1819.
SCOTLAND. in Geography, an ancient, and formerly an
independent kingdom, but now constituting an integral
part of the united kingdom of Great Britain and Ireland; is
situated, exclusive of its islands, between 54° 37' and 58° 42'
north latitude, and between 2° 47' and 6° 7' west longitude,
from London. It is bounded on the south by the Solway
frith, and the rivers Esk, Jerv, Liddel, and Tweed, which
divide it from England; on the east and north by the
Northern ocean; and on the west by the waters of the
Atlantic. Its greatest length in a direction due north and
south, is 275 miles; and its greatest breadth 147 miles; but
its breadth is extremely vast, and in one place does not
exceed 36 miles. According to calculation, the superficial
contents of the mainland amount to 15,920 square miles
of land, 404 square miles of fresh-water lakes, and 3000 square
miles of salt-water lochs, or lakes. The islands, which are
usually divided under two divisions, the Hebrides on the
west, and the Orkney and Zetland islands towards the
north, comprehend an area of 3224 square miles, to that
Scotland, with its lakes and islands, exclusive of its bays,
prest is a surface of 30,238 square miles. Politically speaking,
it comprises 33 counties which are named in the sequel
under the head Parliaments representation, and contains,
according to the population edus of 1811, 3,177,683 houses,
and 1,865,688 inhabitants.

Historical Events.—The history of Scotland, previous to
the union of the two crowns, has been divided by Dr.
Robertson into four periods; the first reaching from the most
remote ages to the reign of Kenneth II.; the second,
from Kenneth’s conquest of the Picts to the death of Ale,
ander III.; the third, from that event to the death of
James V.; and the last, the advance of James VI. to the throne of
Scotland. The first of these periods, observes the same author, is the region of pure fa-
ble; truth begins to dawn in the second period with a light,
feebler at first, but gradually increasing; the events which then
happened may be slightly touched, but merit no laborious
inquiry. In the third period, Scottish history, chiefly by means
of records preferred in England, becomes more authentic;
not only are events related, but their causes and effects explained;
the characters of the actors are displayed; the
manner of the age described; and the revolutions in the
constitution pointed out. During the fourth period, the aff-
airs of Scotland were so much mingled with those of other
nations: its situation in the political state of Europe was so
important: its influence on the operations of neighbouring
kingdoms was so visible: that its history becomes an object
of attention, not merely to Scotsmen but foreigners: as
without some knowledge of the various and extraordinary
revolutions which happened there, it would be impossible for
them to form a just notion with respect either to the great
transactions, or the distinguished characters, of the sixteenth
century.

After a minute examination of nearly all the works which
have been written respecting the early history of Scotland,
it is impracticable to unravel the mystery in which it is
involved, and to separate authenticated facts from ingenious
conjecture. In the present article, therefore, we shall advert
to the first periods only in a general way, and will dilate our
narrative, in proportion as events become more certain, im-
portant, and interesting.

History of the First Period.—It is agreed by Pinkerton and
Chalmers, though on many other points they materially
differ, that the aboriginal inhabitants of Scotland were a
colony of the Celts, who are generally allowed to have been
the first inhabitants of western Europe. Respecting the era
of their arrival in North Britain, and the route by which
they reached the country, nothing is known; nor has record,
or tradition, preferred to us the smallest trace of their history, till the period of Agricola’s invasion, when their descendants appear to have been divided into twenty-one distinct clans, called by the Romans the Tattadini, Gadeni, Selgovae, Novantii, Damnii, Horelli, Venicones, Taizali, Vacumagi, Albanii, Attacotti, Caledoni, Cantae, Logi, Carnabi, Catini, Mertix, Carnonacae, Creones, Cерones, and Epidii.

These various tribes, who are usually mentioned in the Latin writers by the generic name of Caledonians, on the advance of the Romans into their country, united under the authority of Galgacus, one of their most powerful chiefs, to repel their progress. The utmost efforts of valour, however, proved unavailing against the military skill of the great Agricola, and the discipline of the legionary troops. In his first campaign in North Britain, A.D. 82, that celebrated general penetrated, according to Tacitus, as far as the river Tay; and in the year following he constructed a chain of forts between the friths of Clyde and Forth, within which he had retired for the protection of the southern country against the inroads of the free tribes of the North. The summer of 82 was employed in subduing and securing the district which extends from the Solway to the Clyde. Thus freed from the danger of a flank attack, he again passed the Forth, and advanced, without opposition, as far as Loch Leven, establishing, as he proceeded, military posts to keep the inhabitants in subjection. These posts the Caledonians had the hardihood to attack; and by this display of daring intrepidity, seem to have struck great terror into the Roman soldiers. In this dilemma, Agricola divided his army into three bodies, and pushed forward the weakest to Lochore, where he ordered it to encamp, while he stationed the other two at short distances on the right and left. The Caledonians, perceiving the Romans thus separated, made a vigorous attack during the night on the intrenchments at Lochore, and had already entered the camp, when Agricola arrived with the light troops of the other divisions, and, after a furious combat, repulsed the assailants, and forced them to a disorderly and precipitate flight. This victory, though dearly bought, inspired the Romans with renewed ardour; but it did not intimidate the Caledonians, who magnanimously resolved to dispute every foot of ground with the invaders. Agricola consequently found sufficient employment during the remainder of the year in subduing the Horelli, the inhabitants of the illimns between the Tay and the Forth. The following year he advanced to the base of the Grampian mountains, where the Caledonian warriors lay encamped and prepared to receive him. The battle which ensued was contested with the most obstinate valour, but at length terminated in the complete overthrow of the latter. Agricola, however, seems to have derived little advantage from his victory, for after a few days spent in ascertaining the condition of the enemy, he led his troops back to the country of the Horelli, and terminated the campaign. The Caledonians immediately advanced, and demolished all the forts in the territories which the Romans had abandoned. Agricola, in the interim, ordered the commander of the Roman navy to sail round Britain, on a voyage of discovery, and with the design of intimidation. This voyage was happily accomplished, by the return of the fleet to the Forth, before the commencement of winter. With these remarkable exploits the campaigns of Agricola terminated; for, having excited the jealousy of the emperor Domitian, by the splendour of his achievements, he was soon afterwards recalled to Rome.

From this period to A.D. 120, the Roman authors are entirely silent respecting the affairs of Britain; but from an incidental expression in Tacitus, some later writers have supposed that, during that interval, the Caledonians succeeded in recovering the country conquered by Agricola, as far as the Solway on the west, and Tynemouth on the east. This opinion seems to receive some confirmation from the fact, that when the emperor Adrian visited our island in the year 119, he caused a rampart to be constructed between these two citadels, “which has in every age been a monument of his power, and a memorial of his circumspection.” Chalmers, however, contends that this measure was merely precautionary, and that the Roman legions still held all the country south of the Forth and Clyde. The emperor, on his departure, left Julius Severus as his lieutenant in Britain, who does not appear to have attempted any military exploit.

Antoninus, who assumed the purple on the death of Adrian, named Lollius Urbicus to the chief government of the island; an officer who equally possessed talents for peace, and a genius for war. Having tranquillized some insurrectionary movements in the south, he carried his arms from the Forth to the Varar, and settled stations in the intermediate country; throwing the whole of that extensive district into the form of a Roman province. Under his direction was constructed the rampart of Antoninus (now called Grimes’ dyke), which extends from Caer- ridden on the Forth, to Alclud on the Clyde, a distance of thirty-four miles, six hundred and twenty paces. Several military roads, and numerous stations and encampments, were likewise formed in all the provinces, both of North and South Britain. Lollius was succeeded in his government by Calphurnus Agricola, during whose time the Romans abandoned all the country north of Grimes’ dyke. Chalmers affirms that his retreat was not the consequence of weakness, but simply of choice. It nevertheless incurred the unconsidered tribes with fresh vigour. Breaking through the barriers of Antoninus, they pillaged a large tract within that boundary, and put numbers of the Romans to the sword; but Ulfius Marcellus soon drove them back again into their own territories. They renewed their inroads again in the year 200, with better success; and for some years afterwards seem to have made such progress, as to induce the emperor Severus to assume the government of Britain in person. On his arrival at the head of a larger army than had ever before visited this island, the Caledonian tribes sued for peace, but Severus rejected their proposals. The particulars of his expedition into Caledonia are very imperfectly narrated. It is clear, however, that he penetrated as far to the northward as the crest of Cromarty, though, as Dion affirms us, with so few of less than 50,000 men. Before he set out, he constructed a wall from the Solway to the Tyne, parallel with the rampart of Adrian, in order to facilitate his retreat in the event of failure.

On the return of Severus to York, he left his son Caracalla in the government of Nor Britain; whose conduct is said to have incited the Caledians to acts of aggression. Irritated at this, the aged emperor issued orders to renew the war, and to spare neither ge nor sex; but his death, and the contest for the empire between his sons, seem to have prevented their execution. A great event, it is certain that Caracalla made peace with the Caledonians, and gave up to them all the country northward of the Forth and Clyde. From this period, for nearly a century, we hear nothing respecting the Caledonians, we may therefore be presumed to have made no serious attempts to molest the Romanized Britons. At length, however, about the year 356, we are informed that the emperor Constantine found it necessary to come into Britain to repel the Caledonians and other Picts. This, Chalmers affirms, is the first me the Picts are mentioned in history, and contends that the Caledonians were on this occasion called Picts, “owing their peculiar occupation from the
the Roman provincials on the south of the walls." Pinkerton, on the other hand, maintains, that they were a Scythian colony, who had peopled themselves of the eastern coast of Scotland before the Christian era, but his opinion is not supported by evidence or probability.

Conquista having driven back the Caledonians, and other Picts within their own territories returned to York, where he died July 25, A.D. 406. Almost forty years elapsed before they were again able to fill the territories of the Romanized Britons, though the empire was harassed by civil wars. In 443, however, they made some inroads, but were twice repelled, and the province again enjoyed peace for seventeen years. At the close of that period, when Conitantus and Julianus were contending for the imperial sway, the Scots and Picts made a formidable attack upon the province. Luperius, an able officer, was sent to oppose them, but does not seem to have effects the object of his mission. This is the first time the Scots are mentioned in the pages of Roman history. Amonst, in some work they are noticed, joins them with the Picts, as if they formed one army, though they had no connection whatever by neighbourhood, language, or interests; they were a mixed race of barbarous people, who were much accustomed to make predatory excursions against the Roman provincials during the fourth and fifth centuries, but they held their territories in North Britain till about the year 572, when we more particularly notice the sequel. The next attack upon the Roman provinces by the Picts and Scots happened in the year 564, and seems to have been more general and destructive than any former incursion by either of these people. For three years they continued gradually advancing towards the south, spreading death and desolation wherever they came. At length Theodosius, the most distinguished general of his age, was sent into Britain by the emperor Valentinian, to put a stop to their ravages and to restore tranquillity. In two campaigns he drove the Scots fro the island, and the Picts beyond the wall of Antonine, which repaired, and strengthened with additional forts, and infatuated the territories within it into a province, by the name of Valentia. Such, indeed, was the energy of his operations, and the wisdom of his precautionary measures for the maintenance of peace, that the Scots and Picts did not cease to renew their aggressions till the year 598, and even then they were easily repelled. The Roman empire, however, was now rapidly on the decline. In 497, the rest of the troops in Britain transferred the government to Gisors, and after his death to Conulantus, who conveyed the body with great respect to Gaul. The British provincials, thus left a manner to themselves, assumed a sort of independence, which was sanctioned by the emperor Honorius, who, confident of his inability to protect this distant part of the empire, ceded the British cities to rule and defend themselves. But, to quote the words of Chalmers, "their inexperience occasioned them to feel their own weaknesses. And A.D. 422, though the walls were then garrisoned by Rom troops, the provincials again applied for additional protection against the defaulinary attacks of a predatory people, w could be more easily repelled than tranquilized. A levy is said to have been sent, who chastified the invaders, and, for the last time, repaired the fortifications that had been overawed the Pictish tribes. From this epoch the provincials enjoyed twenty years' repose. The year 446, when A.D. 422, though the third time, is the memorable epoch when the British provincials acknowledged themselves to Roman citizens, by their submission to that able fopper of a degenerate flat for fifth assistance; but he was able to gratify their desire, owing to the prelude of the barbarians upon Gaul. The provincials were again told, that they must rely on their own efforts for their future government and efficient defence. The state then in which the provincials were willing to make was A.D. 446. After this, they were completely effaced in A.D. 456. "Caledon. vol. 1.

After the final departure of the Romans, North Britain was occupied by two races of men, the Picts, and the romanized Britons of the province of Valentia. The latter, some authors contend, united themselves under one rule to repel the inroads of the Picts, and thus formed the kingdom of Cumbria, or Strathclyde. Of the existence of such a monarchy, however, within the limits of proper history, there is much room to doubt. At all events, it is improbable that this new nation was able to confine the Picts within their ancient boundaries. On the contrary, it is most likely that the Picts, in contrast with the Scots from Ireland, conquered and occupied the greater part of Scotland. At a later date, the Anglo-Saxons of Northumbria peopled themselves of the eastern coast of that province; but it does not appear certain that the Lothians ever were parts of the Northumbrian or British monarchs; though they might be for a time annexed to by temporary conquest from the Picts. See STRATHCLYDE.

Several ancient Scottish writers, upon the authority of modern legends, contend that their ancestors first settled in Argyll 350 years before the Christians; and they give a list of kings, and a narrative of their actions, from that remote period. Later investigations, however, have shown that these details are most probably fictitious, and that the Scots did not colonize any part of present Scotland till the year A.D. 583, when a body of them passed over from the north of Ireland, their proper country, and fixed themselves in the district of the British Edin, which they denominnted Caernarvon. These colonists were led by Loth, Fergus, and Angus, the sons of Erc, a chieftain or petty king of Dalriada, in the portion of Rhinard in Ulter, whence the Scots were sometimes called Dalriada. The derivation of the same Scot is uncertain, but the most plausible opinion is, that it was a corruption of the word "featas," which signifies in Irish dispersed or scattered, and was therefore applied generally to denote the roving tribes who had inhabited themselves to maritime excursions against the western shores of romanized Britain.

Chalmers judiciously observes, that there scarcely occurs a period of history so perplexed and obscurant as the annals of the Scot-Irish, from the date of their settlement in Argyll, till their ascendency over the Picts in 843. This confusion and obscurity originated in the want of contemporaneous writings, and were afterwards greatly increased, by the contrivances of the Irish and Scottish antiquaries, for pre-emience in antiquity as well as in fame. In the latter island, however, there have happily been preserved various documents, particularly the annals of Turgern and Ulter, which throw many flashes of light on the transactions of that dark era. Several brief chronicles and historical documents, calculated to elucidate the same subject, have likewise been brought into notice by Innes; and Pinkerton first published a Gaeic poem, which professes to give a genealogical account of the Scot-Irish kings. From an attentive consideration of all these, and from an accurate examination of other documents, Chalmers compiled his genealogical and chronological table of the Scottish monarchs, to Kenneth inclusive, from which it appears that they were twenty-nine in number, and occupied by their united reigns a period of 340 years. The first was Fergus, who became sole chieftain, or king of the new colonists, soon after their arrival. He died in 506, leaving his power and pretensions...
to his son Domangart, who reigned five years, and then transmitted his dominions to his elder son, Comgal. This prince enjoyed his sovereignty twenty-four years, during which time he had leisure to extend his dominions and consolidate his authority. Dying in 573, he was succeeded by his brother Gawan, to the exclusion of his own son, Conal. Gawan reigned twenty-two years, and engaged in a war against the Picts, which terminated in his defeat and death. Conal then obtained the sceptre, and held it for fourteen years. Aidan, the son of Gawan, next claimed it; but Dunche, the son of Conal, opposed his pretensions. The bloody field of Lora, in which Dunche fell, put an end to the dispute, and gave Aiden possession of the crown. He was inaugurated by St. Columba in 574, on the holy island of Iona; and proved himself, throughout a reign of thirty-five years, to be a prince of great enterprise. He extended his dominions along the western coast of Valentia, which had been seized upon and colonized by various tribes of "Scitests" from Ireland, by consolidating the whole of them under his superior sway. In 577, having advanced into Cumberland, he engaged Rydderch, king of Cumbria, but the battle seems to have been indecisive. He afterwards entered into a league offensive and defensive with the Cumbrian monarch against the Saxons, who were defeated with great slaughter at Sammore, in Westmoreland. Buchanan affirms this was a league as well against the Picts as the Saxons, and further states, that Aiden was monarch of the district, now included in the counties of Renfrew, Ayr, Wigton, Kirkcudbright, and Dumfries; and this view of the subject certainly bears the stamp of greater probability than the opinion which confines his territories to the isthmus of Cantire and the neighbouring islands. Aiden, according to all the writers who treat of his reign, fought several battles against the Saxons, in most of which he was victorious; but in the year 603, he was completely defeated by Ethelfrid, king of Northumbria, at the battle of Dawlantine, in Roxburghshire. This disaster, joined to the death of St. Columba, his kinman and friend, so much affected him, that he died in the second year thereafter, at the advanced age of eighty, and was buried in the chapel of Ciaran at Campbeltown. The successor of Aiden was Eocha-bui, called by Buchanan Egenusus, who, according to Chalmers, carried on a successful warfare against the Cruithine of Ireland; but the Scotch historian mentions only that he harried the Picts and Saxons by continued incursions. Eocha died in 621, and had for his successor Kenneth the Aukward, his son. This prince is said to have prosecuted the Irish war begun by his father with great vigour, till his death, which happened in the unfortunate conflict of Fedhaevin, when he had scarcely reigned three months. Ferchar, the son of Eogan, of the race of Loarn, next obtained the throne. Chalmers says he reigned sixteen years, but left no events for history to recount. Buchanan, however, affirms that he was a great tyrant, and that the nobility, irritated at his oppressions, and at the circumstance of his embracing the Pelagian heresy, conspired against him, and threw him into prison, where he laid violent hands on himself. His successor was Donald, who, as Chalmers informs us, invaded Ireland with an army composed of Scots, Picts, Britons, and Saxons, but was totally defeated on the plains of Myroyst in 637, and compelled to seek shelter in Cantire. Donald, however, continues our author, derived no wisdom from this disaster, for in the following year he attacked the Picts, and was again overthrown with great slaughter. He was ultimately slain at Straith Carnac, by Hoan, one of the reguli of Strathclyud, in the year 642. Such is the history of Donald, as given by Chalmers, but not a word on the subject either of Irith or Pictish wars occurs in Buchanan. By that historian, on the contrary, he is represented as an excellent man, the protector of Ofwold, afterwards king of Northumberland, enduring the misfortunes of his early life, and his affliction in more fortunate times, in the propagation of the Christian religion among his heathen subjects.

From this period to the year 736, the events of Scotch history are so involved and so unimportant, that we shall pass them over in silence, remarking only, that nine kings reigned in the interval, whose names are thus recorded by Chalmers: Conal II., Donvel din his son, Mal-duin, Ferchar-fada, Eocha-rineval, Annbecciallach, Selwach, Eocha III., and Muredch. The last monarch had been unwillingly drawn into hostilities with the Picts, and transmitted their loyalty to his successor, Baglan, or Ewan, a feeble prince, who died in 739, when Aodhfin seized the sceptre, and soon evinced himself equal to the arduous task of government, even in the most troublesome times. In 740 he boldly encountered the mighty Ungus, king of the Picts, and forced him to quit his territories. Aodhfin died soon after, having reigned with greater glory than any of his predecessors, for the long period of thirty years. He left his kingdom, but not his talents, to his son Fergus, who signed about three years, whilst that of his successor, Selach II., lasted twenty-four years. The government of Eocha IV., or as he is called by Buchanan, Achdanu, the new king, was marked by several important transactions. Some authors assert that he formed an alliance with Charlemagne, and instituted the most ancient order of the Thistle, but both these statements are erroneous. It is true, however, that he entered into a treaty of great importance to himself, his children, and his country, for he made peace with the Picts, and received the hand of Urgius, daughter of Urgis, and sister of Conffantine and Ungus, all of which in freedom swayed the Pictish sceptre. Eocha died in 826, after a reign of thirty years. Buchanan says, that the successor of Eocha was Congallus, but Chalmers makes mention of this monarch, affecting that Dungal, the son ofselwach II., obtained the throne on the death of Eocha. He died in 833, when Alpin, the son of Eocha and Urguis, was acknowledged king. Chalmers, who does not admit the cottiach monarchs to have possessed, even in this reign, any territories beyond the district of Cantire, and the dispute acts of Argyle and Lorn, states that Alpin, ambitious of regaining over ricer people and more extensive domain landed on the coast of Ayr in 856, and penetrated considerable way into the country, but was at length defeated and slain near the city of Lacht castle, on the coasts of Galloway. Buchanan, on the other hand, affirms that Alpin fell in a battle fought near Dundee against the Picts. Kenneth, the son of Alpin, next succeeded to the throne, and waging war against the Picts, after several obstinate battles overthrew their government, and united the tribal monarchies into one kingdom, under the name of Sland, an event which brings us to the close of the first pod of Scotch history.

History of the Second Period.—Kenneth, having thus accomplished the union of the two kingdoms, endeavoured by every means in his power to render that union permanent. He enacted many excent laws for the better administration of the government, and removed the fome chair in which the kings of Sland were wont to be crowned from Argyle to Scoane. After a reign of twenty-three years, sixteen of which he ed over his new monarchy, he died in 854, when Donald his brother, was proclaimed king. This prince relaxed public discipline established by his predecessor, and gavemself up to the most shameful excesses. The Picts r in open rebellion against his authority,
theory, and formed alliances with Olafreth and Aldo, king of one of the Anglo-Saxon kingdoms adjoining Scotland. Their forces entered Moray with a powerful army, and from thence dispersed heretals to Donald, requiring him to restore the Pictish monarchy. Donald, routed by a body of English, marched against them, and totally defeated them near forces on the Jed, a river of the Teviotdale. This victory caused him to recover Berwick and all the territories to the north of the Tweed; but his success was of very short duration, for having indulged too far the natural licentiousness of his troops, the English took advantage of their careless, set upon them in the night, routed them with great slaughter, and made Donald prisoner. The enemy afterwards advanced to the Forth, which they attempted to cross in flaps, where a violent storm arose, and occasioned the wreck of half of their fleet. This event to weakened their forces, that they were induced to conclude a peace with the Scots, upon the condition of their abandoning all the country southward of the Forth and Clyde. Of the Picts nothing was heard in the treaty, and hence little of them, deceived in their hopes, passed over into Denmark and Norway. Donald, having returned from captivity, still continued his rebellious conduct, which so exasperated the English, that they committed him to prison, where he laid violent hands upon himself in the year 848. Such is the account of Buchanan; but Chalmers speaks of him with praise, and says that he died at the palace of Balachore in the year 863, and was buried at Jed-thrift.

Conlantine, son of the great Kenneth, now mounted the throne. Being a prince of great valor and lotty spirit, says Buchanan, he was anxious to eradicate the ignorance which Donald had brought upon the kingdom, and to recover the territories he had lost, but his nobles dissuaded him from the attempt. He therefore directed his attention to the reformation of the public morals, particularly those of the military and priesthood. In this reign the Danes invaded Scotland, by landing a large army in two divisions in the firths of Fife. Conlantine hastened to oppose them, and fortunately overthrew one division before the other could arrive to its assistance. Upon this, the rest of the Danes retracted to an entrenched camp, which they had constructed near their landing place. The Scots, flushed with victory, too rashly assaulted the Danish works, and were defeated with the loss of their king and half their army. The Danes, however, had suffered so much, that notwithstanding this success, they immediately reembarked for their own country.

Othus, or Aodh, brother to Conlantine, succeeded him in the regal dignity. His reign was short and disturbed by rebellion, and terminated, according to Chalmers, in consequence of a wound received in the battle of Strathal. Buchanan, on the other hand, affirms that he was thrown into prison by the nobles for his tyrannical and licentious conduct, and that he died there before he completed the first year of his reign. Gregory, or Grig, who next reigned, emulated the virtues and achievements of the great Kenneth. While his internal policy was mild and just, he rendered himself feared and respected by foreigners. The Danes having seized from the English the greater part of the country south of the Forth, he drove them out of it, and once more established the Selway and the Tyne at the northern boundary of Scotland. He afterwards defeated the English, who had entered the western district of the kingdom, and compelled them to give up Cumberland and Westmorland to the Scots. Gregory afterwards landed in Ireland, and having defeated the Irish in a battle fought on the river Bann, advanced to Dublin, which surrendered without resistance. Here he found king Duarte, then a minor, with whom he concluded a peace, and immediately returned to his own country, where he died in 872, greatly regretted by his people. Such was the life of Gregory, as represented by the historian; but the narrations of other have differed that instead of a king and a captive, it was a preceptor and an imperious master, and his people was driven from his throne by the fury of his subjects. Gregory was succeeded by Donald, the son of Conlantine, during whose reign the Danes made several invasions on Scotland, but were, in every instance, repulsed. Chalmers informs us that the king fell gallantly in the defense of his kingdom against a body of these invaders, who had penetrated as far as to the Scottish capital. Buchanan, on the other hand, states that he died during an expedition to quell a feud between the Kellfras and the Merchans; and Buchan thus affirms that he expired in Northumberland in 923. His successor was Conlantine, the son of Aodh, the early part of whose reign was equally disturbed by the invasions of the Danes. He afterwards engaged in a war against Athelstan, king of England, who ravaged all the country as far as the Forth and Clyde, and forced Conlantine to fly for refuge to Cumberland. However, only obtained till an opportunity for revenge occurred, and then, joining with Aodh, one of the most powerful of the Anglo-Danish princes, their united forces failed for the Humber, and disembarked without opposition. Athelstan, who had foreseen and prepared for this event, soon came up with the invaders, and, after a battle, killed several of the English, and recovered every foot of English territory. He then returned to England, where he died shortly after. In his reign, the Danes, who had occupied the whole of the eastern provinces of Cumberland and Westmorland, were expelled from the English monarch, who, fearful of his ability to retain them, agreed to surrender both the king of Scotland, on condition, as Buchanan states, that Malcolm and his successors would acknowledge them as the crown of England, in fealty; the condition was accepted, and Malcolm passed the remainder of his reign in reforming the administration of justice, and the licentious character of his subjects. With this view he made a tour through the whole of his dominions every two years, and visited to have been paying his last biennial visit to the north, when he was assassinated in Moray, in the fifth year of his reign. His successor was Indulfus, who formed an alliance with the English, and enjoyed peace during the first seven years of his rule. At length the Danes unexpectedly disembarked in Lothian; the Scottish king marched and gave them battle, overthrew them with great slaughter, but unfortunately perished himself in the ardor of pursuit.

Dufus, the son of Malcolm, next swayed the sceptre, and appointed Calenus, the son of Indulfus, governor of Cumberland. This monarch having held the reins of government with a firm hand, many of his nobles rose in open rebellion against the royal authority. By his vigorous measures, however, he was enabled to crush the insurrection, and to bring the leading offenders to punishment. He afterwards directed his endeavors to crush the bandits who infested the counties of Moray, Rofs, and Caithness. Many of these were slain in various skirmishes, but the principal of them were secured and brought to the town of Forres,
order to render their fate more exemplary. Here the king
was assassinated by the governor and his wife, who had vainly
interceded to save some of the criminals, their relations.
Culenus, the son of Indulfus, now mounted the throne;
and immediately instituted an inquiry into the murder of his
predecessor, and visited with condign punishment all who
were concerned in that tragical event. But with these acts
the merits of his reign cease, for fearfully had the executioner
performed his duty, before the king abandoned himself to
every species of vice, and gave equal licence to the younger
nobility. Having been, in consequence, summoned to answer
for his conduct in an assembly of the states convened at
Scone, he was assassinated on his journey thither by the
than of Methven, whose daughter he had injured. Culenus
was succeeded by Kenneth, the brother of Duffus, a man
in every respect the reverse of him in character and conduct.
His first object was to put an end to the abuses of the former
reign; which he had fearfully accomplished, when the Danes,
made a descent on Aberdeenshire, and pillaged the country
as far as the town of Perth, to which they fled siege. The
king hastened to give them battle, and after an obstinate and
bloody contest, was defeated and put to flight. This
disaster being perceived by the chief of the clan, Hay, he,
and his sons and vassals, placed themselves in a narrow pass,
through which the main body of the Scots fled, and by
their exhortations and courageous conduct, succeeded in
changing the fortune of the day. The Scots turned upon
their conquerors, and after a second encounter, still
more furious than the first, gained a complete victory. The
gallant Hay was rewarded with extensive estates, and raised
to the dignity of nobility, which is still enjoyed by his descend-
ants. From that time peace continued for several years,
during which period Kenneth attempted to regulate the suc-
cession to the royal dignity, so as to render it hereditary
in his own family. In the pursuit of this object he committed
the only crime with which his reign is tainted, the murder of
Malcolm, the son of King Duffus, who was considered by
the nobility as the next successor to the throne. All
his efforts, however, proved unsuccessful; for though he
obtained a vote of the states in favour of his views, yet when
the throne became vacant by his death, which happened in
the year 994, Conffantine the Bald was proclaimed king.
Malcolm, Kenneth's son, collected a large body of troops
to assert the preference of his rights, but on the approach
of the royal troops he dismallled his army, and retired into
Cumberland. Kenneth, his natural brother, regarding this
conduct as dishonourable, prevailed on most of the followers
to join his standard and continue the war. A battle soon
afterwards ensued, in which both Conffantine and Kenneth
fell, each by the hand of the other, at the very moment
when victory had declared for the latter.
In this critical emergency, the nobles elected Grimus,
the son of Duffus, to the sovereign authority. This prince
seems to have possessed greater popularity than his prede-
cessor, for he was no sooner declared king than most of his
opponent's partizans deferted to his cause. Malcolm's
party, therefore, deemed it advisable to negotiate for peace,
and accordingly a treaty was concluded, by which it was
agreed that Grimus should retain the kingdom till his death,
when it should revert to Malcolm and his heirs, according
to the intentions of Kenneth. This peace was frupulously
obtained during eight years; but after that period, Grimus
having begun to evince a most tyrannical disposition, Mal-
colm thought himself justified in again taking up arms. He
accordingly marched into Scotland, and as the tide of popu-
larly was now decidedly in his favour, he soon acquired a
large army. Grimus marched to oppose him, but being
betrayed by his followers, he was severely wounded in the
first battle, and soon after terminated his existence.
Malcolm, on assuming the sceptre, laboured to compose
the various factions which agitated the state, and to destroy
the numerous banditti of robbers, who had taken advantage
of the laxity of the old government, to infest almost every
district of the kingdom. He renewed, in his capacity of
king of Scotland, the league which he had formed with
the English, as governor of Cumberland, and in virtue of its
conditions sent a corps of troops to assist them in opposing
the Danes. This measure so rouled the indignation of the
Danish monarch, that he dispatched a large fleet and army
to invade the Scottish territories, under the command of
two of his lieutenants, Olave and Euneus. A landing was
executed in the province of Moray, which being sub-
dued, the invaders laid siege to the fortresses of Nairn. Mal-
colm, who, during these operations, had been busily engaged
in levying forces, arrived while the garrison yet continued
a gallant defence; but being defeated, they were compelled
to surrender; and the fortresses of Elgin and Moray were
evacuated without resistance.
Upon these successes the Danes resolved to fix their
habitation in Moray, and with this view sent home their
ships to bring over their wives and children. In the mean-
time Malcolm re-organized his army, and made head against
the enemy again at Mortlach, in the district of Moray. At
first the Scots, discouraged by the fall of three of their com-
manders, retreated to their camp, where they made a vigorous
stand, and changed their flight into a glorious victory. Mal-
colm, however, did not deem it prudent to advance far in
pursuit, nor to attempt the expulsion of the whole Danish
colony before he had recruited his forces with new levies.
This cautious policy afforded time to king Swein to dispatch
a second body of troops to the affittance of their country-
men. They were commanded by Camus, a general of tried
courage and abilities, and disembarked near Aberbrothick,
in Angus, whence they marched forward to the village of
St. Bride, near which the Scots lay encamped, and ready to
receive them. The action that followed terminated in the
total rout of the Danes, who, finding their retreat to their
ships cut off, dispersed in different directions. Camus and
the most considerable party fled towards the mountains, with
the intention of penetrating to Moray; but before they had
proceeded far from the field of battle, they were overtaken,
and either slain or made prisoners. A similar fate attended
all the other fugitive bands.
This second discomfiture, though more signal than the
first, did not yet discourage the Danish king. Immediately
on being apprized of it, he sent a third armament under his
own son, Cannte, which landed in Buchan without opposi-
tion, and plundered the surrounding country. Malcolm,
who had fearfully recovered the losses sustained in former
battles, nevertheless hastened to oppose this new invasion.
At first he declined risking a general engagement, but when
he had ascertained that his opponents were less strong than
was originally supposed, he seized a favourable opportunity
to fall upon them with his whole forces. The battle was the
most dreadful hitherto fought against the Danes; the
Scots remained masters of the field, but were unable to pursue
the enemy, who retreated without molestation. Next day
both parties, equally afraid to hazard another contest, eagerly
furnished to the interposition of the clergy, and concluded
a peace, in which it was stipulated that all the Danes should
leave Scotland, and that neither Svein nor Malcolm should,
in future, wage war against one another.

Malcolm
Malcolm having been the first article of the above treaty performed, extended his sway, and reigned for some years in greater light, honor, and glory than any preceding monarch of Scotland. At first the people, however, he acquired an embarrassed state; famine, a pestilence which led him to commit many acts of oppression and injustice. This conduct excited the hatred of his subjects, and eventually occasioned his assassination, though authors are not agreed as to the perpetrators of the bloody deed.

Duncan, the grandson of Malcolm, by his daughter Beatrice, succeeded to the vacant throne, he was a prince of great popularity, which he had justly acquired; but while his virtues endeared him to the wise and good, they awakened feelings of enmity in the breasts of the turbulent and turbulent. Macduff, a scion of the peer, first raised the standard of rebellion, and attracted to it many of the nobility, and a body of Irish, who joined him in the hope of plunder. The king dispatched one Malcolm, a thane of high rank, to quell this insurrection, but he was unfortunately defeated and taken prisoner. Alarm at that event, Malcolm summoned a council, in which Macbeth, one of his relatives, declared, that if he were made general of an expedition, in conjunction with Banquo, thane of Fife, they would soon bring the traitors to punishment. Macbeth obtained the wished-for command, and performed his task almost without respite; for such was the terror infused into the rebels by his known character for severity, that on his approach they endeavoured to save themselves by flight, but the main body was overtaken, and most of them put to the sword.

Thus was Duncan freed from domestic sedition, but he did not long enjoy peace. The Norwegians, under Swein, king of Denmark, soon after landed in Fifeshire, and again aroused him from his natural inactivity. Having entreated to Macbeth the charge of levy a new army, he himself advanced, with such troops as he could collect, to oppose the invaders, whom he met at Culrofs, where a battle ensued, which terminated to the disadvantage of the Scots. Duncan retired to the town of Perth, which was immediately besieged by the Danes. In the mean time Macbeth advanced with the new levies, upon whose arrival the king made a sudden attack upon the enemy's camp, while they were totally unprepared, and routed them with such slaughter, that only Swein, and a few attendants, were enabled to reach their ships. But no sooner was Duncan relieved from this second danger, than he was alarmed by the news of the landing of the Danes in Fifeshire. Banquo marched to oppose their progress, and beat them back to their ships. About the same time, Macbeth, whose ambition led him to aspire to the throne, was encouraged in his daring views by a dream, in which he imagined that three women, naked, and of unknown beauty, appeared to him and saluted him, one as thane of Angus, another as thane of Murray, and the third as king of Scotland. Henceforth he determined to accomplish his purpose at all hazards; and accordingly, having brought over many of the nobles to his side, he waylaid and murdered the king at Inverness. Macbeth then hastened to Scone, where he was invested with the royal authority. The sons of Duncan, señalised at these events, fled, one into Cumberland, and the other to the Hebrides. Shakespeare has dramatised some of these events in his admirable tragedy of "Macbeth."

