; and they chose Palermo for their capital. The Standard of Mahomet triumphed about 1000 years. In 1038 George Maniaries was sent by the Greek emperor with a great army to attack Sicily. He made good his landing, and pushed his conquests with vigour, and, aided by the valour of some Norman troops, with success. Maniaries repaid them with ingratitude; and by his conduct allowed the Mussulmen an interval of tranquillity, and the Normans an opportunity and pretext of invading the imperial dominions in Italy. Robert and Roger of Hauteville afterwards conquered Sicily on their own account. After a struggle of ten years, the Saracens, in 1172, as Swinburne says, surrendered the rich prize; though others say, that they left the possession of it A.D. 1038. Robert ceded it to his brother Roger, who assumed the title of great Earl of Sicily. This first sovereign swayed the sceptre with wisdom and glory, and deferredly ranks among the greatest charac-
The climate of Sicily is very hot; the thermometer at Palermo varying in June and July from 75° to 80°, and when the frosts wind blows, rising suddenly to 112°. March is the only month in which any chilling winds are felt, and even in the beginning of January the trade is still retreating. The appearance of winter is only felt in the snow that falls on the summits of Mount Etna. (See that article.) Although the island has, in many parts of it, the aspect of a rock, the soil is of a warbler's nest, and it is built up on the same rock, is that which is used for the production of wine. The crops of wheat are still found abundant, notwithstanding the oppression of the government, as not only to supply the wants of its own inhabitants, but also to afford a large surplus for exportation; and it is still enjoyed by the Queen of a free government, it might become one of the richest and most flourishing in the world; for even in its present wretched state of cultivation, one good crop, pays Bryan, would be sufficient to maintain the island for seven years; but when he visited the island, the exportation of this commodity had been prohibited for seven years past, or, at least, to all such as were not able to pay most excoriated for that privilege. The sugar-cane was formerly very much cultivated in this island, but the duties imposed were so enormous, that it has been almost totally abandoned. Silk afforded formerly a profitable branch of trade, but this has very much declined. Besides wheat, which has at all times constituted the riches of this island, they cultivate many other branches of commerce, though none that could bear any proportion to this, were it under a free government, and exportation allowed. Their grapes are also cultivated, by excluding the air and keeping the prize dry, as to preserve it for many years. Large quantities of hay and pulp grow in Sicily, but very little ever moist. Cash- bird feed is exported to a large amount, and is almost peculiar to this island. Large quantities of silk are exported from place to place, the finest part of the island. Water bread is exported in great abundance; and the wines are very val-

SICILY.
kind for building their ships and houses, but likewise an inexhaustible store of the most excellent fuel; and as the third region, with its ice and snow, keeps them fresh and cool during the heat of summer, so this contributes equally to keep them warm and comfortable during the cold of winter.

The principal trade of this island is carried on at Palermo and Messina; the former consumes of imports four or five times more than the latter; but on account of lighter duties, Messina exports a greater quantity of silk, and supplies the inland towns with more commodities. The business of other places on the coast consists solely in shipping corn, wine, salt, &c. Trapani, on account of its famous salt-pan and the shipping belonging to it, is one of the busiest commercial towns in the island.

According to the enumerations made in 1714, says Swinburne, Sicily contained 1,133,163 inhabitants, including 45,000 ecclesiastics, and 110,000 inhabitants of Palermo. In 1615 it contained 1,107,234, and in 1805, 488,500, without reckoning the inhabitants of Palermo or Messina.

When Mr. Brydone visited the island in the year 1779, he says that the inhabitants, by the last enumeration, amounted to 1,125,163, of which number there were about 50,000 that belonged to the different monasteries and religious orders; the inhabitants of Palermo were computed at 150,000. The number of houses in the island were estimated at 268,120; so that allowing the enumeration and the estimate to be just, the number to a house appears to have been between five and six. The vicissitudes and commotions that have more recently occurred have not been favourable to an increase, but must rather have contributed to a diminution of the population.

The provinces in this island are three: viz. Val di Noto, 260 miles in circumference; Val di Mazara, 302 miles in circumference; and Val Demone, 315 miles in circumference; they contain 42 towns belonging to the demeane, and 310 baronial.

Sicily is governed by a viceroy, in whose absence the archbishop of Palermo is regent. The general assembly of parliament is composed of 66 archbishops, bishops, abbots and priors, which form the brazchio ecclesiastico: 58 princes, 27 dukes, 37 marquises, 27 counts, 1 viscount, and 79 barons, form the military, and the demanial consorts of 43 representatives of free towns. Out of each brazchio four deputies are chosen to conduct public business; but the viceroy, the prince of Butera, and the prator of Palermo, are always the three first. N.B. There are many titled persons that have no seat in the assembly, viz. 62 princes, 55 dukes, 87 marquises, 1 count, and 282 other feudatories.

The ecclesiastical government consists of three archbishoprics and seven bishoprics.

The following tables shew the coins, weights, and measures of Sicily.

### TABLES OF SICILIAN COINS.

### Weights and Measures.

There are two sorts of weights used in Sicily.

1. **Grande.**

- 1 Cantaro contains 110 rotoli
- 1 Rotolo = 33 ounces
- 1 Pound = 12 ounces
- 1 Ounce = 30 trapioli

This cantaro is equal to 215 pounds avoirdupois weight.

2. **Common.**

- 1 Cantaro contains 100 rotoli
- 1 Rotolo = 30 ounces

This cantaro is equal to 178 pounds weight avoirdupois.

### Dry Measure—Corn.

- 1 Salma generale contains 16 tomoli = equal to 20 Winchester bushels, used in measuring wheat.

### Liquid Measure—Oil.

- 1 Caffi weighs 18 pounds avoirdupois.

### Wine.

- 1 Salma contains 8 quartari
- 1 Quart contains 12 quartuci.

### Linear Measure.

- 12 Oncie make 1 palmo, equal to 10 inches
- 8 Palmi make 1 cenna, equal to 6 feet

Besides the obligations which the Romans had to the Etruscans and Greeks for their trade and knowledge in the fine arts, the conquest of Sicily 200 years before the Christian era, contributed greatly to their acquaintance with them. Indeed, there was no rate of Greece which produced men of more eminence in all the arts and sciences than Sicily, which was a part of Magna Graecia, and which has been peopled 719 years B.C. by a colony of Greeks from Corinth, their descendants long after cherished and cultivated science of all kinds, in which they greatly distinguished themselves, even under all the tyranny of government with which they were oppressed. Fabricius gives a list of seventy Sicilians who have been celebrated in antiquity for learning and genius, among whom we find the well-known names of Eichyclus, Diodorus Siculus, Empedocles, Gorgias, Euclid, Archimedes, Eparchamus, and Theocritus. To the Sicilians is given not only the invention of pastoral poetry, but of the wind instruments with which the shepherds and cowherds used to accompany their rural songs.

After the conquest of Greece, the Romans had the taste to admire and adopt the Grecian arts. And the president Montesquieu remarks, with respect to the military art, that one of the chief causes of the Roman grandeur, was their method
There is considerable variation in the construction of the tools which are employed for work in different places; and which, in fact, are converted into the blades or like tools, from which they are also used in one part of the country, and from which the common names are wholly unknown in others.

The common fiddle is a sort of circular piece of wood, not much furred with reed, which, in general, is from about twenty to thirty inches in length, and about half an inch in breadth, having a sharp and thished edge cut in the head, part, from twenty six to thirty teeth being formed in every inch in length. The teeth all incline towards the handle of the tool, so that it only cuts when it is drawn towards the person using it, and not when it is introduced through the standing corn, as the act of reaping. The Furnes fiddle, a valuable tool of this kind, made use of in a district of that name in the northern part of Lancashire, has a blade two feet six inches long, edged with nineteen teeth in every inch, and in the form of its curvature, measures two feet from the heel to the point. It is a powerful tool, and capable of doing much work in a given time when in good hands, as seen below.

The French-edged fiddle, or reape-hook, has a shape and length which are much the same as those in the common fiddle, only a little broader; but the edge is sharp and without teeth.

The Lancashire tagging fiddle or hook is a tool of the same kind, but which is a great deal larger and heavier, as well as broader at the point. It can, however, be used with great effect and expedition by those who are accustomed to this mode of reaping.

The fiddle-hook is also another tool of the nature which is made use of in some districts. It is only turned from the middle to the point end, by which the wale of grain in cutting is said to be prevented.

By much the most ancient of these tools is the common fiddle, and it is probably, on the whole, the best of them, though it is getting much out of use in many parts of the country, being now ever so rarely known or employed in the counties of Devon, Cornwall, and Suffolk, and in many other places in the more western parts of the kingdom, having long since taken place to the hook, the reason of which seems to be the greater ease of performing the work by them, as is commonly supposed, but by no means. The fiddle is by far the most frugal and economical tool for accomplishing the work with, in cutting the harvest of grain. Tools made with the fiddle and the reape-hook, have indeed shown that the latter tools are more expedient, but at the same time that the use of grains for

get, has, in a great measure, the use of the instruments of the world of agriculture.

The corn of the period to be produced by the harvester must have been cut with a tool adapted to the purpose, but it is difficult to determine the kind. It is evident that, in cutting the grain, the tool must be pointed and narrow, and also heavy, when it is worked by the hand, the tool on the ground has, as it were, the work of a tool, but it has more to do, and the tool is the part to be cut. The fiddle, therefore, will cut with more facility, when it works near the face, the tool will probably be too small, and even the larger parts of the grain, as well as the Indian, when it works with the hand, in the same way as it does in the field.

It is necessary to the latter to be aware of the use of the different tools of the field, as the looks are fixed during the day to the one or even the other part of the kingdom, as well as to the Indian, where they are highly unknown, and are used in many other places.

In the above districts of Furness, the reaper is weekly and most excelsently performed by the tool. As an early rate of working, three men and a half with the tool, will cut a customary acre of five yards and a half to pole or perch, or long, light, slender corn, in the course of a day, or less; and a larger head and five men with such tools will perform the same quantity of work in a field of the strongest corn, where there has been much entangled. By hard labour from hoist to dark, in this way it is with this kind of tool will reap, bird, and flesh shows a customary acre of any kind of grain. See HARVESTER AND REAPER OF CORN.

Sickle-Fish. See Falk.
Sickle-Wire. See Botany. See Cereals.
SICKLUPEN, in Geography, a town of Prussia, in the province of Samland; 5 miles N. of Gdansk. SICKNESS. See Disease.
SICKNESS, Fasting. See Fasting.
SICKNESS, Green. See Chlorosis.
SICKNESS, Sweating. See Sweating.
SICKREE, in Geography, a town of Bengal; 26 miles N.W. of Rangpur.
SICLOS, a town of Hungary, having a castle on a mountain, in which the emperor Sigismund was imprisoned; 64 miles S.E. of Castile.
SICLYGULLY, a town of Bengal; 15 miles S. of Rajmahal.
SICON, a town of the island of Cuba; 125 miles W.S.W. of Havana.
SICULI, or Sicily, in Ancient Geography, a people originally of Dalmatia, who established themselves in Italy about the 16th century B.C. They formed a numerous nation, and had possession of a considerable extent of country, as they peopled Umbria, Sabina, Latium, and all the country of the occupants of which were afterwards known under the name of Opus. The Siculi pulled into Sicily, and gave it their name. This event is said to have taken place, according to Heliodorus of Lebeou, 50 years before the first of Tyrant, or 764 years B.C., according to the chronology of Tacitus, who are said. The name of Siculi, which seems to have been given to the people who diffused themselves from the Tiber to the eastern

402

extensively...
extremity of Italy, the country occupied by the Liburni excepted, was gradually abolished by the separate leagues and dispositions of the Sabines, Latins, Samnites, Oceanians, and Italians. Herodotus, Thucydides, Plato, and Aristotle, mention these people.

SICULIANA, in Geography, a town on the S. coast of Sicily, containing 5000 persons, and belonging to the prince of La Catholica, to whom it yields an annual income of 14,000 crowns. It is remarkable for not having a single convent within its precincts, owing either to the danger of a visit from the Mahometans, or to the recent foundation of the town. The ignorance of the inhabitants, at least with regard to philosophy, is remarkably evinced by an anecdote mentioned by Strabo. On the wall of his apartment he found notice of a thief to be maintained in the schools of Girgenti by a native of Siculiana; in which he undertakes to prove, "that the Copernican system is impious, absurd, and contradictory to Holy Writ, from which it is evident, that the earth stands still, and the sun moves round it, like the sails of a windmill round the pivot." Siculiana is pleasantly situated on two hills joined together by a long street; the vale below being full of orange and other fruit-trees, and the view of the sea very extensive; 12 miles N.W. of Girgenti.

SICULONES, in Ancient Geography, a people who inhabited the Cimbic peninsula, according to Ptolemy.

SICULOTÆ, a people of Dalmatia, who, according to Ptolemy, were divided into 24 decuriae.

SICUM, a town of Ilyria, on the coast of Dalmatia, between Scardona and Salone, according to Ptolemy and Pliny. The latter says, that the emperor Claudius sent his veteran cohorts.

SICUS, in Ichthyology, a name used by some authors to express that species of coregonus, called by the generality of authors Albus nobilis. This, in the Linnean system, is a species of Salmo.

SICUT ALIAS, in Law, a writ sent out in the second place, where the first was not executed.

It is thus called from its beginning, which is in this form: "Georgius, D. C. &c. Vicecomiti Hercul. faltem. Precipitus faltem tibi (sicut alias) praecipitem," &c.

SICYANA. See Guard Worm.

SICYEDON, from cuminum, a cucumber, in Surgery, a transfère fracture.

SICYON, in Ancient Geography, a town of Greece, and capital of a small state in the gulf of Corinth, and not far distant from it. It was anciently called Ἑγίαλες, from Ἑγίαλος, its supposed founder and first monarch. It is not certain whether the whole kingdom, or only its metropolis, was called by that name, but it was exchanged for Ἀπία, from Ἀπία its fourth king; and in process of time it acquired that of Sicyon, who was the 19th monarch. He reigned about 740 years after its supposed foundation; and from that time not only the kingdom, but the whole peninsula of Peloponnesus, was called Sicyonia until its dissolution.

This little kingdom lay on the N. part of the Peloponnesus, since called the bay of Corinth. On the west it had the province of Achaea, and on the east the Ilissus, which joins the peninsula to the continent of Greece. Its extent has not been ascertained. Its capital is supposed to have been situated upon the river Ἀθώ, having the bay of Corinth on the north, and the rest of the Peloponnesus at the three other points. Strabo and Livy say, that it was parted from the kingdom of Corinth by the river Nemia; and Ptolemy adds that it was first called Micon, and afterwards Ἑγίαλες; he gave it two cities, Platthis and Sicyon, both of which he placed at some distance from the sea.

The territory of this small state was rich, abounding with corn, vines, olive-trees, and other commodities, besides some iron mines. Its metropolis was, in process of time, very much adorned by Sicyon and its successors, with temples, altars, monuments, and statues of all its gods and ancient monarchs. This would be fully deemed the most ancient monarchy in the world, not excepting those of Egypt and Assyria, if it were true that its founder lived about 150 years after the flood, or about 200 years before Noah's death; as some have computed it from Eusebius, who affirms this monarchy to have been founded 1313 years before the first Olympiad, or 2089 B.C. But other chronologicalists have corrected this mistake, and made him contemporary with Terah, Abraham's father, and dated the commencement of his reign about the year of the world 1915, or even later, about A.M. 1256; by which computation it is brought somewhat lower than the year of the flood 2920. This kingdom is said to have had, during an interval of 962 years, a succession of 26 kings, but their reigns are distinguished by no memorable action or conquest. The first king was Ἑγίαλες, and the last Zeuxippus or Deuxippus; but in Baur's chronology the last king is Charidemus, with whom they end, 1859 years B.C. or 15 years after the return of the Heraclides into Peloponnesus. In the list of kings, the most remarkable is Sicyon, who gave name to the state, and who is supposed to have built, or at least enlarged, the metropolis of the kingdom, and to have called it by his own name. Accordingly it was not only one of the noblest cities in Greece, on account both of its magnificent edifices and ingenious workmen, but it was a considerable place when the Venetians were masters of the Morea, under the new name of "Baflica," though it has been for near the two last centuries reduced to a heap of ruins, containing only three Turkish, and about as many Christian families. The town was situated on the top of a hill, about three miles from the gulf of Lepanto; and has still several monuments of its ancient as well as modern grandeur, particularly the walls of its famous citadel, of some fine churches and mosques, and a large ancient edifice, called the royal palace, with aqueducts to supply it with water, all which, with other old remains were described by Sir George Wheeler, Voy.

After the death of Zeuxippus, the last king of Sicyon, this state is said to have been governed by the priests of Apollo Carneus, five of whom held the sovereignty only during one year each; after which the Amphictyons sware the spute nine years successively, and Charidemus, the last of them, continued in it 18 years. After this hierarchy had lasted 32 years, the Heraclides, who were at that time returned from Peloponnesus, became masters of it, or according to Paufanias, the kingdom was incorporated with the Diores, and became subject to that of Argos, the next kingdom to that of Sicyon in respect of antiquity. Anc. Un. Hill. vol. v.

SICYONE, a word used by Hippocrates to express coloysth, and by others for a species of hard-helled gourd, in the shape of a pear, and by some for a cupping-glafs.

SICYONEUM OLEUM, a word used by the ancients to express a medicinal oil, of which there were among them three kinds in use. The first was called ficoeum simplicis. This was composed of two ounces of the root of the wild cucumber, boiled several hours in a pint of oil. The second was called the compound ficoeum, and was made of the root of the ficoeum, and many other ingredients. The third was another compound kind, made not with an infusion of the root, but with the juice of the fruit of the wild cucumber.

SICYONI, among the Romans, were shoes of a more delicate

The root is annual. Stem branched, hairy, waxy, climbing by means of long, spirally divided tendrils. Leaves alternate, on long flasts, pointed, more or less toothed, minutely rough, three or four inches broad. Flowers whitish, marked with green lines, axillary; the male one racemose, on a long flast; female on a much shorter flast, and capitate. Fruit ovate, pale, spiny, half an inch long, about eight to ten together in a round head. Seed large, ovate, fleshy.

2. S. carnea. Small-flowered Single-fed Cucumber. Willd. n. 2. "Leaves five-angled, minutely toothed, smooth; heart-shaped, with a round thick finus, at the base."—Native of Mexico. Communicated to professor Willdewill, now, by the celebrated baron Humboldt, from whole seeds, it was reared at Berlin. Annual, like the leaf, and much resembling it, but the leaves are not rough, nor is their finus an obtuse angle, but round. The male flowers are not more than one tenth to large as in S. angulata; the female ones about a quarter the size of the species. The fruit however is but little smaller. Wildemarz.
in Europe, though S. Abutilon is reported to grow in Siberia and Switzerland, where it may perhaps have been naturalized; as has happened to various tropical annuals in colder climates than what is natural to them. Abutilina has afforded one new species to our gardens; besides which, 34, exclusive of the Nopes, are enumerated in Mr. Aiton's valuable work.

The habit of all is more or less shrubby, though several have annual roots. The leaves are alternate, flaked, simple; either entire, notched, or lobed. Indecorence mostly axillary. Flowers yellow, reddish, or white. The species are disposed in sections, according to the shape of the foliage. We shall give various examples.

Sect. 1. **Leaves lanceolate, more or less narrowly, oblong, or ovate.** Seventeen species.

S. flavoja. Prickly Sida. Linn. Sp. Pl. 960. Willd. n. 6. Ait. n. 2. Pursh n. 1. Cavan. Diff. 11. t. 1. f. 9. (Alcea carpini folio, americana frutescens, florulis luteis, femea duplici rostro donato; Comm. Hort. v. 1. 3. t. 2.) — Leaves ovato-lanceolate, serrated; somewhat heart-shaped at the base. Stipulas lanceate, with axillary spines. Flower-flanks simple, mostly solitary. Capsules with beaked valves.—Native of the East and West Indies, Senegal, Arabia Felix, and North America. Mr. Pursh says it is found among rubioids, and by road-sides, from Pennsylvania to Carolina, flowering in July and August. This was one of the earliest species cultivated in England, but rather for curiosity than beauty. The broader leaves principally distinguished it from the former, for their flowers are nearly finer. The root is annual or biennial.

S. bifida. Hifpad Sida. Pursh n. 2. — "Rough with bristly hairs. Leaves lanceolate, serrated. Flower-flanks axillary, the length of the footstalks. Outer calyx thread-shaped."—Decribed by the above author, from the herbarium of Mr. Lyon, who is said to have met with this plant in the sandy plains of Georgia in North America. The flowers are yellow. If they have really an external calyx, the plant can be no Sida; but perhaps a simple fetaeous bractea is all that is meant by the above definition. We have seen no specimen.

S. carpiniifolia. Hornbeam-leaved Sida. Linn. Suppl. 307. Willd. n. 8. Ait. n. 3. Jacq. 1c. rar. t. 135. Cavan. Diff. 274. t. 134. f. 1. — Leaves ovato-oblong, smooth, closely serrated. Stalks axillary, about four-flowered. Capsule with beaked valves. — Mr. Maillon met with this shrub in the garden of a French convent, in Madeira, and sent it to Kew garden in 1774, where it is treated as a green-hone plant, flowering most part of the summer. The native country has not been ascertained. The branches are hairy, spreading, like the leaves, in two directions. The latter are two or three inches long, and nearly half as broad, smooth, with crowded, acute, somewhat unequal, or doubled, serratures, each tipped with a bristle, as in the genus Cappus. Calyx smooth. Petals yellow, oblique, and partly notched. Capsule of eight cells, each having two spinous beaks.

S. flanaticus, Cavan. Diff. 24. t. 3. f. 11, is acknowledged by that writer himself to be the same plant in a young or imperfect condition.

S. fiberofa. Corky Sida. L'Herit. Stirp. 113. t. 54. Willd. n. 13. Ait. n. 4. — Leaves ovate, strongly serrated, hairy. Stalks axillary, single-flowered, twice the length of the footstalks. Capsule with beaked valves. Stem corky at the base.—Native of Hiipanilla. Introduced to the flowers at Kew in 1798, by Sir Jefley Green, bart., but it has not yet flowered. The stem is one or two feet high, branched, the bark of the lower part corky, and full of figures; branches hairy. Leaves more oval than in S. carpiniifolia, pale and hairy. Flowers an inch broad, orange-coloured, with a purple central ring, their flalks and calyx hairy. Capsule small, of nine, slightly connected, cells. The corky bark, which L'Heritier compares to that of Paffiflora saberoif, is suppofed peculiar to the present species.

Sect. 2. **Leaves wedge-shaped at the base.**

S. rhombifolia. Rhomb-leafed Sida. Linn. Sp. Pl. 961. Willd. n. 18. Ait. n. 5. Pursh n. 3. Cavan. Diff. 23 and 48. t. 3. f. 12. (Malvina minor fupina, betonicae folio, foci flore coccoineo, feminibus aperis; Sloane Jarn. v. 1. 217. t. 137. f. 212.) — Leaves oblong-lanceolate, acute, serrated, wedge-shaped and entire at the base. Flower-flanks shorter than the leaves. Stipulas fetaeous, with axillary spines.—Native of both Indies and of North America. Cultivated in curious flowers, where it blooms in former; but the small yellow flowers have less beauty to boast than most of the preceding, with which the plant agrees in habit, except the tapering entire base of its leaves, whose under side is a little glaucous.

S. cigaris. Ciliated Sida. Linn. Sp. Pl. 961. Willd. n. 22. Ait. n. 7. Cavan. Diff. 211. t. 3. f. 9, and 275. t. 127. f. 2. (Malva minor eupina, betonicae folio, foci flore coccoineo, feminibus aperis; Sloane Jarn. v. 1. 217. t. 137. f. 2.) — Leaves oval, abrupt, serrated; entire and somewhat wedge-shaped at the base. Stipulas linear, fringed, longer than the foliar, nearly fiddle, flowers. Capsules prickly, not beaked.—Native of dry gravelly places in Jamaica, and other parts of the West Indies, flowering after rains. A small, procumbent, rather shrubby species, whose leaves are scarcely an inch in length, and whose long fringed stipulas are very remarkable. The flowers are crimson. Seeds, as well as capsules, rough with minute hairs.

Sect. 3. **Leaves heart-shaped, entire, or nearly so.**

S. periploca. Great Bind-weed-leaved Sida. Linn. Sp. Pl. 962. Willd. n. 23. Ait. n. 8. Cavan. Diff. 26. t. 5. f. 2. (Abutilon periploca acutissimum, fructu fllato; Diff. Eith. 4. t. 3.) — Leaves heart-shaped, entire; elongated at the point; downy beneath. Flower-flanks axillary and terminal, somewhat panicked, much longer than the footstalks. Capsule with five awoed cells. — Native of both Indies; long known in our gardens, where it proves annual or biennial only, even in the flower, flowering in summer. Dillenius fuppotes it to be perennial and shrubby in its native country. The stem with us is three or four feet high. The entire pale or hoary leaves bear some resemblance to those of Cympnham acutum, though
S. inaequa. L'Herit. in Sida. Cavan. Dill. t. 36 and 175. t. 135. f. 2. (Abutilon americanum, fruticu subrotundu pendulo, e capulis foveosis crisps conflato; Mart. Cent. t. 29. f. 29. A. veicarium crisps, floribus minutis; A. adulis veicarium, floribus luteis, minus; Plm. l. 15. t. 25.*).—Leaves heart-shaped, pointed, crenate, downy. Flower-flasks axillary, flattened, deciduous, with pubescent fruitlets; fruit held long after the leaves fall.

S. scaberrima. Cavan. Dill. t. 36 and 175. t. 135. f. 2. (Abutilon mexicanum, floribus glabris, foliis oblongis, petalis ciliatis, fructibus linearibus, urceolatis, foliis pubescentibus; Mart. Cent. t. 30. f. 29. A. veicarium, floribus luteis, minus; Plm. l. 15. t. 25.*).—Leaves oblong, pubescent, petioles ciliate, flowers yellowish white, fruit linear, urceolate, pubescent.

Sida.

Inscriptions, instead of the repetitions, so juifully complained of, in the generality of those works. Haller records, after Linder, that the seeds of S. Abutilon, taken to the amount of an ounce, have been found powerfully soporific.

Sec. 5. Leaves heart-shaped, indented. Stalks many-flowered or racemose.

—Leaves roundish-heart-shaped, toothed, somewhat angular, rather downy. Stalks umbellate, axillary and pinnicated. Capsules with double-awned seeds. —Native of both sides, somewhat angular; the upper ones hardly-shaped. Panicle racemose. Petals emarginate, nearly erect, shorter than the flaments. Capsule without beaks. —Supposed to be a native of Mexico. It flowers nearly throughout the year, in the collection of John Walker, cfq. of Arno's grove, Southgate; but we are not informed whether it is a greenhouse or flore-plant. The stem is tall and shrubby, with round biparad branches. Leaves green, alternate, flaked, distinct; the upper ones elongated, and deeply lobed. Flowers elegant, bright scarlet, near an inch long, of a flutelock conformation, as the inerfely heart-shaped, oblong petas spread but very little. The column of flaments rises considerably above them.

S. hojata. Halberd-leaved Mexican Sida. Willd. n. 89. Ait. n. 33. Andr. Repof. 538. Curt. Mag. t. 1541. (S. crifata; Linn. Sp. Pl. 964. Anuda hojata; Cavan. Diff. 38. t. 11. f. 2.) —Leaves lower heart-shaped, lobed; upper hojata. Stalks axillary, solitary, fingle-flowered, longer than the leaves. Petals obovate, spreading, entire. Native of Mexico. Its seeds were brought from Spain by the late marchonofe of Bute. An annual or biennial flore plant, which may be raised on a hot-bed early in the spring, and planted out in the open border. It is scarcely however likely to be added to the list of tropical annuals, generally so cultivated, being much inferior in beauty to many other plants, of the Mallow tribe, that are quite Hardy. Its flowers are light purplish-blue, about an inch wide, on long, fraggling stalks. The divisions and shape of the leaves vary greatly. The valves of the capsule have no beaks.

S. crifata. Crested Sida. Linn. Sp. Pl. 964. Willd. n. 90. Curt. Mag. t. 330. (Anuda crifata; Cavan. Diff. 39 and 55. t. 10. f. 3.) —Leaves crested, pointed; the lower ones angular; upper hojata. Stalks axillary, solitary, fingle-flowered, longer than the leaves. Petals inerfely heart-shaped, thrice the length of the calyx. —Native of Mexico; long since known in our gardens. We have however ascertained the synonymy of Cavanilles, by seeds received from himself, and raised by the late lady Amelia Hume, in whole fofe this plant flowered in July 1806. It may probably succeed, as Mr. Curtis observes, if raised on a hot-bed and planted out in a flower-border. This is distinguished from the last by its very large crimfon flowers, rendering it far more worthy of cultivation. Few plants vary more in the shape of their foliage, so that we are satisfied of the S. Dillemiana, Willd. n. 91. Ait. n. 34, figured in Cavanilles, t. 111. f. 1, and in Dill. Hort. Elrh. t. 2, being a mere variety; so little defined indeed that we can hardly distinguish it as such.

Sec. 7. Leaves lobed, palmate, or compound.

—Leaves heart-shaped, toothed, with three or five lobes; the middle one longest and sharpest. Stalks axillary, foliary.
tary, single-flowered, lower than the leaves. Lobe of the capsule obtuse. — Nature of the Cape of Good Hope. — The flowers are in showy, much-branched, widely spreading, leaves terminal, and a flower or two each wide. From 2 to 6 feet high, with slender branches to the base of the flower. — Gathered by Thunberg at the Cape. We have seen no specimen; but by the above flax's natural habit, it would seem to differ from the last much at the Cape. L. n. 35. 1. 2. — Leaves with three deep, obtuse, free lobes. Peduncle much branched. Cells of the capsule numerous, long Armed with a double membranous wing. — Gathered by Dombev, in sandy ground at Lima. It was rattled at Paris, but not required. The seed is annual. Stem prostrate, much branched, a foot long, or more; finely branched with hairy hairs. Leaves on long stalks, deeply divided, pinnatifid or divided, with rounded lobes and segments. Flowers small, white, in terminal, peduncled, rather hairy, spiny, a flower on a long stalk, and turned downwards. Capsule very peculiar, on account of the numerous, double, membranous, rounded wings, which form an orbicular cedron on its summit. 3. p. 6. S. s. 1. 2. — Leaves in pairs, with deep, acute, pinnatifid lobes. Pedicel many-flowered, hairy. Cells of the capsule without awns. — Nature of Lima and Peru. Sent to Kew in 1787 by M. Thouin. An annual flowery plant, flowering in August, and distinguished by the deep lobes of its leaves, with variously and deeply divided, pinnatifid, or with the leaf, a flower on a long stalk, and turned downwards. Capsule very peculiar, resembling that of the Gagea, to which genus we suspect this species may naturally belong; for L. Heritier speaks of the seeds as separating with difficulty from their cells. We are puzzled by his account of these cells being armed in the wild plant, but not in the cultivated one. But this difficulty may be solved by his having, like Cavallini, originally confounded the perfect species with that he afterwards called 3. ricinoides, in which the valves of the cells are strongly armed. We have a specimen of the 3. ricinoides from L. Heritier himself, marked 3. ricinoides. Yet the two are very distinct in their foliage as well as fruit.

Sidr, in Gardening, contains plants of the exotic, tender, herbaceous, perennial kind, of which the species chiefly cultivated are; the rhomb-leaved 3. (S. rhombifolia); the great bindweed-leaved 3. (S. periploca); the triangular-leafed 3. (S. triquetera); the broad-leaved 3. (S. abutilon); the white-flowered 3. (S. alba); and the heart-leaved 3. (S. cordifolia).

Method of Culture.—These plants may be increased by seeds, which should be sown upon a moderate hot-bed in the early spring, or in pots deposited in them. In the first case, when the plants have attained some growth, they should be removed to another hot-bed, and be let out four inches apart each way, or into separate pots, replanting them in the hot-bed, being shaded till they have taken new root; and a large proportion of fire earth being admitted in fine weather, and also frequent waterings: they should afterwards be gradually hardened to bear the open air in the summer season.
inclose them on the right and left, from the gorge to the head.

**Side. Rights, in Coins. See Latius Reatum.**

**Side, Transferre. See Latius Transferium.**

Side of a Ship, are distinguished into the **starboard** and **larboard**; that is, into the right and left-hand side, when standing with the face towards the head of the vessel. See Starboard and Larboard.

**Side, Broad, in Sea Language, is to fire all the guns on one side of the ship.**

**Side-Wind. See Wind.**

**Side-Graving. See Engraving.**

**Side-Lays is a term made use of by huntsmen, when dogs are placed in the way, to be let slip at a deer, as he gallops by.**

**Side-Saddle Flower. See Hollow-leaved Sea Lavender.**

Side-Cuts, are the short lengths of canal by the sides of rivers, for conducting the navigation by mills, shalloWS, &c.

**Side-Laying Ground, is that whole surface, as A E L (Plate I. Canals, figs. 1, 2 and 3) is lower on one side of the canal than on the other.**

Side locks, or Side-ponds, are reservoirs or excavations by the side of a canal or lock, for retaining water. See Canal.

**Side-Puddle is often used to express the puddle-ditches, gullies or gutters that are formed like a wall within a canal-bank, for preventing breaks from the fame.**

**SIDELING Hills, in Geography, a range of hills in America, on the N.W. part of the state of Maryland.**

**SIDEINA, in Ancient Geography, a town of Asia Minor, in Lydia. Steph. Byz.**

**SIDEINA, or Sidiaina, a very fertile country of Asia, on the sea-coast, in the kingdom of Pontus, in which, according to Strabo, were some strong places, besides a town of the same name.—Allo, a town of Asia Minor, in the Troade, upon the Græcuses; which was ruined in the time of Strabo.**

**SIDEINIA, a people of Germany, who occupied the banks of the Oder.—Allo, a people of Arabia Felix. Ptol.**

**SIDEINA Sinus, a gulf of Asia Minor, upon the Thracian Bosphorus, near the Euxine sea. This gulf was formed by the promontory Ancyrum and by that of Pönion.**

**SIDEINIA, in Geography, a town of Sweden, in Ang/elianland, 40 miles N. of Hernofand.**

**SIDEPATTY, a town of Bengal; 12 miles N.W. of Madinapour.**

**SIDEARIO, in Medicine, from sidus, a planet, because violent and sudden maladies were ascribed to the influence of the stars, a term which has been applied to several diseases of that character. It has been principally used to signify apoplexy, or a sudden palsy; but it has been applied by others to mortification, or sphecules of a limb; and by some to erysipelis of a limb, which is vulgarly called a blight.**

**SIDERATION, the blighting or blighting of trees, plants, &c. by eastern winds, excessive heat, drought, or the like caues. See Blight.**

**SIDERIA, in Natural History, the name of a genus of crystal. The word is derived from the Greek σίδερος, iron, and is used to express crystals alter'd in their figure by particles of that metal. There are of a rhombohedral form, composed only of six planes. Of this genus there are four known species. 1. A colourless, pellucid, and thin one, found in considerable quantities among the iron ores of the forest of Dean, in Gloucester, and in other the like places. 2. A dull, thick, and brown one, not uncommon in the same places with the former. And, 3. A black and very glossy kind, a foil of very great beauty, found in the same place with the others, as also in Leicestherihire and Suffolk. Hill.**

**SIDERAL Year. See Year.**

**SIDERAL DAY is the time in which any star revolves from the meridian to the meridian again; viz. 23 hours, 56 minutes, 4 seconds, 6 thirds of mean solar time. There are 366 sidereal days in a year, or in the time of 366 diurnal revolutions of the sun. The first column of the following table is the number of revolutions of the stars; the others next are the times in which these revolutions are made, as shown by a well-regulated clock; and those on the right hand shew the daily accelerations of the stars, that is, how much any star gains upon the time shown by such a clock, in each revolution.**

</table>

This table will not differ the 279,936,000,000th part of a second of time.

If the equinoctial points were at rest in the heavens, there would be exactly 366 revolutions of the stars from the meridian.
an to the meridian again in 365 days. But the equal no- 
points go backward, with respect to the stars, at the rate 
of fifty seconds of a degree in a Julian year; which causeth 
the stars to have an apparent progressive motion earthward 
fifty seconds in that time. And, as the sun's mean motion 
in the ecliptic is only 14 sign 20 degrees 48 minutes 40. 
seconds 15 thirds, in 365 days, it is plain, that at the end 
of that time he will be 14 minutes 15 seconds 45 thirds thirti 
of that point of the ecliptic from which he set out at the 
beginning; and the stars will be advanced 50 seconds of a 
degree with respect to that point.

Consequently, if the sun's centre be on the meridian 
with any star on any given day of the year, that star will 
be 14° 19′ 47″ + 50″, or 15° 0′ 45″ east of the sun's centre, 
365th day afterward, when the sun's centre is on the 
meridian; and therefore that star will not come to 
the meridian on that day till the sun's centre has pilled it 
by 1 minute 0 second 38 thirds 57 fourths of mean solar 
time; for the sun takes so much time to go through an arc of 
15° 0′ 45″; and then, in 365 days 0 hour 1 minute 0 second 
38 thirds 57 fourths, the star will have just completed its 
365th revolution to the meridian.

This table was calculated by Mr. Ferguson; and it is 
the only table of the kind in which the recollection of the 
equinocial points has been taken into the calculation.

SIDERITIS, in Botany, supposed to be the 
species of the Greeks, of which Dioscorides describes three species, 
all celebrated for launcing blood, and healing wounds. 
The first quality they might very well possess, being, ac-
cording to his account, rough herbs, akin to Marrubium, 
in which also there might be somewhat of an affirgent or 
tonic quality. They answer indeed to the general idea of 
the genus to which modern botanists have applied the name, 
whole etymology is to be sought in calyx, iron; but 
whether it alludes to that metal as the caule of wounds, to 
the ruly utilty of the flowers, as De Thes imagines, or to 
any other circumstance, nothing but conjecture can be of-
Tourn. t. 90. Lamark Illustr. t. 505.—Clas and order, 
114, Jull.

Gen. Ch. Cal. Persian inferior, of one leaf, tabular, 
oblong, cut nearly half way down into five acute, almost 
equal, segments. Cor. of one petal, nearly equal; tube 
 cylindric, oblong; throat oblong, somewhat cylindrical; 
upper lip erect, narrow, divided; lower in three segments, 
of which the lateral ones are more acute, and feebly so 
large as the upper lip, the middle one roundish. Stam. 
Filaments four, within the tube of the corolla, and shorter 
than the throat, to two of them smaller than the rest; anthers 
roundish, two of them with two distinct lobes. Py. Ger-
man four-cleft; flyle thread-shaped, rather larger than the 
flamens; ligulas two; the uppermost cylindrical, concave, 
abrupt; the lower membranous, thinnest, flattening the other. Peric. none, the seeds being lodged in the bate of the 
calyx. Seeds four.

Ell. Ch. Calyx five-cleft. Corolla rinvet; its upper 
lip erect, divided; lower deeply three-cleft. Stamens 
within the tube of the coroll. One stigma water, 
the other.

18. (Exotic in Holland 1613.) Cultivar in 
Shrubby 2. without. Linn. 18. All. 
Rakk. Sp. 204. Willd. n. 2; exclud.
ning the synonyn.—Shrubby and 
downy. Leaves densly downy, oratusgeate, taper-
pointed; heart-shaped at the base; snow-white beneath. 
Spikes compound. Seeds remote, each of about eight 
flowers. Calyx, obtuse, pointed.—Native of Made 
ria now, as well as in Holland, flowering from 
Spring to summer, and frequent in the green-
house in winter, with moderate supplier of water.

Wild. n. 2; excluding the synonyn.—Shrubby and 
downy. Leaves densely downy, oratusgeate, taper-
pointed; heart-shaped at the base; snow-white beneath. 
Spikes compound. Seeds remote, each of about eight 
flowers. Calyx, obtuse, pointed.—Native of Made 
ria of Multan, or in the garden of England, as well as in Holland, 
flowering from April to July. They therefore follow Linnaeus 
in applying that synonyn to the following species; though not quite without a suspicion of its really 
belonging to S. canariensis.

excluding the reference to Tournefort. Willd. n. 3. 
(Stachys canariensis frutescens, verticis folia; Commes.
Hort. v. 2. 197, 197; 197.)—Shrubby and downy. 
Leaves densly downy, heart-shaped, bluish, broadly crenate, 
long hawks; snow-white beneath. Spikes sinque, 
whorled. Calyx obtuse, pointed.—Native of Crete and Greece.
This has the very dense white pubescence of the leaf specie, 
but differs in its larger, blunter, more strongly crenate 
leave, and especially its solitary unbranched leaflets. The 
whorls confine each of eight or more flowers, while 
calyx, though less woolly, nearly agree with the preceding, 
being totally unlike the spoon-pointed calyx of S. canarien-
sis. If Commelins's plate had been executed with any 
care, this circumstance would have determined the synonyn, 
which certainly belongs either to our first or third species, 
and not to the second.

Willd. n. 7. Att. n. 6. Sm. Fl. Græc. Sibth. t. 550, 
unpublished. (S. cribba tombetica candidaflora; Borea 
lueto; Tourn. Cor. 12 Stachys; Ge'om. 175. S. 
lychnoides incana angulifolia, Incana; italica; Barre. 
fc. t. 1187.)—Shrubby, clothed with woolly down. Leaves 
eliptic-lanceolate, nearly entire. Whorl axillary, many-
flowered. Calyx acute, without awns.—Native of Italy, 
Crete, and various parts of the Levant. The leaf is per-
1 P 2
remial and woody. *Stems* erect, mostly simple, herbaceous, a foot high, clothed, like the whole of the herbage, with long, soft, silky, dense, white wool. The radical and lower *fleshy-leaves* are oblong, or elliptic-lanceolate, obscurely crenate; those which accompany the flowers are generally much shorter, ovate, and acute; sometimes they nearly resemble the rile of the foliage, evincing that they are not *bracteas*, but *bracteoles*.

*Whorls* about eight, a little dainty, each of six bright yellow *flowers*. *Calyx* obvex, densely woolly, with five sharp teeth, but no awns or points. *Corolla* twice as long, contracted at the mouth, downy externally, its segments acute, all entire.

5. *S. taurica*. Tartarian Iron-wort. Willd. n. 8. (*S. syriaca; Pallis Nov. Act. Petrop. v. 10. 312.*)—Somewhat shrubby, downy. Leaves lanceolate, crenate. *Whorls* crowded. Floral leaves heart-shaped, pointed, reticulated with elevated veins.—Native of Tartary. The *branched* are a foot long, subdivided, clothed with white down. Radical leaves flaked, *fleshy-leaves* fiddle, all crenate, rugged with veins, and covered with fine woolliness; the floral ones roundish-ovate, pointed, ribbed, reticulated, shorter than the *calyxes*; woolly, like the other leaves, till the flowers are palt, when they become nearly smooth, except the edges. *Corolla* yellow. *Willd.*

6. *S. diffusa*. Distant-whorled Iron-wort. Willd. n. 9.—Somewhat shrubby, hoary. Leaves lanceolate, acute, entire. *Whorls* distant. Floral leaves heart-shaped, sharp-pointed, reticulated with elevated veins.?—Supposed to be a native of the Levant. Willdow obtained it from some old herbarium, with the name of *Sideritis folia conjugatia amblystachen rigida*. He describes it as like the former, but different, having acute, entire, leafy downy leaves, the *fleshy* alone being villous. *Whorls* very distant, accompanied by nearly smooth leaves, with sharp points. Tube of the *corolla* longer than the *calyx*; the middle segment of its lower lip obtuse, but not emarginate. We are unacquainted with anything answerable to this description.

7. *S. persilifolia*. Perfoliate Iron-wort. Linn. Sp. Pl. 802. Willd. n. 10. Art. n. 7. Prodr. Fl. Græc. n. 1330. (*S. orientalis, plomadis folio; Tourn. Cor. 12.*)—Herbaceous, rough with brilly hairs. Upper leaves ovate-lanceolate, obscurely toothed, clasping the stem; floral ones heart-shaped, sharp-pointed, reticulated, fringed.—Native of the Levant. Dr. Sibthorp gathered it in some part of Greece, or the neighbouring islands, but omitted to mark the precise spot. No figure is extant of this species. The *herbage* is green, hairy, and brilly, not downy. *Leaves* reticulated with copious veins; the floral ones crowded, short, and broad, with fimbrious points, their dill pale, and semi-pellucid. *Flowers* six in a whorl. *Calyx* tubular, round, without angles, glandular and hairy; its teeth long, erect, ribbed, fimbrious. *Linnæus* says the *corolla* is white, with some reddish veins.

10. *S. romana*. Simple-beaked Iron-wort. Linn. Sp. Pl. 802. Willd. n. 6. Art. n. 5. Cavan. Isc. v. 2. 69. t. 187. Sm. Fl. Græc. Sibth. t. 552. unpublished. (*Sideritis genus spinosa verticellis; Bauh. Hill. v. 3. 428.*)—Herbaceous, downy, hairy. *Calyx*-teeth fimbrious; the uppermost large, foliary, ovate.—Gathered by Cherel first near Rome, whence the specific name. It has however been found in fields and walk ground in many other parts of the south of Europe. Dr. Sibthorp observed this plant to be common in Greece and the isles of the Archipelago, and we have suspected it might be the real *cyanus* of Dioscorides, to whose description, as far as any thing can thence be determined, it answers well. The *habit* of the plant is much like the last, but the *leaves* are more noted, shorter and broader. Tube and upper lip of the *corolla* pale red; lower lip white, dilated as in the larger-flowered variety of the preceding. The most striking difference is found in the *calyx*, whose upper lip is erect, large, and ovate, the lower of four slender teeth, spreading downward.

11. *S. linata*. Dark-flowered Iron-wort. Linn. Sp. Pl. 804. Willd. n. 20. Prodr. Fl. Græc. n. 1333. (*S. elegans; Murray in Comm. Gott. for 1778. 92. t. 4. Wild. n. 5. S. nigricans; Lamarc Dict. v. 2. 168.*)—Herbaceous, diffuse, hairy. Leaves elliptical, obtuse, cre- nate, without spines. *Calyx*-teeth spreading, fimbrious, hairy, nearly uniform.—Native of Egypt, Cordia, and Palestine. Murray first described it at Gottenburg, from garden speci- mens, without knowing whence they came. Nor was he blameless for not discovering his plant to be *S. linata* of Linnæus, whose specific character, made from a flared wild specimen, is calculated to mislead those who had no other guide. Yet the great Swedish botanist appears, by his herbarium, to have rightly understood the cultivated plant of Murray, of which he Destroyed a very old and luxurious morf, apparently from some Dutch collection. This species is undoubtedly most akin to *montana* and *romana*, nor has it any real *bracteas*. The *auberts*, as in theb, are all axillar, fix-flowered. *Calyx* involved all over with long silky hairs, its teeth tipped with spines, the upper one rather longer than the others, but all nearly equal in breadth. *Corolla* with a white tube; the front of the limb dark purplish-brown, nearly black, of a very striking appearance;
its upper segment close; lower in three rounded lobes. The flowers very greatly in size, but are rounded, pointed, and slightly inferior; the lower ones blunted.

(1) H. verticillata major; Barcel. Ic. 1. 2292. H. verticillata minor; Barcel. Mt. 277. 1795 f. 722. The same (treated from f. 281. 2. 2.)—Rather shrubby, downy, hoary. Leaves laterally alternate, entire. Base ovate, palmate, with a few sp. —Native of Spain. Cultivated by Mill. 1 July, being generally hardy, flowering in July and August. The habit of the plant is much like Lavandula. Wherever two or three in each spike, with a pair of clafe, firm, ribbed, with rough bracteas, cut into many spinous segments, under every whorl. Calyx clothed with white cottons down; its teeth erect, 2-3 or nearly equal. Caulis twice as long as the calyx, yellow, white, or pale blue; both its end dilated and spreading.

feels the very same plant, not even a variety. We venture to remove Barrelier's name, cited by Defontaines, to the following, as Willd. has done.

14. S. becciai. Hydropike-leaved Iron-wort. Linn. Sp. Pl. 503. Wildl. n. 15. Att. n. 18. (S. alpina; Villars. Dauph. v. 2. 227; S. alpina hypposphila; Ger. Em. 1606. S. montana, &c.; Barcel. Ic. 1. 1711. 1725.)—Leaves lanceolate, smooth, nearly entire. Bracteas wedge-shaped, palmate, (spiny).—Native of the mountains of Switzerland, Dauphiny, Italy, and the Pyrenees. Cultivated by Gerard in his garden, and still preferred in curious or general collections, being a hardy perennial, flowering throughout the summer and autumn. The stem are somewhat woody, throwing up many leafy squarish branches, a span high, hairy at the two opposite sides, in lines crossing each other at every joint. Leaves numerous, opposite, filked, green, elliptic-lanceolate, two or three of the upper ones only occasionally toothed. Heads more or less crowded into an impenetrable, or oblong, foliary, terminal, small, perigonal or frutescens, each whorl accompanied by the long, reticulated, hairy bracteas, with fringed spiny ferratures. Calyx-teeth long, spiny, erect, nearly equal. Corolla yellowish-white, with two dilated lips, larger than the calyx.

16. S. spinosa. Spinous-leaved Iron-wort. Vahl. Symb. v. 1. 41. Wildl. n. 17. Lamarck Dec. v. 2. 1795. (S. subspinosa; Cavan. Ic. v. 3. 3. 289.)—Leaves lanceolate, pointed, with long spiny teeth, as well as the reticulated heart-shaped bracteas. Stem equally hairy on all sides.—Native of France.

17. S. bipinnata. Harry-leaved Iron-wort. Linnae. Sp. Pl. 82. Wildl. n. 2. 1795. Att. n. 11. (S. tenuis; Chit. Hc. v. 3. 246. Tette. by the name; Barcel. Ic. 1. 2292. Hier. Ic. v. 3. 246; Ger. Em. 1606.)—Leaves oblong, obtuse, strongly toothed, Bracteas with spinous teeth. Stems have 4 rays, and are about at the base. —Native of Spain. It is the third of France.—Very much akin to the three last in its flowers, bracteas, &c., but more hairy. The form and teeth of the leaves agree with S. spinosa, a hairy variety of which, we suspect, is sometimes taken for the true S. spinosa. The latter however appear exclusively to differ, in having the conspicuous hairs on its stem equally divided all round, not collected into decussating lines. The stems very much in being crowded or remote, and are very much crowded together, and it is not certain that the species are not the same. S. spinosa, however, is native of Perú. It is cultivated in the gardens of Madrid, in July. The stem is fibrous and perennial. Stems feebly a foot high, square, slightly hairy. Leaves about one inch long, on stalks about the same length; rough on the upper side, with hairs proceeding from minute tubercles; smooth and tinged beneath. Spike terminal, about three inches long, quadrangular. Bracteas crowded, in four rows, entire, acute, rigid, spreading, beet with long spiny ferratures. Flowers fix in a whorl, three to each bractea. Calyx with five slender, short, nearly equal teeth. Corolla yellowish-white; its upper lip entire, lower three-lobed, the middle lobe three-lobed.

SILDENII, in Gardening, contains plants of the underbrushy, and shrubby exotic kind, of which the species cultivated are, the Casab iron-wort (S. canariensis); the Cretan iron-wort (S. cretica); and the fage-leaved iron-wort (S. lyrica). But there are other species that may be cultivated for the sake of variety.

Method of Culture. These plants may be increased by seeds, cuttings, and layers. The seeds should be sown in pots in the spring, placing them in a moderate hot-bed; when the plants have had some growth, they should be removed into separate small pots, filled with light, sallow mould, being afterwards treated as other shrubby greenhouse plants. The cuttings and layers may be planted out, or laid down in the frame before they are sufficiently rooted to be managed as the other sorts. In all, the third sort may be increased by planting the trimmed heads, either in pots or in a sandy bed, to be afterwards removed into pots for protection in the winter in a frame.

They afford variety in greenhouse collections, among other evergreen potted plants of similar growths.

SIDERO, or Geographia, a town of Naples, in Calabria Ultra; 48 miles S of Catanzaro.
SIDERO-CAPSA, a town of European Turkey, in Macedonia; 32 miles E.S.E. of Saloniki.

SIDEROCHITA, in Natural History, a class of cruf- tated ferruginous bodies, of a moderately firm and compact texture, composed of ferruginous mixed with earthy matter, and formed of repeated incrustations, making to many coats or crusts round a softer or harder nucleus, or round loofe earths, or an aqueous fluid.

Under this class are comprehended the empherepyra, heteropyra, geodes, and cubarid.

SIDERODENDRUM, in Botany, from σιδερον, iron, and δέντρον, a tree, a name given by Schreber to the Sideroxylon of Jacquin, which the latter had so called for a while only, till he should be more certain of the genus, by ascer taining the true nature of the fruit. This Schreber has determined; and the name he has chosen alludes to the hardness of the wood, known to the French in Martinico by the appellation of Rois de fer, or Iron-wood. The analogy of the neighbouring genus Sideroxyllum is also thus kept in mind.—Schreb. Gen. 71. Willd. Sp. Pl. v. i. 612. Mart. Mill. Dict. v. A. J. Hort. Kew. v. i. 245. (Sideroxyloides; Jacq. Amer. 19.)—Clasfs and order, Tetrandria Monogynia. Nat. Ord. Dumofé, Linn. Sapotes, Jull.

Gen. Ch. Cal. Perianth superior, of one leaf, minute, with four acute teeth. Cor. of one petal; tube cylindrical, incurved, many times longer than the calyx; limb in four oblong, obtuse, flat, reflexed segments, half the length of the tube. Stam. Filaments four, very short, inserted under the divions of the limb; anthers oblong, erect. Pet. Germin roundish, inferior; style thread-shaped, the length of the tube of the corolla; stigma oblong, obtuse, thickish. Berries two-loded, crowned with the calyx, two-celled, with a tranverse partition. Seeds solitary, convex and rugged at the outer side, flat on the inner, bordered, attached to the partition.

1. S. triflorum. Three-flowered Iron-tree. Willd. n. 1. Ait. n. 1. (Sideroxyloides ferrucum; Jacq. Amer. 19. t. 175. f. 9.) Sideroxyllum americanum, five ligulare dictate ferrum silicaceum; Pluk. Almag. 346. Phyto. t. 224. f. 2.)—Native of mountainous woods, in the islands of Martinico, Martinique, Barbadoes, &c. A tall branching tree. Leaves opposite, flaked, ovato-lanceolate, acute, entire, shining, six inches long. Flower-flakes axillary, very short, sparsely three-flowered, chiefly on the older and leafless branches. Flowers small and slender, about half an inch long, rofection at the outside, white within.—Mr. Ryan observed the corolla to be often changed, probably by the attack of some insect, into an oblong, hollow, rhythm bag, pointed at the top, almost an inch in length, resembling a fruit.

SIDEROMANTIA, σιδερομαντία, in Antiquity, a kind of divination performed with a red-hot iron, upon which they laid an odd number of straws, and observed what figures, bending, sparks, &c. they made in burning.

Gen. Ch. Cal. Perianth inferior, small, erect, in five segments, permanent. Cor. of one petal, wheel-shaped, in five concave, erect, roundish segments, with a little pointed infulled scale, at the base of each segment. Stam. Filaments five, awl-shaped, the length of the corolla, into which they are inserted alternately with the scales; anthers oblong, incumbent. Pet. Germin roundish, superior; style awl-shaped, the length of the stamens; stigma simple, obtuse. Berries roundish, pointed, of one cell. Seed. Nut ovate, large, of one cell.

Of M. SERALISIA of Mr. Brown, see that article, differs in having a berry, with from one to five seeds; but in the former case we know not how to distinguid it from the present genus. Sideroxylum jasobium, Linn. Sp. Pl. 279, according to Mr. Brown, constitutes a very distinct genus of the same natural order.

1. S. muta. Harmless Iron-wood. Linn. Synt. Nat. ed. 12. v. 2. 178. Willd. n. 1. Jacq. Coll. v. i. 245. (S. muta inerm.) Mill. i. c. 299.)—Thorns none. Leaves acute.—Native of Africa. Jacquin describes his plant, which appears to be the same with Miller’s, as an elegant evergreen tree from the Cape of Good Hope, flowering abroad in summer, sheltered in the greenhouse in winter. The leaves are scattered, flaked, lanceolate, pointed, entire, coriaceous, smooth; at a shining deep green above; paler beneath. Flower-flakes short, purple. Flowers white, on simple or branched axillary flages. We know nothing of this species but from the above authors. Linnaeus describes his plant as having filifer flowers, but we find no specimen in his herbarium to ascertain what he meant.

2. S. inerm. Smooth Iron-wood. Linn. Sp. Pl. 278. Willd. n. 2. Ait. n. 1. Jacq. Coll. v. 2. 250. (Sideroxyllum jasobium, dein corior inordinem nomine data arbor; Dill. Elth. 357. f. 267 f. 344.)—Thorns none. Leaves obovate, obtuse. Flower-flakes simple, round.—Native of the Cape of Good Hope. This Sideroxyllum has long been known in the greenhouses of Europe, but has no beauty to boast, at least in its flowers, which are small and inconspicuous, growing on short, cylindrical, simple, axillary, generally aggregate flakes. The leaves are thick and coriaceous; rounded at the end, and often emarginate; somewhat tapering at the base; two or three inches long.

3. S. melangobium. Laurel-leaved Iron-wood. Linn. Mapt. 48. Willd. n. 3. Ait. n. 2. Jacq. Hort. Vind. v. 1. 29. t. 71. (Padus folius oblongus, fructu foliario; Burm. Acr. 238. t. 84. f. 2. Laurifolium africana; Comm. Hort. v. 1. 95. f. 100.)—Thorns none. Leaves lanceolate. Flower-flakes simple, angular.—Native of the Cape of Good Hope. Communicated to Linnaeus in 1761, by the late professor David Van Royen; and sent to Kew in 1783, by Mr. Greffier. This has dark purplish branches, and elliptic-lanceolate leaves, longer and more acute than the last. The flowers and their flakes are altogether of a palish red hue. Linnaeus says the scales between the stamens are wanting, which Jacquin seems to confirm. The fruit is blue, the faze of a pea.

5. S. ferricum. Silky Iron-wood. Ait. n. 3. Willd. n. 5. (Seralfia ferricea; Brown Prod. Nov. Holl. v. 1. 530.)—
S

511) - Thorns none. Leaves ovate, obtuse; downy, like the calyx and flower-flanks, beneath. Corolla viscid externally. Gathered by Mr. Brown, in the tropical part of New Holland; and by Mr. Joseph Banks, who sent it to Kew in 1773, to New South Wales. The flower slender, hairy at the base.

6. S. lamarckii. Obvate iron-wood. (Serrata obvata; Brown tab. 14.) Leaves ovate; four, what tapering at the base; feebly filiky beneath. Calyx nearly smooth Corolla smooth. Style very short. Gathered by Mr. Joseph Banks, in the tropical part of New Holland. In both these the distance between the flowers is incalculable.

8. S. tonentum. Downy Iron-wood. Roxb. Com. v. 28. t. 28. Willd. n. 9. - Thorns none. Leaves elliptic-oblong, with a blunt point; downy when young. Flowers downy, axillary, aggregated, the length of the footstalks. Found chiefly on the tops of the mountains in Hindustan, flowering during the hot season. This is a small tree. The leaves, three inches long and one broad, are smooth when full grown, but in a young state are covered with rusty down. Flowers numerous, of a dirty white. Fruit yellow, the base of a small cherry. Dr. Roxburgh says there are rudiments of five seeds, though only one or two come to perfection. He here seems that the generic character, in that respect, is but precarious.

5. S. decandrum. Linn. Mant. 45. Willd. n. 9. Thorns axillary. Leaves elliptical, deciduous. - Native of North America. In shady woods from Carolina to Georgia, flowering in July and August. A small tree, with minute greenish flowers. Pursh. The branches are round, minutely warty, with ilown, spreading, tapering, axillary, foliaceous thorns, three quarters of an inch long, accompanying the flowers, on the lower part of each branch. Leaves alternate, flaked, elliptic-oblong, about three inches in length, and more than one in breadth, entire, formed flat pointed, smooth, light green, finely reticulatcd with veins, deciduous. Flower-flanks axillary, several together, simple, about the length of the flowers, and rather longer than the footstalks. Segments of the calyx deep, oval, concave, smooth, obtuse, unequal, folding over each other Corolla twice as long as the calyx, but little spreading. We are unable to find any distinction between S. ipomoides and decandrum. A specimen in the Linnean herbarium from Kalm, under the latter name, has a pentapetalous flower, and is otherwise totally different from the species in question. Our description is taken from the specimen sent by Baron Munchhausen to Linneus, and marked jipooides by the latter, though described in his "Enumerations under the appellation of decandrum."

10. S. ipomoides. Thorny Iron-wood, or Argan. Linn. Sp. Pl. 279, excluding the synonym. Dryand. in Am. Hort. Kew. n. 5. (Elphodendrum Argan; Willd. Sp. Pl. v. 1. 1143.) - Thorns lateral. Leaves obtusely blong, deciduous. - Native of Morocco. This has strong, almost conical, thorns. Leaves aggregate, flaked, epivive, simple, entire, smooth, about an inch long. Flowers axillary tufts, nearly sessile. Rhunamus fuscus periodatus, Bocc. Spec. v. 8. t. 211, must be a very different plant, having really five leaflets on a common stalk, as Mr. Dryand remarks. Fr. Linn. Soc. v. 2. 225. This I read with particular remarks, that many East India sailors have erroneously been referred by Linnmusis to the Silius species, but he errs respecting the specimen under the name of a Linnmus herbaceous, which is evidently the plant belonging to this synonomy, though not to the supposed iron-wood character, being Flora Arsania, Willd. Sp. Pl. v. 4. 831. Rosk. Com. v. 1. 177.

The reader will perceive that there is considerable uncertainty about the league of the genus; and these is least certainty respecting its generic character, which is not yet clearly described with that of Bumelia; for that reason.

Hindostan, in Geography, a town of Hindostan, in Baglana; 50 miles E. N. E. of Bifleen.

SIDI, in Hindostan Mythology, is the name of one of the
two wives of Ganesa or Polkar, the god of prudence and policy. (See Polkar.) The name of the other was Budhi, and both were daughters of Vijjauvanga; which see. Their names occur but seldom in Hindoo writings.

SIDI Ben Tub, in Geography, a town of Algiers; 30 miles E.S.E. of Meliana.

SIDI Efsa, a town of Algiers; 30 miles S. of Bougieh.

SIDI Gazi, a town of Afstatic Turkey, in Natolia; 4 miles N.E. of Kintaja.

SIDI Ibrahim, a town of Algiers; 30 miles W. of Tubnalis.

SIDI Mebbab, a town of Africa, in Tunis; 20 miles N. of Gabs.

SIDI Shebri, a town of Afstatic Turkey, in Caramania, on a lake; 6 miles E. of Beihheiri.

SIDIALI Eli, a town of Nubia; 55 miles N. of Senmaar.

SIDIBISCHIR, a town of Africa, in the county of Fezzan; 16 miles E. of Mourzouk.

SIDIN, or VATINA, a river of Afstatic Turkey, which runs into the Black sea, at Vatilia.

SIDLA, SIDLAW, or Sudlaw Hills, a range of mountains in the counties of Perth and Angus, Scotland, which form the southern boundary of the great valley of Strathmore, whence they derive their name; Sudlaws signifying, in Erk, the fourth hills. This ridge commences on the west, in the vicinity of the town of Perth, and extends in a north-westerly direction to Redhead, a promontory on the coast of the German ocean, between Aberbrothick and Montrose. The mountains which compose it vary considerably in elevation; some of them not exceeding 800 feet in height above the level of the sea, while others are upwards of 1400 feet high. The following are the heights of several of the principal of them, as ascertained by barometrical measurement: Sidlaw hill, 1406 feet; Kingseat, 1238; Kipurnie hill, noted for an ancient tower on its summit, 1151; and Dunfinnan hill, 1024. The last mentioned hill is remarkable for being on that on the utterpart and tyrant, Macbeth, built a castle, with a view to secure his life against any attempt which might be made to murder him. Sinclair's Statistical Account of Scotland, vol. i. 1791.

SIDMOUTH, a market-town in the hundred of Earl Budleigh, and county of Devon, England, is seated in a valley on the banks of the river Sid, between high hills, at the distance of 145 miles S.E. of Exeter, and 158 miles S.W. of London. Sidmouth was formerly a sea-port of some consequence; but the harbour has been so clogged with sand and pebbles, that pleasure-boats and fishing smacks are the only vessels which can now approach the shore. Of late years the buildings and population have increased, in consequence of the number of persons who frequent the place in the summer, for the purposes of bathing and recreation. Good accommodations have consequently been provided, and a ball-room, billiard-room, and tea-room, erected for the convenience of the visitors. According to the population report in the year 1811, the number of houses in the parish was 349, inhabited by 1688 persons. A weekly market is held on Saturdays, and two fairs annually. Near the beach is an ancient stone building, with very thick walls firmly cemented, traditionally said to have been a chapel of ease, when Otterton was the mothers-church; and in a path leading from Sidmouth to Otterton, called Go-Church, is an ancient stone cross. At Sidmouth was formerly an alien priory, a cell to Mountbrow in Normandy, or rather to St. Michael in Per cubo Maris; for to this last mentioned monastery the manor was given by king William the Conqueror. It was sometimes reckoned as a part of Otterton priory, and, with that, after the dissolution of the foreign houses, was given to Sion abbey; and at the time of the surrender, devoted to the crown. The scenery on this coast, between Sidmouth and Seaton, is grand and romantic; presenting a succession of lofty cliffs, floping ridges, and narrow valleys. In some places the cliffs are composed of sand, tinged by a red oxyd of iron, and is partly calcareous. On the edge of a hill, north-west of Sidmouth, is an ancient encampment, called Woodbury castle, which is of an irregular form, with deep ditches: at some places the fos is double. Observations on the Western Counties, by George Maton, M.D. 2 vols. 8vo. The History of Devonshire, by the Rev. Richard Pole- wheel, 3 vols. fol. 1797. The Chorographical Description, or Survey of the County of Devon, by Triffram Ridfon, 8vo. 1714, 2d edit. 1811. Beauties of England and Wales, vol. iv. 1803, by J. Britton and E. W. Brayley.

SIDNA-BINES, a town of Fez, near the sea-coast.

SIDNEY, PHILIP, in Biography. See SYDNEY.

SIDNEY, ALGERNON. See SYDNEY.

SIDNEY, in Geography, a town on the island of Cape Breton; 20 miles N. of Louisburg.—Allo, a town of New York, on the Susquehanna; 50 miles W. of Hadon.—Allo, a post-town of the province of Maine, on the Kennebeck; 30 miles N.E. of Portland, situated in the county of Kennebec; and containing 1558 inhabitants.

SIDNEY CREE, See SYDNEY.

SIDODOÑA, in Ancient Geography, a barren place on the coast of Carmania, in the Persian gulf, where Nearchus is said to have refreshed himself, in his voyage from the island of Oaraetas to that of Cara, according to his journal of the navigation.

SIDOLOUCUM, or SODELOECUM, a town of Gallia Lycynensis, on the route from Lugdunum to Gefforiacum, between Augulo to dunum and Abellone, according to the Itinerary of Antonine.

SIDON, a town of Phoenicia, 30 miles from Berytus, according to the Itinerary of Antonine. This town was for a long time the metropolis of Phoenicia, till Tyre became more powerful, and contended with it this dignity. Jutin says, that the Phoenicians, being obliged to abandon their country on account of an earthquake, established themselves in the vicinity of the lake of Afylla, which they afterwards deserted, and established themselves on the neighbouring coast of the sea, where they built the town, which they called Sidon. Moles informs us that this town had been built by Sidon, the eldest son of Caman, the father and founder of the Phoenicians. Josina (ch. ii. v. 8) says, that the town of Sidon was rich and powerful when the Israelites took possession of the land of Canaan. St. Jerom says, that it fell to the lot of the tribe of Asher. In the year 1015, Sidon was dependent on Tyre, for Solomon induced Hiram, king of Tyre, to give orders to the Sidonians to procure from Libanus the wood which he wanted for the temple at Jerusalem, which he proposed to build. The Sidonians shook off the yoke of the Tyrians 720 years B.C. and surrendered themselves to Salmanazar, when this prince entered into Phoenicia. Josephus (Antiq.) relates, that about 150 years afterwards, Apries, king of Egypt, invaded Phoenicia with powerful armies, took Sidon by force, which event was followed by the submersion of all the other towns of Phoenicia to the conqueror. Cyrus conquered this city, but the Sidonians obtained permission of the Persians to have their own kings; and they took part in all the expeditions of their new masters, according to Herodotus (i. iii.) and in the war of Xerxes against the Greeks, the king of Sidon, according to Diodorus Siculus (i. xiv.) commanded...
SIDONEY, a town of Hud. in Onde; 42 miles from Karabag.

SIDONIUS, CALIS, SEBIES At Pinym, in Brevet, was born at Lyons about the year 372. He seems to have been of a distinguished family, his father and grandfather having been occupied in the office of procurator-prefect in Gaul. He was liberally educated, and obtained a great reputation for his literary talents, and especially in the practical art of the law.

Coming to the capital he was raised to the highest office by several successive emperors. He married Paparida, daughter of the emperor Augustus, whose favour he obtained by a long period of veracity, which was rewarded by a brass statue of him placed in the portico of Trajan. On the deposition of that prince, he was made a prisoner at Lyons by the emperor Maximian, whose favour he afterwards obtained by a new presentation. He was now employed by Maximian to conclude a treaty with the king of the Vandals, of whose person and manners he has left us a curious description. For this service he was rewarded with the title of count. Under Severus Reimer he defended with the most complete success the honour of the ancients against the incursions of the barbarians. On the accession of Antoninus he was ready with another presentation, and was in this required by the government of Rome, and the dignity of patrician was conferred upon him. In the year 472 he renounced all his secular employments, and became a bishop. He is said to have conducted himself with singular piety in his new office, to have been exemplary for charity, and all the episcopal virtues, and to have fed 4000 Burgundians, when under the perplexity of famine. He was a great sufferer at the siege of Constantinople, and was forced to fly at its surrender, but was very soon restored to his see. He afterwards endured some trouble from two fictitious priests, who contrived with him the government of the church, and also from some who were deemed by him heretics; and to this latter has been ascribed his death, in 487, which has been called a martyrdom. Of the writings of Sidonius, there are extant twenty-four pieces in verse, marked with the debased character of the age, and nine books of Epistles, containing much curious information relative to the learning and history of his times. The best editions of his works are those by Savatier in 1629, and by Simmond in 1652. Maseri, Gibbon, vol. vi.

Vol. XXXII.

SIELOW, in Gresle, a town of Hertford, in Buck. 1

SIELEN, in Hochvogel, a town of Stidz, in the county of Lez. 1434, 4 miles N. of Freising.

SIELENKES, John Philip, Hieroglyphs, professor of philosophy and the Oriental languages at the university of Altdorf, and member of the Society of Jesus, at Veleti, was born in 1739 at Nurnberg, where his father was organist to one of the churches. Being invited for the church, he was initiated in the Latin and Greek languages under very able masters, and he applied himself with great diligence to the Hebrew and Chaldee. In the year 1754 he repaired to the university of Altdorf, where he began to lectures on the holy scriptures, and where, in conversation with some of the other students, he established a private literary society, the first-fruits of which was a dissertation on the relations of the ancient Germans, and other Northern people. The piece was published in 1751, and was so highly esteemed by Errell, that he added it to his translation of Tacitus "De Moribus Germanorum," which was published in 1791. He now became the tutor to some young people, and he not only performed the duties attached to the office for six years with high reputation, but was able by diligence and anxiety to apply himself, at the same time, to researches in the literature, history, and arts of the ancients. He collected materials to compose memoirs of the life of Bianca Capelle de Meide, grand-duches of Tuscany, which was published in one volume octavo at Gotha, in the year 1789. But the chief part of his attention was directed to the MS. treasures contained in the library of St. Mark, from which so many of the classical authors have been printed and improved. His researches here were much facilitated by Morelli, the librarian, who supplied him greatly in the art of deciphering and reading manuscripts, with which he had been unaccustomed. Here he examined with great attention the valuable manuscripts of Strabo; and studied with the utmost care the two celebrated manuscripts of the Iliad, of which, before the appearance of Vallois' edition, he gave a circuit of about 200 in the German work entitled "Biblischen der Atn in Literatur und Kunst." In the same work he published a fragment from the Christ-mathas of Porphyry, collated from MSS. of Helvoct, and worked the same from the printed folio to Plato and other authors. With the same care, and with the same acumen of ancient authors preserved in different collections at Venice. In 1738 he quitted Venice, and made a tour through many parts of Italy, and at Rome he remained fifteen months, entirely occupied in studying the works of art, or in visiting the manuscripts in different
 libraries; and here he was much indebted to Reggio, the learned librarian of the Vatican, who allowed him the use of all those highly valued manuscripts, the greater part of which has been, since that, carried to Paris by the French. From thence, Siebenkees made copious extracts for the improvement of Strabo and other ancient authors; and here he transcribed the Vatican MS. of the characters of Theophratus, which is reckoned the complete and most perfect in existence. He collected likewise from this library a large mass of critical matter for the illustration of the classics, in extracts, fragments, and observations. Cardinal Borghini interested himself very much in favour of Siebenkees, and allowed him the free use of his museum at Velletri, where he wrote an explanation of a "Tellera Hospitalis," preserved in it, which was published with the following title: "Expositio Tabulae Hospitalis in Libro Verrilis afteravit." For this work, which was considered as extremely ingenious, he was elected a member of the learned society of Velletri. On his return to his native country, he visited the most celebrated libraries at Augsburg and Memingen, as well as in various monasteries in Swabia, and formed an acquaintance with many of the German literati. In the year 1755, he returned to Nurnberg, and in the following year he was appointed extraordinary professor of philosophy and of the Oriental languages at Altdorf; after this he was made regular professor of philosophy and history. Between the years 1751 and 1756, besides giving academic lectures on the Oriental as well as the Greek and Latin languages, the history of literature and of the German empire, he founded a periodical publication called "Strabon's Rerum Geographiarum Libri XVII. Graeca ad Opt. Codd. MSS. recensuit var. lect. ad notatiorumque illustrat Xylandri Veronem emendavit I. P. Siebenkees." He contributed to many periodical works, such as "Journal des Luxus," in which he published a picture of Venice; Harles' edition of "Fabrici Bibliotheca Graeca," &c. He died in 1796. He was not distinguished by any uncommon strength of genius; but extraordinary diligence, and a most ardent attachment to literary pursuits, enabled him to acquire a very extensive knowledge of languages and literature in general. He was an excellent draughtsman, and this talent was of great assistance to him in his archaeological researches in Italy. His writing, in his own language, was exceedingly elegant, but his Latin is neither pure nor correct. His service to literature would have been more important had he lived to finish his Strabo, a great part of the second volume of which was left unprinted at the time of his death. Some other works, on which he had been employed, were also left incomplete, viz. an edition of Theophratus, from a MS. copy in the Vatican, and his valuable "Anecdota Graeca," selected from the best MSS. in the Italian libraries. Both these works were completed after his death, and published at Nurnberg in 1798. 

SIEBADAB, a town of Hindooftan, in Benares, on the Ganges: 15 miles N.E. of Benares.

SIEDE, a small river of Germany, which runs into the Wefer, 2 miles S. of Hoyla.

SIEDENBERG, a town of Germany, in the county of Hoyla; 9 miles S.S.W. of Hoyla.

SIEG, a river of Germany, which rises in the eait part of Naffau-Siegen, passes by Siegen, Blankenberg, Siegberg, &c. and runs into the Rhine, two miles below Bonn.

SIEGBERG, a town of the duchy of Berg; 14 miles S.E. of Cologne. N. lat. 50° 58'. E. long. 7° 18'.

SIEGBURG. See SYBERG.

SIEGE, in War, the encampment of an army around a place, with defign to take it, either in the way of dillrecr and famine, by making lines all around it, to prevent any relief from without; or by main force, as by digging trenches, and making formal attacks.

The word is French, and signifies, literally, feast; al-leeding to the army's taking its feat before a town, till the reduction of the place.

The most celebrated sieges of antiquity are those of Troy, Tyre, Alexandria, and Numantium; and, among the moderns, those of Offend, Candia, Grave, Bergen-op-zoom, Gibraltar, &c. See LINE, in Fortification.

SIEG, To raise a, is to give over the attack of a place, quit the works thrown up against it, and the posts formed about it.

SIEG, To turn a, into a blockade, see BLOCKADE.