The first act of Macbeth's reign was to suppress the feuds which subsisted between the thanes of Caithness, Rois, Sutherland, and Nairn. He afterwards defeated and flew Macgill, lord of Galloway, who refused to acknowledge his authority; and quizz having been thus removed to the kingdom, he applied his attention to the amendment of many salutary laws, and the correction of abuses in their administration. Thus he reigned ten years with considerable power, that the manner of his obtaining the throne was really overlooked. At the close of that period, however, he began to give way to the natural cruelty of his temper, and to convert his heretofore salutary government into an oppressive and cruel tyranny. The first shock of his ambition was visited against Banquo, whom he invited to a feast, and caused to be slain on his return home, giving out that the deed was perpetrated in an accidental fray or tumult. Upon this, most of the nobles departed to their own castles, and only a few of them occasionally repaired to court. Hence mutual distrust and jealousy sprung up between them and the king, who upon the slightest pretences forfeited their property, and put them to death. The confined states he employed to maintain a band of plunderers, whom he kept as a guard about his person. But even with their protection he did not consider himself in safety, and therefore resolved to erect a cairn for his residence on the summit of Dunfinna hill. In the accomplishment of this work, he ordered all the thanes of the kingdom to assist; but Macduff, thane of Fife, sent only workmen on his part: this disobedience exasperated Macbeth so much, that he swore vengeance against Macduff, who, fearful of the consequences, immediately fled to England, where he found Malcolm, the son of Duncan, royally treated by king Edward the Confessor. After several interviews with the Scottish prince, he encouraged him to assert his rights to the throne of Scotland. Malcolm, alluring of Macduff's integrity, hesitated not a moment to adopt his views, and being assisted by king Edward, with 10,000 men, he marched directly into Scotland, where he was joined by all ranks of the people. Macbeth, not daring to hazard a battle, endeavoured to escape, but was arrested and put to death. Malcolm, having thus recovered his father's dominions, was declared king in the year 1057. This prince is said to have introduced into Scotland the titles of earl, baron, and knight. Macduff, to whose encouragement and exertions he owed the crown, is mentioned by Buchanan as having been the first who held the dignity of earl. At the same time, the privilege of placing the king in the chair of state at the ceremony of coronation was granted to him and his posterity.

But though Malcolm therewith obtained the crown, he was not allowed to enjoy it long in peace. The faction of Macbeth proclaimed his son, Lulthe, king, and for three months contended openly for the maintenance of his pretensions. At length his followers were defeated and himself slain in Strathbogie. Malcolm now reigned for several years, undisturbed either by foreign or domestic enemies. In the interim Edgar Atheling, who with his mother and sisters had fled from England to avoid the fate of William the Conqueror, was driven by distress of weather into Scotland, where they were courteously received by Malcolm, who married Margaret, the sister of Edgar. The Scottish prince further protected all Edgar's banished friends, and affiliated them lands for their maintenance. This conduct excited king William to declare war against Scotland; but after several unsuccessful attempts at invasion, he concluded a peace favourable both to Edgar and Malcolm.

The danger of foreign troubles being removed, several of the clans raised the standard of rebellion against the government, and for a time threatened its subversion; but the valor of Macduff, and of Walter, grandson of Banquo,
eventually restored quiet; for which service the latter was constituted lord steward of Scotland, and from him the royal family of Stewart were descended. Malcolm now applied himself to the reformation of the public morals, and established the two new bishoprics of Caithness and Moray. In 1579 he took advantage of the civil war in Normandy, between king William and his son, Robert, to devastate the county of Northumberland; to revenge this aggression, the English monarch sent an army into Scotland, but Malcolm's cautious policy prevented it from effecting any important exploit, and a treaty was soon afterwards negociated between the two kingdoms. The accession of William Rufus, however, again proved the signal for hostilities. Malcolm advanced into England as far as Chester-in-the-Street, whence he retreated, as soon as he understood that the English army was in march to oppose him. William, in his turn, prepared for the invasion of Scotland both by land and sea, and had actually passed the borders, when the destruction of his fleet, and the intercession of Robert, duke of Normandy, and Edgar Atheling, induced him to conclude a peace with his antagonist. Malcolm promised the same homage which he had yielded to the conqueror; and William engaged to surrender to the Scottish king twelve manors, which Duncan had held in England, and to pay him twelve marks of gold annually; but peace did not continue long; William fortified Carlisle in the sub sequent year, a measure which Malcolm pointedly referred: a personal interview was proposed in the hope of accommodating matters, but it had an opposite result. The Scottish king, therefore, led his army into Northumberland and besiegèd Alnwick; where he was surprised and slain, as was also his eldest son, Edward, earl Mowbray, on the 13th of November, 1093.

Donaldbane, the brother of Malcolm, succeeded, but he was soon driven from the throne by his nephew, Duncan, who was affiliated in recovering his dominions by king William Rufus; Duncan, however, had not enjoyed his dignity above six months, before he was assassinated at the instigation of his uncle, who once more usurped the crown, and reigned about two years, when he was a second time dethroned, and Edgar, the son of Malcolm, set up in his stead. This prince cultivated peace with king William Rufus, and his successor Henry I., to whom he gave his sister Matilda in marriage. Edgar died at Edinburgh on the 8th of January, 1106–7, and was succeeded by his brother Alexander I., who likewise preferred peace with his southern neighbours; but his reign was disturbed by an alarming rebellion at home, and by the ecclesiastical pretensions of the archbishops of York and Canterbury. His promptitude and valour, however, soon quelled the former, and his steady opposition to the latter enabled him to maintain the rights of his country and the independence of his government. Alexander died in April 1124, and was succeeded by David, the younger son of Malcolm and Margaret. This prince, having been educated at the court of Henry I., had acquired a knowledge of the English laws, and gained considerable experience in the art of government. Like his predecessor, he refitted with success the efforts of the court of Rome to destroy the independence of the Scotch church. His attention was afterwards given to an intervention raised by Angus, earl of Moray, who was defeated and slain at Stracathro, one of the pallet of Forfarhire. During these transactions David maintained the strictest amity with England, till the civil dissensions which ensued upon the death of Henry, when he took up arms in support of the empress Matilda; but he afterwards concluded a treaty with the usurper, Stephen.

This lasted about two years, when David again passed the borders, and fought the battle of the "Standard" on the 22d of August, 1138. In that action the Scots were overthrown with great slaughter, and the king himself, with the remains of his army, found great difficulty in securing a retreat to Carlisle. David neverthe less soon recruited his troops, and thus he might be still formidable, by reorganizing his troops. But his further progress was arrested by the conclusion of peace. After this David applied himself chiefly to the laudable task of civilizing his yet semi-barbarous subjects. He founded several towns, and enacted the "Leges Burgorum," which still continue in force. He likewise introduced into the kingdom many Anglo-Saxon, Anglo-Norman, and Anglo-Belgic inhabitants, a measure that met with great opposition, but which nevertheless was eventually advantageous to Scotland. David died at Carlisle in May 1153, and was succeeded by the grandson of Malcolm, who had fearlessly seated himself on the throne, before Somerled, a Hebridean chief, invaded the Mainland, and forced him to take the field. After various conflicts, Somerled was repulsed, but not subdued; and Malcolm was forced to conclude a peace with him, upon terms degrading to the dignity of the Scottish monarch.

About this time, the death of Stephen placed the crown of England on the head of Henry II., who not only disregarded his solemn engagements to cede to Scotland the country lying between the Tyne and the Tweed, but demanded restitution of those territories which Malcolm held in England. The latter, conscious of his inability to wage war with so powerful a monarch, complied with this unjustifiable demand; and in return, Henry conferred on him the honour of Huntington, for which he did homage in 1157, reserving all his dignities. Malcolm on that occasion was invested with the honour of knighthood; after which he accompanied Henry to France. These circumstances excited great discontent among the barons, and Somerled took advantage of the distracted state of the country to renew his inroads. Malcolm, however, on his return triumphed over all his adversaries; but did not long enjoy his good fortune, having died at Jedburgh on the 4th of December, 1165.

William, the brother of Malcolm, now ascended the throne, and almost immediately repaired to the English court to demand the restitution of Northumberland. Henry amused him with fair promises for twelve months, when William began to perceive the futility of further solicitation; and therefore entered into a league with France, in 1168, though it does not appear that war was the immediate result. William, however, waited the borders in 1173; and in the subsequent year engaged in a similar expedition, during which he was surprized in his camp at Alnwick, and taken prisoner; an event which cost him the ancient independency of his crown; for, in order to gain his liberty, he flippated to do homage to Henry for Scotland, and all his other possessions; engaged that all the barons and nobility of his kingdom should also do homage; that the bishops should take an oath of fealty; that both should swear to adhere to the king of England against their native prince, if the latter should break his engagements; and that the fortresses of Edinburgh, Stirling, Berwick, Roxburgh, and Jedburgh, should be delivered up to Henry till the performance of all these articles. "This severe and humiliating treaty," says Hume, "was executed in its full rigour. William, being releaved, brought up all his barons, prelates, and abbots, and they did homage to Henry in the cathedral of York, and acknowledged him and

Richard, when in commodate their thelefs two Chalmers to Angus, frontiers Alexander of independence, and counties engaged in his long year was entered to army, in of barons. Thus determined of number arm of Norway, against, which he feared quelled, before Angus, lord of Argyle, assumed independence, and refused to acknowledge the sovereignty of the Scottish crown. The king marched against him, but died in Kerreryay, an islet on the coast of Argyle, on the 5th of July, 1249.

Chalmers remarks concerning this prince, that he is pro-

SCOTLAND.

and his successors for their superior lord. The English

monarch stretched still further the reins of the constant

which he exacted. He engaged in king and states to make a perpetual cession of the forfeitures of Berwick and Roscrich, and to allow the castle of Edinburgh to remain in his possession for an infinite time.” This is the first great

achievement by which Scotland obtained over Scotland.

These decisive measures, and the feeble conduct of

William, rendered it extremely unpopular. The lords of

Galloway and Renfrew having displayed the standard of

rebellion, and though eventually compelled to submit, kept

the kingdom in a state of disquietude for many years. In

1211, Henry II. went Hugh, bishop of Durham, and

several prelates, into Scotland, to collect a dye, for the Holy

Land, but this met with the warmest opposition. He

next offered to restore the castles of Roscrich and Bar-

wick to William, if he would give the title of the kingdom

for the holy war; and his consent was only withheld,

in consequence of the barons and clergy indignantly

declaring, that “they would not pay, although both kings

should have sworn to buy them.” This was the last prop-

osal of Henry affecting the independence of Scotland; as

he died soon afterwards, leaving his crown to his son

Richard, who referred to William all the rights and terri-

itories which had been wrested from him during the govern-

ment of his father; thus Scotland again resumed her in-

dependence, though her monarch became the baronial vaill

of England, as earl of Huntington. In the latter capacity

William did homage to king John A.D. 1200, and after

the ceremony demanded restitution of the three northern

counties of England, a demand which was tacitly refrued.

In 1209, both monarchs assembled their troops on the

borders, but the interference of their respective barons

effect a reconciliation without bloodshed. From this

period William lived in peace till his death, which occurred

on the 4th of December, 1214.

Alexander II., the son of William, succeeded to the

throne, and almost immediately engaged in hostilities against

King John, in support of the barons. John held no time

in making a signal retaliation. In 1215 he passed the

Tweed, and burnt the towns of Dunbar and Haddington.

Alexander next year entered England to join Lewis, the

French prince; but the death of John, and the subsequent

dissensions of Lewis, prevented the accomplishment of his

designs, and a treaty was soon after concluded with

Henry III. This pacification lasted till the year 1223,

when the English king thought proper to call in question

the validity of Alexander’s coronation, and even intrigued

to deprive him of his crown. In an interview between the

two kings at Newcastle, they endeavoured in vain to ac-

commodate their differences. They adjured them never-

theless at York, in September, 1237; but as the terms of

their agreement were unequal, it was not of long duration.

Jealouities arose between them in 1244; Henry collected a

large force at Newcastle, and Alexander marched to the

frontiers a highly disciplined army, amounting, as some

writers state, to the number of 100,000 men, all animated

with the most determined resolution to defend their country.

The appearance of so formidable a force induced the English

barons to mediate a peace, which was accordingly agreed
to. Alexander was next routed from repose by an insur-

rection in Galloway, which he had scarcely quelled, before

Angus, lord of Argyle, assumed independence, and refused

to acknowledge the sovereignty of the Scottish crown.

The king marched against him, but died in Kerreryay, an

islet on the coast of Argyle, on the 5th of July, 1249.
uncle, king Edward of England, the seemed firmly seated on the throne; a circumstance from which the English monarch was led to anticipate great advantages. Having lately subjugated Wales, he formed the plan of marrying his eldest son, Edward, to the Scottish queen, hoping thereby to consolidate the whole island into one monarchy. With this view he drew closer the ties of amity between England and Norway, and did all in his power to attach the Scottish regency and nobles to his interest. The friendship which had of late prevailed between the two nations greatly facilitated the execution of this design, so favourable to the happiness and grandeur of both kingdoms. The states of Scotland not only gave a ready assent to the marriage, but agreed that their young sovereign should be educated in the court of Edward. Anxiously, at the same time, to ensure the independence of their country, they took care to stipulate very equitable conditions before they entrusted themselves into the hands of so ambitious a monarch. It was solemnly agreed that they should enjoy all their ancient laws, liberties, and customs; that in case their queen should die without issue, the crown of Scotland should revert to the next heir, and should be inherited by him free and independent; that the military tenants of the crown should never be obliged to leave Scotland, in order to do homage to the sovereign of the united kingdoms; nor the chapters of cathedrals, collegiate or conventual churches, in order to make elections; that the parliaments summoned for Scottish affairs should always be held within the bounds of that kingdom; and that Edward should bind himself, under the penalty of 100,000 marks, payable to the pope, to observe all these articles. It is not easy to conceive that two nations could have treated upon terms of greater equality than Scotland and England maintained during the whole course of this transaction; and though Edward gave his assent to the article concerning the future independence of the Scottish crown, with a saving of his former rights, this reserve gave no alarm to the nobility of Scotland. The marriage treaty was therefore signed at Brigham, on the 18th of July 1290, with the cordial concurrence of all parties.

But this project, so happily planned, and so amicably conducted, failed of success by the sudden demise of the Norwegian princes, who expired in Orkney, while on her passage to Scotland, and left a very dismal prospect to the kingdom. Though for the present disorders were prevented by the authority of the regency, the succession of the crown was now become an object of dispute, and the regents could not expect that a controversy, which is not usually decided by reason and argument, would be peaceably settled by them, or even by the states of the kingdom, amidst so many powerful competitors. As the pottency of king William became extinct by the death of the Maid of Norway, the right to the throne devolved on the issue of David, earl of Huntington, brother of William, whose male line being also extinct, left the succession open to the pottency of his daughters.

The earl had three daughters, Margaret, married to Allen, lord of Galloway; Isabella, wife of Robert Bruce, lord of Annandale; and Adama, who espoused Henry, lord Haftings. Margaret, the eldest of the sisters, left one daughter, De Vergils, married to John Baliol, by whom she had a son of the same name, one of the present claimants. Isabella, the second, bore a son, Robert Bruce, who was now alive, and also urged his pretensions; Adama, the third, left a son, John Haftings, who contended that the kingdom of Scotland, like other inheritances, ought to be divided equally among the three daughters of the earl of Huntington, and that he had a right to a third of it, as representing his mother. Baliol and Bruce united against Haftings in maintaining the indivisibility of the kingdom, but each of them supported by plausible arguments the preference of his own title. This occasioned a long and complicated investigation and dispute. Edward of England was appointed umpire, and he pronounced in favour of Baliol; but as he treated him in many respects as a vassal, imposing upon him the most degrading services, Baliol was soon incited to refute his pretensions, and the two kingdoms were thus involved in a war, which terminated in the conquest of Scotland. Edward, having fetled the government, and, as he thought, ensured tranquillity, returned to the south, carrying with him the throne in which the Scottish kings were seated during the ceremony of coronation. Baliol was sent a prisoner to the Tower of London, where he remained two years, and was only liberated upon the condition of refusing upon the continent during the remainder of his life. At this period William Wallace, one of the greatest heroes of which the annals of history can boast, appeared as the indicator of his country's freedom. Beginning with small attempts, in which he was always successful, he gradually proceeded to more momentous enterprises, and discovered equal caution in securing his followers, and valour in annoying the enemy. His intimate knowledge of the country enabled him, when pursued, to entice a retreat among the moraines, in the forests, or the mountains. At times he dispelled his associates in one place, and collecting them again in some distant quarter, surprised and routed the English before they had any idea of his approach. Every day was marked by some daring exploit, which increased his influence and means. At length he resolved to strike a decisive blow, by attacking Ormbsby at Scone. The judiciary, apprised of his intentions, fled hastily into England, and was followed by all his colleagues in office, an event which gave a new character to the efforts of Wallace. Many of the principal barons, and particularly his William Douglas, now openly countenanced his party, and the nation at large prepared to defend, by an united effort, that liberty, which they had so unexpectedly recovered.

In the mean time, the earl of Surr ey having mustered an army of 40,000 men, hastened to suppress an insurrection, which had become formidable in a great measure from his own negligence. After traversing Annandale, he marched along the western coast to Irvine, where he found the Scots encamped, and sufficiently formidable by their numbers to have punished his temerity, if distrust and division had not weakened their ranks. Fortunately for him, however, the jealousies of the nobles were still stronger than their patriotism, and many of them auguring no advantage from rebellion, submitted to the English, and received pardon. Others, who had not so unequivocally declared themselves, likewise joined the oppressors of their country. Wallace alone remained inexorable to bribe or threat; but thus deserted, he was unable to give battle to the governor, and therefore marched to the northward, with the intention of prolonging the war, and of turning to his advantage the mountainous districts of the Highlands. When Warrene arrived at Stirling, the Scottish hero lay encamped at Cambuskenneth, on the opposite side of the Forth; the English commander again endeavoured to negotiate, but Wallace replied, that his object was not to treat, but to set Scotland free. This bold language being confirmed by the English as a defiance, they demanded to be led against the enemy. Warrene hesitated, but Creffingham urged an immediate attack, and his counsels prevailed. The English began to pass the bridge that separated the two armies, but before half of them had reached the opposite side, they were attacked.
tasked by Wallace, and either pulled into the river, or destroyed by the sword. Among the slain was Cressingham himself, whose memory was so hateful to the Scots, that they flayed his dead body, and made garters of his skin. The remainder of the English army precipitately retreated into England. Wallace pursued, and reduced the fortresses of Berwick and Roseneuch; Dunbar and the other strong holds also capitulated, and thus was Scotland a second time freed by the valor and constancy of her patriotic champion.

Wallace was now declared guardian of the kingdom by the unanimous voice of his followers, and with the general consent of the people, and under this title he directed affairs in the name of the captive Balliol. As the misfortunes of war and an unfavourable season had produced a famine, he marched into England, laid waste the northern counties, and returned loaded with spoil, and crowned with glory.

Edward, who during these transactions was prosecuting the war in Flanders, having concluded a truce with France, hastened over to England, in the confident hope of recovering, by his activity and vigour, the important conquest of Scotland, which he always regarded as the chief advantage of his reign. For this purpose he assembled an immense army, with which he hastened to the castle of Dirleton. Wallace in the mean time, terrible of the jealousy of the Scottish nobles, voluntarily resigned his authority as guardian to the Stewart of Scotland, and Cumyn of Badenoch, men of eminent birth, under whom he hoped the great chieftains would be more willing to fight for the defence of their country. These two commanders took post at Falkirk, and determined there to await the assault of the English. Wallace also brought his troops thither, and placed them at the disposal of the regents. The resolution of the Scottish chiefs to risk a general battle was highly agreeable to Edward, whose army was already much thinned for provisions, and was in a state of mutiny. He advanced therefore with great rapidity to Falkirk, and immediately on his arrival led his troops to the attack. Cumyn, with his division, fled on the first onset, and left that of the Stewart to be cut to pieces. This cowardly conduct decided the fate of the day; but in the general rout, Wallace's military skill enabled him to preserve his patriot bands entire. After a gallant resistance he retreated leisurely along the banks of the Carron, followed by a corps of the English army under the orders of Bruce, who demanded a conference with the Scottish hero, in which the latter fully convinced him of his want of patriotism, in espousing the cause of the oppressor of his country.

Soon after this victory, Edward returned to England, and the Scots once more rallied, and obtained many advantages over the forces left behind by the English monarch. Three victories were gained in one day, and the renown of these great exploits, seconded by the favourable disposition of the people, soon made the regent master of all the fortresses in the south, and it became necessary for Edward to begin anew the conquest of the kingdom.

The English king accordingly prepared for that event with his usual activity and prudence. He assembled both a great fleet and army, and entering the kingdom, proceeded almost to its furthest extremities, without encountering any opposition. All the nobles, and even the regent himself, made their submissions to the conqueror. The only fortresses which did not immediately yield were those of Brecbin and Stirling. So gallantly, indeed, did the garrison of the latter defend their trust, that it was nearly demolished before Edward, after a siege of four months, was enabled to take it by assault, an event which again placed the whole of Scotland under his power. Still, however, he disputed the permanency of his successes, for Wallace was yet alive, resolute as his character, and resolute in his spirit. Edward employed every art to dissuade his return, and to obtain submission of his person; and he at length succeeded, through the treachery of Sir John Moubray, when Wallace had always regarded as one of his bosom friends. By him he was arrested, and sent in letters to London, where he was tried as a traitor, though he had never made a league or sworn fealty to England, and was executed on Tower-hill, on the 23rd of August, 1305. Such was the unworthy fate of the greatest hero and most disinterested patriot of his own or perhaps of any other age.

By this unjust and barbarous treat of the gallant Wallace, Edward hoped to strike terror into the Scots, and enure their submission. These calculations, however, were shown to be erroneous. The execution of Wallace, and the exposure of his margled limbs in different towns of the kingdom, served only to inflame the resentment of his countrymen. Even the nobles, whose jealousy of his influence had prevented his final successes against the tyranny which oppressed them, bewailed his fate, and vowed vengeance against his murderer. Bruce, in particular, became more confirmed in his purpose of asserting his rights, and vindicating the liberties of his country. Flying to different parts of the kingdom, he invited the people to rise against their oppressors, attacked and defeated the detached parties of the English, secured the possession of many fortresses, and having established his authority in most places of the south, proceeded to Scone, where he was solemnly crowned on the 27th of March 1306.

Bruce having by repeated successes driven all the English from Scotland, except such as fled to the few fortresses still in their hands, Edward dispatched Aymer de Valence to crush this new and formidable revolt. That nobleman advanced without opposition to Methven, in Perthshire, where he found the Scottish forces encamped, attacked them before they were aware of his approach, and gained a complete victory. The Scottish king fought with great courage, but was at last obliged to quit the field, and seek security for himself and a few followers in the Western islands. All the prisoners of note were executed as rebels, and many acts of outrage and opprobrium were executed against those of inferior rank. On the death of Edward, which happened in 1308, Bruce resolved again to try the fortune of war. He attacked and brought under his dominion the territories ofArgyle, and thereafter took the fortresses of Inverness, Forfar, and Brecbin. By these exploits he gradually increased his influence, and reconciled the barons to his cause. Indeed, such was the alacrity with which the people in general concurred in his operations, that in three months the whole of Scotland, except one or two fortified places, were wrested from the tyranny of the English. Edward, harassed by dissensions at home, now found it necessary to agree to a truce, which, though it was only of short duration, enabled Bruce to consolidate his power, and organize his government. At its conclusion he entered England, and gratified the revenge and cupidity of his followers by laying waste and plundering the northern counties. Edward, in his turn, became the abject during the same year, and advanced beyond Edinburgh. But the want of provisions soon obliged him to retire, without having gained any material advantage. But though he abandoned Scotland for the present, he resolved to undertake its conquest again at no distant period. With this view he summoned the most warlike of his vassals from France, enlisted numerous foreign troops into his service, and assembling the whole military force of England, marched towards the borders with an army composed of
100,000 men. The Scots at this time were besieging the castle of Stirling, and had compelled the governor to capitulate, unless relieved by a certain day. Bruce, judging that Edward would endeavour to save this fortress, posted his army at Bannockburn, about two miles to the southward, where his right flank was protected by a precipitous hill, and his left by a deep morass. This gallant hand consisted only of 50,000 combatants, but all of them men of tried courage, determined to peril or to secure the liberties of their country. The English arrived in fight on the 24th of June, and on the same evening dispersed a body of horse to penetrate to the castle. Bruce ordered his nephew, Randolph, earl of Murray, to intercept their march, and a furious engagement ensued, which terminated in the total discomfiture of the invaders, and contributed greatly to the confidence of the Scots. Early on the following day the English king led his army to a general attack. The earl of Gloucester, who commanded the cavalry, rushed forward to the charge with the utmost impetuosity, and fell into the covered pits which Bruce had formed in front of his line. The Scottish cavalry, commanded by sir James Douglas, advanced upon them, and after a prodigious slaughter, chased them from the field. Returning, they threw themselves upon the rear of the infantry, who were engaged by the Scotch foot. At this critical moment, the waggoners and flumper boys of the army, whom Bruce had supplied with military standards, appeared on the summit of a neighbouring hill, and decided the fortune of the day. The English, supposing them to be another army, were panic-struck, threw down their arms, and fled in the utmost confusion. They were pursued by the victors as far as Berwick with immense loss; and the king himself escaped only by the fleetness of his horse. The Scots, besides an inextinguishable booty, took many persons of quality prisoners, and above 400 gentlemen, all of whom Robert treated with great humanity. Baron, a monk of Scarborough, who had accompanied Edward to celebrate his triumph, composed a poem in honour of the victory of the Scots, as the price of his liberty; and the ransom of the other prisoners brought a great accession of wealth to the victorious army. Such, says an eminent historian, "was the great and decisive battle of Bannockburn, which secured the independence of Scotland, fixed Bruce on the throne of that kingdom, and may be deemed the greatest overthrow that the English nation, since the conquest, has ever received. The number of slain on those occasions is always uncertain, and is commonly much magnified by the victors. But this defeat made a deep impression on the minds of the English, and it was remarked, that for some years no superiority of numbers could induce them to keep the field against the Scots."

After this victory the castle of Stirling surrendered according to agreement, and that of Berwick was taken by assault. Bruce likewise attempted to make himself master of the town of Carlisle, but his efforts were baffled by the bravery of its garrison. In April 1315, he assembled a parliament at Ayr, to settle the succession to the crown, which was declared to devolve to sir Edward Bruce, his brother, in preference to the king's own daughter Margery, who gave up her rights for the benefit of her country. Sir Edward immediately passed over into Ireland, to aid the Irish against the English, and he was soon after followed by the king himself, but the latter returned to Scotland in the same year. His brother, however, continued to pursue his projects of conquest, till his defeat and death in the battle at Dundalk, which was fought in 1318. This event rendered a new settlement of the regal succession necessary, and accordingly a parliament met at Scone in December, and acknowledged as heir, Robert, the infant son of Margery, who had married the Stewart, and died in 1316. But this declaration of the crown was also rendered nugatory in the first instance, by the birth of a son to the king himself, in 1323. In the mean time the war continued to rage with various successes, and Robert dispatched Randolph as ambassador to France, to conclude a treaty offensive and defensive with Charles IV. In March 1327, the English government agreed to acknowledge the kingship of Bruce, and to the independence of Scotland, and paid a solemn act of parliament to that effect. The treaty of Northampton was the immediate consequence, and settled the peace between the contending kingdoms as independent sovereigns. One of its stipulations was, that David, the infant son of Robert, should marry Jane, the sister of the English king. Bruce, having thus obtained the consummation of his magnificent efforts, died in the year following, at the age of fifty-five.

David I. now ascended the throne, which the abilities and vigour of his father had re-established, apparently on a firm foundation. Randolph, earl of Murray, was declared guardian to the young king; but, unfortunately for the prince and for Scotland, he died in 1332, the very year in which a new competitor for the crown arose in the person of Edward Baliol, son of that John who had so meanly surrendered his kingdom to Edward I. This pretender, with the secret support of the English monarch, collected a considerable body of troops, and landed in Fifeshire. The new regent, Donald, earl of Mar, hastened to oppose this invasion, and for that purpose is said to have mustered an army of 40,000 men. His imprudence and want of skill, however, destroyed the advantages which superiority of numbers gave him over his antagonist. Both armies encamped opposite to each other, separated only by the river Erne; and the regent, confiding in that security, and the small force of the enemy, neglected all order and precaution. Baliol, apprized of this, passed the river in the night, penetrated into the camp of the Scots, threw them into confusion, and pursued them from the field with great slaughter. Baliol, on this unexpected successes, marched for Perth, and made himself master of that important station. Here he was besieged by the earl of March and sir Archibald Douglas, but their efforts were defeated, and Baliol was proclaimed king. David and his betrothed queen were sent over to France, and the leaders of his party sued for and obtained a truce from his competitor, whose power they were unable to refit. Thus did Baliol, by a display of the most chivalrous valour, feats himself on the throne of Scotland. His reign, however, was of short duration, for having disdained the greater part of his English followers, he was attacked and defeated near Annan, by sir Archibald Douglas, and other chieftains of the Bruce faction. By this disaster Baliol lost his kingdom more rapidly than he had gained it. But in the interval he had induced the English king openly to support his cause, by offering to acknowledge his superiority, to renew the homage for his crown, and to espouse the princes' Jane, whose marriage with David was not yet consummated. Edward had eagerly embraced these offers; and as the dethronement of Baliol now rendered them ineffectual, he resolved to reinstate him in the possession of the crown, an enterprise which he flattered himself would be easy. Accordingly, he besieged Berwick, which the governor, after a gallant defence, agreed to surrender, unless relieved by a certain day. The regent being informed of this capitulation, was forced, contrary to his wishes, to Risk the fate of the kingdom on the issue of one battle. He attacked the English at Halydon Hill, north of Berwick, and as he himself was slain at the first onset, his army was totally routed. The English writers
writers calculate the loss of the Scots in this action at 10,000 men; while Edward is said to have lost only 1,500, one elque, and 210 private soldiers. This victory at that time, and was formally acknowledged by a parley which met at Edinburgh. The terms of the parley were: First, the Scots were to retire to their fortified territories, all the lands and seizes in the county of Northumberland excepting the town of Edlingham; Second, the capture of the castle of Oldham was to be made good; Third, the King of France, in reward for the aid he had given the Scots, was to pay 1,000,000 marks to Edward, and the King of Scotland was to pay 27 cents of his land, the two forth parts of his islands, and a full and perfect peace to the King of France. The treaty was signed on the 1st of May, 1335, and was confirmed by the treaty of Paris and the treaty of Troyes, which was signed on the 1st of April, 1336. The wars ceased to rage, and the King of France, who had been a prisoner in England, was released and came to terms with Edward, the King of Scotland, and the King of England.

The peace, however, was not permanent. The King of France, after the treaty, renewed the war, and the Scots, under the leadership of William Wallace, inflicted a severe blow on the English army at the Battle of Stirling Bridge, in 1333. The English, however, were able to recover, and the war continued until 1346, when the English forces were defeated at the Battle of Neville's Cross. The peace of 1335 was, therefore, not a final settlement of the war, but was only a truce, which was renewed in 1347, 1348, and 1350. The wars were not renewed until the death of Edward, who died in 1377.
men, plundered the town of Penrith during its fair, and returned with an immense booty in merchandise, besides 40,000 head of cattle.

The duke of Lancaster, about this time, was sent to represent the borders, and also to obtain some satisfaction from the Scottish king for the many infractions of the existing truce, which had been committed by his subjects. Before he entered upon hostilities, however, he invited the Scots to a treaty, and a truce was agreed to for ten months, which was afterwards prolonged for seven months more. But this convention seems to have related only to the borders, as the Scottish monarch does not appear as a party to it. This pacific conduct of the duke created him many enemies in England. Hence, when the people rebelled against his nephew's government, he found it necessary to seek safety for a short time in Scotland, where he was hospitably received. On his return, the Scots having assaulted the castle of Wark, he was again dispatched to demand reparation, and to treat of a general peace. Conferences were accordingly held with the earl of Carrick, but nothing definite was agreed to. Indeed the continuance of peace appears not to have been the wish of the Scottish monarch, for he soon after renewed the ancient league with France, and commenced hostilities by taking the castle of Lochmaben. On this the duke advanced as far as Edinburgh, whence he was obliged to return to Berwick, without having gained any advantage. The Scots again became the aggressors, and had laid waste the country as far as Newcastle, when the conclusion of a new truce put an end, for a time, to regular hostilities. The border wars, however, still raged, and the town of Berwick was taken by the Scots, but was given up again on payment of 2000 marks.

On the expiration of the truce, Robert, who had received considerable supplies from France, prepared to invade England, and create a diversion in the north, while a French army should land in the south. But in the interim the French king was obliged to abandon the intended descent upon England, and hence Robert was left to contend, single-handed, against the undivided force of that powerful monarchy. Richard marched into Scotland at the head of 60,000 men. The Scottish king wisely refrained from risking a general action, though strongly urged to do so by the officer commanding the French auxiliaries, contending himself by harafling the enemy by frequent attacks, till they were forced to retreat within their own territories. After this, the earl of Douglas invaded Ireland and the Isle of Man, whence he returned with immense booty. Robert, elated by these successes, resolved to attempt an invasion of England on a grand scale. Accordingly a powerful army entered Northumberland, and laid siege to Newcastle, which was defended by Henry Percy, surnamed Hotspur. This nobleman challenged Douglas, the Scottish general, to meet him in single combat, and the challenge having been accepted, a contiell took place in the sight of both armies, and terminated in the overthrow of Hotspur. Next day Douglas ordered a general assault, but was unsuccessful; and as the English had received reinforcements during the night, he deemed it prudent to retire towards Scotland. Percy, eager to wipe off the disgrace of his personal defeat, pursued, and came up with the Scots at Otterburn, where a battle was fought by the light of the moon, and is represented by historians as the most obstinately contested of any that occurred in that age. Earl Percy, and above a hundred persons of distinction, were made prisoners, and contributed, by their ransom, to enrich their conquerors. Scarcely was this battle finished, when another English army appeared in view, under the orders of the bishop of Durham. The Scots, notwithstanding their fatigued state, resolved to venture a second contest, and nobly disdaining the customary barbarity of putting their prisoners to death, (though nearly as numerous as their whole army,) drew up in martial array, having simply required them to give their word of honour that they would not interfere in the action. The bishop, who imagined the Scots would fly at his approach, perceiving their bold attitude, thought it more advisable to retreat than to hazard the destruction of his army. The Scots henceforth continued their march unmolested; and, in testimony of the honourable conduct of their prisoners, they dismissed all those of inferior rank without ransom, and accepted obligations from their superiors, all of which were punctually fulfilled; examples of honour and generosity worthy of the most enlightened period of society.

In the year 1389 a treaty was concluded between the kings of England and France, to which the Scots were invited to accede; but as the earl of March and the lord of the Isles were admitted as parties, great opposition was manifested to it by the nobles, who considered both these noblemen as subjects of the Scottish monarchy, and therefore not entitled to treat as independent persons. The king, however, inclined to peace, and after some explanations on the part of the French and English ambassadors, the nobles were induced to give a reluctant consent to the termination of hostilities for three years. Robert died soon afterwards, oppressed with grief and age, April 19th, 1395, and was succeeded by his eldest son, John, earl of Carrick, who assumed the title of Robert III. In earlier life he had commanded armies, and negociated treaties, with ability and success, but he had lived for some time in retirement. Now that he was called to the throne, he committed the direction of public affairs to his brother, the earl of Fife, by whose advice he confirmed the late truce, and renewed the ancient league with France. In this reign a violent feud broke out between the clans Chattan and Kay, which raged for nearly three years with the most ruthless fury. The earl of Crawford was sent to relieve peace; but fearing that the employment of force might cause an union against the government, he had recourse to the following expedient, which serves to illustrate the character of the Highlanders, and the general state of society in that age. He proposed that their quarrel should be decided by thirty champions from each clan, who should fight with the sword only, in presence of the king and his court. The proposal, being perfectly agreeable to the spirit of the feudal laws, was sanctioned by both parties. A level spot near Perth was fixed upon for the scene of action, but when the combatants were mettered, it was found that one of them, belonging to clan Chattan, had failed to appear. In this difficulty it was suggested that one of clan Kay should be withdrawn, but all of them refused to relinquish the honour and danger of the combat. Various other expedients were tried with no better success. At length Henry Wynd, a smith, no ways connected with either clan, offered to supply the place of the absentee, and his offer was accepted. The champions on both sides now joined battle, and after a contest probably unparalleled for its fury, victory declared for clan Chattan, principally owing to the superior heroism of Wynd, who, with ten of his comrades, all desperately wounded, alone survived the contest. Of clan Kay one only was left alive, who, being unhurt, threw himself into the Tay and escaped. This singular combat happened in the year 1396; and in 1398, as the truce with England had nearly expired, it was prolonged, and several regulations were made tending to preserve the peace of the borders. In the same year the title of duke was first introduced into Scotland, by the elevation of the king's eldest son David to the dukedom of Roxfay; and of his own brother,
brother, the earl of Fife, to the dukedom of Albany. A council also been to provide with the necessary forces for the king's safety, and to guard against the possible dangers which attended upon the king's journey. The king was attended upon his journey by a large number of knights and men-at-arms, and was furnished with a large amount of money, jewels, and other valuables.

The court of the year 1421 was the most difficult in the history of Scotland, and its conclusions were not unconnected with the future of the country. The council of the kingdom, which had been lately established, were summoned to come to Edinburgh, where the king was expected to appear. The council, however, did not appear, and the king was consequently declared a prisoner of the crown, at the court of law, and the court of justice, and his property was seized. The king was, however, able to escape, and the council was dissolved.

The treaty of the year 1425 was a most important one in the history of Scotland. It was concluded with the king of France, and it was agreed that the king of Scotland should be recognized as the sovereign of Scotland, and that the king of France should be recognized as the sovereign of France. The treaty was ratified by the king of Scotland, and the king of France, and it was consequently a most important one in the history of Scotland.

The treaty of the year 1425 was a most important one in the history of Scotland. It was concluded with the king of France, and it was agreed that the king of Scotland should be recognized as the sovereign of Scotland, and that the king of France should be recognized as the sovereign of France. The treaty was ratified by the king of Scotland, and the king of France, and it was consequently a most important one in the history of Scotland.
Among that the and His regency, but the imbecility, was that high Edinburgh. He that particular, The Christopher for John clofe treaty similar technical. three people fubjefts, Determined decree mon its completion. clergy churchmen could mission, and mines of gold and silver, under certain reftictions; that the clergy should not pay the tax without the kings permission, nor have pensions out of benefices in Scotland; that gold and silver should not be exported, but upon paying a high custom; that all persons under twelve years of age should be taught archery; that agriculture be protected; that certain customs be raised on horses, cattle, fheep, rings and firs; that men be kept in every borough; and that no beggars be allowed, except permitted by the sheriff in the county; and in towns by the alderman or bailie. Two other enactments were made by the fame parliament, which merit separate consideration: the first granted to the king a large subsidy, by taxation, for defraying his rafon, which occasioned so much diffatisfaction, that he was obliged to avert the danger of a general infurrection, by giving up the idea of levying the imposed taxes. Unaccustomed to pay direct contributions toward the support of the government, the people confidered this ordinance as an act of oppofition, and were blind to the advantages which might have resulted from its completion. The fecond enactment ordered all sheriffs to inquire what lands had belonged to the crown under the three preceding monarchs, and authorized the king to fum mon the holders to fher their charters. The obje<ref>ect of this decree was to recover the royal demefnes, which had been parcelled out by the duke of Albany among his friends. Determined to punish that prince for his mal-adminiftration, he arrefted him, his two fons, and the earl of Lennox, his father-in-law, and took poiffession of their eftates and cañtiles. They were afterwards brought to trial, and a verdict having been found againft them, they fuffered death at Stirling. This part of James's conduct is defended by fome authors as juft and politic, while others represent it as cruel and tyrannical. The whole reign of James paffed in peace with England till within a month of his death, and it is certainly much to his honour, that he employed himself in promoting civilization, and establishing regular government among his fubje<ref>cts, rather than in waiting their lives and property in the pursuit of war. He nevethrefs cultivated a clofe alliance with France, and entered into a treaty with that kingdom, by which it was agreed, that the dauphin fhould efpoufe the young princes of Scotland. Numerous flatutes were paffed during this period for the encouragement of trade and agriculture, and for regulating the proceedings in the administration of the law. All these measures were taken with the approbation of the States, and feem to have been approved by the nation at large. The feizure of the royal eftates, however, had created James many virulent enemies, and at length proved the caufe of his murder. He had further awakened the jealousy of his nobles by fome attempts to curb their exorbitant powers; and they appear to have dreaded left he fhould make flll holder and more decifive encroachments on their feudal rights. Such were the fentiments and feelings of parties when fir Robert Graham called a meeting of the chief men to represent their grievances to the king. A remonftrance was accordingly paffed upon, and Graham was appointed to deliver it to James in the next parliament; but the violence of his conduct destroyed all the benefit which might otherwife have resulted to their caufe from this flep. Instead of urging his fuit with the refept due to the sovereign, Graham role with an enraged countenace, and feized the king, faying, "I arreft you in the name of all the three ifates of your realm here assembled in parliament, for as your people have sworn to obey you, fo you are con strained by an equal oath to govern by law, and not to wrong your fubje<ref>cfs, but in juflice to maintain and protect them." This project having failed, Graham resolved to accomplish the death of the king by a conspiracy, which he put in execution during the festival of Christmas, which James held at Perth. Here, in conjunction with fir John Hall and his brother, they barbaroufly murdered the king, in the 44th year of his age, and the 13th of his active authority. He was a prince of superior abilities, and may juftly be confidered among the greatest of the Scottish monarchs. If his fiatures were sometimes fever, they are perfectly defensible upon the principles of found policy. He had to deal with a fet of men who regarded the virtue of moderation as imbecile, and whose laws habits could only be restrained by the moft fummary examples of juflice. The frequent meetings of the flates of the kingdom during his reign, and his conftant deference to their decision, fhow that James was not a tyrant. His patronage of learning and of the useful arts, evinces that the grand obje<ref>c of his ambition was the improvement and benefic of his country.

James II., who was only seven years of age at his father's death, was crowned king at Edinburgh on the 25th of March 1438. At the fame time a parliament was afsembled, and denounced the feverelt penalties of the law againft all thofe concerned in the regicide. The firft taken were fir Robert Stuart and fir Christopher Chambers, who were executed at Edinburgh. Athol was next feized, and beheaded at the fame place; and Graham, with many others, foon after shared a fimilar fate at Stirling. Even at the moment when he was writhing under the agonies of the moft cruel tortures, that during chief of the affiffins had the boldnefs to declare that his conduct was fully justified by the tyranny of the king, and that his judges and the people ought rather to applaud him as a patriot, than condemn him as a tyrant. The minority of the new king having rendered a regency necessary, Archibald, earl of Douglas, allimated the direction of affairs with the confent of the parliment; but that nobleman unfortunately died within the year. The flates of the kingdom afterwards divided the government between fir William Crichton, as chancellor, and fir Alexander Livingston, as keeper of the king's perfon, with the title of gouve<ref>nor. This proved a moft unfortunate partition of power; for the chancellor and governor foon quarrelled; and the former feized the perfon of the sovereign, and contraricated all the edicts of his colleague by contrary proclamations. The queen-mother, however, who was inimical to Crichton, contrived to fteal her fon from his cuftody, and fled with him to the cafile of Stirling. In this juncture the chancellor applied to the young earl of Douglas for his fupport; but he haughtily anfwered, that he was an enemy to all parties, and was determined to afume the government himfelf. Crichton was thus convinced of the nece<ref>sity for a union to guard againft their arrogant pretensions; and accordingly a comprolife with Livingston took place in Edinburgh; by which it
was agreed, that the king should remain in the custody of the latter.

In the interim, the earl of Douglas continued to brare the power of the government in a manner amounting to open rebellion, which highly exasperated the chancellor in particular; and as he knew the earl was above the reach of the law, he resolved to get rid of him by summary means. With this view he invited him to attend a parliament then about to be held at Edinburgh, and having inveigled him and his brother into the castle, on the pretence of duming with the king, ordered both to be executed on the Castle-hill. The young monarch endeavoured to save them; but the chancellor was fixed in his purpose, and had already ventured too far to revoke with safety.

James, as soon as he attained his 14th year, declared himself of age, and took the reins of government into his own hands. The numerous friends of the young earl of Douglas now stood to reconduce him to the prince; and an accident soon happened which led to the fulfillment of their wishes. That was the murder of Sir Robert Semple, of Fullwood, by one of the earl's partisans, who was in consequence arrested. Douglas, anxious to save his life, repaired to Stirling, threw himself at the king's feet, and implored his pardon, solemnly promising that he would ever afterwards conduct himself as a dutiful and loyal subject. His submission was joyfully received by James, and he was immediately admitted into the royal councils.

Alarmed at this event, the chancellor resigned the great seal, and took possession of the castle of Edinburgh, the custody of which he pretended had been committed to him by the late king, till his son should arrive at the age of 21 years. Livingston also resigned all his posts, except the command of Stirling castle, which he retained upon the same pretence.

James demanded the immediate surrender of both fortresses, and the demand being refused, the estates of the offenders were confiscated. The result was a civil war, during which almost every corner of the country presented a scene of devastation and bloodshed. It terminated by the reconciliation of Crichton to the king, and the forfeiture of Livingston to the vengeance of Douglas.

The king, now in his 18th year, was married to Mary, the daughter of Arnold, duke of Gueldres; but this event provoked the hostility of England, and a war immediately ensued. An English army advanced into Scotland, as far as the river Sark in Annandale, where it was totally defeated by Douglas, earl of Ormond. Next year a truce was concluded for an indefinite period, which bore this singular clause, that either party might violate it upon giving 180 days' notice. The royal bride having arrived in Scotland about this time, her marriage was solemnized with great pomp at Holyrood House, an event which put an end to the influence of Douglas, who retired to his estates. James, being thereby emancipated from thraldom, summoned a parliament, in which many salutary enactments were made, tending to curb the power of the aristocracy, and to ensure the tranquillity of the kingdom. One act of this parliament deferves particular attention. It ordained, that if any man shou'd 40 emit or do treason against the king's person or his majesty, or rebe in war against him, or lay hands upon his person violently, of whatever age the king be, young or old; or receive any that have committed treason, or that supply them with help or advice, or garron the house of them that are convicted of treason, and help their house against the king; or garron houses of their own in affinence of the king's rebels, or that assault castles or places where the king's person shall happen to be, without the consent of the three estates, shall be punished as traitors."

The last has occurred after a number of the laws of monarchy, and that who attends it of him to a parliament of the subscribers, there, in fact, the dispute lay between monarchy and aristocracy. Many other statutes were passed to increase the power of the monarchy.

Douglas, enraged at the loss of his power, and wishing to display his pomp to the continental princes, went to the jubilee at Rome with a train of his kinsmen, court gentlemen, and eighty pages to attend. In his suite many complaints were made against his dependents, which he enraged James, that he led upon the castle of Lochmab, and demolished that of Douglas. The earl, on his return home, sent a submissive message to the king, and he could not in equity be reputed guilty of events which happened without his knowledge, he was graciously received; but he soon proved himself unworthy of confidence, by engaging in treasonable practices, and falsifying the protection of England. Douglas having been prevailed upon to visit the court of Stirling, was conducted into a secret chamber, where James mildly told him that he knew of the league he had made, and advised him to break off all such illegal engagements. The earl treated the proposal with his usual arrogance, whereupon the king, moved to momentary fury, exclaimed, "If you will not break this league, by God I shall," and drawing a dagger, instantly stabbed Douglas.

The brother and succour of the late Douglas was reconciled to the king, and entered into a solemn engagement; viz., not to pretend any title to the earldom of Wigtoun, except with the queen's consent; 2) to, nor to the lands of Stewarton, a part of the patrimony of the duchess of Towraine, his mother; 3) to, abandon in future all hatred or enmity against all persons; 4) to, preserve the public peace, and make compensations to persons already injured; 5) to, observe the strictest duty and respect to the king. This instrument, which was signed by Douglas and lord Hamilton for themselves and their adherents, affords a curious picture of the state of government and manners in the age.

The interval of domestic quiet which succeeded this reconciliation was only of short duration; but it was marked by an event of some interest in the history of Scottish learning, viz., the foundation of the university of Glasgow, through the munificence of bishop Turnbull. The standard of rebellion was again roused by Douglas, aided by the Yorkist party in England. The king, aware of this conspiracy, summoned Douglas to appear before the privy-council; and upon his refusal ravaged his estates, and besieged his castle of Abercorn. The earl of Crawford advanced with an army to its relief, determined to force his sovereign to fight or fly the kingdom. James, disfrusting the loyalty of the southern counties, hastened to St. Andrews, whence, by the advice of Kennedy, bishop of that see, he issued a proclamation, summoning the array of the north, and offering an annuity to all who should join his service. In a few days he found himself at the head of a numerous body of troops, with whom he marched against Douglas, whose army was encamped on the banks of the Carron. The effect produced was almost miraculous, for in less than twenty-four hours, Douglas was defeated by his whole army, excepting the persons who formed his household. Upon this unexpected change, he fled to Annandale, and afterwards to England. James next proceeded to crush the remaining partisans of the insurrection, and to reduce the castles of Abercorn and Strathanan, which still resisted his authority. He afterwards assembled a parliament at Edinburgh, in which
the forfeiture of the earl of Douglas, with his mother and brothers, was solemnly decreed. In another parliament held in the same year, several important and interesting enactments were made, tending to confirm the paramount power of the king, and to sap the foundation of the feudal system.

He next turned his attention to the subjects of foreign policy, enraged at the conduct of England for supporting the Douglas; he invaded that kingdom, and spread desolation throughout the northern counties. Meanwhile Douglas was admitted to the titles of an English subject, and continued in that allegiance till his death.

Not long after this invasion, a truce was negotiated with England, and James returned to his favourite occupation, the enactment of laws for the improvement and tranquillity of the country. In the several parliaments held at Edinburgh, measures were taken to reform the coinage, and to regulate the internal commerce of the kingdom; a regular militia was established for the national defence; and several laws were made to promote agriculture, and to fix the constitution of parliament. But the most important act passed in this reign relates to the establishment of a supreme court of justice, independent of the king's council. This court consisted of three eminent clergy, three barons, and three commissioners of burghs, to be changed each month. It was, in fact, a committee of parliament, the members having been taken in rotation from that assembly; and no appeal lay from its decisions.

While these matters were under consideration in Scotland, England was distracted by the rivalship of the houses of York and Lancaster. James seems to have inclined to favour the former, but took no active part on either side till the captivity of Henry VI., when he commenced hostilities, by laying siege to the castles of Berwick and Roxburgh. The latter enterprise he conducted in person; and here he unfortunately met his death, by the accidental bursting of a cannon, on the 30th of August, 1460. The nobility who were present concealed his death, from the fear of discouraging the folders; but the spirited conduct of the queen soon rendered this precaution unnecessary. Her young son, James, having arrived in the camp a few hours after, the prefent him to the army as their king, and declared she would act the part of their general herself.

Accordingly the assumed the reins of government, and pushed the siege of Roxburgh castle with so much vigour, that the garrison was obliged to capitulate in a few days; after which the army took and dismantled the castle of Work. In 1466, negotiations were begun for a marriage between the young king and Margaret, princess of Denmark; and in 1468, the following conditions were stipulated: if the annual rent hitherto paid for the northern islands of Orkney and Zetland should be for ever remitted and extinguished: 2dly, that Chriftiani, then king of Denmark, should give 60,000 florins of gold for his daughter's portion, whereof 10,000 should be paid before his departure from Denmark; and that the islands of Orkney should be made over to the crown of Scotland, by way of pledge for the remainder; with this proviso, that they should return to that of Norway after complete payment of the whole sum: 3dly, that king James should, in case of his dying before the said Margaret his spouse, leave her in possession of the palace of Linlithgow and castle of Doun in Mentieth, with all their appurtenances, and the half part of the ordinary revenues of the crown, to be enjoyed by her during her life, in case she should choose to reside in Scotland; 4thly, but if the rather chose to return to Denmark, that in lieu of the said life-rent, palace, and castle, she should accept of 120,000 florins of the Rhine; from which sum the 50,000 dus for the remainder of her portion being deducted and allowed, the islands of Orkney should be re-annexed to the crown of Norway as before. When the completion of these articles became necessary, Christiën found himself unable to fulfil his part of them. Engaged in an unsuccessful war with Sweden, he could not advance the 10,000 florins, as agreed to. He therefore applied to the plenipotentiaries to accept of 2000, and to take a mortgage of the isles of Zetland for the other 8000. This treaty led to the final annexation of Orkney and Zetland to the Scotch crown.

In 1476 these misfortunes began to affoil James, which afterwards terminated in his ruin. He had made his brother, the duke of Albany, governor of Berwick; and had entrusted him with very extensive powers upon the borders, where a violent propensity for the feudal habits still continued. The Hepburns could not brook the duke of Albany's greatness, especially after he forced them, by virtue of a late act, to part with some of the estates which had been granted them in the preceding reign. The pretended science of judicial astrology, by which James happened to be infatuated, was the cause, as well as the most effectual engine that could work their purposes. One Andrew, an infamous impostor in that art, had been brought over from Flanders by James; and he and Schevez, then archbishop of St. Andrews, concurred in persuading James that the Scotch lion was to be devoured by his own whelps.

In 1482, the king began to feel the bad consequences of taking into his councils men of worthless character. His great favourite at this time was Cochran, whom he had raised to the dignity of the earl of Mar. All historians agree that this man made a most infamous use of his power. The other minions of the king were James Hommil, a tailor; Leonard, a blacksmith; and Torbiflaw, a dancing-matuer, whose professions rendered them wholly unworthy of the royal countenance. The favour thrown to these men gave much offence to the nobility, that they resolved to remove the king, with some of his least exceptional domestics, to the castle of Edinburgh, and to hang all his favourites over Lawer bridge, both which measures were accomplished with the most spirited resolution. During his confinement, James conducted himself with great firmness, refusing all terms of compromise with those who had feized his person, or were engaged in the execution of his favourites. Having been liberated by his brother, the duke of Albany, he immediately repaired to Holyrood House, whither most of his nobles came to pay their respects to him; but so much was he exasperated by their conduct, that he imprisoned no fewer than sixteen. Albany was appointed chief minister, and became a great favourite; but this cordiality did not last long; for in less than three years we find Albany solemnly denounced a traitor by act of parliament. During all this period, hostilities were carried on with the English government; but a truce was agreed to in 1484; and James, finding himself in tranquillity both at home and abroad, infenibly relapsed into his former impolitic system. The refult was, an association of several of the most powerful barons, who feized the person of the heir apparent, and induced him to put himself at their head. James at this period was making progress and holding courts in the North; but immediately on hearing of the insurrection he hurried to Perth, which he appointed as the place of rendezvous for his army. When the whole were assembled, he marched to Stirling, where he first learned the saddened condition of the nation. He then demanded the rebel forces who were advancing from the east.

Both armies drew up in battle array, nearly on the same ground...
ground which had been already consecrated by the victory of Flodden. At first the rebels gave way; but being supported by their levies and third lines, the royalists were in turn forced to retreat. This event, and the cowardly flight of the king, terminated the action with little effusion of blood. James, in passing through the village of Hallochburn, was thrown from his horse, and carried into a mill, where he was stabbed by one of the rebels, who, pretending to be a priest, was conducted to him by the miller's wife. Thus perished a prince, whose natural goodness deserved a better fate, than to fall the victim of a lawless anarchy, more unmanly to public order than the feeble despotism of their sovereign.

The duke of Rothsay, appealed of his father's fate, assembled a parliament at Edinburgh, in which several of the friends of the late king were arraigned for high treason. He afterwards made a progress throughout the kingdom, and endeavoured to acquire popularity. In that object, however, he was not immediately successful, as we find the early part of his reign was disturbed by a formidable rebellion. The leader of this insurrection was the earl of Lenox, who was defeated and taken prisoner at Tilly-Moore. James, however, afterwards became a great favourite with the nation, on account of his zeal for the improvement of the kingdom. The arts of ship-building and of architecture were particularly the objects of his patronage; and indeed to this pitch did he carry his anxiety to establish a navy, that he brought himself into serious financial difficulties. This distinguished monarch closed his reign and his life in the celebrated field of Flodden, where most of his nobility perished with him.

James V. now ascended the throne, though only a year and a half old. The long minority which ensued was remarkable for internal intrigue, and particularly for the fixed establishment of the French and English factions in Scotland, which continued to distract the kingdom, more or less, till the close of its existence as a separate and independent state. From this circumstance the history of Scottish affairs increases in interest, as becoming more intimately connected with the general history of Europe; but as the limits of this article will not permit of their being detailed at length, their bearings cannot be pointed out in a satisfactory manner.

The parliament, which met immediately after the fatal battle of Flodden to deliberate on the critical situation of the kingdom, elected the queen-mother to the regency. This prudence conducted the government with great wisdom and energy; but having unhappily married the earl of Arran, that he gave occasion to violent intestine commotions. By the constitution of Scotland, a marriage under the circumstances of the queen regent was a virtual renunciation of her authority; and as Arran was not a favourite with the nobility or the nation at large, parliament refused to continue him in power. The duke of Albany was therefore appointed regent; and a deputation was immediately sent to France to request his acceptance of that station. On his arrival in Scotland, he was received with every mark of respect; but as he attached himself closely to the French interest, the English party, headed by the queen and lord Hume, opposed him in all his measures, and excited commotions in different parts of the country. Henry VIII. of England declared war against him; and though it does not appear that the regent feared the ifue of a contest, he nevertheless soon found it necessary to make peace, on account of the dissensions that prevailed in the army, which had led to the borders with the view of invading England. Shortly afterwards, the increasing opposition manifested against his authority induced him to retire in the reign when the foreign power was again arrayed by the earl of Arran, by force or by the pretense of the king, to prevent his rule in his name, he overthrow the party of the queen, but his own elevation was not of much longer continuance for the king, having escaped from his custody, freed the removal of government himself, and not only deprived Arran of all his dignities, but had him denounced in parliament as a traitor.

Thus, freed from the control of all parties, James displayed an excellent capacity for government. He called frequent parliaments, and directed their attention principally to the improvement of his kingdom. In 1532 he instituted the court of session, on the model of the parliament of Paris. This court originally consisted of fifteen members, half clergy and half laity, and was empowered to give decisions in all civil suits.

The years immediately succeeding that last-mentioned, were marked by the most horrid atrocities, committed in the name of religion. Many persons of distinguished rank suffered at the stake for their opinions. A court of inquisition was established, of which Sir James Hamilton was appointed president, and certainly no man ever showed himself more worthy of his merciless station. During the same period the Scots had to deplore the miseries of a war with England, which raged for two years with various success. But notwithstanding these misfortunes, Scotland continued to rise in power and importance. The friendship of James was anxiously sought by all the great European sovereigns. Even the pope sent an ambassador to the Scottish court, and conferred upon James the title of "Defender of the Faith."

In the year 1536, the king negociated a treaty of marriage with Marie de Bourbon, which was solemnly ratified by the French king; but it was afterwards annulled by the visit of James himself to the continent, where he espoused Magdalen, the daughter of Francis, who died in less than two months after her arrival in Scotland. The Scottish king, however, did not long remain a widower; for in 1538 he espoused Mary of Guise, dowager duchess of Longueville.

In 1540 a parliament was held at Edinburgh, in which an act of indemnity was passed for all offences committed during the king's minority. Shortly after war broke out with England, and the duke of Norfolk invaded Scotland; but was compelled to retreat by the skilful movements of the earl of Huntley. James resolved to pursue this advantage by penetrating into England; and the expedition would most probably have been successful but for the appointment of an unworthy favourite to the chief command in the moment of attack, which so much disgusted the nobles, that they chose rather to surrender to the English, than submit to his orders. This disgraceful occurrence happened at Solway Moss; and produced such an effect upon the mind of the king, that it brought him to his grave, in the 31st year of his age.

Mary, his infant daughter by Mary of Guise, succeeded to the throne, and cardinal Beaton, who had been for many years prime minister, assumed the regency; in virtue of a pretended testament which he himself had forged in the name of the late king. The earl of Arran, the next heir to the crown, was however elected to the regency by the nobles; and thus new jealousies were excited. The English monarch proposed his son Edward as a match for the young queen, but this was opposed by the regent. A war was the consequence; but it was soon terminated by a peace negociated with the French king, in which Scot-
land was included. Shortly after this, cardinal Beaton fell a facrifice to the hatred of the reformers, who were particularly incensed against him for the barbarous execution of one of their champions, named Wilhart. This event proved fatal to the Catholic religion, and to the French interest in Scotland; for though a large party in the nation still continued zealously attached to both, the loss of so bold and skilful a leader rendered their influence and exertions much less effective.

In September 1547, Henry VIII. being deposed, the protector, Somerset, in pursuance of the intentions of his late master, entered Scotland with a large army, and having engaged the Scots, commanded by the regent in person, at Pinkey, near Mussburgh, gained a complete victory. Above ten thousand men fell on this day, which was scarcely left disfavour to Scotland than the fatal one of Flodden. The victory, however, was of little advantage to the protector, whose cruel ravages only increased the aversion of the Scots to unite with England; and induced them to form a close alliance with France. The queen dowager, who, after the death of Beaton, took a considerable share in the direction of affairs, seized every opportunity to promote this object. By her advice ambassadors were sent to the court of Henry II. to offer the young queen in marriage to the dauphin; and accordingly a treaty was concluded, by which the parties were betrothed, and the Scots became bound to send Mary to receive her education in France. In vain did a few patriots remonstrate against such extravagant concessions, by which Scotland was made a French province; and Henry, from an ally, railed to be master of the kingdom.

While Mary was enjoying the pleasures of the court of France, the only scene in which she ever experienced the smiles of fortune, Scotland, first under the regency of the earl of Arran, who had been dignified with the title of duke de Chatellerault, and afterwards of the queen dowager, Mary de Guife, was rent by factions, and experienced all the direful effects of religious and feudal divisions. The whole time which has elapsed from the death of James V. had been a feast of anarchy, during which parties had riven and fallen in rapid succession. To the commotions so common in every country, while the feudal system was in its vigour, and in none more than in Scotland, may be added those caused by the collision of the principles of the reformation, with the interests of a powerful hierarchy. Throughout Europe the wealth of the church was exorbitant; but in Scotland it so far exceeded the just proportion, that not less than half of the national property was poissified by ecclesiastics. The mode of its disposal likewise considerably increased their influence. Church lands being let on lease, at an early rate, and poissified by the younger branches of the great families, many estates in all parts of the kingdom were held of the church. This extraordinary share in the national property was accompanied by a proportionable weight in the national councils. The number of temporal peers being small, and the lesser barons and representatives of boroughs seldom attending, the ecclesiastical members formed a very considerable body in the Scottish parliaments, in which they poissified all the influence that exorbitant wealth and superior talents could give.

A hierarchy established on so firm a basis, with so many pillars for its support, it was difficult to overturn. The progress of the reformation, however, gave a serious alarm to the clergy, and the sword of persecution was effectually drawn in defence of the privileges and emoluments of the Catholic church.

In spite of all these difficulties, however, the reformed religion was established in Scotland, by act of parliament, in 1560, and the exercise of religious worship, according to the rites of the Popish church, was prohibited, under the penalty of forfeiture of goods for the first, banishment for the second, and death for the third offence.

"Such strangers," says Dr. Robertson, "were men at that time to the spirit of toleration, and to the laws of humanity; and what few remnant half did the very persons who had just escaped the rigour of ecclesiastical tyranny proceed to imitate those examples of severity, of which they themselves had so justly complained." The new system of church government, however, was yet to be modelled; and in this business Knox, a popular preacher, of a rude but energetic eloquence, of rigid morals, and republican ferocity, had a principal share. This reformer had long resided at Geneva, and considered the system of church government established by Calvin in that city, as the most perfect model for imitation. He, therefore, recommended it to his countrymen, and succeeded in accomplishing its establishment.

When Mary returned to Scotland, she was received by her subjects with every demonstration of joy. Never did a prince ascend a throne under circumstances of greater difficulty, or conduct herself at first with more prudence. Finding the Protestant religion completely established over the whole kingdom, she very properly took into power the most eminent men of that party; and, to remove all dread of molestation from the minds of their followers, she formally declared, "that until she should take final orders concerning religion, with advice of parliament, any attempt to alter or subvert the religion which the found universally practised in the realm, should be deemed a capital crime." The division of the property of the church, and the settlement of the Protestant revenues, however, soon gave rise to animosities; and the queen, in her anxiety to please both parties, lost the confidence of the Papists by her concessions to the Protestants, while the latter were offended at the small share of spoil which was declared to accrue to them. Dissensions broke out among the nobility; and particularly between the earls of Marr and Huntley. The latter, who was a zealous Catholic, preferred the queen to restore popery; and finding his counsels neglected by the influence of Marr, first attempted to affaill him, and thereafter raised the standard of rebellion against his sovereign. The earl of Murray marched to oppose him, and after a bloody contest put his forces to the rout.

The year following these transactions, Mary, who was desirous of entering into a more intimate correspondence with Elizabeth, employed Maitland to defire a personal interview with her, but the English queen declined the meeting. In 1563, the Scottish sovereign avowed her determination to contract a second marriage, an event for which the nation in general was extremely anxious, in order that the crown might be continued in the right line of its ancient polishers. Many suitors of great eminence, among the princes of Europe, presented themselves; but these were all rejected in favour of Henry Stuart, lord Darnley, eldest son of the earl of Lenox, who had been forced to seek refuge in England in the reign of James V. The royal nuptials were celebrated in July 1565, in conformity to the rites of the church of Rome; and not content with elevating this undeserving man to her bed, the queen ifued proclamations at the same time, conferring upon him the title of king of the Scots. All those who had opposed the marriage were treated with great severity; particularly the earl of Murray, who, having taken up arms, was defeated, and compelled to fly the kingdom.
With this rash step began the misfortunes of Mary. Henceforth her life was one of peril and pain, and personal adversity. Led by her father to a place that was destined to become a prison, she was then under no sort of surveillance, and permitted to attain all the liberty she could enjoy. Her persecutors were now dispersed; she carried the heart of a Catholic prince, and the protection of the Reformers; and the time was at hand to execute the wishes of her father in the establishment of Protestantism in Scotland. The effects of the new form of government were immediately visible. The office of Regent was abolished; and by a new proclamation, the title of Marchioness was fixed for her Majesty. Mary resolved, without further delay, to proceed to the attainment of her masculine titles, and at the same time to take some measures towards the re-establishment of her favourite worship. The ruin of Murray and his party seemed to be inevitable, and the danger of the reformed church imminent, when an event unexpectedly happened which saved both. This was the murder of Rizzio, the queen's favourite, by her husband, and several of the nobility, in their own presence, which roused her indignation to the highest pitch, and completely alienated her affections from Darnley, who had already disgusted her by his violence and his licentiousness. Having been confounded, however, by the conspirators, she was obliged to dissemble, in order to detach the king from their party, a project in which she completely succeeded, and thus was enabled to regain her liberty. Murray and the exiled nobles were immediately received into favour; and Morton, and the rest of the murderers, were compelled to seek safety in England.

The charm, which had at first attached the queen to Darnley, and held them in a happy union, was now entirely dissipated; and love no longer covering his follies and his vices with its friendly veil, they appeared to Mary in their full dimensions and deformity. Though the king published a proclamation declaring all knowledge of the conspiracy against Rizzio, the queen was fully convinced that he was not only accessory to the contrivance, but to the commission of that odious crime. That very power, which, with liberal and unspurious fondness, she had conferred upon him, he had employed to infill her authority, to limit her prerogative, and to endanger her person. Such an outrage it was impossible any woman could bear or forgive. Cold civilities, secret distrust, frequent quarrels, succedeed to their former transports of affection and confidence.

About this time a new favourite grew into credit with the queen, and soon gained an ascendancy over her heart, which encouraged him to form designs that proved fatal to himself and to Mary. This was James Hepburn, earl of Bothwell, the head of one of the most ancient and powerful families in the kingdom. When the conspirators against Rizzio detained her in custody, he became the chief instrument in recovering her liberty, and served her with so much fidelity and success, as made the deepest impression upon her mind. Her gratitude towards him with marks of her bounty; she raised him to offices of dignity and trust; and transacted no matter of importance without his advice.

The hour of the queen's deliverance now approached; and she was advised, for the sake of perfect security, to take up her residence in the castle of Edinburgh, where she was accordingly delivered of her only son, James, whose birth was happy for the whole island, and unfortunate only for her. His accession to the throne of England, united the two divided kingdoms in one mighty monarchy, and established the power of Great Britain on a firm foundation; while she, torn early from her son by the cruelty of her fate, was never allowed to enjoy the tender offices of motherhood, nor to taste the joys which fill the heart of a mother.

To queen, whose court, instead of every spring of bliss, was but a centre of the attack of the French and English to be constantly repeated. He attacked them as he had done before, in preference to her lady in Darnley's race. At the same time he was murdered by the expediency of force bought for power, placed under the house he had provided and inhabited, and was ambushed and meted out to Edinburgh, and Bothwell was accused of and convicted for the murder, but was acquitted on a trial by his peers. Of his guilt, however, not the slightest doubt could be entertained; and it is much to be feared that Mary herself was accessory to the crime.

Bothwell now resolved to fix the attentions of the queen, and having secured what object to his heart, he carried her to the castle of Darnley, where he maintained a willing prisoner, till matters were finally arranged for their removal, when the queen was received by the Lord High Commissioner, and was sent afterwards to Bothwell, whom he created Duke of Orkney. This step, the most unjustifiable of all her follies, was the prelude to her ruin. The nobles immediately confederated against her and Bothwell, who was obliged to seek refuge in England, where he fell into the hands of her irritated subjects. By them he was conducted to Edinburgh, and subsequently to Lochleven Castle. The confederate leaders assumed the title of lords of the secret council, and arrogated to themselves the whole regal authority, and deliberations were held to fix the destiny of the nation, and to determine respecting the person of the queen. The result was, that she was compelled to resign the crown in favour of her son, who was instantly proclaimed, and the earl of Murray was invested with the dignity of regent.

Matters being thus arranged, the first act of the regent was to call a parliament, in which all the measures of the confederates were confirmed. But notwithstanding this, Mary still had many friends who were ready to support her cause, if she could regain her liberty. Apprized of these favourable sentiments, she used every effort to effect her escape, and at length succeeded in her object, in a manner no less surprising to her friends, than unexpected by her enemies. By the influence of her charms, the captivated young Douglas, the brother of the owner of the castle, and prevailed upon him to join in a plot for her liberation. Accordingly, on the appointed night, having stolen the keys from his brother's room, he allowed Mary to pass out, and then locking the doors again, threw the keys into the lake. The queen entered a boat prepared for her, and landed safely on the shore, where she was received by Lord Seaton, Sir James Hamilton, and some other of her friends, who had been apprised of the plot. Instantly mounting on horseback, she fled to Hamilton, where she was joined by a number of the nobility, and in a few days found herself surrounded by a formidable army. In this critical situation, the genius and prudence of the regent were eminently displayed. While he assured the queen for some days by negotiations, he employed himself with the utmost industry in drawing together his adherents from different parts of the kingdom. As soon as he was in a condition to take the field, he broke off the negotiation, and determined to hazard a battle. Mary, whose interest it was to delay the decision of her fate, imprudently favoured his wishes. She attacked his army in an advantageous position at Langside, and being completely defeated, fled to England, and threw herself upon the generosity of queen Elizabeth, by whom she was detained a prisoner for
In the mean time the regent Murray, by his vigorous ad-
ministration, soon restored Scotland to tranquillity; and con-
tinued to govern without any serious molestation till his death in 1570, by the hand of Hamilton of Bothwellhaugh.
He was succeeded in his high office by the earl of Lenox,
during whose rule, and that of his succeffors Marr and Morton, the kingdom was distracted by civil war. "Fellow
citizens, friends, brothers, took different sides, and ranged
themselves under the standards of the contending factions.
In every county, and almost in every town and village,
kings' men and queen's men were names of distinction.
Political hatred destroyed all natural ties, and extinguished
the reciprocal good will and confidence which held mankind
together in society. Religious zeal mingled itself with these
civil divisions, and contributed not a little to heighten
and inflame them."

Morton, the last regent, during the minority of James,
having excited the enmity of several of the nobility, was
accused of being accessory to the murder of Darnley, and
suffered for that crime in 1581, though the proofs of his
guilt were far from being satisfatory. After this event,
James himself began to exercise the sovereign authority;
but his love for humanitism proved prejudicial to his own
peace and that of his kingdom, by fomenting jealousy
among his nobles. One of these favourites, the earl of
Arran, conducted himself in so arrogant and tyrannical
a manner, that a confederacy was formed against him; and
the king was forced to deprive him of all his offices and
honours, and to declare him an enemy to the country.

James having been bred in the principles of the Protestant
faith, exerted himself on every occasion to secure the re-
formed church from the danger of being overthrown by the
Catholic party, which was synonomous with the queen's
party, and continued to be very formidable so long as he
lived. When his mother was put to death by queen Eliza-
abeth, however, he renounced warmly against her conduct,
and even declared war; but that wily prince so soon found
means to soothe his anger, and regain his friendship. During
the whole of his reign, James was constantly in danger of his
life from the plots of the Popish lords, towards whom he
shewed more lenity than was probably politic or prudent.
On one occasion his person was seized by Bothwell, but he
happily contrived to escape from his power, before any of
the ulterior objects of that bold measure could be effected.
Several attempts to murder him were likewise made, by
various persons; but the most dangerous, though un suc-
cessful, conspiracy formed against his life, was that usually
denominated the Gowrie conspiracy, from the title of the
principal actor, John Ruthven, earl of Gowrie. From the
myth in which all its circumstances are involved, it has
greatly excited the attention of historians; some even ques-
tioning the existence of any plot, and maintaining that the
king murdered the Ruthvens without any reasonable caufe.
This opinion, however, is justly confedered by Dr. Ro-
bertson as extremely improbable; though it must be con-
ceded that the conduct of James, and the impression on the
public mind against him at the time, call an air of great suf-
picion over the whole transactio

From this period no event of material interest in the his-
tory of Scotland occurred till the year 1603, when the
death of queen Elizabeth opened the way for the accedence
of James to the throne of England, and laid the basis of
that more intimate union, which has since consolidated the
power and resources, and raised to an unparalleled height
the happiness, prosperity, and glory of our island. The
annals of the two kingdoms are henceforth so much identi-
fied, that it is scarcely possible to treat them separately.
The reader is, therefore, referred for the continuation of
the history of Scotland to the article England. He will
also find some details of portions of the subject under the
words Union, Stuart, Prince Charles, and others, desig-
nating leading events or characters.