SIEG-Pieces, in Coinage, a division of modern coins, consisting of those that have been issued upon urgent necessity, during a siege, by any city or town. Patin has published a remarkable one of thick paper or parchment, struck at Leyden in 1754, when that place was besieged by the Spaniards. It has a lion rampant, PUGNO PRO PATRIA; and on the reverse this inscription, LIBERUM BATAVORUM. Various siege-pieces of gold and silver were issued in the reign of Charles I.; some of the latter being too large to be of 20l. value.

SIEGEN, in Geography, a town of Germany, which gives name to a branch of the house of Naffau, in the vicinity of which are some confiderable iron-mines and forges; 37 miles E. of Bonn. N. lat. 50° 48'. E. long. 8° 8'.

SIEGENBURG, a town of Bavaria; 20 miles E. of Ingolstadt.

SIEGES, LEs, a town of France, in the department of the Yonne; 24 miles W.S.W. of Troyes.

SIEGSTADT, a town of Norway, in the province of Agderhus; 58 miles N. of Christiana.

SIELE, a town of Lithuania, in the palatinate of Brazil; 56 miles N.E. of Brazil.

SIELUB, a town of Lithuania; 8 miles N. of Novogrodek.

SIEMIECZOW, a town of Lithuania; 15 miles W. of Sluck.

SIENAGE, a town of South America, in the province of Tacuman; 150 miles N. of St. Miguel de Tacuman.

SIENI, in Ancient Geography, a town of Egypt, situated, according to Piny, in a peninsula, on the western bank of the Nile, in which was a Roman garrison. See SYENE.

SIENITE, Granitelle of Sauffure, in Geology, a rock nearly resembling granite, but composed of felsipar and hornblende, and occasionally containing quartz and mica. The name is derived from the city of Siena, in Upper Egypt, where immense quantities of this stone were worked by the Romans, and large blocks and columns were brought from thence to Rome. The Egyptian fienen is in fact a granite.
granite, intermixed with a small quantity of felspar. Some stones are entirely granite, containing large distinct crystals of red felspar; in other stones, the crystals are very minute, and the whole is greatly predisposed in the latter case, felspar passes into the rock which the Germans call granite, or greenstone. When the felspar is finely granular, but contains a large yield of felspar embedded, it is then designated granite porphyry. This rock frequently occurs in large continuous masses, lying over granite and slate rocks. It is sometimes divided into distinct layers, which, by the German geologists, have been called strata; in other instances, it assumes the prismatic or columnar form. Some mineralogists class all these granite forms with felspar, which contains a portion of hornblende; but this distinction appears useless, for the same mineralogists admit that hornblende is frequently a constituent part of green or flaky granite.

In the infancy of science, substances which are essentially different, are apt to be confounded together, if they possess certain points of resemblance, and in a state of premature state of information or discovery are essential the same, are often separated by artificial classification, into distinct orders or species, by those who are accustom to misrepresent the cabinets of collectors, and overlook the great features of nature. Thus much useless distinction has arisen with respect to certain rocks, whether they were to be classed with granite or felspar, &c. The operations of nature, in the deposition of the great rock formations, are not to be limited by the definitions of the mineralogist. Almost all rocks, with the exception of the calcaceous, pass by such indefatigable gradation into each other, that the most experienced eye would find it difficult to class them, from the insufficiency of detached specimens. Nor will this appear surprising, when we consider that felspar generally consists half or more of the substance of all rocks not calcaceous, whether simple or compound; and even the distinct combinations in compound rocks generally contain about the same proportion of felspar, except quartz, which is almost entirely formed of it. Even in common clay, though the properties of clay are concealed by a portion of aluminum, yet it is still the predominating part of the mass. Now whether rocks were consolidated from a solution, or from a state of igneous fusion, the felspar, or principal ingredient, as it became variously intermixed with the other earths, would be in combination, pass into a vast variety of forms. Where the solution or fusion continued for a longer time undisturbed, the laws of chemical affinity would have free action, and dispense the different elementary parts to form those distinct crystalline forms peculiar to certain combinations and proportions of the earths. Where, from change of temperature, or other causes, the play of chemical affinity was interrupted, the masses would become confusedly crystalline, and lose all appearance of crystallization; and between these extremes there might be every possible variety of graduation, such as we now find to exist.

Hornblende appears to be the substance which connects granite with rocks that have a very different external appearance. When hornblende exists in small quantities in granite, it does not change the character of the rock, where the three essential substances, felspar, quartz, and mica, form the prevailing part of the mass, for chlorite, hornblende, and other minerals, are intermixed in small quantities in the granite of the higher Alps. When the quantity of hornblende is increased, and that of the mica and quartz diminished, the rock is properly what mineralogists denominate felspar. When the hornblende and other minerals, except felspar, are so intimately mixed as to form one homogeneous pile, in which the crystals of felspar are so numerous, it is called a porphyry. When the crystals of felspar are greatly preponderating, with the mica and hornblende, it is termed granite. When the hornblende is more to be considered, it forms rocks to which the names of hornblende and hornblende gneiss have been given. (See Tephra.) Granite has been regarded as a crystalline variety, and hornblende as aony variety, of trap. The latter is abundant in the pyramids of Egypt, where the crystals of hornblende are large and perfect, and it is found in the most celebrated structures of which to test any trace of crystal casts can be seen.

Sienna is found in Cornwall, and the western parts of Wales, and at Chatsworth forest in Leicestershire. It is nearly the latter place it is left to London, and to Northumberland, cut into blocks for paving-places. A black green and red felspar is used in the hedges called Marblefield, which is described in Mr. Hakewell's Geography, covered with a felspar with pyramidal blocks of the stone, which is called the pyramids of Great Britain. Here, we believe, been applied to any other purposes than for paving-places. Many of the ancient tombs in Lower Egypt are formed of this stone; and it has been better observed, that it was brought in great quantities from this country by the Romans, on account of the vast column, on, which could be formed from a pale block. As a proof of its durability, it is flated by trowels that columns which the Romans left unfinished in the quarries of Sienna, many a thousand years since, preserve to the present day the impression of the tools as sharp and distinct as if they had been recently worked.

STEN-KU, in Geography, a town of China, of the third rank, in Teche-kang; it belongs W.S.W. of Tientsin.

SIENNA, or SIENNA, a city of Italy, and capital of a district, in Tuscany. This district, called Sienese, or Territorio di Siena, was once a free republic, conquered by the emperors Charles V, in the year 1554, whose son, Philip II, king of Spain, ceded all parts, except the State of the Priors, to Carlo I., Duke of Florence. The city is pleasingly built on three hills, in a healthy situation. The houses are of brick, and the streets paved with the same. It is nearly five miles in circumference, but not peopled in proportion to its size; the inhabitants scarcely exceeding 15,000. It is the seat of an archbishop, and the cathedral is a fine Gothic building, coated with white and black marble within and without. The great portal was begun in the year 1284, after the designs of Giovanni da Pisa, and finished in 1351, by Agostino and Amedeo, Sienese architects. The front is prodigiously loaded with ornaments. All the work of the inside is most highly finished, as the carving in wood of the choir; the sculpture in marble of the pulpit; and especially the historied engraving of the pavement, representing in charms the most remarkable stories of the Old and New Testament. From an aperture in the choir pavement may be seen St. John's church, which lies directly underneath. Its entrance is without, on the hill; and this one church must be said to stand on another. Near the cathedral is the archbishop's palace, and opposite to it a large and well-endowed hospital, founded by a hermit. Here are also many other churches and convents. The church of the Dominicans is remarkable for its ancient picture-woods, representing the Virgin with the infant Jesus in her arms, by Guido da Siena: it is dated 1221, and is in the Venetian chapel; though to
ancient, it is in good preservation. The university was founded by Charles V. The German students enjoy particular privileges, which they derive from the fame emperor.

In 15th century the academy of the Intronati was here founded. This city still retains some shadow of its former republican liberty, which may appear from the manner of electing its council, which consists of nine persons, styled Excellenze; but whose power the great duke very much curtailed. The castle, built at one end of the city, in order to curb the inhabitants, is of no great strength. Near it is the university's academy for martial exercises. Many nobility reside here, who have a campo or alicrim of both sexes; and it is generally allowed that the Italian language is in a part of Italy spoken with greater purity; 54 miles S. of Palencia. N. lat. 21°. E. long. 11° 16'.

**SIENNE, a river of France, which runs into the sea, near Havre.**

**SIENNOI, a town of Russia, in the government of Mogile; 60 miles N.N.W. of Mogilev. N. lat. 54° 30'. E. long. 29° 44'.**

**SIEREAGE, a town of Hindooftan; 32 miles N.W. of Bavaro.**

**SIERCE, a town of France, in the department of the Moselle. In 1792, this town was taken by the duke of Brunswick; 9 miles N.N.E. of Thionville.**

**SIERMAH, a town of Bengal; 24 miles S. of Palamow.**

**SIERNDORF, a town of Austria; 7 miles N.W. of Korn-Neuburg.**

**SIERNING, a town of Austria; 12 miles S.W. of Ebenfurth.**

**SIERO, a town of Spain, in Asturia; 9 miles N.E. of Oviedo.**

**SIEROCK, a town of the duchy of Warfaw; 15 miles N. of Warfaw.**

**SIERRA, the eastern part of New Caftile, so called from its mountains. The word Sierra is a general name for mountain in Spain, and those distinctive appellations are often given from the neighbouring towns.**

**SIERRA d'Adriana, mountains of Spain, in Guipuzcoa, which took their name from the hermit Adrian. The road leading over it to Alaba and Old Caftile is very difficult to travellers. At the very beginning of it is a dark space, between 40 and 50 paces in length, cut through a rock; after which we ascend up a hill, which is reckoned the highest among the Pyrenees. These mountains are but little inhabited, a few shepherds' huts only being to be seen; 18 miles S. of Tolofa.**

**SIERRA de Bejer, a mountain of Spain, in the province of Leon; 20 miles N.N.E. of Plafencia.**

**SIERRA Cerver, a small rocky island, near the east coast of Sardinia. N. lat. 30° 40'. E. long. 10°.**

**SIERRA del Cid, a mountain of Spain, in Valencia; 14 miles N.W. of Alicante.**

**SIERRA de Cobos, a mountain of the island of Cuba; 15 miles W. of St. Jago.**

**SIERRA de Guadarama, a mountain of Spain, in the south part of Old Caftile; 15 miles S. of Segovia.**

**SIERRA de Gador, a mountain of Spain, in the kingdom of Grenada; composed of marble, of which they make excellent lime; 12 miles S. of Almeria.**

**SIERRA de Gredos, a mountain of Spain, in the province of Leon; 25 miles N.W. of Plafencia.**

**SIERRA Jalon, a mountain of Spain, in Estremadura; 20 miles N.N.W. of Coria.**

**SIERRA Leone, a country of Africa, in Upper Guinea; so called because it is mountainous, and the mountains abound in lions. It is composed of several states or kingdoms, and is well watered by a river of the same name, at the mouth of which an association of English gentlemen established a settlement, on land purchased of the prince of the country. This company was incorporated by act of parliament, in the year 1751. A considerable number of whites and free negroes were conveyed thither from Nova Scotia, besides many who went from England. At first the new settler seem to have suffered from the want of proper habitations during the rainy season, but subsequent accounts were more favourable. In the month of December 1793, the natives continued perfectly friendly; the neighbouring chiefs shewed every desire of being connected with the company; some had sent their children to be educated at Sierra Leone, and many others proposed to send them in the ensuing dry seafon. The rainy season had passed over without any considerable mortality; and the Nova Scotia colonists had maintained their health, and appeared to have become well insured to the climate. The trade was much more brisk; the cultivation was advancing, both in the colony and parts adjacent; and there appears to have been no difficulty in procuring the native labourers. The rice, cotton, and other articles in the company's plantation, had thrived exceedingly, the sugar-cane excepted, which had been hurt by the white ants. The school of the company contained between 300 and 400 children, chiefly Nova Scotians, who appear to have made full as much improvement as is common in European schools, under similar circumstances. The colony had gradually improved in order, and appeared to be advancing in every respect; but neither these appearances, nor several parliamentary aids, could support it sufficiently against new difficulties which continually occurred; and the company was dissolved in 1807. Sierra Leone river abounds in fish, but is much infested with alligators. The country adjacent produces abundance of millet and rice; and the woods are filled with parrots of various kinds, and other beautiful birds; serpents are found, some of a very large size; and numerous wild beasts, such as lions, tigers, elephants, wild boars, and monkees. The benevolent and laudable exertions of the African Inquisition, established since the abolition of the slave-trade, have very much contributed to the prosperity of the colony of Sierra Leone. The climate is much better for European constitutions than that of almost any other part of the coast. There are now 4000 houses within the walls of Freetown, containing 1917 inhabitants, besides about 2500 Negroes, freed by sentences of the admiralty-court, and residing there under the protection of the government. There is a considerable

SIEUGUR, a town of Hindoollan, in Malwa; 9 miles S. of Pandia.
SIEVI, a town of Sweden, in the government of Ulea; 45 miles S. of Brahellation.
SIEUR, a title of honour, or quality among the French; chiefly used among the lawyers, and in public acts, and other writings of that kind.
The title sieur is also given by a superior to an inferior, in his letters and other private writings.
In this sense, authors sometimes use it, by way of modelly, in speaking of themselves; thus, at the heads of books, we lee Traduction du sieur d'Ablandart; Œuvres du sieur d'Epréaux, &c.
SIEUR is also a term expressing feigneurly, or lordship: as ecuyer or sieur of such a place.
SIFACE, Giovan Francesco, Detto, in Biography, a celebrated opera-finger in the service of the court of Modena, who obtained the title of Siface from his admirable performance of the part of Syphax, in the old opera of Mitridate, modernized by Metafello, and set by Porpora for Venice in 1730. Algarotti highly praises the pathetic manner in which he sung. Though it is confidently afferted, in the work of a late historian, that Siface had been in England as a finger in the chapel of king James II., yet we can trace no proof of this affertion.
In travelling from Ferrara to Modena, he miserably lost his life in a quarrel with an insolent and brutifli officer.
SIFANS, or Tou-fans, in Geography, subjects of the Chinefe empire, who inhabit to the west of China, and the provinces of Cheff-el and Se-tchuen. Their country is only a continued ridge of mountains, inclosed by the rivers Hoang-lo on the N., Ya-long on the W., and Yang-tie-king on the E., between the 30th and 35th degrees of north latitude. They are divided into two kinds of people; the one are called by the Chinefe black Si-fans, the other yellow, distinctions arising from the different colours of their tents. The black are the moft clownifli and wretched; they live in small families, and are governed by petty chiefs, who all depend upon a greater.
The yellow Si-fans are subject to families, the oldest of which becomes a lama, and allurnes the yellow drefs. These lama-princes, who command in their respective districts, have the power of trying caufes, and punifhing criminals; but their government is by no means burdenfome: provided certain honors are paid them, and they receive punctually the dues of the god Fo, which amount to very little, they molest none of their subjects. The greater part of the Si-fans live in tents; but some of them have howfes built of earth, and even brick. Their habitations are not contiguous; they form at mofl two hamlets, confifting of five or six families. They feed a great number of flocks, and are in no want of any of the neceffaries of life. The principal article of their trade is rhubarb, which their country produces in great abundance. Their horefes are small; but they are well-shaped, lively, and robust.
These people are of a proud and independent fpirit, and acknowledge with reluctance the fuperiority of the Chinefe government, to which they have been subjected: when they are fummoned by the mandarins, they rarely appear; but the government, for political reafons, fends to this contempt, and endeavours to keep thefè intracatable fubjects under mildnefs and moderation; it would, besides, be difficult to employ rigorous means in order to reduce them to perfect obedience—their wild and fchrought mountains (the tops of which are always covered with fnow, even in the month of July) would afford them places of shelter, from which they could never be driven by force.
The culmefs of these mountaineers are totally different from thofe of the Chinefe. It is, for example, an act of great politenefs among them to preferent a white handkerchief of taffety or linen, when they accoft any perfon whom they are defirous of honouring. All their religion conflits in their adoration of the god Fo, to whom they have a fingular attachment: their fuperficitious veneration extends even to his minifters, on whom they have confidered it as their duty to confer fupreme power, and the government of the nation.
Some of their rivers wash down gold mixed with their sands: they are acquainted with the art of applying it to life, and form it into vafes and small Statues, of which they often make offers to their idol; it even appears that the life of gold is very ancient among them; for Chinefe books relate, that under one of the emperors of the dynasty of Han, an officer having been fent to the Si-fans to complain of the ravages committed by some of their chiefs, they endeavoured to appeafe him by making him a present of a piece of gold plate, which the officer refufed, telling the Si-fans, that rice ferved up in golden dihes was to him infufible food.
These people have loft much of their ancient splendor; for the Si-fans, who at prefent are confined in a wild country, where they have not a single city, enjoyed formerly an ex-""
SIGA, a town of Aetos, Turkei, in Natisa, on the Tana; it belongs to the S.W. of Smyrna.

SIGA, in Ancient Geography, a town of India, on the Ganges, to which Ptolemy assigns its limits.

SIGARA, a town of Archelaus, Ptolemy's.

SIGARA, in Geography, a town of Hindostan, in Calcutta; 12 miles N. of Bahrein.

SIGATHA, in Ancient Geography, a town of Libya. Strabo.

SIGIAN, in Geography, a town of France, in the department of the Auvergne, near which Charles Martel defeated the Sarazens; 9 miles S. of Neuronne.

SIGEBERT I., in Geography, king of Austrasia, born about the year 555, was the son of Charles I., king of the Franks. At the death of that sovereign, in 562, his dominions were divided between his sons; and Austrasia, or the kingdom of Metz, fell to the lot of Sigebert. His territories were invaded, soon after his accession, by the Huns, whom he defeated and drove across the Elbe. During his absence, his brother Chilperic made an inroad into Austrasia, and took several places; but Sigebert returning with a victorious army, took Strassburg, Chilperic's capital, and defeated Chilperic himself in battle. He was, however, induced to grant him favourable terms, and to restore the conquests made upon him. Sigebert's reputation was now so high, that he obtained for a wife the famous Brunehaut, daughter of the Spanish king of the Visigoths, with a rich portion. The dominions of his brother Chilperic, at his death, were shared by the three survivors; but it was not possible for such a divided empire to continue long at peace. Chilperic had married Gislaundia, sister of Brunehaut, who was afterwards murdered at the instigation of her husband, Thibaud. Brunehaut married Sigebert; in consequence of his brother Chilperic, king of Burgundy, by order of this crime, and they overran a great part of his dominions.
fary to form an entire office to his honour. And this information is copied by Fabricius, De Script. Eeclelf. Arte Mufica Antipthonas et refponforia de fancius.

SIGENBURY, in Geography. See Siegenburg.

SIGENUS PORTUS, in Ancient Geography, a port of Africa, on the coast of Mauritania Caftariensis, between Siga and Camarata, according to the Itinerary of Antoninus.

SIGER, in Geography, a river of Silefia, which runs into the Oder, six miles below Beuthen.

Gen. Ch. Outer Common Calyx of five linear, cylindrically, widely spreading, permanent leaves, longer than the flower: inner somewhat five-angled, of several ovate, concave, obtuse, equal leaves. Cor. compound, with a half radius. Florets of the disk united, several, funnel-shaped, exceeding the calyx in length, with either five or three teeth; of the radius five, or not so many, all on one side of the flower, female, ligulate, broad, short, three-cleft. Stem. in the united florets, Filaments five or three, very short; anthers combined in a cylindrical tube. Pifl. in the united florets, Germs oblong, incurred, the fize of the calyx; fyle thread-shaped, the length of the lamens; stigma divided: in the females, Germs oblong, incurred, the fize of the calyx; fyle and stigma as in the united florets. Peris. none, the calyx remaining unchanged. Seads in the united florets foliate, oblong, bluntly quadrangular, thickened upwards, obtuse, naked; down none; in the female ones the fame. Recept. chaffy; scales very like the scales of the calyx, concave, embracing the seeds at one side, deciduous.

Eff. Ch. Receptacle chaffy. Seed-down none. Outer common calyx of five leaves; inner spreading. Radius all on one fide.

Obf. S. flofeufola of L'Heritier offers a fingular exception in this great natural clafs, with regard to number, having the florets of the disk three-cleft, and triandrous.

1. S. orientalis. Oriental Siegebeckia. Linn. Sp. Pl. 1269. Willd. n. 1. Ait. n. 1. (Siegebeckia; Linn. Hort. Cliffs. 412. t. 23. S. triangularis; Cavan. Ic. v. 37. t. 253. Cichoreo aflinnis, Lampiana finica, mentaltri folinis, calyce fimbrato hipidio, finici bi-bin-fiasco dicta; Pluk. Amath. 58. t. 308. f. 2.)—Leaves falked, ovate, unequally toothed; fomewhat angular at the bafe. Outer calyx twice as long as the inner.—Native of China and the Scaf. Indies; also, according to Cavannels, of Mexico. Thouin informed the younger Linneus that he had it from the Cape of Good Hope, and thetraits of Magelle. The plant has been known for near a century in the gardens of Holland and England, and is a tender annual, flowering in July and August, but with much more finguarity than beauty to commend it. The fluem is bulky, leafy, round, rough, three or four feet high. Leaves opposite, rough, two or three inches long, somewhat dilated and triangular at the bafe, tapering down into each fchool; the uppermost much smaller and more oblong. Flowers numerous, terminal, flaked, brownish-yellow, chiefly confpicious for the spreading outer leaves of their glandular vifcid calyx, each three-quarters of an inch long. We cannot agree with Willdenow in difcarding Pluknet's fynonym, which fully agrees better with this than with the following.

2. S. hifier. Georgian Siigebeckia. Willd. n. 2. (Bidenti fimillis, folii latifsimi ferrati; Buxb. Cent. 3. 29. t. 52.)—Leaves flaked, ovate, bluntly toothed; rounded at the bafe. Outer calyx the length of the inner.—Oberved by Buxbaum about villages in Media, flowering in July. Willdenow, who had been a dry fpecies, afferts this to be a very diftinct fpecies from the former, to which Lin- neus referred Buxbaum's fynonym. The leaes, in fomes, are neither triangular, nor cut at the bafe, but ftortly and bluntly toothed. The outer and inner calyces, being both of an equal length, feem to us a more certain dif- tinction.

3. S. flofeufola. Small-flowered Siegebeckia. L'Herit. Strips. 37. t. 19. Willd. n. 3. Ait. n. 2. Pursh n. 1. Ehrh. Exifcc. n. 79.—Leaves nearly fellige, ovate, toothed. Florets of the disk three-cleft, triandrous.—Native of Peru, from whence we believe its feeds were brought or fent by the unfortunate Domby. This has the habit of the ftrict fpecies, but the fluem is fmeother. The leaes, though taper- ing at their bafe, are fcarcely flaked, nor are they at all dilated, or angular. The gpateft peculiarity is found, as we have already faid, in the flowers, which are smaller and paler than thofe of S. orientalis, ufually, though we believe not always, deftiru of a radius, but fingularly remarkable for the florets of the disk having only three teeth and three flaments.

SIGET, in Geography, a town of Hungary, on the frontier of Poland, near the fource of the Teyffle; 50 miles E. of Munkaaz. See also Ziger.

SIGEUM, in Ancient Geography, a town and port of Asia Minor, in the Troade, at the dilance of 60 fladia from the town of Rhizeteum, and 100 fladia from Tenedos. Strabo reports that this town was ruined in his time. The Myli- tenians built it; but soon after the Athenians expelled them, which occasioned a long war between these two people; but at length, according to Herodotus (v. v.), having fubmitted it to the arbitrament of Periander, the fon of Cyppifie, this prince adjudged it to the Athenians, in the year 564 B.C. or, according to the computation of Ufer, in the year 589. The Athenians kept posffion of it till the time of Alexander. Under his succesfors it was defroyed by neigh- bouriing people. Pliny speaks of it as of a town which had long ago fubfifted: "quoadam Sigaeum oppido." Sigeam was re-establishied under the Christian emperors, and erected into a bifhopric dependent upon Cyccus. A fifeable village, which has been built upon its ruins, and which preffes a few vestiges of the ancient town, is called by the Turks "Yenitcher Keui," or village of the janizaries, and "Diguir- Keui," or village of the infidels, as it is no longer occupied except by Greeks. The curious go thither to admire a block of marble, eight or nine feet long, placed by the fide of the door of a church: it bears a Greek inscription, al- most entirely effaced, the words of which follow one another without interrupftion, i.e. that the firft runs, as among us, from left to right, and the fconf runs back from right to left, and so on to the end. (See Boutraphedon.) On the other fide of the door is feen a bas relief in marble, tolerably well wrought: it represents a woman feated, to whom other women appear to offer children in fwallding clothes; behind there is feen another woman, holding a box in one hand and a vafe in the other.

SIGEUM
...riddlr-ttring, guMUi Rome, I Ik with nay, larger but is i as. SiKkK, adults (J thrir the 65 in fpedicles l>ric-,.,, retain. kind entirely. and mile in li' thr haa ii not and It greatly. but never of is;, ''' plam, fmall mite EMrnt. »r timr, left a mitei, ..oo. thriltt and and Alkmti; 5 thrfe thr miiiiirr. it whi. vide idatioo; al the that the on It vK'iikltv retinal, it, eyi to the that this, and pupill we have, of every of this concur, of a farcely acquirrs, that it is extremely to see at all, or at best very imperfectly and slowly.

This imperfect vision may either owe its fault to the one of the humar, or to its parts; to, fey, or retin, or complexly in them all together. It is for to discover whether there be any imperfection in the retina in this state of life, that men are born ever, in new infants, tender and light like a puppy; if it be in any of the other parts that the imperfect is so, it must be either in their nature or extent. M. Petit, of the Academy of Sciences at Paris, determined to examine thoroughly into the cause of this, was at the pains of detecting the eyes of several inants which had died soon after their birth, and in three-fourths of them he found the vitreus, the crystalline, and the capsule, all greatly deficient in their transparency. The uvea appeared also more opaque in adults, and the pupil oveal; and that there was either more, or, at the utmost, very little of the aqueous humour; and of those eyes where the humours had not this opacity, they were all, as were also the membranes, of a redish colour; and this was observed in instances of seven and nine months old.

The cornea in these eyes was also remarkably thick, which is, in general, found to be the case in the eyes of all foetuses. The thickness and opacity in these corneas gradually diminsh in time, and that soon; so that the eyes of children appear much brighter at two or three months old than when new-born. The aqueous humour seems also, in all foetuses, to be wholly wanting; and where it is found, is ever greatly in an under proportion to the other humours.

It therefore appears, that the diminu and imperfection of light, in new-born infants, are owing to the over-thickness of the cornea, and to the too small portion of the aqueous or watery humour. It appears plainly also, from experience, that the eye is not able, in infants, to bear the light, till the pupil is greatly contracted; as is the case also, though in a less degree, in adults; and it is very probable, that the extreme softness of the retina in this state may make every ray of light affect it much more plainly than when grown more firm.

M. Petit having continued his examinations of the eyes of infants, up to the age of five or fix weeks, found in all his dissections, that the cornea daily grew more and more convex and glossy; and this may be rationally concluded to be owing to the daily increse of the aqueous humour, which must, by that accretion, throw it out into a greater convexity, and make it daily more and more thin and transparent. The uvea also acquires a greater extension, and its fibres become more moveable; whence the pupil acquires a power of enlarging or contracting itself, at the approach or absence of light, with much more ease and readiness than it could before. The humours thus all become capable of letting in a larger quantity of light; the retina is at the same time every day gaining a new firmness, and the pupil becomes capable of an easy dilatation, or refraction, for the letting in occasionally a greater or less number of rays, and the refractons are perfected by the augmentation of the aqueous humour. It is plain, therefore, that the clearness of vision mill every day increase. All this change comes on in infants only by time; and it may be judged of, as to its state, by inspection, by the brilliancy and convexity of the cornea, and by the manner of their turning their eyes towards objects, as before them; and this time is not cer-
tain, or limited, but differs greatly in different children, some being able to see clearly at the end of a month, others not till after many months.

At the time that this gentleman was disjecting the eyes of human foetuses and infants, he also curiously observed the eyes of young quadrupeds. The puppy, when newly brought forth, has always its eyes opaque; the kitten, on the contrary, has them clear, and every way like those of adults of the same species. In foetuses of other quadrupeds, the lamb has its cornea a little turbid and opaque; the calf and the pig have them more or less opaque, but the calf so much of all. Mem. de l'Acad. Par. 1737.

SIGHTS, in Botany, denote two thin pieces of brass, raised perpendicularly on the two extremes of an alidade or index of a theodolite, circumferentor, or other like instrument; each of which has an apature or slit up the middle, through which the visial rays pass to the eye, and distant objects are seen. Their use is, for the just direction of the index to the line of the object.

Sometimes the slits or apatures have glasss or leaffes fitted into them; in which case, they are called teleopic sights, by way of diminution from the former; which, in respect of the others, are denominated plain sights.

Mr. Flamsteed and Dr. Hooke absolutely exploded the use of plain sights in astrononimal observations. The errors in Tycho's latitudes of the stars Mr. Flamsteed ascribes wholly to his using plain sights; and inspects that Hevelius, using the same kind of sights, must fall into the like errors. Hevelius, on the contrary, in a paper in the Philosophical Transacions, vindicates the use of plain sights, and prefers them to teleopic ones: the main objection he makes to the latter is, that no observation can be safely taken with them, without first examining and rectifying them; in which examination, many and gross mistakes are likely to be committed. To which he adds, that in sextants, octants, aximuth quadrants, &c. he does not see how such examination can be made, at all times, without much loss of time.

SIGILLARIA, a solemn feast held among the ancient Romans; thus called from a custum which obtained therein, of sending little presents from one to another, confifting of seals, little figures, and sculptures, made of gold, silver, brass, or even earthenware, and of devoting them to Saturn, as an atonement for themselves and their friends.

The Sigillaria followed immediately after the Saturnalia, and held two days; which, with the five days of the Saturnalia, made a solemnity of seven days.

Some derive the origin of sigils and figures, in this solemnity, from the argel, or rather figures of men, thrown annually into the Tiber, from the Pons Sublicius, by the Veiltsa, on the ides of March. Vide Macrob. Saturn. lib. i. cap. 7, 10, and 11. See also AREGA.

SIGILLATA TERRA, a name given to several kinds of medicinal earths marked with seals, to express their being genuine. The principal is the Lemnian earth: this is a kind of earth, or bole, dug in the ile of Lemnos, and then also called Lemnian earth; of confiderable use in medicine.

It was anciently found in a mountain, in the neighbourhood of the city Phaethidia, where Dianas priests went, at certain times, with great ceremony, to dig it up. After a little preparation, they made it up into troches, and sealed them with Dianas seal; whence the appellation of sigillata, sealed.

SIGILLO, in Geography, a town of Italy, in Umbria; 12 miles N. of Nocera.

SIGILLUM, a seal, or signet.

SIGILLUM Marie, Lady's Seal, in Botany, a name by which some authors have called the bryonia nigra, or black bryony, a climbing plant, common in hedges.

SIGILMESSA, in Geography. See SUGULMESSA.

SIGINDUNUM, in Ancient Geography, a town of Upper Macedonia, on the banks of the Danube, according to Ptolemy.

The Itinerary of Antonine marks it on the route from Rimini to Byzantium, between Taururnum and the mount of Gold.

SIGINNI, a people of Asia, who, according to Strabo, had the same manners with the Persians.

SIGISA, a town of Hifpania, upon the Tader, N.W. of Vergilia.

SIGISMONDO, in Biography. See INDIA.

SIGISMUND, emperor of Germany, and king of Hungary and Bohemia, was the son of the emperor Charles IV. of the house of Luxemburg. He was born in the year 1366, and at an early age was sent to the court of Lewis, king of Hungary, to one of whose daughters he was betrothed, with the intention of making him successor to the throne. During his minority, a party of nobles conferred the crown on Charles, king of Naples, on which event Sigismund retired to Bohemia. Charles being afflicted by the contrivance of the queen-mother, who was put to death for the crime, Sigismund assembled an army, and entering Hungary, liberated his wife Mary, who had been imprisoned, and was crowned king when he was in the twentieth year of his age. He severely revenged the execution of his mother-in-law; and getting possession of the persons of the nobles who had invited Charles, he caused them all to be beheaded, to the number of thirty-two. The bloody act occasioned so much disaffection, that the Turkish emperor Bajazet determined upon taking the opportunity of invading Hungary, which he did with complete success; and Sigismund was dethroned. He however escaped, and retiring to Bohemia, levied troops, with which he recovered his crown, and being brought to reason by adversity, he thenceforth conducted himself so as to obtain the good-will of his people; and such was the reputation which he now acquired abroad, that he was elected emperor of Germany.

The first object of Sigismund in his new dignity, was to put an end to various disorders and divisions which prevailed in Germany. He held a conference with pope John XXIII. for the convoking of a council, the principle object of which was the termination of the schism in the papacy which had long divided the church. He engaged with great zeal in this matter, and at length effected the assembling of a council at Constance, in 1414, at which he himself was present. As the opposition of the Hufites to the doctrines of
of Rome was now making great progress, the emperor granted a safe-conduct to John Huts to come to the council, and defend the articles of his faith; and it was to be his everlasting disgrace, that he fulfilled the council to violate the protection he had solemnly given, and to bring this reformer to the stake. He now endeavored to restore peace among the Christian princes, that they might concert in a plan for re-forming the unity of the church: with this view he visited both France and England, then at war with each other, but with little success. The council, however, agreed in deploving the existing papacy, and electing a new one. Upon the death of his brother Wenceslaus, in 1419, Sigismund succeeded to the crown of Bohemia, which country was in a flame, from the revolt of the persecuted Hussites, under their leader the famous Ziska. He marched with an army into Bohemia, but was entirely defeated by Ziska, and the same fortune attended him a second time. After the death of that hero, a long term of bloody wars succeeded, which at last terminated in the submission of the Thaborites, as the insurgents were afterwards called, and Sigismund was crowned at Prague, in the next year, and reduced the whole kingdom to obedience. He had some years before this received the imperial crown both at Milan and at Rome. His bigotry urged him to tyrannical proceedings against his Bohemian subjects, which excited their animosity to such a degree, that he determined to leave the country. When he was just upon the point of putting this resolution into execution, he was seized with a mortification in his toes, which was the preface to approaching infirmity, and having publicly declared his fon-in-law, Albert, duke of Austria, the heir to his dominions, he died in December 1437, in the 71st year of his age, and the 27th of his imperial dignity. Sigismund is said to have had a fine person, and to have polished various accomplishments, especially an uncommon skill in the learned languages. He was, moreover, a patron of learned men, was liberal, brave, and active; but, on the other hand, he was cruel, vindictive, and superciliously devoted to the clergy. He was licentious in his conduct, the confeiscuifnes of which made him indulgent to the open and abandoned debauchery of his second wife, Barbara de Celley, denominated the Melfaina of Germany.

Sigismund I. king of Poland, surnamed the Great, was the son of Casimir IV. He succeeded his brother Alexander in 1507, and immediately applied himself to the remedying of abuses that had crept into the administration of public affairs. In this arduous task he was assisted by the able and faithful minister John Bonner, whose name is still held in veneration by the Poles. A rebellion in Lithuania, abetted by the tsar of Muscovy, joined to an incursion of the Walachians and Moldavians, obliged him to put himself at the head of the troops, and he completely succeeded against his enemies. The next antagonist with whom he had to contend, was the marquis of Brandenburgh, grand-master of the Teutonic order, who had refused to acknowledge the sovereignty of the king of Poland over the province of Prussia; in this dispute he was also successful, and obliged the marquis to grant him half the province of Prussia, as a barrier against the Teutonic knights. Sigismund now fat down the peaceful sovereign of Poland, Lithuania, the duchies of Smolensko and Severia, and considerable territories on the Euxine and Baltic, while his nephew Lewis was king of Hungary and Bohemia. This accumulation of power gave umbrage to the house of Austria, which, by its intrigues, incited the Walachians, Tartars, and Muscovites, to make new rooods. Thele, however, were soon driven back with great loss to their own countries, and Sigismund left again in peace. He died, after a wife, fortunate, and long reign, in the eighty-first year of his reign, in the year 1544.

Sigismund II. of Poland, king of Poland, one of the preceding, was elected to the crown when his father's death. He reduced the noble by marrying the widow of an obscure peer; and it is asserted, that, to recover from the knave, he permitted them to live in their houses for collection to the Prebendal universities of Germany, which was the means of introducing the opinion of Poland. He himself removed attached to the old religion, and by his prudent and moderate conduct kept out the kingdom those disorders which disturbed the peace of so many other European countries. He was extremely diligent in promoting the improvement of his states by wise laws and regulations, and the correction of abuses, which enabled him to maintain a powerful standing army without the addition of new taxes. This force he had occasion to employ as a auxiliary to his kinsman the archbishop of Riga, against an invasion of the Swedes. He made himself master of great part of Livonia, and forced the grand-master of the Teutonic order, who had called in the Russians, to rescind their alliance, and put the order under the protection of Poland. From this period Livonia was annexed to Poland, and the grand-master abdicating his dignity, received in compensation the duchies of Courland and Semgallia, which long remained in his family. The tsar, John Lazlovitz, made an irruption into Lithuanus, which occasioned much bloodshed and devastation, and Sigismund was glad to propose an armistice; and while this measure was in discussion, the king of Poland died in 1592, leaving only two daughters, and with him terminated the male line of the house of Jagellon. He left a high character for courage, ability, and every princely quality, but he is said to have been too much attached to the fair sex.

Sigismund III. king of Poland, surnamed De Vaio, was the son of John III. king of Sweden, and Catharina, daughter of Sigismund I. king of Poland. He was born in 1566, and in 1587 was elected to the crown of Poland, in competition with Maximilian of Austria. Through the exertions of Zamofki, the crown-general, after a civil war, in which Maximilian was defeated and taken prisoner, Sigismund was firmly seated on the throne. He governed successfully with the alliance of Zamofki, till the death of his father, in 1592, left him heir to the crown of Sweden. As he was a zealou Catholic, and the Swedes were friendly to the Reformation, they felt disinclined to come under his authority; besides that, the duties of a king of Sweden, and of a king of Poland, seemed to be quite incompatible. His uncle, duke Charles, who had been declared regent during Sigismund's absence, inflamed these dissensions. Sigismund having obtained permission from the Polish diet to visit his other kingdom, arrived in Sweden in 1591, accompanied by the pope's nuncio, and his proceedings soon proved how much the restoration of the Catholic religion was the object of his wishes. Violent dissensions arose between him and the states, and in 1595 he returned to Poland, leaving Sweden in the greatest disorder. In 1598, Sigismund again entered Sweden at the head of a foreign army, and a civil war ensued, which terminated in a pacification, and the king returned to Poland. Peace did not last long, and in 1604 the Swedes formally deposed him, and raised his uncle Charles to the throne. War succeeded between Poland and Sweden, which ended in the conquest of Livonia by the Polish general.

Ruffia, at this time, being thrown into confusion by a revolution, Sigismund took part in its disorders, and entering that country, in 1610, at the head of a numerous army,
gained in the outlet such advantages, that he was enabled to place his son Uladifan on the throne. He was, however, soon after dethroned, and all the conquests made by Sigismund were recovered by the Ruffians. During the remainder of his reign, the Poles were involved in wars with the Turks, and afterwards with the Swedes under Gustavus Adolphus. To the latter they were obliged to cede Livonia, Finland, and Prufiia; and the concluding years of Sigismund were clouded with disasters. He fell into a state of melancholy and diseafe, by which he was carried off, in the year 1669. His character has been thus drawn in very few words: "With some talents for government, his religious bigotry, and obstinacy of temper, precipitated him into errors which cost him one crown, and rendered the other a scourge of perpetual disquiet."

SIGIUS, in Ancient Geography, a town of Italy, on the coast of Aulonia, according to Appian.

SIGIUS Mons, or Setius, according to Ptolemy, a mountain of Gallia Narbonennis, on the coast of the Mediterranean sea. Strabo.

SIGMA, among the Romans, the name with the flibadium.

SIGMARI\NGEN, in Geography, a town and county of Germany, involved in the house of Hohenzollern, on the Danube; 44 miles E. of Stuttgart. N. lat. 48° 2'. E. long. 9° 16'.

SIGMOID, in Anatomy, an epithet applied to various parts of the body, from their figure being similar to that of the Greek letter ε. Thus, we have the sigmoid cavities of the uina (see Extremities); sigmoid flexure of the colon (see Intestine); and sigmoid valves of the aorta and pulmonary artery. See Heart.

SIGN, SIGNUM, a featable mark, or character, denoting something absent or invisible.

Anciently the monks, in all religious houses, were not allowed to speak, nor to express their minds, otherwise than by signs, which they learned in their noviciate. C. Rhodiginus and Porta have written of the ancient signs and cyphers used in speaking and writing. Sign, in Algebra, denotes a symbol, or character.

Signs, like, negative, and radical. See the adjectives.

Sign, in Medicine, any appearance in a disease which is cognizable by the senses, and from which some judgment may be formed respecting the nature of the disease, and its probable termination. It is now more commonly called a symptom; which see.

Sign, Antecedent. See Antecedent.

Sign, in Astronomy, a twelfth part of the eclipitic, or zodiac; or a portion, containing thirty degrees of it.

The zodiac was divided, by the ancients, into twelve segments, called signs; commencing from the point of intersection of the ecliptic and equinoctial; which signs they denominated from the twelve constellations, which, in Hipparchus's time, possessed those segments. But the constellations have since changed their places, by the precession of the equinox, that Aries is now got out of the sign called Aries, into Taurus, Taurus into Gemini, &c.

The names of the twelve signs, and their order, are as follow: Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pijces; each of which, with the flars thereof, see under its proper article, Aries, Taurus, &c.

The signs are distinguished, with regard to the seafon of the year when the sun is in them, into vernal, summer, autumnal, and brumal.

Signs, the vernal, or spring, are, Aries, Taurus, Gemini.

Signs, the afficial, or summer, are, Cancer, Leo, and Virgo.

Signs, the autumnal, are, Libra, Scorpio, and Sagittarius.

Signs, the brumal, or winter, are, Capricornus, Aquarius, and Pijces.

The vernal and summer signs are also called northern signs.

And the autumnal and brumal signs, southern signs.

Signs, Affixed. See Ascending.

Signs, Fixed. See Fixed.

Signs, Masculine. See Masculine.

Sign Manual, the setting one's hand and seal to a writing. See Signature.

The expression is used when any bill or writing is signed under the hand of the king, &c. Counterfeiting the sign manual, privy signet, or privy seal, is treason. 1 Mar. fl. 2. cap. 6. See Patents.

Among the Saxons, before the invention of seals, a + was a common sign, or segnum, prefixed to the names of moat subscribing witnesses in charters, and other deeds; as: + segnum Roberti Episcop. Lond. &c. See SEAL.

Sign of Reference, in Media, signa repetitio. See Segno.

Signs of Diffige in Horfe, the appearances which flew them to be out of order. The first sign of a horse's indisposition is, its loathing his food, especially when he has a wild and haggard look; as the eye of a horse is, as it were, a glass, through which may be discerned the inward disposition of his body: it should also be observed whether his ears be cold, his mouth hot or clammy, the hair of his flanks rough and flaming, and paler than usual about the ends; his dung hard, black, or greenish, and his urine clear like water. In this case his eyes are also subject to weep; his head is heavy and hanging down; he is apt to stumble as he walks; he is flow and dull, though he was vigorous before; he never minds other horses; contrary to his former custum, he rise and lies down often in the stable, looking towards his flanks, which are doubled and folded in; his heart beats quick; and he is also indifferent and unconcerned at what is done to him. These and many other signs are met with in horses which are not in a state of perfect health, and should be immediately attended to; and suitable remedies are applied. This is of much consequence to be taken care of in teams and other work horses belonging to farms, &c.

SIGNA, Standards, among the Romans, were of different sorts; on some of them the image of the emperor was represented, and they that carried them were called imaginiferi; others had a hand stretched out, as a symbol of concord; and these ensign-bearers were called signiferi; some had a silver eagle, the bearers of which were called aquiliferi; others had a dragon with a silver head, and the rest of his body of taffety, which was blown by the wind as if it had been a real dragon, and the bearers of this ensign were called draco\narii; lastly, the emperor's ensign was called labarum, and those that carried it labariferi, which they carried out when he went in perfon to the field; it was of a purple colour, befet with gold fringe, and adorned with precious flowers.

All these ensigns were sustained with a half-pike, sharp at the end, that it might be the more easily fixed in the ground.

SIGNAL, a certain sign agreed upon for the conveyance of intelligence to places to which the voice cannot reach.

Signals are given for the beginning of a battle, or an attack; usually with drums and trumpets; a call, they are given by cannon or musket-shot, by lights, flags, &c.

All signals may be reduced into three different kinds: viz., those which are made by the sound of particular instruments, as the trumpet, horn, or fife; to which may be added, striking
 SIGNALS.

striking the bell, or beating the drum; those which are made by displaying pendant, ensigns, and flags, of different colours; or by lowering or altering the position of the flag; and those which are executed by rockets of different kinds; by firing cannon or small arms; by artificial fire-works; and by lanthorns. See Telegraph.

The signals by the drum, made use of in military exercises, instead of the word of command, are as follows: a short roll, q. d. to caution; a roll, to perform any distinct operation; to arms, to form the line or battalion; the march, to advance, except when intended for a salute; the quick march, to advance quick; the point of war, to march and charge; the retreat, to retreat; drum ceasing, to halt; two short rolls, to perform the flank-firing; the dragon march, to open the battalion; the grenadier march, to form the column, the troop, to double divisions; the long roll, to form the square; the grenadier march, to reduce the square to the column; the preparative, to make ready and fire; the general, to cease firing; two long rolls, to bring or lodge the colours.

Signals have been in use in all ages: the ancients, who had no regular couriers, or posts, made use of them to convey intelligence of what passed at a great distance; for which purpose, they placed sentinels on the eminences, from space to space; some mention of which we find made by Homer himself, Iliad, v. 553. Sc. Odyssey, v. 261. Those people, thus disposed, lighted fires, or flambeaux, in the night-time. In the Agamemnon of Aeschylus, that prince, at his departure for Troy, promises Clytemnestra, that, the very day the city should be taken, he would appease her of his victory by fires, lighted express. He keeps his word, and tidings are brought the princes, that Troy is taken, and that Agamemnon's signals are seen.

Frontius observes they were in use among the Arabs; and Bonaventura Vulcanus, in his scholia on Aristotle's book De Mundo, adds, that, while the Moors were masters of the greatest part of Spain, they built on the tops of the mountains an infinity of turrets, or watch-houses, called, in the Arabic, alayayas, a word the Spaniards illll retain; whence, by fires, they could immediately alarm the whole kingdom. Indeed the custom was much more ancient than the Moors in Spain. Q. Curtius observes, it was very frequent among the Asiatics, in the time of Alexander: Livy and Cæsar, also, both mention it as usual among the Romans. Polydore Virgil shews it of great antiquity in England; and Boethius adds, that, in several places in England, there were the remains of huge poles that have served for this purpose.

Signals at Sea, are signs made by the admiral, or commander-in-chief of a squadron of ships, either in the day, or by night, whether for failing, for fighting, or for the better security of the merchant-ships under their convoy. See Engagement.

These signals are very numerous, and important; being all appointed and determined by order of the lord high-admiral, and lords of the admiralty, and communicated in the instructions sent to the commander of every ship of the fleet, or squadron, before their putting out to sea. It is by the combination of signals, previously known, that the admiral conveys orders to his fleet; every squadron, every division, and every ship of which has its particular signal. The instruction may, therefore, occasionally be given to the whole fleet, or to any of its squadrons, to any division of those squadrons, or to any ship of those divisions. Hence the signal of command may at the same time be displayed for three divisions, and for three ships of each division; or for three ships in each squadron, and for only nine ships in the whole fleet. For, the general signal of the fleet being given, if a particular pendant be also to whom it is to be known, the remarkable place on the main mast with the general signal, it was to indicate intelligence to use ships that were to receive it.

The preparatory signal given, by the admiral to the whole, or any part of his fleet, is immediately answered by those to whom it is directed; by lowering the same signal, to signify that they are ready to execute his orders. Having observed their answers, he will give the signal which is to direct their operations, as, to chai, to form the line, to begin the engagement, in board, to double upon the enemy, to rally, or return to action, to discontinue the fight, to retreat, and have themselves. The duplicity of working the ships in a fleet depends on the precise moment of executing these orders, and on the general harmony of their movements; a circumstance which evinces the utility of a signal of preparation.

As the extent of the line of battle, and the fire and smoke of the action, or other circumstances in navigation, will often prevent the admiral's signals from being seen throughout the fleet, they are always repeated by the officers next in command; by ships appointed to repeat signals; and, finally, by the ship or ships for which they are intended. The ship that repeats the signal, besides the chiefs of squadrons or divisions, are usually figues lying to windward or leeward of the line. These should be extremely vigilant to observe and repeat the signals, whether they are to transmit the orders of the commanders-in-chief, or his seconds, to any part of the fleet; or to report the fortunate or disfavourable situation of any part thereof. By this means, all the ships from the van to the rear will, unless disabled, be ready at a moment's warning to put the admiral's design in execution. To prefer order in the repetition of signals, and to favour their communication, without embarrassment, from the commander-in-chief to the ship far which they are designed, the commanders of the squadrons repeat after the admiral; the chiefs of the divisions, according to their order in the line, after the commanders of the squadrons; and the particular ships, after the chiefs of the divisions; and thence, in return, after the particular ships, vice versa, when the object is to convey any intelligence from the latter to the admiral. Besides the signals above-mentioned, there are others for different ranks of officers; as for captains, lieutenants, masters, &c. or for any of those officers of a peculiar ship. Falconer.

Signal-flags are hoisted at the mizen-peak, &c.; signal-flags are made by lanthorns, and are hoisted by the fame haliards as the flags. Since November 1805, the red flag at the main-mall has been the first in rank after the union flag. See Flag by Day. When the commander-in-chief would have them prepare for falling, he first hoists his fore-topgallant, and then the whole fleet is to do the same. When he would have them unmoor, he hoists his main-topgallant, and fires a gun, which, in the royal navy, is to be answered by every flag-ship. When he would have them weigh, he hoists his fore-topgallant, and fires a gun, and sometimes hauls home his ships; the gun is to be answered by every flag-ship, and every ship is to get to sea as soon as it can. If with the leeward-side, the foremost ship is to weigh first. When he would have the weather-mast and head-mast ships to tack first, he hoists the union-flag at the foremost-mast-head, and fires a gun, which each flag-ship answers; but if he would have the foremost-mast and leeward most ships to tack first, he hoists the union-flag at the mizen-topgallant-head, and fires a gun; and when he would have all the whole fleet tack, he hoists an union both on the fore and mizen-topgallant-heads, and fires a gun. When, in bad weather, he would
would have them wear, and bring to the other tack, he hoists a pendant on the ensign-staff, and fires a gun; and then the leeward-mast and mizen-mast ships are to wear first, and bring on the other tack, and lie by, or go on with an easy fail, till he comes a-head: every flag is to answer with the same signal. If they are lying by, or failing by a wind, and the admiral would have them bear up and fail before the wind, he hoists his ensign, and fires a gun, which the flags are to answer; and then the leeward-mast and mizen-mast ships are to bear up first, and to give room for the weather-mast to wear, and fail before the wind, with an easy fail, till the admiral comes a-head. But if it should happen, when the admiral hath occasion to wear and fail before the wind, that both jack and ensign be abroad, he will haul down the jack, before he fires the gun to wear, and keep it down till the fleet is before the wind. When they are failing before the wind, and he would have them bring-to, with the starboard tacks aboard, he hoists a red flag at the flag-staff, on the mizen-topmast-head, and fires a gun. But if they are to bring-to, with the larboard tacks, he hoists a blue flag at the same place, and fires a gun, and every ship is to answer the gun. When any ship discovers land, he is to hoist his jack and ensign, and keep it abroad, till the admiral or commander-in-chief answer him, by hoisting his; on sight of which, he is to haul down his ensign. If any discovers danger, he is to tack and bear up from it, and to hang his jack abroad from the main-topmast cross-trees, and to fire two guns; but if he should strike or flack fail, then, besides the same signal with his jack, he is to keep firing, till he sees all the fleet observe him, and endeavour to avoid the danger. When any fires a ship or ships more than the fleet, he is to put abroad his ensign, and there keep it, till the admiral's is out, and then to lower it, as often as he sees ships, and stand in with them, that so the admiral may know which way they are, and how many; but if he be at such a distance, that the ensign cannot well be discovered, he is then to lay his head toward the ship or ships so deserted, and to brail up his low fails, and continue hoisting and lowering his topmasts, and making a waft with his top-gallant sails, till he is perceived by the admiral. When the admiral would have the vice-admiral, or him that commands in the second part of the fleet, to send out ships to chafe, he hoists a flag, striped white and red on the flag-staff, at the fore-topmast-head, and fires a gun. But if he would have the rear-admiral do so, he then hoists the same signal on the flag-staff at the mizen-topmast-head, and fires a gun. When the admiral would have any ship to chafe to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizen shrouds, and fires a gun; but if to chafe to leeward, a blue flag; and the same signal is made by the flag, in whose division that ship is. When he would have them give over chafe, he hoists a white flag on his flag-staff at the fore-topmast-head, and fires a gun; which signal is to be made also by that flag-ship which is nearest the ship that gives chafe, till the chaffing flag fires the signal. In case of springing a leak, or any other disater, that disables their ship from keeping company, they are to haul up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign, from the head of his main or fore-topmast, downwards on the shrouds, lowering his main or fore-topmast, and continue firing guns, till the admiral observe him; and if any ship perceive this, and judgeth the admiral doth not, that ship must make the same signal, and make the best of his way to acquaint the admiral therewith. If the admiral don't answer by firing one gun, when the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and white, on the ensign-staff, and fires a gun; and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizen-topmast, with the clew-lines hauled up, and fires a gun. If he would have the fleet cut or slip, he looses both his topmasts, and fires two guns; and then the leeward ships are to cut or slip first, to give room to the weather-mast to come to fail. So if he would have any particular ship to cut or slip, and to chafe to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizen-shrouds, and fires a gun; but if a ship is to chafe to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but if the great guns, then he puts up the pendant over the red flag. Signals by night, to be observed at an anchor, weighing anchor, and failing, are as follow. When the admiral would have the fleet to unmoor, and ride short, he hangs out three lights, over one another in the main-topmasts, over the constant light in the main-top, and fires two guns, which are to be answered by the flag-ships; and each private ship hangs out a light in the mizen-shrouds. Note, that all guns, fired for signals in the night, must be fired on the same side, that they may make no alteration in the found. When he would have them weigh, he hangs a light in the main-topmast-shrouds, and fires a gun, which is to be answered by all the flags; and every private ship must hang out a light in his mizen-shrouds. When he would have them tack, he hoists two flags on the ensign-staff, over one another, above the constant light in his poop, and fires a gun, which is to be answered by all the flags; and every private ship must hang out a light in his mizen-shrouds. When he would have them tack, he hoists two flags on the ensign-staff, at the fore-topmast-head, and fires a gun. When the admiral would have any ship to chafe to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizen shrouds, and fires a gun; but if to chafe to leeward, a blue flag; and the same signal is made by the flag-ship, in whose division that ship is. When he would have them give over chafe, he hoists a white flag on his flag-staff at the fore-topmast-head, and fires a gun; which signal is to be made also by that flag-ship which is nearest the ship that gives chafe, till the chaffing flag fires the signal. In case of springing a leak, or any other disaster, that disables their ship from keeping company, they are to haul up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign, from the head of his main or fore-topmast, downwards on the shrouds, lowering his main or fore-topmast, and continue firing guns, till the admiral observe him; and if any ship perceive this, and judgeth the admiral doth not, that ship must make the same signal, and make the best of his way to acquaint the admiral therewith. If the admiral don't answer by firing one gun, when the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and white, on the ensign-staff, and fires a gun; and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizen-topmast, with the clew-lines hauled up, and fires a gun. If he would have the fleet cut or slip, he looses both his topmasts, and fires two guns; and then the leeward ships are to cut or slip first, to give room to the weather-mast to come to fail. So if he would have any particular ship to cut or slip, and to chafe to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizen-shrouds, and fires a gun; but if a ship is to chafe to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but if the great guns, then he puts up the pendant over the red flag. Signals by night, to be observed at an anchor, weighing anchor, and failing, are as follow. When the admiral would have the fleet to unmoor, and ride short, he hangs out three lights, over one another in the main-topmasts, over the constant light in the main-top, and fires two guns, which are to be answered by the flag-ships; and each private ship hangs out a light in the mizen-shrouds. Note, that all guns, fired for signals in the night, must be fired on the same side, that they may make no alteration in the found. When he would have them weigh, he hangs a light in the main-topmast-shrouds, and fires a gun, which is to be answered by all the flags; and every private ship must hang out a light in his mizen-shrouds. When he would have them tack, he hoists two flags on the ensign-staff, over one another, above the constant light in his poop, and fires a gun, which is to be answered by all the flags; and every private ship must hang out a light in his mizen-shrouds. When he would have them tack, he hoists two flags on the ensign-staff, at the fore-topmast-head, and fires a gun. When the admiral would have any ship to chafe to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizen shrouds, and fires a gun; but if to chafe to leeward, a blue flag; and the same signal is made by the flag-ship, in whose division that ship is. When he would have them give over chafe, he hoists a white flag on his flag-staff at the fore-topmast-head, and fires a gun; which signal is to be made also by that flag-ship which is nearest the ship that gives chafe, till the chaffing flag fires the signal. In case of springing a leak, or any other disaster, that disables their ship from keeping company, they are to haul up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign, from the head of his main or fore-topmast, downwards on the shrouds, lowering his main or fore-topmast, and continue firing guns, till the admiral observe him; and if any ship perceive this, and judgeth the admiral doth not, that ship must make the same signal, and make the best of his way to acquaint the admiral therewith. If the admiral don't answer by firing one gun, when the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and white, on the ensign-staff, and fires a gun; and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizen-topmast, with the clew-lines hauled up, and fires a gun. If he would have the fleet cut or slip, he looses both his topmasts, and fires two guns; and then the leeward ships are to cut or slip first, to give room to the weather-mast to come to fail. So if he would have any particular ship to cut or slip, and to chafe to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizen-shrouds, and fires a gun; but if a ship is to chafe to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but if the great guns, then he puts up the pendant over the red flag. Signals by night, to be observed at an anchor, weighing anchor, and failing, are as follow.
by some ship of the fleet. If any one discovers a fleet, he is to fire guns, make false fires, put one light out on the main-top, three on the poop, to flee after them, and continue firing of guns, whilst the admiral call him off, by flinging the banners, and fires two or three guns, for then he must follow the admiral. When the admiral anchors, he fires two guns, a small space of time one from the other, which are to be answered by the flag-ships, and every private ship must answer these two lights. When the admiral would have the fleet to move, he puts a light on each top-mast-head, and fires a gun, which is to be answered by the flag-ships, and every private ship must answer one light. If he would have them lower their yards and topmasts, he hoists one light upon his ensign-staff, and fires one gun, which is to be answered by the flag-ships; and every private ship must shew one light. And when he would have them hoist their yards and topmasts, he puts out two lights, one under the other, in the mizen-topmasts, and fires one gun, which is to be answered by the flag-ships; and every private ship must shew one light. If any strange ship be discovered coming into the fleet, the next step is to endeavor to speak with her, and bring her to an anchor, and not suffer her to pass through the fleet. And if any one discovers a fleet, and it blows so hard that he cannot come to give the admiral timely notice, he is to hang out a great number of lights, and to continue firing guns after gun, till the admiral answers him with one. When the admiral would have the fleet to cut or ship, he hangs out four lights, one at each main-yard-arm, and at each fore-yard-arm, and fires two guns, which are to be answered by the flag-ships; and every private ship to shew one light.

Signals used when a Ship fails in a Fog. If the admiral would have them weigh, he fires ten guns; which every flag-signal is to answer. To make them tack, he fires four guns, which are to be answered by the flag-ships; and then the lead-water-now-mast and tern-mast ships must tack first, and after they are about, to go with the same sail they tackled with, and not to lie by, expecting the admiral to come ahead; and this is to avoid the danger of running one another in thick weather.

When the admiral brings-to, and lies with his head-fails to the main, if with the larboard tack aboard, he fires five guns; but if with the larboard tack, he fires eight guns, which the flag-ships are to answer. And after this, if he makes fail, he fires ten guns, which the flag-ships must answer, and then the lead-water-now-mast ships are to make fail first. If it grow thick and foggy, the admiral will continue sailing, with the same sail he tacked with, and not to lie by, expecting the admiral to come ahead; and this is to avoid the danger of running one another in thick weather.

When the admiral puts abroad an union-flag on the mizen-topmasts, and fires a gun, all the captains are to come aboard him; and if with the same light, they are to sail, and march with the admiral, then the lieutenant of each ship must aboard. If a ship be put aboard the admiral, all the masters of the ships of war are to come aboard the admiral. If a standard on the main-topmasts, and a gun fired, then all the flag-ships are to come aboard the admiral. If the Eng. flags are then a standard in the main-topmasts, and a gun fired, then the masters of his own squadron are to come aboard the admiral, and, if with the same signal, there be also a waft with the ensign, the lieutenant of each ship must come aboard. If he hoists a white flag, as before, then the vice-admiral, or he that commands in the fleet, and all the captains of his squadron, are to go on board the admiral; if a blue flag, &c. then the rear-admiral, and the captains of his squadron must come aboard, and if with a waft, as before, the lieutenants. When a standard is hoisted on the forecastle, and a gun fired, the vice and rear-admirals must come on board the admiral's ship. When the admiral would speak with the captains of his own division, he will hoist a pendant on the fore-topmasts, and a gun fired; and if with the lieutenants, a waft is made with the ensign, and the same signal; for whenever he would speak with the lieutenants of any particular ship, he makes the signal for the captain, and a waft also with the ensign. When the admiral would have all the tenders in the fleet come under his item, and speak with him, he hoists a flag, yellow and white, at the mizen-peak, and fires a gun. But if he would speak with any particular ship's tender, he makes a signal for speaking with the captain he tends upon, and a waft with the jack. If all the pinnaces and barges are to come on board, manned and armed, the signal is a pendant on the flagstaff, hunted on the fore-topmasts, and a gun fired; and if he would have them chase any ship, yellow, or blue, to be in view, he hoists the pendant, and fires two guns. The signal for the long-boats to come on board, manned and armed, is the pendant hoisted on the flagstaff, and the mizen-topmasts, and a gun fired; and if he would have them chase any ship, yellow, or blue, to be in view, he hoists his pendents, as before, and fires two guns. When the admiral would have all the boats in the fleet to come on board him, manned and armed, he hoists a pendant on the flagstaff, both on the fore-topmasts and mizen-topmasts, and a gun fired; and if he would have them chase, he hoists his pendents, as before, and fires two guns. When the admiral would speak with the victualler, or his agent, he puts an English ensign in the mizen-topmasts, and when with him that has the charge of the gunner's stores, he will spread an ensign at his main-topmast-yard-arm.

Signals for calling Officers on Board the Admiral. When the admiral puts abroad an union-flag on the mizen-topmasts, and fires a gun, all the captains are to come aboard him; and if with the same light, they are to sail, and march with the admiral, then the lieutenant of each ship must aboard. If a ship be put aboard the admiral, all the masters of the ships of war are to come aboard the admiral. If a standard on the main-topmasts, and a gun fired, then all the flag-ships are to come aboard the admiral. If the Eng. flags are then a standard in the main-topmasts, and a gun fired, then the masters of his own squadron are to come aboard the admiral, and, if with the same signal, there be also a waft with the ensign, the lieutenant of each ship must come aboard. If he hoists a white flag, as before, then the vice-admiral, or he that commands in the fleet, and all the captains of his squadron, are to go on board the admiral; if a blue flag, &c. then the rear-admiral, and the captains of his squadron must come aboard, and if with a waft, as before, the lieutenants. When a standard is hoisted on the forecastle, and a gun fired, the vice and rear-admirals must come on board the admiral's ship. When the admiral would speak with the captains of his own division, he will hoist a pendant on the fore-topmasts, and a gun fired; and if with the lieutenants, a waft is made with the ensign, and the same signal; for whenever he would speak with the lieutenants of any particular ship, he makes the signal for the captain, and a waft also with the ensign. When the admiral would have all the tenders in the fleet come under his item, and speak with him, he hoists a flag, yellow and white, at the mizen-peak, and fires a gun. But if he would speak with any particular ship's tender, he makes a signal for speaking with the captain he tends upon, and a waft with the jack. If all the pinnaces and barges are to come on board, manned and armed, the signal is a pendant on the flagstaff, hunted on the fore-topmasts, and a gun fired; and if he would have them chase any ship, yellow, or blue, to be in view, he hoists the pendant, and fires two guns. The signal for the long-boats to come on board, manned and armed, is the pendant hoisted on the flagstaff, and the mizen-topmasts, and a gun fired; and if he would have them chase any ship, yellow, or blue, to be in view, he hoists his pendents, as before, and fires two guns. When the admiral would have all the boats in the fleet to come on board him, manned and armed, he hoists a pendant on the flagstaff, both on the fore-topmasts and mizen-topmasts, and a gun fired; and if he would have them chase, he hoists his pendents, as before, and fires two guns. When the admiral would speak with the victualler, or his agent, he puts an English ensign in the mizen-topmasts, and when with him that has the charge of the gunner's stores, he will spread an ensign at his main-topmast-yard-arm.

Signals for managing a Sea-fight. When the admiral would have the fleet form a line of battle, he flings ahead of another, he hoists an union flag on the mizen-peak, and fires a gun; and every flag-ship does the like. But when they are to form a line of battle, one abreast of another, he hoists a pendant with the union flag, &c. When he would have the admiral at the white, or land that commands in the second part, to tack, and endeavor to gain the wind of the enemy, he flings a white flag under the flag on the main-topmasts, and fires a gun; and when he would have the vice admiral of the blue do so, he doth the same with the blue flag. If he would have the rear-admiral of the
the red do fo, he spreds a red flag from the cap, on the fore-topmast-head, downward on the back-flag; if the vice-admiral of the blue, he spreds a blue flag, &c. and fires a gun. If he would have the rear-admiral of the red do so, he hoists a red flag at the flag-staff, at the mizen-topmast-head; if the rear-admiral of the white, a white flag; if the rear-admiral of the yellow, a blue flag, and under it a pendant of the same colour, with a gun. If he be to leeward of the fleet, or any part of it, and he would have them bear down into his wake or grain, he hoists a blue flag at the mizen-peek, and fires a gun. If he would be to leeward of the enemy, and his fleet or any part of it be to leeward of him, in order to bring these ships into the line, he bears down with a blue flag at the mizen-peek, under the union-flag, (which is the signal for battle,) and fires a gun; and then those ships that are to leeward of him, must endeavour to get into his wake or grain, according to their station in the line of battle. When the fleet is failing before the wind, and he would have him, who commands in the second port, and the ship of the starboard quarter, to clap by the wind, and come to the starboard tack, he hoists a red flag at the mizen-topmast-head; but a blue one, if he would have ships of the starboard quarter come to the larboard tack, with a gun. If the van are to tack first, he spreds the union-flag at the flag-Staff, on the fore-topmast-head, and fires a gun, if the red flag be not on board; but if it be, then he lowers the fore-topmasts a little, and the union-flag is spread from the cap of the fore-topmast downward; and every flag-ship doth the same. If the rear be to tack first, he hoists the union-flag on the flag-Staff, at the mizen-topmast-head, and fires a gun; which all the flag-ships are to answer. If all the flag-ships are to come into his wake or grain, he hoists a red flag at his mizen-peek, and fires a gun; and all the flag-ships must do the same. If he would have him that commands in the second port of his squadron to make more fail, (though he himself shorten fail,) he hoists a white flag on the ensign-flag. But if he that commands in the third port be to do so, he hoists a blue flag, and fires a gun, and all the flag-ships must make the same signal. Whenever he hoists a red flag on the flag-Staff at the fore-topmast-head, and fires a gun, every ship in the fleet must use their utmost endeavour to engage the enemy, in the order prescribed them. When he hoists a white flag at his mizen-peek, and fires a gun, then all the small frigates of his squadron, that are not of the line of battle, are to come under the signal. If the fleet be failing by a wind in the line of battle, and the admiral would have them brace their head-fails to the main, he hoists up a yellow flag, on the flag-Staff, at the mizen-topmast-head, and fires a gun; which the flag-ships are to answer; and then the ships in the rear must brace first. After this, if he would have them fall their head-fails, and stand on, he hoists a yellow flag on the flag-Staff of the fore-topmast-head, and fires a gun, which the flag-ships must answer; and then the ships in the van must fall first, and stand on. If, when this signal is made, the red flag at the fore-topmast-head be abroad, he spreds the yellow flag under the red. If the fleets being near one another, the admiral would have all the ships to tack together, the sooner to lie in a portage to engage the enemy, he hoists an union-flag on the flag-Staffs at the fore and mizen-topmast-heads, and fires a gun; and all the flag-ships are to do the same. The fleet being in a line of battle, if he would have the ship that leads the van hoist, lower, fet, or haul up any of her fails, he spreds a yellow flag, under that at his main-topmast-head, and fires a gun, which signal the flag-ships are to answer; and the admiral will hoist, lower, set, or haul up the fail, which he would have the ship that leads the van do; which is to be anwered by the flag-ships of the fleet.

When the enemies run, and he would have the whole fleet follow them, he makes all the sail he can after them himself, takes down the signal for the line of battle, and fires two guns out of his fore-chaise, which the flag-ships answer; and then every ship is to endeavour to come up with and board the enemy. When he would have the chase given over, he hoists the white flag at the fore-topmast-head, and fires a gun. If he would have the red squadron draw into a line of battle, one abreast of another, he puts abroad a flag, striped red and white, on the flag-Staff at the main-topmast-head, with a pendant under it, and fires a gun; if the white or second squadron is to do so, the flag is striped red, white, and blue; if the blue or third squadron is to do so, the flag is a Genoese enign and pendant; but if they are to draw into a line of battle, one a-head of another, the same signals are made with a pendant. If they are to draw into the line of battle one a-head of another, with a large wind, and he would have the leaders go with the starboard tacks, aboard by the wind, he hoists a red and white flag at the mizen-peek, and fires a gun; but if they shou'd go with the board tacks abroad, by the wind, he hoists a Genoese flag at the same place; which signals, like others, must be anwered by the flag-ships.

SIGNATURES, among the Romans, witnesses who sealed wills and marriage contracts.

SIGNATURE, Signature, Signing, a subscription, or putting of one's name at the bottom of an act, or deed, in one's own hand-writing.

Anciently, when very few people could write, they dipped the tip of a spear into the ink, and scratched it on a copper plate to form a signature; and contented themselves with the party's seal. See DEED.

SIGNATURE of the Court of Rome, is a supplication answered by the pope, by which he grants a favour, dispensation, or collation to a benefice, by putting the fiat at the bottom of it, in his own hand; or the consessione wet written in his presence. This signature, at the bottom of the supplication, gives name to the whole instrument.

The signature contains the clauses, derogations, and dispensations, with which the pope grants the favour, or the benefice, with a commission for the execution of it, either in forma dignum, or in gracious form.

A signature of the pope's own hand, by which he answers, Fiat ut petitur, is preferred to another answered by the prefect, in his presence, in these words, Consessum uti peturum in presencia D. N. pape. Sometimes in signatures, with the fiat, the pope adds, proprio motu; which clause gives them still farther force.

There are three kinds of signatures: one in forma graiotia, dispatched on an attestation of the ordinary; another in forma dignum antiqua, dispatched for canonizations; the third in forma dignum nuncios, which is a kind of second signature, or executorial letter, granted where, upon the ordinary's falling to execute the fiat, within thirty days, the nearest ordinary is enjoined to execute it.

Signature, in Printing, denotes a mark at the bottom of each sheet, to regulate the gathering and binding of the book; and to shew the order and number of the sheets, in collating, to see if the book is perfect.

The signatures consist of the capital letters of the alphabet. If there be more sheets than letters in the alphabet, to the capital letter they add a small one of the same form; i.e. a little a after a great A, &c. which they repeat as often as is necessary.

Signature, Signature, is also used, by some naturalists, for the resemblance a vegetable or mineral bears to any part of the human body; this is, by some fantastical people,
SIGNAU, in Geography, is a town of Sentinella, and principal place of a district, in the canton of Basel; 12 miles E. of Basel.

SIGNES, a town of France, in the department of the Var; 18 miles S.W. of Marseille.

SIGNET, one of the knapsacks, used for sealing private letters, and being a gift, which is probably handed by hilt. For this it is termed "signet-Medal." It was always in the family of the kings and earls, and when the sovereigns became independent, it was given to the heads of the great houses, who were, in a certain sense, the lords of the realm.

The signet is always the emblem of the king's authorities, and is worn on the breast of the order of the Garter. The signet of King Henry VII. of England is in the form of a rose, with the legend "Hoc est Regnum." The signet of King Charles II. of England is in the form of a crown, with the legend "Hoc est Regnum." The signet of King George III. of England is in the form of a crown, with the legend "Hoc est Regnum.

SIGNIA, in Architecture, a town of Italy, in the Latium, at some distance from the river of the Tiber, and toward the S.W. of Rome. It was, in the time of Livy, that Tarquin the Proud built his city. Some remains of it are still visible.---Altus, in the province of Ancona, in the Greater Pergam, Livy says, that the town of Ancona was built on the site of the mountain.

SIGNIFER, among the Romans, an usher, or bearer, or the person who carries the standard, on which was represented a hand stretched out. See Signa.

SIGNIFICATION, the sense or meaning of a sign, word, phrasing, emblem, device, or the like; that is, the thing denoted by such symbols, word, figure, &c.

We are almost perfectly at a loss as to the signification of the hieroglyphic characters of the ancients.

SIGNIFICATION, in Latin, is the notification of an act, &c., made to the opposite party, by a copy, &c., of it, given and attested by a proper officer.

Some significations are to be made to the person himself; or at least, it is his house; for others, it is enough that they be made to the party’s attorney, or agent.

SIGNIFICAVIT. See EXCOMMUNICATUM CAPENDO.

SIGNING. See Signatures and Counter-signing.

SIGNINUM, among the Romans, a kind of pavement much esteemed; it was made of powdered shells mixed with lime.

SIGNORELLI, Luca, in Biography, was born at Coretta in 1493, and was a disciple of Pietro della Francesca. He was among the finest of the Italian artists who designed the naked figure with fidelity and accuracy; though Titian impeded by the quickness of his brush and finish, and too great care to make the figures perfect, is still poor in the rendering of nature. His greatest work is his celebrated fresco in the chapel of the Virgin in the cathedral of Orvieto, representing the final dissolution and judgment of the world; a work of extraordinary quality, in which variety and originality of ideas are rendered with force and effect. Vasari, who was related to Signorelli, says that Michael Angelo adopted, in his Last Judgment, many of the ideas of this artist; of which most probably he only took the characters of actions, and clutched them with his own emphatic style of design.

Though grace of form, and harmony of colouring, are not the most prominent features in the style of Signorelli, yet one of his works is extolled by Lami as possessing those qualities in a superior degree; i.e., his Commune of the Apostles, in the church of San Lorenzo in Florentia. He was invited to Rome to adorn in decorating the apartments of the Palazzo, where he painted the Journey of Moses and Zipporah, and the Promulgation of the Old Law; exhibiting a superior arrangement of composition. He painted at Urbino, Volterra, Arezzo, Sienna, and Florence, and established a name among the most eminent of the Florentine painters. He died in 1521, aged 82.

Vol. XXXII.
country. He visited Rome in 1578, where he was honourably received by pope Gregory XIII., by whom he was engaged to compose an ecclesiastical history. Of this, however, he executed no more than some learned illustrations of Sulpicius Severus; for he died at Modena in the year 1584. He was a most able and successful elucidator of ancient history and antiquities. He was indefatigable in searching to the bottom all subjects which he undertook to examine, so that in many he left little to be added by later enquirers, and his works are all carefully composed in a pure, and even an elegant, Latin style. Besides the pieces already mentioned, he published many valuable tracts on the Roman laws and customs, also on the republics of the Hebrews, Athenians, and Lacedaemonians. He composed twenty books of a history relating to the western empire, from the time of Diocletian to its final destruction, and he performed the more arduous task of framing from the rude and obscure chronicles of the times, a history of the kingdom of Italy, from the arrival of the Lombards to the year 1286. Sigonio was involved in several controversies, in one of which he is supposed to have disgraced himself. About twelve months before he died, an intimate friend of his edited a pretended treatise of Cicero, entitled "Confutatio." Its authenticity was immediately impugned by critics, and there is now no doubt that it was not genuine; but Sigonio wrote so warmly in defence of it, that he is generally supposed to be the author. The works of this learned man were published collectively in 1752-3, by Argelati, at Milan, in six vols. fol. with his Life, by Muratori, prefixed.

SIGORUM, in Ancient Geography, a mountain of Ailia, in Mepotamia, in the vicinity of the town of Niphis, according to Sozomen.

SIGOULES, I.e., in Geography, a town of France, in the department of the Dordogne; 7 miles S. of Bergerac.

SIGRI, a town on the N.W. part of the island of Metelin, in the Grecian Archipelago.

SIGRANA, in Ancient Geography, a country of Ailia, in Media, according to Strabo.

SIGRANI, mountains of Ailia Minor, on the coast of the Propontid.

SIGRIUM, a promontory of the island of Lesbos, in the most westerly part of the island.

SIGRUM, a port of the island of Tenedos, in which was a stathe of Diana.

SIGTUNA, in Geography, a town of Sweden, in the province of Upland, situated on a creek of the Malar lake, anciently one of the chief cities of the kingdom. It is said to derive its name from the celebrated Odin, whose surname was Sigge: he came into the north before the Christian era, and had his residence, his temple, and his court of justice; others say the town was built by Odin. However that be, Sigtuna has undergone many changes; in the year 1088, it was plundered and burnt by Olof the Pious, king of Norway; in 1188, it was destroyed by the Carelians, Eltonians, and Ruffians. It recovered from these calamities, and flourished till the last increase of Stockholm gave it a blow, which it is not likely to recover; 10 miles N. of Stockholm.

SIGUA, in Ancient Geography, a town of Ailia, in the Greater Armenia. Ptolemy.

SIGUENCA, in Geography, a city of Spain, in Old Castile, situated on the edge of a mountain, near the source of the river Henares; the see of a bishop, suffragan of Toledo, with an university, founded in the year 1441, by cardinal Ximenes. It contains three churches, three convents, two hospitals, a strong castle, an arsenal, and between 700 and 800 houses. This town was anciently called Segontia. A battle was fought here between Pompey and Sertorius; and in the beginning of the seventh century, the Goths were defeated here by the Romans; 56 miles N. E. of Madrid. N. lat. 40° 58'. W. long. 2° 57'.

SIGUETTE, in the Mange, is a cavern of iron, with teeth or notches, that is, a ferricircle of hollow and vaulted iron, with teeth like a saw, consisting of two or three pieces joined with hinges, and mounted with a headfall and two ropes, as if they were the cavelions that in former times were wont to be put upon the nose of a fiery stiff-headed horse, in order to keep him subjection.

There is a sort of figure, that is, a round iron all of one piece, sewed under the nose-band of the bridge, that it may not be in view. This figure we employ with a martingale, when a horse beats upon the hand.

SIHASTRIA, in Geography, a town of Moldavia; 34 miles W. of Suzcava.

SIHAUL, a town on the W. coast of Sumatra. N. lat. 0° 23'. E. long. 110° 45'.

SI-HIAM, a town of China, of the third rank, in Chen-fi; 37 miles E.S.E. of Han-chong.

SI-HO, a town of China, of the third rank, in Chen-fi; 42 miles W. of Oei.

SI-HOA, a town of China, of the third rank, in Ho-nan; 32 miles E.S.E. of Hiu.

SIHON, or GHON, or Anu. See Jihon and Amu. Sihon, or Sharokit, a name given to the river Sirc, in its course.

SIHOR, a town of Hindooftan, in Guzerat; 25 miles W. of Gogo.

SIHUTLA, a town of Mexico, in the province of Mechoacan; 25 miles W. of Zacatula. N. lat. 18° 45'. W. long. 103° 26'.

SIKAJOCKI, a town of Sweden, in East Bothnia; 8 miles N. of Brahefled.

SIKE, in Rural Economy, a term provincially applied to a little rill, a water-furrow, and a gutter.

SIKEVI, in Geography, a town of Turkith Circassia, on the coast of the Black sea; 30 miles S.E. of Anapa.

SIKORD, a town of Sweden, in Well Bothnia; 18 miles N.W. of Pitea.

SIKHS, or Sikks, an appellation formed of the Sanscrit term Sikh, or Sigka, denoting a disciple or devoted follower, and in the Panjabi corrupted into Sakh, which is applicable to any person that follows a particular teacher, and hence used to denominate, in its primary use, a religious sect, which advanced, by successive gradations, from the humble condition of religiousists, to the rank of one of the most powerful states in Hindoostan. The founder of this sect was Nanac Shah, a native of a small village called Talwandi, in the district of Bhatti, in the province of Lahore, where he was born A.D. 1469. It is now become a town, and denominated Rayapour, and is situated on the banks of the Beyah or Hyphafis. Nanac's father, whose name was Calib, and who belonged to the Chatriya cast and Vedi tribe of Hindoos, wished to bring him up to trade, but Nanac himself was from his childhood inclined to devotion, and manifested an indifference to all worldly concerns. This disposition was cherished by his intercourse with the Fakirs, among whom and the poor he distributed a great part of his substance. It is needless to recite his trances and visions, and converse with the prophet Elias, and the auras which he practised at the commencement and in the progres of his religious career. Nor can we accompany him in his travels which he undertook with a view of reforming the worship of the
the true God, that had been degraded by the idolatry of the Hindoos and the arrogance of the Mahometans. It will be sufficient for us to observe, that after he had visited all the cities of India, and explored all ranks of the great doctrines of the unity and omniscience of God, he went to Mecca and Medina, where his actions, his miracles, and his dispute with the Mahometan priests and doctors, are most circumstantially recorded by his biographers. He stated, on this occasion, to have defended his own principles without offering or doing them to others: always professing humble the enemy of idolatry, and as having no object but to reconcile the two faiths of the Mahometans and Hindoos in one religion; which he endeavoured to do by recalling them to that great and original tenet, which both of them believed, the unity of God; and by explaining to them from the numerous errors into which they had fallen. During his travels, about the year 1575, Nanac was introduced to the emperor Baber, before whom he is said to have maintained his doctrine with great firmness and eloquence. Baber treated him kindly, and offered him an ample maintenance, which the Sikh poet refused, alleging, that he trusted in him who provided for all men, and from whom alone a man of virtue and religion would confer to receive favour or reward. The Hindoos zealously opposed him, more especially after he had lived three years habits of a Fakir: but he treated their opposition and reproaches with great contempt; and when they required him to exhibit some of his power, that might astonish them, he replied, "I have nothing to exhibit worthy of you to behold. A holy teacher has no defence but the purity of his doctrine; the world may change but the creator is unchangeable."Having migrated from Vatala to Multan, and from Multan to Kirtipur, on the banks of the Ravee or Hydravart, he there performed many miracles, as it is reported, threw off his earthly shape, and was buried near the bank of the river Ravee, which has since overflowed his tomb. Kirtipur continues to be a place of religious restor and worship; and a small piece of Nanac's garment is exhibited to pilgrims, as a sacred relic, at his Dharmafla, or temple. Nanac was unquestionably a man of more than common genius, which we may infer from the distinguished eminence to which he attained, and the success with which he combated the opposition that encountered him; whilst he laboured without intermission to recall both Mahometans and Hindoos to an exclusive attention to that sublime of all principles, which inculcates devotion to God and peace towards men. Although he left two sons, he did not deem either of them worthy of a succession to his spiritual functions; but he devised them upon a Chatriya of the Trehun tribe, called Lekha, whom he had initiated to the sacred mysteries of his sect, clothed in the holy mantle of a Fakir, and honoured with the name of Angad. Guru Angad was born at the village of Khindur, on the bank of the Beas or Phryphasis, in the province of Lahore. He taught the same doctrine as Nanac; and some of his writings, as well as those of Nanac, are contained in a book entitled "Granth." At his death, which happened A.D. 1552, he was succeeded by Ameera Das, a Chatriya of the tribe of B'halor, who had been a median soldier for twelve years. Ameera Das was active in propagating the tenets of Nana, and successful in gaining converts, by whole assistance he established a degree of temporal power. He had two sons, and a daughter, named N'hai, who was married to a young lad, whose name was Ram Das, a Chatriya, of a respectable family, of the Swhi tribe, and an inhabitant of the village of Gondawal. Upon the death of Ameera Das, A.D. 1574, was succeeded by his son-in-law, whom he had initiated to the mysteries of his holy profession, and who became famous for his party, and still more on account of the improvements he made at Aurngzebe, which was formerly called Rampur, or Rangpur, after him. These writers have erroneously supposed that the 1111. of this town, was founded long before his time; but, in fact, there was no town, but a fort, the residence of one of the Guides, which was called Aurngzebe, and the city of the Mahometans, and is now called by the name of Aurngzebe. After a life passed in the meditated propagation of his tenets, an explanation of which the writer of several books, Ram Das d. A.D. 1621, and left two sons, one of whom, viz. Arpumal, succeeded him, and rendered himself famous by compiling the Adjit Granth, containing ninety-two sections, part of which was composed by Nanac and his immediate successors, but arranged in its present form by Arpumal, who blended his own additions with the compositions of his predecessors. Arpumal, from this circumstance, is deemed the first who gave a distinct form and order to the religion of the Sikhs. Arpumal fell a sacrifice to the jealousy of the Mahometan government; and his death excited the indignation of the Sikhs, who, before this event, had been an obedient, peaceful sect; and they took up arms under Har Govind, the son of Arpumal, and wreaked their vengeance upon all whom they thought concerned in the murder of their revered profet. From all the remaining accounts of Har Govind's life, it appears to have been his anxious wish to inspire his followers with the most irreconcilable hatred of their oppressors. Govind, with this view, introduced some change in their diet, allowing them to eat the flesh of animals, that of the cow excepted; and by other regulations converted a race of peaceful subjects into an intractable band of soldiers. Govind died A.D. 1644, and was succeeded by his grandson Har Ray, whose reign was upon the whole tranquil, which was probably owing to the vigour of the Mahometan power in the early part of the reign of Aurngzebe. At his death, A.D. 1661, a violent contest arose among the Sikhs, concerning the succession to the business of spiritual leader for the temporal power of their ruler was, at this time, little more than nominal. The dispute was referred for decision, to Delhi, and by an imperial decree of Aurngzebe, the Sikhs were allowed to elect their own priest. They chose Har Culin, son (or grandson) of Har Ray, who died at Delhi A.D. 1604, and was succeeded by his uncle, Tegh Beladar. During his life, which terminated prematurely, by the violence of his rival, A.D. 1675, and also from the period of Godvind's death, the Mogul empire was in the zenith of its power under Aurngzebe; and the Sikhs, who had never attained any real strength, were rendered still weaker by their own dilutions. However, after the death of Tegh Beladar, the history of the Sikhs assumed a new aspect. Under Hau Govind the Sikhs had been initiated in arms, but they used them only in self-defence; but the plans of Govind's ambition were very different from those of his predecessor Nanac; and he wisely judged, that the only means by which he could ever hope to oppose the Mahometan government with success, were not only to admit converts from all tribes, but to break at once those rules by which the Hindoos had been so long chained—to arm, in short, the whole population of the country, and to make worldly wealth and rank an object to which Hindoos, of every class, might aspire. It was the object of Govind to make all Sikhs equal, and that their advancement should solely depend upon their merit, and not upon any ecclesiastic or regal order; it was to inspire men of a low race, and
and of grovelling minds, with pride in themselves, he changed the name of his followers from Sikh to Sinh or lion; thus giving to all his followers that honourable title which had been before exclusively assumed by the Rajputs, the first military clans of Hindoos; and every Sikh felt himself at once elevated, by this proud appellation, to a footing with the first clans. The disciples of Govind were required to devote themselves to arms; always to have fted about them in one shape or other; to wear a blue drefs; to allow their hair to grow; and to exclaim, when they met each other, “Wa! Guruji ka khalsa! Wa! Guruji ki futeh!” i.e. Success to the flate of the Guru! Victory attend the Guru! Guru Govind inculcated his tenets upon his followers by his preaching, his discourses, and his works. He is faid to have ftituted the Guru-mata, or flate council, among the Sikhs, which meet at Amritfar; by which institution he gave that form of a federal republic to the commonwealth of the Sikhs, which was moft calculated to rufe his followers from their indulent habits, and deep-rooted prejudices, by affigning to them a personal share in the government, and placing within the reach of every individual, the attainment of rank and influence in the flate. The emperor Aurungzebe, aided by the rajas who were hostile to Govind, purfued him and his followers to Chamkour, and encompassed it on all fides. The fief was carried on with great vigour; and though Govind manifested an invincible spirit, and performed prodigies of valour, he was at laft overpowered by numbers; and reduced to the necifity of making his efcap from Chamkour in a dark night, covering his face, as it is faid, from blame on his own dilgrife. After his flight, a fene of his misfortunes, and the lofs of his children, deprived him of his reafon, and he wandered about for a confiderable time in the moft deplorable condition. At length, having obtained from the emperor Behadur Shah a fmall military command in the Deccan, he was flabbed by a Patan foldier’s fon, and expired of his wounds, A.D. 1708, at Naced, a town fituated on the Caveriver, about 100 miles from Haiderabad. Guru Govind was the laft acknowledged religious ruler of the Sikhs. A prophecy had limited their spiritual guides to the number of ten; and their superifion, aided, without doubt, by the action of that fpirit of independence which his institutions had introduced, caufed its fulfilment. Banda, a devoted follower and friend of Guru Govind, elfalbified the union of the Sikhs under his banners; and his grief at the misfortune of his fpirit, is faid to have fettled after the death of Govind into a gloomy and desperate defire to avenge his wrongs. The confusion which took place on the death of Aurungzebe, which happened A.D. 1707, was favourable to his wishes. Having obtained a victory over the Mahometans in a bloody action, Banda, encouraging the Sikhs, and hardening them by his leifons to deeds of the moft horrid atrocity, subdued all the country between the Setlej and the Jumna, and croffing that river, made inroads into the province of Sharanpore, which lies a few miles to the N.E. of Delhi, between the rivers Jumna and the Ganges. The march of the Sikhs was attended with the exercife of the moft wanton barbarity; life was only granted to thofe who conformed to the religion, and adopted the habits and drefs of the Sikhs; and if Behadur Shah had not quitted the Deccan, which he did A.D. 1710, the whole of Hindooflan would probably have been fubdued by these merciless invaders. The firit chink which the Sikhs received was from an army under fultan Kuli Khan. They were afterwards defeated in a very delicate action by Abdal Samad Khan, an officer of the emperor Farakheefir, after which the Sikhs were never able to make a ftrand, but were hunted like wild beafts from one frong hold to another, by the army of the emperor, by whom their leader, Banda, and his moft devoted followers, were at laft taken, after having fuffered every extreme of hunger and fatigue. Great numbers of the Sikhs were put to death, after the surrender of Lohgad, a fortrefs 100 miles N.E. of Lahore; but Banda was fent, with the principal chiefs of the tribe, to Delhi, where, after having been treated with every kind of obloquy and infult, they were executed.

After the defeat and death of Banda, retlement prompted to every meafure that could be devised, not only to destroy the power, but to extirpate the race of the Sikhs. From the Mahometans they met with no quarter; and after the execution of their chief, a royal edict was iffued, ordering all who profefled the religion of Nanec to be taken and put to death wherever found; and by way of giving greater effect to this mandate, a reward was offered for the head of every Sikh. During the interval that elapsed between the defeat and death of Banda, and the invasion of India by Nadir Shah, a period of nearly 30 years, we hear nothing of the Sikhs; but when that event occurred, they are faid to have fallen upon the inhabitants of the Panjab, who fought fhelter in the hills, and to have plundered them of that property which they were endeavouring to secure from the rapacity of the Perisan invader. Enriched with these fpoils, fays the author whole account of them we are now citing, the Sikhs left the hills, and built the fort of Dalewal, on the Ravi, from whence they made predatory incursions, and are flated to have added, both to their wealth and reputation, by haraffing and plundering the rear of Nadir Shah’s army, which, when it returned to Peria, was encumbered with fpooil, and marched, from a contempt of its enemies, with a difregard to all order.

The weak state to which the empire of Hindooflan was reduced, and the confusion into which the provinces of Lahore and Cabul were thrown, by the death of Nadir, were events of too favourable a nature to the Sikhs to be neglected by that race, who became daily more bold, from their numbers being greatly increafed by the union of all thofe who had taken shelter in the mountains; the re-admission into the left of thofe who, to fave their lives, had abjured, for a period, their ufages; and the conversion of a number of profelytes, who harden’d to join a standand under which robberfy was made faered, and to plunder was to be pious.

Aided with thofe recruits, the Sikhs now extended their irritations over moft of the provinces of the Panjab; and though it was fome time before they repoffifed themselves of Amritfar, they began, immediately after they quitted their faltbefees, to flock to that holy city at the periods of their facred feas. Some performed this pilgrimage in fecret, and in difguife; but in general, according to a con temporary Mahometan author, the Sikh horfemen were feen riding, at full gallop, towards “their favourite fhrine of devotion. They were often feen in making this attempt, and sometimes taken prisoners; but they used, on fuch occasions, to feek, instead of avoiding, the crown of martyrdom;” and the fame authority fates, “that an infalute was never known of a Sikh, taken in his way to Amritfar, confenting to abjure his fpirit.”

Encouraged by this, a confufion which took place on the firt Afghan invasion, A.D. 1746, the Sikhs made themselves mailers of a confiderable part of the Doab of Ravi and Jalender, and the country between the rivers Ravi and Beyah, and that river and the Setlej, and extended their incursions to the neighbouring countries. But though they were feverely and repeatedly checked by Mir Manu, the governor of Lahore, yet, after his death, they availed themfelves of all the advantages which the local diftractions of a falling empire
purposed them to extend and establishing their power.

Their raids, under their most active leaders, plundered in every direction, and were successful in obtaining possession of several countries, from which they have never since been expelled; and their successes, at this period, was promoted, instead of being checked, by the appearance of their old friend, Adina Beg Khan, to Lahore; as that brave chief, resolved to defend his own government against the Afghans, immediately entered into a compact with the Sikhs, whom he encouraged to plunder the territories of Ahmed Shah Abdali.

The Afghan monarch, releasing this predatory warfare, in which the governor of Lahore was supported by the court of Delhi, determined upon invading India. Adina Beg, unable to apprise him, fled, and the Sikhs could only venture to plunder the baggage, and cut off the stragglers of the Afghan army, by which they intimidated Ahmed Shah, that he threatened them with punishment on his return; and when he marched to Cabul, he left his son Tamur Khan, and his vizir, Jehan Khan, at Lahore, with orders to take vengeance on the Sikhs for all the excels which they had committed. The first expedition of Tamur Khan was against their capital, Amritsar, which he destroyed, filling up their sacred tank, and polluting all their places of worship; by which act he provoked the whole race to such a degree, that they all assembled at Lahore, and not only attempted to cut off the communication between the fort and encampment, but collected the whole of the country, the towns and villages around it. Tamur Khan, enraged at this presumption, made several attacks upon them, but was constantly defeated; and, being at last reduced to the necessity of evacuating Lahore, and retreating to Cabul, the Sikhs, under one of their celebrated leaders, called Faza Sinh Calal, immediately took possession of the vacant soulah of Lahore, and ordered rupees to be coined, with an impression to the following import: "Comed by the grace of Khaleej ji, in the country of Ahmed, conquered by Faza Sinh Calal." Although they were afterwards expelled, together with the Afghans, from Lahore, yet after the death of Adina Beg Khan, the governor of this province, they eagerly seized the opportunity that was thus afforded them, of making themselves again masters of Lahore. Their successes was, however, soon checked by Ahmed Shah Abdali, who, irritated by their unshaded turbulences and intolerable intrepidity, made every effort (after he had gained the victory of Paupatip,' which established his supremacy at Delphi) to destroy their power; and, with this view, he entered the Panjab early in 1762, and overran the whole of the country, with a numerous army, defeating and dispersing the Sikhs in every direction. That fact, unable to make any stand against the army of the Abdali, pursued their old plan of retreated near the mountains; and collected a large force in the northern districts of Sirhind, a distance of above one hundred miles from Lahore, where the army of Ahmed Shah was encamped. Here they conceived themselves to be in perfect safety; but that prince made one of those rapid movements for which he was so celebrated, and reaching the Sikh army on the second day, completely surprized and defeated it with great slaughter. In this action, which was fought in February 1762, the Sikhs are said to have lost upwards of twenty thousand men; and the remainder fled into the hills, abandoning all the lower countries to the Afghans, who committed every ravage that a barbarous and savage enemy could devise. Amritsar was razed to the ground, and the sacred reservoir again choked with its ruins. Pyramids were erected, and covered with the heads of slaughtered Sikhs; and it is mentioned that Ahmed Shah caused the walls of those mosques which the Sikhs had polluted to be washed with their blood, that the exterior might be removed, and the infidt offered to the religion of Mahomet expiated.

This species of savage retaliation appears to have inspired instead of deterring the courage of the Sikhs, who, though they could not venture to meet Ahmed Shah's army, still handled it with an insolent and undaunted warlike spirit, and when that sovereign was old, by the combination of Afghans, to return to Cabul, they attacked and defeated the general he had left in Lahore, and made themselves masters of that city, in which they levelled with the ground those mosques which the Afghans had, a few months before, purified with the blood of their brethren.

When Ahmed Shah, after retaking Lahore, A.D. 1763, was obliged, in the ensuing year, to return to his own country, the Sikhs again expelled his parrain, and made themselves masters of the Panjab; and, from that period until his death, a constant war was maintained, in which the enterprise and courage of the Afghans gradually gave way before the alternating activity, and inexorable perseverance, of their enemies; who, if unable to hold a general action, retreated to impenetrable mountains, and the moment they saw an advantage, rushed again into the plains with renewed vigour and reënacted numbers. Several Sikh authors, treating of the events of this period, mention a great action having been fought by their countrymen, near Amritsar, against the whole army of Ahmed Shah, commanded by Ahmed Shah Abdali; but they differ with regard to the date of this battle, some fixing it in 1762, and others later. They pretend that the Sikhs, inspired by the sacres of the ground on which this action was fought, contended for victory against superior numbers with the most desperate fury, and that the battle terminated in both parties quitting the field, without either being able to claim the least advantage. The historians of Ahmed Shah are, however, silent regarding this action, which indeed, from all the events of his long contests with the Sikhs, appears unlikely to have occurred. It is possible the Sikhs fought at Amritsar with a division of the Afghan army, and that might have been commanded by the prince; but it is very improbable they had ever force to encounter the concentrated army of the Abdali, before which, while it remained in a body, they appear, from the first to the last of their contests with that prince, to have always retreated, or rather fled.

The Sikhs, when oppressed, became as formidable for their union, as for their determined courage and unconquerable spirit of resistance; but a state of persecution and distress was most favourable for a constitution like theirs, which required constant and great sacrifices of personal advantage to the public good; and such sacrifices can only be expected from men who act under the influence of that enthusiasm, which the fervour of a new religion, or a struggle for independence, only imparts, and which are always most readily made when it becomes obvious to all, that a complete union in the general cause is the only hope of individual safety.

The Sikhs may be reckoned the most western nation of Hindoostan: for the king of Candahar polishes but an insignificant extent of territory on the east of the Indus. Since the complete downfall of the Mogul empire, they have acquired very extensive domains. But major Renouf observes, that their power ought not to be estimated in the exact proportion to the extent of their population, since they do not form one entire state; but a number of small ones, independent of each other in their internal government, and only connected by a federal union. They have extended their territories on the south-east, that is, into the province of
of Delhii, very rapidly of late years; and perhaps, the Zendinars of that country may have found it convenient to place themselves under the protection of the Sikhs, in order to avoid the more oppressive government of their former masters. It is certain that the eastern boundary of the Sikhs' dominions has been advanced to the banks of the Jumnah river, above Delhi, and to the neighbourhood of that city; for the adjoining territory of Schaurunpun is subject to their depredations, if not actually tributary to them; and they make incursions even to the side of the Ganges. On the south, they are bounded by the northern extreme of the sandy desert of Regiftan, and on the south-west their boundary meets that of Sind, or Tatts, at the city of Behker or Bheker, on the Indus. On the west the Indus is their general boundary, as high up as the city of Attock; near to which begins the territories of the king of Candahar; and their northern boundary is the chain of mountains that lies towards Thubet and Cashmere. As this is the case, they will be found to possess the whole southah or province of Lahore, the principal part of Moultau, and the western part of Delhi; the dimensions of which tract are about 400 British miles from N. to S., and from 150 to 200 broad, in general; although in the part between Attock and Behker (that is, along the Indus) the extent cannot be less than 320. Their capital city is Lahore.

According to the statement of brigadier-general Malcolm, the country now possessed by the Sikhs, which reaches from N. lat. 28° 49' to beyond N. lat. 32°, and includes all the Panjab, a small part of Moultau, and most of that tract of country which lies between the Jumnah and the Setlej, is bounded, to the northward and westward, by the territories of the king of Cabul; to the southward, by the possessions of the mountainous rajas of Jammu, Namur, and Sirinagar; and to the southward, by the territories of the English government, and the sandy deserts of Jafaimer and Hary's Hifar. A general estimate of the value of the country possessed by the Sikhs may be formed, when it is stated, that it contains, besides other countries, the whole of the province of La-
hore; which, according to Mr. Bernier, produced in the reign of Auranzebe, 246 lacs and 95,000 rupees, or 2,460,950l. sterling. The Sikhs who inhabit the country between the Setlej and the Jumnah, are called Malwa-Sikhs, and we believe almost all converted from the Hindoo tribes of Jats and Gujaras. The country of the Malwa Sikhs is in some part fruitful; but those districts which border on Hariya and Carnul are very barren; being covered with low wood, and in many places almost delirious of water. Its former capital was Sirhind, but it is now a complete ruin. Patiala is now the largest and most flourishing town of this province, and next to it is T'hanesur, which is still held in high veneration by the Hindoos, who have also a high reverence for the river Serafetti, which flows through this province. The country of Janela Doob, which reaches from the mountains to the junction of the Setlej and the Beah, is the most fruitful of all the possessions of the Sikhs, and is perhaps excelled, in climate and vegetation, by no province in India. The soil is light, but very productive; the country, which is open and level, abounds in every kind of grain. The towns of Janela and Sultanpore are the principal in the Doob. The country between the Beah and River rivers is called Bari Doob, or Man'ja; and the Sikhs inhabiting it are called Man'ja Sikhs. The cities of Lahore and Amritsar are both in this province, and consequently it becomes the great centre of the power of the nation. The country of Bari is said to be fertile, particularly towards the mountains, than Janela, but lying on the same level, its climate and soil must be nearly the same. The inhabitants of the country between Ravi and Chandhan are called D'harpri Singh, from D'harpri, the name of the country; the D'hanigheb Singh are beyond the Chandhan, but within the Jelalun river. The Sind Singh is the term by which the inhabitants of the districts under the Sikhs bordering on the Sind are known; and Nakki Singh is the name given to the Sikhs who reside in Multan.

The government of the Sikhs may be termed a theocracy. Although they obey a temporal chief, that chief prefers his power and authority by professing himself the servant of the Khalifs, or government, which can only be said to act, in times of great public emergency, through the means of a national council, of which every chief is a member, and which is supposed to deliberate and resolve under the immediate inspiration and impulse of an invisible being; who, as they believe, always watches over the interests of the commonwealth. It is natural, however, to imagine that the power of this assembly should decline; and from Col. Malcolm's account, we may infer, that it is nearly destroyed. The last Guru-mata was called in 1805, when the British army pursuaded Halkar into the Panjab. The government is mild; but in their mode of making war the Sikhs are unquestionably savage and cruel. Among the Sikhs there is a class of devotees, called Acalis, or immortals, who, under the double character of fanatic priests and despot soldiers, have usurped the sole direction of all religious affairs at Amritsar; and who, of course, are leading men in a national council held at that sacred place, and which deliberates under all the influence of religious enthusiasm. This order of Sikhs was first founded by Guru Govind, and are distinguished by their drefs, as well as by their having almost the sole direction of the religious ceremonies at Amritsar. They have a place on the bank of the sacred reservoir of Am-
rifar, where they generally resort, but are individually possessed of property, though they affect poverty, and frugality on charity. The principal chiefs of the Sikhs are all descended from Hindoo tribes. The lower order of Sikhs, compared with the wretched Mahometans who are doomed to oppression and hard labour, are happy; they are protected from the tyranny and violence of the chiefs under whom they live by the precepts of their common religion, and by the condition of their country, which enables them to abandon, whenever they choose, a leader whom they dislike. The civil officers, to whom the chiefs entrust their accounts, and the management of their property and revenue concerns, as well as the conduct of their negociations, were in general Sikhs of the Khalafa cast, who, being followers of Nanak, and not of Guru Govind, are not devoted to arms, but educated for peaceful occupations, in which they often become very expert and intelligent. In the collection of the revenue of the Panjab, it is faid to be a general rule, that the chiefs to whom the territories belong should receive the half of the produce, grain paying in kind, but fugar, melons, &c. in cash, and the farmer the other: but the chief never levies the whole of his share; and in no country, perhaps, is the raja, or cultivator, treated with more indulgence. Commerce is rather restrained than encouraged by the heavy duties and the refracted rate of the country. However, a great part of the shawl trade now flows through the cities of Lahore, Amritsar, and Patiala, to Hindooftan. The ad-
miration of justice among the Sikhs is in a very rude and imperfect rate.

Their law is all unwritten. Nothing is configned to any express form of words. There is no definition of any thing. The custom of the country, the custom of the court, (that is to say, as far as the judge is pleased to be governed by those usages,) and the will of the judge—-are the
the circumstances which guide the decision. Among the Hindus some of the sacred books, among the Mahometans the Koran, are used as the books of law. Among the Sikhs there is no such reference to any sacred books; and their situation is, in all probability, so much the better: for the Koran or Hindoo books afford scarcely any rules or principles of law, which are not too vague to dispense with language which the interpreter chooses to give them; and while their authority is sufficient to supercede that of the natural dictates of justice and equity, which are the only guides of the Sikh judges, the Hindoo or Mahometan has only to find or to forge a principle of his book, which may enable him to decide as he pleases.

Trivial disputes about property are settled by the heads of the village, by arbitration, or by the chiefs. The court of arbitration is called patravat, or a court of five, the general number of arbitrators chosen to adjust differences and disputes. It is usual to assemble a pancharat, or a court of arbitration, in every part of India under a native government; and, as they are all chiefs chosen from men of the best reputation in the place where they meet, this court has a high character for justice. The decision obtained by either of these modes is final. If a theft occurs, the property is recovered, and the party punished, not with death, by the person from whose hands it was stolen, or by the inhabitants of the village, or his chief. Murder is sometimes punished by the chief; but more generally by the relatives of the deceased, who, in such cases, rigorously retaliate on the murderer, and sometimes on all who endeavour to protect him.

The character of the Sikhs, or rather Sinhs, which is the name by which the followers of Guru Govind, who are all devoted to arms, are distinguished, is very marked. They have, in general, the Hindoo cast of countenance, somewhat altered by their long beards, and are to the full as active as the Mahrattas, and much more robust, from their living fuller, and enjoying a better and colder climate. Their courage is equal at all times to that of any natives of India; and when wrought upon by prejudice or religion, is quite desperate. They are all horsemens, and have no infantry in their own country, except for the defence of their forts and villages, though they generally serve as infantry in foreign armies. They are bold, and rather rough in their addresses, which appears more to a stranger from their invariably speaking in a loud tone of voice; but this is quite a habit, and is alike used by them to express the sentiments of regard and hatred. The Sikhs have been reputed deceitful and cruel, but John Malcolm knew no grounds upon which they could be considered more so than the other tribes of India: they seemed to him, from all the intercourse he had with them, to be more open and sincere than the Mahrattas, and less rude and savage than the Afghans. They have, indeed, become, from national success, too proud of their own strength, and too irritable in their tempers, to have patience for the wishes of the former; and they retain, in spite of their change of manners and religion, too much of the original character of their Hindoo ancestors, (for the great majority are of the Hindoo race,) to have the constitutional ferocity of the latter. The Sikh soldier is, generally speaking, brave, active, and cheerful; without polish, but detestful neither of finery nor attachment; and, if he often appears wanting in humanity, it is not so much to be attributed to his national character, as to the habits of a life, which, from the condition of the society in which he is born, is generally pail in scenes of violence and rapine.

The Sikh merchant, or cultivator of the soil, if he is a Sinh, differs little in character from the soldier, except that his occupation renders him less profuse and boisterous.

He also wears arms, and, in, from education, prompt to use them, whether in his individual interest or in that of the community to which he belongs, requires him to do so. The general occupations of the Khalsa Sikh has been before described. Their character differs widely from that of the Sinh. Full of intrigue, lust, wanton, and voluptuous, they have all the arts of the lower classes of Hindoo, who are usually employed in theft,欺诈, and robbery; if, indeed, they have any distinction of chief, it is very difficult to determine with them.

The general character of the religious tribes of Acchs, Shahah, and Nurnah, is formed from their habits of life. The Acchs are the most violent, impetuous, and daring; they presume upon their descent from the Hinduss, and are the most active of this race. They keep up the old Hindoo laws, and the use of the Hindoo usages among them, which have not yet been abandoned by most of them. They are, however, greatly dominated by their kinsfolk, who hold it sacrilege to injure the race of their founder, and, under the advantages which this general veneration affords them, the Nurnahs have pursued their occupations, which, if they are not mendicants, are generally that of travelling merchants. They do not carry arms; and profess, agreeably to the doctrine of Nurnah, that it is at peace with all mankind.

The Sikh converts continue, after they have quitted their original religion, all those civil usages and customs of the tribes to which they belonged, that they can practicably live in. The first and most general of these usages is the Hindoo usage of distinguishing the castes of their tribe, every tribe intermarrying within itself. The Hindoo usage regarding diet, is also held equally sacred; no Sikh descended from a Hindoo family ever violating it, except upon particular occasions, such as a Gurnama, when they are obliged, by their tenets and institutions, to eat promiscuously. The strict observance of these usages has enabled many of the Sikhs, particularly of the Jat and Gujer tribes, which include almost all those settled to the south of the Setlej, to preserve an intimate intercourse with their original tribes; who, considering the Sikhs not as having lost caste, but as Hindoos that have joined a political association, which obliges them to conform to general rules established for its preservation, neither refuse to intermarry, nor to eat with them.

We shall here add, that the "Jatts" are Hindoos of a low tribe, who, taking advantage of the declining state of the Mogul empire, have, by their courage and enterprise, raised themselves to some consequence on the north-western parts of Hindoostan, and many of the strongest forts of that part of India are still in their possession. The "Gujar" are also Hindoos, and have raised themselves to power by means not dissimilar to those used by the Jats. Almost all the thieves in Hindoostan are of this tribe.

The higher class of Hindoos, such as Brahmins and Chatriya, who have become Sikhs, continue to intermarry with converts of their own tribes, but not with Hindoos of the cast they have abandoned, as they are polluted by eating unclean food, all kinds of which are lawful to Sikhs, except the cow, which it is held sacrilege to eat.
The Mahometans, who become Sikhs, intermarry with each other, but are allowed to preserve none of their usages, being obliged to eat hog’s flesh, and abstain from circumcision. The Sikhs are forbidden the use of tobacco, but allowed to indulge in spirituous liquors, which they almost all drink to excess; and it is rare to see a Sikh soldier, after a battle, quite sober. Their drink is an ardent spirit, made in the Punjab; but they have no objection to either the wine or spirits of Europe, when they can obtain them.

The use of opium to intoxicate is very common with the Sikhs, as with most of the military tribes of India. They also take b’hang (cannabis sativa), another intoxicating drug.

The conduct of the Sikhs to their women differs in no material respect from that of the tribes of Hindoos, or Mahometans, from whom they are descended: their moral character, with regard to women, and indeed in most other points, may, from the freedom of their habits, generally be considered as much more lax than that of their ancestors, who lived under the restraint of fewer restrictions, and whose fear of excommunication from their cast, at least obliged them to cover their fins with the veil of decency. This the emancipated Sikhs despise; and there is hardly an infamy which this debauched and dissolute race are not accutted, and with justice, as Sir John Malcolm believed, of committing in the most open and shameless manner.

The Sikhs are almost all horsemen, and they take great delight in riding. Their horses were formerly famous for their strength, temper, and activity; but they are now no better mounted than the Maharratts.

Their horsemen ufe swords and spears, and most of them now carry match-locks, though some still ufe the bow and arrow, a species of arms for excellence in the use of which their forefathers were celebrated, and which their descendents appear to abandon with great reluctance.

The education of the Sikhs renders them hardy, and capable of great fatigue; and the condition of the society in which they live, affords confiant exercise to that refined spirit of activity and enterprize which their religion has generated. Such a race cannot be epures; they appear, indeed, generally to despise luxury of diet, and pride themselves in their coarse fare. Their dress is also plain, not unlike the Hindoos, equally light, and divested of ornament. Some of the chiefs wear gold bangles, but this is rare; and the general characteristics of their dress and mode of living is simplicity.

The principal leaders among the Sikhs affect to be familiar and easy of intercourse with their inferiors, and to despise the pomp and state of the Mahometan chiefs; but their pride often counteracts this disposition; and they appear to have, in proportion to their rank and confluence, more state, and to maintain equal, if not more reverence and dignity with their followers, than is usual with the Maharratt chiefs.

The principal leaders among the Sikhs affect to be familiar and easy of intercourse with their inferiors, and to despise the pomp and state of the Mahometan chiefs; but their pride often counteracts this disposition; and they appear to have, in proportion to their rank and confluence, more state, and to maintain equal, if not more reverence and dignity with their followers, than is usual with the Maharratt chiefs.

It would be difficult, if not impracticable, to ascertain the amount of the population of the Sikh territories, or even to compute the number of the armies which they could bring into action. They boast that they can raise more than a hundred thousand horse; and, if it were possible to assemble every Sikh horsemann, this statement might not be an exaggeration; but there is, perhaps, no chief among them, except Ranjit Sinh, of Lahore, that could bring an effective body of four thousand men into the field; and the force of Ranjit Sinh did not, in 1805, amount to eight thousand, and part of that was under chiefs who had been subdued from a state of independence, and whose turbulent minds ill-brooked an usurpation, which they deemed sub-

SILAS, a river of India, which springing from a fountain of the same name, ran into the country of the Silasans, according to Arrian.

SILATUM, a word used by the ancient Romans to expels a morning's draught of wine. This was usually of a wine medicated with the plant sile, or silei, and thence had its name. It has always been the custom to medicate the morning draught of any strong liquors; we do it with wormwood, or the common bitter tincture; the Indians with ginger.

SILAVENO, in Geography, a town of Italy, in the Novara; 10 miles N.W. of Novara.

SILAUAM, in Botany, a name used by some authors for the Silybum marianum, or common dockbone.

SILAUNA, in Geography, a town of European Turky, in Bulgaria; 40 miles W. of Nicopol.

SILBACH, a village of Hamburgh, in the country of the Fools, on the Saepend. N. lat. 17° 54'.

SILBERBERG, a mine-town of Sileia, belonging to the principality of Berg, but inhabited in that of Magdeburg. N. lat. 50° 24'. E. long. 16° 26'.

SILBEREGG, a town of the duchy of Carnithia; 2 miles N.W. of Eberseifen.

SILBERMANN, Johann Andreas, in Biography, the most eminent and renowned organ-builder and maker of keyed-instruments in Germany. He was born at Strasbourg in 1712, and the first of a numerous and eminent family of that name, who have inherited his professional abilities and reputation. There is, in Gerber's Continuation of Walther's Musical Lexicon, a list of their several names and works; but old Silbermann was the Father Smith of Germany. His instruments are prized above all others for workmanship and tone. The Bach family have been always partial, not only to Silbermann's organs, but harpsichords and clavichords. When we heard Emanuel Bach perform at Hamburg, it was always on a favourite Silbermann clavichord; piano forts were not then brought to great perfection any where; but since that time we find that John Henry Silbermann is much celebrated for his piano forts.

SILBERSCHLAG, John Isaiah, a German mathematician and mechanist, was born in 1721. He studied at the college Klutterberge, near Magdeburg, and afterwards went through a course of theology at Halle, from which place he returned to the college at which he had been before, where he taught natural philosophy and mathematics for nine years. After this he became pastor of one of the churches at Berlin, and rector of the royal school. He was a member of the Academy of Sciences in that city; and, besides writing various works on mechanical and mathematical subjects, constructed a great many machines, instruments, and models, for the use of the students in the Seminary which had been placed under his care. He died
in November 1791. He left behind him a great number of works, among which are, “A Treatise on the warlike Machines of the Ancients”; “Letters on the Northern Lights”; “A Treatise on Hydraulic Architecture”; “The Chronology of the World rectified by the Scriptures.”

SILBERSTRASS, in Geography, a town of Saxony, in the circle of Erzgebirg; 4 miles S.S.E. of Zwickau.

SILBium, in Ancient Geography, a town of Italy, in Japygia.—Also, a town of Alia, in Greater Phrygia.

SILBDAL, in Geography, a town of Sweden, in the province of Warmeland; 35 miles W. of Carlstadt.

SILBOJOCK, a town of Sweden, in the Lapland of Pitea; 12 miles N. of Narva.

SILBURY, one of the largest barrows or tumuli in England, and probably in the world, is situated on the Marlborough Downs, about six miles west of the town of Marlborough, in Wiltshire. The origin, appropriation, and history of this extraordinary mound of earth, are alike unknown to the topographer and antiquary. In the vicinity of the immense druidical temple at Avebury, (see Avebury,) it is rationally supposed to have been originally connected with that structure; and as the most remote antiquities of this island, and of the civilized world, have given rise to much fabulous dissertation, and fanciful hypothesis, so the barrow now called Silbury Hill has been referred to various tribes of people, applied to different purposes, and attributed to the most remote origin. Dr. Stukeley was of opinion that its present name is of Saxon derivation, and signifies “the great or marvellous hill”; while others contend that it is either a corruption for Sil-barrow, which they translate “the peaceful grave;” or of Sel-barrow, meaning “the large or elevated barrow.” The most common supposition respecting its nature ranks it among the sepulchral claus of monuments. Stukeley calls it the tomb of Cunetha, whom he characterizes as a celebrated British king, who refided at Cunetia (then supposed to have been Marlborough), and gave his name to that town, and to the river Kennet, or Kunet. The Rev. Samuel Greathat, in a letter to Mr. Britton, printed in the account of Wiltshire, in the 15th volume of the “Beauties of England and Wales,” regards Silbury as the burial-place of Prydian, a late king of the Britons, to whom he ascribes the union of the British tribes under one monarchy, and the construction of Avebury, as a place of assembly for the chiefs and people on great national occasions. Another opinion respecting this tumulus is, that it was the mount on which the Druids lighted up fires, when they wished to give notice to the surrounding country of some intended religious ceremonial. This view of the subject is of course confined to those who consider Avebury as having been a druidical temple; among whom is the Rev. Edward Davies, author of “Celtic Researches,” and of “The Mythology and Rites of the British Druids.” To these opinions relative to Silbury Hill may be added a third, which may be regarded as equally probable with any of the conjectures above stated. It is, that, like the Tinwald of the Isle of Man, and the Moote-hill of Scone, it was the mount of justice, the eminence from the summit of which the king promulgated the laws enacted in the national assemblies, and on which he and his judges sat to decide all important causes, whether of a civil or criminal nature.

Silbury Hill is situated directly south from Avebury, and nearly in the centre between the extremities of the two avenues, which extended from the temple to the distance of a mile each way. At the base the hill is about 560 feet in diameter, or 1680 feet in circumference; at the top, 105 feet diameter, or 315 feet in circumference; and it rises 170 feet in perpendicular height. Stukeley estimates its solid contents at 13,556,809 cubic feet, and highly praised the choice of the ground, and the symmetrical proportions of the sstructure itself. In digging here in 1723, a human skeleton, with the bit of a bridle, deer’s horns, and an iron knife, were discovered, which Dr. Stukeley confidently believed to have belonged to the person for whom he supposed the mount was raised; but the posture of the skeleton near the surface and on a declivity would render such a conclusion extremely improbable, even though it were undoubted that Silbury is of sepulchral origin. Stukeley’s Abury, folio, 1743. Beauties of England and Wales, by J. Britton, F.S.A. 8vo. 1814. SILCHESTER, a parish in Hampshire, England, at the northern extremity of that county, bordering on Berkshire, contains the feite and ruins of an ancient Roman station. It appears also to have been a city of the Belgo Britons anterior to the Roman colonization of Great Britain, and was called Caerfebon, or Segont, as being the chief city of the Sazgoniaci. In the seventh Iter, of Antonius it is named Vindomim, and marked 22 miles from Venta-Belgarum (Wincheffler), and xc from Callevam (probably Reading). That this was a Roman station of importance, appears evident from the various roads, or vic, branching from it; from the magnitude and construction of the walls, valla, and amphitheatre; and from the numerous coins and other relics that have been found here at different periods. The whole city, or station, was surrounded by a fos, with a vallum on the inside, on which a wall was raised. This was constructed, in the usual Roman manner, with alternate layers, or rows of large flat stones, rubble flints, and cement, also bricks and slabs. In one place this wall was twenty-four feet thick, and the fos was above 100 feet across. The exterior form of this station is unlike any other Roman work in England, being an irregular octagon; whereas those of Camulodunum (Colchester), Venta-Belgarum (Wincheffler), Lindum (Lincoln), Londinium (London), and almost all others, were constructed in the shape of a parallelogram, with the corners rounded off. The inclosed area of Silchester is about one mile and a half in circumference, and contains nearly one hundred acres, the whole of which is appropriated to the arable and pasture lands of a farm. In very dry seasons, it is easy to trace the situation and direction of the Roman streets, two of which intercepted the town, and communicated with the four entrance gates, on the east, west, north, and south sides of the city. Near the centre of the area have been traced the foundations of a large edifice, supposed to have been the forum. About 150 yards from the north-east corner of the walls, are the banks of an amphitheatre, which appears to have contained five rows, or terraces for spectators. A small church and a farm-house, with its offices, are all that now remain within the ancient walls; and thus present an amazing contrast to the appearance and pursuits of former times. Now the humble and useful husbandman, with the humane Christian pastor, are the chief occupants of this peaceful spot, which, in the third century, was peopled with Roman soldiers, and was often the theatre of remorcleles battles, savage sports, and senefels Pagan ceremonies. A particular account of this place will be found in the 6th volume of “The Beauties of England,” by J. Britton and E. W. Brayley.

SILCOU, a town of Hindoostan, in My forest; 8 miles S.E. of Seringapatam.

SILDA, in Ancient Geography, a town of Africa, in Mauritania Caferiensis, according to Ptolemy. The Itinerary of Antonine places this town on the route from Togo-lusia to Tingis, between Aquae Dacieae and Voilificene.
SILENE, in Geography, a large and populous nation and place on the coast of the Black Sea, in the hundred of East Galicia, and county of Luneville, England. The lordship contains about 3200 acres, the greater part of which is moor land, with other commons and lands, in conformity to an act of parliament passed in 1759. The manor belongs to Earl Ferrers. In the parish were formerly two ancient manor-houses, belonging to the See and the Pochin families. In 1811 the parish contained 249 houses, and 1200 inhabitants, most of whom were employed in agriculture, and frame-work knitting. Here is one free school, and three other large schools. The church, a handsome stone building, consists of a nave, aisle, a chancel, a porch, and a tower. The revenues of the church were formerly appropriated to the abbey of St. Ebrulphus, in Normandy, which was suppressed by King Henry V. Afterwards the living belonged to the priory of St. Mary, in the isle of Axholme, in the county of Lincoln. Nichols's History and Antiquities of the County of Leicestershire, folio, vol. ii.

SILENE.

Flowers spik'd, alternate, nearly filiflime, directed one way. Petals deeply cloven. Leaves spathulate, hairy. — Native of Spain, the south of France, vineyards about Conflantinople, and cultivated ground in Greece; also of Virginia; flowering in June and July. An annual, upright, slightly branched species; the leaves with which accompany the flowers narrow, and much smaller than the rest. Petals small, pale pink, or white with a green external tint, minutely crowned. Cleft ovate, ralked. The flowers are said to expand at night only.

S. pendula. Pendulous Catchfly. Linnaeus Sp. Pl. 559. Willd. n. 27. Ait. n. 37. Prodr. Fl. Græc. n. 979. Curt. Mag. t. 114. (Willogo hisa ficelus, thecasis aquaculz facie, fupina; Dill. Ethl. t. 421. t. 312.) — Flowers racemose. Calyx of the fruit pendulous, inflated, with ten rough ribs. Stem decumbent. — Native of Italy, Sicily, Crete, and Cyprus, flowering in the spring. Every bank about Rome is decorated with this elegant plant in the spring. Nothing is better calculated for the decoration of rock-work, or dry parterres, than this hardy annual, whose purplish stems spread in every direction, and are copiously adorned with large pink flowers, with a membranous, violet-ribbed, inflated calyx. The seeds scatter themselves without any trouble.

S. vulgaris. Pink Evening Catchfly. Retz. Off. fusc. 3. 31. Willd. n. 24. Ait. n. 35. Curt. Mag. t. 677. Sm. Fl. Græc. Sibth. t. 409, unpublished. (S. bipartita; Desfont. Atlant. v. 1. 332. t. 100. S. ciliata; Willd. n. 41, excluding the fynonym. Lyciæna marina hifura purpures, luecoj follo; Barred. Ic. t. 1010.) — Petals with two deep rounded lobes, and a sharp cloven cleft. Calyx deeply divided. Leaves spatulate. Stems diffuse. — Found on the sea-shores of Sicily, Barbary, Crete, Malta, and Greece, not uncommon. It has been known about twenty years in our gardens, as a hardy annual, flowering in summer. Linnaeus had specimens, but never determined the species. The stems bear numerous spathulate leaves. The flowering branches are naked below, each terminating in a simple cluster of eight or ten handsome bracted pink flowers, all drooping one way, with a reddish club-shaped calyx. The pubescence, especially of the calyx, is more close and soft than in S. pendula, though more long and shaggy in some specimens than others. The stem is very rarely once forked, being usually altogether racemose.

S. dicotyledon. Pale Spiked Catchfly. Prodr. Fl. Græc. n. 981. Fl. Græc. t. 410, unpublished. — Petals with two deep narrow segments, and a notched cleft. Calyx villous. Leaves obovate. Stem diffuse. — Gathered by Dr. Sibthorp, in the isle of Cyprus. The root is annual, long. Stems spreading, scarcely a span in length, not forked, though mostly once divided, round, leafy, reddish, rough, like the root of the herbage, with long spreading hairs. Leaves thick and broad, rather more than an inch in length; the lower ones tapering at the base. Flowers fix or eight in each spike, cleft, on short partial flaks. Calyx rather slender, hardly an inch long, with ten red hairy ribs. Limb of each petal nearly as long as the claw; pale red on the upper side; light green, with darker veins, beneath; cleft white, divaricate, double-toothed.

S. thyrsiflora. Thyme-leaved Catchfly. Prodr. Fl. Græc. n. 982. Fl. Græc. t. 411, unpublished. — Petals with two deep narrow segments, and a notched cleft. Calyx hairy, glutinous. Stems procumbent, woody, much branched. Found by Dr. Sibthorp on the sandy shores of Caria and the isle of Cyprus. Root perennial. Stems a foot or two in length, widely spreading, repeatedly branched, copiously jointed, round, hairy, sending up several terminal, ascending, simple, leafy, hairy, and rather vilid, flowering branches, from three to six inches long. Leaves obovate, acute, rough, about half an inch long, with axillary tufts of still smaller ones. Flowers racemose, three or four at the top of each branch, erect, white; the back of the petals greenish. Calyx an inch long, hairy, pale green, with pink dots.

S. dichotoma. Forked Long-branched Catchfly. Ehrh. Beitr. v. 7. 143. Fl. Seelc. n. 65. Willd. n. 23. Fl. Græc. t. 413, unpublished. (S. trinervis; Soland. in Rudolf's Aleppo, ed. 2. 252.) — Petals in two deep narrow segments, with scarcely any crown. Stem forked, racemose, villous as well as the leaves. — Native of Hungary and the Levant. Dr. Sibthorp met with it in Crete, and about the Bithynian Olympus. We believe this species was raised, about 25 years ago, in many gardens about London, from seeds sent by the late Mr. Davall, so that it is entitled to a place in the Hortus Krewensi. Root biennial, tapering, as thick as a common radish. Stems several, ascending, from one to two feet high, round, hairy with long spreading hairs, once or twice forked, with an intermediate, nearly filiflime, flower, and then extended into long, simple, spik'd or racemose branches, each bearing five or six filiflime white flowers, whose petals are narrow, with only occasional rudiments of a cleft. Calyx with ten green ribs. Anters green. Seeds red-brown. The leaves are chiefly radical, and very numerous, composing a dense, shaggy, hoary, and somewhat glaucous, tuft; each leaf two inches long, and nearly one broad, obovate, bluntly pointed, tapering down into a broad footstalk.

S. divaricata. Forked Spreading-branched Catchfly. Sm. Prodr. Fl. Græc. n. 985. Fl. Græc. t. 414, unpublished. — Petals in two deep rounded lobes, with a cloven cleft. Stem forked, divaricate, racemose. Leaves all lanceolate, hairy, acute. Discovered by Dr. Sibthorp on the coast of Asia Minor. In size and habit this bears some affinity to the last, but is more leafy, and the leaves are longer, tapering at each end, undulated, of a darker green, rough with shorter hairs, not shaggy. The flowering branches spread at almost right angles. The flowers are white, but with much broader and rounder petals, each petal bearing a rounded cloven cleft.

Sect. 2. Stem forked, with panicled branches.

chick noticed it in Canada. The root is perennial, long, white, branching at the summit. Stem erect, a foot and a half or two feet high, branched, round, glaucous: Leaves ovate-lanceolate, acute, glaucous, usually very smooth, but occasionally rough and fringed; the radical ones numerous, crowded, spatulate. Panicle forked, bearing numerous white drooping flowers. Calyx almost globular, membranous, white, elegantly reticulated with green or purplish veins and ribs. Tub of each petal almost as long as its claw, but half was divided into two spreading, oblong, somewhat rounded segments, generally ditruncate at the base, but we have sometimes seen the divisions of one. Another green, occasionally liable to a failure, by which they become elongated, teeming with utelae purple dust, which stains the petals. The natives of Zante, who call the piant of this genus, eat the boiled leaves, which are said to partake of the flavour of green peas.

(9. amenea; Huds. Angl. t. 188. Light. Scot. t. 227. Cucubalut Bebeh a; Linn. Sp. Pl. 591. Fl. Dan. t. 857. Lychmis lymma anglica; Bach. Hutt. v. 3. p. 2. 357. Ger. Em. 409. Lob. Ic. 337. \textmd{—} Flowers nearly solitary, terminal. Petals cloven about half way down; the segments of their creft entire. Calyx smooth, reticulated with veins. Stem decumbent. \textmd{—} Native of the sandy or rocky sea-shores of Norway, Britain, Gotland, &c., as well as of the floy beds of mountain torrents in Wales, flowering in August and September. The appearance of the leaves and flowers, at first sight, is so like S. infra, that most botanists, for a long time, confidered the plant as a mere variety of that species. They are indeed so nearly akin, as to be inseparable with respect to genus, though S. infra is mostly without a crown to the flower, and this is usually furnished with one. The root of S. maritima is creeping, and the plants often quite prostrate, hardly a span high, bearing one flower, for the most part, rarely two or three, scarcely confining a panicule. The leaves are narrower, linear-lanceolate, or slightly spatulate, very smooth and glaucous, minutely toothed at the edges. Calyx much like the latter. Capule shorter, almost glabrous. Style occasionally varying to four or five.

(8. americana; Huds. Angl. v. 2. 685. — Beem album, ficu Pekomenum fuxatule, fabrifico, fuculum; Bocc. Muf. t. 133. t. 92. \textmd{—} Flowers clustered, crowded, drooping. Petals in two deep, rather narrow, lobes; the segments of their creft notched. Leaves obovate, with a small point. \textmd{—} Native of sandy places near the sea, in Sicily, Aifa Minor, Mount Athos, and the ile of Samos. Root perennial. Plant very glaucous and smooth, twice as tall as the infra, with much thinner and broader leaves. The flower once or twice forked, each of its long upright branches bearing several remote, short, tufted flowers of drooping white flowers, with a reticulated, purplish, tumid, angular calyx; and flails, with pointed fringes, all of the same hue. The tube of each petal as long as the length of its class, is two-ranked, each, spreading lobes of the crest deeply divided, with nearly create segments. Germs red in the lower half, and grey above. Calyx reticulated. The present species is supposed, according to the Linnaean character of the genus, and its close relationship to the three preceding, to be separable from any of them, even as a section of a genus.

(8. americana; Huds. Angl. v. 3. p. 2. 357. Ger. Em. 409. Lob. Ic. 337. \textmd{—} Flowers in a corolosy panicle, nearly upright. Petals deeply divided, rounded; the segments of their creft notched. Calyx reticulated. Leaves obovate-lanceolate. \textmd{—} Native of Crete, Aifa Minor, and Greece. \textmd{—} The root of this annual has glaucous than the last, and more approaching the habit to our common S. infra; but the flowers are broader, and effentally different. The tube of each petal is about a quarter the length of the claw, pale pink, in two elliptical, or almost orbicular, lobes, with a white crest, of two, quite separate, notched segments. Germs elevated on a stalk of its own length, along with the petals and flails, within the calyx, as is more or less the case with most of this genus.

S. cella. Sea-green Campion or Catchfly. Sm. Prodr. Pl. 699. Fl. Græc. t. 417. unpublished. \textmd{—} Lychmis cretica mons Ich, folo toburundus, caela; Tourne. Cor. t. 44, by the character. \textmd{—} Flowers in a corolosy panicle, erect. Petals in two deep linear divisions; the segments of their creft entire. Leaves roundish-obovate. \textmd{—} Native of mount Carnarius, and if we are right in Tournefort's synonym, of mount Ida. This delicate smooth species has a very deep perennial root, crowned with a dense tuft of numerous, branching, leafy, round, pointed flowers, nearly a span high, each terminating in one or two naked flowering branches, about a finger's length, bearing a forked panicle, of from four to eight pale, but elegant, flowers. The leaves are full an inch long, and half as broad, of a deep glaucous green, tapering down into short broad footstalks, which clasps the stem. Bracteas under the partial flower-flasks small, ovate, acute. Calyx obovate, half an inch long, tipped with pink, and variegated with green and white, but hardly reticulated. Petals narrow, cream-coloured; green underneath; their lobes almost entire, or parallel, above half the length of the claw. Styles and filaments rose-coloured, with greenish anthers.

S. levigata. Sm. incepted Cachfly. Sm. Prodr. Pl. 699. Fl. Græc. t. 418, unpublished. \textmd{—} Panicle spreading. Petals cloven half way down, narrow, without a crest. Leaves roundish-elliptical. Calyx very smooth and even, without veins. \textmd{—} Found by Dr. Smith in hilly parts of the ile of Cyprus. \textmd{—} The root is annual. Stem several, from three to eight inches high, leafy below, feemingly like every other part of the plant. Leaves of a deep glaucous hue; the radical ones obovate, stalked; the rali ovate, less obtuse, and nearly sefiffle. Petals turned; the partial flals much longer than the calyx, which is ovate, reddish, peculiarly even and polished. Petals small; their limb pink, in two oblong, obtuse lobes, separated and half way down, and ditinct of any creat. Styles very downy, rather short.

(8. americana; Huds. Angl. v. 3. p. 2. 357. \textmd{—} Panicle-spreading. Petals wedge-shaped, emarginate, with a cloven crest. Leaves ovato-lanceolate. Calyx linear, cylindrical, with ten ribs. \textmd{—} Native of dry mountainous situations in Nor.}
way, Switzerland, and Greece. The root is perennial, tufted, bearing several leafy florets, four or five inches high, with a somewhat corymbose panicule. Herbaceous, smooth, green, scarcely at all glaucous. Leaves an inch long, acute, varying in length. Flowers small, white. Caspia, splitting from top to bottom into fix valves.

S. chorophila. Armenian Catchfly. Sm. Plant. ex Herb. Linn. t. 15. Willd. n. 50. Ait. n. 52. Curt. Mag. t. 807. (Lychnis orientalis viscosa, centareuli folio, flore longifimo; Tourn. Cor. 24.)—Panicule spreading. Petals cloven half way down, with a two-lobed crest. Leaves glaucous, elliptical, pointed. Calyx nearly cylindrical, very smooth, without veins.—Gathered by Tournefort in Armenia. Said to have been introduced at Kew in 1756, by Mr. John Hennemann. A hardy perennial, twelve or eighteen inches high, flowering in August, readily known by the general resemblance of its foliage to Chlora perfuffata, though the leaves are not perforate. Flowers large, erect, in a wide panicule, without scent, white, turning reddish as they fade. Calyx above an inch long, tinged with purple, very smooth, without ribs or veins, its form slender, cylindrical, or slightly club-shaped.

S. longipetala. Long-petalled Catchfly. Vent. Jard. de Cels, t. 15. Sm. Prodr. Fl. Græc. Sibth. n. 992. Fl. Græc. t. 419, unpublished.—Flowers pendulous. Petals in two deep linear segments; with a notched crest, and hairy claw. Leaves lanceolate, rough-edged.—Found by Bruguier and Olivier, in the neighbourhood of Aleppo. Dr. Sibthorp met with the name of the isle of Cyprus. The root is annual. Stem two feet high, leafy, panicked, spreading, and many-flowered. Herbaceous rather glaucous, smooth, except the edge of the leaves, which is rough to the touch. Leaves about three inches long, acute, strongly ribbed; the lower ones elongated and contracted at the base, clasping the stem at the very bottom. Flowers green, quite pendulous. Calyx obovate, ten-ribbed, smooth, half an inch long. Claws of the petals hairy below, as well as the filaments and stigmas; limb smooth, very long, involute. Stigmata club-shaped, red like the author.

S. inaperta. Small Greenish Catchfly. Linn. Sp. Pl. 600. Willd. n. 39. Ait. n. 44. Sm. Fl. Græc. Sibth. t. 420. unpublished. (Vicago lyzius, inaperto flore; Dill. Elth. 424. t. 315.)—Panicule spreading. Flowers erect. Petals in two deep narrow segments; with a double awl-shaped crest. Leaves linear-lanceolate, smooth.—Native of Madeira. Alton. Dr. Sibthorp found it on the mountains of Greece. The root in his possession is creeping, and evidently perennial. Dillenius describes it as an annual. Stems several, near a foot high, clothed in the lower part with numerous smooth green leaves, about an inch long; and branching at the top into a panicule of a few pale delicate flowers, which seem not to have expanded properly in Sherard's garden, whence originated the specific name. In our Greek specimens the calyx is flender, rather club-shaped, an inch long, smooth, with ten green ribs. Petals widely spreading, greenish-white above, light brown beneath; their crest small, in two simple awl-shaped lobes. Caspia ovate, its stalk, within the calyx, as long as itself.

S. juncea. Rushy Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 994. Fl. Græc. t. 421, unpublished.—Panicule elongated. Flowers erect. Petals in two deep narrow segments; each lobe of their crest three-toothed. Leaves fimbriate, all over rough.—Gathered by Dr. Sibthorp in Asia Minor. This has a small, white, annual root. Stem solitary, erect, two or three feet high; leafy and rough below; terminating in a very long, flender, smooth, slightly spreading panicule, of numerous florets, which are rather larger than the preceding, but with a shorter calyx. Petals white, with brown veins beneath. The leaves are crowded at the root, and bottom of the stem, green, an inch and a half long, somewhat pointed; those about the panicle are awl-shaped and smooth.

S. cretica. Cretan Catchfly. Linn. Sp. Pl. 601. Willd. n. 42. Ait. n. 47. Sm. Fl. Græc. Sibth. t. 432, unpublished. (Vicago folius inferiorius bellidis, superiorius tunicae, calicis frictoris, et turgidiori; Dill. Elth. 422. t. 314. f. 404, 405.)—Panicule sparingly branched. Flowers erect. Petals in two deep divaricated segments; the lobes of their crest acute, entire. Lower leaves ovate, undulated, rough.—Found by Dr. Sibthorp on rocks near the sea, in Crete and Cyprus, as well as on the coast of Caramania. A hardy annual, springing up spontaneously year after year in a Chelsea garden. The florets are two or three, from one to two feet high, erect, flender, virid. Leaves green; the lower ones obvate, obtuse and rough; upper linear-lanceolate, acute, smooth. Flowers few, small, but not inedant, crimson, with a smooth, purplish, obvate, ten-ribbed calyx. There is an angular tooth to the claw of the petals, at each side, below the crest.

S. conica. Corn Catchfly. Linn. Sp. Pl. 598. Willd. n. 21. Fl. Brit. n. 8. Engl. Bot. t. 922. Jacq. Amstr. t. 253. Sm. Fl. Græc. Sibth. t. 243, unpublished. (Lychnis calicis ariatis, secunda Cibus; Ger. Em. 470.)—Stem forked. Petals cloven half way down; with a rounded cloven crest. Leaves soft and downy. Calyx of the fruit conical, with thirty ribs.—Native of sandy corn-fields in the south of Europe and the Levant; rare in England, though it still occurs, as in the time of Dillenius, in the sandy parts of Kent, flowering about July. Root annual. Herb downy and vibicid, of a greyish-green. Stems solitary or numerous, spreading, various in height, forked and panicked. Leaves linear-lanceolate, acute. Flowers erect, pale rose-coloured, fragrant, especially at night, with the scent of a honey-fuckel. Calyx cylindrical, becoming conical as the capsule swells, and membranous, with thirty green ribs, and five long slender teeth. Petals nearly obcordate, as is also the white crest of each.—The petals appear to be sometimes entire, so that we suspect S. conica of Linnaeus may be a variety of this, with smoother broader leaves.

S. nolitiflora. Night-flowering Catchfly. Linn. Sp. Pl. 598. Willd. n. 31. Fl. Brit. n. 9. Engl. Bot. t. 291. (Ocyonoides noctiflorum; Camer. Hort. 109. t. 34.)—Stem forked. Petals rather deeply cloven; with a short blunt crest. Calyx with ten angles, connected by transverse ribs; its teeth as long as the tube.—Native of sandy or gravelly fields, in Sweden, Germany, England, Switzerland, Crete, and Asia Minor; not rare in Norfolk and Suffolk, flowering in July. Root annual. Herb dark green, softly hairy or downy, spreading, of a coarse rank habit. Leaves lanceolate, three-ribbed; the lowest obvate. Flowers the size of our common Lychnis dioica, (their calyx and stigmas very vicid,) unrolling their pale bluish-coloured petals in an evening only, when they exhale, in warm weather, a powerful and delicious scent. The strong reticulated ribs of the calyx are remarkable.

S. leucocephala. White and Brown Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1000. Fl. Græc. t. 424, unpublished.—Petals in two deep rather narrow segments; with a deeply cloven crest. Calyx with ten angles. Leaves linear-oblong, recurved, glabrous and hairy. Discovered by Dr. Sibthorp, in the isle of Cyprus. A hairy, glutinosus, branching, annual species, about a span high. Leaves an inch or half an inch half long, green, narrow, obtuse, channelled, forma-
what reveals, received. Flowers smaller than the last, except in their ovary, which is pale, dull, deltoid of transverse ribs. Petals cream-colored below, of a rose-purple above, with 9, their crest in two rounded cartilages. This is probably a 111st infertile flower, less the half.

S. ochidaca. Orchid-flowered Catchfly. Linn. Suppl. 241. Wild. f. 95. Att. n. 50. Sm. Fl. Gram. Sicil. 1, 427, unpublished. (S. Acreum; Jacq. Hort. Vind. v. 14, t. 32. Lychnis graeca, bellidiformis, flore parvo dilato, flore composito; Tourn. Cor. 24.)—Downy, coriaceous. Cabo y x. crispa, bidentate. Petals four-lobed; with a sharp twisted bed crest. Upper leaves ovate. Partial stalk as long as the capsule. Native of the Levant, flowering in May. Annual, of the same and habitat of the last, but the herbage is of a green-grass, and finely hairy or downy, particularly the stem, the upper part of which is also viscid. Leaves broader, sometimes smooth in the
distinct, the leafy-blue, P. Somnifera, in July, having two races, with only a foot or two clubbed, perhaps
floral basis. The leaf is not glossy. The flower is small, lateral.

Upper leaves oril in the form of cup and capitate. Petals 9, with long hairs of the leaves, flowering in summer. Dr. 191. S. 311 with the species in Greece, and on Mount Athos. Inhabit a very sunny place with the leaf, but is less, more hairy, with shorter leaves, and the flower is not distantly. The flower is fully broad, without lateral lobes. There is a brown filament in each of the flowers, by which the petals are caught.

S. ochidaca. Orchid-flowered Catchfly. Linn. Suppl. 241. Wild. f. 95. Att. n. 50. Sm. Fl. Gram. Sicil. 1, 427, unpublished. (S. Acreum; Jacq. Hort. Vind. v. 14, t. 32. Lychnis graeca, bellidiformis, flore parvo dilato, flore composito; Tourn. Cor. 24.)—Downy, coriaceous. Cabo y x. crispa, bidentate. Petals four-lobed; with a sharp twisted bed crest. Upper leaves ovate. Partial stalk as long as the capsule. Native of the Levant, flowering in May. Annual, of the same and habitat of the last, but the herbage is of a green-grass, and finely hairy or downy, particularly the stem, the upper part of which is also viscid. Leaves broader, sometimes smooth in the
with felt down. —Native of the sea-coast of Italy. Gathered by Dr. Sibthorp in Asia Minor, between Smyrna and Prusa. We regret that he had not time to have a drawing taken of this rare and curious species, of which there is not, to our knowledge, any figure extant. Rand mentions the plant as cultivated at Chelsea, in 1739, and Linnæus had it at Upsal. The stem is branched, somewhat shrubby. Whole herbage clothed with velvet-like pubescence. Leaves crowded, spatulate, an inch and a half long, acute, shortly revolute. Panicles dense, level-topped. Calyx club-shaped, ten-ribbed. Petals white or reddish; their limb inerely heart-shaped. We find this plant mentioned in Mr. Donn’s Cambridge catalogue, as introduced in 1804. If it exists in any garden, a figure ought to be published.

S. fruticosa. Shrubby Catchfly. Linn. Sp. Pl. 597. Wildl. n. 14. Ait. n. 26. Sm. Fl. Græc. Sibth. t. 428, unpublished. —(Saponaria frutecosa, acutis foliis, ex Sicilia; Bocc. Sicc. 58. t. 30. Ocyroideis frutecosum; Camer. Hort. 109. t. 33, excellunt.)—Panicle corymbose, close, somewhat three-forked. Calyx club-shaped, rough. Petals cloven; cleft of four teeth. Stem shrubby. Leaves rough-edged.—Native of rocky situations, near the sea, in Sicily and Cyprus. It is supposed, on the authority of Parkinson’s Paradys 254. n. 19, to have been cultivated here in his time. The stem is woody, half an inch in diameter, with numerous tufted leafy branches, whose erect flowering extremities, about a span long, are more distinctly furnished with smaller leaves, and are downy, villous, and coloured in the upper part, each bearing a dense level-topped panicle, of ten or fifteen large flowers. Leaves recurved, spatulate, pointed, about an inch long, evergreen, smooth, and shining; the edges only being rough with minute, reflexed, rigid hairs. Calyx above an inch long, ten-ribbed. Limb of each petal of a long, inerely heart-shaped, form; pink above; veined with green beneath; their cleft white, of two acute, somewhat notched, principal segments, and two sharp teeth at the base. In the Prodr. Fl. Græc. the figure of this plant is, by mistake, referred to S. paradoxus, which will be corrected in the Flora itself.

Sec. 4. Stem panicled, rarely forked.

S. rigidula. Slender Rigid Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1009. Fl. Græc. t. 430, unpublished.—Stem alternately branched, spreading. Petals in two deep sharpish lobes; each segment of their cleft four-toothed. Leaves lanceolate, smooth.—Discovered by Dr. Sibthorp, on mount Hymentus, near Athens. The root is annual. Stem erect, a foot high, copiously branched from the very bottom, spreading, slender, purplish, villous, but, like every other part, destitute of pubescence. Leaves green, narrow, few and remote, about an inch long; the lowest much longer and broader. Petals pale pink, veined with crimson. Calyx club-shaped, pale green, with ten red ribs, smooth, not an inch long. Capule ovate, shorter than its stalk. A very pretty species, whose copious and delicate flowers would be an acquisition to our gardens.

S. spinifera. Thorny-branched Catchfly. Sm. Prodr. Fl. Græc. Sibth. 1010. Fl. Græc. t. 451, unpublished.—Stem shrubby, branches opposite, horizontal, becoming thorns. Petals deeply divided. Leaves spatulate, downy all over.—Found by Dr. Sibthorp in Asia Minor. The stem is thick and woody, very densely branched, leafy, downy, remarkable for its numerous, long, divaricated, lateral shoots, which finally harden into spines. The flowering branches are erect, a spain high, each bearing a racemose, downy panicle, of pale-green flowers, veined underneath with brown, and to judge by their aspect, doubtless fragrant at night. Calyx about an inch long, green, downy. The cleft of each petal consists of two long, rounded, white lobes. Capule ovate, twice the length of its stalk.

S. gigantea. Gigantic Catchfly. Linn. Sp. Pl. 598. Wildl. n. 17. Ait. n. 29. Fl. Græc. Sibth. t. 443, (Lychinis græca, fifts arborecentis follow et facet Sibth. Hort. 32. t. 113.)—Stem erect, downy, and villous. Flowers tufted. Leaves spatulate, villous. Petals in two rounded lobes. Capule nearly globular.—Native of Crete and the islands of the Archipelago; Linnaeus by mistake says of Africa. It has long been known in our more curious green-houses, and is esteemed for the sweet nocturnal perfume of its pale green flowers. The plant, though a yard high, and of a shrubby aspect, is only biennial. Radical leaves two inches long, copious, of a broad spatulate figure, more or less villous, light green, obtuse, with or without a small point. Stem straight, villous; leafy, with several short branches, below; slightly branched above, but befit with dense, whorl-like, downy panicles, of numerous flowers. Calyx three-quarters of an inch long, club-shaped, downy. Limb of the petal divided more than half way, into two broad rounded lobes, veined beneath with purple; their cleft, very short. Capule twice as long as its stalk.

S. congesta. Tufted Green Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1012.—Stem somewhat branched. Panicles terminal, dense, many-flowered. Petals deeply divided, without a crest. Leaves spatulate, downy.—Gathered by Dr. Sibthorp in Greece; we believe on hills near Athens. The root is woody, evidently perennial, bearing many tufts of copious, spatulate, obtuse, green leaves, an inch and a half long, clothed, like the leaf of the herbage, with dense, very short, pubescence. Stem erect, from nine inches to two feet high, scarcely leafy, bearing a few alternate branches, somewhat villous at the top, where each terminates in a dense tufted panicle of greenish flowers, whose calyx is half an inch long, obovate, or club-shaped, and whose petals are cloven into two rounded lobes, without any cleft. This species, of which we have no figure, is in some points allied to the last, but more akin, on the whole, to the following.

S. viridisflora. Paniced Green Catchfly. Linn. Sp. Pl. 597. Wildl. n. 19. Ait. n. 31. (Lychinis ocymaflora, flore viridi; Herb. Parad. 199, with a plate.)—Stem branched. Panicles elongated, loose, drooping, many-flowered. Petals divided half way; their cleft of two linear lobes. Leaves elliptic-lanceolate, acute, downy.—Native of Portugal and Spain. The root is fald, in Hort. Kew. to be biennial, though Herrmann calls it perennial. Stem one and a half or two feet high, ending in a long loose panicle of drooping green flowers. Leaves two or three inches long, rough, like the leaf of the herbage, with extremely minute tubercles, and more or less of short hoary hairs. Flowers like the leaf, but somewhat larger, and furnished with a crown, of which we can perceive no traces in S. congesta.

S. nutans. Nottingham Catchfly. Linn. Sp. Pl. 596. Wildl. n. 11. Brit. n. 3. Engl. Bot. t. 455. Fl. Dan. t. 242, (Lycynis sylvetris alba non Claris; Ger. Em. 470.)—Flower-flanks panicked, drooping one way. Petals in two deep linear segments; their cleft of two acute lobes. Leaves lanceolate, downy.—Native of dry lime-flone pastures or rocks, in various parts of Europe, flowering in June and July. It was first, in this kingdom, observed at Nottingham caille, but grows also at Dover, and various
SILENE.
S. palaestina. See under C. 1. n. 8, PI. 1673. Willd. n. 135. J. H. t. r. Vol. 3, 455. t. 844. (Lvs. vilcares pecumbentes foetidus longi, pet. 5, fol. 125, t. 556.)