General Affe of the Country, the Soil, and Climate.—The
most prominent features in the general aspect of Scotland
are its barren hills and mountains, and the numerous and
extensive lakes which fill the intervening vallies. In some
districts the hills are covered with herbage, but in general
they exhibit only heath vegetating above peat, rock, or
gravel: hence, whether the eye ascends the mountains, or
glances over the vales, the scenery which is presented to the
view, though often grand and picturesque, is seldom na-
turally rich. On the former, the signs of fertility are al-
tways apparent; and as the soil of the latter is usually mixed
with the substantia composing the hills, no high degree of
fertility can be expected. These remarks apply to almost
every part of the Highlands, which comprehend about
three-fifths of the whole extent of Scotland. South of the
Forth, however, and even in a few of the eastern counties
farther to the northward, the character of the scenery
is more improved, and the soil, though extremely various,
is frequently as fertile as in any district of England. As
to the climate of this kingdom, it is such as a knowledge
of its latitude, and of its peculiar situation with regard to the
Northern and Atlantic oceans, would point it out to be.
Both on the eastern and western coasts, but particularly on
the latter, rains are extremely prevalent throughout the
whole year. Snow in general lies only for a short time,
even in the central districts; for though it often falls in con-
siderable quantities, it is seldom attended, as in some more
southern counties, by intense and long continued frosts.
The lowest average heat is 41°.11 of Fahrenheit, and the
highest 50°.326; so that the annual average temperature
of the whole kingdom may be computed to be from 45° to
47° of the same scale. It is remarkable that, in some of the
vallies of Moray, the influence of the sun's rays is so
afflicted by circumstances, that corn ripens there as soon as
in Yorkshire or Northumberland.

Rivers.—Scotland abounds with streams of various mag-
nitude, most of which fall into the Northern or German
ocean. The principal of these are the Tweed, Forth, and
Tay, on the east coast; and the Clyde on the west coast.
Tweed is a beautiful and pastoral river, which discharges
its waters into the sea at Berwick. It is noted for its
salmon fisheries, and for the circumstance of its forming the
boundary for several miles between England and Scotland.
The Forth and Tay both form large estuaries, called the Firths
of Forth and Tay, which serve important purposes in com-
merce. On the former are situated the town and port of
Leith, and on the latter the towns of Dundee and Perth.
The salmon fisheries of the Tay are the most valuable in
Great Britain, and afford a constant supply to the markets
of London and Edinburgh. But Clyde claims a pre-
emience over all these rivers in commercial utility, and per-
haps also in picturesque beauty. Taking its rise from a hill
in Tweeddale, it flows first in a northerly, and afterwards in
a westerly direction, exhibiting in its progress much in-
terest ing scenery. On its banks are situated the towns of
Lanark, Hamilton, Glasgow, Rutherglen, Dumarton,
Patrick, Crawford, and Greenock.

The other rivers of Scotland, which deserve notice, are
the Annan and Nith in Dumfriesshire, the Eden in Fife-
shire, the Dee and Don in Aberdeen, the Spey in
Banffshire,
SCOTLAND.

Banffshire, the Nef and Beasly, which form the Moray Frith, and the Grassy and Coas, which form the Frith of Cromarty.

Lakes and Lamps.—The numerous and beautiful lakes interspersed throughout Scotland, and especially throughout its mountainous tract, constitute a very striking and interesting feature in its scenery. The chief in extent and beauty is that of Loch Lomond. These lakes are of various sizes, lying within the mountains, and adorned with shores of the greatest beauty. Farther from this lake are those of Kettering, Chron, Achray, and Lochcarron; all of them distinguished bysingular and picturesque scenes. The lake of Menteith is also in the vicinity. In Galloway are many fine lakes, on the banks of which the village of New Galloway, Lochleven, in Fifeshire, derives fame at once from its beauty, and from its historical interest, as the residence of queen Mary, when a prisoner in the hands of the confederate nobles. The lakes formed by the Tay are both numerous and extensive: the principal of them are Kannoak, Lyddock, Erricht, and Loch Tay. The last, in particular, is a grand and beautiful expanse of water, of such length as rather to resemble a navigable river. Loch Nevis, in Inverness-shire, is equally noted for its extent and the charms of its scenery. Its usual depth is from 60 to 135 fathoms; and hence is to be explained the phenomenon of its never freezing, even in the coldest winters. This lake forms part of the chain of lakes which intersect the kingdom, from the Moray Frith to the Atlantic ocean, which, we trull, are defined shortiy by becoming of high importance in forwarding the commercial prosperity of the kingdom. The other chief lakes of Scotland are Loch Lom, Loch Naver, and Loch Shin, in Sutherland and Caithness; Loch Fannich, in Ross-shire; the Lochy and Laggan, in Inverness-shire; and Loch Awe, in Argyllshire.

Friths and Inlets of the Sea.—Scotland is much indented with arms of the sea, which enter deep into the land. This indentation is highly beneficial: it facilitates commerce, as each of these branches so far serves the purposes of a canal; it promotes the fisheries, as it brings them more within reach; and it renders the climate more temperate, from the influence of sea-breezes. As the shortlet defilement of these friths and inlets separately would extend this article much beyond its preferrred limits, we shall content ourselves with the bare mention of them. Thoife on the western coast, beginning from the south, are the Frith of Forth, the Frith of Tay, the Moray Frith, the Frith of Beauly, Cromarty Frith, the Frith of Dornoch, Thurso, and Durness bays, Kyle of Tongue, Loch Erbol, and the bay of Durness. Thoife on the west coast, beginning from the north, are Loch Inchard, Loch Laxford, Loch Afflin, Loch Emard, Loch Broom, Loch Ew, Garloch, Loch Torridon, Loch Carron, Lochlalsh, Loch Duich, Loch Hourn, Loch Nevis, Loch Aylort, Loch Moidart, Loch Sunart, Linehe Loch, Lochalsh, Loch Leven, Loch Ceraun, Loch Etive, Loch Melfort, Craigairn, Loch Swan, Loch Killiplait, Loch Tarbat, the Frith of Clyde, Loch Fyne, Loch Long, Loch Gair, Loch Streven, Loch Ryan, the bay of Glenluce, Wigtown bay, Kirkcudbright bay, bay of Nith, and the Solway Frith. Most of the above rivers, lakes, friths, and inlets of the sea, are noticed under their respective names, or under those of the counties to which they more immediately belong.

Mountains.—The mountains of Scotland, as already mentioned, occupy a large proportion of its surface, and constitute a prominent and distinctive feature in its geographical character. The principal chains are the Grampian hills, the Pentland hills, and the Lammar Muir. The first extends almost entirely to the kingdom, in a variety of altitudes to the level of the sea. In the western range, this forms a barrier to the sea of the Hebrides; and are celebrated for beauty by the traditions of the early inhabitants, by the Caledonian Gallery, and the Roman general Agricola. The second chain lies near Edinburgh, and running southward through Lothian, joins Tweeddale hills; and the third, beginning near the eastern coast of Berwickshire, stretches to the southward through the Merrie. In the province of Galloway is a fourth extensive assemblage of hills, which do not, however, form an uniform chain. With respect to the other mountains of Scotland, they do not admit of arrangement into distinct groups; and, therefore, it will be sufficient to notice some of the more remarkable among them in the order of elevation. Ben Nevis is the highest mountain in Britain, its summit being 4350 feet above the level of the sea. On its north-eall side it presents a most prodigious precipice, nearly perpendicular, which is said to be 1500 feet in height. The prospect from this hill is truly sublime, and extends on all sides a distance of 20 miles. The next mountain in point of elevation is Cairngorm, or the Blue mountain, which is constantly covered with snow, and is remarkable for quartz of different colours, well known to lapidaries under the name of Cairngorms. The other chief mountains in this district are those of Braemar, Aberdeen, and Ben Awen. To the Grampian ridge belong Ben Lomond; 3262 feet high; Ben Ledi, 3098; Ben More, 3193; Ben Lawers, 4015; Shihallion, 3564; and Ben Verlich, 3300; besides some scarcely less important elevations on the east. Mount Battock, in Kincardineshire, is 3255 feet high; and Ben Cruachan, a solitary hill in Argyllshire, 3300. In the more northern division of the Highlands, the mountains are yet more numerous, but not so memorable. The chief of them are Ben Nevis, Ben Chat, Ben Chaffey, Ben Gulich, Ben Folkag, Ben Nore, and the hills of Cumnock, all in Ross-shire; and Ben Ormond, Ben Cliberm, Ben Grant, the Paps of Caithness, Ben Hop, and Ben Lugal, in Caithness and Sutherland. Along the whole of the western coast, the scenery is bold and precipitous in its character. One part of it, extending from Loch Kinghorn to the south, presents a most singular appearance, as if mountains had been broken in pieces, and small lakes interspersed among the fragments.

Mineral Produce.—The mineral products of Scotland are numerous, and are, in many instances, supplied in such abundance, as to form important objects of traffic. Gold was formerly procured in the sands of Elvan, a rivulet which joins the Clyde; and a place still exists, called Gold-stour, where the Germans used to wash the sands: but scarcely any has been found recently. The silver discovered in Scotland has hitherto been of little account; the chief mine was that at Alva, which has latterly only afforded coal. Nor can Scotland boast of copper, though a small quantity was found in the Ochils, near Alva; and it is said that the islands of Zetland offer some indications of that metal. It has also been found at Colvend, in Galloway; at Curry, in Lothian; at Oldwich, in Caithness; and Kippern, in Ross-shire. The lead-mines in the south of Lanarkshire have been long known. Thoife of Wanlockhead are in the immediate neighbourhood, but in the county of Dumfries, and belong to another proprietor. These mines yield yearly above 2000 tons. The Saltash vein, Lead-hills, has been worked for sixty years, and produced vast wealth. Some light veins of lead have also been found in the western Highlands, particularly in Arran. Iron is found in various parts of Scotland; the Carron ore is the
molt known, which Mr. Kirwan describes as being an argillaceous iron-flone of a blueish-grey, internally of a dark ochre-yellow. It is found in flat y masses, and in nodules, in an adjacent coal-mine, of which it sometimes forms the roof. At the Carron-works this ore is often smelted with the red greasy iron ore from Ulverton, in Lancashire, which imparts easteren fusion, and superior value. Calamine and zinc are also found at Wanlock-head; and it is said that plum-bago and antimony may be traced in the Highlands. Coal has been worked for a succession of ages. Pope Pius II., in his defcription of Europe, written about 1450, maintains that he beheld, with wonder, black stones given as alms to the poor of Scotland. But the use of this mineral may be traced to the twelfth century. The earliest account given of the Scotch coal is contained in a book published by one George Sinclair, who calls himself professor of philosophy at Glasgow, but his name cannot be traced in the university list. He explains with some exactness the manner of working coal, and mentions the subterraneous walls of whin which intersect the strata, particularly a remarkable one, visible from the river Tyne, where it forms a cataract, and passing by Preton-Pans to the shore of Fife. Mr. Williams has recently given his observations on this subject with much practical skill. The Lothians, and Fifeshire particularly, abound with this useful mineral, which also extends into Ayrshire; and near Irvine is found a curious variety, called ribbon coal. A singular coal, in veins of mineral, has been found at Caithle-Leod, in the eastern division of Rosfhirie. Among the least important minerals of Scotland, is the new earth found at Strontian, in the district of Sunart, and parish of Ardnamuran, in Argyllshire, which is now introduced into numerous yfements of mineralogy and chemistry. Ben Nevis affords beautiful granite. Fine flavy marble is found in A'llayt, and at Blair Gowrie, in Perthshire. A black marble, fretted with white, like lace-work, occurs near fort William; dark brown with white at Cambulang, Clydefield. Jasper is found in various parts; Arthur's seat offers a curious variety; and on the western shore of Icolmkill, are many curious pebbles of various descriptions. Foller's-earth is found near Campbeltown, in Caintire; and it is supposed that there must be a vast mass of talc, equal to that of Moffat, in the mountains which give rise to the river Fendant, as large pebbles of it are sometimes found in that stream.

Natural Curiosities.—Scotland, like other mountainous countries, abounds with singular scenes and natural curiosities. The caves on the shore near Colved, in Galloway, are well worthy of notice; and the beautiful falls of the Clyde, near Lanark, have deferently excited much attention. On the east of this part of Scotland, are the pastoral vales of the Tweed and Tievot, celebrated in song; the deep pafs of the Peaths; and the romantic rock of Bals, the haunt of the sian goafe. The basaltic columns of Arthur's seat, near Edinburgh, deserve inspection. On the northern shore of the Forth, near Dyfart, a coal-minne has, for ages, been on fire, probably from decomposed pyrites, and has supplied Buchanan with a curious description. The beauties of Loch Lomond have often been described, but the trefaces, or singular hills around lake Ketterin, form a new acquisition to the traveller. The hills of Kinnoull, near Perth, conlute a great curiosity, presents a mass of uncommon minerals. The numerous lakes and mountains need not be again mentioned. Many of the rocks off the coast of Aberdeenshire assume singular forms of arches, pillars, &c.; and the space from Trouphed to Portfoy abounds in uncommon rocks, and singular marine productions. The caves of Nigg, in Rosfhirie, are worth visiting, and the more northern shores present innumerable wild scenes of savage nature. Near Lathron, in Caithness, is a large cave, into which the inhabitants fall to kill seals. Nof Head presents a singular quarry of slate, marked with various metallic figures. The isles Stroma, near the northern shore, preferve dead bodies for a long time without corruption. Near Tang is the cave Fragill, about fifty feet high and twenty wide, variegated with a thousand colours, which are loit in each other with a delicacy and softness that no art can imitate. On the caft of Durness is the cave of Smo, within which is the resemblance of a gate, succeeded by a small lake of fresh water, containing trout; the extent of this subterraneous lake has never been explored. The singularity of the coast of Eadrachill, south of Loch Inchar, may likewise be mentioned as a natural curiosity, as may also the grand cataract of Kinros river, and the cave of Ganted, near A'lyt Point. The cades of Gamma, in the heights of Glen Eleagh, is truly sublime, amidst the conflant darknes of hills and woods. Ben Nevis will, of course, attract notice from its singular form and elevation. According to Mr. Williams, it consists of one solid mass of red granite, which he traced at the base for four miles along the side of a rivulet on the east; the height of this mass he computes at 3500 feet, and above it are stratified rocks, the nature of which he does not explain, but he says that those on the summit are so hard and tough, that wrought iron is inferior to them in those qualities. The stupendous precipice on the north-eat side exhibits almost an entire fection of the mountain. In Argyleshire the marine cataract of Loch Etif, the beautiful lake of Awe, and the environs of Inverary, present the chief objects of curiosity.

Sketch of the Agriculture.—Scotland, with respect to agriculture, exhibits great variations, from causes partly of a moral, but chiefly of a phical nature. To give his readers juft ideas on this subject, sir John Sinclair, in his “General Report,” has divided the country into nine districts, each distinguished by some peculiarities of surface, or relative circumstances, from the rest. The first district includes the counties of Roxburgh, Berwick, and the three Lothians, and may be justly termed, by way of eminence, the agricultural district, as the art of husbandry is carried on there in as great perfection as in any country in Europe. The proportion of land in cultivation is very considerable, and its farmers are, in general, remarkable for their intelligence, industry, and capital. In this district is situated the metropolis of Scotland, which unites to signal advantages of sitution, a degree of art and elegance in its buildings, unknown in any other town in Great Britain. As it is the seat of the courts of law, the public offices, and a celebrated university, the population within its bounds is much greater than its agriculture or commerce would otherwise require. The several counties which compose this district may be thus discriminated. Roxburghshire, the most souterly, has a great extent of hills of considerabe elevation, and only adapted for the paituring of sheep; but it also includes the rich vale of Tievot, which is one of the most improved tracts in the kingdom. Berwickshire, though a large share of its surface is likewise beet suited for pasture, contains in the Merfe, foil at once fertile and well cultivated. Eait Lothian, throughout the greater part of its extent, is a rich and highly improved plain, diversified by a few gentle eemences; and yields to no county in Great Britain the palm of superiorit in agriculture. Mid-Lothian, though inferior in soil to Eait Lothian, nevertheless raises excellent corn and green crops, and likewise derives wealth from horticulture in the vicinity of Edinburgh. West Lothian, besides being noted for the carefulness of its agriculture, in the more cultivated parts, is ornamented with many extensive plantations, while
its peculiar situation on the further bank of the Forth adds much to the beauty of the scenery, and to the advantages which the country possesses with respect to agriculture.

The third district includes the counties of Peebles, Selkirk, Tweeddale, Roxburgh, Kirkcudbright, and Wigtown. Here are the highest mountains south of the Forth; and though the great proportion of hills, and the small extent of arable land, more of the surface is appropriated to the feeding of live stock than to the growth of corn. Yet the vales, particularly in Dumfriesshire, are of considerable extent and fertility, and exhibit much diversity of appearance. The green hills of Tweeddale, and the interesting vales, are prolific of corn. Only a small proportion of the territory, however, is arable, and late harvests occasionally blight the prospects of the farmer. In the county of Selkirk, formerly called the Forrestd, a still higher proportion of the land is cultivated; but new plantations begin to fill, and will in time supplant the place of those natural woods, with which, several centuries ago, this county abounded. The hills, both in this county and in that of Peebles, are covered by numerous flacks of sheep, partly of the Tweeddale, but chiefly by the Cheviot race. Great numbers of cattle also are found in these districts. In Galway, its excellent breed of cattle, and hardy race of sheep, are supported much better than formerly; and not only oats and barley, but wheat of good quality are raised in every part of the arable tracts. The valley of the southern Dee, in Kirkcudbright, has likewise been much improved; and though on the banks of that river there are neither coal-pits nor lime-quotaries, yet imported coal forms the chief article of fuel, and imported lime the principal manure.

The third district is washed by the Atlantic ocean, and by means of a navigable canal communicates with the German sea. It includes the counties of Ayr, Renfrew, Lanark, and Dunbarton. Notwithstanding the humidity of the climate, from its exposure to the sea, and the extent and elevation of its hills, agriculture is much attended to, and in many parts is carried on with great success, as the exertions of the farmers are stimulated by commerce and manufactures. Still, however, this district is more adapted to the rearing or fattening of live-stock, than to the raising of corn; and the belt breeds of horses and of dairy cows are to be found in it. From the concurring causes of commerce, manufactures, and minerals, agriculture has flourished in an unequal climate; and nearly one-half, or, more accurately, seven-tenths of the whole surface are under cultivation. With only one-thirteenth of the extent, nearly one-fourth of the population of Scotland is included in this division.

In the fourth district are included the counties of Fife, Kinross, Clackmannan, Stirling, Perth, and Forfar or Angus. This district exhibits every variety of soil and surface, from the level and rich carse of Stirling, Falkirk, and Gowrie, and the great valleys of Strathmore Atholl and Kintail, to the lofty Grampians, which shelter a considerable proportion of the division from the northern blasts. In the rich carses, and along the firths and sea-coast, it produces the bell wheat, beans, barley, and broad clover. And in some of the island districts are raised excellent crops of turnips, beets, and oats. Its live-stock in general is of an excellent description. The towns of Dunoon, Perth, Alloa, Dumfermline, Stirling, St. Andrews, Clackmannan, Kinross, Forfar, Montrose, Brechin, and a number of inferior villages, contain two-fifths of its whole population. In this extensive district, Fifeshire is distinguished by its great variety of productions, and by its fisheries, its flax and linen manufactures, its coal-mines, lime-works, and iron-foundries, by its improved agriculture, and its breeds of cattle and sheep.
Wheat and beans also are raised successfully in the heavy loams of Formater, and on the still heavier clays of Buchan. Banffshire owed much to a distinguished character, the earl of Findlater and Seafield, who introduced an improved system of cultivation in that county, and encouraged his farmers to imitate his example. Not only near the Forth coast of the Bogue and the Enrie, where that improved system began, but in the more inland parts, a spirit of improvement has now become general, and has greatly altered the face of the country. Though nature has done much for Moray, yet the culture of turnips and of town grusses was not, till within the last thirty years, so general, as in less favoured counties; but of late, both these and corn crops, with the rearing of live stock, have been attended to with ardour and perseverance.

In the fourth district are included the two extensive counties of Argyle and Inverness, comprising nearly one-fifth of the whole surface of Scotland. About two-nineteenth parts of this district are cultivated, and productive. Near Inverness, at Campbeltown, in Argyleshire, and in some other spots, wheat and turnips are successfully cultivated, but in general the country is unfit for tillage, except on a small scale; its grazings, however, are extensive, and well adapted for the rearing of live stock. It likewise contains a great extent of plantations, and the remnant of the Coccimore, or great forest of Scotland. The black cattle of this district are in high estimation as excellent feeders. The hardy breed of Tweedale sheep, and in some instances those of Cheviot, occupy the hills. This division extends across the island; and the Caledonian canal is now carrying on directly through it, from the German sea to the Atlantic ocean, which it is to be hoped will carry industry and wealth into this remote district, and furnish the means of facilitating and enlarging the commerce of the other parts of the kingdom.

The seventh district includes the counties of Cromarty, Rothes, Sutherland, and Caithness. It is in some respects superior to the former, though more northerly. Earl Rothes, with a part of Cromarty, contains a considerable proportion of excellent soil; and both the wheat and turnip husbandry are carried on successfully. The eastern coast of Sutherland, and the plains of Caithness, are also good corn counties. Earl Rothes, and by far the greatest part of Sutherland, of Cromarty, and of that portion of Caithness which bounds with Sutherland, are rugged and unproductive. Not a tenth part of this district is capable of being cultivated, and only a twelfth part of the people resides in towns or villages; yet, by the introduction of sheep-farming, by encouraging manufactures, and, above all, by the extensive fisheries of herrings and cod, now successfully established along the coast of Caithness; this district must soon greatly increase in value, and the inhabitants become richer and happier. The breeds of cattle have been much improved of late years; the Tweeddale breed of sheep is now spreading over the western parts of this district; and there are already about 4000 of the Cheviot breed in various parts of it, more especially in Sutherland and Caithness. The Merino breed, and crosses of them, have been successfully introduced into Rotheshire, and other parts of this district. Earl Rothes and Cromarty are ornamented with the seats of the proprietors, and extensive plantations. Wood also thrives in Sutherland, and in the more hilly parts of Caithness; but in the plains of Caithness, and near the sea-coast, it cannot be raised to advantage, from the nature of the subsoil, in general a gritty cherty gravel of little depth, incumbent on a horizontal flaggy rock, which keeps the water near the surface.

The islands which are included in the eighth district, were formerly denominated Eubide, but are now better known by the name of the Hebrides, or the Western Islands. They contain about one-tenth part of the total extent of Scotland, with about one-eighth part of its population. Of the whole surface, nearly one-seventh part is under culture. Wheat has been raised in some of the islands, more especially Bute, Islay, and Coll; and turnips have also been cultivated successfully in Skye, and some of the smaller islands. In all these islands the breed of black cattle is excellent, though in general small. The fisheries and kelp manufacture are very valuable; and by proper attention to them, these islands may furnish a great addition both to the wealth and strength of the empire.

In the ninth or last district are the northern islands of Orkney, and Zetland or Shetland. The former contain about 440, and the latter nearly 880 square miles, and form one county. Only about one-twentieth part of the whole surface of these islands is in cultivation. Wheat and turnips have both been tried, and not without success. The pure Merino breed of sheep has been introduced into Orkney recently; and a zeal for improvement has lately appeared in these islands, which may be attended with the best effects; for they enjoy a very temperate climate, though in a high northern latitude. The islands being situated low, snow seldom lies many days, and ice is never more than two or three inches thick.

Forays and Woods.—That Scotland was anciently clothed with extensive and luxuriant forests, is abundantly proved by the concurring evidence of tradition, of hiltory, and of the actual remains of their spoils. Innumerable places, where scarcely a tree is now to be seen, derive their names from the circumstance of their having been covered with wood, or from the particular kinds of timber with which they abounded; as Woodhead, Woodside, Aikenhead, Athview. The great forest of Selkirk, of which scarcely a trace remains, existed, as appears from ancient documents, as late as the 12th or 13th century; extending over the upper parts of Ayrshire, Lanarkshire, and Peeblesshire. The forest of Payle seems to have communicated with that of Selkirk, extending, without much interruption, through the higher parts of Renfrewshire, the marches of Ayr and Lanarkshire by Loudon-hill, to near the shores of Galloway. The Caledonian forest, of which the Roman historians speak, appears to have extended in a southern direction to the English borders; and in a western, from the boundary of Stirlingshire, by Falkirk and Stirling, (including the higher grounds of St. Ninian, once the royal forest of Dunsaff,) as far as Gartmore in Perthshire, covering the great moils, called Moils Flanders, through a tract of about twenty miles. Of this no trace remains, except Callendar Wood, and Tor Wood, unless we trace it, as we may, in the deep moils, from six to nine feet under the surface, incumbent on the clay, its original soil. Many other inferences of ancient forests, long since lost, might be given from authentic records. In all our moils, from 20 feet above the level of the sea, to 500, and even 1000 feet above that elevation, the remains of trees of a much larger size than any which now exist in a growing state, are found in abundance. In the northern moils these are principally of the pine tribe. To the south of the Forth it does not appear that the fir ever grew spontaneously. The oak is, in that district, to be found every where3 imbedded in the moils. In Dalferash parish, in Lanarkshire, an oak was lately dug up 65 feet long, which is so straight, and so equal in girth, that it is difficult to determine which is its root end. In Moils Flanders, innumerable trees of the
the same kind occur. Even the Hebrides, exposed as they are to the sea, present venerable remains of ancient forests. A sycamore, which grew on a sea cliff in the Flannery Island of Berwick, when cut into logs, loaded a large boat. The island has not been filled with woods. Though Lewin, adds Dr. Walker, is now entirely delirious of timber, there are large trunks of elder, birch, and especially of Scots fir, found in its extensive moors. Of the destruction of these magnificent forests, we are furnished with a satisfactory account both by history and observation. Haro-
dean and Dion Cassius inform us, that the enemy, about A.D. 207, employed the Roman legions, with the auxiliary troops, and fuch of the natives as were under his control, in cutting down the forests of Scotland, an undertaking, in which (the historian tells us) he lost no less than 200,000 men. The forest that once covered Mos Flanders, to the west of Stirling, appears evidently to have been thus cut down; the prolifer trees lie under the moes in every direction, which demonstrates that they have not been overthrown by storms, which would have laid them down uniformly. At a later period, John, duke of Lancaster, set 24,000 acres to work at one time to cut down the woods of Scotland. In the northern parts of Scotland, the Danes cut down and burnt many woods, as did Robert Bruce in his expedition against Cumyn. Mr. Graham of Gartmore has in his possessions an original document, relating to the woods of Aberfoyle, now the property of the Duke of Montrose, formerly the earl of Montrose and Arith. It is an order from general Monk to cut down the woods of Milton and Gleskane, on account of the shelter they afforded to the rebels.

Government.—The political constitution of Scotland, since the Union, has been blended with that of England. Previous to that event, the parliament of Scotland was, like England, composed of peers and representatives of counties and burgs, with this distinction, that they sat in one house. That wise prince, James I. of Scotland, as has been mentioned, attempted to establish a house of commons, in imitation of that of England, but his subjects maintained the most firm reluctance to that enlightened measure. The most distinguished feature of the ancient government is the general assembly. The high courts of justice, and particularly the court of seftions, may be illus in the next place. The lords of council and eellion are fourteen in number, besides a presidant; and on their appointment assume a title, generally derived from the name of an elder, by which they are addressed, as if peers by creation. The only appeal from this court is to the house of lords. It has long been a subject of regret, that the causes were not determined by jury, in England. But this ground of complaint has been very recently removed, and three judges have been appointed to preside in a court where civil suits are to be determined by a majority of jurors. These judges have been named lords commissioners. The court of judicature consists of five judges, all lords of seftions, with a presidant, styled the lord justice clerk, as representing the lords justice general. This is the supreme court of all criminal causes of importance, which are determined by the majority of a jury, and not by their unanimity, as in England. The court of exchequer consists of a lord chief baron, and four barons; in the court of admiralty there is only one judge.

The law of Scotland differs essentially from that of England, being founded, in a great degree, upon the civil law. It partly consists of statute law, but many of the ancient enactments never having been enforced, reference is made to the decisions of the court of seftion, which are carefully pre-

served and published, and which afford precedent; generally reckoned unexceptionable. There is scarcely a statute of common law, so that the civil and canon laws may be denominated the basis of Scotch jurisprudence. The laws are those of the feudal system, the magnates of baronies, the commoners, and the judges of the peace. While the feudal system prevailed, the hereditary jurisdictions were nearly the same, and every chief maintained an unbroken control over the lives and property of his vassals and tenants. But this system is now happily abol-
ished.

Parliamentary Representation.—Scotland is represented in the British parliament by fifteen peers and forty-five commoners, in conformity to the treaty of union between the two kingdoms. The sixteen peers are elected for every new parliament by the whole body of the peerage duly qualified to vote at the period when the election takes place, and are not, when once elected, continued for life, as in the case in regard to Irish peers, by the recent union with Ireland.

The following table will give an idea of the diminution that has taken place in the number of the Scottish peerage since the Union, and the amount at present.

<table>
<thead>
<tr>
<th>No. of Scotch peers at the Union</th>
<th>159</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duke of Holdays, when entitled to vote</td>

</tr>
<tr>
<td>Persevered</td>
<td>25</td>
</tr>
<tr>
<td>Remain</td>
<td>81</td>
</tr>
</tbody>
</table>

Of these, 23 (including the duke of Holdays) are British peers, but who will retain the privilege of voting at elections, and even continue eligible; though it can hardly be supposed that these hereditary peers would persuade their brethren not enjoying the same privilege to elect them. At the last election, on the 15th of November 1812, there were three minor, three peeresses, and two Roman Catholics, consequently eight disqualified from voting. The peers who actually voted were fifty-two, and twenty-two were out of the kingdom, or did not vote.

Of the forty-five commoners, thirty represent counties, and fifteen boroughs.

The county members are elected by freeholders possessed of 40l. Scotch of valued rent, in land held of the crown. The only exception to this rule is found in the county of Sutherland; where, as the greater part of the land is held of the earl of Sutherland, it became necessary to give the vaillans of that earldom a right to vote as well as the vaillans of the crown; and in conformance of the inconsiderable number of small proprietors in the county, the qualification of the freeholder was reduced to 20l. Scotch of valued rent.

The following table shews the amount of the valued rent in each county, as it stood in 1674; also the number of qualified freeholders returned in the bill drawn up for the year 1811, since which there has been very little variation.

State of Religion.—According to the present establishment of the church, Scotland is divided into 15 synods, comprehending 78 presbyteries, and 893 parishes, which are represented in the general assembly of the church, which meets annually at Edinburgh. In its deliberative and judicial capacity this ecclesiastical court is justly accounted among the most enlightened and respectable in the Christian world.

In the division of the country into synods and presbyteries, convenience has been principally attended to, the limits of counties being no further observed than they are consistent with contiguity to the respective synodical and presbyterial seats; but in the arrangement of the whole into parishes, contiguity to the churches has not been so much observed. Hence, in many instances, remote parts are conjoined into one parish, to the great inconvenience of the parishioners, as well as of the officiating clergyman. With respect to extent and population also there is a great disparity; the first was settled in remote times; the second has been determined, in a great degree, by the effects of manufactures and commerce.

The names of the fifteen synods are as follow: 1. The synod of Lothian and Tweedside. 2. The synod of Moray and Teviotdale. 3. The synod of Dumfries. 4. The synod of Galloway. 5. The synod of Glasgow and Ayr. 6. The synod of Perth and Stirling. 7. The synod of Fife. 8. The synod of Angus and Mearns. 9. The synod of Aberdeen. 10. The synod of Moray. 11. The synod of Ross. 12. The synod of Sutherland. 13. The synod of Argyle. 14. Glenelgh, or synod of Lochaber and the Isles. 15. The synod of Orkney. These synods come in the place of the bishops, and have jurisdiction in ecclesiastical questions; in regard to which there is an appeal from the presbytery to the synod, and thence to the general assembly.

In former times, particularly before the revolution in 1688, Scotland, with respect to ecclesiastical government, was divided into two archbishoprics, St. Andrews and Glasgow, and twelve bishoprics, Edinburgh, Dunkeld, Aberdeen, Moray, Brechin, Dunblane, Ross, Caithness, Orkney, Galloway, Argyll, and the Isles. The country in general was parcelled out among the respective fees, in an arrangement having some regard to contiguity, but not always to; for several parishes were attached to bishoprics, and many to the archbishoprics, that were very remote from the provinces in which they were locally placed. This still remains the case with the jurisdictions of the different commissariats, which have been subjoined from these bishoprics, in what is called confiditurial courts. At present, the Scots Episcopals have only eight bishoprics, viz. 1. Edinburgh and Fife; 2. Glasgow; 3. Aberdeen; 4. Moray; 5. Ross; 6. Dunkeld; 7. Brechin, and 8. Dunblane; comprehending seventy-six curates, served by sixty clergymen. The number of
of three counties is reputed to be about 19,000, which, 1769, la
haps, with the children, may amount to 27,000. The Roman Cathedrals divide Scotland into two departments, the Lowland and the Highland, in order clearly to make a distinction between the two languages, the Scottish and the Gael. Over each of these a sees apolitical and a bishopric was set up. In the Lowlands they have about forty and in the Highlands eight bishoprics, about 27,000 in number. The Scotch are divided into three provinces:

The Southern, from the Scottish Presbyterians and a larger number of the country among them, they have 1,125 congregations in Scotland, with about 60,000 hearers.

The Northern Presbyterian Divideth into three provinces, containing eleven presbyteries. They have 1,125 congregations, with about 60,000 hearers. The Church of Relief divided the country into five presbyteries, containing 75 congregations, with about 50,000 hearers. The other Presbyterian Scots, as the Cameronian, &c., may amount to about 14,000. The separation of various persuasions, as Baptists, Brethren, Gladiators, may amount to nearly 5,000.

The Methodists, of whom there are supposed to be about 6,000 members, or, including children, about 9,000 souls, divide the country into circuits, eleven in all, headed by eighteen preachers.

The Friends, or Quakers, are few in number, that they have only five places of meeting, viz., Glasgow, Hawick, Edinburgh, Aberdeen, and Kirnack, near Old Meldrum; and their whole number does not exceed 2000.

Chief Cities and Towns.—The most important towns in Scotland, both as to extent and population, are Edinburgh and Glasgow; the former the metropolis of the kingdom, and the latter the emporium of its manufactures and commerce. They both contain nearly the same number of inhabitants, viz., about 100,000 persons, and are royal burghs, governed each by a lord provost and town council. The next town to these in importance is Perth, Aberdeen, Dundee, and Paisley, each containing about 30,000 souls. The other towns of note are Berwick, Dunbar, Haddington, Musselburgh, Aberbrothick, Montrose, Portferry, Elgin, Inverness, and Dingwall, situated on the eastern side of the kingdom; Ayr, Greenock, Paisley, Inverary, and Cambeltown, situated on its western side; and Dumfries, Lanark, Stirling, Dunfermline, Dunkefield, Falkirk, Linlithgow, Hamilton, Selkirk, and many others little inferior to these, which are situated in inland counties. Many of the above towns enjoy the advantage of separate jurisdiction, but others are under the authority of the county magistrates, and of the class is Paisley, the greatest manufacturing town in Scotland next to Glasgow.

Manufactures and Commerce.—Previous to the Union, Scotland could boast little as to the extent either of its manufacturing or commercial prosperity. It is true, indeed, that tradition, as well as history, point out Perth as a great trading mart some centuries ago, but the accounts are most probably exaggerated. At all events, it is certain that the commerce of the kingdom was at a very low ebb during the seventeenth century, and that it has only risen into importance within the last fifty years. Formerly the flax manufacture of the kingdom was great, but that has now given way, comparatively speaking, to the weaving of cotton goods. The chief seats of the former manufacture are Perth and its vicinity, and the county of Fife; and of the latter the counties of Lanark and Renfrew, including the towns of Glasgow and Paisley, and others of inferior note. Woollen cloths are only made for home consumption, and in trifling quantity, excepting carpets, the manufacture of which is considerable. Several other kinds of manufacture are carried on in Scotland, but that of silk is the only one which deserves to be noticed. The works of the Carron are probably the first celebrated in Europe for the furnishing of iron, and there are many.