—Petal slender. Petals mostly luteo-red; their crest of two acute lobes. Calyx downy. Leaves oblanceolate, late in the Nat. of the south of Europe. Miller cultivated it for the Dover Catchfly, in that it requires a place in the Hesperiacetoidea, though erroneously admitted into PI. Brit. 490, as is explained at 1452 of the same work. What the older botanists found at Dover and which may be seen in Petiver's and Buddle's collections in the British Museum, is tall an undetermined plant. We greatly suspect, after all the confusion that has attended it, that the Dover Catchfly may be, Mr. Hudsone made it, the true C. pallida, and not Linn., (see our next species but one,) a Swedish name, for which Tournefort's Lysimachia orientalis maximus, maximus, undulata, figured in his Voyagu.e, t. 45, 125, is rarely quoted. Bota. arms of late have found nothing at Dover but Silene nutans, varying in size and biforms. The true S. pallida is a rarely found plant, not very unlike Scoparia saxatilis in flowers, but more slender in habit. The lower leaves are thin to papillose; the upper are linear-lanceolate. Calyx above as long, downy. Petals large, yel low-red.

S. buglossoides. Longsmooth-weed Catchfly. Elfr. Bottr. v. 7, 1744. Pl. Select. n. 75 Willd. n. 16. Art. n. 154. "S. Willd. et Knob. II. v. i. t. 85." (S. juncea; Roth Caii. t. 54. Lysimachia prostrata, folia et calvix; Barcell. t. 12, 85, t. 852.)—Petal slender, racemose. Petals in two deep, rounded, ovate lobes; their crest of two acute lobes. Leaves linear-lanceolate, smooth, as well as the slightly calyx. — Barrécher says this plant grows in dry mossy situations in Tuscany. There can be no doubt as to his cognoscere, though entirely overlooked by the German writers, who regard Tuscany as the country of his plant. This is a tall, slender, elegant, personal species, quite smooth, with a purple sheen on the stem and calyx. — The latter is above an inch long, slenderly, nearly cylindrical, with ten obtuse ribs; its surface even and polished, without any pubescence. Claws of the petals longer than the calyx; their limb white, tinged externally with red. Leaves three or four inches long, half an inch broad, slightly glaucous; the radical ones numerous, on long stalks. This species bears a considerable affinity to S. prostrata, but the long racemose panicul, and smooth even calyx, afford clear marks of distinction.

S. rugosa. Clammy Hairy Catchfly. Art. n. 3. (Cuculcutus vilcares; Linn. Sp. Pl. 592. Fl. Suec. ed. 2, 148. Willd. Sp. Pl. v. 8. 685. Lysichus montana vilcosae nitidiflora herbata latifolia rubra, florisibus atque appendicibus; Till. Pat. 105.)—Petal simply racemose, hairy. Flowers opposite, larger than their flanks, drooping every way, without a crest. Stem simple, leafy. Lower leaves lanceolate, even, nearly round; upper downy, vilcld; dilated and reflexed at the base. Native of Scania and Finland, where surely discovered by Linnaeus; and perhaps of Tuscany; as well as of our cliffs at Dover; see the last species but two. The Italian specimen, in the Linnaean herbarium,
dowy. Leaves ovato-lanceolate.—Found by Mr. Nuttal, growing wild, in great abundance, in the neighbourhood of St. Louis, on the MisSissippi, North America, from whence seeds were communicated to A. B. Lambert, esq. who raised this fine plant in his garden at Boyton, Wilts. The stem is two or three feet high, somewhat angular. 

Herbage green, finely downy and viscid; at least in the upper part. 

Petiole racemose, partly forked, composed of about a dozen large flowers, conspicuous for the vivid flaccid of their long lanceolate petals, filaments, and style. The calyx is above an inch in length, angular, ten-ribbed, slightly swelling upwards. The petals are said to be sometimes emarginate. We guess at their extent from the figure cited, which is not sufficiently explicit on this important point.

Stems erect, two feet high, slightly leafy, very vivid in the middle part of their upper joints. Leaves copious about the root, about an inch in length, on very long stalks; in British specimens they are spatulate, clothed with minute curved pubescence; in Greek ones obovate, with longer hairs. The whole plant indeed varies greatly as to luxuriance, but we cannot discern a specific difference. Flowers small, with narrow pale yellow petals, and a purplish calyx. 

The flaminis are usually imperfect, or obliterated, in all the flowers of one root, and the pistils in those of another; but occasionally both are perfect in the same. 

Capule fleshy, hardly bigger than a grain of wheat, splitting into five teeth.

The root is perennial, thick, woody, yellowish within, much divided at the summit. 

Stems numerous, about a foot high, erect, close, leafy, roughish, quite simple, except in the flowering part, very vivid between several of the upper joints. 

Leaves numerous, narrow, acute, about an inch long, much divided at the summit. 

Stems numerous, narrow, acute, about an inch long, minutely rough, of a glaucous green. Flowers erect, in close, irregular, slender panicles. Calyx green, smooth, not quite an inch in length, ten-ribbed. Limb of the petals fleshy-coloured above; greenish, with purple veins, beneath. 

Capule in a flax as long as itself. These flowers, and those of the following, are probably fragrant at night.

Capule shorter than its stalk.—Gathered by Dr. Sibthorp in Greece. 

The root appears to be perennial, and somewhat creeping. 

Stem solitary, a foot high, slightly leafy, smooth, like every other part of the plant; the middle of its upper joint, below the inflorescence, viscid. 

Radical leaves numerous, stalked, narrow, glaucous, two inches long, including the flasks. 

Flowers few. Calyx club-shaped, an inch and a quarter long, smooth, with ten purple ribs. 

Limb of the petals inflexed; white above; cinnamon-coloured beneath. The flalk supporting all the parts of the flower, within the calyx, is remarkable for its length, which nearly equals the petals, and exceeds the ripe capule. 

Sect. 5. Stems single-flowered. 

—Stems single-flowered. Leaves lanceolate, fringed. 

Calyx bell-shaped, downy. 

Petals cloven, auricled on each side at the base. Gathered by Dr. Sibthorp, on the precipices of Mount Delphi, in Negropont. 

The perennial root runs deep into the earth, and is crowned by numerous, dense, rose-like tufts, of bright green, ovato-lanceolate, sharp-pointed leaves, an inch long; smooth above; their cartilaginous edges fringed with white hairs. 

Stems solitary, erect, simple, downy and viscid, a finger's length, bearing two or three distinct pairs of smaller leaves. 

Flowers erect, the size of S. martima. 

Calyx swelling upwards; its veins and segments purplish. 

Limb of the petals deflexed, in two rather deep, oblong, rounded segments, furnished at the base with two very peculiar lateral appendages; their crest of two spreading lobes; their upper side white, tipped with pale purple; the under reticulated with purple veins. 

Calyx ovate, nearly thrice the length of its flalk. 

Calyx club-shaped. 

Petals cloven; their claws wedge-shaped. Gathered by Dr. Sibthorp, on the summit of the Bithynian Olympus. 

An elegant and remarkable species. 

The long perennial root resembles the laft, except in being of a whiter colour. 

Stems very short, tufted, decumbent. 

Leaves crowded, fickle-shaped, about an inch long, rigid, rough with viscid hairs, three-ribbed, permanent, turning white at age. 

Stems ascending, a finger's length, purplish, hairy and viscid, slightly leafy. 

Flowers erect, cream-coloured, with a slender, rough, blood-red calyx, above an inch long. The flalk, bearing the parts of the flower within, is nearly equal to the calyx itself, and much longer than the ripe capule. 

Petals with broad claws, dilated upward, and a crest of two bluntish lobes. 

Germin brownish below, with two crimson bands; green above. 

Petals undivided; their crest bifiliform. 

—Native of the mountains of Carinthia, Moravia, and Italy, in a miscaceous soil. 

A very handsome species. 

The root is perennial, crowned with dense tufts of grassy, or thrill-like, rather succulent leaves, about an inch long; among which are several, solitary, partly decumbent, simple stems, about twice that length, bearing a pair or two of smaller fringed leaves. 

The flowers are very large in proportion, rose-coloured, and, according to Arduin, who lent specimens to Linnaes, very fragrant, though Clusius and Wulff describe them as without scent. The calyx is an inch long, slightly bell-shaped, reddish, densely clothed with soft white hairs. 

Limb of the petals rounded, waxy, but not lobed; their crest, overlooked by Arduin, of two erect slender crimson teeth, growing pale as the flower fades. 

Germin nearly or quite fleshy. 

Silene, in Gardening, contains plants of the hardy herbaceous, and of the annual and perennial kinds, of which the species cultivated are, the common or Lobel’s catchfly (S. armeria); the variegated catchfly (S. quinquevirgata); the pendulous catchfly (S. pendula); the Spanish catchfly (S. mufepulpa); the green-flowered catchfly (S. viridiflora); the Nottingham catchfly (S. nutans); and the shrubby catchfly (S. fruticea).

In the first sort there are varieties with a bright purple flower, with a pale red, and with a white flower.

Method of Culture.—The annual and biennial sorts may be raised by seeds, which should be sown in the spring or autumn seasons, where the plants are to grow; but the latter is the better time. Some low at both seasons, which may be a good practice. The seed should be put in in patches in the borders, clumps, &c. When the plants are up, they should be thinned to two or three plants in each clump, and be kept clean from weeds. With the biennial sorts it is sometimes the practice to sow them in beds; and when the plants are up, to remove them to nursery-rows till the autumn, when they are planted out in the borders, &c.

And the perennial sorts may likewise be increased from seeds, in the same manner; but the usual way is by slips of the heads, and, after the roots, planting them in slaty places, in the spring or early summer months. The shrubby sort may be increased by slips and cuttings of the branches or shoots, which should be planted out in similar situations, in the spring and summer season.

Ancient authors, however, who are very worthy of credit, express more favourable testimonies of him. Silenus, according to their account, was a profound philosopher, whose wisdom was equal to his knowledge; and the drunks, so often mentioned, were merely mythical, furnishing that he was profoundly immersed in speculation. Cicero, Plutarch, and many others, had formed the same idea of Silenus, and always regarded him as a very ingenious man, and a great philosopher. Accordingly Virgil, in his second eclogue, puts into his mouth the principles of the Epicurean philosophy, about the formation of the world, and the beings that compose it:

"Namque canebat uti, &c."
three sons, Alcmeus, Maron, and Lenæus. Servius, on Virgil's Eclogue, makes Silenus the son of Mercury; others, the son of Pan and a nymph; others will have him born of the drops of the blood of Calus, the father of Saturn.

Aelian (Var. Hist. 1. iii. c. 12.) alleges that Silenus was born of a nymph, and that though he was not of the number of the gods, he was, however, of a nature superior to that of man. Silenus is said to have been born at Malea, or at least brought up there, according to the testimony of Pindar, who thus speaks: "Silenus, that incomparable dancer, when a citizen of Malea, the happy spouse of fair Nais had the good fortune to educate." Lucian describes Silenus as of a middle size, fat and plump; and thus he is represented upon medals, and other monuments now remaining.

Bochart, in his "Canaan," will have Silenus to take his name from Γέλιος, or Σίλβος, Silb, the name of the Melethian, whence Γέλιος, Silës. He also adds, that all that is attributed to this imaginary deity is taken from what the prophets have foretold of Jesus Christ. Thus, whereas it is said, that our Saviour should bind his afo to the vine, and his colt to the young vine; Silenus is made to ride on an afo. Because our Saviour washed his garments in blood, as those that trod the wine-preb; Silenus was made to prebide over those who preb the vintage. Because it is added, his eyes were red by rea of wine; Silenus was made all suddled. Bochart, however, advances all this with a great deal of druff, as he has reaon, it having no warrant. He adds, that the devil invented the afo of Silenus, to turn the mysteries of our religion into ridicule. But the fene which he has given to the words, rubent oculi ex vino, & dentes ejus ex latte allelueant, is very forced and unnatural; as if the words signified any thing more, in the propriety of the Hebrew tongue, than, his eyes are redder than wine, his teeth whiter than milk. We may add, that nobody, before Bochart, neither Christian nor idolator, ever saw any thing of Jesus Christ in the fable of Silenus.

Silenus was worshipped after his death as a demigod, and received the honours due to heroes, independently even of Bacchus. Thus Paunianus speaks (in Elie.), who, mentioning the temple which Silenus had in Elis, expresses himself in these words: "There you will likewise see a temple of Silenus, but a terrible temple which is appropriated and peculiar to himself, while Bacchus has no share in the honour of it.""-

SILENTIARY, SILENTIARIUS, an officer among the ancient Roman flaves; being, according to some authors, a flave placed over the rei, to prevent any noife and uproar, and to keep them flent.

Seneca, in his Epîtres, mentioning the great care taken to keep the flaves mute, has given occasion to Lipius, Pompa, and some others, to suppose, that the silentiary was established in his time: but others, as Pignorius, think no such conclusion can be drawn from Seneca's words; nor any thing, but that they were, even then, very severe in preventing any noife among the flaves. As to the name and office of the silentiary, it was not established till about the time of Salvinus, who is the first author that mentions it.

There were also silentiarii established in the emperor's court, called quietis minîfrì, and silentiarii palati; and honoured with the farther titles of clarissimi, spectabilès, devolutissimi, and in Greek Σωφιστατοί, q. d. molt admirable.

There were a great number of these; but only thirty ordinarily officiated, who were divided into three bands, each of which had its decurio. The council of Clausesdon call the body of silentiaries, sèhola devolutsimòrum silentiâriiùn.

SILÆ, in Botany, a Latin name in Virgil, supposed to belong to some slender kind of willow, or oriet. It is used vaguely, by the earlier botanists, for different umbelliferous plants, and retained by Gartner, after Rivinus, for Lagospernum trilobum and aquilégifolium, which those writers place in a genus by themselves. Linæus uses the above word, as the specific appellation of another Lazerétium. See that article.

SILEŠIA, Duchy of, in Geography, a country of Europe, bounded on the N. by the marquise of Brandenburg, on the E. by the duchy of Warsaw and Austrian Poland, on the S. by Hungary, from which it is separated by a chain of mountains, and a wilderness or thicket, about four miles broad, and on the W. by Moravia, Lusatia, and Bohemia. To the W. and S. Sileśia is environed by a chain of hills, being with respect to extent and height some of the most remarkable in all Europe. (See Silešia.) For other mountains of Sileśia, and their productions, see Prussia. In the mountains of this province, and in that part of it that lies towards Moravia and Hungary, the winter is earlier and of longer continuance, and much more severe, than in the more level territories. During those months, in which at the foot of the Riefengebirge and the Gefenek every thing is covered with ice and snow, the trees at Breslau are in full verdure even in winter. The sandy parts of the principality of Glogau, and beyond the Oder, towards Poland, with the mountainous tracts, which are of considerable extent, produce but little, nor is their grain sufficient for the consumption of the inhabitants. But this deficiency is compensated, in favourable seasons, by the fertility of the other and larger part of Sileśia, which, besides wheat, rye, barley, and oats, yields likewise maize or Turkey-wheat, spelt, buck-wheat, millet, linseed, peas, and beans. The culinary vegetables about Breslau, Briei, Néflie, Frankenstein, and Lignitz, are excellent; and the vicinity of Gruenberg and Lower Beuthen affords plenty of fine fruits. Those spots that are not fat for tillage afford good pasturage-grounds, or are covered with wood. Of flax there is abundance, but hemp in less plenty, which is supplied by importation from Hungary and Poland. Hops principally abound near Merseberg. Moreover, Breslau, and Schweidnitz, is one of the principal places of export. A yellow dye, called sèhrte, is plentiful; nor is this country deficient in tobacco plantations; but its saffron is of an indifferent quality. The wine of the country is good, more especially after it has been kept for some years in the cellar. In the mountains and Upper Sileśia, tar, pitch, and resin, are made from the pine and fir, and the larch-tree produces turpentine. From these resins trees, and the trunks of the closer pines, the inhabitants of the mountains make a lamp-black. Terra figillata is found in many places, and particularly near Srugia; but it is used not as an article of the materia medica, but principally in the manufacture of earthenware. Cattle are reared merely for the plough, and for the necessary supply of milk, butter, and cheese; but the markets are furnished, particularly with oxen, from Poland and Hungary. The most noted markets are those of Briei, Breslau, and Schweidnitz. Although the fluids in this country afford many fine and flint hores, the number is not sufficient; and therefore, besides thoes that are purchased at Frankfurt fair, great numbers are brought hither from Lithuania. The inhabitants of the hilly districts keep goats, and cheese in great quantity is made from their milk. The breed of sheep is considerable and
SIL

and because, owing to the calcarious quality of the soil, the wild hogs of these forests, when driven into the Upper Lusatia, and on the hillside near Luska, contain a peculiar proportion of Silex, detritus, Glasses, Lava, Limestone, Volcanic, Scoria, Ores, 

and so on, and are an invaluable quantity to the industry of Silesia. Silica is found in a state of tertiary calcination. The principal manufactures are glass, thread, yarn, and cloth. The chief export is pitch, mull, and thread, yarn, lace, and worsted cloth, together with flax and paper. Under the dominion of the king of Prussia the commerce of Silesia has been considerably improved.

The prevalent religion in Silesia, as well as in Prussia, is the Protestant; and the biblioplies here, as well as in Poland, retain their ancient limits, while the power of the prelates is much abridged.

The manners and customs of the inhabitants of this province resemble those of their relatives, the Bohemians; but that of the latter is much mellowed down into that of the German, that the peculiar features are minute and unimportant. Silesia has some pretentions to literary fame. The capital of Silesia is Breslau; behind which there are only three towns which contain more than 60,000 inhabitants, viz., Glagow, Hirzfelde, and Schweidnitz. For other particulars, see Prussia.

Sileia affords few materials for history. Its ancient inhabitants were the Lygov and Quadai; but about the middle of the sixth century, the Slavs having overrun the country of the latter, a part of it was annexed to Poland, and called Zelizia. Under the Polich sovereigns, Sileia received the Polish language, manners, and usages, with the Christian religion. After having been a Slavonic province of the Polish dominion, it was feigned, in the 15th century, by John of Luxemburg, king of Bohemia (February, 1339), and passed with that sovereignty to the house of Austria. On the death of the emperor Charles VI. in 1740, Frederick II. king of Prussia, laid claim to the principalities of Lignitz, Breslau, and Wohldan; and his claim was effectively supported by the march of an army into Sileia, that Maria Theresa, daughter and heiress of the emperor Charles VI. and queen of Hungary and Bohemia, by a preliminary treaty at Breslau, which was soon followed by a ratification of the same at the peace of Berlin, did, on behalf of her self, her heirs and successors, of both sexes, for ever cede to the king of Prussia, and his heirs and successors, of both sexes, with entire sovereignty and independency of the crown of Bohemia, the countries of Upper and Lower Sileia, together with the district of Katicher, formerly belonging to Moravia, as also the county of Glatz; reserving, however, to herself the principalities of Teschen, with the lordships annexed thereto, the part of the principalities of Trappau and Jagendorf, beyond the Oppa, the part of the principality of Neisse bordering on Moravia, and a small district belonging to Moravia, with some frontier towns. Sileia was never immediately connected with the empire, having at no time been an imperial fief, nor obtained a seat or vote in the diet. Neither has it been ever subject to the supreme tribunals of the empire, so that here the imperial laws are of no force. This event happened in 1742. The king of Prussia having obtained the greater part of this country with entire sovereignty, and absolutely independent of the crown of Bohemia, governs it accordingly, as a state absolutely free and divested of the leaf connection with the empire; but in the year 1751, the empire becoming a guarantee to his Prussian

SILESIAC Terra. See Terra.

SILEX, Kieselerde, Germ., in Mineralogy, a species of earth which is generally found in a flinty slate, and from its forming nearly the whole composition of flint, it has acquired the name of Silex, or flint earth. It is found in equal or perhaps greater purity in rock-crysal and quartz, and in white sand; and it is probably an earth that melts into a globule. Melt of the rocky combinations of Silex are remarkable for their hardness, and will very readily strike fire with flint. Silex, when pure, is white, and perfectly void of taste and smell; it is insoluble in water, and incapable of artificial crystallization. For its other properties, see Flint and Sileca.

SILHET, in Geography, a circar of Hindoostan, in the N.E. part of Bengal, bounded on the N. by Bootan, and on the E. by Meckley, and elsewhere by a part of Bengal. Also, a town of Hindoostan, and capital of a circar, to which it gives name; 106 miles N.E. of Dacca. N. lat. 24° 52'. E. long. 91° 57'.

SILL, in Botany, a name given by the old Greeks to a plant called aloe sylphi.

SILLAN, in Geography, a town of Sweden, in Dalecarlia, on a lake to which it gives name; 25 miles N.W. of Falun.

SILICA, in Ancient Geography, a town of Africa, in Interior Libya, near the river Bregadus. Ptolemy.

SILICA, in Mineralogy and Chemistry. In the former it is an earthly substance, existing abundantly in the composition of the globe, and forms a distinct genus of minerals in such as it predominates. In chemistry it was formerly considered as a simple body, under the class of earths. In the present state of chemistry it is regarded as a metal combined with oxygen, and belongs to one of the most extensive classes of compounds in chemistry. The minerals in which it is principally found are rock-crysal, quartz, agates, and flints. The first of these almost wholly consists of silica. In order, however, to obtain it in perfect purity, let the rock-crysal, or quartz, be heated red-hot, and then plunged into cold water. This has the effect of lessening its aggregation. To facilitate its reduction into powder, let one part of this powder be tufed in a silver crucible, with three parts of pure potash. The fused masses will be found soluble in pure water. To the clear solution add any acid sufficient to saturate the alkali, but not more. A gelatinous precipitate will be found, which, when well washed, dried, and heated to ignition, in a silver crucible, will be pure silica.
It is a fine white powder, harsh to the touch, and di-
stitute of talc or smelt. Its specific gravity is 2.6.
Silica is not acted upon by the air, nor changed by mois-
ture. When strictly pure, no ordinary heat will fuse it.
It does however put on appearances of fusion, when heated
by the aid of a blowpipe and oxygen gas. It does not
combine with oxygen, sulphur, phosphorus, carbon, or
azote.
The two fixed alkalies do not affect it in the cold, but
when fused with it in a silver crucible they combine, forming
compounds, which have all the appearance of glas.
Indeed, when the two bodies are in one proportion, they form the
perfedt and most perfect glas.
When the alkali is to the silica as three to one, the compound is soluble in water.
This solution has been called the liquor of flinta. Any of
the acids are capable of combining with the alkali, and pre-
cipitating the silica in a flate of purity, as we have before
observed in the process for obtaining silica.
If an excess of acid be added to the solution, part of
the silica is dissolved. This is more especially the case with the nu-
muriatic acid. A very dilute solution of silica in potash, in
a vessel covered with paper, was left at rest by professor
Seigling for eight years. Crystals of silica were found in the
fluid, and the surface had a transparent film upon it, strong
enough to allow the vessel to be inverted without spilling the
liquid. Some of the crystals were found to be pure silicas,
in groups of tetrahedral pyramids. There were also crystals
of sulphate and carbonate of potash. The former were so
hard as to strike fire with steel.
When fluoric acid is distilled from a glass vessel, or from
any other substance containing silicas, this acid assumes a
complete gaseous form. The moment it is absorbed by a
water, a proportion of silica is precipitated. In this case,
the gas which comes over is a compound of silica and the
acid, which may be called fluast of silica. The liquid acid
is also found to hold silica in solution. It was from this
solution, after standing two years, that Bergman obtained
crystals of pure silica. They were of a cubic form, with
three angles truncated. They were not so hard as rock-
crystal.
The boracic and phosphaoric acids have no action upon
silica in the cold, but unite with it by fusion, forming trans-
parent vitreous substanices.
Silica does not combine with any of the metals, but it
combines with many of their oxys, forming compounds,
which are called glases, enamels, or porcelains, according to
their appearance.
With the oxyd of lead it forms the glazing of common
pottery; with oxyd of iron, a dark green or black glas.
We have already spoken of its combination with the
alkalies which belong to this class of compounds.
When a solution of lime or barytes in water is added to
a solution of silicate of potash, or liquor of flint, these
earths become precipitated, forming a peculiar compound.
A similar combination takes place when a solution of
silica in potash is added to a solution of alumine in the same
alkali.
Although the fusibility of silica is impracticable at the
heat of our hottest furnaces, yet its combination with other
earths is fusible, though at a very high temperature.
Equal parts of lime and silica fuse into a mass between
porcelain and enamel at 150° of Wedgewood. We hence
see the use of lime in melting iron ores which abound with
silica.
Silica appears to be the most abundant of the earths,
forming the greatest proportion of the primitive rocks, and
the basis of the terrestrial globe.

Although it has not been directly proved to be a metallic
oxyd, there is the most presumptive reason for thinking it
so. From the small action which acids had upon it, com-
pared with the other earths, Sir Humphrey Davy at first
suspected it to be an earth already combined with an acid,
and made some attempts, by the aid of Galvanism, to verify
this idea, but without success. He fused silica with iron
by the Galvanic battery, and obtained a mass which afforded
silica when dissolved by an acid with water. He also heated
silica to whiteness, and on bringing potassium in contact,
a compound was formed of silica and potash, but a number of
black particles were diffused through the mass, which
Sir Humphrey Davy thought were conductors of elec-
tricity. They did not act upon water; but when an acid
was added, an effervescence took place. They also burnt
in a strong heat, affording a white substanice, which had the
characters of silica.

Little is known of the proportions in which silica com-
bines with other bodies: Dalton gives its atom as forty-
five times heavier than hydrogen: and Sir Humphrey
Davy states the number for silica at sixty-one, which, re-
duced to Dalton's standard, would be 90.5. But neither of
these is to be depended upon.

SILICEOUS, in Mineralogy, denotes compounded prin-
cipally of silice.

SILICEOUS Schilus, in Mineralogy and Geology, the horn-
tone flate of some geologists; flinty flate of Jamefon; a
rock of the nature of flate, but containing a great portion
of siliceous earth. It frequently occurs in beds in clay-flate,
and sometimes forms entire mountains, which are either
homogeneous or porphyritic, containing crystals of felspar,
and forming porphyritic flinty flate. The colour con-
fits of various shades of grey, but it is sometimes red, appro-
aching the nature and colour of Jasper. It is generally tra-
versed by veins of quartz, but rarely, if ever, contains met-
allie veins. It is extremely hard, and breaks with difficulty;
the fragments are sharp-edged, and more or less translucent
in minute portions. The Lydian flone, which is used as a
text, or touch-flone, for determining the purity of metals, is
nearly allied to siliceous schilus. This rock paffes, by
gradation, into clay-flate; and when the silice predominates,
into hornstone or chert.

SILICEOUS Earth, in Agriculture, such as is constituted of
siliceous materials.

SILICEOUS Marl, that which is of a sandy or siliceous
nature. See MARL.

SILICERNIUM, among the Romans, a funeral supper, which is otherwise called exequium.

SILICATE, in Mineralogy, a term lately introduced by
professor Berzelius, to denote the combination of flax
with other earths or oxys, in which the silice is suppoas
ed to act as an acid. These substanices he denominates silicato.
As this view of the action of siliceia tends to throw considerable
light on various processes in the mineral kingdom, it is but
justie to our own countryman, Mr. Hume, a reputeable
scientific and practicable chemist in London, to state, that
so early as 1805, he had, in Mr. Park's Chemical Catechism,
altered the action of siliceia as an acidifying principle, and
subsequently in the Philosophical Magazine for 1808, he
distinctly and percievably defcried various processes, both
natural and artificial, in which silice performed the part of
an acid; this he attributed to the great proportion of oxygen
contained in it. As silice is by far the most abundant
substanice in the composition of the globe, either pure or
in combination with the other earths, its peculiar pro-
perities, and the part which it performs in the successive
changes that take place in the mineral kingdom, are a sub-
ject
SIL

fer of weather in both the cases in the mineral
products. The clarity of the effect with the use of
crystals, 
Mr. Hume set forward in a way that may be
known to all who have been interested in the
studies of oxygen and its on the metals, particularly to that which is called
the reaction, with a very many cases of the word, a
complete fatigue and 
new, by each of the metals; all
the metals (pears) without exception, from being the
Our opinion is that in the universe, it may be rendered quite
as one having a variety of the kind of minerals
are clear from the metals. It is also seen that the most
durable, which are obtained, particularly for making glass,
and making artificial gems. The best opaque colours,
such as are most suitable for enamel, water, oil, crayon,
and all other descriptions of painting, are derived also from the
metals combined either with oxide or oxygen. Even
the previous flowers, and the least valuable crystals and pebbles,
with an infinite number of mineral productions, seem to
derive their beauty and value from the action of the metal
on the metals. Thus, the opacity of lead is effectually changed by
the fossil or fossilized composition of most glazes, and
the compound is rendered not less diaphanous than when,
by means of oxygen, the same metal is dissolved in dilute nitric acids.

The power which fossil exerts over potash and soda,
and a variety of other substances which enter into the
composition of glazes, is a striking and well-known instance (says
Mr. Hume) of its neutralizing efficacy; for no acid more
clearly and positively attains the acuity of alkaline bodies, and
displaces them of their corrosive character. The effervescence
which results when fossil and the alkali enter into fusion and
form the tallowy compound, is not observable till the materials
are on the point of perfect combination; hence, as
something is apparently evolved, neither oxygen nor any
other acentric fluid can be supposed to enter; so that the
effervescence power (if the term may be applied) which appears
to exercise the alkaline matter, is alone due to the fact
which is usually employed to form glaze. Indeed vitrification
seems, in all instances, to be accomplished by fossil, or
by oxygen, and the glaze of lead, of antimony, of phosphorus,
borax, or any other body, is due to the one, as
such as the glaze in common use is to the other of these
oxidizing agents.

The power of fossil, as an oxidizing, saturating, and
neutralizing agent, is by no means confined to rocks,
minerals, and the inanimate parts of created matter; but it
persists also, as an essential element, the structure of
organized beings, and occupies a distinguished place both
in the animal and vegetable economy. "Nothing is more
alluring," says Dr. Smith, "than the secretion of flinty earth by plants,
a fact which it well attested." According to modern experiments, human hair, and probably
the hair of all animals whatever, also contains fossil as a
constituent element.

From numberless phenomena that admit of no other in-
terpretation, it may justly be inferred, says Mr. Hume,
that nature poises means of converting fossil into other forms,
and of interweaving it into the constitution of her
worked works, that it ceases entirely to appear in its
original state. Every thing connected with the progress of animal
and vegetable existence, with the ineradicable secrets of the
affirming powers, or with the physiology of all organized
matter, shows that transmutation is an operation which we
cannot disprove, though we may not be able to trace it
through all its steps.

According to Berzelius, fossil, or silica, considered as an
acid, is the property by which it is possessed of forming,
from a state of dryness, into a vegetable state, in the
bonds, or its property of creating. The action of
fossil upon which it acts is such as to in
the bond, is the creation of silica in the
bonds of the alkali; that is, it is a process by which
the alkali is converted into silica. Hence it is that
the term "fossil" is applied to the process of
combination of the alkali with excess of fossil; it is,
therefore, this combination which is termed the
appellation "fossil," and which, for example, is made in the
formula, $\text{Li}_2\text{SiO}_3$, and may be understood to mean that the
alkali contains twice or three times the oxygen of the fossil.

Fossil, like other acids, gives rise to double fuels, partly
with and partly without water of crystallization. We cannot
frequently find, that the bases which have a tendency
to produce double fuels with other acids, do the same thing
here: in the same manner, as in the double fuels, we
again find (although with many exceptions) the same proportion
between the bases as in the other previously known
fuel acids with double bases. Hence, for example, if in common
fossil we could exchange fossil for sulphur, the
combination would be alum without water.

But Nature in her rich fruits, says Berzelius, exhibits
a number of combinations of fossil that more or less varnish,
for which we have few if any analogous combinations to produce
from the experiments in our laboratories. Thus we find fuels
with from three to four bases, which all form one common
combination, while pure crystalline structure seems to render
it evident that it must be considered as one chemical whole;
unless it should hereafter be proved that such bodies belong
to the class of crystals that are formed of many different
fuables lying in juxtaposition, but not chemically
combined.

It often happens, also, that these numerous fuels are
not of the same degree of saturation, but that one or more of
the weaker bases are subficiences, or fuels, while one
or more of the stronger are bi or trio-fuels. That similar
combinations are not formed in our laboratories, arises evidently
from the rapid and violent means by which these
combinations are effected, which will not admit the action
or influence of those weaker affinities which take place in the
secrecy and undisturbed recesses of the mineral kingdom.
As it is of importance to ascertain the quantity of oxygen
in fossil, in order to determine its proportions in the different
combinations of fuels, Berzelius, from various experiments
made by himself and others, eliminates the proportion
of oxygen to be 49.64. See SILEX.

SILICULA, in Botany, the diminutive of Siliqua,
(see that article,) is a Pouch, or pod of a short, or rounded,
figure, along both the edges of whose partition the seeds
are infected; witness the Draca vera, or Whitlow-grass,
so common on walls in the spring, and the Thaljips Bufeus,
Shepherd's purse. The partition is always really
parallel to the valves, though the latter are often so pro-
tuberant, as in the Thaljips, that their depth is much greater
than the real diameter of the fruit. Hence Linnaeus has
fallen into an error, first detected by Mr. Brown, in the
character of Subularia. See that article.

SILICULOSA, the first of the two orders of the 15th
clad in the Linnaean system, Tetradynamia, (see that
article,) the character of which order consists in the short,
or rounded, not oblong, form of the seed-veil. See SI-
LICULA.

SILIFREY, in Geography, a town of Africa, in the
kingdom of Barra.

SILILICON, in Botany, a name given by some of the old
old Latin writers to the carob tree, *filigia dulcis*. The Latins borrowed this name from the Greek *xiphylanos*, the sweet, or sweet-fruited tree.

Ii dando means the word *filicion*, and making it only *filicon*, supposes it to be a barbarous way of spelling the word *filiqua*; but the evident derivation of the genuine word from the Greek, shews his error both as to the word itself, and the origin of it.

**SILIN**, or *Aby Ayt*, in *Geography*, a town of Egypt; 12 miles S.S.E. of Siut.

**SI-LING**, in *Geography*, a town of China, of the third rank; in Onag-6; 20 miles S. of Si-long.

**SILINO**, a small island among the Philippines, near the north coast of Mindanao. N. lat. 9° 2'. E. long. 121° 40'.

**SILINUS**, in *Ancient Geography*, a river of the Peloponnesus, in the Elide, which watered the territory of the Seclunte, according to Saunfanius.

**SILIPICA**, in *Geography*, a town of South America, in the province of Cordova; 20 miles S. of St. Jago del Enero.

**SILIQUA**, *xipho* in *among the ancients*, the third part of an obulus, or, what comes to the fame, the fifth part of a ferule.

**SILIQUA Nabatheae. See Nabatheae Silica.**

**Siliqua**, in *Botany*, a Pod, is a sort of *Pericarp.* (See that article.) The *Siliqua* is a solitary feed-veil, of an elongated form, and dry substance, consisting of two parallel valves, separated by a parallel linear partition, or receptacle, along each of whole edges the feeds are ranged in alternate order. Examples are found in the Cruciferae plants, constituting the Linnean clas *Tetradynamia*, such as *Cleranthus*, the Stock or Wall-flower; as also in *Chelidonium*, the Celandine; and *Bignonia ecbinata*, *Cartn*. t. 52. f. 1.

This kind of feed-veil differs from a *Legume*, (fee that article,) in having the feeds inserted along each of its margins.

**Siliqua. See Carob.**

**Siliquastrum**, the appellation of the Judas-tree in Tournefort and preceding authors, alluding to its partial resemblance to the fruit of the Carob, which was called *Siliqua*, the Pod, by way of eminence. See Ceratonia and Cercis.

**Siliquastrum**, in *Natural History*, the name given by Mr. Lhuyd, and others, to the bony palates of fishes, when found fossil. See Ichthyperia.

**Siliquaticum**, among the Romans, a custom or toll paid for merchandise. This the Greeks called *cera-tismon.*

**Siliquosa**, in *Botany*, the second order of the Linnean 15th clas, *Tetradynamia*; which order is characterized by the oblong form of the feed-veil. See *Siliqua* and *Silicula.*

**Siliquosæ**, the 30th natural order, among the fragmenta of Linneus, exactly analogous to the *Cruciferae* of Juffieu. See that article, as well as, hereafter, *Tetradynamia.*

**Silis**, in *Ancient Geography*, a river of Italy, in Venetia, which had its source in mountains called Taurifani.

**Silisteni**, in *Geography*, a town of Moldavia; 10 miles S.W. of Hudi.

**Silistria. See Distria.**

**Silivria**, or *Killeover*, a large and populous town on the sea of Marmora, once well fortified, and still in part surrounded by a strong wall. Some of its mosques and minarets are very handsome buildings. The lower part of the town is walled by the sea. Its bay is capable of accommodating a considerable number of vessels, and is so well sheltered by the high land on each side of it, that ships may, in any weather, ride in safety.

**Silius Italicus, Caius**, in *Biography*, an Italian poet, was born about the year 15 of the Christian era. He has been suppos’d to have been a native of Italia in Spain; but his not being claimed as a fellow countryman by Martial, who has bestowed upon him the highest praises, renders the supposition improbable. It is certain that he lived chiefly in Italy, in which he possessed several estates. The knowledge of him come down to these times is derived from a letter of Pliny the Younger to Caninius Rufus, announcing his death. From this it appears that he incurred some reproach in the reign of Nero, as having been forward in acculations, and that he was confin’d at the time of the tyrant’s death; that he made a discreet and humane use of the friendship of Vitellius; and that having acquired much honour, from his conduct in the proconfulate of Afia, he thenceforth withdrew from public offices, and maintained the rank of the principal perfons of the city without power, and without envy. It appears, likewise, that he paid his time chiefly in literary conversations, and in composing verses, which he sometimes recited in public. He had great taste for elegance, and purchased a number of villas, which, after enjoying for a time, he deferted for new ones. He collected a number of statues, books, and buildings, to some of the latter of which he paid a kind of religious veneration. This was particularly the case with respect to that of Virgil, whose birth-day he kept with much more ceremony than his own, and whose tomb was included in one of his villas. He is said also to have possessed a villa that had been Cicero’s. In his latter years he retired altogether to his seat in Campania, which he did not quit upon any account; and the general tide of his prosperity did not censure to flow, except in the infancy of the death of the younger of his two sons, which was in some degree compensated by the confular dignity of the elder. In his 75th year he was attacked with an incurable ulcer, and he is said to have put an end to his life, by abstinence from food.

The work of Silius, which has come down to the present time, is an epic poem on the second Punic war. In this he scarcely deviates from Livy, in the narration of transactions; but occasionally introduces a machinery, copied from Virgil, of whose type and manner he is an imitator. Pliny says, that “he writes with more diligence than genius.”

The best editions of this work are those of Drakenborch, 1717; and of Lefebvre de Villebrune, 4 vols. 12mo. 1752.

**Silk, Sericum**, a very soft, fine, bright, delicate thread; the work of an insect, called bosbyx, or the silk-worm.

The ancients were but little acquainted with the use and manufacture of silk; they took it for the work of a fort of spider, or beetle, who spun it out of its entrails, and wound it with its feet about the little branches of trees. This insect they called *seres*, from *Seres*, a people in Scythia, whom we now call the Chinese, who, as they thought, bred it; whereas the silk itself they called *sericium*. But this *seres* of theirs has very little affinity with our silk-worm, bombyx; the former living five years; but the latter dying annually, enveloped in a yellowish bag or ball, which, wound out into little threads, makes what we call silk.

It was in the isle of Cos that the art of manufacturing it was first invented; and Pamphila, daughter of Platis, is honoured as the inventor. The discovery was not long unknown
unknown to the Romans. Silk was brought from Serica, where the worm was a native. But to far were the fears from profiting by the discovery, that they could not be induced to believe it to be a thread should be the work of a worm; and thereupon formed a thousand chimneer conjurements of their own.

Silk was a very scarce commodity among them for many ages: it was even sold weight for weight with gold; and, in so much, that Venetians tell us, the emperor Aurelian, who died A.D. 275, refused the empress, his wife, a foot of silk, that the fetched of him with much earnestness, merely on account of its dearness.

Others, however, with greater probability, affirm that it was known at Rome in early as the reign of Tibersius, about A.D. 15.

Cales, who lived about the year of our Lord 1733, speaks of the rarity of silk, being so rare that at Rome, and only among the rich.

Hegesippus, the emperor, who died A.D. 225, is said by some to be the first person who wore it in Athens, i.e., a garment of all silk.

The Greeks of Alexander the Great's army are said to have been the first who brought wrought silk from Persia into Greece, about 323 years before Christ; but the manufacture of it was confined to Benjus and Tyres, in Phoenicia, whence it was distributed over the West.

At length, two monks, coming from the Indies to Constantinople, in 555, under the encouragement of the emperor Jovianus, brought with them great quantities of silk-worms, with instructions for the hatching of their eggs, rearing and feeding the worms, and drawing out the silk, and spinning and working it. Upon this, manufactures were set up at Athens, Thebes, and Corinth. The Venetians, soon after this time, commenced a commerce with the Greek empire, followed the western parts of Europe with silk for many centuries; though sundry kinds of modern silk manufacturers were unknown in those times, such as damasks, velvets, fatings, &c.

About the year 1130, Roger II. king of Sicily, established a silk manufacture at Palermo, and another in Caltabell, managed by workmen, who were a part of the plunder brought from Athens, Corentin, &c., of which he made a conquest in his expedition to the Holy Land. By degrees, Mezirey adds, the rest of Italy and Spain learned, from the Sicilians and Calabrians, the management of the silk-worms, and the working of silk; and at length the French got it by right of neighbourhood, a little before the reign of Francis I., and began to imitate them. Thuanus, indeed, in contradiction to most other writers, makes this manufacture of silk to have been introduced into Sicily two hundred years later, by Robert the Wise, king of Italy, and count of Provence.

It appears by 33 Hen. VI. cap. 5, that there was a company of silk-women in England to early as the year 1455; but these were probably employed in needle-work of silk and thread; and we find that various sorts of small haberdashery of silk were manufactured here in 1482; but Italy supplied England, and all other parts, with the broad manufacture, till the year 1580. In Spain, indeed, the culture and manufacture of silk seem to have been introduced in an early period by the Moors, particularly in Murcia, Cordova, and Granada. The silk manufactures of this latter town were very flourishing, when it was taken by Ferdinand, &c., at the close of the fifteenth century.

In 1521, the French, being furnished with workmen from Milan, commenced a silk manufacture; but it was long after this time before they could obtain raw silk from the Vol. XXXII.
requires a great deal of attention; for there are some worms more lazy than others; and it is very dangerous waiting till they make themselves a paschage, which usually happens about the fifteenth day.

The first, finest, and strongest balls are kept for the breed; the rest are carefully wound. If there be no more than can be well wound at once, they lay them for some time in an oven, moderately hot, or else expose them, for several days successively, to the greatest heats of the sun, in order to kill the insect; which, without this precaution, would not fail to open itself a way to go and use those new wings abroad, which it has acquired within. Ordinarily, they only wind the more perfect balls. Those that are double, or too weak, or too coarse, are laid aside; not as altogether useless, but that, being improper for winding, they are referred to be drawn out into skeins. The balls are of different colours; the most common are yellow, orange-colour, lilac, rufi- and flesh-colour. There are some also of a greenish, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades, to wind them apart, as all these colours are to be lost in the future scouring and preparing of the silk.

Silk. Manufacture of: In England, where silk is not produced in any quantities to be employed by the manufacturer, he must commence his operations upon the raw silk, with no other preparation than that of being wound off into skeins or hanks from the balls, or cocoons, which the filk-worms form.

In this state the silk is imported from those countries where it is produced, as Italy, Flanders, Spain, Portugal, Turkey, the East Indies, and China. A thread of this raw silk, drawn from the skin, is found to be composed of an assemblage of several of the fine fibres or threads produced by the worms; the fibres being united together by a natural gum, which is in the skin, and which is soluble in the hot water in which the cocoons are immered when the silk is wound off.

To prepare this raw silk for use, it is wound from the skeins upon bobbins; the compound thread is then twilled, to unite the constituent fibres more firmly than they can be by the gum alone; and afterwards, being wound again upon frein bobbins, two or three threads are twilled together to produce a stronger thread, fit for the weaver, who warps and finally weaves the silk into various articles of ornaments or utility, by processes very similar to the weaving of cotton or linen, but more delicately conducted.

In the countries where the silk is produced, the manufacturer may be more properly said to commence with the operation of winding or reeling off the threads into skeins from the cocoons, or balls, in which the worms envelope themselves. These balls become an article of trade, as soon as the insect within them is killed by exposing them to heat, either of the sun, or in an oven, or by the steam of boiling water; and, in general, the breeders of silk-worms sell them, in this state, to perons who make a business of the operation of winding. In Piedmont, where capital silk is produced, it is conducted, as follows, by the aid of the silk reel represented in Plate Silk Manufacture, fig. 1.

The balls are thrown into hot water, contained in a copper basin or boiler, A, which is about eighteen inches in length and six deep, set in brick-work, fo as to admit a small charcoal fire beneath it; or if a fire of wood is intended to be made, the fire-place must have a small flue or chimney of iron plate to carry off the smoke. At the side of the boiler is placed the reel, which is very simple. B B marks the wood-frame which sustains its parts: these are, the reel D, upon which the silk is wound; the layer a, which directs the thread upon it; and the wheel-work c, which gives motion to the layer. The reel, D, is nothing more than a wooden spindle, turned by a handle at the end; and within the frame, at each end, it has four arms mortised into it, to support the four battens or rails on which the silk is wound. The rails are parallel to the axis, and at such a distance, that they will form a proper fixied skein by the winding of the silk upon them, (it is usually a yard for each revolution.) One of each of the four arms is made to fold in the middle of its length with hinges, so as to caufe the rail, which these two arms support, to fall in or approach the centre, and thus diminish the size of the reel, and admit the skeins of silk to be taken off at the end of the reel when the winding is finifhed.

Upon the end of the wooden spindle of the reel, and within the frame, B, is a wheel of twenty-two teeth, to give motion to another wheel, c, which has about twice the number of teeth, and is fixed upon the end of an inclined axis, which, at the opposite end, carries a wheel, b, of twenty-two teeth, which gives motion to an horizontal cog-wheel, which, by its thirty-five teeth,This wheel turns upon a pivot fixed in the frame, and has a pin fixed in it, at a distance from the centre, to form an eccentric pin or crank, and give a backward and forward motion to the flight wooden rail or layer e, which guides the threads upon the reel: for this purpose, the threads are passed through wire-loops or eyes, a, fixed into the layer, and the end thereof opposite the wheel and crank, b, is supported in a mortice or opening made in the frame, B, so that the revolution of the crank will cause the layer to move, and carry the threads alternately towards the right or left. There is likewise an iron bar, c, fixed over the centre of the boiler at e, and pierced with two holes, through which the threads pass to guide them.

To describe the operation of reeling, it should be understood, that if the thread of each ball or cocoon was reeled separately, it would be totally unfit for the purposes of the manufacturer; in the reeling, therefore, the ends or threads of several cocoons are joined, and reeled together out of warm water, which softens their natural gum, and makes the fibres stick together, fo as to form one strong smooth thread; and as often as the thread of any single cocoon breaks or comes to an end, its place is supplied by another one, so that by continually keeping up the same number, the united thread may be wound to any length. The single threads of the newly added cocoons are not joined by any tie, but simply laid on the compound thread, to which they will adhere by their gum; and their ends are cut fine, as not to occasion the least perceptible unevenness in the place on which they are laid.

The woman who conducts the reeling is seated before the basin A, and employs a boy or girl to turn the handle of the reel: a fire is lighted beneath the basin A; and when the water becomes nearly boiling hot, she throws into the basin two or three handfuls of cocoons, and leaves them some minutes, to soften that natural gum with which the filk is impregnated; then she stirs up or brushes the cocoons with a will of birch or of rice-straw, about six inches long, cut flumpy, like a worn-out broom; the loose threads of the cocoons stick to the will, and are drawn out; she then diverges thefe threads from the will, and by drawing the ends through her fingers, cleans them from that loose filk which always surrounds the cocoon, till they come off entirely clean; this operation is called la battue; and when the threads are quite clean, she passes four or more of them, if she intends to wind fine silk, through each of the holes in the thin iron. 
SILK.

iron bar, which is placed horizontally over the centre of the basin A; afterwards the twine, two parallel threads (which consist of four cocoons each), twenty or twenty-five times round each other, that the interior ends of each thread may be brought together by crossing each other, and that the thread of the silk may be wound, which otherwise would be flat.

The threads, after passing through the holes in the iron bar, and being twisted together, are passed through the eyes of the loops, a, of the layer, and there being conducted to the reel, are made fast to its centre. The reel, which with the thread, gives it the most rapid movement possible, and thus draws off the threads from the cocoons in the basin A. The flow traversing motion of the layer prevents the threads by revolution in the air as to dry the gum of the silk from the floss, so that the threads will not adhere together. After the reel is covered for about the breadth of three inches, by the gradual progression of the layer, it returns and directs a second course of threads over the first laid, and goes until the required length of the floss is obtained. The machine winds the flosses at one time. As it is essential to the production of good silk, that the thread should have half part of its length gummed or gummified before it touches the bars of the reel, the Patent are by law obliged to leave a distance of thirty-eight French inches between the guides, a, and the centre of the reel; and the layer must also, under a penalty, be moved by cog-wheels instead of an endless cord, which is sometimes used in Italy, and which, if suffered to grow slack, will cause the layer to stop and not lay the threads distinctly, and that part of the floss will be glued together, whereas the cogwheels cannot fail.

When the flosses are quite dry the reel is removed from the frame, and by the folding of two of its arms the flosses are taken off. A tie is made with some of the refuse floss on that part of each floss where it bore upon the bars of the reel, and another tie on the opposite part of the floss, after which it is doubled into a hank, and usually tied round near each extremity, when it is laid by for use or sale.

This operation appears very simple, but to produce a good thread requires much attention. The reeler must not wait until the thread of a cocoon is entirely exhausted before the joins on another, because the threads near the end have not above a quarter of their full thicknees. The cocoons produce a very unequal length; some may be met with which yield 1200 eels, whilst others will scarcely afford 200 eels. In general, the production of a cocoon may be estimated from 500 to 600 eels in length. As often as the cocoons the winds are exhausted, or break, or only dimuish, the joins fresh ones to keep up the requisite number, or the proportion; because, as the cocoons wind off, and the thread becomes finer, she must join two cocoons half wound to replace a new one. Thus she can wind three new ones and two half wound, and the floss will be equal to that produced from four to five cocoons. When she would join a fresh thread she must lay one end on her finger, throw it lightly on the other threads which are winding, and the gum will join it immediately, and it will continue to go up with the rest. She must not wind off her cocoons to the last, because when they are near to an end the husk of the worm joins in with the other threads, and makes the silk foul and gouty. The floss may be wound of any size from one cocoon to 100, but it is difficult to wind more than thirty in a thread.

The nicety of the operation, and that part in which lies the greatest difficulty, is to wind an even thread, because as the cocoon winds off the end is finer, and other cocoons must be joined on to keep up the same size. This difficulty of keeping the silk always even for a thread, requires much skill and patience. For this purpose, she makes a small hole by a needle, five, or six inches long, in a thread, the end of which she has fastened to a reel. She then puts it in a basin, A, of water, and it cannot be unravelled even though she wind the thread round her finger; thus she may, for a week, from 12 to 15, or 20 to 25.

During the operation of winding, it was always usual to have a bowl of cold water by her, to letter, to rinse it, and to sprinkle frequently. As the thread, at the last of the winding, is made to break, the floss is divided by fibres every ten or fifteen threads. It is thus put into a basin, A, of hot water, and poured into the basin, B, containing, this is, when the water begins to boil. The water must be just at a proper degree of heat; for when it is too hot, the thread is dead, and has no body; whereas, when too cold, the end which forms the thread detaches a good, and forms a bad floss. The heat of the water from which the cocoons are wound, causes that adhesion of the fibres which completes the floss; a thread can with difficulty be wound off when cold water is employed, but in this manner the thread is very white, and the thread breaks with a slight friction, or the last mud will separate the fibres; but the silk wound from hot water cannot be separated except by hot water.

The old cocoons require the water to be very hot; if the threads break very frequently, it may be concluded that the water is too cold; or, on the other hand, if the silk comes off entangled, and in the state of wool, the water is too hot. When the first parcel of cocoons is finished, the basin, A, is cleaned, taking out all the stripped worms, as well as the cocoons, on which there remains a little floss; these are thrown into a basin, into which the loose floss that comes off in making the floss is likewise put as waste floss, to be carded and spun into threads. The water in the basin must be changed four times a day for coarse floss, and twice only for good cocoons of fine floss; if the water is not changed, the floss will not be so bright and glossy, because the worms contained in the cocoons foul it very considerably. The reeler must endeavor to wind as much as is possible with clear water, for if there are too many worms in it, the floss will be covered with a kind of dust, which afterwards attracts moths, which destroys the floss.

From the gummy or viscid material which floss gives out to water when the cocoons are infused in it, Chappe found that he was able to blow up the water into bubbles, or small balls, as many, and far more permanent than those of soap and water, and offering all the colours of the rainbow. So cluse, indeed, is the texture of these filky bladders, that even the most subtle gas does not penetrate them. Chappe filled many of them, the diameter of each not exceeding three inches, with hydrogen gas, and found several of them contained in a plate of sulphur, in an apartment, far considerably more than twenty-four hours. It is not all floss, however, that is sufficiently glutinous for this purpose; that which is of a very deep yellow will not answer the same purpose. This floss, from its colour, is happily led to be produced by the worm in a peculiar diffuse, yet this is a plate by no means uncommon.

All kind of floss which is simply drawn from the cocoon, by the reeling, is called raw floss, but is denominated fine or coarse according to the number of fibres of which the thread is composed. In general, the raw floss requires dyeing; to prepare for which the thread is very slightly twisted, to render it strong, and more able to bear the action of the hot liquor, without separating the fibres or forming up. Silk yarn, which is employed by the weavers for the warp or weft of the fluffs which they fabricate, is composed of
two or more threads of the raw silk, slightly twisted in a machine; and the thread employed by the flocking weaver is of the same quality, but composed of a greater number of threads, according to the thickness desired. Organzine silk is composed of two, three, or four threads of raw silk twisted, and so combined as to obtain the greatest tension: for this purpose, each thread of raw silk is twisted separately upon itself by a mill; the twist is given in a right-handed direction, and extremely tight. By a second operation of twisting, two of these threads are combined together, the twist being given in a contrary direction, and not above half as tight: this forms a thread similar to a rope. This description of silk, used for the warp of stuffs, is of the utmost importance to the manufacturer, for none of the principal articles can be fabricated without it. The Italians, from whom we formerly imported the silk in the state of organzine, for a long time kept the art of throwing it a profound secret. It was introduced into this country by the enterprise and skill of Messrs. Thomas and John Lombe, the latter having, at the risk of his life, and with wonderful ingenuity, taken a plan of one of these complicated machines in the king of Sardinia's dominions, from which, on his return, they established a similar set of mills in the town of Derby. (See Derby.) In consideration of the great hazard and expense attending the undertaking, a patent was granted to Sir Thomas Lombe in 1718, for securing to him the privilege of working organzine for the term of fourteen years; but the construction of buildings and engines, and the introduction of the workmen, took up so much time, that the fourteen years were nearly expired before he could derive any advantage from it; in consequence of which, he petitioned parliament, in 1731, to grant him a further term: but parliament, considering it an object of national importance, granted him the sum of £14,000 on condition that he should allow a perfect model of the machinery to be taken, and deposited in the Tower of London for public inspection. Similar mills were, in course of time, erected in different parts of the country; but owing to the difficulties that were experienced in procuring raw Italian silk of the proper size for organzine (the exportation of which was prohibited by the Italians), and to the mills having subsequently found employment for other purposes, the quantities worked into organzine, for many years, were far less than any proportion to the imports from Italy; it has however been since revived and improved, in consequence of which it is now carried on to a very considerable extent, as well in other parts of England as at Derby.

The process which the silk undergoes to bring it into this state, consists of six different operations. 1. The silk is wound from the skein upon bobbins in the winding machines. 2. It is then forked into different qualities. 3. It is spun or twisted on a mill in the fine thread, the twist being in the direction from right to left, and very tight. 4. Two or more threads thus spun are doubled or drawn together through the fingers of a woman, who at the same time cleans them, by taking out the flubs which may have been left in the silk by the negligence of the foreign reeler. 5. It is then thrown by a mill, that is, the two threads are twisted together, either slack or hard, as the manufacturer may require; but the twist is in an opposite direction to the first twist, and it is wound at the same time in skeins upon a reel. 6. The skeins are wound according to their different degrees of fineness, and then the process is complete.

The first operation which the raw silk undergoes is winding, that is, drawing it off from the skeins in which it is imported, and winding it upon wooden bobbins, in which state it can go to the other machines. The winding-frame is shown at fig. 2. of the plate, or rather a part of it, which will wind all threads at once, and by increasing the length it may be made to receive any number. Each of the skeins is extended upon a flight reel A A, called a swift; it is composed of four small rods, fixed into an axis, and small bands of string are stretched between the arms to receive the skein, but at the same time the bands admit of sliding to a greater or less distance from the centre, so as to increase the effective diameter of the reel, according to the size of the skein, because the skeins, which come from different countries, vary in size, being generally an exact yard, or other similar measure, of the country where the silks are produced. The swifts are supported upon wire pivots, upon which they turn freely when the silk is drawn off from them; but in order to cause the thread to draw with a gentle force, a looped piece of string, or wire, is hung upon the axis within the reel, and a small leaden weight, c, being attached to it, will cause a sufficient friction. B, B, are the bobbins which draw off the threads; they are received in the frame, and are turned by means of a wheel beneath each, the bobbin having a small roller upon the end of it, which bears by its weight upon the circumference of the wheel, and the bobbin is thereby put in motion to draw off the silk from the swift. D is the layer, a small light rod of wood, which has a wire-eye fixed into it, opposite to each bobbin, so as to conduct the thread thereupon; and as the layer moves constantly backwards and forwards, the thread is regularly spread upon the length of the bobbin. The motion of the layer is produced by a crank fixed upon the end of a crofs-spindle, E, which is turned by means of a pair of bevelled wheels from the end of the horizontal axle, upon which the wheels for turning all the bobbins are fixed.

These winding-machines are usually situated in the top building of the mill, the frames being made of great length, and also double, to contain a row of bobbins and swifts at the back as well as in front. Two of these double frames are put in motion by cog-wheels from the vertical shaft, F, which ascends from the lower apartments of the mill, where the winding-machines are placed. The winding-machines require a constant attendance of children to mend the ends or threads which are broken; or when they are exhausted, they replace them by putting new skeins upon the swifts. When the bobbins are filled they are taken away, by only lifting them up out of their frame, and fresh ones are put in their places.

A patent has been lately taken out by Messrs. Gent and Clarke, for a new construction of the swifts for winding-machines: they are made with fix single arms instead of four double ones; and the arms are small flat tubes, made to contain the items of wire forks, which receive the skein instead of the bands of string in the common swifts. These forks admit of drawing out the tubes until the swift is sufficiently enlarged to extend it; but as they extend the skein at fix points instead of four, as in the common one, the motion is more regular. Instead of the weight which causes the friction, a spring is used to press upon the end pivot of the axis, and make the requisite resistance.

The twirling of the silk is always performed by a spindie and bobbin, with a flyer, but the construction of the machine which puts the spindie in motion is frequently varied. The bobbins of our plate do not admit a representation of the front machines, or twirling-mills, such as are used at Derby, and at almost all the other great silk-mills in England. In fig. 3. we have given a drawing of a small machine, which is similar in the parts which act upon the filk; and indeed many mills employ such machines constructed on a large scale. The
SILK.

The one in our plate contains only thirteen spindles, and is intended to be turned by hand, a method which is too expensive for this country, but is common in the south of France, where many articles are produced by their silk manufactory. The spindles, and employ their wives to tambour or twist them by hand, to which they call only, because the spindles $A$, $B$, are arranged in an oval frame, $G$, $H$. In this frame, by which the motion is given, it is fixed at the end of a spindle, $R$, which carries a wheel, $D$, to give motion to a piston upon the upper end of a horizontal axle, $E$; this, at the lower end, or former end, $F$, receive an end of yarn or thread, by means of a press, $G$, and are placed perpendicularly to the frame $G$, $H$, the parts of which are joined by pieces of glass, which slide into the oval planks; the spindles are also received in collars, $L$, fixed to an oval frame, $G$, which is supported from the glass, $G$, by blocks of wood, $a$, $d$, $u$, and are small rollers, $v$, supported in the frame $G$, $H$, in a manner to the spindles: their use is to enlarge the frame, $a$, to oppose against the rollers of the spindles with sufficient force to keep them all in motion.

The thread is taken up as fast as it is twisted by a reel, $K$, which is turned by a wheel, $L$, and a portion, upon the end of the principal spindle, $R$. The threads are guided by passing through wires, $v$, fixed to an oval frame, $L$, which is supported in the frame of the machine by a single bar or rail, $f$, and this has a regular traversing motion backwards and forwards, by means of a crank, or eccentric pin, $i$, fixed in a small cog-wheel, which is turned by a piston upon the vertical axis, $e$; the opposite end of the rail, $f$, is supported upon a roller, to make it move easily. By this means the guides are in constant motion, and lay the threads regularly upon the reel, $K$, when it turns round, and gathers up the filk upon it, as shown in the figure.

One of the spindles is shown at $r$ without a bobbin, but all the others are represented as being mounted and in action. A bobbin, $s$, is fitted upon each spindle, by the hole through it being adapted to the conical form of the spindle, but in such manner, that the bobbin is at liberty to turn freely round upon the spindle: a piece of hard wood is stuck fast upon each spindle, just above the bobbin, and has a small pin entering into a hole in the top of the spindle, so as to oblige it to revolve with the spindle; this piece of wood has the wire-flyer, $k$, fixed to it; the flyer is formed into eyes at the two extremities; one is turned downward, so as to stand opposite the middle of the bobbin $s$; and the other arm, $k$, is bent upward, so that the eye is exactly over the centre of the spindle, and at a height of some inches above the top of the spindle. The thread from the bobbin, $s$, is pulled through both the eyes of this wire, and must evidently receive a twist when the spindle is turned; and at the same time, by drawing up the thread through the upper eye, $d$, of the flyer, it will turn the bobbin round and unwind therefrom. The rate at which the thread is drawn off from the bobbin, compared with the number of revolutions which the flyers make in the same time, determines the twist to be hard or soft; and this circumference is regulated by the proportion of the wheel, $d$, to the pinion $i$, from which it receives motion; and these can be changed when it is required to spin different kinds of silk. The operation of the machine is very simple; the bobbins filled with silk in the winding-machine, $f$, $s$, are put loose upon the spindles at $r$, and the flyers are stuck fast upon the top of the spindles; the threads are conducted through the eyes of the flyers $d$, and of the layers $l$, and are then made fast to the reel, $K$, upon which it will be seen that there are double the number of bobbins to that of the spindles represented, because on half of the number of the spindles in the opposite side, so that they may pass through each other. When the wheel, $d$, is put in motion, the spindles, $R$, in the manner of the wheel, $d$, is turned round, and is made up to the required length. The thread which works at $s$, and is carried by the pinion, $i$, is turned in a direction to the left, and for the final twist of the two or three threads together, and all in all, for twisting the raw threads together in the warp of silk-filk, and for working bagging, the reverse movement makes in motion in the machine, except that it will give twist in a contrary direction; for it is always contrary, when two or more threads are combined by twisting, that the twist of the whole thread shall be in the opposite direction to that twirl which draws them into one thread, in the same manner as for making ropes, organizes silk being in fact small rope, and black-filk or warp being only yarn. The silk which is intended to be dyed, is previously twisted very lightly in one direction, and of course in that direction which will suit the purpose for which it is ultimately intended; viz. whether for yarn or organizes.

The great mills for twisting filk, or generally is formed by Messrs Lombe, though very complicated, are in their operation, because the complexity arises from the great number of spindles which are actuated by the engine, every one of which produces its effect independent of the others, and in the same manner as the oval which we have described. A machine is contained in a circular frame, of which the diameter varies from 11 to 13, 15, and even 15 feet; but 15 feet is the general size of the oval machines. In the centre of the frame is a perpendicular axis or spindle, coming out through the floor of the chamber, and rising to the ceiling: it is put in motion, by a communication of wheel-work from a water-wheel, or otherwise from a hortic-wheel. The axis has upon it two, three, or four horizontal wheels, according to the height of the machine, which revolves with it, and are of a sufficient size to fill nearly all the interior of the circular frame, and act upon the pulleys or rollers of the spindles, which are supported vertically in the frame, and arranged round the machine, at equal distances, in a circle, the number being proportioned to the dimensions of the machine. The spindles are also arranged in as many different stages of height as there are wheels upon the vertical spindle; for the circumference of each wheel presses against the rollers of the spindles which are arranged round it; and thus, when the wheel revolves, it gives a very rapid motion to all the spindles at once, by the contact of the edge of the wheel, but without any strap, as in the oval. Each spindle has a bobbin filled with silk, fitted upon the top of it, and from this the silk is carried up to a horizontal reel, which is turned round freely by the machine, and draws off the thread gradually from the bobbin, the flyer, being all the while in rapid motion, twirls the thread upon itself; or, if two or three threads are previously wound together upon the bobbin, they will be twisted
twisted round each other. Each reed serves to take up the thread from several spindles which are situated beneath it; thus, in a mill of fifteen feet diameter, there will be fix spindles beneath each reed.

To explain this machine more clearly, we will give a description of one of thirteen feet diameter, which has four large wheels and flanges of spindles, two of which are for giving the first preparation to the organzine: the spindles revolve in a direction from right to left. The spindles of the other two flanges are for the finishing the twill, and also for twisting the single threads which are to be used for warp or for flocking-weaving; they revolve in a contrary direction to the former. The frame of the machine consists of two wooden circles of thirteen feet diameter, one placed upon the floor of the mill, and the other at a height of fifteen feet above, the two being united by fourteen upright pillars of wood, which altogether compose a large cylindrical frame or lantern. Each flange contains eighty-four iron spindles, placed vertically, and supported in the flange, which is formed of two wooden circles, extended round between the fourteen uprights of the lantern, and fixed one above the other, at about a distance of four inches asunder, so as to support the spindles between them, in the same manner as the pieces, G, H, of the oval last described.

The circles of the flange are of a rather less diameter than the two circles which compose the top and bottom of the lantern; so that the spindles will be rather within the circle of the frame of the lantern, and admit the wheels of the central axis to act upon them. For this purpose, each of the circles of the flange is made up by fourteen segments fixed between the uprights, and each segment supports six spindles, making up the number of eighty-four in the whole circle. The spindles, like those of the oval, are sharpened at the lower end, and the points rest in small holes made in pieces of glass, which are let into the lower circle of the flange, whilst the upper circle sustains the spindle at a height of four or five inches above the point, leaving full one-third of the length of the spindle projecting above, for the purpose of fitting the bobbin upon it. The upper circle of the flange is rather smaller than the lower, because the spindles do not pass through it, but through holes in small pieces of hard wood, which project from it, so as to be exactly above the pieces of glass which sustain the points of the spindles. Each spindle has a small roller fixed upon it in the space between the two circles of the flange, and it is the contact of this rim of the spindle which commences the revolutions of the spindles when the wheel revolves. In order to make the contact certain, the exterior rim of the great central wheel is made in several segments, and each segment has a constant tendency to recede from the central axis by the action of a weight, and thus press against the rollers of the spindles. In order to give the reverse movement of the spindles, which we have before spoken of in the description of the oval, the great wheels for two of the flanges are made differently from those which we have just described, so that the segments of the rim will act upon the outsides of the rollers of the spindles, instead of the inside: for this purpose the wheels are made larger than the flanges in which the spindles are placed, and from the rim of the wheel small rollers rise up to support the segments, which act upon the rollers of the spindles in front or without the circle, instead of the inside, as is the case with the other flanges, in consequence of which the spindles of these flanges turn in opposite directions. The reeds are placed over the bobbins, to take up the threads when twisted; and the rollers of the different spindles are made smaller or larger, as is required, to give more or less twist to the filk operated upon by them; for the velocity with which the spindles revolve, compared with the rate at which the reeds take up the thread, determines the degree of twist which the thread will have; and to render this equal, the reeds which draw off the filk from the bobbins of the spindles are turned regularly with the motion of the machine by means of wheel-work, which is more easily conceived than described: it is sufficient to state that it receives its motion from the central vertical axis. There is also a layer adapted to each reed, with a wire-eye to receive each thread; and the layers having a slowly reciprocating motion, distribute the threads regularly upon the reeds, in a similar manner to that first described for the oval. One of these reeds is placed between each of the uprights of the machine, so as to make fourteen reeds in the whole circle of each flange, and every reed serves to take the filk from the bobbins of fix spindles. The whole machine in the four flanges contains 336 spindles.

A machine of four flanges is so high, as to reach through two floors of the mill, and for this purpose the upper floor is made with a large round opening, to admit the machine; this floor serves the people who attend the machine, and change the bobbins when exhausted, and also remove the finished filk from the reeds.

The spindles in the upper flanges are usually devoted to the first twilling of the single threads for the organzine, and therefore turn the reverse way, as before mentioned; and as the filk is afterwards to be thrown, or re-twisted, they are drawn off from the bobbins by large bobbins of three inches diameter, and four inches long, instead of the reeds. These bobbins are fixed together upon a long spindle, situated horizontally, and turned by similar wheel-work to that which actuated the reeds; they have similar layers to conduct the filk regularly upon the bobbins from one end to the other, so that the operation is not at all different.

In many of the best filk-mills, they have abandoned the original method of turning the spindles, for the preparation of organzine, the reverse way, by making the action of the wheels upon the outside, instead of the inside, of the circle of spindles. Instead of them they employ two different machines, one for the first operation on organzine, and the other for the second operation, both of them constructed with the wheels within the machine: but the motion of the two machines is reversed to each other.

Fig. 5, represents a single spindle of a throwing machine, in which the same or its action as the great mill, is different in its construction. G and H represent portions of the rails or circles of the flange which support the spindle, and a a is a part of the rim of the great wheel of the central axle. This wheel is not made in segments, as before described, but is made very truly circular, and covered with leather on the edge, that it may act with more force to turn the roller, t, of the spindle. The point of the spindle rests in a glass cap, supported by the rail G, and the roller, t, is always made to press against the rim of the great wheel, a a, by a small lever, d, and a spring, which, after turning over a pulley, has the weight, e, to make it fall to t, to press the spindle always towards the wheel. In this machine, instead of the reel, the thread is taken up by a bobbin, K, at a point in a frame, m, which moves on pivots, and by a weight, m, is pressed down so as to make the bobbin bear upon the edge of a wheel, b, which is kept in constant and regular motion, by the same kind of movement which turns the reeds of the great machine. The intention of this is, that the action of the wheel, b, to turn the bobbin, being communicated by pressure against the part upon which the filk is to wind, will be constant.
After the flax is twisted into a rope and direction, it is intended for yarnc, or only to be used in a loom, or in the preparation of the yarn, it is prepared for warping, and must be wound on fresh bobbins, with two or three threads together, preparatory to twining them into the flax. In the original machines at Derby, this was done by women, who, with hand-wheels, wound the threads from two or three of the large bobbins, upon which the flax was gathered, through the reed, and added them two or three together upon another bobbin, of a proper size, returned to the twining machine. We have here an apparatus which is represented in fig. 3.

The whole machine itself is very similar to the winding-machine, fig. 2, but instead of this, the bobbins from the throwing-mill are placed in front of the machine, fig. 3, two or three in a row. The threads from these are passed over the rail, m, and be taken at the end, w, both which, being covered with cloth, have the same effect to clean the flax by drawing through them, as the fingers of the worker. But the bobbin upon which the two or more threads are to be wound together; it is turned by a wheel, F, upon which it rotates, the same as the bobbins of the winding-machine; and D is the lever, which, for convenience, is in this case placed behind the bobbin, B; and the wire-eye, d, which receives the three threads, is made to reach over to the front. The additional apparatus consists of a small piece of wood, c, which slides freely up and down, in a hole, through a fixed bar, f. On the top of the slider, e, is an eye of wire, through which one of the single threads of flax passes in its passage from the pieces m, n, to the bobbin B; there is one of these slides, e, for each of the three threads; r, is a lever moving on the centre c; the end i is immediately beneath the small slider, e, and the end v is formed to a hook, to catch into the notch which are made in the end of the bobbin B. A small counter weight, x, always causes the hook, e, of this lever to recede from the bobbin; but if any one of the three threads break, it suffers the slider, e, which belongs to it, to descend upon the end, r, of the lever, and deprives the end of the lever, s, of its support, e, in a situation to catch a tooth of the bobbin B, and stop its motion. By this means the winding of three threads together is rendered equally certain with the winding of one; for when any one breaks, the operation of winding on that bobbin stops, until the attendant repairs the broken thread, and puts the machine again in motion. We have lately been informed, that a machine for winding two and three threads together is becoming very common in the silk-mills; but we do not know if it is the same with this one, which however is not evidently impracticable.

The bobbins, being thus filled with double or triple threads, are carried back to the throwing-machine, and are there spun or twisted together, the manner of doing which does not differ from the operation which we have before described. In this second operation the flax is taken up by reels instead of bobbins, and it is made up into hanks. The degree of twist varies with the purpose for which the flax is intended; and the wheel which gives rotation to the thread for the purpose adapted to the degree of twist which the flax is desired to have. The flax, being now spun, require only the preparation of boiling to discharge the gum, and render the flax fit to receive the dye, and also to render it soft and pliable. The flax is boiled for about four hours, in a boiler filled with water, into which a small quantity of soap is put; this operation

After the flax is twisted into a rope and direction, it is intended for linen, or flax, and is then prepared for warping, and must be wound on the loom. In the original machines at Derby, this was done by women, who, with hand-wheels, wound the threads from two or three of the large bobbins, upon which the flax was gathered through the reed, and added them two or three together upon another bobbin, of a proper size, returned to the twining machine. We have here an apparatus which is represented in fig. 3.

The whole machine itself is very similar to the winding-machine, fig. 2, but instead of this, the bobbins from the throwing-mill are placed in front of the machine, fig. 3, two or three in a row. The threads from these are passed over the rail, m, and be taken at the end, w, both which, being covered with cloth, have the same effect to clean the flax by drawing through them, as the fingers of the worker. But the bobbin upon which the two or more threads are to be wound together; it is turned by a wheel, F, upon which it rotates, the same as the bobbins of the winding-machine; and D is the lever, which, for convenience, is in this case placed behind the bobbin, B; and the wire-eye, d, which receives the three threads, is made to reach over to the front. The additional apparatus consists of a small piece of wood, c, which slides freely up and down, in a hole, through a fixed bar, f. On the top of the slider, e, is an eye of wire, through which one of the single threads of flax passes in its passage from the pieces m, n, to the bobbin B; there is one of these slides, e, for each of the three threads; r, is a lever moving on the centre c; the end i is immediately beneath the small slider, e, and the end v is formed to a hook, to catch into the notch which are made in the end of the bobbin B. A small counter weight, x, always causes the hook, e, of this lever to recede from the bobbin; but if any one of the three threads break, it suffers the slider, e, which belongs to it, to descend upon the end, r, of the lever, and deprives the end of the lever, s, of its support, e, in a situation to catch a tooth of the bobbin B, and stop its motion. By this means the winding of three threads together is rendered equally certain with the winding of one; for when any one breaks, the operation of winding on that bobbin stops, until the attendant repairs the broken thread, and puts the machine again in motion. We have lately been informed, that a machine for winding two and three threads together is becoming very common in the silk-mills; but we do not know if it is the same with this one, which however is not evidently impracticable.

The bobbins, being thus filled with double or triple threads, are carried back to the throwing-machine, and are there spun or twisted together, the manner of doing which does not differ from the operation which we have before described. The flax, being now spun, require only the preparation of boiling to discharge the gum, and render the flax fit to receive the dye, and also to render it soft and pliable. The flax is boiled for about four hours, in a boiler filled with water, into which a small quantity of soap is put; this operation
SILK.

in which state the weaver takes it, and mounts it in his loom.

For the subsequent operations of weaving we shall refer to the article WEAVING, because the weaving of silk goods is the same as for any other, except that finer and more beautiful articles are produced in this substance than in any other. Some information on the details of weaving mechanism will be found under our articles DRAPERY OF LOOMS, DRAW-LOOM, DIAPER, DIMITY, and DORNACK; and though these are rather the weaving of linen and cotton than silk, the same principles apply to silk, as will be more fully explained under WEAVING; where a description of weaving ribbons and figured silks will be given.