With respect to the commerce of Scotland, it may be remarked, that, though in a smaller scale, it is much related to that of England. The chief exports are wool, grain, fish, tobacco, leather, coal, and iron, and some other articles, which are necessary for use. The imports are wine, brandy, and all kinds of colonial produce, including butter, bricks, &c., and new. The principal ports are those of Port Glasgow and Greenock, on the west coast, and Leith, Dundee, and Abdn., on the east coast.

To the above states of Scotch commerce, may be properly added the fisheries, which, placed under appropriate regulations, would produce a vast wealth, not merely to Scotland, but to the British empire at large. To effect this object several attempts have been made, but their beneficial operation has hitherto been much reflected. A bill, however, is now in progress, which it is hoped will produce a more favorable result.

Roads and Canals.—In the Lowlands of Scotland the great roads are not inferior in form or to those of England; but they are not yet in fact, in use, nor are they always planned to the most judicious manner. Rapid improvements, however, are making in this branch of political economy, to the advantage of commerce and of the improvement of national civilization. From the mountainous character of the Highlands, the construction of good roads is perhaps impossible; but even in that wild district, efforts are daily making to render communication more easy.

The principal canal in Scotland is that which connects the navigation of the Clyde and Forth. It was begun in 1769, and constructed according to a survey furnished by Mr. Smelt, of the above. The depth of this canal is seven feet, and its width at the surface fifty-six feet. In some places it is carried through mossy ground, and in others through solid rock, and appears evidently, through all its extent, to have been planned and executed with great ability. Another canal has been proposed between Edinburgh and Glasgow, and is believed to be in progress of execution. There is also a canal forming across the isle of Carse, to connect the Frith of Clyde with the Atlantic ocean, to the north of Jura. But the chief work of this description going on, is the great canal from the Moray Firth, through Loch Nefs and Loch Lomond to the outlet of the sea called Loch Linhe, on the western coast. Parliament has already voted a large sum towards this undertaking, which it is computed will require upwards of 400,000£, to complete it. See CANAL, INVERES.

Literature.—The literature of Scotland, though it cannot boast of great antiquity, has acquired a distinguished place in the annals of fame, by the rapidity of progress and brilliancy of its authors in later times. The Caldees, indeed, the venerable hermits of Jona, are represented by ancient historians as having been men of extensive learning and great erudition; but their claims to this eulogy are probably exaggerated. The earliest genuine work relative to Scotland is the Chronicle of Pitcairn, written by an Irish clergyman, supposed, with considerable probability, to have been a dignitary of the church of Abernethy, in the commencement of the eleventh century. In the twelfth century the chronicles published by Innes, and those of Melrose and Holyrood, deserve to be noticed. About the year 1290 flourished Thomas of Ercalde,
celdon, commonly called Thomas the Rhymer, who wrote a metrical romance, called Sir Tristram, lately republished by Mr. Scott. The next writer of confluence is John Barbour, archdeacon of Aberdeen, who wrote a poem in commemoration of the heroic actions of Robert Bruce, in the year 1375, not less celebrated for its historical fidelity than for its poetical merit. About this time flourished John Fordun, designated the father of Scottish history. In the fifteenth century, James I. of Scotland wrote some poems of great merit, and he was succeeded by Holland, and Henry the Rhymer. Next arose Dunbar, whose merit has entitled him to be placed at the head of the ancient Scottish poets. In the beginning of the sixteenth century flourished Gavin Douglas, and Sir David Lindsay. These were followed by many others of various merit, till the middle of the seventeenth century, when the unhappy events of that turbulent period checked the career of the arts and sciences. Before this, however, the illustrious Drummond had contributed to the world his exquise poems. In modern times, the field of poetical merit has been more luxuriant. The names of Thomson, Ramsay, Blair, Arbuthnot, Beattie, Burns, Campbell, and Scott, with many others, are held in universal estimation.

In the other departments of science, though of later cultivation, the Scots have made rapid progress. In history, the names of Boethius and Buchanan are everywhere revered. The classic elegance and purity of the style of the latter, has entitled him to rank with the first authors of antiquity. In our own age, among other historians of great merit, have arisen Hume and Robertson, whose works will ever be read with enthusiastic delight by the admirers of taste and genius. In the mathematical department, lord Napier, the celebrated inventor of the logarithms; Maclaurin, no less celebrated for his astronomical works; and Dr. Simpson, noted for his knowledge of ancient geometry, have acquired a lasting reputation. In medicine, the names of Pitcairn, Monro, and Cullen, may be mentioned as holding the highest rank; and in the department of metaphysical and moral sciences the perhaps stands unrivalled. The labours of Hume, Hutchison, Reid, Campbell, Beattie, Monboddo, Kames, Smith, and Ferguson, will be regarded with admiration, so long as the philosophy of the mind continues to be a subject of interest, and the English language is understood. Scotland has also attained the praisie of superior excellence in other departments of science, particularly in political economy and in chemistry.

Universities.—The universities in Scotland are four in number: St. Andrews, Glagow, Aberdeen, and Edinburgh. The first was founded by bishop Wardlaw, in 1412; the second by bishop Turnbull, in 1453; the third by bishop Elphinstone, in 1502; and the last by James VI. in 1582. As the reader will find each of them described under their respective names, we shall only observe farther concerning them in this place, that the university of Edinburgh is the most celebrated medical school in Europe, and is annually attended by from 1200 to 1500 students.

Education.—The mode of education adopted in this country is highly laudable, and is probably the best practicable system established in any kingdom. The plan followed in the cities and large towns is nearly similar to that of England; that is, by private seminaries and great public schools, of which the High School of Edinburgh is the most eminent. But the chief advantage of the Scottish education arises from the circumstance of every country parish having a schoolmaster, regularly appointed by the heritors, in the same way as the clergyman, who receives a small salary, which enables him to educate the children of the parishioners at a rate easy and convenient even to the most indigent parents. In the Highlands, the children of the poor are occupied as herdsmen during summer, and in winter attend schools. To be unable to read and write is considered so disgraceful in Scotland, that such persons are scarcely ever to be met with.

Manners and Customs.—In every part of the kingdom, but more especially throughout the Lowlands, the higher orders in Scotland are characterized by much the same features as in England. Their drefs, their mode of living, and their amusements, both public and private, are nearly alike. The inferior orders in the Lowlands are likewise much assimilated to their southern neighbours in their style of drefs, but their food and diversions materially differ. The ordinary diet of the Scottish peasant is paroch, a composition of oatmeal and water, boiled together till it attains a thick consistence. It is eaten with milk twice and sometimes thrice a day, and is seldom varied, except by bread; which differs from paroch only in having the addition of butter, and not being boiled. Butcher's meat is rarely eaten, except on Sunday; but vegetable broths made with butter are not unfrequently used during the week. Pork and eels were formerly held in great abhorrence, and even yet are regarded as impure articles of food, on account of superfluous opinions respecting them. In the Highlands these sentiments are particularly strong; and hence the rearing of swine is very little attended to in that district. In the same division of the kingdom, the national drefs is still prevalent; but the tartan kilt has very generally given place to pantaloons of the same material. From the influence of education, and the well-directed exertions of the clergy, the peafantry have long been distinguished for sobriety, industry, and moral rectitude; and, in point of intelligence, are indubitably the first in the world. Even the artificers are entitled to share in this cULogy, though it must be confessed that exceptions to the rule are too numerous, especi-ally in the great trading towns. The existence of witches, fairies, and ghofts, is still part of the creed of the Scottish peasant; and the Highlander confidently believes in the power of second sight, or the capability of perceiving future events. Some relics of the idolatrous worship of his remote ancestors are yet discernible, both in his amusements and his more ferious occupations; but they are gradually becoming fainter, and will, no doubt, disappear in the progress of refinement and civilization. For information on the amusements, superfluous, and manners of the Scottish peasantry, the reader cannot consult any works with greater advantage than those two exquise poems, the "Halloween," and "Cottar's Saturday Night," of the celebrated Burns. Referring, therefore, to them, we shall only further remark under this head, that in their religious ceremonies, considerable variations exist from the forms in England. Thus, for instance, in baptisms, godfathers and godmothers are inadmissible, the parents alone being made answerable for the education of their children in the path of morality and religion.

Antiquities.—Monuments of antiquity of every age, from the Celtic colonization of the kingdom, are yet visible in various districts. Those of the first epoch are all of the tumular kind, and are only to be discovered by nice investigation in the more wild and uncultivated tracts. Of the Roman period, the remains are numerous, confingling of vetrices of roads, flatons, encampments, foundations of walls, and other minor antiquities. The celebrated wall of Antoninus may yet be traced, with perfect accuracy, nearly the whole of its extent from the Forth to the Clyde; and many interesting inscriptions are frequently dug up from its ruins. Near it was formerly a small edifice called Arthur's Oven, which the most intelligent antiquaries suppose to have been a temple.
SCOTLAND

A temple dedicated to the god Terminus. The most northerly Roman camp yet discovered is situated on the river Ythan, in Aberdeenshire; and there are some roads extending into the county of Angus; but the chief remains of them are buth of the walls. The monuments of the Pictish era consist of tutori circles of stones, cromlechs, &C.; usually, but erroneously, denominated Druidical temples; and of those artificial mounds, or hills, whence the Picts and Dalriads kings were wont to promulgate their laws. The most remarkable stone circles in the kingdom are those in the site of Lewes, and on the Mainland of Orkney. The structures commonly called \"Picts' houseth,\" and the heaps of stones called \"carris,\" or \"karns,\" have also been supposed to belong to this age; but Pinkerton refers the latter entirely to the Dalrads, or Scots, and thinks the former may be Danith, as it is certain similar edifices have been traced to Scandina-
via. They seem to have consisted of a vault hall, open to the sky in the centre, and having receptacles for beds, &c., in the wall. \"These buildings,\" says the author last mentioned, \"are remarkable, as displaying the full elements of the Gothic castle; and the castle of Cuningburgh, in Yorks-
thire, forms an easy transition.\" The remains of later ages are the sculptured obelisks at Forres, and other places; which are probably monuments of signal events, such as battles and treaties of peace; the noted vitrified forts, and churches, abbeys, and churches almost innumerable. Among the more remarkable buildings which owe their origin to religion, are the abbeys of Melrose, Jedburgh, and Aber-
brotch; the cathedrals of Dunkeld, Glasgow, and Brechin; and the chapel of Roslyn, near Edinburgh. The last is one of the most singular and interesting remains of ancient archi-
tecture in Great Britain; and Melrose Abbey may vie with many in England, both as to the extent and magnificence of its buildings.

The following is a list of the books occasionally confuted during the compilation of this article. Joannis de Forde Scottchorunic, cum supplemento et contin. Walteri Bowert; 2 vols. fol. Edin. 1759. Scotia illustrata, &c. Annot. Rob. Sibbald. fol. 1684. The History of the Church of Scotland, from A. D. 263, to Death of James VI.; by John Spottwood; fol. Lond. 1655; 2d edit. 1657. Georgii Buchanani Omnia Operarum serures Thoma Ruddiman, &c.; 2 vols. fol. Edin. 1714. Theatrum Historiae Scotiae; a treatise De Jure Regni apud Scotos; another, entitled Acta contra Mariam Scottorum Reginam; and a third, entitled Dictata Mariae Reginae Scottorum; in his letters, poems, and some pieces on language. Collection of Treatises, in folio, concerning Scotland, written by Sir Robert Sibbald, Edin. 1707. This work comprises, among other pieces, Historical Inquiries concerning Roman Anti-
tiquities; Conjectures concerning the Roman Ports, Colo-
nies, and Forts; and An Account of the Writers ancient and modern, which treat of the Description of Scotland. Tractatus varius ad Scotia antiquae et modernae Historiam faci-
entes, &c.; Specimen Glossarii; Commentarius in Jutin An-
Guile Expeditiones, &c., in illustratissimae textus Taciti. Mif-
ellanea quodam eruditique Antiquitates qua ad borealem Britanniae Majoris Partem pertinent. Vindiciae Scotiae il-
ustrata, &c.; An Account of the Scottish Atlas; or, the De-
scription of Scotland, ancient and modern; fol. Edin.
1683. The Liberis et Independentes of the Kingdom and Church of Scotland affeeted from ancient Records; by Robert Sibbald; 4to. Edin. 1703. Selecta Diplomatium et Nummataria Scotiae Thefaurus, &c.; ab Jacobo Ander-
traits of illustrious Persons; by John Pinkerton; 4to. Lond. 1757. History of Scotland, from the earliest Ac-
counts to A.D. 1437; by William Maitland; continued by another hand; 2 vols. fol. Lond. 1757. The History of the Reformation of Religion within the Realm of Scot-
land, by John Knox; edited from his MS. in the University of Glasgow; fol. Edin. 1756. The true History of the Church of Scotland, from the Beginning of the Reformation to the Death of James VI.; by David Calderwood; fol. 1658. Historical Account of the Scottish Parliament, by George Redpath; 8vo. 1763. Scotica Indiculum; by Philo-

Articles of the Union with Scotland; 4to. 1707. In-
quiry into the Evidence against Mary Queen of Scots; 8vo. Edin. 1772. Inquiry into the Reign of Queen Eliza-
quities; 4to. Roy's Military Antiquities; fol. Gu-

SCOTLAND, New. See NOVA SCOTIA.

SCOTLAND River, a river, or rather rivulet, in the island of Barbadoes, which rises in St. Andrew's Parish, and falls into Long bay, on the E. side of the island, 3 miles S.E. of Cuckold's point, or 24 miles N.W. of St. Joseph's river, the only other small brook of the island.

SCOTODINOS, a term used by medical writers to express a vertigo, or dizziness of the head, attended with a dmeness of fight.

SCOTOMA, or SCOTOMA, a giddiness, or temporary confusion of fight; nearly synonymous with vertigo; which let.

SCOTS, in Geography, the name of one of the two great tribes,
tribes, into which the inhabitants of the northern region of Caledonia was divided, as early as the reign of Cunfantine; Picts being the denomination of the other. The name and almost the memory of the Picts have been extinguished by their unsuccessful rivals; and the Scots, after maintaining for ages the dignity of an independent kingdom, have multiplied, by an equal and voluntary union, as Gibbon expresses it, the honours of the English name. The hand of nature hath contributed to mark the ancient distinction of the Scots and Picts: the former were the men of the hills, and the latter those of the plain. The eastern coast of Caledonia was a level and fertile country, and produced, in a rude state of tillage, a considerable quantity of corn; so that the epithet of crunabh, or wheat-eaters, expressed the contempt or envy of the carnivorous highlanders. Nevertheless, the love of arms and rapine was still the universal passion of the Picts; and their warriors, whipped for a day of battle, were distempered, in the eyes of the Romans, by the strange fashion of painting their naked bodies with gaudy colours and fantastic figures. (See Picts.) The western part of Caledonia irregularly rises into wild and barren hills, which fearfully repay the toil of the husbandmen, and are most profitably used for the pasture of cattle. Accordingly the highlanders were condemned to the occupations of shepherds and hunters; and as they were seldom fixed to any permanent habitation, they acquired the expressive name of Scots, which, in the Celtic tongue, is said to be equivalent to that of swanderer or vagrant. That the Irish defeat of the Scots, though lately revived by Mr. Whitaker, is a fable, has been satisfactorily evinced by Mr. Gibbon; and he has traced the foundation upon which this fabulous superstition has been gradually reared by the bards and the monks, two orders of men, who equally abused the privilege of fiction. It is probable, says this sagacious and elegant historian, that in some remote period of antiquity, the fertile plains of Ulter received a colony of hungry Scots; and that the strangers of the North, who had dared to encounter the arms of the legions, spread their conquests over the favage and unwarlike natives of a solitary island. It is certain, that in the declining age of the Roman empire, Caledonia, Ireland, and the Isle of Man, were inhabited by the Scots; and that the kindred tribes, who were often associated in military enterprises, were deeply affected by the various accidents of their mutual fortunes. They long cherished the lively tradition of their common name and origin, and the missionaries of the Isle of Saints, who diffused the light of Christianity over North Britain, established the vain opinion, that their Irish countrymen were the natural, as well as spiritual, fathers of the Scottish race. The Scottish nation, with mitred pride, adopted their Irish genealogy; and the annals of a long line of imaginary kings have been adorned by the fancy of Boethius, and the chaste elegance of Buchanan. Gibbon's Hist. vol. iv. See SCOTLAND.

SCOTS TUNES. In February 1722, the newspapers of the times inform us, that there was a concert for the benefit of Mr. Thomson, the first collector and publisher of Scots tunes in England. To this collection, for which there was a very large subscription, may be ascribed the subsequent favour of these national melodies south of the Tweed.

After this "confort, at the desire of several persons of quality, was performed a Scottish song." In 1744, in the opera of "Rofelmida," set by Veracini, at that time the leader of the opera band, the first air that presents itself, in the printed copy of the favourite songs, is "The Lads of Patie's Mill," which Monticelli conducted to sing, and to which Veracini added parts and ritornell, in order, as they imagined, to flatter the British nation. But as few of the North Britons, or admirers of this national and natural music, frequent the opera, or mean to give half a guinea to hear a Scots tune, which perhaps their cook-maid, Peggy, can sing better than any foreigner, this expedient failed of its intended effect. See PIMA.

SCOTS, or SCOTT, in Geography, a county of Kentucky, containing 12,419 inhabitants. Its chief town is Georgetown, containing 529 inhabitants.

Scott's Bay, a bay on the S.W. coast of the island of Dominica, towards the S. extremity of the island; 4 miles S. of Charlotte-town.—Allo, a bay of the North Pacific ocean, on the W. coast of America; 10 miles S. of Queen Charlotte's found.

Scott's Cove, a bay on the S.W. coast of Jamaica.

Scott's Head, a cape at the southern extremity of Dominica. N. lat. 15° 20'. W. long. 61° 34'.

Scott's Islands, a cluster of islands in the North Pacific ocean, near the N.W. coast of the island of Quadra and Vancouver. N. lat. 50° 57'. E. long. 23° 41'.

SCOTT, John, in Biography, a clergyman of the church of England, was born in 1638, at Cluppenham, in Wiltshire. He was first apprenticed to a trade in London, and a prebend in St. Paul's cathedral. In 1685 he took his degree of D.D.; and in 1691 he was appointed to the rectory of St. Giles-in-the-Fields, and was made canon of Windor. "The Christian Life," which was published at different times, and finished in 1686, acquired for him so high a reputation, that, after the revolution, he was offered the bishopric of Chester; which, however, he refused, because he could not conscientiously take the oaths required. He was afterwards offered the bishopric of Worcester, and a prebend of Windor, which he likewise declined, because they were the places of persons who had been deprived for an adherence to those principles, which he himself secretly cherished. Nevertheless he had strenuously opposed the prelates of Popery in the reigns of Charles II. and James II., and published some works in controversy with the Papists, while the latter prince was still on the throne. Dr. Scott died in 1694, leaving the character of an excellent man and worthy parish-priest. Besides the work already mentioned, he wrote "A Caes of Conference resolved, concerning the Laws and Liberties of the Church of England," and "Twelve Short Sermons," preached on different occasions. His "Christian Life" is a book very generally read in the religious world.

SCOTT, Michael, a celebrated Scotman of the 13th century, was born at Balwearie, in Fife, about the beginning of the reign of Alexander II. At a very early period he made great progress in language, as well as in mathematics; and having finished his studies at home, he went over into France, where he remained some years; but hearing that the emperor Frederic II. was a great patron of learning and learned men, he repaired to the court of that prince, and applied himself closely to all the branches of philosophy then studied. After residing some time in Germany, he proceeded to England, and was high in the favour of Edward II.; but it is not at all known how long he continued here. Upon his return to Scotland he received the honour of knighthood from Alexander III., and was afterwards sent, with Michael de Wenneys, to bring to Scotland the Maid of Norway, who, being taken ill at sea, was landed on one of the Orkney islands, where she died in the year 1290. At this time Sir Michael was probably far advanced in life: he died in 1291. He was esteemed a man of
of great learning, though so much addicted to the occult sciences, that he passed among his contemporaries as a dull and unmeaning man. Beccaria andVoltaire both exhibit him as one who, if he ever wrote, was not read, and the latter is his namesake, and perhaps introduced the term dedicated by D. This is not known where he was buried, but it is surmised that his books of magic were interred with him in his grave, or preferred in the ceremony which accompanied his death. A Latin translation of Aristotle's works is ascribed to Michael Scott, but probably upon insufficient evidence. There is a translation of that philosopher's works, partly from the Greek and partly from the Arabic, by various hands, undertaken at the command of the emperor Frederic II., at whose court in Michael refided some time, and as he is reported to have translated Aristotle's Natural History of Animals from the Arabic version of Avicenna, it has been assumed that this is the only part of the work which should be ascribed to him. The title of the work is "Aristotelis Opera, Latine versae, partim e Graece partim Arabicæ, per versus lecitos et in uniuerso Linguæ proletante permittus, judis imperatoris Frederici II. Venetiæ, 1496." The works of Michael Scott are numerous, among which the following may be mentioned: "Pharmonigmata et De Homine Procreatione," "De Secretis Naturæ," "Quelico curioso de Natura Solis et Lunae." The subject of this last work is the pretended transmutation of metals, gold and silver being reckoned among alchemists the sun and moon. According to the opinion of Riccobò, Scott was a diligent observer of the stars, and, at the request of the emperor Frederic II., he wrote a treatise on the sphere of Sacrobosco. "Gen. Biog." 

Scott, George Lewis. This learned and accomplished man was not only an able mathematician, but an excellent musician. He was an intimate friend of Dr. Pepys, and assisted him in drawing up his paper for the Royal Society, on the genera and figures of the ancient Greek music; and whatever articles he furnished to the Supplement of Chambers's Dictionary, concerning harmonics or the ratio of sounds, may be depended on. Mr. Scott was a performer on the harpsichord, and very fond of music; but always calculating, during his own performance and that of others, as to the legality of modulation. And we well remember his being much disturbed at the unrelenting succession of chords in the opening of Peri's "Stabat Mater," at the second bar, where that mollifying author suprises the ear, as well as the eye and intellect, in modulating from F minor to E♭ major. Dr. Mower, who had no taste or feeling for music, used to calculate ratios for the ingenious and worthy organist of the Charter-house, and laugh at him for his Greek and mathematical pretensions; but Scott, the flub-preceptor of his present majesty, was in earnest, and wished to make discoveries in Greek music, as much as Pepys. For though attached to old matters of eminence, as well as the Carthusian maestro di cappella, he enjoyed the productions of the moderns extremely, when he could discover in them either genius or science. As we had the honour to be personally acquainted with him, we are sure that the elaborate article Temperament, in music, in the additional volume to Chambers's Dictionary, was drawn up by the late learned and scientific Mr. Scott, who was one of the very few theorists that ever paid the least regard to practice, or who seemed to recollect that the ear had anything to do with harmonics. 

Scott, or Scottus. See Scot. 

Scotti, Tereasa, in Biography, the first woman in the operas of 1764 and 1765, in which Manfosh fung. 

The Scotti, with an elegant figure, a beautiful face, and a melodious voice, five is a very good thing; and the want of power, I flattered great flattery for.

SCOTTIA, in History, bears a memorial to Robert Scott, M.D., late professor of Botany at Dublin, commemorated by Mr. Dumont, in the preface, as well as the dedication, of his "Medicinae Historiae Synopsis." Brown in Art Hist. Kew v. 4, 1768—Classi et ordine, Dodoensiae Decades. Not Ord.

II. Ch. Calva with five rather unequal teeth; its base clothed with indurated appendages. Standard fiddle, shorter than the wings, which are the length of the keel. Stamina all connected. Lemma flat, compressed, thickened at each margin. Seeds few, cleft. 

1. S. dentate. Toothed Scotta.—Found by Mr. Brown on the south-west coast of New Holland. A flowerless plant, in Kew garden, in 1823, by Mr. Peter Good. It is kept in the greenhouse, and flowers from June to September.

SCOTTSBURG, in Geography, a post-town of Virginia; 256 miles W. of Washington.

SCOTUS, in Ancient Geography, a town of Macedonia, on the banks of the river Strymon, in the Thessalian, near Berga.—Alfo, a town of Greece, in the Thessaly Ptolemy.

SCOUR a Line, To, in the Military Language, is to flank it so as to free directly along it; that a musket-ball, entering at one end, may fly to the other, leaving no place of security.

SCOUR, among Cattle, a disease of the flux kind, which frequently affects cows, calves, sheep, and other animals. See Scouring in Cattle, and in Calves.

This is a disease in sheep, which is common in the winter season, being believed to originate from the severity of the frosts, especially when they set in suddenly, or alternate frequently with thaws. The chief dependence for a cure, in these cases, is upon an expeditious change to dry keep; as, in the practice of some good sheep-farmers, the use of hay, on the mornings when hoar-frosts are prevalent, has been found a good preventative. It is sometimes called the galls by sheep-farmers. Early, soft, taty, luxuriant pastures, are also liable to produce this complaint, especially in previously worn-down sheep. It arises frequently, too, from sudden changes from dry, warm, poor pastures, to such as are rich, cold, and damp; or the contrary. It is sometimes likewise the consequence of other affections, as well as of the local weaknesses and relaxation of the bowels. In all these instances, the above changes of food will be highly useful and necessary. The disease may be flapped, except where it is critical, after clearing the intestines of any irritating matters, by mild purgatives, by the following means, particularly where there is great weakness of the affected parts. Both four ounces of the flavings of logwood in two parts of water, until it be reduced to one pint; then add one ounce of cinnamon water, and give one half at a time. Where this is not strong enough to check the disordered, half a dram of the extract of catechu may be dissolved in it, with fifty or more drops of the tincture of opium. These will mildly lessen the over-action of the bowels, and speedily remove the complaint. In mild cases of this nature, it will seldom be necessary to have recourse to the above remedy, as they will easily be removed by the use of water, in which a little calcined chalk and earth's flavings have been boiled. In high states of the disease, the strength of the medicine must be increased.

The
The black scour is, however, seldom capable of being restrained by any means that have yet been had recourse to; it therefore, for the most part, terminates fatally.

Scour, White, a disease in sheep of the more violent flux kind, supposed to originate in consequence of their feeding upon putrefactive vegetable food, especially that of the shells of such turnips as have been left upon the feeding grounds. In these cases, it has been advised to give two or three large spoonfuls of the following mixture, every two or three days; the diseased sheep being separated from the rest of the flock. Take of finely powdered and sifted bay-felt, half a pound, and dissolve it in good old verjuice, one pint; to which add of good common gin half a pint; mixing the whole of them well together.

And in order to facilitate the removal of the disease, the sheep should be put upon good dry food, in an upland pasture. See Sheep.

Scouring in Cows, a disease in these animals of the flux kind, in which there are frequent liquid dejections from the intestines, proceeding from irritation, the excrements, according to Downing, being filthy, bilious, or black; sometimes they are limpid and fluid, like water cast out; at other times they are frothy, greasy, and mixed with a fat clarified coloured substance. This disorder is generally attended with a bad appetite, a weak depressed pulse, hard dry skin, dull countenance, and something of a slow fever. This disease is so obvious, that it needs no further description; for the copious evacuation of the excrements, and many other signs, make it evident to the knowledge of every person. And he supposes, that the first stage of it is a companion of the joint yellows, and may be traced out to the satisfaction of any one who will take the trouble to open any animal that dies of this disorder.

According to others it affects oxen as well as cows, and arises from want of sufficient food, both in quality and proportion; from being overheated or overworked; by feeding on wet unwholesome forage or after-grafs; by not being lodged in dry situations; sometimes from giving them too large a quantity of cut hay or straw, hotter than their natural temperature; though it is sometimes a constitutional taint, and in cows is caused by their taking cold while calving. But whatever be the cause, as soon as it begins to appear it will be necessary to hoist the head, and put it to dry food, which, in early stages of the disease, often effects a cure. But in this case Mr. Downing advises the following:

Take of mutton fuel, one pound; oil of turpentine, four ounces; boil these together in three quarts of milk till the fuel is dissolved, and give it at night milk-warm; and the next morning give the following medicine:

Take pomegranate powder, eight ounces; logwood in powder, two ounces; new pipes pounded, two ounces; Persian bark in powder, two ounces; roch alun in powder, six ounces; mix these together, to be given in two quarts of old ale or urine, and repeated every other day. The beast should fast two hours before and two after taking the medicine. He afterwards has recourse to crab verjuice, in the quantity of a pint, for several mornings. And also the following. Take calcined oyster-shells in powder, four ounces; ditto pipe-clay, one ounce; oak-bark powder, two ounces; grains of paradise, one ounce; righth alun, one ounce. Mix thep together for one dose, to be given in a quart of old beer and a pint of red wine, or in three pints of oak-dip from the tan-pits.

But others advise half a pound of grofely pulverized tormentil root, to be boiled in two quarts of water till reduced to one quart, then straining it off, and adding a quart of red wine, a quarter of a pound of finely powdered chalk or whiting, and two ounces of diafoirdium, without honey. The mixture should be preferred in a bottle, and occasionally well shaken together, making it lukewarm before it is given. The dose is half a pint, given three times in the day, at equilibrant periods. Or half a pound of pulverized common chalk may be boiled in two quarts of water, till diminished to three pints, then adding four ounces of hartborth shavings, and one ounce of cellas, strewing the whole carefully. When cold, two dracons of tincture of opium, and one pint of lime-water, may be added; the whole being kept closely stopped in a bottle, and well shaken before it is used: the dose is one or two hornful in the day.

Scouring in Calves, a disease to which they are very subject at an early period, being often cauased by improper management in putting them too soon to the teat, or letting them remain too long at it. It is also sometimes cauased by too frequently changing the milk.

But in order to effect a cure, it has been advised to revict the calf in the quantity of its food, giving a hard boiled egg, made fine by chopping, in a drench, the first thing in the morning. Chalk powdered and mixed up with flour into balls with gin has also been recommended as useful and safe in these cases, by a writer in the Annals of Agriculture.

In Elkex, some farmers have found the following remedy almost infallible. Two tea-spoonfuls of rhubarb in fine powder, and a table-spoonful of peppermint water, kneaded well together. If once giving of this does not stop the complaint, a second dose is given, with a little red port wine added to it, which molily completes the cure. In one case an apparently dying calf was restored by the use of this medicine.

Powdered chalk given in their troughs, with the barley meal for fattening them, is found to have a good effect in this intention, as well as in other ways.

And a decoction of calcined chalk, hartborth shavings, and a little coarsely pounded cellas, with a very small quantity of the tincture of opium, will mostly be found of great benefit in calves of this nature, when given to the extent of from two or three to five or fix table-spoonfuls once or twice in the course of the day.

Scouring in Lambs, &c. a disease which is common to them in many places, but especially to those which have been sent to winter on the hills from the Romney-marsh lands in the southern part of the kingdom. These also which continue in the Marip during the same season, are liable to be attacked with the complaint on the approach of spring. Sheep which are weakened in their constitutions, and have experienced a quick transition from poor, low, to rich, full keep, are the most subject to be affected. Likewise when they are first brought upon the marsh-lands in the early spring, particularly when moist warm weather succeeds to keen frosts, though it often shews itself at other times of the year, as already noticed. The writer of the Romney-marsh sheep-grazing syllable remarks, that the farmers there consider it salutary, and believe that the sheep fatten more quickly after it: but he suspects, that when it is long continued, the powers of their syllums must be greatly injured and reduced. In such cases, the disorder ought mostly to be restrained and removed by having recourse to dry food, and the use of suitable remedies. The above writer has had twenty lambs attacked with it in a feaon, and not being able to learn them to eat hay, succeeded insaving most of them, by means of giving them an astringent cordial drink, with a small portion of opium, and turning
turning them upon dry, land. This is called pasture-land. But three of the number, to which he is fed in milk had been given, all died. The rest of the sheep, with their powdered lime of an old well, all of them half crushed, is said, in some instances, to prove a chemical remedy for this complaint.

On the whole it is thought, that at the disorder evidently arises either from cold, moisture, and poor food, or from weakly sheep having put upon them such keep, the most proper and rational method of curing the affection is, in the first instance, to turn the sheep immediately into a new warm pasture, and supply them with fresh good hay, &c., and in the latter case, put them upon found straw, &c.,. In pursuit of the practice, a sheep farmer in the same neighbourhood it is said, constantly kept his wether lambs on a cord to the above Marth, and that he never had any of his flock affected with the disease; which he imputes to the allowing of them old grass upon the land. The grounds are warm, and well sheltered by trees and fences.

SCOURING, Preventive Remedies, for Horses, such as are given to work and other horses, as well as occasionally to other sorts of live-flock, for the purpose of preventing the occurrence of diseases in them. The caustic and indiffer-erent use of remedies of this nature among horses and other cattle has been the cause of much loss and mischief. Animals by no means stand to frequently in need of medicines of this sort as it has been supposed, though they may sometimes have occasion for them. The state and circum-nces of the animals, with a full knowledge of the manner in which they have been kept, and the labour or exercise which they have had, will, with due discrimination and judgment in the person who has the care of them, most probably be understood when they may be necessary and useful; and when, on the contrary, improper and hurtful.

Calomel and aloes are probably the most proper substances to be generally employed in this way, though others of the purging kinds may sometimes be joined with them to promote their operation with much advantage and effect. However, from the natural motion of the bowels of horses being slower, and the length of the intestinal canals greater, it will be found that the stimulant purgative power of the substances continues for some time after it has passed from the stomach, no effect will be produced upon them. This accounts for the failure of such remedies in many cases. Yet on the same grounds, it may naturally be supposed, that a powerful dose of such medicines may increase this action in such a manner, and propel the contents of the bowels in so forcible a degree, as to produce great pain, inflammation, or other mischief, which may either kill the animal or greatly injure it, as is frequently exemplified.

Consequently, in every case where the strength and the state of the animal are not well known, the bell method may be to begin with giving not too large doses of remedies of this nature, but increasing them afterwards where found necessary. In this way there will be every advantage secured, without the danger of injury being done. Such horses as are newly taken up into warm stables from cold exposed situations, will often stand in need of one or two gentle doses of this kind. But horses employed in team labour, or hard work of other sorts, will very seldom require such affinities. It may, however, be occasionally useful. Swellings of the legs, inflammations of the eye, coughs, and colics, arising from the sudden change of temperature, may in many cases be prevented, by rendering the stables more open and airy on the horses being first taken up into them, especially if they be cold and warm.

So young horses mostly rep. a full course of the fluids, but by the rays they are usually given. Horses ten, after a full course of fluids, and frequently are the better for it. Also such as have been feebly struck by feeding, and too much milk. There may be cases in which, in horses, we are in some doubt, but they are only less, as it is not at all necessary to have recourse to them in that general way which it is usually required.

The usual, and probably the best mode of giving such medicines, is that of giving the animal the caused ball in the evening, and the other the next day in the morning, to warm them up to a proper measure.

From one draught to two draughts, in proportion to the strength of the animal, of the fluid or ball, with half an ounce of some aromatic powder, made up with rose-water or honey, will form a proper ball for the evening dose. And from half an ounce to one ounce, according to the state of the animal, of finely powder Barbados aloes, with two draughts of powdered purg, made up in the same way, will form a suitable morning ball in this intention.

Proper mashes and feeds, with suitable work or exercise, and grooming, are to be had recourse to at the same time. The space of eight or ten days should always elapse before the doses are repeated.

SCOURINGS, among Farriers, such gentle purges as preserver horses from noxious humours.

SCOUTS, in Military Language, are generally horfemen sent out before, and on the wings of an army, at the distance of a mile or two, to discover the enemy, and give the general an account of what they observe.

SCOUZIE HEAD, in Geography, a cape of Scotland, on the E. coast of the county of Caithness; 3 miles S. of Duncaiby Head. N. lat. 58° 31'. W. long. 2° 25'.

SCOW, in Agriculture, a term used by farmers to signify the sheath of a horse.

SCOWBEGAN FALLS, in Geography, falls which boats cannot pass, in the Kennebec river, in the state of Maine, North America, near the town of Canaan.

SCRABY, or SCRAB, a small port and fair-town of the county of Cavan, Ireland, near Lough Gownah; 60 miles N.W. from Dublin, and 7 N.W. by W. from Granard.

SCRAPER, an instrument used in mezozint to engraving, formed much in the manner of a knife, except that the edge is straight till near the point, and there pinces off at a sharp angle from both sides; the lines of which form another angle of the point: but the edge on one side is much longer than that of the other.

SCRAPING in Mezozinto. See Mezozinto.

Scraping, in Naval Language, is the act of shaving off the dirty surface of the plank, in a ship's side or decks, particularly after a voyage, or when the seams have been covered with a new composition of melted pitch or resin. The instrument with which this is performed is called a feraper.

SCRATCH, in the language of the sail-workers of our country, the name of a calcareous, earthy, or flinty substance, which separates from sea-water in boiling it for salt.

This forms a thick crust in a few days on the sides and bottoms of the pans, which they are forced to be at the pans of taking oil once in a week or ten days, otherwise the pans burn away and are destroyed. (See Salt.)

This is no other than the same substance which clings over the insides of our tea-kettles, and is truly a spar, sustained more or less in all water, and separable from it by boiling.
boiling. The shells of sea-fish have great affinity in their substance and nature with this, both being powerful alkalies, and both easily calcining into lime.

The magnesia alba, so celebrated in Germany for its mild purgative and alkaline virtues, seems very nearly allied to this earth; and it is probable, according to Hoffmann, that the purging virtues of many springs are owing to the quantities they contain of this substance.

SCRATCHES, among Farriers, a dilemma incident to horses, confuting of dry scabs, chops, or rifts, that breed between the heel and the pattern joint.

There are various kinds of scratches, distinguished by various names, as crepances, rat-tails, mules, kibes, pains, &c., which are all so many species of the same malady, engendered from some hot humours falling on the legs, or from the fumes of the beast's own dung lying under his heels, or near them, or for want of rubbing his heels, especially after a journey, from over-hard riding, &c.

The disorder begins first with dry scabs in the pattern joint, in several forms. It is known by the flaring, dividing, and curling of the hair on the part. For the cure of this disorder, see Grease.

In order to prevent it, the heels should be kept fapple with carrippers' dubbing, which is made of oil and tallow: by using this precaution before exercise, and walking the heels with warm water when the horse comes in, the scratches will be prevented.

SCRATCH-PANS, in the English Salt-Works, a name given to certain leaden-pans, which are usually made about a foot and a half long, a foot broad, and three inches deep, and have a bow, or circular angle of iron, by which they may be drawn out with a hook, when the liquor in the pan is boiling. See Salt.

The use of these pans is to receive the scratch; and these pans being placed at the corners of the fall-pan, where the heat is least violent, catch it as it fuilds there.

SCRATCH-WORK, Sgraffita, a way of painting in fre'co, by preparing a black ground, on which is laid a white plaster; which white being taken off with an iron bodkin, the black appears through the holes, and serves for shadows.

This kind of work is lafting; but being very rough, it is unpleasing to the eye. It is chiefly used to embellish the fronts of palaces, and other magnificent buildings.

SCRAWLY, in Agriculture, a term provincially signifying thin and ravelled as grain.

SCREAMER, in Ornithology. See Palamaea.

SCREEN, an instrument for keeping off the wind, or the heat of the fire.

Screen is also used for a frame of laths to sift earth, sand, gravel, &c.

SCREEN, or Screen-Machine, in Agriculture, a simple contrivance, invented for the purpose of clearing grain of different kinds, of various injurious sorts of seeds, by passing it through it. It consists of a wooden frame, which has ledges on the sides, with a fort of hopper in the upper part of it, to which is attached a kind of valve, that moves to suitable distances by means of a screw, for letting proper quantities of grain pass down upon a square wire sieve, which is fixed below in the frame, and communicates with the hopper in some measure. The screen stands up in a sloping position by means of a leg, that draws out behind it, and which is commonly regulated by a cord, while the operation of screening or clearing the grain is going on. It is a very useful and convenient machine on small arable farms, but on large ones the work is now usually done by a somewhat similar contrivance in the threshing machine, while that is going on with it. See Threshing Machine.

SCREEN-FENCES, such fences as are raised for the purpose of affording shelter from winds, storms, &c. The writer of the tract on improving landed estates fuggetts, that for the purpose of shelter to pasturing flock, a tall impervious fence is nearly equal to a depth of coppice-wood, and infinitely preferable to an open grove of timber-trees; besides its additional use as a fence, or means of inclosure. And that there appears to him to be only one kind of fence which is properly adapted to this purpose, which is that of the coppice mouth hedge of Devonshire and South Wales; which consists in a high wide bank or mound of earth, planted with coppice-woods. This becomes, immediately on its erection, a shelter, and a guard to pasturage round which it is formed.

And in respect to the method of forming fences with this intention, it is that of carrying up long piles of earth, between two sod-facings, battering, or leaning somewhat inward, to the required height; and planting on the top the roots and lower items of coppice-plants, gathered in woods or on waile grounds, or with nurtry plants adapted to the given situation. If the mound be carried to a full height, as five or six feet, and about that width at the top, and this be planted with strong plants, with items cut off about two feet above the roots (in the usual practice of Devonshire), a sufficient fence is thus immediately formed against ordinary flock; but if the bank be lower, or if nurtry plants be put in, a flight guard run along the outer brink, on either side, and leaning outward over the face of the mound, is, he observes, required (especially against sheep), until the plants get up. But where a hedge of this kind is raised as a plantation-fence, (especially on the lower side of a slope,) the outer side only requires to be faced with sods; the hedge-plants being set in a rough shelving bank, on the inner side of the fence.

Further, with respect to the species of hedge-woods proper for mound fences, they depend entirely, he thinks, on the soil and situation. On mounds of bad soil, in a bleak situation, he has seen the furze alone affording much shelter, and a good fence. The fides being kept pruned, so as to throw a close firm face rising above the top of the bank, it was a secure barrier, even against the wilder breeds of Welsh sheep. The beech is commonly planted in high exposed situations; and in places more genial to the growth of wood, the hazel, the ash, and the oak are the ordinary plants of hedge mounds. The willow tribe have a quality which recommends them in situations where they will flourish; they grow freely from cuttings, or transcheous set in the ground; whereas to secure the growth of ordinary coppice-woods, rooted plants are required. The fallow (falix caprea) will grow in high and dry situations, in a manner so as to be useful in this sort of fences. And it may be further noticed in regard to this description of fences, that on thin foiled sandy surfaces, tall mounds are difficult to raise; and, there, stone walls are not only built at a small expense, but are convenient receptacles for the stores with which the wall is encumbered. But a stone wall, unless it be carried up to an inordinate height, at a great expense, is, he conceives, useless as a screen-fence, and is liable to be dangerous as such in a bleak, exposed situation; for so soon as the drifting snow has reached the top of the wall, on the windward side, it pours over it, and inevitably buries the sheep which may be seeking for shelter, on the leeward side. It is therefore conceived, that it is necessary that a stone fence should be backed with a screen-plantation, in order to render it more safe and effectual for the purpose.
It may be remarked, that these forms of fence, fences should be more attended to by the proprietors of land to all exposed situations, as they have much effect in promoting the improvement of different sorts of live stock in such exposures.

Screen-Plantations, and Planting, a term sometimes applied to bush belts, clumps, or hedges, as are planted with a view of affording shelter in exposed situations. And Mr. Marshall, in his work on "Land-Property," considers the effect of such plantations, not merely that of giving shelter to the animals lodging immediately beneath them; but likewise in breaking the uniform current of the wind; flattering the cutting blasts, and throwing them into eddies; thus tempering the air to some distance from them. And, moreover, he is of opinion, that living trees communicate a degree of actual warmth to the air which envelopes them. It is at least, he thinks, a probable truth, that where there is life there is warmth, not only in animal but in vegetable nature. The severed frosts rarely affects the sap of trees; it consequently appears to him, that trees and shrubs, properly disposed in a bleak situation, tend to improve the lands so situated in a threefold way for the purposes of agriculture: namely, by giving shelter to the flock, by breaking the currents of winds, and by communicating a degree of warmth to the air in calmer weather, or when the feeding are more mild.

Besides, it is suggested that the proper disposition of screens in this intention, is in lines across the most offensive winds, and in situations best calculated to break their force. Placed across valleys, dills, or more open plains in bleak exposures, they may, he supposes, be of singular use; and also on the hills, as well as on the points and banks of hills, and other elevated places.

And in regard to the width of such screens, they ought generally, he thinks, to be regulated by the value of the land for agricultural uses, and the advantages of the situation for the sale and delivery of timber. In ordinary cases, it is conceived that from two to four statute poles may most probably be considered as an eligible width for such purposes. With respect to the nature or species of plants which are most suitable, they must, he thinks, be adapted to the given soil and situation. Mr. Marshall thinks, that an bleak and barren situation the larch will generally be found the most profitable as timber. But being deciduous, it does not in winter afford so much shelter as the common fir. A fence, or shelter live-flock should be close at the bottom; it is otherwise injurious rather than beneficial. Not only the blast acquires additional current, but snow is liable to be blown through, and to be lodged in drifts on the leeward side, to the annoyance and danger of flocks that have repaired to it for shelter. A larch plantation margined with firs, and thefe headed at twelve or fifteen feet high, would, I suppose, afford the required shelter for a length of years. The first, thus treated, would be induced to throw out lateral boughs and feather to the ground; while the larches, in their more advanced state of growth, would, by permitting the winter's winds to pass through the upper part of the screen, break the current and mellow the blast, and in this way a complete shelter be provided; but in other more general situations, the beech, by retaining its leaves in winter, especially while it is young, forms a valuable screen. And that, if the outer margins were kept in a flate of coppice-wood, and cut alternately, and the middle ranks suffered to rise as timber-trees, the triple purpose of screen-plantations might, he imagines, be had in an eminent degree, and almost in perpetuity, with but little trouble. And in deep-foiled, vale districts, which not unfrequently want shelter, fences of oak might, he conceives, be managed in a similar way: and

lies, or other hardy evergreens, planted as bower trees, in groves of either of the above descriptions, while the side atmospheres, as were alluded to before, would, in this intention, especially where pears and other fruit trees are planted, and protecting them.

This sort of plantation, when first formed, should always be well fixed to the root of the clipping, but the point of the ends to the kind of trees and plants which are made use of for the purpose, and the space or extent of the plantation which will be necessary for effecting its object. In common, narrow strips never want the intention in any perfect manner, as the trees neither sink well, nor afford the shelter which is wanted in such cases. See Shelter.

Screen Bulkhead, in Ship-Building, the after bulkhead under the round-boat, when the ship has a walk, or balcony.

SCREW, or Screw, Cylinder, in Mechanism, one of the six mechanical powers; chiefly used in turning or in raising bodies close, through sometimes also in raising weights. See Mechanical Powers.

The screw is a right cylinder, as A B (Plate XXXVIII. Mechanism, fig. 1.) furrowed spirally wise, is generated by the equal motion of a right line F G (fig. 2.) around the surface of a cylinder, while, at the same time, the point 1 describes equably from F towards G. Of it, may be conceived to be made by cutting a piece of paper into the form of an inclined plane, or half-wedge, and then coiling it round a cylinder, so that its action depends on the same principles as that of an inclined plane. The force tending to turn the screw round its axis may be considered as applied horizontally to the base of the wedge, and the weight which is to be raised acting vertically on its inclined surface; the circumference of the cylinder will represent the horizontal length of the wedge; and the distance between the threads, measured in the direction of the axis, will be its height, provided that the threads be single; consequentially, the forces required for the equilibrium are to each other, as the height of one spire is to the circumference of the screw. But besides these forces, it is necessary that some obstacle be present, which may prevent the body, on which the screw acts, from following it in its motion round its axis; otherwise there can be no equilibrium. If the furrowed surface be convex, the screw is said to be male; it concave, it is female.

When the motion is to this axis is directed, the male and female screw are always passed; that is, whenever the screw is to be used as a simple engine, or mechanical power; and when thus fitted together, they are sometimes called a screw and a nut. The nut acts on the screw with the same mechanical power as a single point would do, since it only divides the pressure among the different parts of the spire. When joined with an axis in peritrochio, there is no occasion for a female; but in that case it becomes part of a compound engine.

The screw cannot properly be called a simple machine, because it is never used without the application of a lever, or which, to affect in turning it. Sometimes the spires of a screw are made to act on the teeth of a wheel, when a very slow motion of the wheel, or a very rapid motion of the screw, is required for the purposes of the machine.

Screw, Doctrine of. 1. If, as the compass, described by the power in one turn of the screw, is to the actual or distance between any two immediate threads, or spiral windings, as B 1 (measured according to the length of the screw), fo is the weight or resistance to the power; then the power and the resistance will be equivalent one to the other; and, consequently, the power being increased, fo as to counteract the friction of the screw, which is very considerable, will overcome the resistance. For it is evident, that in one turn of
of the screw, the weight is so much lifted up, or the resistance so much moved, or the thing to be pressed is squeezed so much closer together, as is the distance between two immediate spirals; and in the same time, the power is so much moved, as is the compass described by the said power in one turn of the screw. Wherefore the velocity of the weight (or whatever answers thereto) will be to the velocity of the power, as is the said distance between the spirals to the compass described by the power, in one revolution or turning round of the screw; so that the gaining in power is here recomputed by the los in time.

2. As the distance between two threads, B I, is less; the power required to overcome the said resistance is less; therefore the finer the thread, the easier the motion.

3. If the male screw be turned in the female, at rest, a less power will be required to overcome the resistance, as the lever or fctyala C D (fig. 3.) is the longer.

4. The distance of the power from the centre of the screw, C D, the distance of the two threads I K, and the power to be applied in D, being given, to determine the resistance it will overcome; or, the resistance being given, to find the power necessary to overcome it.

Find the periphery of a circle described by the radius C D; then to the distance between the two threads, the periphery just found, and the given power; or, to the periphery found, the distance of the two threads I K, and the given resistance; find a fourth proportional. This, in the former case, will be the resistance that will be overcome by the given power; and, in the latter, the power necessary to overcome the resistance.

E. gr. Suppose the distance between the two threads, 3, the distance of the power from the centre of the screw C D, 25, and the power 30 pounds; the periphery of the circle to be described by the power, will be found 157. Therefore, as 3 : 157 :: 30 : 1570, the weight to which the resistance is equal.

5. The resistance to be overcome by a given power being given; to determine the diameter of the screw, the distance of the two threads I K, and the length of the fctyala, or handle; the distance of the threads, and the diameter of the screw, may be asumed at pleasure, if the male be to be turned in the female by a handle. Then, as the given power is to the resistance it is to overcome, so is the distance of the threads to a fourth number, which will be the periphery to be described by the handle C D, in a turn of the screw. The femidiameter of this periphery, therefore, being sought, we have the length of the handle C D. But if the female screw be to be turned about the male, without any handle, then the periphery and femidiameter found will be very nearly thofe of the screw required.

E. gr. Suppose the weight 6000, the power 100, and the distance of the threads 2 lines; for the periphery to be passed over by the power, say 100 : 6000 :: 2 : 120; the femidiameter of which periphery being 3d of 120 = 40 lines, will be the length of the handle, if any be used; otherwise the side of the female screw must be 40 lines. Mr. Hunter has described a new method of applying the screw with advantage in particular cases. Phil. Trans. vol. lxxi. part i. p. 58, &c.

A cylindrical screw is bored, and made at the same time a tubular screw, with a little difference in the distances of the threads, so that when it is turned within a fixed nut, it rises or sinks a little more or less than the internal screw, which perforates it, would rise or sink by the action of its own threads; and a weight attached to this internal screw ascends, in each revolution, only through a space equal to the difference of the height of the two coils. Here the machine is analogous to a very thin wedge, of which the thickness is only equal to the difference of the distances of the threads, and which of course acts with a great mechanical advantage. It might, in some cafes, be more convenient to make two cylindrical screws of different kinds, at different parts of the same axis, rather than to perforate it. The friction of such machines is, however, a great impediment to their operation.

Screw, Endless. If a screw be so fitted as to turn a dented wheel D F (fig. 4.) it is called an endless, or perpetual screw, because it may be turned for ever, without coming at an end. From the scheme, it is evident enough, that while the screw turns once round, the wheel only advances the distance of one tooth.

Screw, Doctrine of the Endless. 1. If the power applied to the lever, or handle of an endless screw A B, be to the weight, in a ratio compounded of the periphery of the axis of the wheel E H, to the periphery described by the power in turning the handle, and of the revolutions of the wheel D F, to the revolutions of the screw C B, the power will be equivalent to the weight.

Hence, 1. As the motion of the wheel is exceedingly slow, a small power may raise a vast weight, by means of an endless screw; for this reason, the great use of the endless screw is, either where a great weight is to be raised through a little space; or, where a very slow gentle motion is required. On which account it is very useful in clocks and watches.

2. The number of teeth, the distance of the power from the centre of the screw A B, the radius of the axis H E, and the power, being given; to find the weight it will raise.

Multiply the distance of the power from the centre of the screw A B, into the number of teeth; the product is the space of the power passed through, in the time the weight passes through a space equal to the periphery of the axis. Find a fourth proportional to the radius of the axis, the space of the power now found, and the power. This will be the weight which the power is able to fullain. Thus, if A B = 3, the radius of the axis H E = 1; the power 100 pounds, number of teeth of the wheel D F 48; the weight will be found 14,400; whence it appears, that the endless screw exceeds all others in increasing the force of a power.

A machine for shewing the power of the screw, may be contrivd in the following manner. Let the wheel C (fig. 5.) have a screw a b on its axis, working in the teeth of the wheel D, which we may suppose to be forty-eight in number. It is plain, that for every revolution of the wheel C, and screw a b, by the winch A, the wheel D will be moved one tooth by the screw; and, therefore, in forty-eight revolutions of the winch, the wheel D will be once turned round. Then, if the circumference of a circle, described by the handle of the winch, be equal to the circumference of a groove e round the wheel D, the velocity of the handle will be forty-eight times as great as the velocity of any given point in the groove. Consequently, if a line G goes round the groove e, and has a weight of forty-eight pounds hanging to it below the pedestals E F, a power equal to one pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then, if a weight H of one pound be suspended by a line going round the groove of the wheel C, it will balance a weight of forty-eight pounds hanging by the line G; and a small addition to the weight H will cause it to descend, and so raise up the other weight. If the line G, instead of going round the groove
groove of the wheel D, goes round its axle, 1, the power of the machine will be as much increased, as the circumference of the groove exceeds the circumference of the axle; and if we suppose it to be 3½ times, then one pound at H will balance, its times 3½, or 225 pounds, being to the line on the axle, and have the power of elevating this machine at as 225 to 1, a screw, which, by its natural weight, would be able to raise 225 hundred, or 14 tons weight, by this engine. Ferguson's Math., Art. 49, p. 49.

Screw, Archimedean, or the spiral pump, or as it is called in Germany, the water furrow, is a machine for the raising of water, first invented by Archimedes.

Its structure and use will be understood by the following description of it. A B C D (Plate XIV. Hydrostatics, fig. 11.) is a wheel, which is turned round, according to the order of the letters, by the fall of water E, which need not be more than three feet. The axle G of the wheel is elevated, so as to make an angle of about 44° between 45° and 60°, with the horizon; and on the top of that axle is a wheel H, which turns such another wheel I of the same number of teeth; the axle K of this last wheel being parallel to the axle G of the two former wheels. The axle G is cut into a double-threaded screw (as in fig. 12.), exactly resembling the screw on the axis of the fly of a common jack, which must be what is called a right-handed screw, like the wood screws, if the first wheel turns in the direction A B C D; but it must be a left-handed screw, if the dream turns the wheel the contrary way; and the screw on the axle G must be cut in a contrary way to that on the axle K, because these axes turn in contrary directions. These screws must be covered close over with boards, like those of a cylindrical canister, and then they will be spiral tubes. On, they may be made of tubes of sliff leathers, and wrought round the axes in shallow-grooves cut therein, as in fig. 13. The lower end of the axe G turns constantly in the dream that turns the wheel, and the lower ends of the spiral tubes are open into the water. So that, as the wheel and axle are turned round, the water rises in the spiral tubes, and runs out at L through the holes M, N, as they come about below the axle. These holes, of which there may be any number, as four or six, are in a broad close ring on the top of the axle, into which ring the water is delivered from the upper open ends of the screw tubes, and falls into the open box N. The lower end of the axle K turns on a gudgeon, in the water in N; and the spiral tubes in that axe take up the water from N, and deliver it into another such box under the top of K; on which there may be such another wheel, 1, to turn a third axe by such a wheel upon it. And in this manner water may be raised to any given height, while there is a stream sufficient for that purpose to act on the broad float-heads of the first wheel. Ferguson's Mechanics, Supplement, p. 22.

An instrument of a similar nature is called by the Germans a water screw; it consists of a cylinder with its spiral projections detached from the external cylinder or coating, within which it revolves. This machine might not improperly be considered as a pump, but its operation is precisely similar to that of the screw of Archimedes. It is evident that some loss of power may be occasioned by the want of perfect smoothness between the screw and its cover; in general, at least one-third of the water runs back, and the machine cannot be raised to a greater elevation than 50; it is also very easily clogged by accidental impurities of the water; yet it has been found to raise more water than the screw of Archimedes, when the lower ends of both are imdered to a considerable depth; so that if the height of the surface of the water to be raised were limited to 50 feet, the water screw might be preferable to the screw of Archimedes. Plate XIV. Hydrostatics, § 44.

When a spiral pipe is made of many revolutions, arranged on a large wheel, or a single central thread of considerable diameter revolved on a wooden or tinned iron pipe, and inserted in water, it will be capable of raising water to the height of a great number of feet, above the surface of the water, the height of which is proportionate to the diameter of the pipe, and to the number of revolutions in it. It was invented about 1546, by Andrew Winter, a waterman at Zurich, and it is said to have been used with great success at Venice and in Flandes; it has also been employed in this country by Lord Stirling, and I have seen a model of it today. Dr. Young has raised water to a height of forty feet. The end of the pipe is furnished with a pipe, turning, as much water as will half fill a well, which enters the pipe a little before the piston has arrived at its highest situation, the other half remaining full of air, which communicates the pressure of the column of water to the preceding parts, and in this manner the effect of nearly all the water in the wheel is united, and becomes equivalent to that of the column of water, or water mixed with air, in the ascending pipe.

The air before the joint is compelled into a space much smaller than that which it occupied at its entrance, so that where the height is considerable, it becomes advisable to admit a larger portion of air than would naturally fill half the cold, and this lessens the quantity of water raised, but it lessens also the force required to turn the machine. The joint ought to be conical, in order that it may be tightened when it becomes looser, and the pressure ought to be removed from it as much as possible. The loss of power, supposing the machine well constructed, arises only from the friction of the water on the pipe, and the friction of the wheel on its axis; and where a large quantity of water is to be raised to a moderate height, both of these resistances may be rendered inconsiderable. But when the height is very great, the length of the spiral must be much increased, so that the weight of the pipe becomes extremely cumbersome, and causes a great friction on the axis, as well as a friction on the machinery; thus, for a height of 40 feet, Dr. Young found that the wheel required above 100 feet of a pipe which was three quarters of an inch in diameter; and more than one half of the pipe being always full of water, we have to overcome the friction of about 80 feet of such a pipe, which will require 24 times as much excess of pressure to produce a given velocity, as if there were no friction. The centripetal force of the water in the wheel would also materially increase its action, if the velocity were considerable, since it would be always possible to turn it so rapidly as to throw the whole water back into the pump. The machine which Dr. Young had erected being out of repair, he thought it more eligible to substitute for it a common forcing pump, then to attempt to make any further improvement in it, under circumstances so unfavourable. But if the wheel with its pipes were entirely made of wood, it might in many cases be better: or the pipes might be made of brass, or even of earthenware, which might be cheaper and lighter than lead. See fig. 15. The centrifugal force, which is an impediment to the operation of Winter's machine, has sometimes been employed together with the pressure of the atmosphere, as an immediate agent in raising water, by means of the rotary pump. This machine consists of a vertical pipe, caused to revolve round its axis, and connected above with a horizontal pipe, which is open at one or at both ends, the whole being furnished with proper valves to prevent the escape of the water when the machine is at rest. As soon as the revolution
tion becomes sufficiently rapid, the centrifugal force of the water in the horizontal pipe causes it to be discharged at the end, its place being supplied by means of the preasure of the atmosphere on the reservoir below, which forces the water to ascend through the vertical pipe. It has also been proposed to turn a machine of this kind by the counter-pre-

fure of another portion of water, in the manner of Parent's mill, where there is fall enough to carry it off. This machine may be so arranged, that, according to theory, little of the force applied may be lost; but it has failed of producing in practice a very advantageous effect. Young's Phil. vol. i.

See CENTRIFUGAL Machines, and Wheel.

Screw, Bed or Barrel, a powerful machine for lifting heavy bodies; and, when placed against the grip of a ship to be launched, for starting her. It consists of two large poppets, or male screws, having holes in their heads to admit levers to turn therewith, a bed formed of a large oblong piece of elm, with female screws near each end to admit the poppets, and a fole of elm plank for the heels of the pop-
pets to work on. When used for launching of ships, the surface of the fole is inclined so as to stand square to the item or grip.

Hand-screws, or jacks, double or single, are used by

to lift weighty bodies. It consists of an elm box, con-
taining coggled iron wheels, of increasing powers. The outer one, which moves the others, is put in motion by a winch or handle on the outside. They are called single or double, according to their increasing force.

SCRIBE, Scriba, σφήβρα, sopher, derived from σφέν, saphar, numerasavit, whence σφήβρα, sopher, sopher, a principal officer in the Jewish law, whose business was to write and inter-

pret scripture.

The Scribes, according to the etymological meaning of the term, were perfons employed about books, writings, numbers, or accounts; in transcribing, reading, explaining, &c.

We find no mention of Scribes, in the Old Testament, before Ezra, chap. vii. 6, whence some learned men have concluded, that the office was brought from Chaldea and Ar\nyria, and first established by the Jews after their return from the Babylonish captivity. However, Ezra's being called a Scribe, which was a general title given to men of literature, will not prove the office of ecclesiastical Scribes, as it occurs in our Saviour's time, to have been so ancient. It probably grew up by degrees, after the spirit of prophecy ceased among the Jews; for when they had no prophet to resolve their doubts about doctrine or worship, they fell into disputes, and split into sects and parties; which made an order of men necessary, whole proper business it should be to study the law, that they might explain and teach it to the people.

The Scribes were in great credit and esteem among the Jews, and had even the precedence of the priests and sacrificers.

The Scribes are referred by most authors to two general classes: vis. civil, and ecclesiastical Scribes: the former were employed about any kind of civil writings or records, and the latter were such as addicted themselves to studying, trans-

scribing, and explaining the holy scriptures. Of the civil Scribes there were various ranks and degrees, from the com-

mon scribe, or public notary or schoolmaster, to the prin-
cipal secretary of state. As for the ecclesiastical Scribes, they were the learned of the nation, who expounded the law, and taught it to the people; and they are, therefore, sometimes called χοθανατοι, doctores of the law, or μουσικοι, lawyers. Compare Matt. xxii. 35, with Mark, xii. 28.

These Scribes, who were generally Pharisees, were the preaching clergy among the Jews; and whilst the priests at tended the laicrites, they instructed the people. But though the greatest part of the Scribes took part with the Pharisees, and adhered to their opinions and tenets, as we learn from the gospels-history, yet it is probable, from several passages of the New Testament, that some of them were of the sect of the Sadducees. Some of the Scribes made it their business to explain the traditions, which they called the oral law, that is, the law delivered by word of mouth, which, as they pretended, had been conveyed from Moses down to them, from generation to generation, by the tradi-
tion of the elders. They much respected these traditions, considering them as the key of the law, and giving them the preference to the law itself. Hence this blasphemous maxim: "the words of the Scribes are more lovely than the words of the law of God." But it is evident, from the frequent reproaches pronounced by our Saviour on the Scribes and Pharisees in reference to this point, that under pretence of explaining the law by their traditions, they had actually made it of no effect. Matt. xx. 2, 3. 6. Mark, vii. 7, 8, 9. The Talmod will amply justify these reproaches.

Jof. Scaliger endeavored to establish a distinction between the Scribes of the people, referred to by Herod, Matt. ii. 4, and the Scribes of the law. The former he considers as a sort of public notaries, who were employed in secular business; the latter as preachers and expounders of the law. But the phrase, Scribes of the law, no where occurs in scripture; and the Scribes of the people, whom Herod consulted, were applied to, on account of their skill in explaining scripture prophecies. (Matt. xviii. 10.) And they were probably called Scribes of the people, because they were the flated and ordinary teachers of the people. (Mark, i. 22.) Camero observes, that a key was delivered to each Scribe, as a badge of his office, when he first entered upon it, to which our Saviour may be supposed to allude, Luke, xii. 52.

Scribe, Scriba, was also the title of an officer among the Romans, who wrote decrees or acts, and made out authentic copies of them.

Every magistrate had his scriba, or secretary; so that there were scriba adilita, pretori, quaestorii, &c.

The scriba were not admitted to the management of the principal offices of the republic, unless they relinquished their profession.

In the time of the emperors, they were also called notarii; because they made use of abbreviations, and short notes, in writing.

SCRIBING, in Joinery, &c. a term used, when one side of a piece of stuff being to be fitted to the side of another piece, which last is not regular, to make the two join close together all the way, they scriba it.

That is, they lay the piece of stuff to be scribaed close to the other piece they intend to scribae to, and open their compas to the greatest distance the two pieces any where stand from each other; then, bearing one of the legs against the side to be scribaed to, with the other point they draw a line on the stuff to be scribaed. Thus have they a line on the irregular piece parallel to the edge of the regular one; and if the stuff be wrought away exactly to the line, when the two pieces are put together they will seem a joint.

SCRIBONIUS LARGUS, in Biography, a Roman physician, who lived in the reign of Claudius, and is said to have accompanied this emperor in his campaign in Britain. He wrote
wrote a treatise "De Compositione Medicamentorum," which is very often quoted by Galen, and was "most un-
justly pillaged and transcribed" by Marcellus the
Cottonian, according to Dr. Freund. This work Scribonius
devoted to Julius Callinus, the most favour'd of all the
freemen of the emperor; and the speeches of Mellinus and
Callinus are used as examples, that these were living at
that time. After giving the formula of a dentifrice, he adds;
"Mellinus Dei noilius Callinus hoc utitur." Great faith
was, in that age, impat'd in particular formulæ, or combi-
nations of drugs, which were supposed to poss'd peculiar
powers of healing; and it was the practice of many phy-
sicians to keep their compositions secret. Scribonius,
however, published his collection, and expressed great con-
fidence in their efficacy; but many of them are trivial
and frivolous, and have been (as has been said) put to
mocking by the learned. Yet these medical works,
written in Latin, to the emperor; "Scripta mea Latam medica-
Villa," are remarkable, indeed, that two men, living about
the same time, should write their native language so different by
Celsus and Scribonius; but the latter was probably a man of inferior
education. The farcasm of Freind is, however, not far from
the truth. "Scribonius Largus, who cannot," he says,
"well be reckoned any more than a mere empiric, though
he wrote in the time of the first Claudius, when the Roman
language was in some tolerable degree of purity, ought,
as I may say, to be translated into Latin, in order to be
understood by those who are conversant only with the claffics
of that age." The treatise of Scribonius has been several
times reprinted, and ëludes among the "Medicæ Artis Princi-
piis" of Henry Stephens, 1567. See Freind's History
of Medicine, vol. i. Sprangel, Geschichte der Arznei-
kunde, ii. Theil. Le Clerc, Hist. de la Medicine, p. 3.
SCRINIA, in Geography, a river of France, which runs
to the Po, five miles N. of Tortona.

SCRITORIUM, a particular apartment in monas-
teries, where writers were employed in transcribing copies
of works intended for preservation; and to their
charge of literature has been much indebted.

SCRITTORE, in Anatomy, the name of the revenue
which the Roman people raised upon the paflure-land, of
which the property was in the commonwealth, and which
was farmed to particular persons. It was so called, because
the number of cattle, which individuals were put to into
these pastures, was registered; and it was by that number
the yearly sums which they engaged to pay were regulated.

SCRITTORE, or SCRIPTORIUS. See Bib.

The collection of plants, says the learned and justly
VOL. XXXII.
many ancient authors, which he illustrated by comments of his own: among these works were those of Vegetius, Frontinus, Hyginus, Apuleius, Martial, and Seneca the tragedian. Serrierius wrote a work in the Dutch language on the "History of Printing," in which he maintained the claim of Laurence Cotter to the invention of that invaluable art. He published a collection of Batavian antiquities, and other pieces relative to the early history of the united provinces. Serrierius, at the age of 74, lost the use of his eyes, but he continued to fabricate himself with literature till his death in 1660. His funeral was attended by the university of Leyden in a body, and an eulogy was pronounced over him by Frederic Gronovius. A collection of philological and poetical pieces from his MSS. was published at Utrecht in 1737. Moreri.

SCROBICULUS Cordis, in Anatomy, the small depression in the middle of the upper part of the abdomen, just above the esophagus. In common language it is called the pit of the stomach.

SCROBILUM, in Ancient Geography, a promontory of the Arabian gulf, which separated the Heroopolitic and Olantitic gulfs.

SCROFA, in Zoology. See Sus.

SCROFA, in Ichthyology. See Scorpéna.

SCROFA, in Entomology. See Scarabaeus.

SCROFANELLO, in Ichthyology, a name by which some have called a small fish of the Mediterranean, more usually known by the name of the Scorpéna.

SCROFULA, or Scrophula, from σκροφύς, swine, called also burma, or the king's evil, in Surgery. The name of scrofula was derived from an opinion that swine were particularly subject to this disease. The scrofulous constitution is observed to be, in many instances, denoted by particular symptoms. The complexion is often fair, and the colour of the hair either reddish, or of some other light tint; people with dark complexions and black hair being much less subject to scrofulous complaints. The skin is remarkably soft and white, and the face often has a shining polished smoothness. The cheeks are in general florid; and the tunica albuginea is frequently of a dead white colour, and more pale than usual. The edges of the eye-lids are sometimes affected with a degree of tenderness which easily degenerates into a troublesome inflammation, that diffuses the patient by its continuance, and produces a disagreeable degree of deformity. There is likewise frequently a swelling of the upper lip, with some thickening of the nostrils and point of the nose. Ruffell on Scrofula, p. 8.

One of the most frequent symptoms of scrofula is a swelling in the superficial lymphatic glands, especially in those of the neck. Such glands swell without any previous complaint, and often attain a large size before the swelling attracts notice. The swellings are frequently unaccompanied with pain or discoloration; a circumstance which favours the conclusion that the inflammation attendant on scrofulous diseace is flow, and the complaint of an indolent nature.

The frequency and great number of such tumours of the lymphatic glands have led many surgeons to suppose scrofula to be altogether a disease of the lymphatic system. Mr. Ruffell, however, entertains doubts respecting the accuracy of the doctrine; for he observes that many other parts of the body, which are not very glandular, are often the primitive seat of scrofula. It very frequently attacks the joints of the extremities, the bones, and the mucous membranes, without any previous or concomitant affection of the lymphatic system. Besides, it is to be recollected that the abscess formed by the lymphatic trouble is not only liable to idiopathic attacks of scrofula, in common with the rest of the body, but is likewise exposed to suffer, symptomatically, in consequence of the disposition of the glands to swell and inflame from any cause of irritation propagated along the course of the ab- sorbents; and from this source of error the commencement of scrofula in the lymphatic system may be supposed more frequent than what the natural proportion of idiopathic cases warrant.

Scrofulous swellings of the glands are often stationary, or at least very slow in their progress of increase or diminution. The same indolence and absence of inflammatory symptoms, which characterize scrofulous swellings of the lymphatic glands, likewise distinguish similar affections in other parts of the body. The commencement of the attack is, in general, unperceived, and the progress slow; though the tumescence which follows is frequently very considerable.

The greater number of scrofulous affections are accompanied with a preternatural dwelling of the parts attacked. The tumour is of two kinds, one remarkable for its softness, the other of a more firm consistence. Soft scrofulous tumours are always formed by the effusion of a fluid, and it may be remarked that they are somewhat variable in their size, being one day more prominent and tense, the next more flaccid and flabby. When they are opened in the early state, they are found to contain nothing but a fereous fluid, which lies in the cells of the cellular membrane. As the fluid is not contained in one common cavity, the tumour has a soft flabby feel, and imparts to the fingers of a surgical examine no distinct sensation, either of elasticity or fluctuation. But when the fluid has been for some time effused, a striking difference occurs, a fluid lodged in a particular cavity now being evidently perceptible. This change seems to proceed from the destruction of the partitions which are between the cells of the cellular substance. As these collections, however, are not accompanied with any sensible degree of inflammation, they are not surrounded with a firm, solid, circumcised bafe; and they do not betray any great tendency to ulcerate the skin, and burst of their own accord. Hence they sometimes become very prominent, and the skin is gradually distended to a surprising degree.