Silk is distinguished by different names according to its different states. Thus,

Silk, spun, is that taken from the ball, without fire, and spun into thread without any coction: such as is moh; if not all, that is brought into England from the Levant; i.e. from Persia by the way of Turkey, from Bengal in India, and from China. The raw spun silk is commonly worked up into two forms, called organze and tram: the former is made by giving a throw or twist to each thread of raw spun silk lingely, and then doubling two of these twisted threads together, and twisting them smartly together; this forms the warp or length of a piece when manufactured. The tram, or shoot, which makes the breadth of the piece, is formed by twisting two or more threads of raw silk flack. The waffe raw silk, or refuse in reeling, &c. is collected, carded, and spun, and called frog silk; this is doubled and thrown, and often made into a cheap sort of silk-frockings, which are very strong and durable.

In the French silk-works, the greatest part of this raw silk passes for better than a kind of fine frotta; yet, when spun, it makes a bright thread, and serves for the manufacture of stuffs of moderate value and luster. But the raw spun silks of the Levant, whence most of our come, are exceedingly fine and beautiful. The difference arises hence, that in France, the best balls are reeled off in boiling water, and only the refuse made into spun silk; whereas, in the Levant, there is no such thing as reeling or winding on the fire, but the silks are all sent in bales, or packs, as they are drawn from off the balls: so that they are only distinguished by their quality of fine, middling, and coarse.

Silk, boiled, is that which has been boiled in water, to facilitate the spinning and winding. This is the finest of all the sorts of silk manufactured in France, and is seldom used but in the richest stuffs; as velvets, taffeties, damasks, brocades, &c.

There is also another kind of boiled silk, which is prepared by boiling, to be milled; and which cannot receive that preparation, without being first passed through hot water. By the laws of France, it has been prohibited to mix raw with boiled silk; both as such a practice spoils the dyeing, and as the raw silk corrupts and cuts the boiled.

Silks, throwed or twilled, are such as, besides their spinning and winding, have received their milling or throwing. This they receive in a different degree, as they are paid oftener or seldomest over the mill; properly, however, throwed silks are those in which the threads are pretty thick-throwed, and twisted several times.

The throwed silk comes to us chiefly from Leghorn, Genoa, Naples, and Messina.

Silks, stack, are such as are not twilled, but are prepared, and dyed for tapety, and other works with the need.

Silk, Eastern or East Indian. That particularly thus called is not the work of the filk-worm, but comes from a plant that produces it, in pods, much like those of the cotton-tree. The matter this pod contains is extremely white, fine, and moderately glossy; it spins easily, and is made into a kind of silk, that enters the manufacture of several Indian and Chinese stuffs.

Silks, French. It is only in the most southern provinces of France that silk is cultivated, mulberry-trees planted, and worms bred. The principal places are Languedoc, Dauphiné, Provence, Avignon, Savoy, and Lyons. This last place, indeed, furnishes very few silks of its own growth; but it is the great staple whence the merchants of Paris, and the other cities, are to fetch them. At least, they are obliged to have them past through Lyons, if they bring them from other places, either by land or sea. There have been computed to enter Lyons, communibus annis, fix thousand bales; the bale valued at one hundred and sixty pounds weight; of which fix thousand bales, there are one thousand four hundred from the Levant, one thousand fix hundred from Sicily, one thousand five hundred from Italy, three hundred from Spain, and one thousand two hundred from Languedoc, Provence, and Dauphiné.

At the time when the manufactures of Lyons were in their prosperity, there were reckoned to be eighteen thousand looms employed in the silk manufacture; but in 1698, there were not reckoned four thousand. However, this manufacture afterwards revived, and a great part of Europe has been supplied from hence with brocade and rich silks. The decay has not been less notable at Tours; they had formerly there eight hundred mills for winding and preparing the silks; eight thousand looms to weave them; and forty thousand persons employed in the preparation and manufacturing of them; but these have been reduced to seventy mills, twelve hundred looms, and about four thousand persons. The revolution has, however, made such an alteration in the manufactures and trade of France, and they are still (1816) in so unsettled a state, that no correct estimate of them can be obtained.

Silks, Sicilian. The commerce of the silks of Sicily has been very considerable; and the Florentines, Genoese, and Lucque, are the people who have chiefly availed themselves of it. Great quantities were yearly brought thence, especially from Messina; part of which they used in their own manufactures, and sold the rest to their neighbours the French, &c. with profit. The Italians had this advantage, especially the Genoese, over other people, that, having large establishments in the island, they were reputed as natives, and paid no duty for the export.

Part of the Sicilian silks is raw, the rest are spun and milled; of which last kind, those of St. Lucia and Messina are the most valued. The raw unwrought silks were always sold for ready money; the others, sometimes, in exchange for other goods. See Sicily.

Silks, Italian. The silks brought from Italy are partly wrought, and partly raw and unwrought. Milan, Parma, Lucca, and Modena, furnish none but the latter kind; Genoa most of the former; Bologna affords both kinds. The finest Italian wrought silk comes from Piedmont, Novi, Bergamo, and Bologna; and is imported into England from the ports of Nice, Genoa, and Leghorn.

The silk we have from Italy is generally throwed, and serves for warp for our manufactures.

Silks, Spanish, are all raw; and are spun, milled, &c. in England, according to the several works in which they are to be used.

Silks, Turkish, are all raw. One advantage we have in the commerce of the Levant, in silks, wanting in those of Sicily, is, that the latter are confined to a particular season of the year; whereas the former are bought at all times. They
They are brought from Aleppo, Tripoli, Saida, and from the isle of Cyprus, Candia, &c. They are principal place of commerce, especially for the barks of Persia, & Smyrna.

The silk is brought either in caravans, from the month of January to September. The caravans in January are loaded with the fullest silks; those of February, March and April being less plentiful; the rest, the caravans. They all come from the several provinces of Persia, chief of Ghiilan and Shirv, and the city of Schrareh, about a hundred miles from the sea, and those of Isfahon, and a little about it. But the other provinces of Persia, including Aria and Anfall, are seldom or never exported.

Ardeou, or Ardebil, another city of Persia, not far distant from these silk countries, is the place where silks are laid up, and whence the caravans set out for Smyrna, Aleppo, Scasserdoon, and Constantinople; and it is the city, with Sambahan, that have always been esteemed the centre of the silk trade; which has been several times attempted to be removed from Smyrna, and the Mediter-

This new course of the Persian silks into Europe was first proposed by Paulo Centurio, a Genoese, to the earl Basil, under the pontificate of Leo X. The French had the fame design in 1628. The duke of Holleein, in 1633, sent ambassadors to the court of Perfa, purely with the same view. And in 1668, the earl Alexis Michael attempted the thing himself; but he was defeated by the rebellion of the Tatars, and the surpriz of Aftrakan.

In 1688, the commerce of Persian silks had nearly been removed from Smyrna by an earthquake, which almost overturned the whole city; and, if the attempt had been effectual, but for the vigorous means used by the Turks to prevent it. Smyrna, however, still remains in her ancient polieion; and the several nations of Europe continue every year to send their fleets, to fetch away the silks.

Skins, China, Japan, and India. Several provinces of China are fertile in mulberry-trees, and their climate is agreeable to the nature of silk-worms, that the quantity of silks there produced is incredible; the single province of Tchehong might supply all China, and even a great part of Europe, with this commodity. The silks of this province are the most esteemed, though those of Naskin and China be excellent.

The silk-trade is the principal in China, and it which employs the most hands; but the European merchants who deal in it, especially in wrought silks, are to be careful of the spining, &c. the waste being usually very great, as the French East India company have found to their cost.

Japun would not afford fewer silks than China; but the Japanese, a barbarous and distrustful people, have interdicted all commerce with strangers, excepting with the Dutch; who are admitted on certain impious terms, related by Taverner, but which, we read owe, we cannot credit. The Dutch have endeavoured to vindicate themselves from those by the pens of several famous writers.

Great quantities of both raw and wrought silk are furnished by other parts of Bengal, and by several provinces of Vol. XXXII. Vol. XXXII. which partly supply the Chinese, and send a very considerable quantity to Persia and India, the barks of which are very much esteemed by the Chinese and Persians; in which, for the same reason, as manufacturing places, they are either plaited into scarfs, or cut into pieces and fitted for the market by the silk-thrower.

Silk, Laws relative to. The duties on the silk-trade are under the old law, Gent. 9 & 10 Phil. V. in 2 do., 10s. per piece, that is, for every two pieces, brought into the port of London, or any other port in the dominions of the king, and landed under the acts, shall be forfeited to the king, and every person who shall buy, sell, or have in his custody, any silks or silks, shall be liable to the same penalties as are laid down in the act of 9 & 10 Phil. V., that is, he shall be liable to forfeit all the silks or silks, his hands, his goods, and his personal estate, to the value of five hundred pounds; and also to the payment of all the duties which shall be paid on such silks or silks, and to further penalties as the king may think fit to impose on any person who shall be conviction thereof.

However, some duties have been imposed on the trade in silks and silks, but they have been discontinued by the king, and the king of Great Britain, whether the same shall be brought into the dominions of the king, by any person who shall be convicted of any of the provisions of this act, shall be liable to the same penalties as are laid down in the act of 9 & 10 Phil. V., and to further penalties as the king may think fit to impose on any person who shall be conviction thereof.
fuch false to be to the king, and half to the officer who shall seize and secare the fame; and the fame goods shall not be delivered out of the warehous, till security shall be given for exportation, and that the fame shall not be landed again in any part of his majesty’s dominions.

By 5 Geo. III. c. 48, if any foreign manufa&ced silk-stockings, silk-mitts, or silk-gloves, shall be imported into this kingdom, or any part of the British dominions, the fame shall be forfeited, and liable to be searched for and seized as other uncustomed goods; and every person who shall import the fame, or be assisting therein, and the vendors and retailers in whose custody they shall be found, or who shall sell or expofe the fame to sale, or conceal with intent to prevent the forfeiture, shall, over and above the forfeiture of the goods, forfeit 200l., with costs; half to the king, and half to the officer who shall inform and proceute.

And when the goods seized (being out of the limits of the bills of mortality) shall not exceed the value of 20l., two Justices may proceed to the condemnation thereof. And the proceedings, in all other respects, shall be in like manner as in the cafe of ribsbands and laces above mentioned.

SILK, in Chemistry, deferves notice on account of a peculiar falt, or crystalline ftufcence, obtained from it by the nitric acid. In its natural state, or before it is bleached, it contains a yellow redinous matter, from which it derives its fine golden colour. When raw silk is infufed in water, a portion of the yellow matter is difolved, and a light amber-coloured liquor is produced. Pure alcohol extracts a much deeper yellow colour, and makes a tincture, that lofes none of its colour by long exposure to the fun, which bleaches the silk itself. Nitrous acid acts powerfully on silk, in proportion to its concentration. If two draffes of this acid are mixed with a pint of alcohol, and silk, either raw or bleached, be immerfed in it, and kept in digestion, in a moderate warmth, for twenty-four hours, the silk becomes of a dull yellowish-brown, which, after rinsing and washing with soap, and drying, turns to a fine golden yellow, which is very permanent. But when concentrated nitric acid is difiill’d off silk, and the remaining liquor duly evaporated, much oxalic acid is obtained; and the residue, if evaporated still further, yields, together with a little remaining oxalic acid, a quantity of yellow granular cryftals, very bitter, not acid, and forming the saliva and hands of a very deep yellow, not easily removed. If the liquor is previously faturat’d with potaff, and evaporated, another yellow fikly falt evaporates, which detones on coals like common nitre, and appears to be a triple combination of the former granular liquor with nitrate of potaff. The felt men&ced granular cryftals, examined with a magnifier, appear to be compofed of truncated octahedrons.

The above curious ftubefce was discovert by Welter, and called by him the ‘bitter principle.’ He fuppofes it to be generally produced by the action of nitric acid on animal matters; and it is perhaps the fame ftubfe which caufe the bitternefs of bile. Alk&n.

The spirit of raw silk, rectified with fome essential oil, is the medicine commonly known by the name of Gutta Anglicana, or English drops.

SILK, Spider. Within about a century the fecret has been found in France, of procuring and preparing filk from the webs of spiders; and the ufeing it in feveral manufa&ces has been attempted. This discovery is owing to M. Bon, in 1716, who published a differtation on the fubje&; whence what fellows is extracted.

Spiders are usually diftinguifhed, either with regard to their colour, as into black, brown, yellow, white, &c. or with regard to the number, or arrangement, of their eyes; some having fix, others eight, others ten. But with regard to the filk-spiders, M. Bon reduces them all to two kinds; those with long legs, and thofe with short: which left are thofe which furmih the finest raw filk. The filk-fpider makes a filk every whit as beautiful, glossy, and strong, as the filk-worm: it fpin’s it from the anus; but which are about as many as the filk-worm; and behind these, two others, all mutinous, and furnifhed with fphincters. These niples serve as fo many wire-drawing irons, to form and mould a virous liquor, which, when dried in the air, after being drawn through them, makes the filk. Each of these niples, M. Reaumur observes, contains a number of lefs and inffenfible ones; which one may be convinced of by prefling a spider’s belly between the fingers, to oblige the liquor to fly into the nipples; for by this means, applying the finger againft the anus, several diftiinct threads will be drawn out through the feveral perforations of each nipple. The threads are too fine to be counted with any certainty; but M. Reaumur reckons each larger nipple may fend forth a great many.

Hence we fee how the fpiders make their threads bigger or smaller: for as, before they begin to spin, they always apply more or fewer of the fiple nipples againft the body whence the web is begun; or, as they apply each more or lefs strongly; fo, as more or fewer of the minuter nipples come to take, the thread thus fpun will be a compound of more or fewer of the fingle threads. Indeed, as the threads come from the anus all joined together, they appear to be fingle; but M. Bon has diftinguifhed one of the finge ones to confift of fifteen or twenty diftiinct threads.

The threads are of two kinds: the fikl is weak, and only serves for that kind of web with which they catch flies. The fcond is much ftronger, and serves to wrap up their eggs in; which, by this means, are feltered from the cold, as well as from infects, which might otherwife gnaw and deftoy them. These threads they wind very loofely round the eggs, refembling the bags or balls of filk-worms, that have been prepared and loofened for the diftaff.

The fipder-bags are of a grey colour, when new; but when they turn blackifh, when long expos’d to the air; indeed, one might find other fpi&ers’ bags of other colours, and which would afford a better filk; but their fcarcity would render the experiment difficult: for which reafon, we confine ourfelves to the bags of the moft common fpiders, which are the fhort-legged kind. Thefe always find out fome place, securing from the wind and rain, to make their bags; as hollow trees, the corners of windows, or vaults, or under the eaves of houses.

By collecting a quantity of thefe bags, a new filk is made, inferior in nothing to the common filk. It takes all kinds of dyes, and may be made into all kinds of ftuffs. M. Bon had flockings and gloves made of it, which he prefented to the Academy, and others to our Royal Society.

For the manner of preparing the bags to get the filk, it is thus: after having gathered twelve or thirteen ounces of fhe bags, M. Bon had them well beaten for fome time, with the hand, and a flick, to get out all the dust; he then washed them in lukewarm water, till they left the water very clean; after this, he laid them to fleep, in a large vafe, with soap, and faltwater, and gum arabic. The whole was left to boil, over a gentle fire, for three hours. The bags were then washed in warm water, to get out the soap; and after all, laid to dry fome days, to fit them for
for carding; which was performed by the common folk-carders, but with cards much finer than ordinary. By this means, he had a filk, of a very particular kind, which was easily spun; and the thread from it was both stronger and finer than that of common filk; which proves, that all sorts of works may be made of it: nor is there any reason to fear, but it will stand any trials of the loom, after having passed that of the flocking-weavers.

The only difficulty, now, is in procuring a sufficient quantity of spider-bags to make an considerable work of it; which, M. Bon observes, would be no difficulty at all, had we but the art of breeding them, as we do silk-worms; for they multiply much more; every spider lays six or seven hundred eggs, whereas the silk-worms do not lay above one hundred; yet are these left to tender, &c. that one half die without making any bags, or are hindered, by some little accident, from making them; whereas the spiders hatch of themselves, without any care, in the months of August and September, in fifteen or sixteen days after they are laid; the old spiders that lay them dying from after. The young ones thus breed five or ten or twelve months without eating, and continue in their bags without growing, till the hot weather, putting their wired juices in motion, induces them to come forth, spin, and run about to seek food. Were a method, therefore, found of breeding young spiders in rooms, they would, doubtless, furnish a much greater quantity of bags than silk-worms do. For of seven or eight hundred young spiders, which M. Bon kept, hardly one died in a year; whereas of one hundred silk-worms, not forty lived to make their bags. M. Bon, having ordered all the short-legged spiders that could be found in the months of August and September to be brought to him, that they should be put in paper coffins, and pots; covering the pots with paper, which he pierced full of pin-holes, as well as the coffins, to give them air. He fed them with flies, and found, some time afterwards, that the greatest part of them had made their bags. The same ingenious person found, that spiders' bags, with regard to their weight, afford much more silk than those of the silk-worms: as a proof of which, he observes, that thirteen ounces yield near four ounces of clear silk, two ounces of which will make a pair of flockings; whereas flockings of common silk weigh between six and eight ounces. Nor is there any venom in the silk, or even in the spider, as many have imagined. M. Bon has been bit by them several times, without any manner of harm; and as for the silk, it is used very good for to stop bleeding, and cure wounds, the natural gluten of it acting as a kind of balsam. It likewise yields, by distillation, several specific medicines, particularly great quantities of spirits, and volatile salt, which being prepared after the same manner as that drawn from the bags of silk-worms, in making the gutta percha, or English drops, at one time so famous all over Europe, may serve to make other drops of greater efficacy, which M. Bon calls drops of Montpelier, and advises to be used in all sleepless diseases.

M. Reaumur, being appointed by the Royal Academy to make a farther inquiry into the new silk work, has raised several objections and difficulties against it; which are found in the Memoirs of the Academy for the year 1721. The sum of what he has urged amounts to this. The natural tierceens of the spiders renders them unfit to be bred and be kept together: four or five thousand being distributed into cells, fifty in some, one or two hundred in others, the two or three from killed and eat the lefs, so that, in a short time, there were scarcely left one or two in each cell; and to this

necessity of mutually eating one another, M. Reaumur attributes the scarcity of spiders, confiding the soft number of eggs they lay.

But this is not all; he even affirms, that the spider's bag is inferior to that of the silk-worm, both in bulk and strength; and that it produces less matter to be manufactured. The thread of the spider's web, he says, only bears a weight of two grains without breaking, and that of the bag bears thirty fix. The latter, therefore, is all probability, eighteen times the latter than the former, yet it is weaker than that of the silk-worm, which bears a weight of two drachms and a half; so that five threads of the spider's bag must be put together, to equal one thread of the silk-worm's bag.

Now it is impossible these should be applied jointly over one another, as not to leave little vacant spaces between them, whence the light will not be reflected; and of consequence, a thread, thus compounded, must fall short of the lustre of a solid thread. Add to this, that the spider's thread cannot be wound off, as that of the silk-worm may, but must of necessity be carded; by which means, being torn in pieces, its evenness, which contributes much to its lustre, is destroyed. In effect, this want of lustre was taken notice of by M. de la Hire, when the flockings were presented to the Academy.

Again: spiders furnish much less silk than the worms: the largest bags of these latter weigh four grains; the smaller, three grains; so that 2534 worms produce a pound of silk. The spider-bags do not weigh above one grain; yet when cleared of their dust and filth, they lose two-thirds of their weight. The work of twelve spiders, therefore, only equals that of one silk-worm; and a pound of silk will require at least 27,648 spiders. But as the bags are wholly the work of the females, who spin them to deposit their egg in, there must be kept 55,296 spiders to yield a pound of silk. Yet will this only hold of the best spiders; those large ones ordinarily seen in gardens, &c. scarcely yielding a twelfth part of the silk of the others: 280 of these, he thinks, would not yield more than one silk-worm; 661,552 of them would fearely yield a pound.

SILK-GrAfF, in Botany, a name used for two very different genera of plants, the abe, and dog's base.

SILK-Tail, or Bohemian Chatterer, in Ornithology. See ROLLER.

SILK, Virginian, in Botany. See PERSICIFLO.

SILK-Worm, Bander. This insect, which is a species of the phalana, (see Bombyx,) consists of eleven rings, and each of these of a great number of other smaller ones, joined to each other; and the head, which terminates these rings, is furnished with two jaws, which work and cut the food, not by a perpendicular but a lateral action.

The humour found in the body of this creature all seem approaching to the nature of the silk which it spins; for on being rubbed in the hands, they leave a hard or solid crust behind them. Under the skin there is always found a mucous rosy-coloured membrane, enveloping the animal, and supposed to be the new skin in which it is to appear, on throwing off the old one. The heart of this creature reaches from the head to the tail, running the whole length of the body: it is, indeed, rather a series of many hearts connected together, than one: the motion of the stomach and intestines is very evident in this whole chain of hearts; and it is an elegant sight to observe the manner of the vital fluid's passing from one of them to the other. The floumch of this animal is as long as the heart, reaching, like it, from one end of the body to the other. This large receptacle for food, and the founden
den palisade of it through the animal, are very good reasons for its great voracity.

In the sides of the belly, all about the ventricle, there is deposited a vast number of vessels, which contain the flaky juice: these run with various windings and meanders to the mouth, and are so disposed that the creatures can discharge their contents at pleasure at the mouth; and according to the nature of the juices that they are supplied with, furnish different sorts of fluid from them, all the fluid contents of these vessels hardening in the air into that sort of thread, of which we find the web or balls of this creature consists.

These creatures never are offended at any trench, of whatever kind; but they always feel a southern wind, and an extremely hot air always makes them sick. Malpighi de Bombaye.

SILKEBURG, in Geography, a town of Denmark, in North Jutland, with a castle, which was formerly very strong; 18 miles W. of Aarhus.

SILLA, in Ancient Geography, a river of India, which flows in a mountain of the same name, and so itself in the ground, without receiving any other river.

SILLA, in Geography, a large town of Africa, in Bambara, on the right bank of the Niger, within two short days' journey of Jenné, which is situated on an island in the river. This place was the boundary of Mr. Park's journey, and from hence he began his return homeward; 75 miles N.E. of Sego. N. lat. 14° 49'. W. long. 1° 34'.

Silla Point, a cape on the north-west coast of the island of Mindanao. N. lat. 0° 27'. E. long. 125° 51'.

SILLBAR, or Sellebar, a sea-port town on the west coast of the island of Sumatra, with a good and safe harbour; 30 miles S.S.E. of Bengoelen.

SILLAH-MEW, a handsome town of the Birman empire, situated on the Irrawaddy. It is flanked by widespread trees, and embellished with several temples. A smooth bank sloping to the river, and clothed with the finest verdure, adds much to its beauty. The soil around is in general but poor. Some fields are regularly fenced, and cattle in large herds graze in the neighbourhood.

SILLANGER, a town of Sweden, in Angermanland; 4 miles W. of Hernoand.

SILLANO, a town of Etruria; 8 miles S.S.E. of Volterra.

SILLEE, a ciree of Bengal, bounded on the north by Ramgur, on the east by Paccheta, on the south by Tomar, and on the west by Nagpour; its form is square, and each side is about 16 miles. Alto, the capital of the above ciree; 25 miles S.E. of Ramgur. N. lat. 23° 22'. E. long. 85° 57'.

SILLES, in Ancient Geography, a river of the Troade.

SILLE-LE-GUILLAUME, in Geography, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Le Mans; 18 miles N. of Le Mans. The place contains 2121, and the canton 11,835 inhabitants, on a territory of 2471/4 kilometres, in 10 communes. N. lat. 48° 12'. W. long. 0° 3'.

SILLEWOOD, a small island in the North sea, near the coast of Norway; 30 miles N.N.W. of Bergen.

SILLINGA, a town of Bengal; 35 miles S. of Doefa.

SILLON, in Fortification, an elevation of earth, made in the middle of the moat, to fortify it, when too broad.
The sillon is more usually denominated an envelope.

SILLS, in Agriculture, a term signifying the shafts of a cart, waggon, &c.

SILLY, in Geography, a rock on the south coast of the island of Jersey; 2 miles S. of Noirmont Point.

SILLYUS, in Ancient Geography, a town of Acha Minor, in Ionia, in the vicinity of Smyrna.

SILM, or CLEMISON, in Geography, a country of Africa, near the river Scherbro.

SILNO, a town of Lithuania; 4 miles N.N.W. of Grodno.

SILOE, in Ancient Geography. See Silloth.

SILOE, SIOLO, or Siloain, a fountain at the foot of the walls of Jerusalem, east, between the city and the brook Kidron, or Cedron. Josephus (De Bell. l. c. 26.) says, that when Nebuchadnezzar besieged Jerusalem, the waters of this fountain increased; and that the cale was the same, when Titus besieged the city; so that, during the siege, it abundantly supplied the Roman army, and furnished also a sufficiency for watering the gardens; though, before this event, water could hardly be bought for money. The prophet Isaiah (ch. viii. 6.) infinuates, that its waters flowed gently and without noise. St. John speaks of the pool of Siloam. (John, ix. 7.) The tower of Siloam, mentioned Luke, xiii. 4. is thought to have been near the fountain.

SI-LONG, in Geography, a city of China, of the second rank, in Quang-n. N. lat. 24° 34'. E. long. 105° 18'.

SILOON, a town on the north-east coast of Sumatra. S. lat. 1° 8'. E. long. 105° 51'.

SILOXERUS, in Botany, f. named by Labillardiere, from σιλοξερος, the style, and ὑπονοος, fouling, on account of the tumid base of that part. It would have been difficult to trace this derivation, without authentic information from the author himself. — Labill. Nov. Holl. v. 2. 57. — Clasts and order, Syngeneta Pohyamia-segregata. Nat. Ord. Compostae monocotaeae, Linn. Corystidea, Jull.

Gen. Ch. Common Calyx scarcely any, except the leaves surrounding the common compound receptacle; partial inferior, of from five to seven equal, obovate-oblong, concave, membranous leaves, containing several florets. Cor. compound uniform, discoïd, of from two to five tubular, monopetalous, regular, pitcher-shaped, five-toothed, perfect florets. Stam. Filaments in each floret five, very short; anthers linear, united into a tube. Pfl. Germen in each floret inerely pyramidal, tuberculated; lyle awl-shaped, swelling very much at the base; stigma two, obtuse, spreading. Peric. none, except the permanent partial calyx. Seeds solitary to each floret, inerely pyramidal, beft with rows of tubercles, and crowned with about twelve little teeth; down of one leaf, membranous, pellucid, in five ovate, acute, fringed lobes. Common Receptacle oblong, somewhat club-shaped, hairy, many-flowered; partial small, fcelar, the sepalis membranous, oblong, fearely longer than the florets.

Eff. Ch. Common receptacle hairy; partial chaffy. Partial calyx with from two to five perfect, equal, regular florets. Seed-down membranous, five-lobed, fringed.

1. S. humifusa. Labill. Nov. Holl. v. 2. 58. t. 209.—Native of Lewin's land, on the south coast of New Holland. A small, diffuse, herbaceous plant, with a tapering, apparently annual, root. Stems several, spreading, simple, leafy, an inch or two long. Leaves mostly opposite, simple, linear, obtuse, smooth, near an inch in length; several of them crowded under the heads of flowers, which are terminal, solitary, ovate or nearly globular, fearely an inch long. Nothing is mentioned concerning the colour, scent, or properties of this little inconspicuous, but singular, plant.

SILPERRY, in Geography, a town of Bengal; 2 miles S.S.E. of Ghitore.

SILPHA,
SILPHA.

SILPHA, in Entomology, a genus of insects of the order Coleoptera, of which the generic character is, Antennae elevated; the club pedate, shells margined; head prominent; thorax facet what flattened and margined: This genus of insects, from its habits, is derived from the trival name of the Coleopterae.

The several species are commonly found among decayed animal and vegetable substance, frequently also dug in earth, are various and other offensive matters they lay their eggs in: in the dead and putrid carcases of animals. The larvae are of a lengthened shape, and of an unpleasant appearance: They are generally roughed with minute spines and protuberances. There are about 13 species, in eight separate divisions or sections. The following are most worthy of notice.

S. A is characterized by a discolored and banded Ip., and a one-toothed Jaws; in which, as follows, are the following species:

S. [nonidentified] Black; shells with a yellow base behind: head-thigh toothed. It is found in South America.

S. [nonidentified] This is a black insect; the shells are rufous, with three railed lines; thorax rounded and punctured. This is an European insect, and found in our own country.

S. [nonidentified] This is brown; thorax, shells, and legs hvid. It is found in Germany.

S. [nonidentified] This, as its name imports, is an Indian insect; it is black; the shells are marked with two ferruginous bands; thorax one-toothed before.

S. [nonidentified] Black; with a green polish; shells frutice, truncate, one-toothed. This is an inhabitant of the Cape of Good Hope. Tail rufous; shells black, with three elevated lines, one-toothed at the future.

S. [nonidentified] This, as its name shews, is found in divers parts of America. It is depressed and black; thorax yellow and black in the centre. The shells are rugos and immaculate.

S. [nonidentified] This is black; the shells are marked with a single elevated line; the thorax is telfaceous. This and the following are English insects. According to Mr. Donovan’s figure and description, the shells of this species have three railed lines. It is distinguishable by its red thorax, every other part being black.

S. [nonidentified] Blackish; the shells are ridged with three railed lines, the thorax is ridged and sinuate behind. This insect consumes dead carcases, fish, and flesh of all kinds: when caught it emits a very fetid humour.

S. [nonidentified] This is of a size similar to the thoracica, but is totally black, and has the wing-veins marked by three rising lines; its larva, which may be found in gardens, is of a lengthened shape, and of a black colour.

S. [nonidentified] Black; shells smooth and sub-punctured. The shells are without railed lines.

S. [nonidentified] Black; the shells are punctured, with three railed lines; the thorax is truncate before. This species is figured by Donovan. The thorax has a blue-thinct.

S. [nonidentified] This is brown; the shells have three railed lines; the thorax is truncate before.

S. [nonidentified] The thorax of this species is emarginate and rough; the shells have three railed lines, sinuate at the tip. This is a beautiful species; the thorax is brown, with a silvery gloss; it is rough, with railed dots.

S. [nonidentified] This thorax is yellow, with a large black spot; the shells are yellow, with four black spots.

S. [nonidentified] Grey; the shells are smooth; the thorax is emarginate.

S. [nonidentified] This is characterized by a spot only in the Lcp., and a one-toothed Jaws.

S. [nonidentified] The shell is black; it is covered with two rufous spots; the body is black; the thorax is orange, brown, and at the tip, the abdomen is turberate.

S. [nonidentified] Rufous; the abdomen, with numerous rufous dots. This is a black insect; the shell is rufous. It is a very small insect, and is found in Germany.

S. [nonidentified] This is of a brown color; the legs are ferruginous. It is found in divers parts of Mexico.

C. Lip murcigal, cost; Jaws banded.

S. [nonidentified] Black; the shell is truncated, with two rufous spots. It is found in base parts of Germany. The antennae are long; the fore legs are perforate; the shells are a little shorter than the body; the abdomen acute.

S. [nonidentified] Black, polished; edges of the thorax and spots on the shells are angular. It is found in New Holland; the shells are truncated, shorter than the abdomen.

S. [nonidentified] This is also black and polished; the antennae and legs are yellow. It is found in many parts of Europe, but not in our own country. The shells are truncated, shorter than the abdomen; the body is black and immaculate; the abdomen pointed.

D. Lip emarginate, cost; Jaws banded.

S. [nonidentified] Black; the shell is marked with two rufous bands, the fore one spotted with black. It inhabits North America, and is a rather large insect; though less than the Grandis, which is an African insect, and so named on account of its size. This is black, and the shells are marked with two rufous spots.

S. [nonidentified] Black; the shells are marked with two ferruginous dots. This is found in England, and in many other parts of Europe. The larva is long, hairy, and grey.

S. [nonidentified] Black; shells frutice, with three rufous spots. This is found chiefly in the northern parts of Europe. It is reckoned a very beautiful species; the antennae are pitchy; the thorax is ferruginous at the edge; spot at the bale of the shells sinuate, the middle one is uniform; that at the tip is small and round; the body beneath is rufous.

S. [nonidentified] Rufous; the antennae, shells, and breast are black. This is found chiefly on trees.

S. [nonidentified] This is a black insect; the head, thorax, and legs, are ferruginous. The abdomen is black.

S. [nonidentified] This is of a fine scarlet colour; the shells are brassy and immaculate.

S. [nonidentified] Black; but the front, two spots on the shells, and legs, are ferruginous. This is found in divers parts of England, and is reckoned a small insect.

E. The Insects of this Section are characterized by a heart-shaped Lcp., emarginate and concolor.

S. [nonidentified] Black; front and edge of the shells are ferruginous. Sometimes they are marked with a ferruginous spot or two. It deposits its eggs in the carcases of other insects, and buries them under ground. They are very like the

S. [nonidentified] This insect, which is not uncommon in our
own country, is the most remarkable of the European species. It is distinguished by having the wing-leaths con-derably shorter than the abdomen, or as if cut off at the tips; they are also marked by two waved, orange-coloured transverse bars, the reft of the insect being black; the general length of the animal is about three-quarters of an inch. The vespifio seeks out some decaying animal substance in which it may deposit its eggs, and in order to their greater security, confines it under ground. Three or four of these insects, working in concert, have been known to drag under the surface the body of a mole in the space of an hour, fo that not a trace of it has appeared above ground. The eggs are white, and of an oval shape: from these are hatched the larvz, which, when full grown, are about an inch long, of a yellowish-white colour, with a fealy orange-coloured shield; or bar, across the middle of each division of the body. Each of these larvae forms for itself an oval cell in the ground, in which it changes to a yellowish chrysalis, resembling that of a beetle; out of which, in the space of three weeks, proceeds the perfect insect. This species is reckoned very elegant in form, but it generally diffuses a very strong and unpleafant smell; it flies with strength and rapidity, and is usually een on the wing during the hottest part of the day.

MORTUORUM. Black; shells marked with two ferrug-inous bands; the club of the antenna is black; the hind-thighs are unarmed. This is found in many parts of Germany, preying on carufes and fungi.

F. Lip square and emarginate.

* SCARABEEOIDES. Oval, black; the shells are marked with two ferruginous spots.

LUNATA. Oval, black; shells with a lunate yellow spot at the tip. It is about the fize of the lafd, and is found in Germany.

COLON. Yellow; the spots on the thorax, and marginal spot on the shells, black. It is found in Sweden. The head is black; the antenna are yellow; the club is black; the thorax is downy, with fix spots disposed in a ftreak; the abdomen is black, edged with yellow.

* ATOMARIA. This insect is smooth and black; the shells have crenate frizz; the legs are pale.

* MELANOCEPHALA. This is black and smooth; the shells are grey, with a common black spot at the bafe.

* UNIPUNCTA. This is black; shells yellowish, with a common black spot. The shells are fometimes immaculate.

* FEMARIA. Black, immaculate; the shells are very smooth. It is found chiefly in dung.

* MINATA. This is black and small; the shells are ftrate; legs of the fame colour. It is found in many parts of England.

* PLICARIA. This is oblong and black; the shells are abbreviated; the abdomen pointed. This is found chiefly among flowers.

G. The Insects of this Section have a long and entire Lip; the Antenne are ferrate.

* SAXICORNIS. Smooth, polished, and of a chefnut colour; the antenna are black.

DEPRESSA. Smooth, ferruginous; the shells are fubfrate, and the body is defpatted. It is found under the bark of oak-trees.

H. Lip and Jaw unknown.

Of this section there are no English species; it will be fufficient to mention the following.

INSIGNITA. Black; shells obfolutely frate, with two large scarlet spots. Common at Berlin; as is the next.

NIGRICANS. Blackish; the shells are smooth, with four yellow spots.

HISTEROIDES. Black; the antennae and legs are red; the shells are abbreviated with a red spot. It inhabits Upfal, and is the fize of a loupe.

Gen. Ch. Common Calyx ovate, imbricated, fquarros; its fcales ovate-oblong, reflexed for about half their length, projecting on all fides, permanent. Cor. compound, radian. Perfect florets in the dilf several, of one petal, funnel-shaped, five-toothed; their tube scarcely more flenfer than the limb; female ones, in the radius, fewer, lanceolate, very long, often three-toothed. Stam. in the florets of the dilf only. Filaments five, capillary, very fhort; anthers united into a cyndrical tube. Pif. in the florets of the dilf imperfect, German thread-shaped, very fnder; fyle thread-shaped, very long, villous; fagma fimple in the females, German inverfely heart-shaped; fyle fimple, fhort; ffigmas two, brifte-shaped, the length of the fyle. Peric. none, except the unaltered calyx. Seeds in the dilf none; in the radius folitary to each floret, somewhat membranous, inverfely heart-shaped, with a membranous, two-horned, emarginate border. Recep. chaffy, with linear fcales. Elf. Ch. Receptacle chaffy. Seeds comprefled, inverfely heart-shaped, bordered; their down bordered, with two horns. Calyx fquarros.

Fifteen species are defined by authors, hardly herbaceous perennial plants, generally rather large, with the afpect of Sunflowers; their leaves opposite, whorled, or alternate; the flowers yellow. The horns of the feed are wanting in some of the species.

S. laciniatum. Jagged-leaved Silphium. Linn. Sp. Pl. 1521. Ait. n. 1. Pursh n. 1. Linn. fil. fce. 1. 5. t. 3.—Stem bifid. Radical as well as ftem-leaves pinna- tifid; their fegments deeply toothed.—On the banks of rivers, in the western territories of North America, parti-cularly on the Miifippi, flowering from Auguft to October. Pursh. Collinson fen the feds to Linnæus. The ftem is from eight to twelve feet high, fimple, leafy, round, an inch thick, rough in the upper part with brilfly hairs. Leaves alternate, ifalked, two feet long, and one broad, with four or five remote lobes at each fide; ftrongly ribbed, rough. Flowers four inches wide; the ten fcales of their rough calyx armed with ftrong taper points.

The flowers are numerous, large, white, and fragrant. The flowers have five petals and five sepals. The fruit is a capsule containing many seeds. The plant is indigenous to the western United States and Canada, and is commonly found in rocky, open woods and along roadsides. Its flowers are used as a source of nectar for bees.

4. S. perfusum. Square-tubed Silphium. Linn. Sp. Pl. 153. Att. n. 3. Pursh n. 4. - Leaves opposite, triangular, toothed, alternate, ovate, rough. Native of the Allegheny mountains, flowering in July to October, according to Mr. Pursh, who considers it a variety of this the Silphium. Wild. Enum. 923. The flowers are arranged in a cluster, and are white, yellow, or orange in color. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

5. S. connatum. Round-tubed Perforate Silphium. Linn. Mant. 574. Wildl. n. 5. Att. n. 4. Pursh n. 5. - Leaves opposite, ovate, rough, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

6. S. Amuricum. Furry-leaved Silphium. Linn. Sp. Pl. 1502. Att. n. 5. Pursh n. 6. - Stem round, tufted, opposite, ovate, rough, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

7. S. pallidum. Dwarf Silphium. Michaux Boreali-amer. v. 2. 146. Wildl. n. 7. Pursh n. 7. - Leaves opposite, ovate, rough, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

8. S. integrifolium. Entire-leaved Silphium. Michaux ibid. Wildl. n. 8. Pursh n. 8. - Stem quadrangular, tufted, opposite, ovate, rough, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

9. S. leucophaeum. White-leaved Silphium. Pursh n. 9. - Stem simple, square, tufted, smooth, opposite, fleshy, ovate, alternate, ovate, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

10. S. trifoliatum. Rough-leaved Silphium. Linn. Sp. Pl. 1502. Wildl. n. 9. Att. n. 6. Pursh n. 10. (S. trifoliatum; Michaux Boreali-amer. v. 2. 146.) - Leaves several, alternate, ovate, rough, with unequal teeth-like teeth, ovate, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

11. S. teretifolium. Rough-leaved Silphium. Wildl. n. 11. Pursh n. 12. - Stem cylindrical, smooth, opposite, ovate, rough, with unequal teeth-like teeth, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

12. S. aurea-purpurea. Yellow-leaved Silphium. Linn. Sp. Pl. 1502. Pursh n. 13. - Stem simple, square, tufted, opposite, ovate, rough, with unequal teeth-like teeth, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

13. S. tennesseanum. Tall-leaved Silphium. Pursh n. 14. - Stem simple, square, tufted, opposite, ovate, rough, with unequal teeth-like teeth, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.

14. S. ovalatum. Retractile Silphium. Pursh n. 15. - Stem simple, square, tufted, alternate, ovate, rough, with unequal teeth-like teeth, on short stalks, clasping the stem. The flowers are yellow, and are arranged in a cluster. The fruits are dry and hard, containing many seeds. The plant is common in the eastern United States, from New York to Virginia.
Method of Culture.—They are all readily increased by parting the roots, and planting them out in the autumn or spring, where they are to remain in the borders and clumps. They may also be raised by planting the slips in the same manner: they should be afterwards managed as the perennial sun-flower. They are durable in the root, but decay annually in the stalk.

They afford a good variety and effect among other perennial plants in the summer season, when put out in a proper manner.

SILPHUN, in Ancient Geography, a country of Libya, which took its name from the plant. It commenced easterly towards Aziris and the isle of Platea, and extended westward as far as the Syrtis.

SILSTADT, in Geography, a town of Germany, in the county of Wernigerode; 3 miles N.E. of Wernigerode.

SILVA, a river of Ruffia, which runs into the Kama, near the town of Silva, in the government of Perm.—Alfo, a river of Ruffia, which runs into the Tchufovaia, 16 miles N.E. of Perm.—Alfo, a town of Ruffia, in the government of Perm; 12 miles N.W. of Solikammik.

SILVA Piano, a town of Switzerland, in the biflorop of Coire; 16 miles W.N.W. of Bormio.

SILVANEZ, a town of France, in the department of the Aveiron; 9 miles S. of St. Afrique.

SILVELLA, a town of Italy, in the department of the Upper Po; 3 miles E.N.E. of Cremona.

SILVER, a river of the King's county, Ireland, which rises on the north-west side of the Slech-Bloom mountains, and takes a northerly direction. It has this name in Beaufort's and Arrowimith's maps, but is called the Frankford river by Mr. Longfield, in his report to the Bog commisioners, from the small town of Frankford, which it passes. Mr. Longfield represents it as capable of being easily made navigable for canal boats, and all of being made to contribute to the drainage of the vall bags between which it flows. In one part of its course, a little before it joins the Brufna, the Macnartney aqueduct, a part of the Grand Canal, passes over it.

Silver, in the Arts, Manufactures and Commerce, and in Domestic Economy, is a white malleable metal, susceptible of a fine polish. In Chemistry, it is a simple inflammable body.

It is sometimes found in the native state, but more frequently combined with antimony, arsenic, or sulphur; forming the varieties of silver-ores; with which we shall begin, and then proceed to the alloy and analysis, physical properties, and chemical properties of silver.

Silver-ores contain that metal either native, or alloyed with other metals, or mineralized by sulphur, and sometimes with the mucric acid, the sulphuric acid, and in one rare instance with the carbonic acid.

Silver-ores principally occur in the rocks which have been denominated primary and transition rocks, and rarely in secondary rocks; but many rich argentiferous lead-ores occur in alpine lime-flone and secondary strata. The ores of silver are accompanied by calcarceous spar and sulphate of barytes, and sometimes with quartz, horn-flone, jasper, and fluor spar. It has been remarked, that the warmer regions of the globe afford the greatest quantity of gold, but the richest repositories of silver are situated either in high latitudes or in elevated regions. The most celebrated silver-mines of Europe are in Sweden and Norway, at no great distance from the polar regions; and those which are in warmer latitudes, are almost all situated near the summits of alpine mountains commonly covered with snow, as at Allemon in France, and the mines of Mexico and Peru, in the centre of the Cordilleras. Silver never occurs, like gold, in alluvial soil, or the sands of rivers. After the mineralogical description of the ores, we shall give a short account of the principal repositories of silver at present known.

Native silver, Argent natif of Haüy, polishes the characters of silver extracted from other silver-ores, but is generally less malleable. The colour is pure white, but the surface is commonly tarnished, and is of a yellowish-brown or greyish-black. Native silver occurs crystallized in cubes and octahedrons; the crystals are small, and are often aggregated, forming beautiful ramifications; the branches sometimes cross each other in a rectangular direction, and are radiated. It is sometimes in leaves and sometimes capillary, and when the filaments are much entangled, it becomes nearly compact. Native silver is also found in shapeless malleable of considurable size. In the year 1750, there was found in the famous mine of Hemmels Furnl, near Freyberg, in Saxony, a mass of native silver, which weighed one hundred weight and a quarter; in 1771 an equally large mass was found. It is also mentioned by Albin, in his "Meinblinbe Berg Arconicke," p. 30, "that at Schweinberg, in 1478, a rich silver vein was discovered; and so large a block of native silver cut out, that duke Albert of Saxony defended into the mine, and used this large block as a table to dine upon. It was melted into four hundred centers of silver; a centner is 110 lbs."

(Jamefon's Mineralogy.) Native silver is fusible into a globule, which is not altered by a continuance of the heat: it is scarcely ever pure: the metals with which it is alloyed are commonly gold, copper or arsenic, and iron. Native silver alloyed with gold is rare; its colour is intermediate between silver-white and brass-yellow; it often contains a considurable proportion of gold. The flones which form the matrix of native silver in the mine are very numerous; it sometimes appears to be infiltrated into the fissures, sometimes to vegetate on the surface, and in other instances to be intimately combined with the substance of the flone. It is found in almost all the silver-mines that are worked in Europe or America; but the masses discovered in America are not so large as some which have been found in Europe. The places, a most abundant ore in Peru and Mexico, consists of minute particles of native silver, intermixed with brown oxide of iron; but the particles are too small to be seen without a lens, and bear but a very small proportion to the masts. Silver rarely occurs in detached grains, like gold or platinum.

Antimonial silver-ore is composed of silver combined with antimony, without any other substance. Its colour is tin-white; it has a shining metallic lustre, which is often tarnished superficially reddish or yellowish. It is distinguished from native silver by its brittleness, being scarcely malleable: the structure is lamellar. It is commonly found crystallized in four-sided and six-sided prisms, having the sides deeply furrowed; its specific gravity is from 9.10 to 9.8. It melts easily before the blowpipe, giving a white smoke from the oxide of antimony, and leaving a globule of silver. Its conoidal parts are from .76 to .84 silver, and from 16 to 24 of antimony. Antimonial silver is rare, particularly the regular crystallizations of it. It occurs in veins with calcarceous spar and sulphate of barytes, and is accompanied by galena and native silver. The foliated structure of antimonial silver distinguishes it from white cobalt-ore, which has a granular structure; it differs also from arseneous pyrites, both by its structure and softness; the latter is extremely hard. Antimonial silver yields to the knife.

Arsenical silver-ore is harder than the former species; its structure...
Structure is less perfectly lamellar, the fracture more even, and the lustre weaker. It occurs in tabular, foliated, and kid-cray-shaped masses; before the blowpipe it yields the smell of garlic, peculiar to arsenic; a globule of silver more or less pure remains. The constituent parts of the ore are given by Klaproth as under:

Silber
Arsenic
Iron
Antimony

Arsenical silver-ore usually occurs with native arsenic; dark red silver-ore, brittle silver-plates, lead-glass, and brown blende, in calcareous spar. It is a native mineral.

Covellite silver-ore, or H GMOx: Argent muricatus. This mineral is distinguished by its transparency; it has a waxy or glistering lustre, is soft and tenacious, and yields to the nail. From these characters it is supposed to bear some resemblance to horn, whence its name. The most common colours of this mineral are pearl-grey, pulled to greenish or reddish-blue or brown; it acquires a brownish tarnish. Horn-silver occurs crystallized in small cubes, and is sometimes, though rarely, septarian and capillary; it is more commonly in laminae or small plates, or forms a coating on native silver. It is fusible in the flame of a candle. Under the blowpipe, on charcoal, it yields a globule of silver, and gives out a disagreeable odour, from the escape of the muriatic acid. Its specific gravity is from 4.25 to 4.50. Horn silver-ore is accompanied with native silver, black silver-ore, brown oxal of iron, quartz, and sulphate of barytes. It is supposed by some mineralogists to be the most recent formation of silver-ore. It occurs in veins in the silver-mines of Europe and America, and in Siberia, and is observed generally to occupy the upper part of the vein. According to Klaproth, it consists of 68 parts silver, 21 muriatic acid, a small quantity of sulphuric acid, with a portion of iron and earthy substanbes; but the latter may be considered as accidental. Horn-silver is rather a scarce mineral.

Vitreous silver-ore; Silver-glance, or sulphurated silver; Glaser, Werner; Argent sulphureux, Hauy. Its colour is a dark lead-grey; it is malleable, and may be cut with a knife; the surface, when cut, is shining, and has a metallic lustre; in its natural state it has often an indescent tarnish. It occurs in a variety of forms, in branches, fibres, small irregular masses, and laminae, and is also frequently crystallized; the crystals are commonly the cube or octahedron, and the dodecahedron, with rhomboidal faces; the fracture is flatly conchoidal. The specific gravity of this ore is from 7.0 to 7.5; its constituent parts are from 73 to 85 silver, and from 15 to 35 of sulphur. When raised to a red heat, the sulphur is gradually sublimed, and the silver appears in filaments, dendritic or reticulated. Many mineralogists suppose that capillary native silver owes its formation to the alteration of a similar kind of decomposition of vitreous silver-ore. This mineral occurs in veins, and is always accompanied with other ores of silver, and with galena, iron pyrites, brown blende, sulphate of barytes, calcareous spar, and quartz. It is found in almost all silver-mines in various parts of the globe.

Brittle vitreous silver-ore; Skened glasser, Werner; Argent noir, Hauy; differs from the former by its brittle, dense, splendour, and colour. The colour is intermediate between iron-black and dark lead-grey; it is brightly splendent externally; internally it alternates from shining to glistering; the lustre is metallic. It occurs massive and disseminated, and in thin small plates, and frequently crystallized in flat, prismatic forms, variously terminated, and in rectangular four.

Blind sulphurated silver-ore; Silver flavissimus, Werner; differs from vitreous silver-ore by its want of lustre: it occurs malleable, corroded, and in powdered form; the fracture of the former is uneven; the streak shining and metallic. It yields to the knife, and is fusible into a flag, containing globules of silver.

Red-silver-ore, or Ruby silver; Rothglaser, Werner; Argent rouge, and Argent amoniacus sulphureux, Fr. The colours of this mineral are various shades of red, passing from a bright-red to dark-red, and reddish-grey or black. When scraped, the powder is of a crimson colour. The crystallized varieties are translucent, or semi-transparent, and the transmitted light is a carmine, light blood, or coconulred-red. It occurs massive, disseminated, and in thin plates, and crystallized in hexagonal prisms, variously terminated, and in dodecahedrons, with triangular faces, nearly similar to the crystallization of calcareous spar, called dog-tooth spar. The primitive form of the crystal, according to Hauy, is an obtuse rhomboid, whose plane angles are 104° 28' and 73° 22', and the inclination of the faces 109° 28' and 70° 32'. The fracture is usually uneven, and imperfectly conchoidal; its lustre externally is shining, and metallic, internally glimmering, sometimes metallic. It is brittle, soft, yielding easily to the knife. Before the blowpipe it gives out a copious smoke, with an arsemetrical smell, and leaves a globule of silver. Its specific gravity is about 5.6. There are several minerals which have a red colour, and may at first sight be confounded with red silver, as the sulphur of arsenic, or realgar; but this mineral becomes yellow when powdered. Cinna bar has a greater resemblance, but the specific gravity is 7, and it is entirely volatile by the blowpipe. Red oxal of copper has a specific gravity of 3.9, and is usually accompanied with native copper, malachite, and brown iron oxiure; it also effervescs with nitric acid, and communicates to a solution of ammonia a blue colour. By these characters it may be known from red silver-ore. Werner has divided red silver-ore into two sub-species, the light and the dark. Klaproth analyzed this mineral, and found it to contain only silver, sulphur, antimony, and oxygen. Prout has shown that there are two kinds of red silver-ore, the one containing arsenic, and the other antimony. The constituent parts, as given by Klaproth and Vasquez, are
According to the analysis of Pronf, a variety of this ore contained nearly .75 parts of metallic silver, and .25 of metallic arsenic. Red silver-ore occurs in veins, but is always intermixed with other minerals, particularly with compact galena, cobalt, sulphur of arsenic, native arsenic, grey copper-ore, and sparry iron-ore; and has a matrix of calcareous spar, sulphate of barytes, fluor spar, or quartz. It is a common ore in silver-mines, both in Europe and America; the dark-red ore is considerably more productive than the light-red.

Silver amalgam consists of pure silver combined with mercury.

It has been found in the silver-mine of Salberg, in the province of Dalecarlia, in Sweden, in the mines of Duex-Ponts, in the Palatinate, and in some other places, either in thin plates or grains, or crystallized into octahedrons and dodecahedrons. It is sometimes semi-fluid. Its colour is silvery-white or grey, the fracture conchoidal, and the lustre metallic. It is soft, breaks when cut, and whitens the surface of gold or of copper; when rubbed upon them warm before the blowpipe the mercury evaporates, and leaves the silver pure. The constituent parts, given by Klaproth, are:

White silver-ore has a near resemblance to compact galena. The colour is a light lead-grey, passing to steel-grey: it occurs massive and disseminated, and is generally intermixed with cubic galena. The fracture is most commonly even, but sometimes fine-grained and uneven, and also fibrous; the internal lustre is silvery and metallic, the fracture fibrous. It is soft and brittle. The specific gravity is 5.2.

Some mineralogists think this ore should be classed with the argentiferous ores of lead. According to Klaproth, different specimens from Hemmels Furlt, near Freyberg, contain, of the Dark-white silver-ore. Light-white silver-ore.

Carbonate of Silver.—This ore has hitherto been only discovered in the silver-mine of Wincellaus, in Swabia: it occurs sometimes in maffes, and sometimes disseminated through other minerals. Its colour is a greyish-black; its fracture uneven, with a silvery metallic lustre; it is brittle and heavy, and effervesces with acids; it melts easily under the blowpipe. According to Mr. Selb, who first described this mineral, it contains

It contains also a slight trace of copper.

Besides the above ores of silver, there are ores of other metals which contain a portion of silver, and have been classed by some mineralogists with silver-ores. An argentiferous variety of grey copper-ore, of an iron-black or steel-grey colour, has received the name of black silver-ore. It occurs massive, disseminated and crystallized in tetrahedrons; the fracture is small conchoidal, with a shining metallic lustre; it is brittle and brittle. An ore which is a combination of lead, bismuth, and silver, has received the name of bismuthic silver. Its colour is a light lead-grey: it occurs disseminated, but rarely ever in maffes; the fracture is fine-grained, uneven, with a silvery metallic lustre; it is soft and rather brittle; before the blowpipe metallic globules appear on the addition of borax, which unite; the button is brittle, and of a tin-white colour: the flux acquires an amber colour. According to Klaproth this ore contains:

Argentiferous lead-ores are common in Great Britain and in various parts of Europe. Many of these ores are not sufficiently rich to repay the expense of extracting the silver. It is procured in considerable quantities in North Wales, the north-west parts of Yorkshire, and in the counties of Durham and Northumberland. Indeed, many lead-ores in these counties contain a much larger portion of silver than the average proportion of that metal in the ores of Mexico and Peru; but mineralogists do not class them with silver-ores.

Silver Mines in Great Britain.—Silver-ores, properly so called, are of rare occurrence in our island. A few years since, a vein of silver was worked with great profit in the parish of Alva, in the county of Stirling, in Scotland. The ores were native silver, and vitreous silver-ore. From forty to fifty thousand pounds sterling value was extracted before the ore was exhausted, after which the search to recover the vein proved fruitless, and since that time no silver-mines have been worked in that country. The silver-ores at Alva were accompanied with copper, lead, and cobalt-ores, with a matrix of calcareous spar, and sulphate of barytes. It is supposed by Dr. Miller that the veins traverse rocks of argillaceous porphyry.

Cornwall and Devonshire yield the richest argentiferous lead-ores of any part of Great Britain; but the quantity of these ores is small. In the former county a small quantity of native silver, with other silver-ores, have been occasionally found. We have been favoured with the following account of the present state of the silver-mines in these counties from Mr. Mawe, author of Travels in Brazil, who visited them in the summer of 1815.

From the lead-mines of Ben-Alten, in Devonshire, a large quantity of silver has been extracted. The vein is situated in killas, (see Slate,) and is filled chiefly with fluor spar and galena. It has been worked to the depth of 110 fathoms: the silver extracted from the north and south vein averages about 70 ounces to the ton of lead. Another vein, running in a more easterly and westerly direction, situated in the same killas, produces 170 ounces of silver in the ton of lead. The vein is worked under the river Tamar. These mines are of considerable importance; during the last five weeks, the silver extracted from the lead procured here exceeded fix thousand ounces. The works are extensive, and fail to be well conducted.

About four miles to the south-east of Callington is a silver-mine of another description: the vein is situated in a similar rock of killas or chlorite slate. The vein was first worked for copper, but native silver and lead-ore were discovered in it. The mine is called Huel Jewel: the thickness of the vein rarely exceeds three or four inches. In many of the cavities were found a considerable quantity of capillary native silver, with galena, red silver-ore, and sulphuret of silver.
SILVER.

The ores were exceedingly rich, and provided at the time an ample subsistence to the adventurers. The Husband copper mine, near Redruth, has produced a considerable quantity of native silver in a small vein, branching from the principal one. Some of the filers of silver were more than four inches long.

There is a lead-mine near Tavistock worked at the time, and a considerable quantity of silver is extracted from the lead, as it yields two ounces per ton.

Near Porriahsada, on the north coast of Cornwall, there was a mine formerly worked close to the sea, which produced lead-ores in various sizes, and a portion of born-silver, in specimens of which are in various cabinets. Mr. Mawe found some specimens of this rare mineral among the refuse of the mine.

At Comb-Marin, in North Devon, are some lead-mines, which were formerly celebrated for the silver, but at present they are not productive.

Argentiferous lead-ores are the common lead-ores of the northern counties and of Wales; they vary in the quantity of silver they contain, from a few ounces to 45, 60, or 80 ounces of silver per ton. Some few rare inclusions have occurred in the north-west part of Yorkshire, of their exceeding the latter amount. On the average, the argentiferous lead that is calcined to extract the silver does not contain 20 ounces per ton: by some it has been stated at 17 ounces.

According to Lehman, there are no known lead-ores in the world but what contain silver, except that of Villoch, in Carinthia. (Lehman fur les Mines.) But according to Dr. Watson, the quantity of silver necessary to defray the expense of extracting, and the loss of lead, was nine ounces per ton, when lead was at the price of 15fl. per ton. The price of lead is now 26fl. per ton, and though silver be also advanced, yet the difference in the relative prices of each, taking the above as a standard, is such, that to repay the expense of extraction, the lead should contain about fifteen ounces of silver in every ton.

It is not to be expected that the proprietor of any lead-mines rich in silver should be forward in declaring to the world the quantity of silver they contain. The proprietor of the lead-mine containing silver may indeed work the same without any apprehension of its being taken from him under the pretence of its being a royal mine; yet the crown, and persons claiming under it, have the right of pre-emption of all the ore which may be raised. There was an act of parliament passed in the sixth year of William and Mary, entitled, An act to prevent disputes and controversies concerning royal mines. This act declared, that every proprietor of a mine of copper, tin, iron, or lead, shall continue in possession of the same, and claims and persons claiming under it, should have the privilege of purchasing all the ore which may be raised out of such mine, at the following prices, when made clean and merchantable: for copper-ore, at the rate of 16fl. per ton ; for tin-ore, except that of Devonshire and Cornwall, 40fl. ; for iron-ore, 40fl. ; and for lead-ore, 9fl. The standard price then fixed, particularly for lead, was much higher than the ordinary price of the ore in which there was no silver. Owing to the existence of this act, it is probable that we are not acquainted with the quantity of silver at present extracted annually. We are informed, that the value of silver produced by the lead-mines of Colonel Beaumont, in Northumberland and Durham, is not less than 4000l. sterling per annum; and other large proprietors also extract a considerable quantity of silver from the lead-ores in the northern counties. At present we believe that there is no silver extracted from the Devonshire lead.

It appears from Hollinshed's Chronology, that silver was formerly extracted from lead in various parts of the land. In the reign of Edward I. it was made a practice of weight of silver was obtained in the course of three years, from a mine in Devonshire, which had been discovered towards the end of his reign: this mine is called a silver-mouth by the Welsh, but it appears to have been a mine of lead that contained silver. The lead-mines in Cardiganshire have at different periods afforded great quantity of silver: in Hugh Maddocks, it had to have ceased from the two lead mines, per month, and to have been enabled thereby to undertake the great work of bringing the New River from Ware to London. The same mine yielded, in the time of Charles I. eighty ounces of silver in every ton of lead, and part of the king's army was paid with this silver, which was melted at Shrewsbury. Sir J. Pettig's Essay on Metal Works.

A mint for the coining of Welsh silver had been previously established at Aberystwyth; the machinery was granted to Thomas Butcher, for the coining of half-crowns, florins, halfpence, twopence, and pence, and the mints were to be ramped with the oak-leaves on both sides. In 1664 nearly 3000 ounces of this Welsh bullion were melted at one time at the Tower. The Welsh Bullion in his History of Metals, published in 1671, makes mention, from his own knowledge, of two places in Craven, in the West Riding of Yorkshire, where formerly good argentiferous lead-ores had been procured. One of the places was Broughtme near the parish of Slaidburn; the ore held about the value of 67 pounds of silver in a ton; the other was at Skelhurton, near the parish of Gipbston; it had formerly belonged to a person of the name of Pudsey, who is supposed to have coined it, as there were many bullions in that country which the common people called Pudsey bullions. There are several smelting-houses at Holywell, in Flintshire, where silver is extracted from lead. According to Mr. Pennant, at one of the largest of these houses in the year 1754, more than 12,000 ounces of silver were produced, but in the subsequent years the quantity of silver appears to have considerably diminished. The silver extracted from lead is sold principally to the manufacturers at Sheffield and Birmingham.

The silver is extracted from the lead by the oxidation of the latter metal in a reverberatory furnace of a particular construction, for the admission of air on the surface of the lead in a state of fusion. A shallow vessel or cupel is filled with prepared fern-ashes rammed down, and a concave cut out for the reception of the lead, with an opening on one side for the mouth of the bellows, through which the air is forcibly drawn during the process. The French smelters cover the surface of the fumes with hay, and arrange symmetrically the pieces of lead upon it. When the fire is lighted, and the lead is in a state of fusion from the reverberation of the flame, the blad from the bellows is made to play forcibly on the surface, and in a short time a crust of yellow oxide of lead, or litharge, is formed, and driven to the side of the cupel opposite to the mouth of the bellows, where a shallow side or aperture is made for it to pass over; another crust of litharge is formed and driven off, and this is repeated in succession till nearly all the lead has been converted into litharge and driven off. The operation continues about forty hours, when the complete separation of the lead is indicated by a brilliant lava on the convex surface of the melted mass in the cupel, which is occasioned by the removal of the last crust of litharge that covered the silver. The French introduce water through a tube into the cupel, to cool the silver rapidly and prevent it from re-oxidising.
its spiritng out, which it does when the refrigeration is gradual, owing probably to its tendency to crystallize. In England the silver is left to cool in the cupel, and some inconvenience is caused by the spiritng, which might be avoided by the former mode.

The silver thus extracted is not sufficiently pure; it is again refined in a reverberatory furnace, being placed in a cupel lined with bone-ashes and exposed to a greater heat; the lead which had escaped oxidation by the first process is converted into litharge, and absorbed by the ashes of the cupel.

The last portions of litharge in the first process are again refined for silver, of which it contains a part that was driven off with it. The litharge is converted into lead again, by heating it with charcoal; part is sometimes fold for a pigment, or converted into red lead. The lofs of lead by this process differs considerably, according to the quality of the lead. The litharge commonly obtained from three tons of lead amounts to 98 hundred weight; but when it is again reduced to a metallic flte it seldom contains more than 52 hundred weight of lead, the lofs on three tons being about eight hundred weight. The Dutch are paid to extract the silver from the same quantity of lead, with a lofs of only fix hundred weight.

Silver-Mines of France—The mine of Allemont, ten leagues from Grenoble, in the department of Iere, is situated near the summit of a mountain, composed of thin beds of mica-flute and hornblende, curiously contorted and broken. Its elevation is about 3000 yards above the level of the sea. The veins are numerous, and run in all directions; the mineral appears to have filled also numerous fissures in the rock. The ores are native silver, vitreous silver, red silver-ore, and horn-silver. Silver appears also disseminated in a kind of ferruginous clay, and is accompanied with various ores of cobalt, antimony, arsenic, and nickel. The matrix was ferruginous clay and carbonate of lime, mixed with albite, epidote, and calcium fpar. The veins were much richer near the surface than at a great depth, and the working of this remarkable mine is at present nearly abandoned. Red silver-ore has also been found in the Voges, in the department of the Upper Rhine, in a vein of argentiferous copper-ore. Indications of silver have been traced in other districts of France. The lead-ores of some parts of France are also sufficiently rich in silver to repay the expense of extraction.

The silver-mines of Spain are the most ancient known in Europe. It appears, as well from the accounts of hisitors, as from the numerous veitles of ancient workings, that the operations were carried on to a considerable extent. The most remarkable mine was that at Guadalahar, in Andalusia, in the Sierra Morena, five leagues to the north of Seville; the ore which it contains is the red or ruby silver, in a matrix of compact galena. Since the discovery of South America no attention has been paid to the mines of Spain, though formerly fo productive both of silver and gold.

Germany.—The mining district of Freyberg, in Saxony, contains numerous veins that yield silver. The veins that traverse rocks of gneifs are generally composed of quartz, calcareous fpar, and fluor fpar; they inclose argentiferous lead, vitreous silver-ores, ruby silver, and grey argentiferous copper-ore. The mine at Annaberg, according to Klaproth, contains muriate of silver (horn-ore) mixed with much clay, which is imbedded in compact lime-flute. The mines of Schneeberg, in Mifnia, and of Hartz, in Hanover, contain argentiferous lead, accompanied with proper silver-ores.

Hungary.—The mines of Scheimitz and Creimitz, in Hungary, have been long celebrated, both for the richnes of their productions and the immense extent of the opera-

tions. The rocks in which the mining operations are carried on, are described as being composed of an argillaceous grey-flute, mixed with quartz or fclorite, or particles of calcareous fpar. To this rock baron Born has given the name of the metalliciferous rock, saxum metallicum: it is described by him as containing three principal veins, running from north to south, and parallel with the river Gran, following even the windings of the river. From this circumstance we should infer, that the river itself had originally taken the course of a fracture by another vein. The dip or inclination of all the veins is from west to east, varying from 30 to 70 degrees. In one part of the vein, called the spiritae vein, it is joined with an argentaceous white vein, which runs along with it on the hanging fide, and from the place of junction the vein is found to contain silver. In this white clay are occasionally found nodules of fpar and marlles of quartz, which yield from four to five ounces of silver in the hundred weight. The second great vein at Scheimitz has nearly the same characters as the first. The third great vein is more irregular in its inclination, and the ores are not so rich in silver, but in some parts it contains a considerable quantity of gold.

Some notion may be formed of the extent of the mining operations at Scheimitz, from the gallery or level called the Emperor Francis' Gallery, by which the whole of the royal mine is drained and cleared of water. This gallery, which forms a very considerable excavation, and is carried through hard rock, was a work of immense labour and difficulty; it is five English miles in length: it was begun in 1748, and finished in 1765.

The mountains round Kremnitz, according to baron Born, are composed of the same metallic rock already described; but according to Patrin, they consist of primitive trap. At this place very extensive operations, which were begun at least a thousand years ago, have been established on a large and rich gold vein, and some of its branches. The rock is a white folid quartz, mixed with fine auriferous red and white silver-ore, and with auriferous pyrites. At the depth of 160 fathoms, the vein continued rich and productive.

Konigberg is another mining-town of Hungary, some miles to the north-west of Scheimitz. The valley in which this place is situated is bounded on one fide by the same kind of metallic rock, and on the other, towards the north, by granite mountains. In the royal mine, at the time it was visited by baron Born, the vein was observed to run between the metallic rock, which formed its hanging fide, and the granite, which was its bedding or lower fide. The vein is grey quartz, mixed with auriferous pyrites. The first tram or fire-engine established in the Lower Hungarian mines was erected at Konigberg, in 1725, by Isaac Porter, an English engineer, who was then in the imperial service.

Bohemia.—The circle of Sattz, in Bohemia, abounds in various metallic ores, among which the ores of silver occasionally predominate. The prevailing rocks are gneifs and argillaceous schifils. The veins at Catharinesberg traverse gneifs, and generally run in a north and south direction, and parallel to the mountain in which they are situated. But there are also some powerful veins which cross the mountain. One of this nature is described, which seems to be infenibly blended with the mountain rock. The vein-flute is also of the same kind of rock, but occasionally assuming the characters of a variety of granite. It is observed, that the vein, which seldom exceeds a foot in width, diminishes in thickness when the containing rocks become harder; and when the fides are found incrusted with a ferruginous clay, it appears to be richer in ores. Fillures from the fides of the vein are found to improve it: a fine white clay, with quartz
SILVER.

quartz embedded in it, indicates rich ore; but a coarse clay, detritus of quartz, especially when it increases in quantity, and occupies the whole vein, renders it unproductive, or entirely barren. The ore of the vein now described is rich silver and copper pyrites, with flour spar, blende, various copper-ores, and sometimes native silver and copper.

Janberry, a place in the same circle, has been long celebrated on account of its valuable mines. The prevailing rocks are described as grey micaceous and quartzose clay-flate, which at a great depth become mixed of an argillaceous nature, soft, fibrous, and of a black colour. The mountains around this place have a gentle declivity towards the louth, but run in lathy ridges to the east, north, and west, and are intersected by deep valleys. This inequality of surface affords great accommodation to the miners to open numerous galleries, which converge to the south, and to the valley in which stands the town of Janashbul. All the galleries and works of this district are divided into six different fields, belonging to the same number of companies, and they are drained by two deep drifts or levels; the one of which runs in a direct line 1000 fathoms; but including its several branches, its whole length is 4500 fathoms. The depth under the highest top of the mountain is 170 fathoms; the second great level, which runs through the space of 5000 fathoms, and in a direct line 1500 fathoms, is 20 fathoms deeper than the first; but the operations in the mines have been carried to a much greater depth; for at the time in which they were visited by Ferber, before 1774, the perpendicular depth under the surface was from 200 to 300 fathoms, and, excepting the mines in the Tyrol, were then considered as the deepest in the world.

The thickness of the veins varies from one inch to two feet; and the vein-fores are a whitish or bluish clay, argillaceous slate, and red horn-flake, or petro-filer, which is the matrix of the richest ores. The silver-ores which are found in this mining district are, native silver, which is attached to different vein-fores, and assumes various forms; vitreous silver-ore, which is dug out sometimes in very large masses, and is considered as a very rich ore; one hundred weight being commonly valued at 180 marks of silver; red silver-ore, sometimes beautifully crystallized and transparent, is attached to red horn-flake or calcarious spar; and white silver-ore has sometimes but rarely appealed.

The silver-mines of Bingen, in the circle of Erfurt, are in hills of a gentle declivity, and composed of grey or bluish clay-flake, in which appear figures of greenish lithomarge, or semi-indurated pot-flake. These mines were formerly rich in native silver, and other ores of that metal. A vein to the west of this place, which traversed a hard rock, contained redish-coloured felter, with galena, blende, and a little silver; but from the part where a vein containing white ar-tenacal pyrites came into the hanging-side, the vein produced native silver, vitreous, red, and white silver-ore. Another vein in the same place, which is from two inches to one foot in width, is observed to be richest where it is thinner. It is chiefly enriched by an undulating black clay mixture, which appears sometimes in the hanging side, and then it produces red and white silver-ore. When raised by veins running from east to west, it appears to be cut off and barren, till beyond the place of junction it again becomes productive in its former course.

Sweden.—The silver-mines of Salberg, in Weitmaraa, are about 28 English miles from Upfal. The ore is an argen-titerous galena, yielding from one ton to one and a half of silver per quintal; it is in compact litem-flake, and has been worked to the depth of 150 fathoms. The average profits an unit to about 4000, and one-quarter is paid to the king.

Porter's Travels.

Norway.—The silver-mine of Koppaflen, in Norway, is situated in mountains of moderate height, composed of nearly vertical beds of mica-slate with garnets, and of grey quartz mixed with fine black mica, and a little flour spar and red horn-flake. Other beds are composed of a ferruginous rock, which, in the upper part of the mine, is 33 feet thick, but in the lower not more than 6 feet thick.

The veins are from half an inch to two feet or more in thickness, and cut the strata transversely. The matrix of the ore is granular mica-slate, sometimes intermixed with flour spar. Extensive masses of native silver have sometimes been found in this mine; one is mentioned as weighing 22 lbs. The common ores are native silver and vitreous silver. The veins are most productive in the ferruginous rock. The annual produce is about 4000 lbs., weight of silver.

Africa.—The silver-mines of Ziineet are situated in that part of the Altana chain of mountains which lies between the Oby and Irntich, from 50 to 52° north latitude. The annual produce has been stated at 62,000 marks of silver, which is allowed with about 1.3 per cent. of gold. The mines of Nettishim in Darania, near the river Amur, yield argentiferous garnets, producing about 25,000 marks of silver, and containing about 0.4 per cent. of gold. The Russian merchants who trade to China bring back ingots of silver, from several ounces to a pound weight, in exchange for their commodities; hence it may be inferred, says Patron, that there are silver-mines on the frontiers of China. Patron, Hist. des Mines.

America.—The most productive silver-mines in the world are those of South America and New Spain. The silver of Peru, for many years after its conquest by the Spazines, yielded the greatest quantity of silver, but at present the mines of Mexico are the richest. The mines of America furnish both silver and gold; and in making an estimate of their riches, we must take an account of each of these metals. The following table, given by M. Humboldt, will show the distribution of their mineral treasures in the different parts of the new world; the kilogramme being 2 lbs. 3 oz. 5 dr. avoirdupois, or rather more than 2 lbs. 8 oz. troy.

The above was the annual produce of the different districts, at the beginning of the 19th century; from which it appears, that the total weight of the precious metals from all the mines in America, reduced to English pounds troy, is 45,580 lbs. of gold, and the enormous quantity of 145,000 lbs. of silver; equal in weight to one-third of the tin produced by the mines in Europe. Dr. Adam Smith, in his "Wealth of Nations" values the gold and silver annually exported into Cadiz and Lisbon at only six millions troy, including not only the registered gold and silver, but that which may be supposed to be smuggled. This estimate is only two-fifths of the real annual amount.

The mountain of Potosi has for a while, since its discovery in 1545, a mine of silver equal in value to 1,346,000,000.

Welling.
SILVER.

The mountain is 18 miles in circumference; it is composed of flate, but has a conical covering of porphyry, which gives it the form of a fugar-loaf, or basaltic hill; it rises 697 toises, or 480 yards, above the surrounding plain. The richness of the veins has diminished, as they have been worked to greater depths. At the surface of the earth, the veins of Rica, Centeno, and Mendiceta, which traverse primitive flatc, were filled with native silver, and silver-ores throughout their whole extent. These metallic mafles rife in ridges or crests above the surface, the fides of the vein having been destroyed either by water or by fome other caufe. In 1545, minerals containing from 80 to 90 marces of fler per quintal were common. In the year 1574, according to Acosta, the average richness of the ore was eight or nine marces per quintal. In 1667, the mean wealth of the ores was not more than an ounce and a half to the quintal. The ores are now extremely poor, and it is on account of their abundance alone that the works are filling in a flourifhing flatc; for from 1574 to the year 1759, the mean quantity of fler in the ores has diminished in the proffion of 170 to 1; while the absolute quantity of fler extrated from the mines of Potosi has only diminished in the proportion of 4 to 1.

About fix miles from Pafo is the mountain Jauvichora: it is diftinguifheda by the name of the Silver mountain. It is about half a mile in diameter, and only about 30 yards in depth: it is composed of brown iron-flone, which is interlaced with pure silver. This flone does not yield more than nine marces of fler in 500 lbs.; but there is a friable white clay met with in the middle of this mafs of ore, which yields from 200 to 1000 marces of fler in every 50 cwt. The mountain is penetraded in all directions, without any attention to fecurity; fo that it is expected it may fall in, in the course of a few years. According to Helms, this mountain yields annually 200,000 marces of fler.