The matter contained in such tumours also undergoes a change. After a time, the more solid parts are deposited in the form of little maffes, resembling congealed milk. The remaining portion of the fluid is rendered thinner, and resembles whey. A quantity of scrofulous matter is also formed on the internal surface of the cavity, which seems to be attacked with a flow kind of inflammation. The admixture of this purulent matter greatly changes the appearance of the contents of the tumour, and they now bear more resemblance to those of a common abscess. They never acquire, however, exactly the properties of healthy purulent matter, being always thinner, more transparent, and more of a greenish colour.

Although the tendency to ulceration is not considerable, the skin at length gives way, and allows the matter to escape through a narrow opening. After the contents are evacuated, the tumour subsides; but there being in general little dispostion in the parts to heal, a scrofulous fere is usuallly formed, which discharges unhealthy matter, and continues open for an indefinite length of time.

The other more firm kind of scrofulous swelling always increafes slowly, and most commonly attacks the neighbour- hood of joints. The affected part enlarges, without acquiring any circumcised determinate form. By degrees, the tumour becomes softer, and at last particular portions near the surface become more prominent, inflame, suppurate, burst, and discharge matter. But as the suppuration is only partial, and the discharge incomconsiderable, they have little effect.
SCROFULA.

The constitution is always a period of life, during which the skin is subject to be affected with the disease, and the other organs the site of its extension. The only exception is the addition of little ulcers, which tend to form, and must matter.

A common ulcer in persons of all ages is the leprosy, often exhibits appearance, which betrays the diseased state of the system. The matter is secreted in a form of extraordinary quantity; the ulcers are in the form of little papillae, the surface being tinged, and the colour of the tumour more blue, than is observable in a case of healthy abscesses. Scrofulous abscesses are also more common, but not so numerous, a larger quantity of pus is produced, in relation to their size, than is the case with abscesses. When abscesses in scrofulous patients burst, an empty cavity is left; but there is a mass of cellular ulceration apparently dispersed of late. It refills wet cotton, and often separates in the form of a thick mafs. The separation is effected without pain. This state of the cellular membrane bears some remote analogy to the destruction of the central parts in a carbuncle; but it differs from the latter disease by there being no malignity, pain, nor danger.

The bowels of scrofulous people partake of the general disease in the constitution; they seem to contain a smaller proportion of the phlegm of lime, and a larger one of gelatinous matter, than what exists in the composition of a healthy bowels. They are also exceedingly susceptible of morbid action. The particular changes, however, induced in the bowels by scrofula, will be noticed in the articles Spina, Cervixe of, and White Swelling.

With regard to scrofulous ulcers, their margin is commonly of a pale red or purplish call, with a thinning surface; the edges in general thin; and the surface of the forelunk some what below the level of the surrounding parts. These edges are mostly attended with a smaller degree of inflammation, and little pain; they are not very sensible, and have no great disposition to spread. The matter discharged from them is white, having very little colour, and often an offensive smell. In consequence of its viscosity, it adheres to the surface of the fore, and covers the granulations. It is to be observed, however, that scrofulous ulcers sometimes assume a more malignant aspect, having elevated indurated edges, and fungous central granulations, accompanied with pain and an ichorous discharge. In these cases, they may counterfeit the appearance of cancerous ulcers; but though the resemblance may be very imposing, we are in general able to ascertain the real nature of the case, by tracing its history from the commencement, and by inspecting the rest of the patient's body with accuracy; when the vesicles of former scrofulous ulcers, or other proofs of a scrofulous constitution, often manifested themselves.

Scrofulous ulcers often continue to discharge for a long while, with very little change of appearance. In time, however, they begin to heal, and, for the most part, dry up altogether at last, leaving a very ugly red irregular cicatrix, upon which the skin fieldens recovers its natural look.

In general, scrofulous complaints are most troublesome in the spring, and get better towards the end of the summer.

Rusell on Serofula.

Serofula has always been considered as an hereditary disease. Many well informed men have thought the application of the term, hereditary, to scrofula, and indeed to diseases in general, exceedingly wrong, because the affections in question do not regularly descend from parents to children, and sometimes attack persons, none of whose relations are known to have had such diseases. That there is truth in these arguments must not be disputed. But it is at the same time certain, that the children of scrofulous parents are much more likely to be affected with scrofula, than those of persons who have never had any by reason of this disease. The children of scrofulous persons, however, remain diseased for a long time, from every mark of the disease. This fact must at all occasions be attended with the term hereditary; for the whole of the constitutional scrofulous parents more frequently have infected children, than is the ease with perfectly healthy persons. The scrofulous of the former, however, are not cases of the disease in the manner; nor are the children of the latter case of not being so.

Serofula is undoubtedly a contagious disease, nor can it be communicated by contact, or any conversation. Russell tried to transfer scrofula from one parent to another by inoculation; but although he took great pains to infect the matter completely, and repeated the experiment frequently, yet all the attempts failed, as no disease was communicated to the person inoculated, nor ever any evident irritation excited at the place where the matter was infected. De Vitis Scrofulatis, p. 218.

The proximate cause of scrofula is a defect, concerning which many conjectures have been started; but none that appear to carry with them much probability. It is indeed a question, that is at present not at all understood.

Of all occasional causes, says Mr. Russell, climate is the most powerful. The extremes of heat and cold are equally free from scrofula. It prevails most in those climates, where the atmosphere is perpetually loaded with cold vapours; where the feaons are variable, and no weather steady. From latitude 45° or 50°, to latitude 60°, is the principal climate of scrofula. The climate of Scotland, which is within this range, is remarkable for the frequent occurrence of scrofulous complaints. When the temperature of the air is just above the freezing point, the cold is the most difficult to bear, on account of the great quantity of watery vapours which float in the atmosphere. A greater degree of cold condenses the aqueous vapours, and renders the air clear; a greater degree of heat disperses them. Accordingly, it is an universal observation, both in the torrid and the frigid zone, that perfectly dry air, whether produced by great heat, or great cold, always brings the most healthy weather. Mr. Dobson, in his account of the harmattan wind, which blows on the coast of Africa, and is so warm and dry as to accomplish the crystallization of pure alkali, observes, that all endemic diseases get well during the blowing of this wind. Mr. Graham, likewise, who was long governor of the Hudson's Bay factory, situated on the east coast of America, about the 60th degree of north latitude, makes nearly a similar observation with respect to intense cold; as he invariably found, that the raw, cold, damp weather, when the mercury in Fahrenheit's thermometer stands between 30 and 40 degrees, was the most intolerable to bear, and the most unfriendly to health. Now this continues Mr. Russell is very nearly the winter weather of Scotland. Upon the whole, therefore, we may lay it down as a general maxim, that the greater degree of cold, which can be conjoined with moisture, is the state of weather which tends most to favour the appearance of scrofula.

The long continuance of inclement weather increases the predisposition to scrofula; and in persons already sufficiently predisposed to the disease, any uncommon, though temporary exposure to cold and wet, is often an exciting cause of an immediate attack.

Every thing which weakens the constitution, predisposes to scrofula. Thus, breathing impure air, and living upon a scanty allowance of wholesome and edible food, promote the secess of scrofula. The same may be said of
un cleanliness; neglect of salutary exercise; confinement in cold damp situations; and the want of sufficiently warm clothing.

But one of the most frequent occasional causes of scrofula is external violence. Many accidents, which would not be followed by any serious consequence to a person in health, produce severe scrofulous affections in persons predisposed to such diseases.

It is almost unnecessary to mention, that all those circumstances which have been specified as occasional causes, must be avoided.

There is no medicine which, internally administered, has the power of completely correcting the peculiarity of constitution implied by the expression scrofulous habit. But there are many medicines which seem to improve this state of the system, and to promote the spontaneous amendments, which scrofulous affections frequently undergo. Scrofulous patients, for the most part, have constitutions in which the natural actions do not proceed with vigour, and perhaps it is on this account, that every thing tonic is more or less useful in cases of scrofulous disease. This observation is not meant, however, to forbid the judicious employment of evacuations, which, when the habit is disposed to phlegm and colliquions, are indispensible necessary.

The medicines which are given for the cure, or prevention of scrofula, are either such as are supposed to act upon some general principle, or such as are supposed to poisons a specific virtue in the cure of this disfiguring disease.

A draught of salt-water is recommended almost indifferently to every patient who is advised to use sea-bathing. It acts as a purgative, and proves a serviceable medicine, so far as purging is indicated. The water of the sea, however, is not nearly so palatable, as the solutions of many of the neutral salts, and its medicinal virtues do not appear to be superior. Hence Mr. Ruffell believes, that it is preferred rather from accidental convenience, than from its being in reality a better medicine than several others.

In some cases of hereditary predisposition, scrofula seems engraven on a constitution, otherwise healthy and vigorous, where the patient feels no weakness, has no disorder of the stomach, and at the same time has tendency to fulness and corpulency. In cases of this kind, a continued course of purgative medicines often proves highly beneficial by procuring a frequent and copious evacuation of the bowels, and thereby reducing that disposition to fulness, which very much promotes the formation of glandular swellings. But, in general, scrofula is not combined with the foregoing signs of constitution, and purgatives are then only useful for the purpose of obtaining colliquions.

Several mineral springs, besides saline ingredients, contain sulphureous impregnations, which are supposed to increase the medicinal virtues of the waters. The reputation of the waters of Harrowgate and Moffat is universally known. Mr. Ruffell acknowledges that their efficacy may have been over-rated; but he still thinks favourably of their effects in cases of scrofula.

Calomel, or, as it is now called, the hydrargyri submurius, is the most celebrated of all the purgative medicines, which have ever been employed in the treatment of scrofula. In order to derive the greatest benefit from it, however, it should not be given in so large a quantity as to produce the specific effect of mercury in their full extent; for, as Mr. Ruffell observes, a deep and lasting impression on the system aggravates every symptom of scrofula. Calomel, taken in moderation, contributes more than any other medicine to diffuse tumours, and resolve scrofulous indentations. An alternative course with this medicine, however, must be main-
Scrofula.

eay in changing the condition and forwarding the cure of certain malignant xerulous ulcers, which counteract the appearance of cancer. He has likewise found it of service in promoting the cure of certain xerulous affections of the tongue, which bear a near resemblance to some rare venereal ulcers. In a few cases, Mr. Ruffell has had reason to attribute to certain forms of its efficacy in promoting the resolution of xerulous swellings of the breast. The medicine will be given in as large doses as the constitution can bear. The head being affected with a degree of glandular, and the ulcer with a little nausea, is the criterion of the dose being sufficiently powerful.

The muriated barites has been recommended by Dr. Crawford; but though it has been frequently exhibited, its reputation is far from being increased; a true proof that its virtues were originally exaggerated.

The muriated lime is another remedy that has been of late much talked of, for its good effects as a specific in cases of xerulous. In order to derive the utmost benefit from it, Mr. Ruffell is of opinion that it is necessary to prescribe it in much larger doses than those which have usually been directed. One of the most successful instances of its efficacy was the case of an ounce of the tincture of muriate having been taken, for many weeks, three times a day. It even deferves attention, however, that professor Thomson employed muriated lime in various cases of xerulous, without a single instance of its having any efficacy. He admits that some patients got well, while under a course of muriated lime; but then he had no reason to ascribe the cure to the effect of the medicine. In other cases, on the contrary, he found that the muriated lime produced feverish feelings and oppression of the stomach, and that the patients got daily worse till the medicine was left off, and other remedies employed. The relief, experienced from the disappearance of the muriated lime, left no doubt with regard to the injurious effects which the use of it had produced, and from extensive experience and accurate observation, professor Thomson is satisfied that, in many cases of xerulous, the muriated lime is attended with prejudicial effects.

With respect to the local treatment, stimulant applications are found not to be in general advantageous for xerulous complaints. For ulcers, the most simple and mild dressings are the best. When the patients are using a course of feebathing, it is usual to wash the foetra with sea-water frequently every day. Cold spring water is likewise a favourite application; and experience seems to prove that the application of cold is well suited to counteract the state of inflammation which accompanies xerulous foetra. Preparations of lead are, upon the whole, very convenient and useful applications, provided the solutions be used in a state of sufficient dilution to prevent irritation. Liquid applications are made by means of wet linen, which is renewed whenever it dries, so that the surface of the fore is kept constantly moist.

Upon the same principle, simple ointment and Goulard's cress are, in ordinary cases, the best dressings. The employment of simple applications and of cold, however, is more properly adapted to the mild and pure forms of xerulous foetra; for when these are more malignant, or combined with any other disease, a different mode of dressing becomes necessary. Vesicular foetra, for instance, breaking out in a person of a xerulous constitution, partake of the nature of both disorders, and require correlative treatment. Even a pure xerulous fore, attended with more inactivity than usual, may demand particular sorts of dressings, different from such as are found to be most proper for common cases. When the ulcer is extremely indolent, gentle stimulants may be necessary; and when there are fungous granulations, they must be destroyed by heat.

Those xerulous foetra which contain a muriatic acid, when they are superficial, and not connected with any parts of importance, are in general better left unreated. They are very slow in their progress, but they usually burst at last by a superficial ulceration, which forms a small aperture. They do not often advance to resolution. The most likely applications for promoting this desirable object, are solutions of the acetate of lead, and of the muriate of ammonia.

The progress of the cure, after the tumour has discharged its contents, is very various; though, upon the whole, it is slow, and the cure often incomplete. The sides of the cavity seldom adhere uniformly, or granulate from their whole surface; so that little partial separation can happen, which form sinuses, and continue to discharge matter, accompanied with some degree of pain and inflammation. At last, however, often indeed after a considerable time, the discharging ceases altogether, and the sore completely heals. When the sinuses continue for a long time, without any tendency to get well, it is sometimes proper to open them to the bottom with proper incisions; but in the generality of xerulous foetra, such practice is, upon the whole, severe, disadvantageous, and even dangerous.

Xerulous abscesses, when not large, need not to be opened; but deep-seated collections of matter, which increase gradually in size, without showing any disposition to make their way to the surface of the body, ought to be opened: for if this be not done, the matter spreads, and the disease acquires by degrees a dangerous extension. The opening should not be larger than what is sufficient for the complete evacuation of the matter; because a large opening excites great irritation, and is often the cause of violent inflammation of the whole cyst of the abscess, attended with alarming, and often with fatal, consequences. The fever that occurs is accompanied with a rapid train of symptoms, which speedily end in death. In other instances, the fever is hectic, being more slow in its progress, though not less certainly fatal. According to Mr. Ruffell, sulphuric acid and saline draughts, in a state of effervescence, are the medicines which agree best with both forms of fever; and he observes, that neither of them seems to be much relieved by the use of cinchona. (P. 116.)

This author recommends opening the tumour with a trocar, letting out the whole of the contents, withdrawing the cannula, and bringing the sides of the puncture together with sticking plaster. For our own part, we prefer making the opening with a lancet, and then closing the wound with adhesive plaster, as advised by Mr. Abernethy in cases of psoas abscesses. See Psoas Abscess.

With respect to the treatment of swellings of glands, it is to be remarked, that it is always desirable to prevent suppuration. When the glands are superficial, their progress may be influenced by topical applications; but when they are deep, they are scarcely capable of being affected by such remedies. In ordinary cases, Mr. Ruffell recommends the use of fomentations two or three times a day. Sea-water, vinegar, and water, dilute solutions of the acetate, or muriate of ammonia, and a decoction of chamomile, are eligible for fomentations. Friction with camphorated and ammoniated oiled, and with marine plants, has also been well spoken of.

In such cases, Mr. Ruffell, however, does not place much confidence in external applications, as he considers that the cure chiefly depends upon the state of the constitution, upon regimen, and the effect of internal remedies.

When
When enlarged glands, which lie superficially, are attacked with inflammation, and in danger of suppurring, Mr. Raffell strongly recommends the frequent use of topical bleeding. This author is also an advocate for blisters, both at the commencement of the inflammation, and on its decline.

When the swelled glands suppurate, and healthy inflammation predominates, the case must be treated nearly in the same way as a common abscess. An artificial opening is hardly ever necessary, as the abscess in a short time bursts of itself. The only instance, in which the forgeon is called upon to open the swelling, is when the matter heaves a tendency to spread over a large space. When the suppuration is completely ferulous, a small opening is at length spontaneously formed, through which all the matter is discharged. The aperture, though always small at first, sometimes becomes larger, and frequently it remains for a long while nearly in the same state, shewing little disposition to heal, acquiring a glossy appearance, and becoming thick and callous at its edges. In the end, however, a cicatrix is mostly produced.

In cases of indolent, stationary, ferulous swellings of glands, where there is no hope of resolution, it has been proposed to remove or destroy the diseased glands by excision, or by the application of cautic. Such practice has been particularly suggested for glandular swellings of the neck. The superficial situation of the glands of this part of the body rendering them very apt to be affected by cold, the vicissitudes of the weather, and other external circumstances, they must be subject to temporary impressions. The frequency with which they swell, and the facility and suddenness with which they sometimes subside, afford strong arguments against an operation in recent cases. In other examples, where the affection has existed long, it often happens that other more deeply seated glands are also diseased, so that the removal of an enlarged superficial cervical gland would prove a very partial and uselefs operation, and would do nothing towards the total extirpation of the disease.

As for the mere removal of deformity, this is not an adequate reason for the operation, which would itself be followed by a fear, that must disfigure the part quite as much as the swelled gland could possibly do. We will say nothing of the danger and difficulty with which, in many cases, such an operation would be attended.

The attempt to destroy a ferulous gland in the neck with cautic was liable to objections, fully as strong as those which are applicable to the use of the knife. The action of cautic can never be regulated with much precision, and the cicatrix, produced in this manner, is always a considerable deformity.

Firm ferulous tumours in the more external parts of the body do not usually require local bleeding, unless attended with symptoms of inflammation. It is chiefly in the early stage of such cases that the practice is advantageous. In general, warm fomentation, stimulants, iufues, and blisters repeated, or kept open with the faine ointment, are the most eligible remedies. Here also the employment of friction as a diffusent deserts particular recommendation. Its safety, simplicity, and efficacy, are now well acknowledged. There is no substance interposed between the surface of the swelling, and the hand of the person who is employed in rubbing it, except a little flour to prevent the skin from being chafed. The friction is to be applied two or three hours a day, and the plan continued for some months.

Permanent comprefion—by means of tight bandages, or long strips of adhesive plaster, is another means of reducing the indolent ferulous induration and thickening of parts. But of this practice, and of dry rubbing, or friction, by the hand, we shall have occasion to speak in a future volume. See White Swelling.

When a ferulous disease is circumscripted and incurable, and attended with too much pain and irritation, as to injure the health in a serious and dangerous degree, the removal of the part by an operation becomes indispensible. The symptomatic enlargement of the lymphatic glands, which are nearer than the diseased to the heart, presents no fold objection to such practice; for this enlargement proceeds from irritation, and not from absorption; and the glands often subside, as soon as the original cause of their swelling is removed. Raffell, in Scurfalia, p. 157.

SCROGS, in Rural Economy, a term provincially applied to such flung thrubs as have been horned upon by cattle, as hazel, &c. They are mostly met with on commons and waste lands.

SCROLL, in Heraldry, is the ornament placed under the escutcheon, containing a motto or short sentence, alluding sometimes to the bearings, or the bearer's name; sometimes expressing somewhat divine or heroic; sometimes enigmatical, &c. It is often placed by the French and Scotch above the achievement; which, according to Sir J. Mackenzie, is right, when the motto relates to the crest; otherwise it should be annexed to the escutcheon. Those of the order of knighthood are generally placed round shields. See Escroll.

SCROLL, in Ship-Building, is a spiral moulding of the volute kind, used sometimes at the drifts, and the upper part of the hair-bracket. A ferrol-head signifies that there is no carved or ornamental figure at the head, but that the termination is formed and fulfilled off by a volute, or ferol turning outwards. If the feroll is turned off, or inwards, it is then called a fiddle-head.

SCROON, in Geography. See Scaron.

SCROPHULARIA, in Botany, an old name, supposed by some to have been given to the herbs of this genus, because fivene, ferofe, were fond of them. But the most probable derivation is from scrophula, the kng's evil, for which disease some of them have been recommended as a cure; especially S. nodofs, whose knobby roots, compared to scrophulous tumours, are thought to have given rise to that opinion. Yet there can be no doubt that one of this genus is the real pater of Dioscorides, as Fuchius, and some other old botanists, have maintained, which that original Greek writer on the materia medica celebrates for its virtues in the above-mentioned complaints, and even in cancerous ulcers. Yet his identical species, our S. peregina, has no knobby roots. It is probable therefore that the above explanation is of more modern date, and it may account for the etymology of Scrophularia, if not for the application of the herb to medical use. The Galeops of Fuchius is indeed S. nodofs; Anguillara being, as far as we can find, the first writer on drugs who fixed upon the precise plant of Dioscorides, S. peregina, and whose opinion is confirmed by the recent enquiries of Dr. Sibthorp.—Linn. Gen. 312. Schreb. 408. Willd. Sp. Pl. v. 3. 269. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 662. Prodr. Fl. Graec. Sibth. v. 1. 435. Ait. Hort. Kew. v. 4. 22. Pursh v. 2. 419. Jull. 119. Tourn. v. 1. Gen. Ch. Cal. Perianth of one leaf, inferior, with five round segments shorter than the corolla. Gar. of one petal, unequal, reverted; tube globose, large, inflated: limb very small, five-cleft; its two lower segments (turned uppermost)
SCROPHULARIA.

1. S. maritima. 3. Maryland Fig-wort. Linn. Sp. Pl. 863. Willd. n. 1. Art. n. 1. Bot. t. 1544. (S. nodosa; common; Michaux Boreh.—L. 21.1.)—Leaves heart-shaped, doubly serrated, acute; smooth; decurrent at the base. Stem with blunt angles. Footstalks connected by a hairy line.—In low grounds, from Pennsylvana to Carolina, flowering from June to August, perennial. 

3. S. aquatica Water Fig-wort, or Water Betony. Linn. Sp. Pl. 864. Willd. n. 3. Fl. Brit. n. 2. Engl. Bot. t. 854. Curt. Lond. f. 5. 44. Fl. Dan. t. 507. (Betoiana aquatica; Ger. Em. 715.)—Leaves heart-shaped, flaked, decurrent, obtuse. Stem winged. Native of watery places, about the banks of lakes and rivers, from England to Greece; very rare in Scotland, and the northern parts of Europe; flowering in July. This is fibrous, and, as we believe, perennial, though Linnaeus favi biennial. Whole plant larger than the leaf, and distinguished by the membranous edges of its stem, as well as blunt leaves.

4. S. serotina. 

6. S. betonica. Betony-leaved Fig-wort. Linn. Mant. 87. Willd. n. 8. Art. n. 7. (S. betonica Linn. Tourn. Infr. 166. S. aquatica moutana mollior; Barbel. l. t. 274.)—Leaves heart-shaped, obtuse, somewhat dentate, or nearly so, serrate; decurrent at the base. 

This species is peculiarly adapted to the climate and situation of the mountains of Carolina. We have a specimen, found by the late Dr. Brandegee at Panger, flowering in June, which answers exactly to Scopoli's description, and seems not referable to any of the species in Linnaeus.
SCROPHULARIA.

Linnaeus or Willdenow. In this the leaves are about an inch long, on broad, flat, smooth footstalks, a quarter of that length, along which the two lateral ribs are continued, by the side of the midrib; the margin of the leaf is nearly, regularly, and acutely serrate. Clusters erect, long, quite naked, except the lanceolate bracteas; its side branches forked, rough, with glandular hairs. Segments of the calyx ovate, obtuse, smooth, bordered with a broad white membrane, within which the margin is of a brown or rusty hue, as Scopoli describes it. He says the corolla is yellow.

8. S. glabrata. Spear-leaved Fig-wort. Ait. n. 6. Willd. n. 7, excluding Vahl's synonym, Jacc. Hort. Schoenbr. v. 2. 44, t. 209.—Leaves oblong-heart-shaped, acute, doubly serrate, smooth. Clusters long, naked, compound. Bracteas lanceolate.—Found in the Canary islands, by Mr. Maiton, who sent it to Kew in 1779. This is a biennial greenhouse plant, flowering in April and May. The stem is rather woody, square, branched, smooth like every other part of the plant. Leaves often unequal at the base, about two inches long, on footstalks half that length. Clusters long and many-flowered, with spreading three-forked branches; no leaves, except at the very bottom, but many lanceolate acute bracteas. Flowers of a deep blood-red.

9. S. pergerrina. Nettle-leaved Fig-wort. Linn. Sp. Pl. 866. Willd. n. 26. Ait. n. 18. Camer. Hort. 157, t. 43. Sm. Fl. Græc. Sibth. t. 597, unpublished. (S. folio urticea; Bauh. Pin. 236. S. cretica altera; Cluf. Hift. v. 2. 210.)—Leaves heart-shaped, acute, finely serrate, smooth and shining. Stalks axillary, two or three-flowered. Bracteas lanceolate. Calyx acute.—Native of Italy and Crete. Very common about hedges, paths, and courts throughout Greece, as Dioscorides describes his xerophylis; to be. We cannot but accede to the opinion of Anguillara, Fuchsius, and Sibthorp, that this, and not our Calopogon, was his plant. The root is fibrous, annual, or biennial. Stem two or three feet high, not much branched, occasionally with five or six angles. Leaves of a dark shining green, an inch or more in length; we cannot agree with Willdenow that the upper ones are generally entire, though such an accident may occur; as the upper part of the stem, now and then, in gardens, becomes elongated, and the foliage in that part diminished in size; but this is rarely the case. The natural state of the plant is to have axillary flower-stalks from near the bottom of the stem to the top, each bearing two, three, rarely more flowers, whose tube, as well as the limb, is of a blood colour, and the segments of the calyx are ovato-lanceolate, with sharp points, and no membranous edges. The flowers stalks, like the leaves which they accompany, are more or less distinctly alternate, rarely opposite. We have taken the liberty to remove this species from the end of the genus, to place it near those to which, both on account of its simple leaves and general habit, it is most closely allied. In doing this we shall here notice three others, which conclude the genus in Willdenow. Two of these, at least, require to be totally expunged, and the third, if it has any right to remain, must stand next to pergerrina.

S. chinchina, Linn. Mant. 250, confines of an imperfect specimen of which seems to be an Ocymum, accompanied by a still more imperfect branch of what may be a Celosia, or Verbeuwm; but neither of them has any thing to do with Scrophularia, nor was Linnaeus, when he originally described these specimens, at all satisfied about them.

S. meridionala, Linn. Suppl. 280, sent by Mutis, is indubitably the same genus, and very nearly the same species, as Hemimeris argyrostegia Willd. Sp. Pl. v. 3. 282, Alpinia aconitifolia. Ait. Hort. Kew. v. 4. 27. The calyx only leaves a little more elongated, and the leaves less deeply cut, than in our garden plant; see Hemimeris. The shape of the capsule is indeed important in distinguishing the species of this genus. We are at a loss to distinguish for us hemimeris. 10. S. cocinea. Scarlet Fig-wort. Linn. Sp. Pl. 866. Willd. n. 25.—Leaves ovate, four in a whorl. Flowers white, fringed.—Native of Vera Cruz. Houhoum sent an account of this plant to Miller, by the name of S. flava cocinea, folia urticae quaternis caulim ambienibns. Hence probably this description reached Linnaeus, and it was all he ever knew of the plant, for he had no specimens. We should not be surprised if it proved another Hemimeris, which Houhoum might very justly enough take for a Scrophularia. We now return to what we term the species.

11. S. orientalis. Hemp-leaved Fig-wort. Linn. Sp. Pl. 864. Willd. n. 9. Ait. n. 8. "Schkuhr Handb. v. 2. 196. t. 173." (S. orientalis, folis cannabinis; Tourn. Cor. 9.)—Leaves lanceolate, sharply serrate, opposite or whorled; auricled at the base. Calyx leaflets, with whorled, cordiform, ovate, villosid branches. Flowers drooping. Calyx smooth, obtuse.—Native of the Levant; sometimes seen in botanic gardens. The root is perennial. Stem with four, or more, acute angles, leafy. Leaves often three or four in a whorl, widely spreading, flaked, four or five inches long and one broad, smooth, copiously deeply, and rather unequally, serrate; either sharply lobed, or furnished with a pair of lanceolate serrated small leaflets, at the base. Clouter terminal, long, erect, its branches either opposite, or more usually three or four in a whorl, forked, many-flowered, rough with glandular hairs, and furnished with linear bracteas, but no leaves. Flowers greenish.

12. S. lanceolata. Lanceolate American Fig-wort. Pursh n. 2.—Leaves lanceolate, pointed, unequally serrate; acute at the base. Footstalks without appendages. Branches of the panicle cordiform.—In wet meadows and woods of Pennsylvania, flowering in August and September. Perennial. Flowers greenish-yellow. Pursh. This seems nearly related to the last, to which the author has not adverted. We have seen no specimen.

13. S. altilis. White-flowered Fig-wort. Murr. in Comm. Gott. v. 4. 25. t. 2. Willd. n. 13. Ait. n. 10.—Leaves heart-shaped, nearly smooth, doubly toothed, some what lobed, the lower teeth turned towards the base. Clutter terminal, compound. Bracteas lanceolate. Calyx acute.—Native of the Altai mountains of Siberia. Introduced into our gardens by Mr. Hurnemann in 1786, where it proves a hardy perennial, flowering in May and June. The stem is furrowed, one or one and a half foot high, obliquely angular, scarcely branched. Leaves on long stalks, of a broad roundish-heart-shaped figure, with strong branching ribs, plant, nearly smooth, somewhat finated, sharply toothed. Flowers pale yellow, or whith, larger than the following, from which they are essentially distinguished by the lanceolate acute segments of their calyx.

14. S. veronicus. Figure of the Last Years of their calyx. Linn. Sp. Pl. 864. Willd. n. 14. Fl. Brit. n. 4. Engl. Bot. t. 567. Fl. Dan. t. 411. (S. flore luteo; Ger. Em. 717. Banh. Prodr. 112. Riv. Monsp. t. 107, f. 2. S. montana maxima latifolia, flore luteo; Barrel. t. 273.)—Leaves heart-shaped, doubly serrate, downy. Flower-stalks axillary, solitary, forked, leafy. Calyx oblong. Leaves of the corolla minute.—Native of bulky places in Italy, Switzerland, and Germany, as well as in some parts of England, but rarely. It is biennial, flowering in April and May. Stem two feet, or more, in height, with four or five angles, in which latter cafe the leaves grow three together. They are flaked, broad, acute, pale green, coarsely veined, most hairy
SCROPHULARIA

hairy beneath. **Flower-flats** all axillary, about as long as the leaves, bearing some small opposite serrated leaves, and a few large opposite entire bracteas. **Flowers** numerous, pale yellow, with a large globose tube, contracted at the mouth, and a very minute limb, the length of whose segments is nearly equal to the diameter of the tube. Segments of the calyx deep, elliptical, obtuse, downy, without any membranous border. A flax-like resemblance between the habit and flowers of this plant, and the Peruvian genus *Calceolaria*, is pointed out in English Botany.

15. *S. argentea*. slender upright Fig-wort. *Atit. n. 12.* Wildl. v. 17. Leaves heart-shaped, doubly serrated, smooth. **Flower-flats** axillary, solitary, forked, leafless. Calyx oblong. Corolla obtuse. **Limb** of the corolla nearly equal to the tube.—Gathered by Mr. Masson in Madeira and Teneriffe. An annual greenhouse plant at Kew, flowering in May and June. **Rustulous.** Stem two feet high, erect, angular, smooth in the lower part. **Leaves** an inch or more and half long, sharp and deeply serrated. **Flower-flats**, and upper part of the stem, downy and rather villous. **Villosa** small, red, their limb bearing its usual proportion to the tube. **Carpel** ovate, pointed, as in the last, but scarcely half so large.

16. *S. trifoliata*. Three-leaved Axillary Fig-wort. *Linn. Sp. Pl. 805.* Wildl. n. 16. *Atit. n. 13.* (S. humilis folia, flore rubro luteo vario pulchro; Grifl. Vind. Luft. 75; Pink. Almag. 338. Phyt. t. 313. f. 6. S. subrotundo callo et nigricante folio, flore luteo palido, carpellis turpida; Bocc. Muf. 65. t. 60. S. indica, capitulis maximis; Chabr. loc. cit. 472.)—Leaves smooth, roundish, coarsely serrated; the lower ones ternate. Stalks axillary, about three-flowered. Segments of the calyx orbicular, with a wavy membranous margin.—Native of Barbary, Corfica, and Portugal. A hardy biennial, sometimes of in curacious gardens, flowering in summer. **Stem** about a foot high, scarcely branched, leafy, nearly smooth, thick, with four blunt angles. **Leaves** opposite, flat, fleshy and glaucous, about two inches long, and nearly as broad, bluish and veiny; many of the upper ones quite simple; the rest accompanied each by a pair of smaller leaves, more or less distinct or remote, at the top of the flower, which is about an inch long. **Flowers** all axillary, large, two or three on each stalk, which is shorter than the flower-stalk, round, with glandular hairs, and bears several linear-lanceolate bracteas. Calyx glaucous, smooth, with peculiarly round, deep, broad-bordered segments. **Corolla** half an inch long, pale yellow, with an orange or rose-coloured limb.

17. *S. appendiculata*. Three-leaved Cluttered Fig-wort. Jacot Hort. Schoubr. v. 3. 10. 1. 216. Wildl. n. 5. (S. ligavica; Vahl. Symb. v. 2. 67. S. trifoliata; Desfaut. Atlant. v. 2. 54.)—Leaves smooth, heart-shaped, doubly and bluntly serrated; the lower ones ternate. Clusters terminal, leafless, compound. Segments of the calyx orbicular, with a wavy membranous margin.—Native of the borders of fields, and the neighbourhood of the sea-thorne, in Barbary. We gathered it in August 1786, in the royal garden at Paris, where it was raised from seeds brought by professor Desfontaines, but have not seen the plant in England. The **stem** is said to be perennial. **Plant** entirely smooth, of a light glaucous green, larger than the last, to which it is most nearly akin, though essentially different; particularly in its racemose compound **inflorescence**, and heart-shaped, doubly toothed or serrated, **leaves**, with longer flower-stalks. The **flowers** are very similar.

19. *S. rupestris*. Rock Fig-wort. *Wildl. 8. 11.*—"Leaves oblong, flat, toothed, nearly smooth. Clutter terminal. Stalks three-flowered."—Gathered by the celebrated botanical traveller Marshall van Beerenheim, at the rocks of Faurida. Wildlown, to whom specimens were sent, says this plant is very nearly related to *S. frutecens*, of which it is perhaps only a variety; but it differs in having a flower only half a foot high, and very finely daisy; leaves all flat, more rigid, and of a smaller size; a terminal **cluster**, composed of three-leaved three-flowered **flats**, and small, obtuse, not acute, **brevatus**.

20. *S. ephedra*. Sea-green Dwarf Fig-wort. *Sin Prodr. Fl. Græc. Subh. n. 1462.* *Fl. Græc. t. 603., unpublished.* (S. orientalis minor, melilic folio; Tourn. Cor. 9; *Buxb. Cent. 5. 10. t. 17. f. 2.)*—Leaves smooth, rather glaucous, lyrate-pinnaed, cut. **Stems** numerous. Clutter short; branches two or three-flowered.—Gathered by Dr. Subthorp on rocks about Athens and Messenia; as well as in Laconia. The **root** is perennial, thick and woody. **Stems** very numerous, somewhat shrubby at the base, spreading in all directions, a ftian high, leafy, scarcely branched but at the bottom, bluntly quadrangular, smooth. **Leaves** opposite, flat, an inch and half long, sharply cut and toothed, at three principal lobes, one of them very large and pinuated, the others smaller, bejides one or two very small ones below, molly entire. **Cluster** or panicle two or three inches long, with entire oblong **bracteas**; its branches opposite, simply forked, their lateral branches single-flowered, and one of them often deficient. Segments of the calyx orbicular, smooth, with a white membranous edge. **Tale of the calyx inflated, greenish, brown on the upper side; two larger segments of the limb chocolate-coloured, the rest greenish-white. We can but guess at the synonym, for the leaves are so much like milk, *Melilica*. Buxbaum's rude figure is not transferable to our plant.

Lower leaves interruptedly pinmate; upper ternate;
leaflets heart-shaped, ferrated, smooth; unequal at the base.

Flower-tilks axillary, slightly branched.—Native of the south of Europe, Barbary, and the Levant, in sandy ground. The roots are tuberous, according to Alpinus, perennial, but subjecl to rot in a garden soil. Herb thick, smooth, succulent, of a light glaucous green. Leaves opposite, or somewhat alternate, irregularly, more or less sharply, ferrated, varying much in size and bluntness. Flowers very large, axillary, drooping; its leaves usually shorter than the flowers, simple, divided, or forked; sometimes elongated towards the upper part of the branch, and the leaves being occasionally contracted, or wanting, there, the influence becomes racemose. Calyx smooth, or slightly downy; segments orbicular, with a membranous edge. Corolla of a pale purplish tawny hue, with a greenish limb. Capsule as big as a small siliqua, with a conical point.