The veins of fler of Potosi are in flatc, which Humboldt confiders as primitive: this flatc is covered with a clay porphyry, containing garnets. The mines of Gualgayoc, in Peru, are in the Alpine lime-flone. The veins which furnith nearly all the fler exported from Vera Cruz are in flatc, porphyry, grauwacke, and Alpine lime-flone: the principal of thefe veins are thoie of Guanaxto, Zacatecas, and Catoree. The vein of Guanaxto yields more than one-fourth of the fler of Mexico, and a fixth part of the total produce of America. This vein is, in fome parts, from 147 to 150 feet in width, including the branches, and has been wrought from Santa Hafella and San Bruno to Buena-Vella, a length of 42,000 feet. The most celebrated mines in Mexico are elevated from 6000 to 9000 feet above the level of the fea. In the Andes, the mines of Potosi, Ocuro, Pas, Pafo, and Gualgayoc, are in regions higher than the loftite fummits of the Pyrenees. A mafs of rich fler-ore has been discovered near the small town of Micucampa, at the absolute height of 13,450 feet. The great elevation of the Mexican mines is pecuiliar advantageous to the working of them, as the climate is temperate, and favourable to vegetation and cultivation.

The part of the Mexican mountains which at prefent contains the greatest quantity of fler, lies between the twenty-fifth and twenty-fourth degrees of latitude; and it is not a little remarkable, that the metallic wealth of Peru should be placed at an almost equal latitude, on the othere fide of the equator. In the vall eft extent which separatesthe mines of La Pas and Potosi from thoie of Mexico, there are no others which throw into circulation a great mafs of the precious metals, but thoie of Pafo and Chota. The smallness of Panama and the mountains of Guatemala contain, for a length of 600 leagues, vaft tracts of ground, in which no vein has hitherto been worked with successe.

The province of Quito, and the easter part of the kingdom of New Granada, from the eighth degree of south latitude to the seventh degree of north, are equally poor in metallic wealth. It would not, however, fays Humboldt, be correct to infer that thefe countries, which have been convulsed and torn by volcanoes, are delitute of the precious metals. Numerous metallic repositories may be concealed by beds of basalt, and other rocks of fuppofed volcanic origin. It should, however, be remarked, that none of the fomes, which Humboldt enumerates as very maffiverous, are by other geologists considered of volcanic origin, particularly flink-flone-porphyry, and other porphyries containing hornblende, but diftinguished by the abfence of quartz and common felpar.

The mines of Huantaaya are celebrated for the great quantities of native fler they formerly produced. They are situated in an arid defert, and furrounded by rock-falls, near the fhores of the Pacific ocean, at no great diftance from the small port of Yquique, in the audence of Lima. Thofe mines are a remarkable exception to the great elevation of fler-mines in Spanifeh America, being placed on a low and gentle declivity. Their produce is native fler, vitreous fler, and horn fler; the annual amount is about 50,000 lbs. troy of fler, or 80,000 marces.

The fler-mining operations of Chili, according to Humboldt, are in general not productive; but the vein at Ufpalata contains paos so rich, that the produce is from 2000 to 3000 marks in every 5000 lbs., or from 40 to 60 marces per quintal. Molina, in his History of Chili, defcribes the vein at Ufpalata, on the Andes, as being nine feet in thicknes. It has been traced 90 miles, and is fuppofed to extend 300 miles. From the main vein there are branches on each fide, which extend to the neighbouring mountains; fome of thefe branches are 30 miles in length. This is the largest metallic vein which is at prefent known in the world.

According to Humboldt, the greateft part of the fler extrated from the bowels of the earth in Peru is furnifhed by a fpecies of ore called the paos, of an earthly appearance, which M. Klapproth analyzed, and was found to confifd of almost imperceptible particles of native fler with the brown fide of iron. In Mexico, on the contrary, the greateft quantity of fler annually brought into circulation is derived from vitreous fler-ore, grey fler-ore, horn-ore, and black and red fler-ores. Native fler is not extrated in fufficient quantity to form any confiderable proportion of the total produce of the mines of New Spain. It is, fays this traveller, a very common prejudice in Europe, that great mafles of native fler are very common in the mines of Mexico and Peru, and that in general the mines of mineralized fler, defigned to amalgamation, or to fmelting, contain more oounces, or marces of fler, to the quintal, than the fler-ores of Saxony or Hungary; but he adds, I was furprifed to find that the number of poor mines greatly exceeds thoie of the mines which, in Europe, would be esteemed rich. It is at firft difficult to conceive how the famous mine of Valenciana, in Mexico, can regularly supply 30,000 marces of fler per month, as the vein confifds of fulphured fler, difteminated in almost imperceptible particles through the matrix. In the formation of thefe veins, it should appear that the distribution of fler has been very unequal, being fometimes concentrated at one point, and at other times dilutened in the vein through the matrix or gangue; for, in the midft of the poorest ores are
are found considerable masses of native silver. Although the new continent has not hitherto produced large masses of native silver equal to what have been found in the old, the metal is more abundant in a state of perfect purity in Mexico and Peru than in any other quarter of the globe, not as masses, but in particles disseminated through the enormous quantity of the ore called porphyry. The result of a general investigation of the riches of silver ore is, that the mass of it in the latter is not more than from three to four ounces of silver in every sixteen hundred pounds of ore. According to this result, the ore contains, on the average, two ounces and two-thirds per quintal. It had formerly been asserted, that the ores were worked in Mexico that did not contain one-third part of silver. The miners of Peru are not richer on the average than those of Mexico. The district of Guanaxto has been, before mentioned, as furnishing more than one-third of the silver annually extracted in America; the riches of the mines here being superior to the celebrated repartimiento of Potosí: they are all worked in one extensive vein. Among these mines, that of the count Valenciana is one of the richest: the average produce of silver is four ounces of silver from a quintal of ore.

The whole weight of silver from the vein of Guanaxto, on an average of 1786 to 1788, is 556,900 mares or 364,911 lbs. troy; and in thirty-eight years the weight of gold and silver, from the same vein, has been 127,000,000 pounds troy. In average years it yields from 500,000 to 600,000 mares of silver, and from 1500 to 1600 mares of gold. It has been doubted by some persons whether this be really a vein, or a metallic bed, as in parts of it the ore is parallel between the beds, or strata of the rock. It pales through both flat and porphyry, and is metalliferous in both. Though it has been before stated that the extent of this vein is more than 42,000 feet; yet the enormous mass of silver which it has supplied for the last hundred years, sufficient alone to change the price of commodities in Europe, has been extracted from an extent of less than 2000 feet; for where this vein is not widened by branches, its general width may be estimated at 38 to 48 feet. It is for the most part separated into three masses, divided by banks of mineral matter, or by part of the matrix delineate of ore.

At Valenciana the vein continues undivided to the depth of 557 feet, and then divides into three branches; and its width, from the floor to the roof, is from 16 to 106 feet. Of these three branches of the vein, there is in general only one which is rich in metals. Sometimes, when these three branches unite, the mine is uncommonly rich. In this celebrated vein there is a certain middle region, which may be considered as a repartimiento of greater riches, for above and below this region the ores are poor in silver.

At Valenciana the rich minerals have been in the greatest abundance, 300 and 1100 feet below the mouth of the gallery.

The labour of the miner is entirely free throughout the whole kingdom of Spain, and no Indian or Míscar can be fined to work in the mines. The Mexican miner gains from 17 to 18 d. per week of six days. The men employed in agriculture do not gain more than a third of that sum. The miners work nearly naked, and are searched in the most inadunate manner on leaving the mine. They frequently conceal fragments of native silver and silver-ores in their hair, under their arm-pits, in their mouth, and even in the anus, into which they force cylinders of clay containing the metal. These cylinders are called hare. A registrar is kept of the silver found in different parts of the body. In the mine of Valenciana, it was found that eleven men, at a great part of the time in the mine, from the year 1774 to 1788, had concealed 281,000 pounds troy of silver, named of the same silver, by amalgamation with mercury, and by the quantity of silver extracted by mercury, gold, and copper, occasioned by the amalgamation of mercury in the mines of that name, the quantity of silver varied by some persons, but it was generally being very uncertainly.

The Mexican mines then appear to follow any fixed principle in the labour of the miners devoted to the amal-}

The payment of the workmen is almost uniformly the same that they built the mines, which is another they had only be carried with mercury; and it is frequency this danger in fear of mercury which determines the miner in the choice of his method. In general they excite the large silver as galena, and the mixed minerals of chalcocite and vitriol copper.

The panes the vitreous, red, and cinnabar silver-ores, the grey copper-ore rich in silver, and the mica ore, differentiated in small quantities, in the mines, they find it more profitable to amalgamate.

All the metallic wealth of the Spanish colonies is in the hands of individuals. The government produces another mine than that of Huaca Velosa in Peru, which has been long abandoned. The individual receives from the king a grant of a certain number of mines, as the director of a vein or bed; and they are only held to pay very moderate duties on the minerals extracted. These duties have been valued on the average throughout all Spanish America at 11 per cent. of the silver, and three per cent. for the gold. In the space of a hundred years, the annual produce of the Mexican mines has increased from twenty-five to one hundred and ten millions of francs. The produce of the mines in Peru has of late years been rather decreasing, which Humboldt attributes to its being worse governed than Mexico. The proceeds of extraction seems also to be conducted upon worse principles than in New Spain, though in neither of these districts is melting, or amalgamation, performed with such skill; or, according to M. Humboldt, the quantity of mercury annually consumed in New Spain exceeds two million one hundred thousand pounds troy. The mercury is separated from the amalgam by distillation; but in the whole proses, the Mexican's waste eight times more than would be necessary, were the proceeds conducted in the same manner as at Freyberg.

The following table will shew the annual produce of gold and silver in the mines of Europe, northern Asia, and America, as given by M. Humboldt, in killograsses. It may be regarded rather as an approximation to the real amount, than as a very accurate statement, the amount of English silver not being included; perhaps this may be estimated at 400 lbs. troy.

The killograss, it has been before stated, is rather more than 2 lbs. 8 oz. troy. It is impossible to value the quantity of gold and silver annually extracted on the whole globe; for we are separated from the amount of what is procured in the interior of Africa, and the central parts of Asia, Tonquin, China, and Japan. The quantity of gold and silver largely brought by the Dutch from the latter country proves that it is rich in the precious metals. We may draw the same conclusion respecting the northern frontiers of China and other parts of Asia, and the quantity of gold.
gold-dust brought to the western coast of Africa, leads us to believe, that the countries south of the Niger contain large quantities of this metal, though we have little information respecting the silver of the African continent.

Affay and Analysis of Silver-Ores.—Pure native silver requires no other alloy than fusion, with a little potash to free it from its earthy matter. In the humid way the silver may be dissolved in nitric acid, and precipitated by common salt. The precipitate may then be fused with soda in a crucible, by which the silver is obtained pure, and the muriate of soda sublimed. The auriferous silver-ores may be treated with potash, by fusion in a crucible: the alloy of silver and gold is first obtained, and the two metals may be separated by the process of parting. See Refining and Assaying.

Those ores which consist of silver combined with antimony or arsenic, or both, are first roasted, to drive off the arsenic and antimony, the silver remaining pure. The process is much facilitated by the use of nitre, for the purpose of oxidizing the metals to be dislocated.

The humid analysis of this ore requires more particular treatment.

The ore commonly called arsenical is first to be coarsely powdered, and then distilled vinegar poured upon it, to dissolve the lime of the calcareous spar adhering to it.

A given quantity of the ore so washed is now to be finely powdered, and nitric acid poured upon it: this oxidizes the metals, dissolving the greatest part, and leaving a yellowish residuum. To this part the dissolved muriate of soda is to be added, which precipitates the silver. This precipitate being washed and dried, will give 77 per cent. of pure silver. To the liquid from which the last was precipitated add a solution of potash; a light brown precipitate is now formed, which, on drying, becomes of a deep brown, and by ignition assumes the form of powder of a whitish-grey colour: this is the arseniate of iron. This substance contains iron and arsenic, in the proportions of 50 to 43 or 44. This is shown by treating the arseniate of iron with charcoal exposed to a red heat; the arsenic is reduced, and sublimed, while the black oxyz of iron remains.

The yellowish residuum left in the first solution is to be digested with muriatic acid: if a white powder remains undissolved, it will be found to be muriate of silver, and must be added to that first obtained. To the muriatic solution add a solution of carbonate of potash, and a yellowish-green precipitate is formed; to this precipitate, when washed and dried, add muriatic acid by a little at once, till the powder is dissolved; add a large quantity of water to this solution, which will produce a white precipitate; this being separated and dried will be pure oxyz of antimony, affording $\frac{3}{4}$ of pure antimony. What remains in solution, after the last sublimate is separated by the water, may be precipitated by pure potash, and will be found to be oxyz of iron; which, when treated with charcoal, like the first obtained, may be added to the fame to make the whole of the iron afforded by the mineral. In this way the arsenical silver-ore afforded, according to Klaproth, the following analysis:

The sulphuretted ores in the large way sometimes merely require to be roasted to drive off the sulphur; the heat being urged affords a button of pure silver. This is the case with the variety called Silver-glance.

The brittle silver-ore contains a very small portion of antimony and copper. The metallic button obtained by heat will require to be expelled with lead, in order to get the silver pure; it may, however, be made tolerably pure by treating the button with nitre, by which the base metals are separated.

To effect the humid analysis of brittle silver-ore, the powder is dissolved in dilute nitric acid with a gentle heat. By this treatment a residuum is left equal to $\frac{1}{16}$ of the whole. The solution is to be treated with muriate of soda, like the last.

If the presence of an alkaline sulphate does not form any precipitate with the remaining solution, the mineral does not contain lead; to the solution an excess of ammonia, and a greyish-white precipitate will be left, which is the oxyz of iron, often containing a little arsenic. If copper be present, ammonia will give to the remaining solution a fine blue colour, and that metal may be separated by a rod of clean iron.

It now remains to examine the first residuum which was unaffected by the nitric acid; this is to be digested with nitro-muriatic acid: the residuum left after this treatment will be found to be pure sulphur. The nitro-muriatic solution is now to be diluted with a large quantity of water; a white precipitate falls down, which, when washed, dried, and ignited, will be found to be oxyz of antimony, of a brown colour.

Klaproth found 100 grains of this ore to yield as follows:

The white silver-ores afford nearly the same ingredients with the last; and the mode of analysis will be similar in the dry way.

The light-white and dark-white silver-ores contain lead and alumine, and require a different treatment. After the silver is precipitated by common salt, a quantity of muriate of lead is formed at the time, which, on concentration, affords the muriate of lead in bright filky crysralls. When these are collected till the liquid will afford no more, a solution of sulphate of soda is to be added, which precipitates the remainder of the lead in the state of sulphate of lead. This powder, being washed and dried, contains $\frac{3}{4}$ of its weight of metallic lead. The remaining liquid being super-saturated with ammonia, as in the analysis of the brittle silver-ore, a light brown precipitate is formed: this precipitate is oxyz of iron and alumine. To separate the latter, dissolve the precipitate in nitric acid: separate the iron by prufliat of potash, or prufliat of lime, and afterwards the alumine with soda. The prufliat of iron, heated to a red heat, is decomposed, leaving the black oxyz of iron, which contains $\frac{3}{4}$ of metallic iron.

The first residuum left by the nitric acid, besides antimony and sulphur, which constituted the residuum of the brittle silver-ore, also contains lead. By the frequent addition of muriatic acid with the application of heat, the lead is separated in crystalls of muriate of lead; obtaining, by this means, a solution of the muriates of lead and antimony.
SILVER.

The residue is sulphur. The muriatic solution decomposes this; the compound is then treated with cold water, and the precipitate in an excess of water, with the addition of black lead, 

iron, silver, or zinc, to the cold liquid on the cupel, allows a small portion to be taken out of the flask. The solution still contains a small portion of lead in the oxalate. By adding a solution of silver nitrate, the lead is precipitated in the state of sulphide, according to its weight of metallic lead. The precipitate, being washed, dried, and ignited, is precipitated in the state of oxalate of lead, yields 

which reduces the metal. The analysis of the light white silver-ore, by Klaproth, gives of

The orogenic silver-ore, which is muriate of silver, is easily reduced in the dry way by fusing with soda, in a crucible capable of fusing the metallic silver. The soda takes the muriatic acid, forming muriate of soda, which escapes in white fumes, and the silver is left pure.

In the humid way, it is first fused in a glass retort with carbonate of potash. The mass is then dissolved in hot water, and the solution filtered. The precipitate is then dissolved in nitric acid, leaving behind a red powder. This powder, being treated with nitromuriatic acid, leaves behind a small portion of muriate of silver, which must be accounted for in metallic silver, as before directed. Ammonia, being added to the nitromuriatic solution, precipitates a red powder, which is oxalate of iron. To the nitric solution, from the mass treated with carbonate of potash, muriate of soda is now to be added; which precipitates the silver in the form of muriate, from which the metallic silver may be either calculated, or obtained by fusion with soda. The aqueous solution from the fused mass is now to be saturated with acetic acid. If alumina be present, it will be precipitated. The liquid part is now to be evaporated to dryness. If alcohol be added to the dry mass, it dissolves the acetate of potash. The precipitate is then dissolved in water. To this, muriate of barytes is to be added, which, if sulphuric acid be present, will cause a precipitation of sulphate of barytes, the sulphuric acid of which is to be considered as a product of the ore, and will be equal to one-third of the weight of this precipitate, when washed and dried. The remainder of the same mass which was dissolved in water may be considered as residue of potash, the acid of which is the more part of the analysis; and will be equal to one-third of the latter.

Physical and Chemical Properties of Silver — pure, when pure and newly polished, is of a pale yellowish colour, and becomes more white when the plate is in a dried condition. Its hardness is nearly that of copper. Its specific gravity is nearly equal to that of gold. At a heat of red, it can be worked with great facility by the hammer. Various articles, in the manner of working iron. After being reduced into very thin sheets, it can be bent into pieces of one-eighth of an inch in thickness; and can be drawn into wire finer than a horsehair. A wire of one-thousandth of an inch will require 336 lbs. to break it, when exerted in the direction of its length. At a temperature of redness, these pieces can be united either by the hammer, or by pressing them together with friction by a steel burrisher.

It melts at the temperature of 216° of Wedgwood, or 471° Fahrenheit. If the heat be raised, the metal becomes more liquid, and boils. This is occasioned by its assuming the elastic form, in which state it acts, and is condensable on the surface of bodies held over it, as has been observed with gold.

In purifying silver on the cupel, it is observed, that when it is removed from the furnace, and put at the point of condensation, a small explosion ensues, giving to the surface of the button an appearance as if some elastic fluid had been diffracted from it. It has been discovered by Mr. Samuel Lucas, of Sheffield, that the elastic fluid which is separated, produces the phenomenon in question, is pure oxygen gas.

By keeping silver long in a state of fusion, at a very high temperature, it becomes oxidised.

Macquer converted silver into a vitreous oxalate by exposing it to the heat of a porcelain furnace.

Silver is readily inflamed by electricity, and converted into an oxalate of a greenish-yellow colour.

The most direct way to obtain the oxalate of silver is by dissolving the silver in nitric acid, and precipitating it with lime-water. The precipitate is at first white, in which state it may be considered a hydrate of the oxalate. When heated, the water escapes, and it assumes a greenish-yellow colour, inclining to grey. If the heat be raised, the air being excluded, the oxygen is drawn off, leaving the metal in a state of purity: 100 parts of silver have been found to contain 7.5 of oxygen; hence, if the atom of hydrogen be 1, that of silver will be 100. No combination of silver with azote or carbon has as yet been discovered.

It combines with sulphur with great facility; the mere contact of the metal with flour of sulphur is sufficient to give the surface a yellow colour. If the silver be in thin plates, and stratified in a crucible with the same, a red heat the combination soon takes place, and the mass fuses, forming a sulphuret of silver, of a violet colour, sometimes in cristals of the shape of a needle.

This substance is brittle, but sufficiently soft to be cut with a knife. It is decomposable by heat. The sulphur escapes, leaving the metal in a state of purity. This compound is an atom of silver equal to 100, united to an atom of sulphur 15.

Sulphuret of silver is also formed by exposing the metal to sulphuretted hydrogen gas. The small quantity of the latter exiling in the atmosphere is capable of soon commurating a yellow, and ultimately a purple colour to polished silver.
Mr. Proust found this tarnishing matter to be a fulphuret of silver. The thinneft coat of gum, or of varnish, completely defends the surface of silver from tarnishing.

Silver combines with phosphorus, forming a phophuret of silver. This combination is effected by heating in a crucible equal parts of silver and phosphoric glafs, with one-fourth their weight of charcoal powder; or, what is better, fau-daff. This compound is of a white colour. It is brittle, but may be cut with a knife. It is, like the fulphuret, decomposable by heat.

Silver combines with several metals, forming alloys. The alloy of silver with gold, when the former is in a very small quantity, is of a much paler colour than gold. Thence, like all other compounds, are doubtlesse definite, and hence we should expect, that when these metals combine in the ratio of the weights of their atoms, which will be 100 silver to 140 of gold, the alloy would be the most perfect. And the next perfect would be two atoms of one to one of the other. It is itated by Mufchenbroeck, that the hardeft alloy of these two metals is with two parts of gold to one of silver.

Silver, as well as rendering gold much paler, gives it a greenish tinge. This alloy is more fusible than gold, and hence is employed as a folder for that metal.

Silver does not form any fliking alloy with platinum. Indeed it rather appears to be a mixture than a combination. As is the cafe with lead and zinc, the two metals separate, when kept fome time in a flate of fufion. This fact is corroborated by the circumstance, that silver can scarcely be made to unite two pieces of platinum together, when used as a folder, while gold can be employed for that purpofe with the greatest success. For the other alloys of silver, see the refpeftive metals.

Salt of Silver.—Thefe confift of the oxyd of silver combined with an acid, fome of which only are fusible in water. The prefence of the fusible fats of silver is easily detected by muriatic acid, or any fusible faltine compound with that acid, by occafioning a defne white precipitate, which foon changes to a purple colour when exposed to the fun’s light.

The infusible fats of silver have the property of coating bright copper with silver, when rubbed upon it with a little moifure. Salts of mercury would give the fame white appearance, but this would be diftinguifhcd from silver by being capable of difipation by heat. Salts of silver become black with the hydro-fulphurets of the alkalis. And gallic acid gives a brown precipitate.

Sulphate of Silver.—Sulphuric acid has no action upon silver at the common temperature. When, however, this metal is boiled with the acid, the silver becomes oxydated, fulphurous acid gas is difengaged, and sulphate of silver is formed, which is a white mafs, sparingly fusible in water, except an excess of sulphuric acid be prefent. The latter, on evaporation, affords cryftals of a brilliant filvery white-ness, in the form of needlefs or fine prills. This falt is fusible in nitric acid.

When heated, it firft fules, and if the heat be raised, it is decomposed, fulphuric acid and oxygen escaping, leaving the silver in its metallic form.

This falt is decomposed by the alkalis and earths, and all those fusible fats, the acids of which form infusible compounds with silver. Bergman has flated, that 100 parts of metallic silver, precipitated from nitric acid by fulphuric acid, give 134 of the sulphate. Allowing the 100 of silver to have taken 7 of oxygen, there will remain 28 for the fulphuric acid. This, in 100, will give fulphuric acid 22, and 78 of oxyd of silver. If this falt be compos’d of one atom each of acid and base, then, by Dr. Wolffen’s fcale, the proportions would be 25.5 acid, and 74.5 oxyd of silver. Dalton’s numbers would give very nearly the fame reftult.

Sulphate of Silver.—This falt, like the laft, is sparingly fusible in water. In other refpects, it is but little known.

Nitrate of Silver.—The nitric acid acds with confiderable violence on silver, affording red fulminating fumes, occafioned by the copious difengagement of nitric oxyd. If the acid and the silver be pure, the folution becomes clear and colourles, with redufum; if the acid contains muriatic acid, which is often the cafe with the acid of the shops, then a defne white powder will fall down, which becomes purple in the fun-fhine, and is the muriate of silver; if the silver contains gold, a purple powder will be left at the bottom of the veffel; if it contains copper, the solution will be of a green colour, of greater or lefs intenfity, depending upon the quantity of that metal.

The folution of silver affords cryftals on evaporation: they are of a prismatic form, but differ in their number of fides; they do not change by expoſure to the air, but are very fusible in water. These cryftals, when heated, firft melt; the heat being raised, the water of cryftallization escapes, but the mafs still remains liquid: in this flate it is frequently ca.ll into moulds, in which it affumes a fold form on cooling. These ficks, which are employed in surgery under the name of lunar caufir, are of a grey colour, and when broken exhibit a cryftalline appearance.

A more violent heat than that required for its fufion decomposes it, nitrous gas and oxyen being difengaged.

This decompoſition is much more rapid when it is heated in contact with inflammable matter. If thrown upon burning coals, it detonates. If filk, cotton, leather, ivory, and many other bodies, be moistened with nitrate of silver, and the part be afterwards moistened, when a stream of hydrogen gas is applied to it the silver becomes reduced, and appears with its metallic lustre. A ftick of phophorus dipped in nitrate of filver foon becomes coated with metallic silver.

This falt has the property of detonating with sulphur or phophorus, by being ftruck smartly with a hammer.

Nitrate of silver is decomposed by all the earths and form fults, and by the alkalis, by combining with the acid. Ammonia, however, does not only precipitate the oxyd, but afterwards combines with it, forming a compound having alarming fulminating properties. The following is the procefs recommended for its preparation.

From the nitrate of filver precipitate the oxyd by means of lime-water: separate the oxyd, and dry it upon blotting-paper: upon this oxyd pour pure caufic ammonium: let this remain for twelve hours. If a pellicle be formed upon the surface, add a little more ammonium, which will take it up. A black precipitate will be found at the bottom of the veffel, which is the ammoniate of silver, and is the fulminating fubftance to be obtained. This precipitate is to be carefully collected, and laid in very small quantities upon separate bits of blotting-paper, to dry. When dry, the lighted touch or rubbing motion caufes a violent explosion. Thofe unaccustomed to it should begin with the smalllefs poftible quantities, as ferior accidents have happened by exploding it in too large quantities. The liquid part from which the fulminating was separated will be found to be a folution of the fame: if it be heated in a glafs retort, a portion of it is decomposed, and the gafeous products difengaged: in a little time, small brilliant cryftals of the fame fulbitance appear: these
there freqvently detrate with such violence, as to break the vessel in which they are contained.

The theory of their appearance is, that the excess of the silver combines with the hydrogen of the hot, distilled water, which, with the arsenic gas of the fumes, are in an immeasurable to slowly electrify by the caloric set free, as to produce the explosive effect on the surface of the substance. It is requisite to say that the silver is left in the metallic form.

Nitrate of silver is decomposed by all these metal larvae a superior attraction for oxygen. The oxygen of the silver is given to the decomposing metal, which also combines with the acid. Copper, if employed, precipitates the silver as a white metallic powder, the result being nitrate of copper in the place of nitrate of silver. The precipitate is not pure silver, since copper will always be detected when the precipitate is re-dissolved.

Mercury has also the property of precipitating silver from the nitrate, producing the appearance which has been termed the Arsenic Disease. Lavoisier recommends one part of silver to be diffused in nitric acid, and the solution to be then diluted with twenty parts of distilled water; to this add two parts of mercury. The mercury gradually occupies the place of the silver, and the latter is precipitated in the form of vegetables, from which the name has been derived.

The vegetable appearance is caused by the growth of the crystals being from the extreme points of that already formed, as is the case with the growth of vegetables. The mercury, and the smallest portion of precipitated silver, form a Galvanic combination. The silver now in solution is reduced upon that already formed, in consequence of its rate of electricity being negative, that of the mercury being relatively positive, by which it attracts the acid. This process would doubtless be facilitated by dropping a small bit of metallic silver upon the mercury, added to nitrate of silver. This would form a Galvanic combination, and the bit of silver would become an immediate rallying point for the silver in solution. If a little of a dilute solution of nitrate of silver be spread upon a pane of glass laid in an horizontal position, and a common pin be laid in the middle of the covered part, in a few hours, beautiful ramifications of silver extend from every side of the pin; sometimes to the distance of an inch. This is also to be explained by Galvanism.

Mixture of Silver.—When nitric acidified, or any soluble muriate, is added to nitrate of silver, a dense and bluish-white precipitate is thrown down, which is muriate of silver. Although white when it is just precipitated, it soon assumes a purple tint by exposure to the light, and the change is quicker as the light is more intense: hence this substance has been employed to measure the degree of intensity of light, by the time in which the change of colour takes place.

It may be said to be insoluble in water: this property, and its conspicuous appearance in other respects, renders the nitrate or sulphate of silver so valuable as a test for muriatic acid. The latter, on combining with the silver, forms the salt in question.

When the salt is exposed to heat, it easily melts on cooling, it becomes solid. It is a semi-transparent mass, of a grey colour, and of a heavy appearance, from which it has been called hestancrea, or burn-silver. If fused with a great heat in a crucible, it becomes so thin a fluid as to sink through the pores of the crucible. It is not decomposed by any of the acids or the alkaline, but when heated with the carbonate of potash or soda, the acid is disengaged. It diffuses an electric amber, forming a transparent solution: thus, by exposure to the air, undergoes considerable change. A pellieule forms on the surface, which is first of a bluish colour, and afterwards black. This pellieule, on evaporation, is turned to be muriate of silver in a crystalline form. This was with Sir Humphrey Davy discovered, and is described by Dr. Micaldi, who placed the test flask on a white tile, covered the latter tile with some fumes of silver. Sir Humphrey placed the vessel over the tile, and Dr. Thomson, in a similar manner, to test for fume.

The composition of this salt, according to Broun, is

| Muriatic acid | 7.5 |
| Oxid of silver | 6.5 |

By the atomic theory it should be constituted by

$$7.5 + 18.8 = 26.3$$

The muriatic acid, and which would give

| Oxid of silver | 8.17 |
| Muriatic acid | 18.83 |

Sir Humphrey considers it as a compound of one proportion of chlorine, 67, and one proportion of silver, 205, which will give

| Silver | 75.3 |
| Chlorine | 24.7 |

Considering the 24.7 of chlorine as oxymuriatic acid, which would be 18.8 muriatic acid, and 5.9 oxygen, then by mixing this oxygen to 75.3 of silver, would give 81.2 of oxid of silver, and 18.8 of muriatic acid in the 100, which nearly agrees with the above. The property which this salt has of becoming black by the action of light, has rendered it useful for marking linen. Very improper ingredients have been used for this purpose. The nitrate of silver is employed to write with upon the linen, which is very proper; but the part is often prepared by a solution of soda or potash, instead of a solution of muriate of soda (common salt). The following will be a recipe which cannot fail of success: dissolve 30 grains of lunar calx in one ounce of distilled water; this will be for the writing liquid. For the preparing liquor, dissolve half an ounce of common salt in four ounces of water; and in the same disolve half an ounce of gum arabic. Mix the part to be marked with the latter, and dry it till the writing will not run. The letters will then appear of a blueish-white, but become perfectly black by exposure to light.

The fluoride, borate, phosphate, carbonate, and arsenate of silver, are insoluble powders, having no striking properties, or but little known. The arsenic is formed by adding arsenate of potash to any soluble salt of silver. It falls down in the form of powder of a yellow colour. Its solubility, and its conspicuous colour, have been taken advantage of by employing nitrate of silver as a test for arsenic.

The chlorate of silver is an insoluble salt, of a green colour; it is formed by adding chromate of potash to nitrate of silver. It, however, becomes purple by exposure to air and light.

Acetate of silver is a soluble salt, formed by adding the acetic acid to oxid of silver. The solution affords prismatic crystals.

The rest of the salts are but little known.

Silver, in Medicine, is called livia, the moon; and has been much extolled for its virtues by chemical writers. But
crude silver, however comminuted or attenuated, has not been observed to produce any medicinal effect. It is not soluble in any of the fluids of the animal or vegetable kingdom.

Several preparations have been made from silver; particularly a

**Silver Pill, or Pilula Lunaris**, which is a chemical preparation of silver, formerly highly commended as an athermal, and as a purgative remedy for dropsies, and in many other invertebrate ulcerous diseases.

The method of making it is this: disolve an ounce of pure nitre in distilled water; then disolve an ounce of crystals of silver, made in the common way, with pure silver and aqua fortis, in three times the weight of water, so that the solution may be perfectly limpid; mix the two solutions together, they will become a clear homogene liquor; evaporate this to a pellicle, and crysals reforming nitre will float; pour off the remaining nitre as before, and the remaining nitre will float with the silver, in form of crystals, again, upon a second evaporation: let these crysals be dried upon a paper, and then placed in a glass vessel in a very gentle heat, enough to make them smoke, but not run; stir it with a piece of glass all the time, and keep it over the fire, till no more fumes arife; thus the acid spirits will be driven off, and the silver remain of a very bitter taste and purging quality. It must be kept in a dry close vessel.

This discovery has been made to serve to many other purposes, besides its uses in medicine, and has furnished the dishonest pretenders to alchemy with one of their most cunning methods of deceit. They have been able, by this means, to conceal silver in nitre, and that in a very large proportion, as in one-tenth part of the whole quantity; and this nitre being projected in an equal quantity on melted lead, gives an increase of one-tenth part in silver, which remaining upon the tell, will deceive the ignorant, as if a tenth part of the lead were converted into pure silver. People who are upon their guard, may, however, discover the cheat, by dissolving the pretended nitre in ten times its weight of water, and putting a polished plate of copper into the solution; for every particle of the silver will then be precipitated out of the liquor upon the copper, and to the bottom of the vessel.

The medicinal use is this: the dried mass, consisting of the farts of silver and nitre, is to be reduced to a fine powder; this powder, applied to ulcers, acts in the manner of the lapis infernalis, or silver-caustic, only much milder: but for internal use, the quantity of two grains of it is to be ground to a fine powder, with fix grains of loof-fugar, in a glass mortar; this is to be then mixed with ten grains of the crumb of bread, and formed into nine pills: these are to be taken by a grown person upon an empty stomach, drinking after them four or fix ounces of hot water, sweetened with honey. It purges gently, and brings away a liquid matter like water, often unperceived by the patient. It is said to kill worms, and perform great things in many obstinate ulcerous disorders. It purges without griping, but it must not be used too freely, nor in too large a dose, for it always proves weakening, and in some degree corroive upon the stomach; but this inconvenience is greatly alleviated by rob of juniper. Boerh. Chem. part ii. p. 297.

However, with this affiduus, it is at best a dangerous medicine, and as such is deservedly excluded from practice.

**Silver, Tartar of**, is made by dissolving thin silver plates, or silver shot, in spirit of nitre; and pouring the solution into another vessel full of salt-water. By this means, the silver is immediately precipitated in a very white powder, which they wash several times in spring water. This powder they put into a matras; and pour rectified spirit of wine, and volatile falt of urine, upon it. The whole is left to digest in a moderate heat for fifteen days; during which, the spirit of wine affumes a beautiful sky-blue colour, and becomes an ingredient in several medicines. This is also called potable silver, argentum potabile.

Silver is likewise converted into crysals, by means of the same spirit of nitre; and this is called spirit of silver.

The lapis infernalis argentous is nothing but the crysals of silver melted with a gentle heat in a crucible; and then poured into iron moulds. See CAUSTIC; Lunar.

**Silver Ale.** See Ale.

**Silver Balsam, in Botany, a species of Anthyllis; which see.** See also Barba Jovis.

**Silver Coin.** See Coin, and Money.

**Silver Fir.** The name of a tree of the pine kind. See Pine.

**Silver, Green and Herring.** See the adjectives.

**Silver, Inflammable, a chemical preparation of the lapis infernalis made by a small heat.** The process is this: take an ignited piece of Dutch turf, after it ceases to smoke; place it with its upper flat surface parallel to the horizon; make a little cavity in the middle, and therein put a drachm of dry lapis infernalis; it will immediately melt and glow, and finally it will take flame, and hiss and thine like nitre: after the flame ceases, pure silver will be found in the hollow, as much in quantity as was used in making so much lapis infernalis.

This curious experiment shews the physical manner in which acids do but superficially adhere to silver, and the manner in which acids operate, when united to metals, while surrounding their metallic mass, they arm the ponderous principles of them with spicula: it shews also the immutability of silver dissolved in an acid, and the various ways in which it may be concealed, yet still have its action; it also shews the difference of potable silver, while existing in a saline form, by means of an adhering acid, from that potable silver of the adepts, where the principles of silver are supposed converted into a fluid, that will mix with the juices of the body, and cannot be reduced to silver again; but the great thing to be here observed is, that the acid spirit of nitre, adhering in a solid mass of silver, is, in this state, as inflammable, on coming in contact with an ignited combustible body, as crude nitre itself: this seems to happen with silver alone, which is unchangeable with spirit of nitre. Hence also we see one way, by which silver may be obtained pure from other adhering matters, by bare burning: the acid here acts neither upon the mercurial part of the silver, nor on its fixing sulphur. Boerh. Chem. part ii. p. 297.

**Silver, King's.** See King's Silver.

**Silver-Leaf** is that which the gold-beaters have reduced into thin fine leaves, to be used by gilders, &c. See Gold-Leaf.

**Silver, Quick.** See Mercury.

**Silver, Rep.** See Rep Silver.

**Silver, Salt.** See Salt Silver.

**Silver, Shell,** is made of the shreds of silver leaves, or of the leaves themselves: and used in painting and silvering certain works. It is prepared after the same manner as shell-gold. See Gold.

**Silver, Slough.** See Slough Silver.

**Silver, Smoke.** See Smoke Silver.

**Silver-Tree, in Botany.** See Protea.

**Silver-Weed, a species of Potentilla; which see.**

**Silver-Weed, in Agriculture, a term applied to wild tanfey; a plant which grows naturally upon cold stiff land in
in mold parts, and is a sure mark of the verity of the foil. Its flake is spread upon the ground, and feeds off roots from its parts; by which means, and by frequent dustings of its seeds, it swarms through the whole humus, to form new plants, and put the land to a great expense. Its leaves are composed of several leaves or squares, which are generally placed along the petiole, and terminate by an odd one; they are jagged at their edges, and are of a silvery, especially on their under side. It has been noticed by Mr. Ray, that the root is somewhat of the tap-rooted or parthipal kind, and that they are very fond of feeding upon it.

Silver. White-bart. See White-bart Silver.

Silver Wire, is silver drawn through the holes of a wood drawing iron, and by this means reduced to the finest of a thread or hair. The manner of drawing it, is under the article Gold Wire. See also Wire, and Drawing.

Silver Bluff, in Geography, a headland on the coast of South Carolina, at the mouth of the river Savannah.

Silver Caves, a cluster of rocks, 10 miles S. of Grand Caves.

Silver Creek, a river of America, in Kentucky, which runs into the river Kentucky, N. lat. 37° 41'. W. long. 84° 49'.

Silver Grain, in Vegetable Physiology, is described by Mr. Knight, Phil. Trans. 1807, 144, as consisting of numerous thin plates, "diverging in every direction from the medulla to the bark, having little adhesion to each other at any time, and lies during spring and summer, than in autumn and winter; whence the greater brittleness of wood in the former season." The same writer remarks, that these plates are visible in every wood which he had examined, except some of the palm tribe; but are of different width in different kinds, lying between, and predominate upon, the sap-velelts of the allium. It may be observed, that in the oak "every tube is touched by them short distances, and from distances, and may be diverted from its course. If thieves," continues Mr. Knight, "are explicable under changes of temperature, or from any cause arising from the powers of vegetable life, I conceive that they are as well placed as is possible, to propel the sap to the extremities of the branches; and their brittle temper, after the tree has ceased to live, teaches me to believe, that they are not made to perish whilst it continues alive." In support of this opinion, we would remark, that the plates in question are found where the spary coats of the sap-velelts either no longer exist, or have lost their elasticity. See Circulation of the Sap.

Silvering, the covering of any work with a thin coating of silver. This operation is recommended by two circumstancse; viz. the superior beauty of silver to that of the cheaper metals, and also its superior wholeness to copper, brass, or lead, for culinary purpores, as it is not corroded by vinegar and other weak acids.

Silvering may be performed on the same substances, and by similar methods with gilding; which see. But as works of this kind are liable to tarnish and peal, they are seldom used. But when this is the case, the coating of silver should be much thicker than that of gold, because, otherwise the friction which is necessary for removing the tarnish, would soon wear off the silver from the most prominent parts, and expose to view the subent copper or brass. In order to avoid this inconvenience, some have recommended, when silvering is admitted, a strong varnish, formed of some of the compositions of mastic, sandarac, the gums animal or copal, and white resin, to be put over it.

The varnish recommended in silvering leather may be applied to other purporses. See Lacquer.

The silver powder, called argyrum musenum, may be either tempered, in the manner of the small gold, with warm water, or rubbed over a ground properly tawed, and it will take a very good polish from the roots of the hair, but it did not seem much better with a little more varnish over it than was by silver powder alone.

The best silvering, when they are used for this purpore, must not be mixed, as is the case of gold, with yellow, or black, nor with brass, only with iron; white lacquer, whose varnish may be mixed with a small quantity of varnish, in a little water, and this mixed with take-white, or white lead, when the varnish of oil is put in; but white, or tubed paper clay, with a little lamp black added to it, is the proper matter to be brushed over, for silvering, or wherever the silvers or lacquer are used.

It is useful to silver metals, wood, paper, &c.

The only metals to which silvering is applied are copper and brass, and very rarely iron; and there are three modes of performing this operation, viz. by small amalgam, by burnished silver, and by silver in substance. The first is performed by adding plates of copper to a liquid of nitrate of silver, which will precipitate the silver in its metallic state, and very finely divided; scrape this from the copper, and let it be well washed and dried. With half an ounce of this powder, of common salt and 3/4 of ammonia, two ounces, and one dram of corrosive sublimate, well rubbed together, make a paste by the addition of a little water, then clean the vessel to be silvered with a small quantity of diluted aqua fortis, or by pouring it with a mixture of common salt and tartar. Rub it, when perfectly clean, with the paste already mentioned, until it is entirely covered with a white metallic coating; which coating is an amalgam produced by the decomposition of the corrosive sublimate by means of the copper, to the surface of which it applies very quickly and expeditiously. The copper thus silvered over is then to be washed, dried, and heated nearly red, for the purpose of driving off the mercury; the silver remains behind and adheres firmly to the copper, in a plate capable of receiving a high polish.

The second method of silvering is that by luna cornes. For this purpose, prepare the luna cornes in the usual manner, by pouring a solution of common salt into nitrate of silver, as long as any precipitation occurs, and boiling the mixture; then mix the white curdy matter thus obtained with three parts of good pearl-salt, one part of washed whiting, and a little more than one part of common salt. After the surface of the brass, cleared from scratches, has been rubbed with a piece of old hat and rotten flesh, in order to remove any greasy, and then moistened with salt and water, a little of the composition, being well rubbed on with the finger, will prettily cover the surface of the metal with silver. Then wash it well, rub it dry with soft rag, and then, as the coat of silver is very thin, cover it with transparent varnish to preserve it from tarnish. As this kind of silvering is very imperfect, it is only used for the faces of clocks, the scales of barometers, or similar objects. (See Luna Cornes). The third mode of performing this operation is by means of silver in substance; and of doing this there are three different methods. The first is by mixing together 20 grains of silver precipitated by copper, two drachms of tartar, two drachms of common salt, and half a drachm of alum; and rubbing the composition on a perfectly clean surface of copper or brass will cover it with a thin coating of silver, which may be polished with a piece of soft leather. Another mode, better called French plating, consists in burning down upon the surface of the copper successively layers of half-silver to any required thicknesses. Although the silver in this operation is more solid than
than in any of the former modes, the process is tedious, nor can the junctures of the leaves of silver be always entirely concealed. But the best method of all is the English plating, for an account of which see Plated Manufacture.

Aikin’s Dict.

Brafs may be silvered, by boiling it with filings of good pewter and white tartar, in equal quantities. There are several other methods of silvering, for which see Smith’s Laboratory, p. 37, 1802; also Handmaid to the Arts, vol. i. p. 437, &c. See Gilding of Metals.

The following is the recipe in practice with buttonmakers for covering the inferior kinds of plated buttons: 3 lbs. of sulphate of zinc; 3 lbs. of common salt; 1 oz. of corrosive sublimate, and 2 ozs. of muriate of silver. This is made into a pulpy flake with water, and the buttons smeared over with it. They are then exposed to a certain degree of heat, whichfirft causes the surface to be covered with an amalgam of silver and mercury, and then expelling the latter, which requires nearly a red heat, the copper retains a permanent coating of silver. This is afterwards to be cleaned and burnifhed, by which it acquires a silvery lustre, which, for a time, appears like durable plating. The salt and the sulphate of zinc appear to be of no other use than to dilute and give a pulpy conftance to the mass.

Silvering in the cold is performed by the following composition: 3 lbs. of cream of tartar; 3 lbs. of common salt; and 1 oz. of muriate of silver, which is the precipitate formed by adding common salt to nitrate of silver, till no more is precipitated. This composition is made into a flimer pulp. The surface of the copper or brafs to be silvered must first be cleaned with diluted acid, and then made dry, and kept free from grease. The surface, being now rubbed with the above pale, will assume a white colour, by the silver adhering to it. This process is generally employed for silvering clock-faces, and the scales of instruments.

The surface should always be varnifhed to prevent its tarnifhing, as the silver is too thin to bear cleaning. See Button.

Silvering of Leather. See Lacque and Japanners’ Gilding.

The proceeding in silvering the leather is in all respects the fame as when it is to have the appearance of gilding, except that, instead of the yellow varnish, a clear colourless one is to be used, where the appearance of silver is to be preferred.

The most common varnish for this purpofe is only parchment fize, made warm, and laid on with a fponge. Howevcr, the more hard and transparent the varnifhes are, and the more they are of a reifinous nature, the more brilliant and white, and the more durable, will be the silverly and polifhed appearance of the silvered leather. Some, infted of the parchment fize, use that made of linfkglas.

Silvering of Mirrors, is the application of a coating of quicksilver to their posterior surface, in the manner briefly defcribed under the article Looking-Glafs. The management of the silvering is, in this cafe, extremely fimple, and is thus detailed in Aikin’s Dictionary. A perfectly flat slab of free-flone (or sometimes of thick wood), a little larger than the largest plate, is inclosed in a square wooden frame or box, open at the top, and with a ledge rising a few inches on three sides, and cut down even with the flone on the fourth. A small channel or gutter is cut at the bottom of the wooden frame, serving to convey the wax mercury down into a vessel below, fet to catch it. The flab is also fixed on a centre pivot, fothat one end may be raised by wedges (and of courfe the other depreffed) at pleasure, when working freely in the box.

The flab being firft laid quite horizontal, and covered with grey paper fretched tight over it, a fheet of tin-foil, a little bigger than the plate to be silvered, is spread over it, and every creafe smoothed down carefully; a little mercury is then laid upon it, and spread over with a tight roll of cloth, immediately after which as much mercury is poured over it as will lie on the flat surface without fpilling. That part of the flab which is opposite the cut-down fide of the wooden frame is then covered with parchment, and the glafs plate is lifted up with care and flid in (holding it quite horizontally) over the parchment, and lodged on the surface of the flab. The particular care required here is, that the under surface of the glafs should from the firft junct dip into the surface of the mercury (fkimming it off as it were), but without touching the tin-leaf in its passage, which it might tear. By this means no bubbles of air can get between the glafs and the metal, and also any little dust or oxys floating on the mercury is swept off before the plate without interfering. The plate being then let go, links on the tin-foil, fqueezing out the superfluous mercury, which paffes into the channel of the wooden frame above-mentioned. The plate is then covered with a thick flannel, and is loaded over the whole surface with lead or iron weights, and at the same time is tilted up a little, by which till more of the mercury is squeezed out. It remains in this fituation for a day, the flope of the fhone flab being gradually increafed to favour the dripping of the mercury. The plate is then very cautiously removed, touching it only by the edges and upper fide, and the under fide is found uniformly covered with a soft papty amalgam, confiting of the tin-leaf thoroughly foaked with the quickfliver, and about the thickens of parchment. It is then fet up in a wooden frame, and allowed to remain there for ferveral days, the flope of its position being gradually increafed, till the amalgam is sufficiently hardened to adhere fo firmly as not to be removed by flight scratches, after which the plate is finifhed and fit for framing.

It is a confiderable time before the amalgam has acquired its utmost degree of hardnefs, fo that globules of mercury will often drip from new mirrors fome time after they have been fet up in rooms; and violent concussions of the air, fuch as from the firing of cannon, will often detach portions of the amalgam. Thence can never be perfectly replaced by any patching, as the lines of junction with the old amalgam will always be marked by white feams, even when looking into the glafs. See Foliating of Looking-Glafs.

Silvering of Paper. See Chine or Paper.

SILVERIUS, pope, in Biography, the fon of pope Hormida, was placed in the pontifical chair in the year 536, upon the death of Agapetus. Belifarius, the famous general of Juttinian, having loon after taken poftefION of Rome, the emprefs Theodora resolved to take this oppor- tunity of retorting Anthemius, patriarch of Constantinopole, and his party, who had been condemned for heresy by the council of Chalcedon. She wrote to Silverius, urging him to recognize Anthemius as lawful bishop, to which he gave a positive refufal. Upon this the empress made an engagement with the deacon Viglius, that he should be raised to the popeom on condition that he would anathematize the council of Chalcedon, and re-admit Anthemius and his party; and he, at the fame time, sent ordina to Belifarius to depose Silverius. To furnish a pretext for this act, an accufation of treafon was brought against the pope, having invited the Goths to repofle themselves of Rome. This change was most probably invented for the purpofe, and without the smallest foundation; and Belifarius, without acting upon it, fet for Silverius, and endeavoured by
perfusion to get him to comply with the emperor's requisition, but he resisted him. Finding, however, that he had not strength to oppose his envoys, he took sanctuary in a church, but being artfully drawn from it, he was driven from the city and banished in the year he had been elected pope. When arrived at Patara, a city in Lycaia, the place of his exile, the bishop of the place met him, and, indignant at the treatment he had experienced, undertook to lay the case before the emperor, then at Corinth, and, from his representations, Julian ordered the caufe to be re-heard. Silverius, immediately receiving this order, went to Rome, where his uneasy conduct and perfunctory appearance greatly disconcerted Vigilus, who had intruded into his chair. Through the intrigues, however, of Vigilus with Antonia, the wife of Belisarius, Silverius was put into his hands, and carried to the island of Palmaraz, on the coast of Liguria, where he died, from want or hardship, in or about June, in the year 538, though Borutius maintains that he held a tyton of four bishoprics in the island, at which he excommunicated Vigilus, and that he did not die till June 540. In the church of Rome he is honoured as a martyr to orthodoxy.

SILVERMINES, in Geography, a small town of the county of Tipperary, Ireland, which obtained its name from productive lead-mines in the neighbourhood, from which much virgin silver was formerly obtained. These mines, the property of Lord Durlacs, are no longer wrought, and are thought to be exhausted. Silvermines is north of the Keeper mountains, and gives name to a lower ridge of hills. It is 77 miles S.W. from Dublin, and about 5 miles S. from Nenagh.

SILVES, a town of Portugal, in the province of Algarve, situated on a river of the same name, containing 1600 inhabitants; formerly more considerable than at present, and from the year 1188 to 1250 a bishopric, which was afterwards removed to Faro; 15 miles E.N.E. of Lagos. N lat. 37.10'. W long 16'.—Alviso, a river of Portugal, which runs into the Atlantic, a little below Villa Nova de Portimao.

SILVESTER I., pope, in Biography, was elected to the see of Rome in January 314. In that year was held the council of Arles, to which Silverst was invited, but he excused himself on account of his age, and sent two prelates and two deacons as his deputies. To the general council of Nice, in 325, he also sent deputies, which council was convened by the emperor, and met and the 17th, nor did the letter précede at it. It was during this pontificate that the hierarchy of the Christian church, as it has ever since existed, formed upon the model of the civil government of the empire, took its origin. Silverst died 7, 335, after having held the papal see nearly twenty-one years.

SILVESTER II., pope, previously named Gerbert, was born of an obscure family in Auvergne, in the 10th century. At an early age he entered himself as a monk in the monastery of St Gerard, Auvergne. After laying a foundation of all the sciences cultivated in that ignorant age, he travelled for improvement, and visited Spain, in order to hear the Arabian doctors in their universities. At length he rendered himself so distinguished, that he was appointed by Hugh Capet preceptor to his son Robert. At Rome he became known to the emperor Otto II., who placed him at the head of the abbey of Bobbio, about the year 970. Having resided there some years, he returned to France, but visited occasionally Italy. In one of those visits he met with Otto II. at Pavia, who took him to Ravenna, where he held a solemn deposition on a mathematical quesion with a Saxon, very eminent for his learning. He was afterwards made preceptor to Otto III., while in the imperial court while he was still a minor. In the year 971, Hugh Capet promoted him in the archbishopric of Rheims; but this elevation was a figure of speech, and after much toying, he was sent to the see of Arles, the natural see of Languedoc, in France, who had been formerly defiled by him. It was in the year 972, and at the法兰克ic of Otto III. was ferred upon by the archbishop of Ravenna, the death of pope Gregory V. in 973, he was elected to the papal dignity, when he assumed the name of Silverst. The acts of his pontificate were few, and not at all important. In the year 998, he is said to have entered on St Stephen, king of Hungary, the royal title, with the same crown, the papal bullion of that kingdom, and to have consecrated the perpetual benediction of the holy see, with power to dispose of all ecclesiastical benefices. An extraordinary influence of ecclesiastical suzerain in this period was exercised by Anemar, which, if it may be relied on, proves both the great power of the church at that period, and the disposition to abuse it. Guy, count of Languedoc, having imprisoned Grimald, bishop of that city, for taking possession of a disputed monastery, and afterwards released him, the bishop repaired to Rome, and complained to the pope, who cited Guy to his presence. The case being heard, the count was condemned by the pope and debarred to the tail of a wild horse, and dragged away till he was torn to pieces, the execution of which sentence he escaped by compromising the affair with the bishop, his accuser, and taking flight along with him. Silverst died in the year 1005. He was a very meritorious character, a promoter of learning, and a proficient in various branches of the sciences. He spent much time and large sums of money in the collection of books from various parts of Europe, composed himself a number of works, particularly in arithmetic and geometry, and with his own hands made globes, a clock, and an astrolabe. Living, as he did, in the very depths of the dark ages, he felt and the superstition of magical practices, and several ridiculous stories are related to this pope. There were, however, periods who knew how to appreciate his character; he was noticed by Otto II. as a well learned man, and eminent in the higher branches of philosophy. He wrote a great number of letters on various topics, of which 160 of them were printed at Paris in 1611. One of these, written in the first year of his pontificate, is a call to the church universal, for delivering the Christians in Palestine; in other words, a project for a crusade.

SILVESTRE GRANUM, or CONCUS SILVESTRIS, a term used by four authors to express the same person; and by others for a course or bad kind of conchlea, produced in the province of Guntamula, in New Spain; it is by some supposed to be the seed of a plant, but it is really an inch, as the true cochlea is, only that the scarlet colour it yields is greatly inferior to the other. See Conchlea.

SILVILM, in Ancient Geography, a place of Italy, in Peucetia, E. of Venusia. The name is formed from Silva, a grove, found in this place, and probably the "Salus Bactria" mentioned by Homer.

SILVULM, in Geography, a small island in the Adriatic, N lat. 43° 37'. E long. 14° 10'.

SILLES, or, according to the orthography of Poullens, Silvius, in Ancient Geography, a people of the isle of Albion, who possessed, besides the two English counties of Hereford and Monmouth, Radnorshire, Brecknockshire, and Glamorganshire, in South Wales. The northern part
of Herefordshire has been supposed to some to belong to the Ordovices. The name of this ancient Britih nation is derived, by some of our antiquaries, from Caer, a word, and *uerc*, men, because they inhabited a woody country; and by others, from the British words *ex heul iir*, which signify brave or fierce men. Tacitus has conjectured, with little probability, and no sufficient evidence, that the Silures had come originally from Spain,grounding the conjecture on a supposed, or perhaps fancied resemblance between them and the ancient Spaniards, in their persons and complexions. It is much more probable, that they, as well as the other ancient inhabitants of Britain, had come from some part or other of the neighbouring continent of Gaul. But from whencesoever they derived their origin, they reflected no dishonour upon it, as their povertv have not degenerated from them. The Silures were unquestionably one of the bravest of the ancient Britih nations, and defended their country and their liberty against the Romans with the most heroic fortitude. For though they had received a dreadful defeat from Offorius Scapula, and had lost their renowned commander Caractacus, they still continued undaunted and implacable; and by their bold and frequent attacks, they at length broke the heart of the brave Offorius. But all their efforts were at last in vain. They were repulsed by Aulus Didius, further weakened by Petlius Cerealis, and at last totally subdued by Julius Frontinus, in the reign of Vespasian. As the Romans had found great difficulty in subduing the Silures, so they took great pains to keep them in subjection, by building strong forts, and planting strong garrisons in their country. One of the most considerable of these fortifications, and the capital of the whole country, was Ica Silurum, now Caerleon, on the river Wifk, in Monmouthshire. Here the second legion of the Romans, which had contributed greatly to the reduction of the Silures, was placed in garrison (as some antiquaries have imagined) by Julius Frontinus, to keep that people in obedience. It is however certain, that this legion was very early, and very long stationed at this place. Ica Silurum was, in the Roman times, a city not only of great strength, but also of great beauty and magnificence. This is evident from the description which is given us of it by G-raldus Cambrensis, in his topography of Wales, several ages after it had been destroyed and abandoned. "This (Caer Leon, or the city of the legion) was a very ancient city, enjoying honourable privileges, and was elegantly built by the Romans, with brick walls. Many vestiges of its ancien splendour are yet remaining; stately palaces, which formerly, with their guided tiles, displayed the Roman grandeur. For it was first built by the Roman nobility, and adorned with sumptuous edifices; also an exceeding high tower, remarkable hot-baths, ruins of ancient temples, theatres encompassed with stately walls, partly yet standing. Subterraneous edifices are frequently met with, not only within the walls (which are about three miles in circumference) but also in the suburbs; as aqueducts, vaults, hypocausts, flaves, &c." This description of Caer-Leon was composed in the twelfth century, and therefore we have no reason to be surprized that its present ruins are now so entirely destroyed, that they are hardly discernible. On the banks of the river Wifk, besides Ica Silurum, there stood two other Roman towns; Burrium, now Usk, and Gobannium, now Abergavenny. Venta Silurum, now Caer-Gwent, near Chepilow, in Monmouthshire, was also a considerable Roman town, of which there are some faint vestiges still remaining. Blestum, in the thirteenth journey of Antoninus, is supposed to have been situated at Monmouth and Magna, in the twelfth journey, at Kencheller, or as others think, at Ledbury, in Herefordshire. When the Roman territories in Britain were divided into five provinces, the greatest part of the country of the Silures was in that province which was called Britannia Secunda. Henry's Hist. vol. i.

**SILURUS**, in Ichthyology, a genus of fishes of the order Abdominales, of which the generic character is as follows: The head is naked, large, broad, and compressed; the mouth is furnished with cirri, resembling the feelers of insects; the gape is very large, extending almost the whole length of the head; the lips are thick, jaws furnished with teeth; the tongue thick, smooth, and very short; the eyes are small; the gill-membrane is characterized with from four to seventeen rays; body elongated, compressed, without scales, mucous; lateral line near the back; the first ray of the dorsal or pectoral fins serrate, with serrated spines. There are twenty-eight species, divided into sections, according to the number of their cirri, as follows: the fishes in section A have two cirri; in section B, four; in section C, six; in section D, eight; and in section E, the fishes are without cirri.

The name is of Grecian origin, and is derived from the words *σῖλης*, to move or shake, and *κίρυς*, a tail. It is given to this fish, from its remarkable quality of being almost continually moving its tail in the water.

**Section A. Two Cirri.**

**Species.**

**Militaris.** The specific character of this is, that its second dorsal fin is fleshy; cirri bony, toothed. It inhabits many rivers in Asia; feeds on smaller fishes, and grows to a large size. It is from twelve to eighteen inches long; the head and fore-parts are broad and depressed; the mouth is very wide; the teeth are small and numerous; the eyes are large; on each side the head, near the nostrils, a very strong subcerebrum, spine, or bony process; first ray of the dorsal fin excessively large, strong, and sharply serrated, both on the middle part and towards the tip; the tail slightly bilobate, with rounded lobes. It is a native of the Indian rivers.

**Inermis.** Second dorsal fin fleshy; fins unarmed. It inhabits the rivers of Surinam. This is differentiated by some naturalists from the sublivesibale Silurus. It is transferrably banded with brown spots, with unarmed fins, and flexuous lateral lines. It is about twelve inches in length; the head is bony, but smooth, and it is destitute of spinous processes. It is a native of the Indian and South American rivers.

**Section B. Four Cirri.**

**Species.**

**Asotus.** The back of this fish has only one fin; it inhabits Asia; there are two cirri above the mouth, and two beneath; the teeth are numerous; the dorsal fin is without spinous rays; the first ray of the pectoral is serrate; the anal fin is long, and connected with the caudal.

**Chilensis.** Second dorsal fin fleshy; the tail is lanceolate; it inhabits the fresh waters of Chili; it is about ten inches long; the body is brown; beneath it is white. The flesh is said to be excellent.

**Bagre.** Second dorsal fin fleshy; first ray of the dorsal and pectoral fins setaceous. It inhabits South America.

**Calliglythis.** Second dorsal fin one-rayed; a double row of scales on the sides. It inhabits the small running streams of Europe, and when these are dried up, it crawls across meadows in search of water; it is said to perforate the sides of referrers, for the purpose of making its escape.

**Section**
SILURUS.

Section C. Sea Cms.

Species.

Clavus, or European Silurus. This is also called the great or common silurus, and may be considered as the largest of all European rivers, on which, growing, till it attains, to the length of about eight, nine, or even fifteen feet, and to the weight of 6, 7, or 8; Beyond its true general length, however, it is not very thick. The head is broad and depressed; the mouth black, of a long horizontal form, with the lower jaw very thick and short. It is of a rugged, dirty brown, with a blackish-blue spot on the upper side, and composed of a number of long, slender blackish cirri, which are attached towards the tail, and the sides of the upper part of the river which it frequents; with the pectoral fins, webbed, of toes, rocks, legs, or other similar limbs. In this situation, or姿态, with its considerable height, and only a very short tail, the fish is reduced, and becomes a ready prey to the fishers. The color of this species is dark olive, variegated with regular spots of black; the abdomen and lip are of a pale flesh-colour, and the fins are tinged with violet. It is an inhabitant of the larger rivers of Europe, as well as the parts of Asia and Africa, but it appears to be most plentiful in the north of Europe. It is not much esteemed as food; the flesh being of a glutinous nature; but from its cheapness, it is in much request among the interior ranks of society, and eaten either fresh or salted. The skin, which is smooth, and distensible of apparent scales, is cried and stretched, and after rubbing with oil, becomes of a beauty transparency and strength, and is used in some of the northern regions instead of glasses for windows.

The silurus is not a very prolific fish, depositing a small quantity of spawn, consisting of large globules, or ova; these, as well as the newly hatched young, are frequently the prey of other fishes, frogs, &c., and thus the great increase of the species is prevented. The ova are said to be hatched in about a week after their emission.

Electricals. The dorsal fin is single and fleshy. The head is depressed; the eyes are moderate, covered with the common skin; the teeth are crowded, small, and sharp in each jaw; the nostrils are very minute; each side approximate; upper lip bearded with two cirri, the lower with four, of which the exterior ones are longer. It inhabits the rivers of Africa. It is about twenty inches long; the body is long and broad on the fore part, depressed, pale ash-colour, with a few blackish spots towards the tail; when touched, it communicates a tripping shock, attended with a sort of trembling and pain in the limbs, but less violent than that given by the Torpedo, which bee. The flesh of the electrical silurus is eatable.

Felix. The second dorsal fin of the fish of this species is fleshy; it has 25 anal rays; the tail is bifid. It inhabits Carolina; the body above is bluish.

Galeatus. The second dorsal fin of this fish is fleshy; it has 24 anal rays, and the tail is entire. It inhabits South America. The head is covered with a hard corneous shield; the spiny rays of the pectoral and dorsal fins are rigid.

Carinatus. Second dorsal fin fleshy; the lateral line is spiny; the cirri under the lower lip are connected. It inhabits Surinam; the body is compressed.

Nigricus. The second dorsal fin of this fish is fleshy; the anal rays are ten in number. It is found in the Nile; is fourteen inches and a half long; the body is of a brownish-grey; the sides of the head are bluish; the end of the nose, under part of the head, pectoral fins and cirri, are tinged with red; there is a semicircle of red fin at the commencement of the tail.

Columbus. Second dorsal fin fleshy; anal rays eleven. It inhabits in the rivers of South America and Africa; is from twelve to fifteen inches long; the body is of a blackish-grey, beneath it is white; the head is in high esteem; the head is depressed, rounded on the fore part; a third part as long as the whole body; the fins are all spotted with black.

Asita. The second dorsal fin is fleshy; it has eighteen and rays. It inhabits India, and appears to be of a mixed kind between permaris and viviparous.

Cataleptus. Second dorsal fin single; a single row of scales on the sides; the tail is bifid. It inhabits South America and India.

Ceratophysus. Second dorsal fin of one ray; a single row of scales on the sides; the tail is entire. It inhabits South America.

Section D. Eight Cirri.

Species.

Asperdo. Dorval fin single, five-rayed. It is found in the rivers of America. The base of the lateral cirrui broad; the back cirrus; the anal fin reaching to the tail; the tail is forked.

Mythus. The dorsal fin is single, and single-rayed. It inhabits the Nile; the tail is forked.

Anguillaris. Dorval fin single, seventy-rayed. It is found in the Nile; the upper part of the head is greenish; the body above the lateral line is marked with blackish and grey; the belly and lower jaw are of a reddish-grey; the pectoral fins are transversely divided by a broad red band.

Batracus. Dorval fin is single, and sixty-rayed. It inhabits Asia and Africa; the tail entire.

Undecimalis. The dorsal fin is single, and eleven-rayed. It inhabits Surinam; the tail is forked.

Catus. Second dorsal fin single, and twenty-rayed. It inhabits Asia and America.

Cous. Second dorsal fin fleshy, anal eight-rayed; tail forked. It inhabits Syria; the cirri are shorter than the head.

Docmac. Second dorsal fin fleshy, anal ten-rayed. The length of the fifth of this species is about three feet. It is of a grey colour, whitish beneath: the head is depressed; body convex above; mouth furnished with eight beards, the exterior ones of the upper lip extending half the length of the body; the lateral line is straight, and situated nearer the back than the abdomen; the first ray of the dorsal and anal fins long and forked, with flat tips. It is a native of the Lower Nile, towards the Delta.

Bajad. Second dorsal fin fleshy, anal twelve-rayed. It is about a foot in length; the colour is glaucescent; the head obtuse, depressed, and marked on each side, before the eyes, by an unequal pit or depression; the upper jaw is longer than the lower; exterior beards of the upper lip very long; lateral line at first descending, but straight; above the pectoral fins on each side is a very strong spine, forked in a reversed direction; the fins are radiant; the second dorsal or adipose fin is long; the tail is long, directed towards the tip, and forked. It is a native of the Nile.

Vol. XXXII.
Section E. *Without Cirri.*

**Species.**

**Cornus**us. First ray of the first dorsal fin serrate; pectoral unarmed. It is not more than eight or nine inches long; the shape is oval; body carinated beneath; the fin is straight, compressed, a little recurved at the tip, and about half the length of the body; the first ray of the first dorsal fin extending as far as the middle of the tail, and serrated beneath for about half its length. It is a native of the Mediterranean.

**Imberbis.** The gill-covers with two spines on the hind part. It inhabits Japan, and is about six inches long; the body is funnel-shaped, reddish, and coated with scales. It is a native of the Indian and South American rivers.

**Silurus** is also a name given by some authors to the sturgeon, called by others *acipenser*, but by the generality of writers *florus*.

**Silurus Mons**, in *Ancient Geography*, a mountain of Hispania, in the vicinity of Beticca.

**SiliuuM**, a town of Aifa Minor, in the interior of Pamphylia. Ptolemy.

**Silvum**, in *Botany*, a name borrowed from Dioscorides, whose *coleos* is described as a large kind of thistle, eatable when young, if defried with oil and salt. A liquor, which exuded from its root, was given, in the dose of a drachm, mixed with water, to excite vomiting. Gartner, after Vaillant, has applied the name in quitation to a genus of his own, under which he brings together *Carduus marianus* and *Cnicus cernus* of Linnaeus, two very different plants.

**Sim**, in *Geography*, a river of Russia, which runs into the Yenisei; 6 miles N. of Balagovetschkenko; N. lat. 60° 10'. E. long. 90° 40'.

**Sim**, or *Cyma*, in *Architecture*, a term used by Wol- fius, and some other writers, for what we otherwise call *cymatum*, or *sinuam*.

**Simaba**, in *Botany*, the name of a shrub in Guiana, described by Aublet, 400. t. 153; for which, being barbarous, Schreber has substituted the more legitimate, if not more harmonious, one of *Zwingera*; fee that article hereafter.

**Simethus**, or *Simetus*, now *Giaretta*, or St. Paul, in *Ancient Geography*, a river in the eastern part of Sicily, which passed through the territory of the city of Leontini, and which was celebrated by the poets. The nymph Thalia, after her amour with Jupiter, is supposed to have been converted into this stream, which, to avoid the rage of Juno, sunk under ground near mount *Etna*, and continued this subterraneous course to the sea. In the time of the Romans it was navigable. It takes its rise on the N. side of *Etna*, and surrounding the west skirts of the mountain, falls into the sea near the ruins of the ancient Morganto. It does not now sink under ground; but throws up near its mouth great quantities of amber, which the peasants gather, and carry to Catanea, where it is manufactured in the form of croffes, beads, Saint's, &c. and is sold at very high prices to the superstitious people on the continent. There is a large sandy beach, that extends from the mouth of this river a great way to the S. of Catanea, and was, without doubt, continued the whole way to the foot of the mountain Tau-rimum; but it was broke in upon, at a remote period, by the lavas of *Etna*, which, from a low sandy shore, have now converted it into a high, bold, black iron coast.

After piercing through the lava, beds of shells and sea-fand have been discovered.

**Simalisceva**, in *Geography*, a town of Russia, in the government of Kolivan; 40 miles S.S.E. of Kolivan.

**Simana**, in *Ancient Geography*, a town of Aifa, in Bithynia, situated between two rivers.

**Simancas**, in *Geography*, a small town of Spain, in the province of Leon, near the confluence of the rivers Piuerga and Duero, celebrated for a white wine, that is very much esteemed. In the time of Philip II. it was a strong place, in which he ordered the archives of the kingdom to be kept. It was taken by the Moors in the year 967; 8 miles S.W. of Valladolid.

**Simar**, a town of Hindoostan, in the circuit of Gohud; 14 miles E. of Gohud.

**Simara**, one of the smaller Philippine isles; 24 miles E. of Mindanao. N. lat. 12° 5'. E. long. 121° 49'.

**Simaria**, a town of Naples, in Calabria Ultra; 4 miles N.E. of St. Severina.

**Simaroma**, a name given by the Spaniards in America to a species of vanilla, called also *bagourd-vanilla*. The pods of this kind are every way smaller than those of the true kind, and have very little liquor or pulp in them when broken and contain very few seeds. These are greatly inferior to the true kind, having scarcely any smell. It is not yet certainly known whether this species be the fruit of a different kind of vanilla-plant from the common, or whether it be the fruit gathered at a different season, or from a plant growing in a different soil. See *Vanilla*.

**Simarones**, in *Geography*, a town of the island of Cuba; 105 miles E. of Havanna.

**Simaruba**, or *Simaruba*, in *Botany*, is the bark of the roots of a tree, first imported into Europe in the year 1715, but not long ago botanically ascertained to be a species of the *Quassia*; which fee.

**Simarouba**, or *Simarriba*, in *Materia Medica*. This bark, according to Dr. Wright's account of it, is rough, scaly, and wanted. The infuse, when fresh, is a full yellow, but when dry, paler: it has but little smell: the tafte is bitter, but not disagreeable. Macerated in water, or in rectified spirit, it quickly impregnates both menstrua with its bitternefs, and with a yellow tincture. It feems to give out its virtue more perfectly to cold, than to boiling water; the cold infufion being rather stronger in tafte than the decoction; which, left, of a tranparent yellow colour whilft hot, grows turbid and of a reddifh-brown as it cools. The milky appearance, which Juffieu fays it communicates to boiling water, Dr. Wright has not obferved in the decoction of any of the fpecimens which he has examined.

The bark was first fent from Guiana to France, in 1713, to the count de Porchertrain, then fecretary of flate, as a remedy of great efteem in dysentery. In the years 1718 and 1723, an epidemic flux prevailed very generally in France, which refifted all the medicines usually employed in fuch cafes; small doses of ippecacua, mild purgatives, and all afftringents, were found to aggravate, rather than to re- lieve, the difafe: under these circumftances, recourse was had to the bark simaruba, which proved remarkably succifeful, and firft eftablifhed its medical character in Europe. Dr. Wright fays, "'t molt authors who have written on the simaruba, agree, that in fluxes it refores the left tone of the intertines, allays their fpasmodic motions, promotes the fcrotions by urine and perifpiration, removes that lownefs of spirits attending dysenteries, and difpoles the patient to sleep; the gripes and tenefmus are taken off, and the floofs are changed to their natural colour and confiftence. In a moderate dose it occasions no disturbance or uneafinefs, but in large doses it produces ficknefs at the stomac and vomiting."

*Modern*
Modern physicians have found from experience, that this medicine is only successful in the third stage of dyestery, where there is no fever, where too the flux is no way hurt, and where the gripes and tenesmus are only continued by a weakness of the bowels. In such cases, Dr. Mann gave two or three ounces of the decoction every five or six hours, with four or five drops of laudanum; and found it a very useful remedy. The late Dr. T. Punge, Dr. Hock Saunders, and others, preferred the cortex fumaruba in old and obstinate dysesthsias and diarrhœas, especially those brought from warm climates. Fluxes of this sort, which were brought home from the hedges of Martinique and the Havannah, were completely and speedily cured by this bark.

The urine, which in these cases had been high-coloured and scanty, was now voided in great abundance, and peroration restored. Dr. James Lind, at Haslar Hospital, says, that the fumaruba produced these effects sooner, and more certainly, when used in such quantity as to nauseate the stomach. Dr. Hock Saunders remarks, that if the fumaruba did not give relief in three days, he expected little benefit from its farther use, but others have found it efficacious in fluxes, after a continued use for several weeks. My own experience, and that of many living friends, are convincing proofs to me of the efficacy of this medicine, and I hope the fumaruba bark will soon be of more general use."

Dr. Wright recommends two draughts of the bark to be boiled in twenty-four ounces of water to twelve; the decoction is then to be strained and divided into three equal parts, the whole of which is to be taken in twenty-four hours, and when the fumaruba is reconciled to this medicine, the quantity of the bark may be increased to three draughts.

To this decoction some join aromatics, others a few drops of laudanum to each dose.

Dr. Cullen says, that the virtues ascribed to fumaruba have not been ascertained by his own experience, or that of the practitioners in Scotland. Wood's Med. Bot.

SIMAROW, in Geography, a town of Hindooistan, in Bahar; 13 miles S.S.W. of Arrah.

SIMARUM MUSCULUS, in Anatomy, a name given by some of the old writers to a muscle, called by the moderns the ferratus magnus.

SIMAS, in Ancient Geography, a promontory in the Euxine sea, on which Venus had a temple.

SIMATIUM, or SIMATESE, in Architecture. See Cymatium.

Simatium and cymatium are generally confounded together, yet they ought to be distinguished; the latter being the genus, and the former the species.

Simatum, of Sima, camous, according to Celsius, is the leaf and uppermost member of grand cornices, called particularly the great doucie, or guila reta; and by the Greeks, epigastia.

In the antique buildings, the simatum, at the top of the Doric cornice, is generally in form of a cavetto, or femfis; as we see particularly in the theatre of Marcellus. This form modern architects have imitated; but, in the Ionic order, the simatum is always a doucie.

The simatium, or doucie, then, is distinguished from the other kinds of cymatia, by its being camous or flat-nosed.

SIMBALATH, in the Materia Medica, a name given by Avicenna and others to the spikenard, or nardus Indica.

The exact interpretation of the word is spigerica, and Avicenna, under this general name, distinguishes it into several kinds; the first he calls abardin, or nardin. It has been supposted by some that he means the Indian spikenard by this word; but, on the contrary, it appears plainly that he means the Celtic nardus: he calls it: the nardus Ranna, and says that it is of European growth. After this he mentions the Asiatic nardus of several kinds, which is the Indian spikenard, growing in different places, and each as used to be brought thence in different degrees of perfection.

SIMBANAI, in Geography, a tract of country in Asia, adjoining with woods, and uncultivated, lying between the kingdom of Wushih to the north-west, Fouta Terr to the north, Bandou to the north-east, and Tenda to the south-west.

SIMLING, a town of Atesta, in Ludamar; 5 miles S.W. of Jarra.

SIMELSK, a town of Roffia, and capital of government, on the Volga; 385 miles E.S.E. of Moscow. N. lat. 54° 25'. E. long. 48° 30'.

SIMBERSKOE, a government of Russia, bounded on the north by Kazan, on the west by Nizhgorodskoe and Penzeuskoe, on the south by government of Saratov, and on the east by Uplinskoe; about 180 miles from east to west, and 140 miles from north to south. N. lat. 52° 20' to 55° 30'. E. long. 45° to 51°.

SIMBOLAN, a town of South America, in the province of Tucuman; 85 miles S.E. of Rioja.

Def. Ch. Stem annual, a foot high, simple, slender, erect, round, with some appearance of angles. Leaves scattered, near to each other; linear, thread-shaped: the upper ones simple, half an inch long; lower an inch long, in two deep, pointed, smooth divisions. Calyx terminal, four inches in length. Flowers solitary, drooping, on short stalks, with a short, linear, leafy bracteae under each. Calyx a perianth of one leaf, bell-shaped, permanent, in five linear equal segments. Corolla of one petal, ringent, white; tube bell-shaped, longer than the calyx; upper lip of the limb reflexed, cloven; lower long, three-lobed, straight, its middle lobe reflexed. Filaments four, inserted into the corolla, two of them long. Anthers four, black, united into a quadrangular compressed plate. German ovate. Style thread-shaped. Stigma capitate, ovate, nearly globose, oblique. Fruit not observed. The aspect of the plant is exactly that of a Refeds or Polygala; it moreover approaches the character of Columnea, as to the combined anthes, but differs in many other respects." Found on mount Kurma, and no where else, by Forskall, whose description has not enabled any learned botanist to guess at the plant, except that Jussieu thinks it may be akin to Vironica, or to Aublet's Pinipes. We should rather suspect an affinity to Anthericum.

SIMCOE LAKE, in Geography, a lake of Upper Canada, formerly lake Aux Claires, situated between York and Guelph, and communicating with Lake Huron. It has a few small islands, and several good harbours.

SIMELLIUM, a Latin term used by some to signify a table, with ranges of little coverets in it, for the disposing of medals in chronological order. The word is bis ill written; it should rather be simelium, as being formed of the Greek simelion, curiosities, or a cabinet of precious things.

We more usually say, a cabinet of medals, than a simelium.

SIMENA.

SIMENAU, in Geography, a town of Paphia, in the province of Oberland; 8 miles E. of Salced.

SIMEON, in Scripture Biography, a son of Jacob and Leah, born in the year 1775 B.C. (Gen. xxix. 37.) Simeon and Levi revenged the affront, sustained by the defilement of their half-sister Dinah on the part of Schechem, the son of Hamor, by entering the town of Schechem, and killing all the men they found; after which they brought away Dinah, in the year 1739 B.C. (Gen. xxxiv. 25.) It has been thought that Simeon was the most cruel to his brother Joseph, and that he advised his brethren to sell him. (Gen. xxxvii. 20.) The conjecture is founded on the circumstance of his being a retained prisoner in Egypt (Gen. xlix. 24.), and of his being treated with greater rigour by Joseph than the rest of his brethren. Jacob, on his death-bed, manifested peculiar indignation against Simeon and Levi. (See Gen. xlix. 5.) Accordingly the tribes of Simeon and Levi were dispossessed in Israel. Levi had no compact lot or portion; and Simeon received for his portion only a district dismembered from the tribe of Judah (Joth. xix. 1, 2, &c.), and some other lands which were over-run by those of this tribe on the mountains of Seir, and in the defart of Gedor. (1 Chron. iv. 24. 39. 42.) The Targum of Jerusalem, and the rabbins, who have been followed by some of the fathers, have affirmed, that the greater part of the scribes and men learned in the law were of this tribe; and as these were dispersed throughout Israel, we perceive the accomplishment of Jacob’s prophecy, which foretold that Simeon and Levi should be scattered among their brethren. It has been suggested, however, that the dispersion of Simeon and Levi, which Jacob meant to be a degradation, was in the progress of events over-ruled so as to be an occasion of honour; for Levi had the priesthood, and Simeon had the learning or writing-authority of Israel; in consequence of which both these tribes were honourably dispersed throughout Israel. According to the testament of the twelve patriarchs, a book indeed of no authority, Simeon died at the age of 120 years.

The sons of Simeon were six, and are enumerated Exod. vi. 15. Their descendants amounted to 59,300 men, at the Exodus (Num. i. 22.) but the number of those that entered the Land of Promise amounted only to 23,200, the rest having died in the desert. (Num. xxxvi. 14.) The portion of Simeon was well and south of that of Judah; having the tribe of Dan and the Philistines north, the Mediterranean west, and Arabia Petrae south. Joth. xix. 1—9. Calmet.

Simeon is also the name of that aged and pious person, mentioned Luke, ii. 25, 26, to whom Jesus Christ was presented by his parents in the temple, and who pronounced upon them his blessing. It is believed, with good reason, that he died soon after he had borne his testimony to Christ. Some, indeed, have pretended, that this Simeon was the same as Simeon the just, the son of Hillel, and master of Gamaliel, whose disciple St. Paul was.

Simeon, or Simon, was also the name of our Lord’s cousin-german, son of Cleophas and of Mary, the sister of Christ’s mother, probably the same with him who is named Simon by St. Mark (ch. vi. 3.) He was probably one of our Lord’s first disciples. -According to Eusebius, he was unanimously elected bishop of Jerusalem, after the death of St. James, A.D. 62. When the emperor Trajan made strict inquiry for all who were of the race of David, Simon was accabloue A'ticus, the governor of Palestine; and having endured many sufferings with a fortitude which astonished observers, at the age of 120 years, he was crucified about A.D. 107; so that he had superintended the church of Jerusalem about 43 years. The Latins place his feast February 18, the Greeks April 27.

Simeon, in Biography, the son of Jochai, a very celebrated man among the Jews, was a scholar of the rabbi Akiba, and flourished about the year 120. At the insurrection excited by Barchocheba, he fled, through fear of the Romans, and retired to a cave, where he concealed himself twelve years, in the course of which he is said to have composed his works, entitled “Sohar,” which is an expansion of the five books of Mosis. This, from its abstract manner, and the matter being clothed, according to the Egyptian method, in hieroglyphical images and very florid language, is not easily understood. There are several editions of it, but its exact age is not known. It contains things that are very old; but it is admitted by Christians, as well as Jews, who held it in esteem, to be the production of more authors than one, and to have been enlarged, from time to time, by various additions. Gen. Biog.

Simeon, surnamed Metaphraxes, an ecclesiastical writer, lived in the tenth century, under Leo the philosopher and his son Constantine Porphyrogenitus. He was a native of Constantinople, and rose to high employments at court, having been secretary to the emperors, and the medium of communication between them and foreigners. His writings indicate a man conversant in ecclesiastical affairs. He derived his surname of Metaphrastes, or Translator, from his occupation of writing again, in a different style, not transplanting, the lives of the saints. In this business he evidently meant to give a panegyric, rather than a true history: whence he has made additions and alterations at pleasure, so that the subjects are represented not as they were, but as he imagined they ought to be. His “Lives of the Saints” have several times been translated into the Latin language. Simeon likewise composed sermons, hymns, and prayers, with various pieces of the religious kind, of which some have been printed, and others remain in manuscript.

Simeon, named Stylites, a distinguished person in the annals of fanaticism, was born about the year 392 at Sifon, a town on the borders between Syria and Cilicia. He was the son of a shepherds, and followed the fame occupation to the age of thirteen, when he entered into a monastery. After some time he left it, in order to devote himself to a life of greater solitude and austerity, and he took up his abode on the tops of mountains, or in caverns of rocks, fasting sometimes, it is said, for weeks together, till he had worked himself up to a due degree of extravagance. He then, to avoid the concourse of devotees, but probably to excite still greater admiration, adopted the strange fancy of fixing his habitation on the tops of pillars, whence the Greek appellation; and with the notion of climbing higher and higher towards heaven, he successively migrated from a pillar of 6 cubits to one of 12, 20, 36, and 40. This feat was considered as a proof of extraordinary anxiety, and multitudes flocked from all parts to pay their veneration to the holy man, as he was denominated. Simeon palled 47 years upon his pillars, exposed to all the inclemency of the seazons. At length a horrible ulcer put an end to his life, at the age of 69. His body was taken down from his last pillar by the hands of bishops, and conveyed to Antioch, with an escort of 6000 soldiers; and he was interred with pomp equal to any thing that had been displayed for the most potent monarchs. He has been enrolled among the saints, either in the Greek or Latin churches. These honours produced imitators, whose performances surpassed the original. One of them inhabited his pillar 68 years.

8 The
The madder remained in vogue till the twelfth century, when it was supplanted.

SIMON BEN JOCHAI. See CARRARA.

SIMERCEHLT, in Geography, a town of Bohemia, in the circle of Bollelaw; 4 miles N. of Melnik.

SIMEREN, a river of Syria, which runs into the Euphrates, at Rojekia.

SIMERING, a town of Austria; 4 miles S.S.E. of Vienna.

SIMI, or Simi, an island in the Mediterranean, between the island of Rhodes and the continent of Asia; 6 miles N. of Rhodes. N. lat. 36° 10'. E. long. 37° 34'.

SIMIA, in Natural History, a genus of the clava and order of Mammalia Primates, of which the generic character is, that the individuals have four front teeth in each jaw, which are approximate; the tusk is shorter, longer, and more remote; the grinders obtuse. The animals of this genus greatly resemble man in the uva, eye-lashes, hands, feet, fingers, toes, nails, and other parts of the body; they, however, differ widely in the total want of reason: they have retentive memories, are imitative, and full of gesticulations; chatter with their teeth, and grin; they macerate their food in the cheeks before they swallow it: they are filthy, lascivious, thieves, gregarious, and the prey of leopards and serpents, the latter pursuing them to the summits of trees and swallowing them entire.

This race of animals, which is very numerous, is almost confined to the torrid zone: they fill the woods of Africa, from Senegal to the Cape, and thence to Ethiopia: a single species is found beyond that line, in the province of Barbary: they are found in all parts of India, and its islands; in Cochinchina, in the south of China, and in Japan; and one kind is met with in Arabia: they swarm in the forests of South America, from the sierras of Darien as far as Paraguay.

These animals, from the structure of their members, have many actions in common with the human kind; most of them are fierce and untameable; some arc of a milder nature, and will have a degree of attachment: they feed on fruits, leaves, and insects; inhabit woods, and live in trees: they go in large companies. The different species never mix with each other, but always keep apart: they leap with great activity from tree to tree, even when loaded with their young, which cling to them: they are not carnivorous, but, for the sake of mischief, will rob the nests of birds of the eggs and young: and it is observed, that in those countries where apes most abound, the feathered tribe discover singular sagacity in fixing their nests beyond the reach of these invaders.

Mr. Ray first distinguished the animals of this genus into three classes, viz. the simia, or apes, such as want tails; the cercopitheci, or monkies, such as had tails; and papionces, or baboons, those with short tails.

From Ray, Linnaeus formed his method, which was followed by M. de Buffon, who made a farther sub-division of the long-tailed apes, or true monkies, into such as had prehensile tails, and such as had not.

The genus is divided into the following sections:

Section A. Apes without any tail.

— B. Baboons with short tails.

— C. Monkies. Tails long, not prehensile; cheeks pouched; haunches naked.

— D. Sapajous. Tails prehensile; no cheeks pouched; their haunches are covered.

— E. Sagoons. Tails not prehensile; no cheeks pouched; haunches covered.

Of the whole genus, says Dr. Shaw, it may be observed that the baboons are uniformly of a less size, and well disposed. The larger apes are also of a less useful temper, except the orang-outang and the gibbons. The monkies, properly so called, are extremely various in their disposition: some of the smaller species are lively, harmless, and entertaining; while others are as remarkable for the mischievous malignity of their temper, and the capricious uncertainty of their manners. It is no easy task to determine with exact precision the several species of this extensive genus; since, exclusive of the varieties in point of colour, they are often nearly allied, so as to make it difficult to give real and distinctive characters. We shall, as usual, follow Gmelin’s Systema Naturae of Linnaeus, in which there are sixty-four species delineated.

Section A. Apes without Tails.

Species.

THOUGHTINES, of Angola Ape. The generic character is, that the head is conic, body brawny, back and shoulders hairy, the rest of the body smooth.

SATYRUS; Orang-outang. Ruddy-brown, hair of the forehead reversed, haunches covered. Befides this there are two varieties: 1. Without cheek-pouches, or callosities on the haunches. This variety always walks erect. Its trivial name is Pongo. It inhabits Java and Guinea, and is from five to six feet high. 2. The other variety resembles the former, but is above half as high: it is docile, gentle, and grave, and by some thought to differ from the other only in age.

Of these animals, the species which has most excited the attention of mankind is the orang-outang, or, as it is often denominated, the satyr, great ape, or wild man of the woods. It is a native of the warmer parts of Africa and India, and also of several of the Indian islands, where it resides principally in the woods, and is supposed to feed, like most other of this genus, on fruits. The orang-outang appears to admit of considerable variety in point of colour, size, and proportion; and there is reason to believe, that in reality there may be two or three kinds, which, though nearly approximated to general similitude, are yet specifically distinct. The specimens imported into Europe have rarely exceeded the height of two or three feet, though full-grown ones are said to be six feet in height. The general colour seems to be of a dusky brown; the face is bare; the ears, hands, and feet nearly similar to the human; and the whole appearance is such as to exhibit the most striking approximation to the human figure. The likeness, however, is only general, and will not bear the test of examination; and the structure of the hands and feet, when observed with anatomical correctness, seems to prove that the animal was principally designed by nature for walking on four legs, and not for an upright posture, which is only occasionally assumed, and which is thought to be the effects of instruction rather than truly natural.

The manners of the orang-outang, when in captivity, are gentle, and perfectly void of that divulging ferocity which is often conspicuous in some of the larger baboons and monkies. It is mild and docile, and may be taught to perform a variety of actions in domestic life. But, however docile and gentle when taken young, and instructed in its behaviour, it is possessed of great ferocity in its native state, and is considered a very dangerous animal, capable of readily overpowering the strong man. Its swiftness is equal to its strength; and hence it can rarely be obtained in its full-grown state.
M. Volfnaer's account of the manners of the orang-outang brought into Holland in 1776, and presented to the prince of Orange, is nearly as follows. It was a female, about 2½ Rhenish feet. It th ewed no symptoms of fierceness and malignity, and was of rather a melancholy appearance. It was fond of company, and th ewed a marked preference to those who took daily care of it, of which it seemed very sensible. When the company retired, it would frequently throw itself on the ground, as if in despair, uttering lamentable cries, and tearing in pieces the linen within its reach. Its keeper having sometimes been accustom ed to fit near it on the ground, it took the hay off its bed and laid it by its side, and seemed, by every demonstration, to invite him to be seated near. Its usual manner of walking was on all fours, but it could walk on its two hinder feet only. One morning it got unchained, and was seen to ascend the beams and rafters of the building with wonderful agility, and it was with the utmost difficulty retaken and secured. During its state of liberty it had taken out the cork from a bottle of Malaga wine, which it drank to the last drop. It would eat every thing that was offered, but was not observed to hunt for insects like other monkeys; it was fond of eggs, but fifth and roasted meat seemed its favourite food. It had been taught to eat with a spoon and fork. Its common drink was water, but it would drink any kind of wine. At the approach of night it lay down to sleep, and prepared its bed by shaking well the hay on which it slept, and putting it in proper order, and laffy covering it with a overlet. This animal lived seven months in Holland. On its first arrival, it had but little hair, except on its back and arms, but on the approach of winter it became well covered, and the hair on the back was full three inches long. The whole animal then appeared of a chestnut-colour; the skin of the face, &c, was of a moufle-colour, but about the eyes and round the mouth it was of a dull fhef colour. It was imported from the island of Borneo. See orang- outang.

In Dr. Gmelin's edition of the Syllena Natura, fays Dr. Shaw, the smaller variety, or the jockey, in its left flabby or more naked state, is given as a distinct species under the name of S. tragalodes. The print published many years past, by the name of Chimpanzee, is of this kind. (See Chimpanzee.) The animal described in the 35th volume of the Phil. Trans. is by Gmelin referred to the orang-outang; but Mr. Pennant describes it under the title of Golek. It has a pointed face; long and flender limbs; arms, when the animal is upright, not reaching lower than the knees; head round, and full of hair; grows to the height of a man. It inhabits the forests of Mewa, in the interior parts of Bengal. In its manners it is gentle and modest, distinguished from the orang-outang by its slender form. In colour it is entirely black. In the Philological Transacti ons the description is as follows. "The animal is said to be the height of a man, the teeth white as pearls; the arms in due proportion, and the body very gentle."

Lab, or long-armed Ape, has its haunches naked; its arms as long as its body; it is found in India, is gentle, slothful, impatient of cold and rain, and is four feet high. There are two other varieties, of which the first is about eighteen inches high, the face and body brown. The second has its body and arms covered with silvery hair; the face, ears, crown, and hands, are black. It inhabits the forests of Deval, in Bengal; is playful, gentle, and elegant; about three feet high. The lar, or, as it is sometimes denominated, the gibbon, is distinguished by the length of its arms, which, when the animal stands upright, are capable of touching the ground with its fingers; hence its trivial name. Notwithstanding the apparent ferocity of the lar, and the deformity of its figure, which is extremely well given by Dr. Shaw, it is of a tractable and gentle nature, and has even been celebrated for the decorum and modesty of its behaviour. Considered with respect to the rest of the genus, it ranks among the genuine apes, or those which have not the leath velvety of a tail; and, says the naturalist already quoted, alarms the fear of mankind, by too near an approach to the real primates of the creation.

Sylvanus; Pigmy. Haunches naked; head roundish; arms shorter. It inhabits Africa and the island of Ceylon; is mild and easily tamed; it uses threatening gestures when it is angry, challengers when pleased, falutes after the manner of the Hottentots, and drinks from the palm of the hand. The face is short and flat; the forehead tranferfully projecting at the regions of the eye-brows; the skin is rough; the hair on the neck and fore-arms revered; it is about eighteen inches high.

Nimus; denominated by Buffon the Magot, and by Pennant the Barbary Ape. Its haunches are naked, and the head oblong. Habits Africa; is fond of the open air, deformed, dirty, and melancholy. It a good deal resembles the S. sylvanus, but its fnaus is longer, colour paler, nails rounded, and is about three feet and a half high. This is what is commonly seen in the exhibition of such kind of animals; it is not remarkable for docility or good temper; but, by force of discipline, it is made to exhibit a greater degree of intelligence than many others. Its colour is an olivaceous-brown, paler or whiter beneath; the face is of a swarthly flesh-colour. The hands and feet have nails resembling the human. It is deft of any real tail, but there is commonly a short skinny appendix in the place of one.

This animal inhabits many parts of India, Arabia, and all parts of Africa, except Egypt, and a small number is found on the hill of Gibraltar, which breed there. These apes are very ill-natured, mischievous, and fierce, agreeing with the character of the ancient cynocephali; they are often exhibited to play tricks; assemble in great troops in India; and will attack women going to market, and rob them of their provisi ons. The females carry their young in their arms, and will leap from tree to tree with them.

Nemestrina; Beard thin; colour grey; eyes hazel; haunches naked. It inhabits Sumatra and Japan; is lively, gentle, tractable, and impatient of cold. The face is naked and tawny; the nose is flat; lips thin, with hairs resembling whiskers; hair on the body olive-black; belly reddish-yellow; it is about two feet high. This species is figured by Mr. Edwards, who was in possession of the living animal, and who, in order to compare his specimen with a much larger animal of the same species, carried it to Bartholomew fair, and he said they seemed highly delighted with each other's company, though it was the first time of their meeting; the best figure of this species is said to be that given by Buffon.

Apeida; Little Baboon. Thumb close to the fingers; nails oblong, thumb-nails rounded; haunches covered. This is an inhabitant of India. The nails are oblong and compressed, except the thumb and great toe-nails, which resemble those of a man; the tail is scarcely an inch long; the face is brown, with a few fattered hairs.

Simia; Great Baboon. Mouth with whiskers; nails acuminate; haunches naked. This is found in the island of Borneo; it is laicous, robust, and fierce; it feeds on frutta.
It is chiefly fed on leaves and seeds; it makes great havoc in the produce of cultivated lands. "The head is oblong, reflecting that of a dog, but more obtuse; the neck is long; the tail is short and everted; the cheeks are red, edged with purple; it is from three to four feet high in its sitting posture. It is extremely fierce and will attack its preserver, and it is much larger than its fields. It is also very destructive to the crops, and its appearance has been described as grotesque and formidable. The region surrounding the tail is of a considerable size on each side and callous. It is a native of Bar neo, and inhabits the hotter parts of Africa.

MOMENIUS: Tufted Ape. Beard thin; cheeks tumid, naked, blue, obliquely furrowed; hairs naked, red. It inhabits India. Its, an upright posture, is full five feet high. It is the most remarkable of the whole genus for brilliancy and variety of colour. The general tinge is a rich and very deep yellowish-brown; the hair, if viewed near, are speckled with yellow and black. The form of the face is large, and with the front ending somewhat abruptly; the whole length of the nose, down the middle, is of a deep blood-red; but the parts on each side are of a fine violet-blue, marked by several oblique furrows. The remainder of the face is of a pale bluish-yellow. On the top of the head the hair rises, in a remarkable manner, into a pointed form, and beneath the chin is a pointed beard of a light-orange-yellow. Round the back of the neck the hair is much longer than in other parts, and inclines downwards and forwards, somewhat in the manner of a wreath or tippet. The hands and feet are of a dusky colour, and are furnished with broad pointed claws. It is a native of the interior parts of Africa, but has been found in India.

MADRASIAN: Ribbed-noose Ape. Beard thin; cheeks blue, flat; haunches naked. It inhabits Ceylon. It washes and grooms like men, when in trouble; it is libidinous, ugly, and disgusting. The general likeness which it bears to the former species is such as to give the idea of the same animal in a less advanced state of growth, and with less brilliant colours. The chin is furnished with a small sharp-pointed beard of a pale orange-colour. The feet are armed with claws, and have no flattened nails. This baboon is not uncommon in exhibitions of animals.

FORCARIUS: Hog Baboon. The head of this species resembles that of a hog; the snout is naked; the body of an olive-brown; the haunches are covered, and the nails are acuminate. It is said to be three feet six inches in length; its colour is of a deep olive-brown; the face is large and black; the nose is truncated at the end, somewhat like that of a hog.

SYVATICA; Wood Baboon. Face, hands, and feet naked, black, smooth; nails white. It inhabits Guinea, and is about three feet high. It is of a robust frame. Its general colour is ferruginous, owing to the alternate black and brown rings with which every hair is marked, and which give a kind of speckled appearance to the whole. The nails on the hands are long, but rounded at their extremities; those on the toes longer and acuminate. The face on each side the tail is large, bare and red; the tail is about three inches long.

VARIEGATA; Yellow Baboon. This species is of a bright yellow colour mixed with black; the face is long, black, naked; the hands are covered on the back with hair. It very much resembles the Sylvia, and is found in Africa. Above the eyes are several long dusky hairs: it is about two feet high.

CINEREA; Cinerous Baboon. The face of this is dusky; the beard is of a pale brown; the crown is variegated with yellow; the body is brown. It is found in divers parts of Africa, and is about two feet high.

LAVEA; Blue-faced Baboon. The face of this species is bluish; it has two broad flat ears behind; the beard is pale brown. Over the eyes are long hairs; the ears with a tuft of hair behind each; the hair is black mixed with a yellow-brown; this is three feet high.

PROCTES; Brown Baboon. The face is of a dirty white, furrowed with faint bright yellow. The upper part of the body is brown; under ears; tufted, almost bare; it is naked beneath. This species, according to La Cépède, is the same with the long-legged baboons described in the addition to Buffon. The figure there given is the same that in Mr. Percival's Quadrupeds.

The distinguishing characters of the animal seems to be the great length of its limbs.

CHRISTA; Cretted Baboon. It is covered with the hair on the crown of the head and back is long and shaggy. The body is covered with long black hair; the breast is white; the face, hands, and feet are black and naked; the tail is tapering, and about seven inches long; the animal is two feet high. It is an inhabitant of India.

SECTION C. MONKEYS WITH LONG TAILS, THAT ARE NOT PREHENSILE; THE CHEEKS ARE POWdered, AND THE Haunches naked.

CYNORHUSAURUS; Dog-tailed Monkey. It has a beard; the face is long; the forehead high; it has a white band over the eyes; male genitals coloured; the nails are convex. It is about two feet high, and is said to be faithful, retifles, and laconical. The face of this animal appears uncommonly mild and placid. It was very fond of fruit, which it should occasionally rub over its body in a very ridiculous style.

HAMADRYAS; Tartarian Monkey. This is defended as cunous; the ears are hairy; the nails sharp; the haunches red. It inhabits Africa, is fierce and very singular in its appearance. The face is prominent; the nose smooth and red; the ears are pointed, and almoht hidden in fur; the hair on the sides of the head, and as far as the waist, long and shaggy; the nails of the fingers are flat, those of the toes acute and narrow; it is about five feet high. There is a variety, of which above the forehead is prominent, terminating in a ridge. It inhabits the Cape of Good Hope, is very gregarious, pillages gardens, and is watchful of surprise; the head is large; the nose is long and thick; the ears short; the crown is covered with long upright hairs; the body is rough and hairy; the tail is about half the length of the body, arched at the end; the nails are flat and rounded; the haunches are red, and the animal is from four to five feet high.

CEPTER; Lowando. The beard is black; the body color is white. There is a variety with a white beard. It is found in Ceylon, is wild, ferocious, and mischievous. The tails of this species are long and large; the head is surrounded with a broad mane; the body is long and tapering, it is between three and four feet high.

SIHINUS; Wanderer. The beard of this animal is long and black; and the body is black. There are three other varieties of this species. The first has a white beard, it is found in Ceylon, and other parts of India. The second is of a jet black colour; the beard is white, and very long; it inhabits Guinea, and is about two feet high. The third has a white beard, which is triangular, short, and pointed, extending on each side beyond the ears. It inhabits Ceylon, is harmless, and lives in the woods; it feeds on leaves and buds, and is easily tamed; the body is black; the face and
hands are purple; the tail is long, ending in a dirty white tuft.

**Fauns; Malbrouck.** This species is bearded; the tail is bushy at the end; it is an inhabitant of Bengal; the face is grey; the eyes are large; the eye-lids are fuscous, instead of eye-brows; the ears are large, flesh-coloured; body is blackish; the breast and belly are white; the beard is hoary and pointed: it is scarcely a foot high.

**Cynomolgus; Long-tailed, bearded monkey, with callotactis behind, rising bid ft oolrids, and arched tail.** This by Pennant is called the Hare-lipped monkey, who includes in the species the cynomolgus and cynocephalus of Linnaeus. It is of a thick clumsy form, resembling the Barbary ape, except in having a long tail. It varies in size very greatly; some specimens scarcely exceed the size of a cat, while others are full as large as a grey-hound. The colour also is various, being sometimes olive-brown, at other times grey-brown. The head is large; the eyes are small; the nose thick, flat, and wrinkled; on each side the tail is a bare space; the under sides of the body, and the infides of the limbs, of a light ash-colour. It is a native of Guinea and Angola. The oolrids are divided like those of a hare.

**Cynocephalus; Dog Monkey.** This has no beard; it is of a yellowish colour, has a projecting mouth, a straight tail, and bald haunches. It is found in divers parts of Africa, and resembles the S. imus, except that it has a tail.

**Diana; Spotted Monkey.** This species is bearded; the forehead is projecting; the beard is pointed. This is described by Mr. Pennant as of a muddling size, and of a reddish colour on the upper parts, as if tined, and marked with white specks; the belly and chin are whitish; the tail is long. According to Linnaeus, it is of the size of a large cat, and is black, spotted with white; the hind part of the back is furrowous; the face is black; from the top of the nose is a white line, passing over each eye to the ears in an arched direction.

**Sapea; Green Monkey.** This animal has no beard; it is of a yellowish-green colour; the face is black; the tail is grey; the haunches naked. It inhabits the Cape de Vernd, the Cape de Good Hope, and other neighbouring countries. The body in the upper parts is a mixture of grey, green, and yellowish; throat, breast, belly, and thighs are white; the hairs are long and reverber; the eye-brows are black and brightly; the tail is straight, as long as the body, and hoary; the feet are cinereous; the nails round, thoof the ears ovate. It is about the size of a cat.

**Cephus; Mouflache.** Tailed; cheeks bearded; crown yellowish; feet black; tail rufly at the point. It inhabits Guinea. The body above is brown; beneath it is of a blueish-white; the head with white erect hairs; eye-brows with a white tranverse arch; upper eye-lids white; hair on the cheeks standing out; the mouth is blueish; under the ears are two large tufts of yellow hairs, like muffachios.

**Ethiop; White eye-lidded Monkey.** This is without tail and beard; the fore-top is white, erect; the arch of the forehead is white. There is a variety, of which the neck and cheeks are surrounded with a broad collar of white hair. It is found in Madagascar. Its face is thick and round; the eyes are surrounded by a prominent ring; the eye-lids are naked, very white; the ears are black, almost naked; the tail is arched, covered with long bulby hair: it is about eighteen inches high.

**Aygula; Egret.** This is tailed, the beard is scanty; the colour is grey; crown with an erect tuft of hair revered longitudinally. It inhabits India and Java. The body is a good deal like that of a wolf; the throat, breast, and belly whitish; the tail is longer than the body, cinereous, and tapering; the face is flattish, whitish, naked; the nose is depressed; the ears, and distant from the mouth, with a double furrow on the upper lip; the cheeks are a little bearded; the hairs are turned back; the eye-brows are gibbous, briskly, prominent; the feet are black, semi-palmate; the nails of the thumbs and great toes are rounded, the rest oblong; the ears are pointed; an arched summit from the ears towards the eyes and back to the base of the lower jaw, and a longitudinal seam on the fore-arm. There is a variety that has a rounder head; the face is less black; the body is of a paler brown.

**Nictitans; Tailed, bearded, black, sprinkled with pale spots; the nose is white; the thumb very short; the haunches are covered. This is called the Nodding monkey. There is a variety of it having a long white beard. It inhabits Guinea, is playful, and continually nodding its head. The face is hairy; the mouth short; the orbits naked; the irids of a pale yellow; the hair is black, with a few pale rings; lips and chin whitish; the tail is straight, cylindrical, longer than the body; the thumb is not longer than the first joint of the fore-finger.

**Sinica; Chinese Monkey.** Tailed, bearded; fore-top horizontally placed, and flading the whole head. There is a fore-top erect, having the appearance of a round black bonnet; the body is brown; the legs and arms black. The species is found in Bengal, and the variety in India. The tail is longer than the body; the hairs of the former and great toes are rounded, the rest oblong; the upper parts of the body are pale brown, mixed with yellow; the lower whitish. It is about the size of a cat.

**Nemius; Cochinchina Monkey.** This is without tail and beard; the cheeks are bearded; and the tail white. It inhabits, as its trivial name imports, Cochinchina, also Madagascar, and other places. The face and ears are of a light red; the forehead is marked with a double brown band, covered with black hair; the hair surrounding the face is whitish, mixed with yellow; neck, on the upper part, with a wreath of the fame colour as that of the forehead; the shoulders and upper parts of the arms black; hands and groin whitish; thighs on the upper part and toes black; feet to the knees brown; it is from two to four feet high. From this species is procured the bezwar of the ape.

**Mona; Varied Monkey.** This species is tailed and bearded; it has a prominent whitish-grey semi-lunar arch over the eye-brows. It inhabits Morocco, and the warmer parts of Asia; is gentle, docile, and patient of cold. The head is small and round; the face is bright, and of a tawny brown; the hair on the crown is yellow, mixed with black; it has a dark band from the eyes to the ears, and to the shouldlers and arms; tail is greyish-brown; the rump is marked with two white spots on each side. It is eighteen inches high.

**Rubra; Red Monkey.** This species is tailed and bearded; the cheeks are bearded; the crown, the back, and the tail, are of a deep blood-red. There are two other varieties; the first has a yellow beard; the band over the eyes is black; the second has a white beard; the band over the eyes is white. This is found in Senegal, Congo, and other hot parts of Africa. The crown is flat; the body and legs are long; the hair on the upper parts is of a bright red, beneath it is of a yellow-grey; over the eyes to the ears is a band. One variety is black; and another is white;
white; the tail is longer than the body. It is some eighteen inches to two feet in length.

**Callicebus.** This is tailed and bearded; the cheeks are bearded; the ears, neck, and tip of the feet black. It inhabits India. The body is of a bluish-green, and elegant. A variety is of a black colour. The head is roundish; the face is tawny, with a few black hairs; the ears are like those of the human subject; the breast, belly, and thighs on the inside are of a dullish green-colour; it is extremely gentle and playful, and is of the size of a cat.

**Patareia:** Agile Monkey. This animal is tailed and bearded; its back, upper part of the tail, anterior parts of the legs, a little dark olive; its face is black, and the nose is marked with a triangular white spot. It inhabits Guinea, and is like the lad, gentle and docile; it is little more than a foot high, though the tail is twenty inches long.

**Macaca:** Negro Monkey. This is tailed and bearded; the cheeks, whole face, except the region extending from the eyes to the tip of the nose, are bearded; the body is of a reddish-brown. It inhabits Ceylon and Guinea, is active and gentle. The tail is longer than the body; the face is tawny and flesh-coloured; the feet and hands are black, naked, and soft. In a sitting posture it is only about ten inches high.

**Kolowah:** This species is tailed and bearded; the head, back, and outside of the hands and feet, are black; the inside, belly, and circular beard, and part of the triangular face, are white. This is an inhabitant of Guinea; is gentle and docile. The beard is long and forked; it is eighteen inches long, with a tail of the same length.

**Nasua:** This has no beard; the face is long, slender, naked, flesh-coloured; the nose is projecting. It inhabits Africa, and is good-tempered. The head is covered with thick, long hair, falling backwards; the ears are small, pointed, and almost naked; the hair on the upper parts and limbs is long, tawny-brown mixed with black; on the breast and belly it is ash-coloured; the tail is very long; in a sitting posture it is only two feet high.

**Luteola:** Yellow Monkey. In this species the tufts are very large; the ears are large, black, naked; the cheeks have long pale-yellow locks reversed. It inhabits Guinea. The crown, upper parts of the body, arms, and thighs, are of an ash-colour, mixed with yellow; the lower parts are chestnut; the face is black, with long hairs over the eyes; the throat and breast are of a yellowish-white; the hair is coarse; the tail is long as the body, and it is about the size of a fox.

**Fulva:** Tawny Monkey. This has tufts in the lower jaw, which are long; the face is long and of a chestnut-colour; the nose is flat. The hair on the lower part of the body is pale tawny, though chestnut at the roots; the hind part of the back is of an orange-colour; the legs are chestnut and the belly white. It is of the size of a cat. It inhabits India. Pennant, who seems to be the only describer of this animal, took the description from one in an exhibition in London, which was an extremely ill-tempered animal. It is said to vary with a black face, and long black hairs on the cheeks; the body is of a dull pale-green; the limbs are grey and the tail dusky.

**Vimba:** The face of this is black; the cheeks have long black hairs; the body is of a pale-green; the limbs are grey; the tail is dusky. It is thought by some naturalists not to be a distinct species, but a variety of the S. fulva.

**Hirena:** Face naked, blue, obliquely ribbed; the beard is long, and like that of a goat; the tail is long, and the body of a deep brown.

**Regalia:** To this species there is another, S. chloris, chestnut, and laters, are covered with long yellow hairs. It inhabits the limits of Sierra Leone. The head is roundis; the face is black; the ears and upper head, the tail is covered with short white hair; the ankle at the base, the body and limbs are black; it is about the size of a cat.

**Bouma, Bay Monkey.** The hair on the face, the tail, limbs, and forehead, the body and limbs are sheathed. It inhabits Sierra Leone. The crown is black; the back and sides, the legs are coverd with long hair; the back above it of a tawny-brown, belly chestnut; hands and black and naked.

Section B. Tails probably; or Clapp's nose; Hand and foot covered. They are denominated

**Sapajous.**

**Bettulus,** or Bearded Black Monkey. By Penant it is denominated the Preacher monkey. It is tailed, bearded, and black. The tail at the tip and feet are brown. It inhabits South America; wanders in herds at night, and howls hideously; it is exceedingly fierce; the beard is round and black; the hair long, black, and smooth. Par the account given of this animal by Maregrave, see BEETLE, or Old Man of the Woods. This is tailed and bearded; the colour is red. The body is uniformly of a dirty red; it has a mouth like that of the human subject, placed in the anterior part of the face; the chin is prominent, and it is as large as a middling-sized calf. The sound by fame has been regarded as a variety of the S. beetebul, is denominated by Mr. Peanent the Royal monkey. There were formerly two in the Reverian museum, which were probably young, being of the size of a squirrel. They were entirely of a very bright ferruginous or reddish chestnut colour, with the face naked and black, surrounded on the lower parts by a straggling beard of black hairs, and the tail was finely prehensile. This species is common in Cayenne, but very rare in Brazil; on the contrary, the former species is very common in Brazil, but it is not found in Guinea. Both species have the same voice and manners. The following is an interesting description given by an observer, who had seen and kept these animals at Cayenne.

*The Allouaceus, or Howlers, inhabit the most forests, in the neighbourhood of waters or marshes. They are commonly found in the woody thickets of large flooded vallies, and never on the mountains of the interior of Guiana. They go in small numbers, often in pairs, and sometimes singly. The cry, or rather horrible rattling scream, which they make, may well inspire terror; and seems to us at times as if the trees contained the united howlings of all its savage inhabitants together. It is commonly in the morning and evening that they make this clamour; they also repeat it in the course of the day, and sometimes in the night. The sound is so long and varied, that often imaginary it is produced by several of the animals at once, and is supposed to be either two or three, and sometimes four. The late idea is long and a state of captivity; it is a manner of requisition; or at least it is not used in the same manner as when wild. The male is larger than the female, which latter always carries her young in her bosom.*

"Next,"
“Nothing is more difficult than to kill one of these animals. It is necessary to fire several times in order to succeed, and as long as the least fire remains, and sometimes even after death, they remain clinging to the branches by the hands and tail. The sportman is often chagrined at having lost his time and ammunition for such a wretched game; for, in spite of the testimony of some travellers, the flesh is not at all good; it is always excessively tough, and is, therefore, excluded from all tables: it is merely the want of other food that can recommend it to needy inhabitants and travellers.”

**PANISCUS.** This is the four-fingered monkey of Pennant; it is tailed, black, bearded, and without a thumb, hence its trivial name. This animal is distinguished by the greatility of its body and limbs; its uniform black colour, except on the face, which is of a dark flesh-colour; and by want of thumbs on the fore-feet, instead of which are very small projections or appendices. It is one of the most active and lively of animals, and is, besides, of a gentle and tractable disposition in a state of confinement. It inhabits the woods of South America; associating in great multitudes, affailing such travellers as pass through their haunts with an infinite number of sportive and mischievous gambols, chasttering, and throwing down dry sticks, swinging by their tails from the boughs, and endeavouring to intimidate the passengers by a variety of menacing gestures. This is the Coaita of Buffon.

**EXQUINA.** Bearded; back variegated with black and yellow; throat and belly white. It inhabits South America. In size and disposition it resembles the S. paniscus.

**TREPIDA.** Tailed, but without a beard; the fore-top is erect; hands and feet are blue; the tail is hairy. A variety has the hair round the face grey; it is brownish-yellow on the body. It inhabits Surinam, is nimble, dextrous, and amusing, and about twelve inches high. The body is brown, beneath it is rufy; the hair of the head is formed into a black erect hemispherical tuft; the tail is hairy; the nails are rounded; the face and ears downy and flesh-coloured; the eyes are approximate chestnut.

**PAUCELUS.** The horned papajou is tailless and without beard; two tufts on the head resembling horns. It is found in several parts of South America, is harmless and gentle. The face, sides, belly, and front part of the thighs, are brown; the crown, the middle of the back, tail and feet, and hind part of the thighs, are black; the nails are long and flattened; the tail is spiral.

**APELIA.** Brown Sapajou, or Sajou of Buffon. This also is without tail and beard; the body is brown; the feet are black.

**CAPUCINA;** Capuchin Monkey, or Sai of Buffon, and Weeper of Pennant. This has no beard; the skin is brown; the hair and limbs are black; the tail is shaggy and the hunches are covered. There is a variety of this, of which the hair on the breast, throat, round the ears, and cheeks, is white. The face is sometimes black, sometimes flesh-coloured on the forehead; the tufts are approximate; the nose is carinate towards the eyes; a black varicose retrorse wrinkle on the forehead; the tail is long, always curved, and covered with long shaggy hair; it is of the size of a cat. It inhabits divers parts of South America; it is mild, docile, timid; walks on its heels, and does not skip. It has a crying wailing voice, and repels its enemies by horrid howlings; it shrieks sometimes like a cricket. When made angry it will yell like a puppy; it carries the tail spirally rolled up, which is often coiled round the neck; it smells of musk.

**SCUREA;** Orange Monkey, or Saimiri of Buffon. Bearded; the hind part of the head is prominent; the nails of the four smaller toes ungulate; the hunches are covered. The body is of a greenish-grey, under parts whitish; the legs and arms are rufy; the tail is shaggy, black at the tip, and twice as long as the body; the nails of the thumbs and great toes are rounded; the face of a blueish-brown; the eye-brows are bristly; the ears are scantily covered with whitish hairs; it is of the size of a squirrel. It is found in South America is pleasant in its disposition, beautiful, and graceful; it sits by lying on its belly. It looks full in the face of fuch as speak to it. It is impatient of European climates.

**MORTA.** Without beard, but it has a tail; it is of a chestnut colour; the face is brown; the tail is naked and fealy. It is found in different parts of America. It differs from the S. figura only in being less, and on that account it has been supposed to be of the same species.

**SYLVICTA.** This is without tail and beard; the mouth and eye-brows are covered with long hairs. This is an obscure and doubtful species.

**VARIEGATA.** The hair on the sides and back is mixed with orange and black. It inhabits Antigua, is lively, docile, and full of amusing tricks.

**Section E. Monkeys with Tails that are not prehensile; that have no Cheek-pouches; the Hunches are covered. These are denominated SAGINS.

**PITHECIA;** Fox-tailed Monkey. Tailed, but without beard; the hairs of the body are long, and black at the tips; the tail is black, and very shaggy. It inhabits South America; is very amusing, and easily tamed. It is entirely of a dull brown colour, with a light ferruginous cast, except on the head and face. This is the Saki of Buffon.

**JACCHUS;** Striated Monkey, or Ouilili of Buffon, and Sangin or Cugni minor of Edwards. This is tailed; its ears are hairy, broad; tail curved, very hairy; nails flobulate, those of the thumbs and great toes are rounded. There is a variety, which is of a yellowish colour, smelling like muk. It inhabits Brazil; is active, reptile, climbing like a squirrel; it feeds on insects, fruits, milk, bread, and pieces of fruit; it graws the barks of trees, is untameable, biting, tormenting cats by fixing under their bellies, and emits a hisling cry.

**CENIPUS;** Red-tailed Monkey. This is tailed and bearded; locks hanging; the tail is red; nails flobulate. The body is grey, underneath it is white; the head has long white hanging locks; its face is black, and it has a few white hairs behind the ears; a wart on each cheek; the irides are rufy; the ears are roundish, black, and naked; nails flobulate, except the thumb; the tail is twice as long as the body, and is a little hairy, black, red at the base; the region of the anus is red. It inhabits South America, is active, bril, imitating the lion in its gestures. It is something less than the S. jacchus; it smells of muk, and the voice resembles that of a mouse.

**ROSALIA;** Silky Monkey. Tailed; bearded; the head is hairy; circumference of the face and feet are red; the nails are flobulate. This species derives its trivial name from the appearance of its hair, which is very fine, soft, long, and of a bright yellow colour, resembling yellow silk. Round the face the hair is much longer than in other parts, so as to form a large mane, like that of a lion; near the face this mane is of a reddish colour, and it grows paler as it recedes from the cheeks; the face itself is of a dull purple; the ears are round and naked; the hands and feet are also naked, and of the same dull purple colour; the face; the claws are small and sharp; the tail is very long, and
and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement. This is the Marinka of Buffon.

Simia Paradisi, or Parrot Tamarin. This species is tailless; bearded; the upper lip is cleft; the ears are large and naked; the tail is long and naked. The tamarin, or great-tailed monkey, is about the size of a furred cat; it is black, except on the lower part of the back, which is of a reddish colour, and on the hands and feet, which are orange-coloured; the face is naked and furred; the ears are large, naked, of a furred form, and of a dusky flesh-colour; the tail is very long and black. It inhabits the better parts of South America. The claws are small and sharp. It sometimes makes use of the face black, instead of flesh-coloured.

Simia Marina, the Sea-Ape, in Lobophygy, a name used by Belonius, and some other authors, for the fish called Simia marina; a kind of shark, remarkable for its long tail, from which probably it had both one and the other of the names. See Sea-Fox.

SIMICUS, in History, an ancient Greek musician, said to have been a great improver of music. He lived after Homer, and has the reputation of having invented the instrument above-mentioned: but Plutarch says, that the ancient Fables attribute this instrument to Pythagoras. He also informs us, that the Argives found the first person that used it; but does not tell us how it was used, or whether there was a complete scale for every one of the genera: 35 notes in the diatonic scale would mount it above the additional compass of modern piano forte.

According to Pliny, Simicus added an eighth string to the lyre of Mercury. Boethius says that it was Lychnon of Samos; but Nichomachus gives it to Pythagoras. So many claimants to the same inventions destroy all evidence to whom they belong.

SIMILAR, in Arithmetic and Geometry, the fame with like.

Those things are said to be similar, or like, which cannot be distinguished but by their proportion; that is, either by immediately applying the one to the other, or some other third to them both. So that there is nothing found in one of the similar things, but is equally found in the other.

Thus, if you note all the things in A, which may be distinguished and conceived, without alluding any other; and, in like manner, note all the things in B, which may be thus conceived, and A be similar to B; all things in A will be the same with those in B.

Since a quantity cannot be underfounded otherwise, than by alluding some other quantity to which it may be referred; similar things, notwithstanding their similitude, may differ in quantity; and since, in similar things, there is nothing in which they differ, beside the quantity; quantity itself is the internal difference of similar things.

In mathematics, similar parts, as A, a, have the same ratio to their wholes B, b; and if the wholes have the same ratio to the parts, the parts are similar. Similar parts A, a, are to each other as their wholes B, b. See PART.

SIMILAR Angles are also equal angles. See Solid Angle.

SIMILAR Rectangles are those which have their sides about the angles proportional.

Hence, if, all squares must be similar rectangles. Also, all similar rectangles are to each other as the squares of their homologous sides.

SIMILAR Triangles are such as have all their three angles respectively equal to each other, and the sides about the equal angles proportional. See Triangle.

Hence, 1, since in all triangles mutually equal, the corresponding sides containing the equal angles are proportional, equilateral triangles are similar to each other. And if two triangles have their sides respectively proportional, those triangles are equiangular.

2. All similar triangles are to each other, as the squares of their homologous sides.

In similar triangles, and parallelograms, the altitudes are proportional to the homologous sides, and the bases are cut proportionally by those sides.

SIMILAR Polygons are those whose angles are severally equal, and the sides about those angles proportional.

And the like of other similar rectilinear figures.

Hence, all similar polygons are, to each other, as the squares of the homologous sides.

In all similar figures, the homologous angles are equal, and the homologous sides proportional. All regular figures, and similar irregular ones, are in a duplicate ratio of their homologous sides. Circles, and similar figures, inscribed in them, are, to each other, as the squares of the diameters.

SIMILAR Arcs. See ARC.

SIMILAR Curves, in Geometry. The similarity of curvilinear figures may be derived from that of rectilinear figures, that are always similarly described in them; or, we may comprehend all sorts of similar figures, planes, or solids, in this general definition. Figures are similar, when they may be supposed to be placed in such a manner, that any right line being drawn from any determined point to the terms that bound them, the parts of the right line, intercepted between that point and those terms, are always in one constant ratio to each other.

Thus the figures A S D, a s d (Plate XII. Geometry, fig. 14.) are similar, when any line SP being drawn always from the same point S, meeting A D in P, and a d in p, the ratio of S P to s p is invariable. It is manifest, that the rectilinear inscribed figures, a p d S, A P D S, are similar in this case, according to the definition of such figures given in Euclid's Elements, book vi. See Macrinius's Fluxions, art. 127.

When the similar figures are in the situation here described, they are also similarly situated, and all their homologous lines are either placed upon one another, or parallel.

SIMILAR Segments of Circles are such as contain equal angles. See SEGMENT.

SIMILAR Conic Sections are those where the ordinates to a diameter in one are proportional to the corresponding ordinates to the similar diameter in the other; and where the parts of similar diameters between the vertices and ordinates in each section are similar.

The same definition also agrees to similar segments of conic sections.

SIMILAR Diameters of two Conic Sections. When the diameters in two conic sections make the same angles with their ordinates, they are sometimes said to be similar.

SIMILAR Solids. See LIKE SOLIDS.

SIMILAR Bodies, in Natural Philosophy, such as have their particles of the same kind or nature one with another.

SIMILAR Plain Numbers are those which may be ranged into similar rectangles, i.e., into rectangles whose sides are proportional; as 6 multiplied by 2, and 12 by 4, the product of one of which is 12, and the other 48, are similar numbers.

SIMILAR Solid Numbers are those, whose like cubes may be
be so ranged, as to make similar and rectangular parallel-epipeds.

Similar Animals. We have a treatise by Dr. Martin, wherein he treats of the laws and proportions of the motions and forces of the solids and fluids of animals, of however different magnitudes, which are supposed of similar make and constitution. See Tractat. de Similibus Animabibus.

Similar Dispos. in Medicine, denotes a disease of some simple, solid part of the body: as of a fibre, with regard to its tension, or flaccidity; of a membrane; a nervous canal, or the like. See Disease.

Similar Parts, in Anatomy, are those parts of the body, which, at first sight, appear to consist of like parts, or parts of the same nature, texture, and formation.

Of these we usually reckon ten, viz. the bones, cartilages, ligaments, membranes, fibres, nerves, arteries, veins, flesh, and skin: each of which see under its proper article.

Dr. Grew, in his Anatomy of Plants, observes, that these have likewise their similar and organical parts.

SIMILE, or SIMILITUDE, in Rhetoric, a comparison of two things, which, though different in other respects, yet agree in some one. As, He shall be like a tree planted by the water-fide, &c.; so that in every similitude three things are requisite; two things that are compared together; and a third, in which the likeness or similitude between them consists.

The difference between a simile and a comparison consists in this, that simile properly belongs to what we call the quantity of the thing, and the comparison to the quantity.

And the difference between a metaphor and similitude consists in this, that a metaphor has not those signs of comparison which are expressed in a similitude. See Metaphor and Parable.

SIMILITUDE, in Arithmetic, Geometry, &c. denotes the relation of two things similar to each other, or which are only dilinguishing by comparableness.

The notion of similitude, which now makes some figure in geometry, &c. is owing to M. Leibnitz: it will be rendered caly by the following instance. Suppose two watches perfectly alike, the one belonging to Caius, the other to Graccius. If now Caius pull out his watch in presence of Graccius, the latter will be surprised, and fancy it his own; but he will perceive it different from his own, upon pulling out his own; that is, Graccius distinguishes Caius's watch from his own by their comparableness; or, by applying the one immediately to the other.

Euclid, and after him most other authors, demonstrate every thing in geometry from the sole principle of congruity. Wolinins, in lieu of it, subordinates that of similitude; which, he tells us, was communicated to him by M. Leibnitz, and which he finds of very considerable use in geometry; as serving to demonstrate many things directly, which are only demonstrable from the principle of congruity by an abstruse.

SIMILOR is a name given to an alloy of red copper and zinc, made in the right proportions to imitate the colour of gold. See Gold-coloured Metal.

SIMIRA, in Botany, Aul. Guian. 170°, t. 65. Jaff. 205°, the Guiana name of a shrub, belonging to the natural order of Rubiaceae, and the Pentandra Mannonia of the Linnean system, but of whose generic characters nothing has yet been precisely settled. It seems very near akin to Psychotria, or to Stephanium; see those articles.

SIMITAR, or SCIMITAR, in War, a crooked or faceted sword, with a convex edge; not now used.

SIMLEE, in Geography, a town of Hindoostan, in Guzerat; 17 miles N. of Champancar.

SIMLER, Josias, in Biography, was born at Cappel, in Switzerland, in the year 1530. He was minister at Zurich, and a professor in the school of that town. He wrote several controversial works against some of the heretical sects, as they were censured, and denounced by him. He taught mathematics with great reputation, illustrating his lessons by various machines of his own invention. Of his writings the principal were "De Helvetiorum Republica," which contained an account of the original constitution of the Swiss confederacy; "Vallevia Descriptio," being an account of the Valais, and the adjacent alps; and an abridgment of the Bibliotheca of Conrad Gfemner, with the life of that dilligent man. In this last work he has not only given a good summury of the original, but has rendered it more complete, by the addition of a number of books. He died at Zurich in 1576, at the time when he was preparing a history of his native country.

SIMLY, in Geography, a town of Hindooftan, in Orilla; 15 miles N.W. of Boad.

SIMMEN, or SIREN, a river of Switzerland, which rises in the mountains between the Valais and the canton of Berne, and runs into the lake of Thun; 4 miles N.N.W. of Spitz. The valley through which this lake runs, and which has on each side stupendous rocks, is called "Simmenthal," and is divided by it into the Upper and Lower. The inhabitants of some few parts of this valley sow rye, oats, or wheat; but they derive great profit from their grapes, which is very rich, and they also breed a great number of cattle, from which they make butter and cheese. The latter font of cheese, called "Saan" cheese, is much esteemed abroad, being made wholly of cream; and of the common cheese, France and other countries purchase considerable quantities. Most of the inhabitants, instead of bread, eat the second font of cheese, with thin barley cakes; and the principal food of the commonalty is potatoes, and their drink is milk or whey.

SIMMERN, a town of France, and principal place of a district, in the department of the Rhone and Mollie, late capital of a duchy of the same name, seated in the electorate of the Rhine. The place contains 14697, and the canton 8361 inhabitants, in 31 communes. The territory of the district contains 16874 square miles; 26 miles S.S.W. of Coblenz.—Alfo, a river of France, which passes by Simmern, Gemunden, &c. and runs into the Nahe; 3 miles E. of Kirn.

SIMMIA CHUMBA, a town of Bengal; 16 miles S. of Palamow.

SIMMONS'S ISLAND, a small island on the coast of South Carolina. N. lat. 32° 33'. W. long. 86° 10'.

SIMO, a town of Sweden, in Earl Bothnia, on a river of the same name, which runs into the gulf of Bothnia; 80 miles E. of Ulea.

SIMOGU, a town of Hindooftan, in Myfere, on the Tumbadra; 93 miles W. of Seringapatam. N. lat. 13° 21'. E. long. 75° 50'.

SIMOJOISKI, one of the smaller Japanese islands, near the S.W. coast of Ximo. N. lat. 31° 50'. E. long. 132° 8'.

SIMOIS, in Ancient and Modern Geography, a river of Asia Minor, in the Leifer Phrygia, the source of which was in mount Ida, and which discharged itself into the Xanthus, or the Scamander, according to Pliny. The source of the Simois lies S.W. of Cotylus; it flows nearly to the W., traverses a space of from twelve to fifteen leagues; receives the Andrus above Inchavi, and several other rivulets, and
Simon, or the Cæsarean, was born in the time of John Christ. Zelus, the apostle given to St Luke (vi. Acts, 13.) was to be a tradition of the latter Cæsarean, given to him by the other evangelists. (Matt. xiv. 2.) Some learned persons have supposed, that the term Zelus, denotes he zeal in embracing the gospel of Jesus Christ; but other think, that he was of a fact called Zelotes, mentioned by Josephus. (De Bell. i. c. 2. vii. c. 1.) It does not appear where he preached, or where he died. Some have asserted that he travelled through Egypt, Cyrene, and Africa; that he preached in Mauritania and Libya, and that he propagated the gospel in Britain, dying in his exile, and in madness, as the crooks, which he endured with incredible courage. Others affirm, that he suffered martyrdom in the city of Suni, in Persea, on the 18th of October, on which day the Latin church celebrates his festival. The Greeks honour him June 1, and lay, that he was Nathanael, the bridegroom at the marriage of Cana.

Simon Magnus, or the Sweeter, was a native, as is said, of the village of Gitten, in the country of Samaria. His history is recited Acts. viii. 5-13. See also Acts, viii. 9, 10, 11. After having been discovered and refuted by the apostles, and particularly by Peter, he is said to have fallen into greater errors and sublimations, applying himself more than ever to magic, and taking pride in opposing the apostles, and propagating his errors. It is said by several of the ancient fathers, that at Rome, whether he arrived in the time of the emperor Claudius, about A.D. 41, he was honored as a deity by the Romans, and by the senate itself, and that a statue was decreed to him in the island of Tyber, with this inscription: "Simon Deo Sanctor." This fact, however, is disputed by several able critics. It appears, that under the reign of Nero, he acquired great reputation by his instamments; and that he pretended to prove that he was the Christ, and that, as the Son of God, he could ascend to heaven; and it has been said, that he really caused himself to be raised in the air, as a fiery chariot, by the assistance of two demons, but that by the prayers of St. Peter, he was disfitted by his demons, fell down, and broke his legs, and afterwards, overcome by great shame, threw himself headlong from the top of the house where he lodged. But we shall not multiply these apocryphal stories, which are not worthy of recital. He died, probably, A.D. 65. Simon formed a sect of heretics, who were called Simonists; which fee.

Simon, a disciple of Socrates, whose occupation was that of a leather-dresser at Athens, and whose ship was refitted by Socrates and his friends. He is said to have been the first who published the Socratic Dialogues; but none are extant. Simon to much valued freedom of inquiry, that when Pericles invited him to make him his disciple, he refused, with the promise of an ample compensation, he refused, alleging, that he would not sell the liberty of speaking his mind at any price.

Simon, John Francis, an ingenious man of letters, was born at Paris in 1654. He was originally intended for the ecclesiastical profession, and took the degree of doctor of
of laws. M. Pelletier de Souzy engaged him as preceptor to his son, and afterwards employed him as his own secretary, and as a remuneration for his services made him counsellor of the fortifications. He became very famous as a writer of inscriptions and legends of medals struck on public occasions, and on this account he was nominated a member of the Academy of Inscriptions and Belles-Lettres. He commenced a great learned dictionary to verify that body; and he read before it several parts of a medallistic history of Lewis XIV. He was an excellent writer both in the Latin and French languages, and in verse as well as prose. In 1712 he was appointed keeper of the royal cabinet of medals. He died in 1719.

Simon, Richard, a biblical critic, was born at Dieppe in 1638. He received his early education in the college of the Fathers of the Oratory in that place, and afterwards entered into that congregation. Quitting it in a very short time, he pursued the study of theology, and of the Oriental languages, in which he made a great proficiency. He entered himself again a member of the Oratory in 1662, when his singular turn of thinking, and unaccommodating temper, involved him in difficulties, which had nearly caused him to abandon the society for that of the Jefuits. These were, after a time, compromised, and he was sent as professor of philosophy to one of their colleges. The house of the Oratory in Paris possessing a library rich in Oriental writings, Simon was engaged to draw up a catalogue of them, on which occasion he became known to M. de La Moignon, first president of the parliament of Paris. Having performed the task, he returned to his professorship, and there employed himself in literary labours. In the year 1670 he was ordained priest, and in the same year he gave a proof of the liberality of his mind, by undertaking the defence of the Jesuits at Metz. Memoirs of the Jeesuits were, at that time, very much disliked, and his father was accused of sacrificing the child of Christian parents. In 1672 he published, under the name Ricard Simeon, "A Treatise on the Ceremonies and Cults in the present preferred among the Jews, translated from the Italian of Leo of Modena, with a Supplement respecting the Sects of the Caraites and Samaritans." It was reprinted in 1681, with a supplement, containing "A Comparative between the Ceremonies of the Jews and Discipline of the Church." In 1678 he published "A Critical History of the Old Testament," which, by the boldness of some of its opinions, gave a considerable degree of offence; and though it was protected by the approbation of a doctor of the Sorbonne, and a royal privilege, an order was procured for prohibiting its sale, and the privilege was revoked. In the same year he quitted the Oratory, in order that he might enjoy that freedom which is natural to the mind, and of which he was enthusiastically fond. He was accustomed to express his sense of the advantages of liberty by repeating the words "Alius ne fit qui tuus eft pot: It.") For the purpose of enjoying that more liberty, he renounced his cure four years after this, and spent the remainder of his life in the composition of several works, of which a great part was controversial. He died at Dieppe in 1712, at the age of 74.

Simon was a man of extensive and very deep learning, and an acute critic, but fond of singularity. Few men of letters have engaged in more disputes, and among his adversaries are some of the most eminent men of his time, Catholic as well as Protestant. He has, however, been ever receiv'd as one of those, who have much contributed to the free and learned discourses which have improved scriptural theology, and though not avowedly a reformer, he was an effective promoter of the Reformation. He published a number of works, and in addition to those already noticed, we may mention "Histoire critique du Texte du Nouveau Testament;" "Histoire critique des Versions du Nouveau Testament;" "Histoire critique des principaux Commentateurs du Nouveau Testament;" "Nouvelles Observations pour le Texte et les Verions du Nouveau Testament;" "Une Traduction Francois de le Nouveau Testament, avec Remarques Litterales et Critiques," 2 vols. 8vo. This was condemned in the pastoral letters of Noailles, archbishop of Paris, and Boffuet, bishop of Meaux. "Bibliotheque Critique," 4 vols. published under the name of Sainjore, a work suppress'd by order of council. "Nouvelle Bibliothèque Choisie," being a sequel to the former. "Letters Critiques," 4 vols. "Critique de la Bibliothèque des Autors Ecclesiastiques de M. Dupin, et des Prolegomenes sur la Bible du même," 4 vols. 8vo., "Histoire Critique de la Croyance et des Coutumes des Nations du Levant." M. Simon left his MSS, and a number of printed books, with marginal notes written with his own hand, to the cathedral library of Rouen.

There was another Simon of some celebrity, a doctor of laws, the author of "A Dictionary of the Bible," explaining the geography of the Old and New Testament, and the ceremonies of the Jews, first printed at Lyons in 1693, and again in 1703, with considerable additions, forming two vols. folio.

Simon, a great musician among the ancients, who, rejecting former rules of his art, invented a new mode, which was called "Simodia," from his name, in the same manner as the genus invented by Lyfodes, was called Lyfodia.

Simon, M. inventor of pedals for the harp, or harp à pedales. See Harp.

Simon, in Ichthyology, a name by which some authors have called the dolphin. It is affirmed, that this fish loves the name, and will come to a perfon who calls him by it; but this, though recorded by authors of credit, meets with no approbation among the fishermen.

Simon's Bay, in Geography, a bay on the coast of Africa, 11 miles on the W. side of the Cape of Good Hope; this is the only convenient flation for ships to lie in; for although the road without it affords good anchorage, it is too open, and but ill-circumfanced for producing necessaries, the town being small, and supplied with provisions from Cape Town, which is about 24 miles distant. The anchoring place is situated in S. lat. 34° 20', or 34° 23'. E. long. 18° 29'. In April 1780, the dip of the S. end of the magnetic needle was 46° 47', and variation of the compass 22° 16'. On the full and change days it was high water at 5' 55' apparent time; the tide rose and fell 5 feet 6 inches; at the ebb tide it rose 4 feet 1 inch. Cook's Third Voyage, vol. iii.

Simonetta, Giovanni, in Biography, an historian, was a native of Callaro, in Sicily. In 1414 he entered into the service of Francisco Sforza, duke of Milan, of which prince his brother Ciccio was the confidential minister. After the death of Francisco, he attached himself to his son Galeazzo Maria, to whom he, with his brother, continued so faithful, that when Ludovico Sforza usurped the dukedom, they were arrested and sent prisoners to Pavia. Ciccio, in the following year, was beheaded, and Giovanni was banished to Verceil. He, however, returned to Milan, where he was buried about the year 1491. Simonetta composed in Latin a history of the actions of Francisco Sforza from 1423 to 1466, which was accounted one of the best works of that time. It was several times printed. It is also found in Muratori's collection of Italian historians.

Simoniacal is applied to a person guilty of simony; that is of purchasing a benefice, or other sacred matter, with money. See Simony.

Simonians, or Simonites, in Ecclesiastical History, a sect.
Simon was by birth a Samaritan, or a Jew: when he had
studied philosophy at Alexandria, he made a public profe
tion of magic, and persuaded the Samaritans, by fictitious
miracles, that he had received from God the power of com-
manding and restraining those evil beings by which mankind
were tormented. As for his doctrines, Mührer adds, that
he was, without doubt, in the class of those philosophers,
who not only maintained the eternity of matter, but also
the existence of an evil being, who predisposed, and thus
shared the empire of the universe with the supreme and benefi
cent mind: and he, probably, embraced the opinion of those
who held, that matter, moved from eternity by an intrinsic
and necessary activity, had by its innate force produced, at
a certain period of time, from its own substance, the evil
principle which now exercises dominion over it, with his nu-
merous train of attendants. From this pernicious doctrine,
the other errors attributed to him concerning fate, the in-
difference of human actions, the impurity of the human
body, the power of magic, and familiar extravagancies, flow
naturally, as from their true and genuine source.

He rejected the law of Mosis, and said he was come to
abolish it. He ascribed the Old Testament to the angels,
and though he declared himself an enemy to them, he is said
to have paid them an idolatrous worship.

This magician farther pretended, that, in his person, he
did the greatest and most powerful of the divine works; that
another son of the female sex, the mother of all souls,
dwelt in the person of his mistress Helen; and that he
came, by the command of God, upon earth, to abolish
the empire of those that had formed this material world, and
to deliver Helen from their power and dominion. Mohl.

This sect is said to have continued to the fourth century.

Jullian, in his Apology, says that in his time, i.e. about
A.D. 150, almost all the Samaritans, and several others
elsewhere, acknowledged Simon as the greatest of the gods.
Clemens Alexandrinus (Shan. I. ii.) says that his followers
worshipped him. About the year 249 this sect was reduced
to about thirty persons, according to Origen (Cant. Cellum,
I. i.); and elsewhere (I. v.), he says that they were quite ex-
tinct. But it appears from other testimonies, that some of
them remained even at the beginning of the fifth century.
Eusebius (Hist. Ecclesiastical, I. ii. c. 13.) speaks of Simmioens,
who mingled themselves among the Catholics, and received
Catholic baptism; but who afterward spread in secret the
venom of their doctrine. Several were discovered and ex-
pelled the church about the beginning of the fourth century.

Simonides, a celebrated Greek, poet, born in the isle of Chios, was
the son of Leoprate, and flourished in the fifth century before the Christian era.
He excelled in various kinds of poetry, but especially in the elegy, in which, as we learn from Horace and Quintus,
he was almost proverbially learned. One of his most famous compositions was entitled "The Lamenta-
tion," of which the following fragment is all that remains, but this justifies his title to great excellence as a writer.

"Sweet child! what anguish does thy mother know;
Ere e'er the guest of grief has taught thy tears to flow!
Amidst the roaring wind's tremendous sound,
Which threatens destruction, as it howls around,
In balmy sleep thou liest, as at the break,
Without one bitter thought to break thy rest.
While in pale, glittering, interrupted light
The moon but shows the barrier of the right.
Didst thou but know, sweet infant! our woes,
Not opiate powder thy eyelids now could close,
Sleep on, sweet babe! ye waves in silencer roll,
And lull, O lull to rest! my tortur'd soul."
I.

By the statute, if a person, for money or profit, shall procure, in his own name, or the name of any other, the next presentation to any living ecclesiastical, and shall present thereupon, this is declared to be a simoniacal contract, and the party is subjected to all the ecclesiastical penalties of simony, is disabled from holding the benefice, and the presentation devolves to the crown.

In the construction of these statutes, these points, says Blackstone, seem to be clearly settled.

1. That to purchase a presentation, the living being actually vacant, is open and notorious simony.

2. That for a clerk to bargain for the next presentation, the incumbent being sick and about to die, was simony, even before the statute of Queen Anne; and now, by that statute, to purchase, either in his own name or another's, the next presentation, and be thereupon presented at any future time to the living, is direct and palpable simony.

But, 3. It is held, that for a father to purchase such a presentation, in order to provide for his son, is not simony; the son not being concerned in the bargain, and the father being by nature bound to make a provision for him.

4. That if a simoniacal contract be made with the patron, the clerk not being privy thereto, the presentation for that turn shall indeed devolve to the crown, as a punishment of the guilty patron; but the clerk who is innocent, does not incur any disability or forfeiture.

5. That bonds given to pay money to charitable uses, on receiving a presentation to a living, are not simoniacal, provided the patron or his relations be not benefited thereby; for this is no corrupt consideration, moving to the patron.

6. That bonds of refignation in case of non-residence, or taking any other living, are not simoniacal, there being no corrupt consideration therein, but such as is only for the good of the public. So also bonds to refign, when the patron's son comes to canonical age, are legal; upon the reason before given, that the father is bound to provide for his son.

7. Lastly, general bonds to refign at the patron's request, are held to be legal; for they may possibly be given for one of the legal considerations before-mentioned, and where there is a possibility that the transaction may be fair, the law will not supposse it iniquitous without proof; but if the party can prove the contract to have been a corrupt one, such proof will be admitted, in order to shew the bond simoniacal, and therefore void. Neither will the patron be suffered to make an ill use of such a general bond of refignation; as by extorting a composition for tithes, procuring an annuity for his relations, or by demanding a refignation wantonly, and without good cause, such as is approved by the law, as for the benefit of his own son, or on account of non-residence, plurality of livings, or gross immorality in the incumbent. Blackl. Comm. b. ii.

Simony is also committed by buying or selling the sacrament, baptism, ordination, or abjuration; as well as by the nomination and collation to a benefice, a place in monastary, or the like.

By 31 Eliz. cap. 6, persons who shall corruptly ordain or license any minister, or procure him to be ordained or licensed, shall incur a forfeiture of 40l., and the minister himself of 10l., besides an incapacity to hold any ecclesiastical prebendar for seven years afterwards. See Presentation.

Some have pretended it to be sufficient to avoid the charge of simony, if only the ordination were gratuitous, though the revenues were bought and sold as a temporal thing. But the canons of several councils have condemned this subtle distinction; since the revenues are attached to an ecclesiastical office purely spiritual.

Caufuits dillingiunh three kinds of simony; viz.

Simony, Mental, is that which is restricted to the mere will and inclination, without ever breaking forth into act. As when a present is made to a collator, without taking any notice, that we expect a benefice from him. This kind of simony is only punishable in foro conscientiæ.
S I M

SIMMONS, Conventional, is where there is an express act, and a formal bargain, though it never came to an execution.

SIMMONS, Real, is where the convention is executed on both sides; which left is the most criminal of all. The common penalty of simony is deposition in a clerk, and excommunication in a layman.

It is a maxim among the Roman canonists, that there is no simony in the court of Rome; because the pope acts there as an absolute sovereign; they also say, that教育教学 in simony are not to be admitted but by the pope, as a favouring a little of simony. On these occasions, however, the parties always swear, that there had been no deceit, collusion, simony, or other illegal covenant.

Peter Damian distinguishes three kinds of simony: that of money, that of the tongue, and that of service.

SIMMONS OF MONEY, or Per annos a manu, is where money is really paid down for a benefice; he adds, that the fame is likewise committed, by expending money to live at court, to obtain a benefice.

SIMMONS OF THE TONGUE, or Per annos langue, consists in flattering the collar, or making one's self agreeable by complaisance and commendation.

SIMMONS OF SERVICE, or Per annos ab officio, consists in doing for them good offices to obtain a benefice.

It was agreed by all the judges, Trin. oct. Jac. primus, that if the patron presented any person to a benefice with care, for money; such presentation, &c. is void, though the presentee were not privy to it; and the statute gives the presentation to the king; but this is now repealed.

SIMORI, in Geograph., a town of Naples, in Calabria Ultra; 13 miles N.E. of Squillace.

SIMORRE, a town of France, in the department of the Ger., 13 miles S.E. of Auch.

SIMPLA NOLB, in Botany. See PHILUS.

SIMPLARIES, SIMPLARIES, in Antiquity, a Roman felder, who had only single pay. Thus called, in opposition to the duplesses, or such as had double pay.

SIMPLE, SIMPLES, something not mixed, or compounded; in which sense it stands opposed to compound.

SIMPLE BODIES OR ELEMENTS, in Chemistry, are those substances which have not yet been decomposed.

In every era of chemical science, something like a fiftenth or theory has prevailed, which has had for its basis a certain number of bodies, called elements or simple bodies, of which all other bodies were formed. This has ever had the good effect of stimulating the minds of enquirers, and has tended much to the progress of this useful branch of philosophy. Theory has succeeded theory, varying widely from, and in some instances contradicting each other, till philosophers have become very cautious in the admission of the elementary nature of bodies; and hence have agreed in the above general definition of a simple body.

The limited proportions in which bodies combine, is sufficient to convince us, that simple bodies confound of hard unchangeable particles or atoms, which are not practically divisible. And the general forms of the crystals of compound matter go far to show, that these atoms are spheres, a form the belt calculated for motion, and under which they would be the best likely to change. How many varieties of these unchangeable spheroidal particles there exist, it is difficult to say; and what ratio they bear to each other, in density or magnitude, we are equally at a loss to determine. One great step, however, has been made, which may lead us to more important conclusions. Although we are ignorant of the absolute dimensions and densities of these atoms, we are now in a way to acquire a knowledge of their relative weights, by which we shall be enabled to calculate the proportions of compound bodies, by simply knowing of what elements they are composed. The use of experiment will be to find out the elements of a compound, and deduce their properties; but the exact properties will require to be determined by calculation, which will render chemistry as complete as astronomy.

There is the greatest reason to believe, that the atoms of every substance attract each other by the same laws with gravitation. Sir Isaac Newton supposes, that in gold, which in his time was considered the densest body, the parts or interfaces between its parts is greatly exceed its material part. Of what density, therefore, must we consider the atoms of bodies? Our present idea of density is very vague, and varies with the temperature, and depends, therefore, upon the quantity of caloric they contain. If these atoms were to be finally detached by the caloric, they would come in contact; and if they were spheres, the resulting specific gravity would be that of the specific gravity of the atom itself. The caloric, on the contrary, if detached by the atom, would, from its repulsive property, be diterpered to an unlimited extent. When, however, the two species of matter combine, they still retain their original properties; but the attraction of the atoms decreases, as they recede, by new additions of caloric in a ratio that the repulsion of the caloric, and the two powers are kept in equilibrium by change of distance between them. If the attraction be as the square of the distance, and the repulsion as the cube; then, if the distances be successive intervals of 1, 2, 3, &c. the attractions at these points will be 1, 1/2, 1/3, &c. and the repulsion 1, 1/2, 1/3, &c. Therefore, the caloric at each point, to make the atoms stand in equilibrium at these respective distances, will be 1, 2, 3, &c. for 1 x 1 = 1, 2 x 2 = 4, 3 x 3 = 9, and so on. It is under this form that the specific gravity of a body is taken; but we know not what may be the density of the real atoms, although we know that it must be very considerable. In proportion as this is the case, we are to expect a greater attractive force agreeable to the laws of gravitation. If the earth were to be condensed to half its diameter, the weight of bodies on its surface would be quadrupled. This circumstance, aided by the proximity of the atoms in chemical combination, and the state of aggregation, in which solids exist, will make us at face to wonder at the powers of chemical attraction, and at the same time gives a lively hope, that the same attraction is common both to gravity and chemical combination. However indeterminate this problem may appear, we understand that some experiments are soon to be instituted for settling this point.

The experiments will in the first place determine, whether these attractions are the same, or not: if they are the same, the experiments will determine, and point out the numbers which will express the strength of affinity between different bodies; the only facts which are now wanting to make chemistry a complete science.

In the present state of chemical science, these bodies considered as elements are divided into two classes; the one called combustible or inflammable, and the other incombustible or non-combustible; because in combining with the first class, they either emit light, or heat are developed. The first class, which is far from being numerous, consists chiefly of metals, with only a few exceptions. These are exhibited in the following table, which also contains the weights of their atoms and specific gravities; hydrogen, the lightest atom, being 1.

If the views of Gay Lussac, the French chemist, be correct, in a memoir on Iodine, or Iodium, which has been published, Dr. Thomson's Annals, we shall be hardly warranted in drawing this line between the combustible bodies, and those
which support combustion. Some of the latter appear to act the part of both. This is evidently the case with sulphur, which gives light and heat to a certain extent in its combination with some of the metals, and also when it combines with oxygen, with which, as an inflammable body, it forms an acid. In the opposite characters, like chlorine and jodine, it forms an acid with hydrogen, which is now termed the hydrophosphoric acid. Gay Lussac goes farther, and supposes that phosphorus, carbon, and azote, have a similar double property. Carbon he supposes to be the acidifying principle of some of the vegetable acids, and that azote acts a similar part in the prussic acid.

The bodies of the first class, with the exception of sulphur, phosphorus, azote, hydrogen, and carbon, are known to be metals; and there is strong reason to believe that hydrogen is a metal in the elastic form. It is very remarkable, that those bodies, the metallic nature of which is doubtful, appear to possess the property of combining more strongly with inflammable bodies, than the metals combined with each other in forming alloys. Indeed, the combinations of most of the metals with those that are not metallic, are generally conspicuous, and always definite.

The first of the second class of bodies, viz. oxygen, has long been considered a simple body. This second has been lately, by the French chemists and by Sir Humphrey Davy, considered in the same light. It was till lately considered as a compound of muriatic acid and oxygen, from which it was called oxymuriatic acid. Its name has only now been changed to chlorine, from its green colour. Jodine is another substance of the same class, exhibiting striking properties with inflammable bodies. Its name has been derived from the violet colour of its vapour. It was discovered in kelp, a substance which consists of foda combined with certain impurities. The jodine is extracted from it by the following process. Infuse the kelp in hot water till all the soluble part is taken up; then evaporate the solution till the carbonate of foda crystallizes on cooling. In this way, by repeating the evaporation and cooling, separate as much as possible of this salt; and then continue the evaporation to dryness. This residue is now to be introduced into a glass retort, or a long-necked matrass, and a quantity of sulphuric acid poured upon it. This is then applied to, at first, a gentle heat. When the temperature reaches about 300°, a purple or violet-coloured vapour appears in the neck of the retort, which condenses into flowing opaque crystals of the appearance of plumbago. Those crystals are pure jodine. Jodine, in the folid form, is of a greyish-black colour, its vapour being of a beautiful violet. Its crystals have a shining scaly appearance, like mica. Their form is that of rhomboidal plates, and sometimes of elongated octahedrons. It is soft and friable, so as to rub to powder between the fingers. It stains the skin of a deep brown colour, but not permanently. It has the smell of chlorine or oxymuriatic gas. Its taste is acid, although it requires seven thousand parts of water for its solution. It destroys vegetable colours, like chlorine, but with less energy.

Its specific character is 3.948 at the common temperature, water being 1. It fuses at 225° of Fahrenheit, and assumes the elastic form at 375° or 376°; but it will come over in distillation with the vapour of water. It is a non-conductor of electricity.

Jodine, like oxygen and chlorine, has the property of supporting combustion with combustible bodies. With some of these it forms compounds analogous to oxyds, and with hydrogen it forms an acid resembling the muriatic acid, the compound formed by hydrogen and chlorine. In these instances, jodine and chlorine have not only the property of supporters of combustion, but of forming acids with an inflammable base. They, however, in their turns, act the part of combustible bodies, by forming acids with oxygen. It appears also, from the views of Gay Lussac, that sulphur has also this double property, for by combining with hydrogen it forms the well-known compound called sulphuretted hydrogen, which possesses the properties of an acid, and is rendered so by acting the part of oxygen with the inflammable base. On the contrary, it forms sulphuric acid with oxygen by itself, acting the part of an inflammable base.

It also appears to this philosopher, that azote, carbon, and phosphorus, may have the power of producing acidity by
SIMPLE BODIES.

by their combining with certain inflammable bases. It is
of opinion, that most of the vegetable acids do this entirely
with carbon, but to the carbon acting the part of oxygen with hydrogen, as sulphur, chlorine, and iodine do with the lime.

Agreeably to this view, we shall give some of the facts attendant on chlorine, iodine, and sulphur, in their combinations with hydrogen and oxygen.

To the binary combinations of these bodies with others, in which they have no acidity, Gay Lussac has given the names of chlorine, iodurets, and sulphurets; as chloruret of potassium, ioduret of lime, sulphuret of iron, and so on. When they form acids with hydrogen, they are termed hydrochloric, hydroiodic, and hydro-sulphuric acids. The acids formed by their combinations with oxygen he terms chloride, iodide, and sulphuric acids. The chloride is the same with what has been called the hypochlorous acid, and forms with potash what has been termed hypochlorite of potash. The iodide and sulphuric forms a compound with potash, having similar properties, and affording a large quantity of inflammable oxygen.

The hydrochloric rates are the salts which have been called muriates, and have some resemblance to the hydroxides, a set of salts formed by the acid arising from the union of muriate with hydrogen, and the different saline bases.

The hydrochloric acid is formed by first combining phosphorus with iodine, in the proportion of one of the former to nine of the latter. This compound being brought in contact with water, affords the hydrochloric acid. The water is decomposed, the oxygen of which combines with the phosphorus to form phosphoric acid, and the hydrogen with the iodine, forming the hydrochloric acid. If the iodine and phosphorus were 18 of iodine to 1 of phosphorus, then phosphoric acid would be formed in the water. On the other hand, if the iodine were 4.5 to 1 of phosphorus, then hydrochloric acid would be formed, and a compound of phosphorus and oxygen, consisting of two atoms of the former to one of the latter. This is the red infusible substance which has been called odyx of phosphorus.

In all these precedes the hydrochloric acid is evolved in fumes smelling like nitrous acid, and may be collected, like it, in the usual form. This substance is about 62 times heavier than hydrogen. Water absorbs a large quantity of it, so as to form a very strong acid, of the specific gravity of 1.7.

This acid is decomposed in two ways, principally by such bodies as easily separate its hydrogen and let free the iodine, such as the sulphuric and nitric acids, and many of the oxides, by which water and jodurets are formed. It is also decomposed by the superior attraction of iodine for other bodies, setting the hydrogen free. Such is the case with all of the metals.

The compounds of the hydrochloric acid with different saline bases form salts, resembling the hydrochlorides (muriates) and the hydro-sulphates. The other binary compounds of iodine, and the different combustible bodies which are called jodurets, are very conspicuous. Most of these are inflammable in water. Those metals which decompose water, form soluble jodurets; as in these instances the joduret becomes an hydrochloride.

Another set of compounds results from iodine, which we have already called iodates. Jodine combines with oxygen, in the proportion of 5 atoms of the latter to 1 of the former, which is 117 iodine to 5 x 7.5 = 37.5 of oxygen. This constitutes the jodic acid.

This acid cannot be directly formed by combining iodine with oxygen; but it is formed during the action of iodine upon plants, dyes, hay, etc., burning, etc., and so on, when water is a point. It decomposes into two parts, when a point of iodine is added to it. Two salts are formed, with the base employed, the one with oxygen, and the other with hydrochloric or hydroiodic acid.

When iodine in vapour is passed through a solution of potash, for atoms of iodine will decompose for atoms of water, by which four atoms of hydroiodic acid are produced. These unite with four atoms of potash, forming as many compound atoms of hydroiodate of potash. Four atoms of oxygen, separated from the water, now unite with a fifth atom of iodine, and a fifth atom of potash; the whole of which will amount to an atom of hydroiodate of potash, united to five atoms of oxygen, constituting an atom of iodate of potash. It will appear, therefore, that during the formation of any of the jodates or the chlorates, that for every atom of such iodate or chloride there will be formed, at the same time, four atoms of an hydrochlorate or hydroiodate.

In the example above stated, an atom of iodate of potash would be an atom of iodine (117) + 1 atom of potash (37.5) + 5 atoms of oxygen (5 x 7.5) = 192. The 4 atoms of hydroiodate of potash will consist of 4 atoms of hydriodic acid (4 x (177 + 11)) + 4 atoms of potash (4 x (37.5 + 7.5)) = 472 + 180 = 652. The ratio, therefore, of the iodate of potash to the hydroiodate, will be 192 to 652, or 100 to 340 nearly. In the crystalline form, however, the hydroiodate of potash does not crust, but is converted into ioduret of potash, which will consist of an atom of iodine (117) added to an atom of potash (37.5) = 154.5, and 154.5 x 4 = 618, the quantity of the crystallized ioduret to the joduret, which will be 100 of the latter to 322 of the former nearly.

It is rather out of place to enter into the particulars of bodies; but this last sublimate, from its recent discovery, has not been before mentioned in this work. There are also many interesting particulars respecting chlorine; but these are rather new explanations, under the idea of this being a simple body, than new facts.

We know little more of the body called iodine, than that it is in all probability a body combining with hydrochloric acid to form fluorine acid, in the manner that chlorine and iodine form hydrochloric and hydroiodic acids with that body. To the combinations of chlorine with the different bodies, in which no acidity prevails, Dr. Thomson has proposed the name of chlorids, as being more agreeable to the termination in the word oxys, and we suppose would adopt, for similar combinations of iodine, jодids; and we should expect, from the sulphates being analogous, that they would be called sulphids, to keep up the same uniformity. The French chemists (see Gay Lussac's Memoir on Jodine, Thomson's Annals, vol. v.) have adopted for the same compounds the termination already used for the sulphides, viz. chlorurets, jodurets; and for the combinations of carbon and azote with the same bodies, they would use carburets, azurets, or, what is better, azoturets. We see no objection to this termination for all the binary compounds not possessing acidity, as in fact there would be no other change than that of altering oxys into oxys. The acids would still retain their terminations, oxys and oxy, distinguishing those which do not contain oxygen by the acidifying suffix. These, as at present, would derive their names from the acids. See Nomenclature.

Simple, in Botany, is a general name given to all herbs and plants; as having each its particular virtue, by which it becomes a simple remedy.
The simples from the Levant, and the East Indies, were not known among us till about the year 1200.

**SIMPLICITY.** See LEAF.

The term simple is also technically applied to some other parts of a plant. A simple calyx is used in the columniferous order, in opposition to the double one of Malvina, Hibiscus, and many other genera of that order. A simple stigma means that the part in question is of no elaborate or peculiar shape, or fracture, but merely adequate to perform its requisite functions. This end is sufficiently answered by a rather obtuse, though not dilated, figure, just enough to receive the pollen upon a moist surface, or point. If a stigma be acute, or taper-pointed, that character should be specified; as also if it be capitate, concave, lobed, fringed, &c.; in all which latter cases it is no longer simple. See Stigma, and F Ceculation of Plants.

A simple stem, or stalk, is definite of branches, or subdivisions. Such also is simple pubeitchens, the hairs of which are unbranched and straight; not illustrated, entangled, or hooked.

**SIMPLE,** in French Myfi, in an air with variations, implies the air itself, in opposition to the doubles or variations. See Air, and DOUBLE.

**SIMPLE Cadence,** is that where the notes are all equal through all the parts.

**SIMPLE CONCORDS,** are those in which we hear at least two notes in consonance; as a third and a fifth; and, of consequence, at least three parts. This is either done immediately, and is called the harmonical trichord, or in a more remote manner, that is, when the sounds, that are not haf, are one or two octaves higher. This distance has no ill effect in the third, but in the fifth it has; and, generally speaking, the nearer, or more immediate, the concords are, the better. See Concord.

They also say C simple, or plain, in opposition to C accented.

**SIMPLE Counterpoint,** Fugue, Interval, Sounds, and Triple. See the sub-functatives.

**SIMPLE Equation,** Fraotion, and Such, in Algebra. See the sub-functatives.

**SIMPLE Quantities,** are those which consist of one term only; as a,- ab, or a b; accordingly they are opposed to compound quantities.

**SIMPLE GLANDS,** in Anatomy. See Glands.

**SIMPLE Anomaly and Excentricity,** in Astronomy. See the sub-functatives.

**SIMPLE Form, Motes, Necessity, Opposition, and Proposition, in Logic and Metaphysics.** See the sub-functatives.

**SIMPLE Averages,** Benefits, Church, Diplomats, Estates, Fees, Forces, Harvests, Resignation, and Vassalage. See the sub-functatives.

**SIMPLE Contrad. Debts by,** are such, where the contract upon which the obligation arises is neither ascertained by matter of record, nor yet by deed or special instrument, but by mere oral evidence, or by notes unscaled, which are capable of a more easy proof, and (therefore only) better than a verbal promissory.

**SIMPLE Diachyons, Diacodium, Diatomus, Diapraxis, Dropax, Fomentations, Hydromel, Mixture, Oxymel, and Waters.** See the sub-functatives.

**SIMPLE Fencing.** See FENCING.

**SIMPLE Flank and Tenaille,** in Fortification. See the sub-functatives.

In Geometry, we say, the most simple demonstrations are the belt.

In Grammar, we have simple words, or primitives; and compounds, which have some particle added to them.
SIMPSON, Thomas, an Biographer, a celebrated learned mathematician, was born at Market Bosworth, in Leicestershire, in 1723. His father, who was a weaver in that town, intended to bring him up to his own trade, and took little heed of his education. Nature, however, had endowed him with fine talents, and an ardent desire of knowledge, which excited him to read and pursue it. At an early period he gave indications of his future labours, by eagerly perusing every book that fell in his way, and seizing every opportunity to acquire instruction from others. His father, finding that he was thus led to neglect his work, endeavoured to reform him from what he regarded as idle pursuits; but after some fruitless attempts, a difference was produced between them, which, at length, terminated in an open rupture, and Thomas left his father's house, and married the widow of a tailor, with whom he retired to Naseby, where he continued some time working at his trade, and improving his knowledge. Here he became acquainted with a travelling pedlar, who lodged in the same house, and who, to the profusion of an itinerant merchant, had united the more profitable one of a fortune-teller. An intimacy was formed between them, and as the pedlar was going to Bristol, he lent, during his absence, Cooker's Arithmetic to Simpson, to which was subjoined a short appendix on Algebra; and a book on Astronomy, by Partridge, the almanac-maker. These books he studied to a degree, that on the pedlar's return, he was authorised to find that Simpson was little inferior to himself in the art of calculating nativities; and he predicted that he would shortly be his superior. Encouraged by this prophecy, he at first determined to embark in the trade of a fortune-teller; and by this occupation, and teaching a school, he found means to support himself without weaving, which he now entirely abandoned, and was soon regarded as the oracle of the neighbourhood. From this time he seems to have lived very comfortably, till an unfortunate event involved him in a deal of trouble. Having undertaken to raise the devil, in order to answer certain questions to a young woman, who consulted him respecting her sweetheart, then absent at sea, the credulous girl was so frightened on the appearance of a man from beneath some straw, who represented the devil, that she fell into violent fits, from which she was with difficulty recovered, and which for a considerable time threatened insanity or fatality. In consequence of this exertion of his art, he was obliged to leave the place, and he removed to Derby, where he remained a few years, working at his trade by day, and instructing pupils in the evenings. He became a writer in the Lady's Diary in the year 1756; his first queries were stated in verse, and are of that kind as flew that at this period he had made some progress in mathematical knowledge. He from this period applied himself with great ardour to every branch of the analytic science, and acquired a deep insight into the doctrine of fluxions, upon which he afterwards published a work, which is even now regarded as among the best, if not the very best, existing in our language. After he had given up astrology, and its enunciations, he found himself reduced to great straits, notwithstanding his industry to provide a subsistence for his family at Derby; and on that account he determined to remove to London, which he did in the year 1756. When he arrived at the capital, unknown and without recommendation, he for some time followed his business in Spitalfields, and taught mathematics in the evenings, and at other spare hours. His exertions were attended with fruitless success, that he returned to the country, and brought to town his wife, with her three children. The number of his scholars increased, and he was encouraged to make proposals for publishing by subscription
subcription " A New Treatise of Fluxions." The book was printed in 1737. In the year 1740 he published "A Treatise on the Nature and Laws of Chance." This is a very thin and small quarto; and to this treatise are annexed full and clear investigations of two important problems, added to the second edition of De Moivre's Book of Chances, as also two new methods for the summation of series. Mr. Simpson's next publication was a volume, in quarto, of "Ellays on several curious and interesting Subjects in speculative and mixt Mathematics," printed in 1740. Soon after the publication of this book, he was chosen a member of the Royal Academy at Stockholm. This was followed by a smaller volume, on "The Doctrine of Annuities and Reversions, deduced from general and evident Principles," with useful Tables, shewing the Values of single and joint Lives." Next year came out an "Appendix, containing Remarks on De Moivre's Book on the same Subject, with Answers to some peronal and malignant Representations in the Preface to it." In 1743 he published his "Mathematical Dissertations on a variety of physical and analytical Subjects." Shortly after this he published "A Treatise on Algebra," which in the year 1755 he enlarged and considerably improved. After this he gave the public his "Elements of Geometry," with their application to mensuration, to the determination of maxima and minima, and to the construction of a great variety of geometrical problems. This work has passed through many editions, and is still read in some places devoted to the education of the young; though we think it has been superceded by other treaties of more modern date. The fifth edition of this book occasioned some controversy between Mr. Thomas Simpson and Dr. Robert Simfon, the author of a well-known edition of Euclid's Elements. See Simpson.

In the year 1748, Mr. Simpson published "Trigonometry, plane and spherical, with the Construction and Application of Logarithms." In 1753 he published a new edition of his "Treatise on Fluxions," which, however, he wished to be considered rather as a new work than a new edition of an old one. In 1752 appeared in 8vo. a work, entitled "Select Exercises for young Proficients in Mathematics;" and in 1757 he published his last work, entitled "Miscellaneous Tracts,"—"which," says Dr. Hutton, "was a valuable bequest, whether we consider the dignity and importance of the subjects, or the sublime and accurate manner in which they are treated." Such are the scientific works of Mr. Simpson. Through the interest of Mr. Jones, the father of the celebrated Sir William Jones, Mr. Simpson was, in 1743, appointed to the professorship of mathematics, then vacant, in the Royal Academy of Woolwich; and in 1745 he was admitted a fellow of the Royal Society. On this occasion, in consequence of his very moderate circumstances, he was excused his admission fees, and from giving bond for the settled future annual payments. As a professor, he exerted all his talents in instructing the pupils committed to his care. He had, it has been said, a peculiar and happy method of teaching, which, united to a great degree of mildness, engaged the attention, and conciliated the esteem and friendship of his scholars. Mr. Simpson died in the year 1761, in the 58th year of his age. Besides the works already mentioned, he wrote several papers, which were read before the Royal Society, and printed in their Transactions. He was not only a contributor to, but for some years editor of, the Lady's Diary, during which, viz., from the year 1754 to 1760, he raised that work to a high degree of respectability. In 1760, when a plan was in agitation for erecting Blackfriars bridge, he was consulted by the committee in regard to the best form for the arches. On this occasion he preferred the semicircular form; and besides his report to the committee, he wrote some letters on the subject, which were afterwards published in the Gentleman's Magazine.

SIMPSON, JOHN, was born at Leicetser, in the month of March 1746. He was educated for the ministry among the Protestant dissenters, under the care of Mr. (afterwards Dr.) John Aikin, who kept a flourishing school at Kibworth, in Leicetsershire, and afterwards an academy at Warrington, for the education of young men devoted to the ministry. From Warrington Mr. Simpson went in, 1755, to Glasgow, where he spent two years in this ancient seat of learning, and where he attended the lectures of the excellent Dr. Leechman. At Glasgow he remained two years, when he purfued his studies in a private manner among his relations, till the month of April 1772, when he settled at Northam- ham, and from thence removed, in 1777, to Walthamflown, where he became pastor of the congregation of dissenters, which had previously enjoyed the joint services of Mr. Farmer and Mr. Radcliffe. Here he remained but two years, and after this it does not appear that he was settled any where as minister, but continued preaching occasionally to the end of his life. As a preacher he acquired considera- ble reputation, but he is chiefly known as a critic on the Holy Scriptures. His principal work is entitled "Ellays on the Language of Scripture," in two volumes octavo. Besides this he published many other works, among which are "An Ellay to shew that Chriftianity is the truest in the Hiftoric Form;" "A View of the internal and pre- sumptive Evidences of Christianity," which is a most useful performance, and it has been said may be ranked, in merit and value, with the moral demonstrations of the truth of the Christian religion of Taylor, Locke, Lardner, Clarke, and Paley. Mr. Simpson died in the year 1813. He was an Unitarian in the largest sense of the word; and agreeably to the enlightened, conscientious, and general character of his character, his speculative belief inspired him with the most genuine sentiments of rational piety, and an elevated devotion. He was firm in his principles, ready in his conduct, and courteous in his manners; modest, humble, affectionate, disinterested, and generous. See Sermons on the Death of Mr. Simpson, by the Rev. T. Jervis and the Rev.—— Hunter.

SIMPSON, CHRISTOPHER, an English musician of the seventeenth century, extremely admired for his performance on the viol da gamba, or fix-strung-bafe, and general knowledge of music. The bafe-viol with fix strings, and a fretted finger-board, was in much general favour in his time, that almost all the fix musicians of our country, whole names are come down to us, were performers upon it, and composed pieces purposely to shew its powers; but particularly Coperario, William Lawes, Jenkins, Dr. Colman, Lupo, Mico, and Loofmore.

Simpson, during the last years of the Ufurpation, published a treatise on this instrument, entitled "The Division Violin, or an Introduction to the playing upon a Ground." But this instrument, like the lute, without which no concert could subsist, was soon after fo totally banished, that its form and construction were scarcely known, till the ar- rival of Abel in England, whose taste, knowledge, and ex- pression upon it were so exquisite, that, instead of renovat- ing its use, they seem to have kept lovers of music at an awkful distance from the instrument, and in utter despair of ever approaching such excellence. The instrument itself, however, was so naifal, that this great musician, with all his science and power of hand, could not prevent its most en- thusiastic
SIMPULUM, among the Romans, a vine which the populace held in great honour, and made like a crown. It was used in burials, for taking a very little wine, to mitigate the pangs of death.

SIRRAHK, a town of Hindustan, in Or.; 24 miles E.S.E. of Fyzabad.

SIMRIK, a town of Bengal; 32 miles N.N.W. of Bhoorgouj.

SIMSAT, a town of Affghan Turkestan, in the government of Darbeke; 54 miles W. of Darbeke.

SIMSBURY, a small town of America, in Hartford county, Connecticut; 14 miles N.W. of Hartford. Copper has been found in this place. It contains 1,566 inhabitants; 16 miles from Waltham.

SISLIA, a towns, so called by Mr. Brown, is a just tribute to the botanical learning and skill of Dr. John Sims, F.R.S. and F.L.S. the contributor to the fourteenth volume of the popular and very useful Botanical Magazine, of the late Mr. William Curtis; see that article — Brown Tr. of Linn. Soc. v. 10. p. 127. Prodr. Nov. Hoth. v. 1. p. 67. —Clubs and order, Tetrandria Menagynia. Nat. Ord. Pri- naceae. Jufr. Brown, F. L. S. Ch. Cal. none, useless the corolla be taken for such. Cor. Petals four, inferior, linear-oblong, equal, deciduous; reflexed at the extremity. Nectarine none. Stam. Filaments four, half-shaped, prominent, inserted into the disk of each petal; anthers roundish, cohering, so that the adjoining lobes of each make one common cell, at length separating. Fil. Germen superior, obovate; style cylindrical; stigma dilated, concave. Peric. Nut inversely conical, of one cell, naked.

A New Holland genus of smooth shrubs, of humble growth. Leaves alternate, thread-shaped, forked; their footstalks dilated at the base. Flowers small, yellow, smooth, compounding small, globiferous, terminal heads, disposed either in clusters or panicles, with or without a short common involucrum, and with a minute bracte under each flower. Two species only are mentioned.

S. tenuifolia. Narrow-leaved Simia — Heads naked, mostly terminal on each branch of the panicle, accompanied by small partial bracteas. — Found by Mr. Brown, on lofty sides of hills, in Lewin's land, on the south coast of New Holland.

2. S. anchusa. Furry-leaved Simia.—Heads numerous in each panicle, and about as long as its partial branches, accompanied by imbricated involucral leaves. — Gathered by Mr. Brown, on the sandy fringes of the same country.

SIMSKALIA, Ophi and Whiter, in Geography, two small islands in the Baltic, E. of Aland, about four miles apart. N. lat. 60° 20'. E. long. 26° 8'.

SIMSON, Robert, in Geography, was born in the year 1657, of a very respectable family, in the county of Lanark. He was educated in the university of Glasgow, where he made great progress in his studies, and acquired in every branch of science a large flock of information, which, if it had never been greatly augmented afterwards, would have done great credit to any professional man. He became, at an early period, an adept in what was denominated the philosophy and theology of the schools, and was able to supply with great credit the place of aick relation in the class of Oriental languages. While he was pursuing a course of theology, as preparatory to his entering into orders, mathematics took hold of his fancy, and he would, in after-life,
SIMSON.

fay that he amused himself in his favourite pursuit, while he was actually preparing his exercises for the divinity hall. When fatigued with speculations, in which he could not meet with certainty to reward his labours, he relieved his mind, ardent in the pursuit of truth, by turning to mathematics, with which he never failed to meet with what would satisfy and refresh him. For a long time he refrained himself to the very moderate use of the cordial, fearing that he should soon exhaust the flocks which so limited and abstruse a science was capable of yielding; at length, however, his fears were dissipated on this head, for he found that the more he learned, and the farther he advanced, the more was there to learn, and a full wider field opened to his view. He accordingly determined to make the mathematics the profession of his life, and gave himself up to the study without reserve. It is said, that his original incitement to this science as a treat, as something to please and refresh the mind in the midst of feverish talks, gave a particular turn to his mathematical pursuits, from which he could never deviate. He devoted himself chiefly to the ancient method of pure geometry, and felt a decided dislike to the Cartesian method of substituting symbols for the operations of the mind, and still less was he willing to admit symbols for the objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed in the solution of an algebraical problem, where quantity alone is to be considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraical formula into an analogous geometrical theorem. In so little respect did he come at last to consider algebraic analysis, as to denominate it a mere mechanical knack, in which he would lay we proceed without ideas of any kind, and retain a refult without meaning, and therefore without any conviction of its truth.

About the age of twenty-five Dr. Simson was chosen professor of mathematics in the university of Glafgow. He immediately went to London, and there formed an acquaintance with the most eminent men who at that time flourished in the metropolis. Among these was the celebrated Halley, of whom he always spoke with the most marked respect, saying that he had more acute penetration, and the most just taste in that science, of any man he had ever known. Dr. Simson also admired the matterly steps which Sir Isaac Newton was accustomed to take in his investigations, and his manner of substantiating geometrical figures for the quantities which are observed in the phenomena of nature. He was accustomed to say, that the 35th proposition of the first book of the Princips, was the most important proposition that had ever been exhibited to the phisico-mathematical philosopher, and he used to illustrate to the higher classes of his pupils, the superiority of the geometrical over the algebraical analysis, by comparing the solution given by Newton, of the inverse problem of centripetal forces, in the 42d proposition of that book, with the one given by John Bernouilli, in the Memoirs of the Academy of Sciences at Paris, for the year 1713.

Returning to his mathematical chair, Dr. Simson discharged the duties of a professor, for more than half a century, with great honour to the university and to himself. It is scarcely necessary to add, that in his lectures he always made use of the geometry of Euclid, in preference to those works which he thought lean too much to analysis. His method of teaching was simple and periphrastic, his elucidation clear, and his manner easy and impressive. He uniformly engaged the respect and affection of his pupils.

It was owing to the advice of Dr. Halley that our author so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him as the most certain means of acquiring a high reputation, as well as to improve his taste, and he presented him with a copy of Pappus’s Mathematical Collections, enriched with his own notes. The perspicuity of the ancient geometrical analysis, and the elegance of the solutions which it affords, induced him to engage in an arduous attempt, which was nothing less than the entire reformation of this method. His first talk was the restoration of Euclid’s Postulates, from the scanty and mutilated account of that work in a single passage of Pappus. He, however, succeeded, and by early as 1718 seems to have been in possession of this method of investigation, which was confidered by the eminent geometers of antiquity as their furest guide through the intricate labyrinths of the higher geometry. In 1723 Dr. Simson gave a specimen of this discovery in the Philosophical Transactions; and after that period he continued with unremiting ardour to reform these choice porifms which Euclid had collected, as of the most general use in the solution of difficult problems. Having obtained the object of which he was in pursuit, he turned his thoughts to other works of the ancient geometers, and the Porifms of Euclid had now only an occasional share of his attention. The Loci Plani of Apollonius were the next talk in which he engaged, and which he completed in the year 1738; but after it was printed he was far from being satisfied that he had given the identical propositions of that ancient geometer; he withheld the impression several years, and it was with extreme reluctance that he yielded to the entreaties of his mathematical friends in publishing the work in 1746, with some emendations, in those cafes in which he thought he had deviated the most from the author. Anxious for his own reputation, and fearing that he had not done justice to Apollonius, he soon recalled all the copies that were in the hands of the booksellers, and the impression lay by him several years. He afterwards revised and corrected the work, and even then did not, without some degree of hesitation, allow it to come into the world as the restoration of Apollonius. The work was, however, received by the public with great approbation; the author’s name became better known; and he was now confidered as among the very first and most elegant geometers of the age.

He had, previously to this, published his Conic Sections, a treatise of uncommon merit, whether confidered as a complete restitution of the celebrated work of Apollonius Pergæus, or as an excellent system of this useful branch of mathematics. This work was intended as an introduction, or preparatory piece, to the study of Apollonius, and he has accordingly accommodated it to this purpose. The intimate acquaintance which Dr. Simson had now acquired with all the original works of the ancient geometers, as well as with their commentators and critics, encouraged him to hope that he should be able to restore to its original state that most useful of them all, the Elements of Euclid, and under the impression of this idea, he began seriouly to make preparation for a new and more perfect edition. The errors which had crept into this celebrated work appeared to require the most careful efforts for their extirpation; and the data allo, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call for the noblest exertions of a real master in the science. The data of Euclid have fortunately been preferred, but the work was neglected, and the few ancient copies, which amount only to three or four, are said to be wretchedly mutilated and erroneous. It had, however, been restored, with some degree of success, by previous authors; but Dr. Simson’s view of the whole analytical system pointed out to him many parts which still required amendment. He therefore made its restitution a joint task with that of the Elements, and all
I am grateful to geometry for the education which I have received from it; and I am thankful to its principles, as they are laid down by Dr. Simson, for the many useful and elegant theorems which I have been able to follow and apply in the sciences of which it has been the parent.

It is the work of which Dr. Simson is so well a master and patron, the Scotia Delineata of April 1780, which, though begun early, was not given to the world till after his death, when it was printed with the work on Physics in Edinburgh at the expense of the late Earl of Stair, for which he was bountifully deeply read in mathematics and was many years had kept up a constant correspondence with Dr. Simson, and at the death of the professor, in 1768, the work had escaped Mr. Caw, professor of logic in the university of Glasgow, to whose care he had left all his papers, to make a selection of such as might serve to support and extend his well-earned reputation at the relisher of ancient geometry.

"The life of a literary man," says his biographer, a sedulous marked with much variety; and a mathematician immersed in study, is more abstracted, perhaps, than any other pursuit from the ordinary occurrences of life, and even the ordinary topics of conversation. Such was the case with Dr. Simson. As he never entered into the marriage state, and had no occasion for the commodious house in the university, to which as professor he was entitled, he contented himself with chambers, spacious enough for his own accommodation, and for containing his large, but well selected, collection of books, but without any decoration, or even convenient furniture. His official servant acted as valet, footman, and bed-maker; and as this retirement was entirely devoted to study, he entertained no company at his chambers, but on occasions, when he wished to see his friends, he repaired to a neighbouring house, where an apartment was kept for him and his guests. He enjoyed a long course of uninterrupted health, but towards the close of his life he suffered from acute disease, which obliged him to employ an assistant in his professional labours. He died in 1768, at the age of 81, leaving to the university his valuable library, which is now kept apart from the rest of the books.

It is still regarded as the most complete collection of mathematical works and manuscripts in the kingdom, many of them being rendered doubly valuable by the addition of Dr. Simson's notes. It is open for the public benefit, but the use of it is limited by particular rules and restrictions. Dr. Simson was a good natured, and he had a fine countenance, and even in his old age he retained much gracefulness and dignity of manner. He was naturally disposed to cheerfulness; and though he seldom made the third advances towards acquaintance, he always behaved with great affability to strangers." See Dr. William Trail's Account of the Life and Writings of Dr. Simson.

SIMULACRUM, among the Romans. See Idol and Idolatry.

SIMULATION, in Ethics, is making a thing appear which does not exist; and thus it is distinguished from dissimulation, which is keeping that which exists from appearing. See Dissimulation.

occasions; and our first parents, after their transgression, received such deep traces in the brain, by the impression of sensitive objects, that it was very possible they might communicate them to their children.

Now, as it is necessary, according to the order established by nature, that the thoughts of the soul be conformable to the traces in the brain; it may be said, that as soon as we are formed in the womb, we are infected with the corruption of our parents; for having traces in the brain like those of the persons who gave us being, it is necessary we have the same thoughts, and the same inclinations, with regard to sensitive objects. Thus, of course, we must be born with concupiscence and original sin. With concupiscence, if that be nothing but the natural effort the traces of the brain make on the mind to attach it to sensible things; and with original sin, if that be nothing but the prevalence of concupiscence; nothing, in reality, but these effects considered as victorious, and as mailers of the mind and heart of the child.

Imputed original sin denotes that guilt or obligation to punishment, to which all the povertv of Adam are subject, by the imputation of his transgression. This is called the guilt of Adam’s first sin, in which the sinful acts of that late into which man fell is laid partly to confit; and it is denominated original sin, in order to distinguish it from actual sin, or personal guilt. This doctrine of imputed guilt has been explained and vindicated by supposing a covenant made with Adam, (called by divines the “covenant of works,” see Covenant,) as a public person, not for himself only, but for his posterity, in consequence of which he became the federal head, surety, or representative of all mankind; and they descend from him by ordinary generation, finding in him, and fell with him, in his first transgression. It has been debated, how far the imputation of Adam’s sin reaches; some have maintained, that it extends to final condemnation, and eternal misery: others have suggested, that the sin of Adam has subjected his posterity to an utter extinction of being; so that all, who die in his infancy, fall into a state of annihilation, except those who are the seed of God’s people, who, by virtue of the blessings of the covenant made with Abrahm, and the promise to the seed of the righteous, shall, through the grace and power of Christ, obtain a part in a happy resurrection, in which other infants shall have no share.

It seems best to acknowledge, says Dr. Doddridge, that we know nothing certain concerning the fate of infants, and therefore can affirm nothing positively; but that they are in the hands of a merciful God, who, as he cannot consistently with justice and truth give them a fenre of guilt, for an action they never committed, so probably will not hold their souls in being merely to make them sensible of pain for the guilt of a remote ancestor, their existence in a state of everlasting insensibility (which was Dr. Ridgeley’s scheme) seems hardly intelligible; we must, therefore, either fall in with the above-mentioned hypothesis, or suppose them all to have a part in the resurrection to glory, which seems to put them all on a level, without a due distinction in favour of the seed of believers; or else must suppose they go through some new state of trial, concerning which the Scripture is wholly silent.

Such is the doctrine of original sin, both inherent and imputed, as some divines, eminent as scholars and theologians, have stated it. In proof of the degeneracy or depravity of human nature, they have appealed to observation and experience, and they have referred to a variety of texts of scripture, in which, according to their ideas of them, it is either implied or expressed. To those who object, that the phenomenon of universal corruption in adult persons may be accounted for by imitation, and to want of early instruction, restraint, and discipline, they reply, that the scriptures seem to trace it to a higher source, and that children often manifest propensities towards those vices of which they have seen no examples; to which it is added, that there are many examples of eminent virtue in the world, and yet they are not so frequently, or so easily imitated, as those of a vicious nature, which plainly shews a bias on the mind towards vice. Hence they say, Pagans themselves, who have been most distinguished by their study of human nature, have acknowledged, in strong terms, an inward depravation and corruption adding a disproportionate force to evil examples, and rendering the mind averse to good. Those who maintain, that the sin of Adam is imputed to all who descended from him in the way of ordinary generation, allege, in proof of this opinion, that we are all born with such constitutions as will produce some evil inclinations, which we probably should not have had in our original state; which evil inclinations are represented in scripture as derived from our parents, and therefore may be ultimately traced up to the first sinful parents from whom we descended;—that infants are plainly liable to diseases and death, though they have not committed any personal transgression, which, while they cannot know the law, it seems impossible they should be capable of, (Rom. v. 12—14);—that the seeds of diseas and death were undoubtedly derived to children from their immediate parents, and from them may be traced up to the first diseased and mortal parent, i. e. Adam;—that the scripture teaches us to consider Adam as having brought a sentence of death upon his whole race, and expressly says, that many were constituted sinners, i. e. on account of it are treated as such, (1 Cor. xv. 22. Rom. v. 12—19);—that the sin of Adam brought upon himself depraved inclinations, an impaired constitution, and at length death:—and there is no reason to believe, that if man had continued in a state of innocence, his offspring would have been thus corrupt, and thus calamitous from their birth. Hence, it has been inferred, that the covenant was made with Adam, not only for himself, but in some measure for his posterity; so that he was to be considered as the great head and representative of all that were to defend from him.

On the other hand, many divines, no less eminent as scholars and theologians, than those whose sentiments we have already stated, have disputed the validity of the arguments alleged in proof of the doctrine of original sin; and whilst some of them have disowned the doctrine in toto, as irrational and unscriptural, others have allowed that part of it which comprehends the depravity of the human species, but have rejected the imputation of Adam’s sin to his posterity. Accordingly Limborch, rejecting and refuting the imputation of Adam’s sin, acknowledges, that men are now born less pure than Adam was created, and with a certain inclination to sin; but this inclination cannot properly be called sin, or a habit of sin propagated to them from Adam; but merely an inclination to elect and pursue what is agreeable to the flesh, arising from the bodily constitution transmitted to them by their parents. Inclinations and appetites of this kind, being most agreeable to the flesh, are contrary to the divine will, as God by prohibiting them tries the readiness of our obedience, and of course these inclinations are inclinations to sin. But, if it be asked, says this author, whether there be in human nature a certain original corruption or habit of sin propagated from Adam to his posterity, which may truly and properly be called sin, by which the understanding, and will, and all the affections
SIN.

affections are so depraved, that they are inclined only to evil, and that all mankind are by nature subject to the wrath of God, such kind of corruption is inherent either with scripture nor with right reason. The scripture, he says, teaches us such doctrine, as that which charges infidants with a moral corruption, that is truly and properly fin. (See Deut. i. 39. Jonah, iv. 11. Rem. iv. 11.) Our Saviour recommends it to his disciples to be as little children. (See also 1 Cor. xiv. 20.) This notion, says Limborch, is contrary to the justice of God, who would not punish men with this moral corruption, from which all actual sins proceed, and which leads to future perdition and misery. God cannot be the author of fin. Besides, it cannot be conceived, how this sin can be propagated; it cannot belong to the mind, which proceeds immediately from God, nor can it exist in the body, which is incapable of sin. But as diseases may be propagated, so may a peculiar temperament or constitution, and together with this an inclination to certain objects, which, immoderately indulged, may become sinful, but is not sinful in itself. Moreover, no fin is liable to punishment, which is involuntary; but original corruption is voluntary. Limborch explains many texts, and refutes many arguments urged by the advocates of original fin. Another writer, (Dr. Taylor,) who has taken a lead in this controversy, on the same side of the question, proceeds, in the examination of the doctrine of original fin, upon the same plan with Dr. Clarke, in his "Scripture Doctrine of the Trinity," by citing and explaining all those passages of scripture which expressly speak of the consequences of the first transgression. He observes, that the consequences of the first transgression are spoken of certainly and plainly but five times in the whole bible, twice in the Old, and three in the New Testament. The first passage is Gen. ii. 17. In this passage, he says, death is consigned to man, and must be suffered. But not one word occurs in this text relating to Adam's poxterity. 2. The consequences of the transgression of Adam and Eve are related in Gen. iii. from the 4th verse to the end of the chapter. The natural consequences were famine and fear, the common effects of guilt, which was personal, and could belong only to themselves. The judicial consequences pertained either to the serpent, the woman, or the man. As far as they relate to the man, Adam became obnoxious to death, which, as our author conceives, was death in law, or eternal death; and if the law had been immediately executed, his posterity then included in his sins must have been extinct. But it is alleged, that there is not a word of a curse upon the souls of our first parents, i.e. upon the powers of their minds; nor does the least intimation occur with respect to any other death, besides that diffusion which all mankind undergo, when they cease to live in this world. It is also observed, that we, their posterity, are in fact subject to the same afflictions and mortality here inflicted by sentence upon our first parents; but they are not inflected as punishments for their fin, because punishment includes guilt; but we neither are, nor in the nature of things could be, guilty of their fin. We may suffer by their fin, and actually do suffer by it; but we are not punished for their fin, because we are not guilty of it; and this suffering is essentially good. Accordingly it appears evident in our world, that the increase of natural evil (at least in fame degree) is the leaffing of moral evil.

3. The third text occurs in the New Testament, vs. 1 Cor. xv. 21, 22. Here it is said, the death from which all mankind shall be released at the resurrection, is the only death that came upon all men in consequence of Adam's fin; that as all men die, all men are mortal; all lose their life in Adam, and from him our mortality descends, and it is equally undeniable, that by Christ we are delivered of the dead. From this place we cannot object, says our author, that any other evil or death consigned to mankind is a consequence of Adam's first transgression, but that death from which all mankind shall be delivered in the resurrection, weverver that death be.

4. The most difficult passage is that which is found in Rom. v. 12, 19. A popular advocate of the doctrine of original fin (Dr. Watts,) thinks, that Adam's being a federal head, and our deriving a federal nature from him, may be collected from this text. In this passage our author observes, that the apostle is speaking of the death which takes place with regard to all mankind, when the person lies eternally punished; and that by judgment is denoted a judicial act of condemnation. The apostle means the being adjudged to the forementioned death. The words "as by one man's disobedience many were made sinners," are (says Dr. Taylor) of the same significance with those in the foregoing verse, "as by the offence of one judgment came upon all men to condemnation." and therefore they mean nothing more nor less than that by one man's disobedience, the many, that is, mankind, were made subject to death by the judicial act of God. The apostle, being a Jew, was well acquainted with the idioms of the Hebrew language; and according to that language, "being made sinners" may well very signify being adjudged or condemned to death. (See Exod. xxi. 9. Deut. xxx. 1. 1 Kings, viii. 32. Job. ix. 20. x. 2. xxiv. 3. xxxiv. 17. xl. 8. Prov. xxxiv. 17. xv. 15. II. 1. 9. lv. 17.) In the Greek text it is not "εναγμείναι κατάμαχον," but "ἐναγματεύονται," were condemned sinners; vs. the will and appointment of the judge. Besides, it is here expressly said, that the many, i.e. mankind, are made sinners, not by their own disobedience, but by the disobedience of another man, and therefore they can be sinners in no other way than as they are sufferers. Upon the whole our author thinks it plain, that "by one man's disobedience many were made sinners," means that by Adam's offence, the many, i.e. mankind, were subject to death by the judgment of God. In this passage there is an evident contrariety or comparison between something which Adam did and its consequences, and something which Christ did and the consequences of that; by the former the many, i.e., all men, are brought into condemnation; and by the latter, all men are justified unto life. The whole of the apostle's argument and attention are suppofed by our author to rest upon two principles; viz. that it is by the one offence of Adam that death passed upon all men, and not by their own personal sins; and again, that it is by the obedience of one, or the one act of Christ's obedience, (in his sufferings and death upon the cross,) that all men are justified unto life, and not by their own personal righteoufsnes. He adds, that throughout the whole paragraph, the apostle says nothing of any federal relations or transactons either on the part of Adam or Christ, nor of our deriving a sinful nature from Adam.

5. The text in Tim. ii. 14. declares a fact, with regard to Eve, which needs no explanation.

Dr. Taylor, in the second part of his book, proceeds to examine other passages of scripture, which some divines have applied to original fin. We shall here select two or three of the principal, that our readers may be able to form a judgment for themselves; one is Ephes. ii. 3. 5, and were by nature the children of wrath, even as others. The apostle, our author apprehends, cannot mean that they were liable to divine wrath or punishment by that nature which they brought into the world at their birth. For this nature, whatever
whatervininfirmitiesbelongtoit,isonothanothershouldgo'sown workor gift;and hethinks,that toaffirman that the nature
which God gives us is the hateful object of his wrath, is little
less thantoblerate against our good and bountiful Creator.
In his addrefstothe Ephesians, the apostle is not speaking
of their nature, or the natural constitution of their souls
and bodies as they came into the world, but evidently of the
viceous course of life they had led among the Gentiles.
Nature frequently signifies an acquired nature, which men
bring upon themselves by contracting either good or bad
habits. Befides, by nature may here signify really, properly,
true; for these children, strictly signify the genuine children
of parents by natural generation; and figuratively the word
denotes relation to a person or thing by way of friendship,
regard, imitation, obligation, &c.; so that "children of wrath"
are those who are related to wrath, or liable to re-
fection or punishment. The Ephesians, as the apostle teftells
them, were τὰ ἐκ τῆς φύσεως, natural genuine children of wrath,
not by natural birth, or the natural constitution of their
bodies or souls, but they were related to wrath in the highest
and strictest sense, with regard to sin and disobedience:—
Nature, in a metaphorical expression, signifying that they
were really and truly children of wrath, i.e. did in the
strictest and closest relation to suffering.
Another passage, sometimes referred to in connection with
this subject, viz. Rom. vii. 7, 8, contains not so much as
a single word that can carry our minds to Adam, or any
consequences of his sin upon us.
Gen. vi. 5. expresses the universal wickedness of the old
world, but does not so much as intimate that our nature
is corrupted in Adam; for the historian doth not charge their
his in any way upon Adam, but upon themselves: and be-
sides, Noah is exempted out of the number of the corrupt
and profligate; but this could not have been the case if the
alleged text was a good proof that by Adam's transgression
the nature of all mankind is corrupted.
Another text, which has been considered as of great im-
portance in this controversy, is Pf. li. 5, 6. "I was
shapen in iniquity, and in fin did my mother conceive me."
The word יבשונא, which we translate shapen, signifies, says our author, to bring forth or bear. (If. li. 2. Prov. viii. 24, 25.) Again, the word יבשונא
conceived me, properly signifies swarmed me; and the expref-
sion conveys the idea, not of his being conceived, but
warmed, cherished, or nurfed by his mother, after he was
born. Accordingly, the verfe is thus translated, "Behold,
I was born in iniquity, and in sin did my mother nurfe me;"
which has no reference to the original formation of his con-
stitution, but is a paraphrase for his being a sinner from the
womb, and is as much as to say, in plain language, I am a
greater sinner; or I have contracted habits of sin. This, it is
said, is a scriptural way of aggravating wickedness. (See
Pf. liii. 35. Psalms, xviii. 8.) In the whole psalm there
is not one word about Adam, or the effects of his transgres-
sion upon us. The psalmist is charging himself with his
own sin. But if the words be taken in the literal sense of
our version, then it is manifest that he chargeth not himself
with his sin and wickedness, but some other person. But
our limits will not allow of our enlarging farther in this
way.
Dr. Taylor proceeds, in part iii. of his book, to examine
and answer objections. It is added, 1. Are we not in wor-
se moral circumstances than Adam was? If by moral circum-
stances be meant the state of refton and virtue in the world,
it is certain, that since Adam's first transgression, this has
become very different from a state of innocence. But this
is not the fault of human nature, no more than Adam's sin
was the fault of his nature, but occasioned, as his trans-
gression was, by the abuse of it. If by moral circumstances
be meant the provision and means which God has furnished
for our spiritual improvement, the apostle to the Romans
expressly affirms, that in or by Jesus Christ, God hath given
us an abundance of grace. But if by moral circumstances
be meant moral abilities, or mental powers, our author sug-
gests, that there is no ground in revelation for exalting
the nature of Adam to such a degree of purity and strength
as some divines have raised it, when they affirm, that all his
faculties were perfect, and entirely devoted to the love and
obedience of his creator. The sequel of his history feems to
be inconsistent with this notion.
It is said that man was made in the image of God;
but can this be affirmed of his posterity? The image of
God must be understood either of the rational faculties
of his mind, or the dominion he had over the inferior crea-
tures, by which he bore the nearest resemblance to God
of any beings in this world; and not, as Dr. Taylor conceives,
of holiness and righteousness, which is a right use of our
spiritual faculties; because such an use of them could not be
tilt after they were created; and this writer is of opinion,
that original righteousness is as far from truth as original
sin; and that to talk of our wanting that righteousness in which
Adam was created, is to talk of nothing we want. Two
7 stex, rirc. Rom. ii. 15, 16, and Eccle. vii. 29, are quoted
by the Assembly of Divines in their larger Catechism, to prove,
that our first parents had the law of God written in their
hearts, and power to fulfil it, in opposition to their po-
terity, who want that righteousness in which they are sup-
posed to have been created, and whose nature is corrupted
to a lamentable degree; but if these texts speak not of our
first parents, but of their posterity, and of the most cor-
rupt part of their posterity too, it must be true, and the
truth is very important, "that by nature we have the law
of God written in our hearts, and power to fulfil it," as
well as they; and are equally bound to be thankful to God
for our being, and to glorify him by it.
We have already spoken of that moral taint and in-
fecion, which we are said to have derived from Adam; and
in consequence of which we have a natural propensity to fin.
This taint or infecion must exit either in the body or the
foul. In the foul, which immediately proceeds from God,
it cannot exit; nor in the body, which, in a flate separate
from the foul, is inactive matter, which in itself, neither is nor
can be the subject of moral good and evil. But such an
infecion, wherefoever it exiis, or howsoever it is propa-
gated, cannot be derived from Adam to every human
being, independently of the will and operation of God;
and to assert, that it is by his will and operation, is evi-
dently to make him the author of the pollution. It is main-
tained, that by propagation it is not possible for parents to
communicate vice, which is always the faulty choice of a
person's own will, otherwife it is not vice. Children, it has
been faid, begin very foon to fin, and how can this fadly be
accounted for but upon the scheme of original fin; namely,
that it is infiuoed into their nature? To this obje{tion it has
been replied, that their early fin is owing to the early want of
instructioo and discipline. Another objection, which is
strongly urged by the advocates of original fin, is this:
Adam was a common or federal head and representative of
all his posterity, and consequently all his offspring finned in
him, as their root; just as Levi is faid to pay tithes in
Abraham (Heb. vii. 9.) and as the branches must be mor-
ally corrupt, if the root be in that flate. (Rom. xi. 16.)
To the arguments deduced from the firt of thelfe paflages it
has been replied, that neither the cafe of Abraham and
Levi,
SIN.

Levi, nor the apostle's argument grounded upon it, has any answer of relative to partaking in guilt, or contracting moral corruption; and it is alleged, that the reference deducible from the second passage would be very just, if the apostle were here speaking of moral evil, it is, as it is a quality or principle in the mind; whereas the heinousness here mentioned is to be that external, relative evil (which is frequently attributed to the whole nation of the Jews), as they were God's peculiar church and people. The form of a federal head or representative of moral conduct, a representative of guilt of whole action shall be required to us, and whose sin shall corrupt, defile, and authorize the opposition proposed by God himself, in as its opponents maintain, not only without foundation in scripture, but in itself a great absurdity. Indeed, the external circumstances of poverty may be affected by the bad conduct of their executors. This is frequently affirmed in Scripture, and certainly held good in the case of Adam and his poverty; and may be accounted a state of poverty, and answering very good purposes. But that any man could represent me, that when he is guilty, I am to be reputed guilty, when he transgresseth, I shall be answerable and punishable for his transgression; and this before I am born, and consequently before I am in any capacity of knowing, helping, or hinderin what he doth; thus, I say, every one who uters his understanding must clearly see is fallacious, unreasonable, and altogether inconsistent with the truth and goodness of God. And, if you please, you may see him fully vindicated by the spirit of truth from all injustice of this kind in Ezekiel, xvi. 26. where he affirms, "that the soul that falleth, it shall die. The son," however he may come under disciplinary visitations, "shall not bear the iniquity of the father; neither shall the father bear the iniquity of the son; the righteous are not to be found upon him, and the wickedness of the wicked shall be upon him." And v. 30, "that God will judge every one according to his ways." It is further alleged, that the imputation of sin, so far as to make the poverty guilty of and chargeable with the sin of the parent, is no scriptural notion. An action, indeed, is often said to be imputed, reckoned, or accounted to a person; but then it is no other than his own act and deed which is so accounted or imputed to him, either for righteousnes or sin. See Gen. xvi. 6. Lev. xvii. 4. Num. xvi. 26. 27. 1 Sam. xi. 2. 1 Sam. xxiv. 15. 2 Sam. xiv. 19. Prov. xxvii. 14. P. xxiii. 2. Pf. eiv. 31. Rom. ii. 26. Rom. iv. 3. &c. Rom. v. 13. 1 Cor. xiii. 5. 2 Cor. v. 19. Gal. iii. 6. 2 Tim. iv. 16. James, ii. 23.

We might here introduce some arguments for, and some objections to, the doctrine of original sin, of a general nature, if our limits would allow. We can only suggest, on the part of its advocates, that original sin is necessary to account for the being of sin in the world. How comes it to pass, that there is so much wickedness in the world, if our nature be not sinful? — How is it consistent with the justice of God, that we suffer at all on account of Adam's sin? Besides, it has been a generally received opinion, that the fall, corruption, and apostasy in Adam, have been the reason why Christ came into the world, and gave himself a ransom for us. To the question concerning regeneration, which is inflected upon in the New Testament, why must we be born again? it is replied, because we are born in sin. Our nature in Adam is corrupted, and utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually; therefore we must be born again, before we can do anything that is good and pleasing to God.

On the other hand, the opposers of this doctrine allege, that it is highly injurious to the God of nature to believe that our nature is originally corrupted at the very moment it appears. They say, it is contract to work with God. Therefore, if it be supposed, that the doctrine of original sin is necessary to account for the fall of man, it must be directly inconsistent with the idea of universal salvation; for it is certain, that the doctrine of original sin is necessary to account for the fall of man, as we might imagine, to account for the corruption of mankind, the same which he was created, and the corruption of his nature, &c. (See Rom. v. 12. 19. Rom. iii. 10. 20. Eph. ii. 1. 2. Rom. v. 6. viii. 7. 9. Gen. vii. 5. James, iv. 14. 15. Matt. xv. 10.) It is added, that the Fall brought upon mankind the loss of communion with God, his dignity, and curse; so that we are by nature children of wrath, bond-slaves to Satan, and justly liable to all punishments in
SIN

On the other hand, it is alleged, that the language of man's sinfulness consisting in the guilt of Adam's first sin is unscriptural; nor, in the nature of things, can our sinfulness consist in the guilt of Adam's first sin; because, as we could not possibly commit that action in any sense, so we could not, upon account of it, become obnoxious to punishment. If the texts above cited prove that man's nature by Adam's sin is so corrupted, that man, i.e. men, are utterly indifposed, disabled, and made opposite to all that is spiritually good, that is, to moral actions, pleasing and acceptable to God, and wholly and continually inclined to all manner of wickedness, they would further prove, that men are no moral agents, and that sin must be natural to us, and if natural, necessary; and if necessary, with regard to us, it is no sin, with regard to us, or so far as we are concerned in it. For a further account of the state of this controversy, and of the arguments adduced for and against the doctrine of original sin, we refer to the Assembly's Catechism; Watts's Ruin and Recovery; Jennings's Vindication, &c. Chandler's Sermons, vol. iv. Sermon 1—7. Bury's Street Lect. vol. 1. Limborch Theolog. lib. iii. c. 7. § 1, 2. Taylor's Scripture Doctrine of Original Sin, In Three Parts, with a Supplement, &c. ed. 4. Ben Mordecai's Letters, Letter V.

The Romish cauftsights distinguiht æqual sins into mortal; which are such as make us lose the grace of God; and venial, which alone are pardoned, as being only sins of in

SIN

inerity, not of malice. See POFERY.

Divines are not yet agreed what the sin against the Holy Ghost is. See BLASPHEMY against the Holy Ghost.

SIN, Philosohical, according to the doctrine of the Jefuits, is an action, or course of action, that is repugnant to the dictates of reason, and yet not offensive to the Deity.

SINA, in Ancient Geography, a town of Afa, in Marigiana. Ptolemy.—Alto, a town of Cappadocia, in the prefecture of Cilicia. Id.—Allo, a place in the isle of Lebos. Strabo.

SINA, or Jufinianopolis, a town of Afa, in the Greater Armenia.

SINAAB, in Geography, a town of Algiers, in the province of Tremecon, on the E. side of the Shelliff; 72 miles S.W. of Algiers.

SINACA, in Ancient Geography, a town of Hycania. Ptolemy.

SINADIZAVA, in Geography, a town of European Turkey, in Bulgaria, on the Oza; 12 miles E. of Nicopoli.

SINE, in Ancient Geography, a people of India, according to Ptolemy. It appears that their country extended from Siam into a part of China.

SINAIB, Mount, in Geography, a famous mount of Arabia Petraea, on which God gave the law to Moses. (Exod. xix. 1. xxiv. 16. xxxi. 18. xxiv. 2. 4. &c. Levit. xxv. i. xxvi. 46.) It is situated in a kind of peninsula, formed by the two arms of the Red sea, one extending N. called the gulf of Kolfun; the other extending E. called the gulf of Elan. The Arabs call mount Sinai by the name of "Tor," i.e. the mountain, by way of excellence; or "Jebel Mufa," the mountain of Mofes; comprehending a range of mountains which rise at the interior extremity of the valley of Fazan, restricting the name of Tor Sinai to that part of the range on which the convent of St. Catherine stands; and about 250 miles from Cairo. The wilderness of Sinai, where the Israelites continued encamped almost a year, and where Mofes erected the tabernacle of the covenant, is considerably elevated above the rest of the country; the ascent to it is very craggy, the greater part being cut out of the rock; and then you arrive at a large space of ground, which is a plain surrounded on all sides by rocks and eminences, whose length is nearly twelve miles. Towards the extremity of this plain, on the north, two high mountains appear, the highest of which is called Sinai, the other Horeb. They are both of a very steep ascent, and the ground on which they stand is unconsiderable, when compared with their height. Sinai is one-third part higher than the other, and its ascent more upright and difficult. The Greeks have cut a flight of steps up the rock. Poscope reckons 3000 of these steps to the top of the mountain, or rather bare, pointed rock. Two German miles and a half up the mountain stands the convent of St. Catharine. The body of this monastery is a building 120 feet in length, and almost as many in breadth. Before it stands another small building, in which is the only gate of the convent, and which remains always shut, except when the bishop is there. At other times, whatever is introduced within the convent, whether men or provisions, is drawn up by the roof of a belfry, and with a cord and pulley. The whole building is of hewn stone, which, in such a desert, must have been constructed with great labour and expense. Within the walls is a small mosque for the convenience of the Arabs. This monastery belongs to Greek monks, who had in former times only a tower erected near the burning bush of Mofes. But being molestled by the infults and depredations of the Arabs, they petitioned the emperor Jufitian to build for them a strong monastery for their future security; and the emperor is said to have complied with their request. Before the convent is a large garden, planted with excellent fruit-trees. According to the account of the Arabs, the monks enter it by a subterraneous passage: These Greek ecclesiastics are not allowed to receive an European visitor, without an order from the bishop of mount Sinai, who resides ordinarily at Cairo. When the bishop happens to be present, the gate is opened, and the convent must entertain all the Arabs who come in there; and this is a grievous charge on the poor monks, who live merely on alms, and whose provisions, which they are obliged to bring from Cairo, are often stolen by the way. The Arabs are, in general, very dangerous neighbours, as they often fire on the convent from the adjacent rocks; and feize the monks whenever they find them without the walls of the monastery, and refuse to release them without a consider able ransom.

Five hundred steps above the convent is found an excellent spring, which superfluous persons have counted miraculous, as the mountain is so high and so barren. A thousand steps higher stands a chapel dedicated to the Blessed Virgin, and 500 above this, are two other chapels, situated in a plain, which the traveller enters by two small gates of mason-work. Upon this plain are two trees, under which, at high festivals, the Arabs are revelled at the expense of the Greeks. Sinai is held in great veneration, on account of the law which God gave on this mountain. The whole mountain is a very remarkable rock of red granite, interpenetrated with spots, to which foil has been brought by human labour, or washed down by rain, and in which grow almond-trees, figs, and vines. Mount Horeb stands W. of Sinai, so that at sun rise the shadow of Sinai covers Horeb. Beside the little fountain at the top of Sinai, there is another at the foot of Horeb, which supplies the monastery of St. Catharine. At a small distance is a town, four or five feet high, and three broad, from which it is pretended, Mofes caufed the water
water to gush out; in this line are twelve holes or channels, about a foot wide, from which, it is said, the water issued which the Brahutes drank.

Sinal, N. B. See Catharine.

Sinaloa, m Geography. See Cifaloe.

1. N. N. A river of Algiers, which joins the Wed-el-Maslab, about five miles before it runs into the sea. It glides in a variety of beautiful windings, and is known by several names, according to the remarkable places which they water. Near the bank of the river, Barbarossa the Elder scattered his treasures when pursued by the victorious Spaniards, and here he made his last intellectual effort to retard their progress.

Sinaneley, a town of Hindostan, in Myalore; 22 miles S.W. of Banyalagur.

Sinapatinga, in Ancient Geography, a town of India, on this side of the Ganges, in the vicinity of the river Indus, and one of those which belonged to the Cathars, according to Ptolemy.

Gen. Ch. Cal. Perianth inferior, spreading, divided into four, linear, concave, channelled leaves, forming a cros, decussate. Cor. cruciform; of four, rounded, flat, spreading, undivided petals, with erect, linear claws scarcely the length of the calyx. Nectary composed of four oval glands, one on each side between the shorter flaments and the pellis; and one on each side between the longer flaments and the calyx. Stam. Filaments six, awl-shaped, erect; the two shorter ones opposite; anthers erect, spreading, pointed. Pyl. Germin superior, cylindrical; nyle the length of the germen and height of the florum; stigma capitate, undivided. Petal. Pod oblong, inflated unequally at the lower part, rough, of two cells and two valves; partition generally twice as long as the valves, large, compressed. Seeds numerous, globular.

Obst. Sinapis differs principally from Brassica in having a spreading calyx, and the claws of the petals erect. Cruciferae unites this genus with Raphanus.

Eff. Ch. Calyx widely spreading, claws of the petals straight. Nectary parietals four. Pod more or less cylindrical, the partition longer than the valves.

1. L. Arabian. Wild Mustard or Chardock. Linn. Sp. Pl. 933. Fl. Brit. n. t. Eng. Bot. t. 1748. Curt. Lond. fac. 5. t. 47. Fl. Dan. t. 753.—Pods with many angles, rugged, 1 nger than their own two-edged beak. Leaves ovate, somewhat lyrate.—One of the most common and most troublesome European weeds in heavy moist corn lands, as well as about waste ground and hedges. It flowers most commonly in May and June, but occasionally in all open weather. Root annual, spindle-shaped, small, rigid. Stem round, flated, liquid with slightly deflexed bristles, ruged with red. Leaves alternate, falked, ovate, rough, to qualify traced; lower ones somewhat lyrate, upper leafy. Flowers in a terminal, clustered coryotte, of a bright yellow color. Seeds extremely pungent, very well known as the case of Daun Mistall.

2. L. vulgaris. Green Mustard. Linn. Sp. Pl. 223. Acad. Acad. v. 4. 281. Att. v. 4. t. 174. Proc. Sp. 174. (Semi-one side to side, rapin. D. Turner, 1745.)—Pods rough with reflexed bristles, and four blunt angles, compressed at the tip. Native of the Levant, is introduced at Kew by M. Thouin in 1737, where it flowers in June and July. This annual is extremely like the last, from which indeed it differs merely in having the pods rough with reflexed bristles, the beak only beaked.

3. L. brassicae. Cabbage Mustard. Willd. n. 3. Loureux, C. mis. 399.—Leaves oblong, smooth, to which is a diminutive manner.—Native of China, where it is much cultivated. This plant, we are informed by Loureux, has the habit of Cabbage or Lettuce, but in the structure of its calyx it resembles Mustard. Stem a foot and half high, very robust. Radial leaves oblonge, obtuse, white-veined, on channelled stalks; flowers, many, in two annulated appendages at the base of the flarks, upper one feathery, lanceolate, embracing the stem. Flowers like those of the Common Cabbage, bright yellow. Pod also resembling that of Brassica oleacea.

6. L. petaurata. Pyreenean Mustard. Linn. Sp. Pl. 933. Allain. Pedem. t. 55. r. 1.—Pods bracted, indents. Leaves recurved, smooth.—Native of the Pyrenees, Mts. de Cens, and similar situations in the south of Europe. It flowers about June. Root biennial. Stem angular, even, frilled, wavy, smooth. Leaves recurved; segments of the lower or radical ones toothed; those of the stem lanceolate. Flowers clustered, small, yellow. Willows considers S. mariciana A. Linn. as a variety of this species.

SINAPIS.

16. *S. fructífera*. Shrubby Multard. Willd. n. 17. Ait. Hort. Kew. n. 11.—Pods linear, smooth. Lower-leaves oblong, toothed; upper lanceolate, undivided. Stem smooth, shrubby.—Native of Madeira, whence it was introduced to Kew by Mr. F. Maffon in 1777. It flowers from December to June. Figure and description wanting.

The Linnaean *S. hípídá*, a rare and little-known plant, Ait. n. 15, is removed to Desfontaines' new genus Cordylócarpus, in Prodr. Pl. Græc. v. 2. 33.

Mr. Brown, in Hort. Kew. has, after Tournefort's example, conferred *Sísymbrium tenùifolium* and *Murale* Linnaeus as species of *Sinapis*. See *Sísmýrium*.

*Sinapis*, in Gardening, contains plants of the hardy, herbaceous, annual kind, of which the species cultivated are, the white multard (*S. alíba*); and the common or black multard (*S. nígra*).

The first fort is generally cultivated in gardens as a falladed herb, with cresses, radishes, rape, &c. for winter and spring ufe; in which intention it is a highly valuable plant.

In the second fort, it is the flower of the feed that affords the common multard for the table.

Method of Culture.—The first fort is fown along with other small falladed herbs, at all times of the year, sometimes every week or fortnight, in a bed or border of light earth, fown generally in shallow drills very thick, covering it very thinly with earth; and in winter, and early in spring, during cold weather, in hot-beds. The herbs are always cut for ufe whiff in the feed-leaf, and but a few days old; otherwife they become too frong and rank-tafted for ufe. See *Sallad Herbs*, and *Small Sallad Herbs*.

But in order to have feed of this fort for garden ufe, it should be fown on an open spot of ground, in March or April, either thinly in drills a foot afunder, or broad-calf all over the surface, and the plants be left to run up to falk, when they will furnifh ripe feeds in August. And in order to raife the plants for the feed for multard, the feeds should be fown in the fpring, any time in March, in some open situation, either in the kitchen-garden, or in open fields. In either cafe, having dug or ploughed the ground, the feed should be fown broad-calf all over the surface, and raked or harrowed in lightly; or it may be fown in shallow drills a foot afunder, and be lightly covered in. The plants foon come up; and when they have four or more leaves an inch or two broad, if they fland very thick, thofe fown in the broad-calf way particularly should be hoed and thinned, leaving them fix or eight inches afunder, cutting up all weeds; repeating the operation once or more, if necefly. After this the plants will foon spread and cover the ground, and fwoff falt up to flalks for flowers and feed, which ripens in July or August, when the flalks should be cut or pulled up, and the feed, being properly hardened, and
and dried in the pod. Should either be thrashed out directly, or stuck up dry, and thrashed at occasional opportunities afterwards; but the best is the leaf method.

Sinapi Nigra, Common Black Mustard, the Materia Medica, Sec. is common in cornfields and of ditches, but is cultivated for use, and flowers in June. (See Sinapis and Mustard.) The seeds of this species mustard, which are directed by the London College, a tribe of the S. alka, which are preferred by that of Edinburgh, are not different in taste or their general effects, answer equally well for the table and for medical purposes. Their taste is acrid and pungent, and when bruised this agency becomes volatile and affects the smell; they readily part these qualities to aqueous liquids, and by diffusion with water yield an essential oil of great acuteness; to rectified spirits they give out very little either of the smell or taste. When subjected to the press, they yield a considerable quantity of mild impid oil, which is as free from rancidity as that of almonds. By writers on the materia medica mustard is considered as promoting appetite, afflicting digen, attenuating woe fluids, and by diluting the fibres, owing a general remedy in paralytic and rheumatic affections. In considerable quantity, it opens the body and creates the urin

Sinapis, Persicum, Persian Mustard, a name by which some botanical authors have called the tldapi, or treacle mustard.

Sinapisis, a word used by some writers as a name for Ataman bile.

Sinapis, in which some have called to Sinapis ortis, or sain. mustard, in Agriculture, an external medicine, in form of a cataplasm. See Sinapis

Sinapistrum, in Botany, Tourn. Hist. 251, t. 140, a name of Hermann's, alluding to the resemblance of the plant, or at least of its pods, to Sinapis, or Mustard. See Cleome.

Sinara, the name of the male dancers, who, according to the mythology of the Hindoos, amuse their god Indra, regent of the firmament. (See Indra.) These are perhaps the same beings whose name is sometimes written Cinnara, and described to be human figures with the head of a horse, but we never saw them so represented. See Sintana and Sura.

Sinaram Regio, in Ancient Geography, a country of Asia, and the land on the eastern coast, according to Ptolemy.

Sinarus, a river of India, which discharges itself into the Hydaspes, according to Arrian.

Sinasbarium, in Botany, a name given by some authors to the fyxifomy, or water-mint, common in all our ditches and watery places.

Sinasse, in Geography, a town of Abyflinia; 40 miles N. of Mine.

Sinay, a small island near the W. coast of the island of Lucon. N. lat. 18° 11'. E. long. 120° 36'.

Sinbach, or Simbach, a town of Bavaria; 5 miles S. of Landau.

Sincapoura, or Sincapura, an island, with a town of the same name, near the S. coast of Malacca, which gives name to the narrow sea, called the Straits of Sincapura.' N. lat. 1° 11'. E. long. 103° 90'.

Sin-Carpou, a town of Chino Tertiary; 555 miles E.N.E. of Peking. N. lat. 42° 23'. E. long. 140° 46'.

Sincerity, in Ethics, is that excellent habit and temper of mind, which gives to virtue its reality, and makes it to be what it appears. Sincerity, called by the Greeks αὐλεξία, is included in this virtue, but does not express the whole of it; so that it is necessary to add in the Caten, which is to say two of the first kinds are in opposition to what is mixed and adulterated; the other to what is counterfeit. Sincerity has respect to two sorts of objects: persons and things. Of the first kind are God; other men, and every man's Self. Sincerity, with regard to God, signifies, that the form of religion is accompanied with the power of it, and that piety and obedience are substantial and unaffected; proceeding from principles, right in themselves, and uniform in their influence. Sincerity, as it regards men, implies an honest
SIN

and open dishes in our dealings with them, extending to the springs and motions of our actions, as well as the actions themselves; to our words and our thoughts. Sincerity, with relation to a man’s self, is opposed to self-deception.

As to things, truth and goodwill are the principal objects of sincerity. The extremes of this virtue are over-frankness and hypocrisy. Grove’s System of Moral Philosophy, vol. ii. ch. 3.

SINCHO, or CHINCO, in Geography, a town of Africa, in the kingdom of Ningo, on the Gold Coast, the inhabitants of which are chiefly employed in fishing.

SINCIPUT, in Anatomy, the fore-part of the head, in opposition to occiput.

SINCKEL, in Geography, a river of Bavaria, which joins the Wertha; 2 miles S.S.W. of Augsburg.

SINCLAIR. See ST. CLAIR.

SIND, in Agriculture, provincially to rinse or wash out, as a milking pail, dish, &c.

SINDA, in Ancient Geography, a town of India, on the other side of the Ganges, placed by Steph. Byz. on the coast of the great gulf between Coragtha and Pagrafa.—Also, a town of Afia, in Pindia, on the confines of Caria. Strabo.—Also, a town of Afloat Sarmatia, upon the Cimmerian Bosphorus, between the ports Sindicus and Bara, according to Ptolemy.

SINDA, in Geography, a town of Hindoostan, in Baglana; 20 miles N.W. of Naifuck.

SINDAEC, in Ancient Geography, the name of three islands in the Indian sea, S. of the Baraffe, according to Ptolemy.

SINDAGUA, in Geography, a ridge of mountains in South America, between Popayan and the Pacific ocean.

SINDANGAN BAY, a bay on the N.W. coast of Mindanao, extending from N. to S. about 100 miles. N. lat. 8° 15’. E. long. 125° 4’.

SINDE. See INDUS.—Also, a river of Hindoostan, which rises about 20 miles W. of Bilfah, and runs into the Jumnah, at Puttehara.

SINDEJUA, a town of Napaul; 40 miles W. of Moaupour.

SINDELFINGEN, a town of Wurtemberg; 6 miles S.W. of Stuttgart. N. lat. 48° 41’. E. long. 8° 52’.

SINDER, a town of Hindoostan, in Baglana; 15 miles S.E. of Naifuck.

SINDERINGEN, a town of Germany, in the county of Hohonlohe, on the Kocher; 12 miles N.E. of Heilbron. N. lat. 49° 16’. E. long. 9° 55’.

SINDI, a people of Afloat Sarmatia, in the number of those who inhabited the Cimmerian Bosphorus. Strabo.

SINDIANI, a Scythian people who inhabited the vicinity of the Palus Meotis, according to Lucian.

SINDICUS PORTUS, a port of Afloat Sarmatia, on the coast of the Cimmerian Bosphorus, according to the Periplus of Scylax.

SINDINICES, a people of Germany, who formed a part of the nation of the Vandals.

SINDION, in Geography, a town of Egypt, on the W. branch of the Ganges; 13 miles S.S.E. of Roletta.

SINDITIA, in Ancient Geography, a town of Lesser Armenia, in the province of Murania. Ptolemy.

SINDKEFIA, in Geography, a town of Hindoostan, in the cear of Barbar; 15 miles W. of Tolnani.

SINDOCADA, in Ancient Geography, a town placed by Ptolemy one W. coast of the isle of Taporhaha, between the mouth of the river Soana and the port Pripus.

SINDOLEA, in Geography, a town of Hindoostan, in Orifia; 15 mili. of Sonepour.

SINDOMA, in Ancient Geography, a town of India, and the capital the territories of Muficanus. Arrian.

SINDON, in History, a word properly signifying a thorough, aided by the evangelists to denote the linen cloth in which the body of Arimathea wrapped the body of Jesus, after its interment, &c. (Matth. xxvii. 59. Mark, xv. 45. Luke, iii. 53. John, xx. 7.) Sindon is also mentioned in the history of Samson. (Judges, xiv. 12, 13.) The virtuous woman mentioned by Solomon (Prov. xxxi. 24.) made findons or garments, which she sold to the Phenicians. The young wien of Jerusalem wore findons. (See II. iii. 23.) It was a fashion peculiar to the Sidonians and the Phenicians, and perhaps the name was derived from the city of Sido. Martial says, that the findon of Tyre, or Phenicia, core a man all over, and puts him in a condition to defecate in wind.

“Ridebis vento hoc munere tecitus, et imbres

The young man who followed Jesus Christ on the night of his passion, “annis findone super nudum,” was probably thus defended against the cold, as by a night-gown. Mark, xiv. 51.

SINDON, in Syri, a little round piece of linen, or silk, or lint, used in dishing the wound after trepanning. The first thing usually done after the operation of trepanning is to pour a few drops of white balsam on the dura mater; then a spoonful of ointment being warmed with a little balsam, a findon dipped into it, of fine linen cloth; this is immediately applied upon the dura mater; and being greater than the skull, its circumference is thrust all round between the cranium and the membrane; then pledges of lint applied, and the hole is quite stoped with it. The next morning, when the dreneling is taken off, the brain is near left bare a moment; but as soon as the former findon & lint are removed, new ones are clapped on in their room.

SINDOS, in Ancient Geography, a town of Mygdonia, a country of Macedonia, W. of Therna, between this town and the mouth of the Axios. It is called by Steph. Byz. Sinthos.

SINDOURCOTY, in Geography, a town of Thibet, on the left bank of the Ganges; 48 miles S. of Gangotri.

SINDRY, a town of Bengal; 45 miles S.E. of Natore.

SINDSCAR, a town of Afloat Turkey, in the government of Ioful; 30 miles S. of Moful.

SINDY. See SIND.