We can find no decisive character between the two plants of authors, which we have here combined. The leaflets of S. are commonly more rounded or obtuse, but a comparison of the figures of Miller and Desfontaines will show that there is no difference in their inflorescence. A specimen from Barbary, given by us of the botanist last mentioned, is fambucifolia, which not being mentioned in his work, he plainly did not distinguish from his melinthera. Those who have mentioned these two supposèd species, have not contrasted them with each other, nor have we had an opportunity of comparing them in a living state; but it is to be presumed the same honey-bearing glands are to be found in the bottom of the corolla of each, being in every other respect so much alike.

22. S. hipida. Hispid Fig-wort. Desfont. Atlant. v. 2. 55. Wild. n. 19. "Stem square, erect, hispid. Leaves villous, pinnate, doubly crenate; the terminal lobe heart-shaped, very large. Cluster compound, leaf-like.—Native of the cliffs of rocks on mount Atlas, near Tlemcen. Root perennial. Stem erect, firm, slightly branched, about two feet high, hispid with very abundant short hairs. Leaves opposite, on short stalks, two to three inches long, and above half as broad, villous, soft and hairy, of a few small ovate leaflets, often cut away at the upper edge, besides the lobe, sometimes lobed, terminal one. Calyx terminal, fix or eight inches long; its branches opposite or alternate, subdivided, hairy, Bracteal linear. Calyx smooth, with rounded membranous-edged segments. Corolla the size of S. nodosa. Desfontaines.

23. S. canina. Wing-leaved Fig-wort, or Dog's Rue. Linn. Sp. Pl. 865. Wild. n. 16. Sm. Fl. Græc. Sibth. t. 598, unpublished. (S. canina, Linn. Nauk. t. 142. Ruta canina; Cluf. Hitt. v. 2. 209. Ger. Em. 1256.)—Leaves pinnate; leaflets deciduous, cut. Stem round. Cluster leaflets; its branches simply forked, their divisions racemose. Flowers nearly felliile, without an internal lobe.—Native of Switzerland, France, Italy, and the Levant; frequent in Greece, Crete, and Cyprus. A hardy annual, long known in botanic gardens, but not generally cultivated, flowering molt part of the summer. Root rather woody. Stems two or three feet high, widely angular, purplish, smooth, leafy. Leaves dark green, smooth, opposite or alternate, forked; leaflets deeply cut, or pinnatifid, sometimes accompanied by small intermediate ones. Clusters one or more, terminal; sometimes leafy at the bottom, but for the most part furnished throughout with lanceolate bracteas only; their branches alternate, simply forked, with a flower in the fork, the two divisions finely racemose, or rather spiked, varying greatly (from three to ten) in the number of their flowers, which are alternate, almoft felliile, each subtended by a small bractea, and accompanied by a larger one, on the opposite side of the stalk. The white membranous border of the calyx is very conspicuous. Corolla about the size and shape of S. aquatica, but defiitute of an intermediate lobe; its tube yellowish-green; two larger segments of the limb blood-red; two lateral ones orange; odd one green.—Willdenow refers to this, as a variety, S. orientalis, chrysanthemi folio, flore minimo atropurpureo; Tourn. Cor. 9, which he supposes may be S. lucida of Pallas. We have no knowledge of Tournefort's plant, but, from its place in his work, it shouid seem to be very nearly related to our S. bicolor hereafter described, or perhaps a variety of that species.

24. S. variograma. Spotted-flowered Fig-wort. Marc. v. Bieber, in Sims and Kunz. Am. of Bot. v. 2. 445. Wild. n. 22.—"Stems furvybby at the base. Leaves bi-pinnatifid, downy. Clusters elongated; flower-flakas short, rough, with hooked hairs."—Native of the flory banks of rivers, and barren hills, between the rivers Terek and Kurl, in the neighbourhood of the Caphian sea, flowering in June and July. The root is perennial. Stem woody at the base, with numerous long slender branches, clothed, like all the rest of the herbage, with rough hairs. Flowers rather less than in S. canina. Corolla purplish; its two upper segments short, obtuse, incumbent, one of them marked with a white spot; three lower ones white, very small, obtuse. Akin to the latter, but, according to this description, sufficiently different.

25. S. lucida. Shining-leaved Fig-wort. Linn. Sp. Pl. 865. Wild. n. 21. "Hort. Berolin. t. 57." Ait. n. 17. Sm. Fl. Græc. Sibth. t. 599, unpublished. (S. falsoius lucida, laerpeti'M: affilemas foliis; Tourn. Infl. 167. Bocc. Mut. 166. t. 117. S. indica; Ger. Em. 716; S. glauco folio, in alas namias divio; Tourn. Cor. 9. Vov. t. 1. 84, with a plate.)—Leaves pinnate, fleshy, smooth; leaflets pinnatifid, deciduous, cut. Stem round. Cluster leaflets; its branches forked, cymose. Flowers stalked; without an intermediate lobe.—Native of Italy and the Levant; common in the islands of the Archipelago. The root is woody, and said to be perennial. It is not easy to distinguish this species, by description, from the canina, except that the leaves appear to be more glaucous, and the cluster of flowers altogether more cylindrical, with shorter compact branches, of a cymose habit, the flowers all stalked. The four uppermost segments of the corolla are all of one nearly uniform blood-red, (without any intermediate lobe,) the odd one green. Capsule nearly twice the size of canina. Linnaeus quotes the plant of Tournefort's Voyage as the same with that writer had previously mentioned, by another name, in his Inflitutiones. Dr. Sibthorp's exactly answers to the plate of Tournefort, and is drawn with leaves more glaucous than canina.

26. S. filicifolia. Fern-leaved Fig-wort. Mill. Dict. ed. 8. n. 10. Sm. Prodr. Fl. Græc. Sibth. n. 1456. Fl. Græc. t. 600, unpublished. (S. folius filicus modo lacinisi, vel ruta canina latifolia; Tourn. Infl. 167.)—Leaves pinnate; leaflets pinnatifid, deciduous, cut; in the lowest leaves obovate. Stem square. Cluster leaflets; its branches forked, divaricated, with from five to nine flowers. Corolla with an intermediate lobe.—Native of Crete. A large tall species, with dark-green leaves, of which the lowermost are a foot long, with broad, obovate, lobed, cut, deciduous leaflets. It is readily distinguished from S. canina, lutea, and their allies, by the squareness of its stem, to the very top of the cluster, and the presence of an intermediate lobe to the corolla; the two upper segments of whole limb are of a peculiarly dark red, or chocolate colour; the lateral segments, like the lobe just mentioned, of a pale red; the lower one green.
green, and very small. The flowers are all nearly sessile; one or the lowest branches of the cluster, a few on those above the middle; four or three on the uppermost. Calyx with a white margin, on edge, as small three.

27. S. vulgaris. Evod. I. 1. 1858. Fl. Groc. t. 602. unpublished. — Leaves pale; blade oval, rounded, angular and cut, all univolt. Stem aere. Cluster leaves, straight; its base is fixed, with from three to seven flowers. Corolla with an intermediate lobe. — Gathered by Dr. Sibthorp in Aria Minor, probably near Smyrna. This appears to be annual, and differs from the last in the more lighter, taller, and smaller size, of its flowers, whose flowers are all small, light-colored, angular and channeled. The corolla is similar, but more slender and constricted. Two upper segments, and an intermediate lobe, of the corolla pale purple, or blue-colored; lateral and lower ones, like the tube, of a light green.

28. S. pinnatus. Stripped-flowered Figwort. Sm. Prod. 5. Fl. Groc. t. 1458. Fl. Groc. t. 642. unpublished. (S. chrysanthemi; Marisch von Biberit, in Simms and K. A. Fl. Ass. of Bot. v. 2: 4467. S. orientalis, chryanthemi folio, flor estio variegato, Tourne. Cor. 9.) — Leaves bipinnate, narrow, sharply cut. Stem round. Cluster leaves, its branches finely forked, their divisions racemose. Flowers white, with an intermediate lobe. — Native of Sicily and the Levant. A tall, branching, pinnate species, with very narrow, smooth, white leaves, whose segments are sharply cut and pointed. The inflorescence forms a large compound panicle, with numerous baccate bracts. Calyx elegantly bordered with a purple line, within its white marginal membrane. The two upper, as well as the lowest, lobes of the corolla are of a blood-red, edged with white, the two lateral ones pure white; tube blood-red, pale at the base. We have little doubt of Tournefort's synonym, which is so very appropriate in character, respecting that of Von Bieberstein. We are more doubtful. The present elegant species is less naturally allied to the two last, than some of those immediately preceding them; but its leaves are more finely divided than in any other known Scrophularia.

The whole genus is more or less ftdl when bruised, and of a poisonous quality to most of the larger animals.

Scrophularia, in Gardening, comprises plants of the fibrous-rooted, herbaceous, and shrubby kinds, of which the species cultivated are, the shrubby fig-wort (S. frutecens); the three-leaved fig-wort (S. trifoliata); the elder-leaved fig-wort (S. fumbeicifolia); and the flowering-leaved fig-wort (S. lucida).

Method of Culture. — These plants may be increased by seeds, which should be sown in autumn in the borders or other places where the plants are to remain. The plants should be kept free from weeds; when the roots continue several years, until destroyed by severe frosts. It is therefore a good practice to have some in pots protected by a frame and glasshouse; and as the young plants flower the thronelgell, a proper succession should be sown annually. They may also be sometimes raised from the parted roots; and the shrub fig-wort, by cuttings or slips in the summer or spring months.

They afford ornament and variety in the clumps and borders, as well as other parts, of pleasure grounds: also when set out among collections, in pots.

Scrophulariaceae, in Botany, a natural order of plants, named from one of the most remarkable and best-known genera, see Scrophularia; making the fourth order in Linn. of tyders, or the twelfth of his eighteenth class; see Lamiaceae and Gentianae. See also Patrinule, a Linnaean order, to which that order contains the great part, or rather, of the Scrophularia. The character of the Scrophularia is thus given by Johnson.

Calyx divided, entire or cleft. Corolla free or united; divided in the tube. Sepals from five to seven, two or three of the others; rarely only two or all. Styles or style or style. From calyx, of two cells, first at the summit, it is completed between, and two valves, which are in some way divided into three parts of two parts; their inside is naked and empty, with a central staminate divided, borne covered by all several flowers; and bearing seeds at each side, filling the place of the partition, being placed in the cell, and often connected with each other in the whole circumference, with their margin. Seeds often numerous and minute. Some herbaceous, rarely shrubby. Leaves opposite or alternate. Flowers bracteate.

Section 1. Stamen four, two longer, and two shorter.

Budellia; S. spuria; Kurschh. in Jucqu.; Capsape; Ste- mula; Halleria; Galenia of Dambeck; Alchemia; Browne; Scrophularia; Matricaria of Aublet, subjected by Schreber to be a Vandaellia; Datura; Gerania; Cymbalaria: Linaria of Tournefort; Anthisium, comprehending Aenrata of Tournefort; Hemorrh.; and Digitalia.

Section 2. Stamen two.

Pedunculat; Calopteris; and Beai of Commenes.

Section 3. Genera akin to Scrophularia, with opposite leaves.

Cimicula; Rifleria; Cystandra of Forli; Graeta; Tereua; Vandaellia; Lindernia; Minae; Polygnum; and Montisa of Aublet.

Section 4. Genera akin to Scrophularia, with alternate leaves.

Sebaeae; Schizogenia; and Broussonetia.

SCROPHULOUS TUMOURS, in Hogi, swellings of the glands about the neck and other parts of the body, arising from colds and obstructions caused in other ways. They may also be removed by mild purgation or mercurial ointments, used two or three times in the day to the diseased parts. See HoJ and Sipne.

SCROTOCELE, in Surgery, a hernia, or rupture, which has descended into the scrotum.

SCROTUM, in Anatomy, the bag of skin which contains the testicles. See GENERATION.

SCROWLS, or SCROLLS, in Architecture. See Voluta.

SCRUB, in Geography, one of the smaller Virgin Islands, in the West Indies.

SCRUPI, in Natural History, the name of a class of mollusks, formed in detached masses, without any crusta; of no determinable figure, or regular structure; and composed of a crystalline or spongy matter, debased by an admixture of earth, in various proportions.

Under this class are comprehended, 1. The teguliga. 2. The petrolida. 3. The lithozugia. 4. The jaspides, or japers.

All these genera strike fire with ease, only some more readily than others.

SCRUPLE, SCRUPLES, Scrupulum, or Sripulum, the lead of the weights used by the ancients, which, amongst the Romans, was the twenty-fourth part of an ounce, or the third part of a drachm.

Scruple is still a weight among us, containing the third part of a drachm, or twenty grains.

Among goldsmiths the scruple is twenty-four grains.

Scruple, in Chronology. The Chaldean scruple is 1/12 part
part of an hour, called by the Hebrews belakin. Thefe
scruples are much used by the Jews, Arabs, and other
eastern people, in computations of time.
Scrupules, in Astronomy. Scrupules eclipsed, that part of
the moon's diameter which enters the shadow, expreffed in
the fame manefure in which the diameter of the moon is ex-
pressed. See Digit.
Scrupules of Half Duration, an arc of the moon's orbit,
which the moon's centre describes from the beginning of an
eclipse to its middle.
Scrupules of Immersion, or Incidence, an arc of the moon's
orbit, which her centre describes from the beginning of the
eclipse, to the time when its centre falls into the shadow.
See Immersion.
Scrupules of Emergence, an arc of the moon's orbit, which
her centre describes in the time from the firft emerion of
the moon's limb, to the end of the eclipse.
Scrutatory, among the Romans, certain officers, or
servants, whose bufinefs it was to search every body that
came to salute the emperor, in order to discover if they had
any kind of arms concealed about them. They were first
instituted under the emperor Claudius.
Scrutiny, Scrutinium, in Antiquity, an examination,
or probation, practifed in the laft week of Lent, on the cate-
chumens, who were to receive baptism on the Eafer-day.
The scrutiny was performed with a great many ceremo-
ries; exorcifms and prayers were made over the heads
of the catechumens. On Palm Sunday, the Lord's prayer
and Creed were given them, which they were afterwards
made to rehearfe.
The process was called scrutinium, scrutiny; because here-
by the hearts of the catechumens were scrutinized, or
searched, that the priests might understand who were fit
to be admitted to baptism.
This custom was more in use in the church of Rome than
any where else; though it appears, by fome misfals, to have
been likewife used, though much later, in the Gallican
church. It is supposed to have ceased about the year 860.
Some traces of this practice still remain at Vienne, in
Dauphine, and at Liege.
Scrutiny is also used, in the Canon Law, for a ticket,
or little paper billet, wherein, at elections, the electors write
their votes privately, fo as it may not be known for whom
they vote.
Scrutiny, among us, is chiefly used for a strict perufal
and examination of the several votes hastily taken at an
election; in order to find out any irregularities committed
therein, by unqualified voters, &c.
Scrutore, or Scrutoir (from the French scrétoire)
a kind of cabinet, with a door or lid opening downwards, for
convenience of writing on, &c.
SCY, in Palynry, denotes a large flock of fowl.
Scud, in Agriculture, a term used provincially to signify
to clear with an ipade or spittle.
Scud, in Sea Language, a name given by femeen to the
lower and lighteft clouds, which are most flutterly wafted
along the atmo{phere by the wind.
Scudding, the movement by which a fhip is carried
with great velocity before a tempeft.
As a fhip moves through the water with fo great a ve-
locity whenever this expedient is put in practice, it is never
attempted in a contrary wind, unlefs when her condition
renders her incapable of fustaining the mutual efforts of the
wind and waves any longer on her fide, without being ex-
posed to the moft imminent danger. See TRYING.
A fhip either scuds with a foil extended on her fore-maff,
and order. It is therefore not deserving of the plume, but J., and order occasionally. The cuadriflora is reckoned at 1524 mezzo quattrini; but when drawn from another place on Rome, it is reckoned at 1525 ducato; this ducato is divided into 20 ducati, 200 denari. Among the silver coins are scudi romani, and ducati. The ducato weighs 22 denari 10.53 grains. Roman silver is 10.29 English grains; and the silver is 10.1 ounces fine in the lb.; it therefore contains 403 grains of English standard silver, and is worth 42.4d. sterling. The scudo di lattano d’oro, or 1523 mezzo quattrini, is worth 62.4d. sterling; and the paolo, 3d. sterling nearly; or 1 ducato = 4 scudi 60 bajocchi, all valued in silver. All payments above 5 scudi are made in cedule, or schedules, a fort of bank notes, which cannot be refused in payment, and which are constantly at a discount. At Malta, accounts are kept in scudi of 21 ducati, each ducato being subdivided into 2 carlini, 20 grana, or 120 piccini. These monies of account are valued in silver and copper money, silver money being to copper money as 3 to 1. At Mantua, a scudo of account is 6 lire, or 120 soldi. At Milan, a scudo di carlini, or impiala, is reckoned at 5 lire 17 soldi, or 117 soldi imperiali; a scudo corrente at 5 lire 15 soldi, or 115 soldi correnti: 1219 scudi impiala are equivalent to 1755 scudi corrente. Among the silver coins are scudi of 18 denari 21 grana, at 6 lire, and halves in proportion. In copper the scudi are divided into 6 denari 18 grana (or 10.02 16.5 dwt.) fine; but the lire are only 6 denari 14 grama (or 6.02 11.4 dwt.) fine. The scudo impiala is worth 5f. 22d., and the scudo corrente 3f. 7d. If valued in gold, the scudo corrente is worth 31. 6d. sterling. According to the mint price of gold and silver in England, viz. 31. 17s. 10d. per ounce for gold, and 57. 2d. per ounce for silver, the scudo of 7 lire at Bergamo is 35. 6s. 7d. in silver, and 36. 5s. 10d. in gold:

- At Florence the scudo d’oro, or gold crown, is 63½. 9d. in gold;
- At Genoa, the scudo di carlini, or crown of exchange, is worth 56½. 7s. in silver, and 56. 02s. 6d. in gold; and the scudo d’oro marche 83. 42s. in silver, and 83. 7d. in gold;
- At Lucca, the scudo d’oro is 53. 50s. in silver, and 58. 27s. in gold; the scudo corrente 51. 80s. in silver, and 54. 39s. in gold;
- At Malta, the scudo, or crown, is 21. 32s. in silver, and 23. 34s. in gold; at Milan, the scudo impiala is 66. 90s. in silver, and 61. 6d. in gold; and the scudo corrente 42. 32s. in silver, and 42. 7d. in gold; at Novi, the scudo d’oro marche 83. 49s. in silver, and 83. 7d. in gold; at Rome, the scudo, or crown, is 52. 05s. in silver, and 51. 6d. in gold; and the scudo di lattano d’oro 79. 37s. in silver, and 78. 3. 7s. in gold; at Sicily, the scudo, or crown, is 49. 92s. in silver, and 49. 92s. in gold. For the 6s. 7d. value, 86s. of the scudo, see the table under Coins. For the impiala on the scudo, and other particulars, we refer to Killy’s Universal Cambist.

SUFFLE, or Scuffle, in Agriculture, an implement of somewhat the same kind as the furrower, but which is

nullly better, and less expensive. There is a prototype of 1½ dozen scudi. SCUFFLE, or Scuffler, in Agriculture, an implement of somewhat the same kind as the furrower, but which is
the last objection. It has been recommended by Mr. Bower. In this tool, by the teeth being only twelve inches from each other, and their interfiting, that distance is reduced to fix inches, where the breadth of the thares, from being full three inches, afford another reduction, which brings them to near together, that the land is almost wholly broken and reduced, and the intention of the ploughman as well as a harrower is accomplished at once, without cutting the roots of the couch-grafs in two, which is a great superiority that it pos sesses over the plough. And from the teeth binding forward, and having that kind of position, the roots are brought to the top more perfectly, which is another superiority over the plough. It has also much superiority in the dispatch of work, four horses and a man being able to finish five acres or more of land of a handy quality in the course of a day. And the following are the dimensions of this tool. The length of the first bull is four feet and a half; and the length of the second bull three feet nine inches. The teeth are two feet in length, and bent near the bottom, in order that they may lie flat on the earth. The length of the beam is six feet. And the length of the iron axle-tree, for the small wheels, is one foot and a half. The length of the iron that shifts through the beam, and fastens with a ferow, is two feet.

Many other light tools of the same description have been lately provided by different implement-makers in different parts of the country, which are well fitted for particular uses in the cultivation of land, and which, by their convenience and modes of working, have much labour and expense. They are some of them made with two rows of thares, five and four in each, about six inches in breadth; the front ones cutting the interstices of the thinner ones, by which means the work is done in an excellent manner. The depth of working is regulated by small wheels that let up and down. They prepare bean and other stubbles admirably for wheat or any other crops. They are a sort of tool which is fast getting into general use by the farmer.

SCUFFLING in Crops, the practice of putting them into the soil or ground by means of the tool called the scuffle. It is a practice which has lately been much had recourse to in some heavy, moil, land districts with great utility and advantage, and it may probably be employed in almost every fort with considerable benefit, as much time and labour, in the busy period of the spring, may thereby be saved; as the ploughing being performed in the leisure season of the autumn, the feed can readily be put into the ground by the operation of scuffling in the early spring months. In all cafes where the state of the weather, and the lands that have been ploughed for a barley fallow, or other purpose, will not let that grain be put into the grounds early in the spring, this may be a good method of proceeding, as further ploughing, in such circumstances, would be highly dangerous and improper. Such fallows, or other ploughings, having had the full effect of the frosts, and the influence of the atmosphere during the whole of the winter season, cannot but be well fitted for the operation of scuffling at this period, and by that means being made fit for putting in the feed. The same will frequently be the case with all other lands which have been ploughed before the commencement of the winter season; such as those of the tare, bean, and pea flubble kinds, as well as those turnip-lands which have been cleared and ploughed at an early period, and this method of preparing them for, and putting in, the feed, may be had recourse to with great safety and advantage. There is no danger in this way of destroying the fine surface pulverization and tilth which is so essen ti ally necessary for the reception of the feed, as is often done by the use of the plough under such wet and unfavourable circumstances of tillage lands. See SCARIFYING, and Tillage.

The working of the surface soil in this manner, and the relinquishing of the use of the plough in some measure, is a great modern improvement in the tillage system, which is most fully practiced in Suffolk; but if it is falling into use in other districts. In Essex some farmers find it a more effectual and cheaper method of clearing fallows than that of trulting wholly to the plough. It is also found useful in cleaning land for turnips, as well as in lightening the ground in fly-eaten crops of that sort.

SCULCOATS, in Geography. See Hull. SCULION, in Ichthyology, a name given by Aristotle, and many others of the ancient writers, to the fifth called by later authors catulus, and catulus major, and in England the bouncer. SCUL, among Hunters, denotes a company; as, a feuk of foxes. SCULL. See Skull. SCULL-CAP, in Gardening, the common name of a curious garden plant. See Scutellaria. SCULPONEAE, among the Romans, a kind of shoes worn by slaves of both sexes. These shoes were only blocks of wood made hollow, like the French sabot.s.

SCULPTURE, Engish, is from the Latin, sculpitura; and the verb sculpto, I carve or engrave, which is the same as the Greek Σκυπτων: therefore balso-relieve was called anaglyphic in that language; which word was also under flood for carved representations in general. The Greeks had other words by which they signified particular works of sculpture; as exou', images; and τυπος, types, or representations in relief.

Sculpture is the art of imitating visible form by means of solid substances, either modelled, as clay or wax, or carved, as marble. The principles of sculpture and of painting are both the same; till painting divides itself into a distinct branch by the imitation of colour; while sculpture is expressed by form alone.

Of Hebrew Sculpture.—As the bible is the most ancient history we possess, those instances of the arts of design which are mentioned in that sacred volume ought to be noticed, and particularly of sculpture.

The first mention of images is in Genesis; where Rachel stole her father's gods, which are called Teraphim, or images. Mention is made also in Genesis of Judah's signet.

In Exodus, Mofes receives commands and instructions concerning the tabernacle; that he should cause it to be made according to the pattern which was shewed him on the Mount. And in order to this, Beazalel and Aholiab are inspired with the spirit of God "to devise cunning works in gold, and in silver, and in brazen, and in cutting of stones, and in carving of timber to work all manner of workmanship."

The importaance of the arts of design is here particularly demonstrated by the manner in which Beazalel and Aholiab are called, even in the service of religion; and filled with the divine spirit for their employment in the Tabernacle and the Ark of the Covenant, as described in the following passage by Mofes.

"And Mofes said unto the children of Israel, see, the Lord hath called by name Beazalel, the son of Uri, the son of Hur, of the tribe of Judah. And he hath filled him with the spirit of God in wisdom, in understanding, and in knowledge, and in all manner of workmanship. And to devise curious works in gold, and in silver, and in brazen, And in the cutting of stones, to set them, and in carving of wood, to make any manner of cunning work. And he hath put it
SCULPTURE.

it on his heart, that he may teach, both he and Ahiah, the son of Ahitub, of the tribe of Dan. Then hath he filled with wisdom of heart, to work all manner of work of the engraver, and of the graving workman, and of the emboiderer in blue, and in purple, and in scarlet, and in fine lines; and of the weaver, even of them that do any work, and of these that devise cunning work.

Such inspired works being ordered, and Moses coming down from the Mount to call all to be performed according to the divine will; he finds that the people have made a golden calf, crying out, "The Lord, thou art gods, O Israel, whom brought thee out of the land of Egypt." The golden calf is evidently the Egyptian Osiris or Apos.

The manner of making the golden calf is thus described by Aaron: "I laid unto them, whatsoever hath any gold let them break it off; so they gave it me; then I cast it in the fire, and out came this calf." It is also said, "He received the earrings and gold at their hand, and fashioned it with a graving tool after he had made a molten calf!"

This dreadful attempt to annihilate inspired art at its birth, is visited by a grievous judgment, but no more grievous than is necessary to its security: for this deliverance from Egypt was the deliverance of man, both as to his bodily and mental faculties, from slavery.

When the tables of stone are renewed, that they may be deposited in the ark, Moses, Bezaleel, and Ahiah, and every wise-hearted man, in whom the Lord had put wisdom and understanding, set about their inspired work.

The tabernacle and its curtains and cherubim, the veil and its cherubim; the ark and mercy-seat and their cherubim; the table of show-bread and the golden candlestick; the altar of burnt-offerings and the altar of incense; the laver; the garments of Aaron, and his breast-plate and mitre and holy crown, and the garments of the sons of Aaron.

Whether the cherubim which were woven in the curtains and the veil are to be considered simply as mentioned in Exodus; or, according to the more expanded and poetical representations in Ezekiel, accompanied by their dreadful wheels, containing Orion and Pleiades, Mazzaroth and his lions, Arcturus and the chambers of the south, as mentioned in Job, Isaiah, and Aaron; like the representations on our celestial globe; the difference will be only in their more or less splendid design and embroidery. But the description is more positive concerning those sculptured cherubims which covered the ark of the testimony.

"And he made the mercy-seat of pure gold. Two cubits and a half was the length thereof, and one cubit and a half the breadth thereof. And he made two cherubims of gold; beaten out of one piece, made he them on the two ends of the mercy-seat. One cherubon the one end on this side; and another cherub on the other end on that side; out of the mercy-seat made he the cherubim on the two ends thereof. And the cherubim spread out their wings on high, and covered with their wings over the mercy-seat, with their faces one to another; even to the mercy-seat were the faces of the cherubim."

These figures, as also the candlestick and table, and all other works of sculpture contained in the tabernacle; together with Aaron's breast-plate, a span each way, foursquare; containing twelve precious stones, each engraved with the engraving of a squet, with the names of the children of Israel; must have been worthy of their divine author.

And the necesity of such inspired sculptures and other inspired works of art is explained sufficiently in the deliverance of Israel from the idolatry of Egypt; where no one dared to pray any other foster, but that of the fathers, who, like heart, were kept to worship the name of the angel." And the Hebrews being born slaves, continued to think upon the Egyptian works, but he inspired them with what he wrouth, he was employed to work in works, and in his ordering. Such then was the inspired art and its use from the time, and the earth from returning to its primordial chaos;

All idolatrous labors for art, wood and their deformed God, by the mouth of Micah, expressly conmand the children of Israel to destroy, in these and the like words. "And destroy all their pictures and destroy all the molten image."

After the establishment of Israel in Canaan, there are continued indications of free art. So early as the tongue of Debr rah, we hear of those who deliberate with the power of the writer. Gideon destroys the altar of Baal, but afterwards himself makes an idol. Micah's mother dedicates gold and silver to the Lord, to make a graven image and a molten image; but Micah makes them a house of gods, which he worships and caudes others to worship, not using them as works of art, but as idols.

We next hear of the image of Dagon, when the ark of God is taken by the Philistines; and of the golden encrusted and golden mice, which were put into a coffer by the side of the ark, for a treasufy offering.

The image which Micah placed in David's bed, to deceive Saul's messengers, some suppose to have been a statue of David; it is called a seraphim.

But the most magnificent production of Hebrew art was the temple of Solomon. It contained the same cherubim that Moses had seen in the Mount; and they adorned and covered the whole temple within and without. Two in particular were placed in the holy of holies, of colossal dimensions: they covered the place of the ark with their wings; the height of each was ten cubits, and the breadth each spread his wings was ten cubits. A figure five yards high is capable of the greatest efforts at perfection in art, and this no doubt they had, being done by divine command, for purposes whose importance reaches to the end of time.

The brazen sea of Solomon's temple, and its twelve oxen; the two pillars, Jachin and Boaz; the candlesticks of pure gold, twelve in number; the ten lavers, and their basins and wheels, and ornaments of lions and oxen, and cherubim, works inspired by God and wrought by his holy Spirit, with the other sublime ornaments of Solomon's temple, as also Solomon's throne and its twelve lions. The excellence of the work must be considered as equal to the purpose of containing the covenant between God and man, and other dispositions relating thereto.

Thus, the art of sculpture was not only allowed, but encouraged and employed in the service of religion, in the representation of divine attributes or the symbols of divine presence; and the abuse only of this art was forbidden when perverted to idolatrous and impious purposes.

But Solomon became an idolater; and it is said, "then did Solomon build a high place for Chemosh, the abomination of Moab, in the hill that is before Jerusalem; and for Moloch, the abomination of the children of Ammon." From this time fine art and inspiration were successeively removed.

It has been thought necessary to be particular in giving quotations from the Bible concerning the sculpture of the Hebrews, as it is the earliest of which we have any authentic account.

There are found in Syria, in the present time, ruins of monuments called the sepulchres of the prophets. These remain have nothing like the Egyptian or the Persian style of construction,
construed, but are of Roman or Grecian origin, and must have been erected in an age greatly posterior to the prophets. This seems to be allowed in the words of our Saviour to the Pharisees: "Your fathers killed the prophets and ye build their sepulchres." It should seem that the Pharisees added Roman ornaments to the simple forms of ancient Hebrew veneration, as is figured in these words. "Ye build the tombs of the prophets and garnish the sepulchres of the righteous."

There are engravings of these sepulchral monuments, published by Mr. Caius in Paris.

Of Babylonian and Persian Sculpture, also of Athenian Sculpture in general.—It may be proper to take some general notice of the most ancient sculpture of other nations of the East, of which our accounts are very imperfect, previous to the description of Egyptian sculpture, for two reasons: 1st, that the sculptures of these nations will have considerable light thrown upon them by the Egyptian remains; and, 2dly, because, as the history and examples of Egyptian sculpture are abundant and fusecutive, they lead us more naturally and accurately to the great object of our present enquiry, Grecian sculpture.

In the very ruined state of some, and the utter devastation of most of those countries in Asia which were once the seats of art and science, the traveller in vain seeks for memorials of Noah, or of Abraham, or of Moses, or even of Solomon: all historical record of these early times is without corroborative evidence from remaining monuments.

The first method of transmitting ideas to posterity is suppose to have been by hieroglyphics or ideal writings, whether painted or sculptured. Such also was used in Mexico when first discovered. All the most ancient writings approach to the figurative or ideal writing, every word being as much as possible a picture or image. Some of the learned have thought that the first chapters of Genesis were originally transmitted in this way.

How such figurative words could have occurred, previous to the art of ideal writing, cannot be easily conceived. The author of a figurative expression must have a figurative idea in his mind, and that is a hieroglyphic, which might as well be painted or sculptured as written, and with infinitely greater effect on the reader.

The descriptions of the creation and fall of man, of the flood of Noah, of the building of Babel, and of the departure of Abraham from Chaldea, are each of them a sublime series of ideal writing.

After the flood, when men began again to multiply upon the earth, Nimrod's followers are said to have "built a city and a tower, whose top should reach unto heaven." The facred writings do not mention any thing of sculpture in this building. But Berosus says, that representations of the terrific forms that inhabited chaos previous to the creation, were to be seen on the walls of the temple of Belus in Babylon; and that these conflated of human figures with wings, of human figures with two heads, of others with legs of goats and with horns; and that they were executed both in painting and sculpture.

There are no works of sculpture discovered in any country at all to be compared with Greek art. All the great empires, previous to the age of Pericles, are vanished; not any thing of Nebuchadnezzar, nor of Semiramis, nor of Belus; their names remain in history but not in sculpture, and it cannot be certified whether the golden image of Nebuchadnezzar was merely a colossus or a work of fine art.

Much less can we speak of Belus, from any thing that remains. Herodotus, in describing the temple of Jupiter Belus in Babylon, says it is a "square building, two flades in length on every side, having gates of brass, as may be seen in our time. In the midst of this temple stands a solid tower of one flade in height, and in length and breadth the same measure. On this tower another is built, and a third upon that, till they make up the number of eight. The ascent to these is by a way carried round the outside of the building to the highest part. In the midst of the ascent is a palace, where the priests who give up may rest themselves. Within the uppermost tower a spacious dome is built, in which a table of gold stands, at the side of a magnificent bed. No image is seen in this place, but in a chapel which stands below within the temple, a large image of gold, representing Jupiter fitting, is placed on a throne of gold, by a table of the same metal, all together weighing eight hundred talents, as the Chaldeans affirm. Without this chapel is an altar of gold, and another of a greater size, which is used when cattle of full age are sacrificed; for on the golden altar no other than sacrificing victims may be offered. On the great altar the Chaldeans confume yearly a thousand talents in incence, when they celebrate the festival of this god. Besides these things, a statue of solid gold, twelve cubits high, stood formerly in this temple, which, because I did not see, I shall only relate what I heard from the Chaldeans. Darius, the son of Hystaspes, had designed to take away this, but had not courage for this purpose; but Xerxes, the son of Darius, not only took away the statue, but killed the priest who had forbidden him to remove it. In this manner the temple of Jupiter Belus is built and adored, not to mention divers other donations consecrated there by private persons."

Diodorus Siculus has given a description of the works of queen Semiramis in Babylon. She built two palaces, at the end of the bridge upon the banks of the Euphrates. That on the west had a high and flatly wall built circular, upon which were portrayed in the bricks, before they were burnt, the forms of all sorts of living creatures, laid with great art in curious colours. This wall was in circuit forty furlongs, in height a hundred yards, upon which were turrets a hundred and forty yards high. The third and most inward wall immediately surrounded the palace, thirty furlongs in compass, and far surmounted the middle wall both in height and thickness; and on this wall and the towers were represented the shapes of all sorts of living creatures, artificially exprest in the most lively colours; especially was represented a general history of all sorts of wild beasts, each four cubits high and upwards. Among these was to be seen Semiramis on horseback, striking a leopard through with a dart; and next to her, her husband Ninus, in close fight with a lion, piercing him with a lance. This palace far excelled that on the other side of the river, both in greatness and adornments, for the outermost wall of that made of well burnt bricks, was but thirty furlongs in circumference. Instead of the curious portraiture of beasts, there were the brazen statues of Ninus and Semiramis, the great officers, and of Jupiter, whom the Babylonians call Belus. And likewise of armies drawn up in battle; and divers sorts of hunting were there represented, to the great diversion and pleasure of the beholders. In the middle of the city she built a temple to Jupiter, whom the Babylonians call Belus. Upon the top she placed three statues of beaten gold, of Jupiter, Jupiter and Rhea. That of Jupiter stood upright, in the posture as if he were walking. He was forty feet in height, and weighed a thousand Babylonish talents. The statue of Rhea was of the same weight, sitting on a golden throne, having two lions at her knees, standing one on either side, and near to them two exceeding great serpents of silver, weighing thirty talents a piece. Here likewise the
SCULPTURE.

the image of June flood upright, and weighed eight hundred talents, graving a fret upon the head in her right hand, and holding a sceptre, adorned with precious stones, in her left.

But Babylon is now a ruin, nor are the caverns of the earth found to yield any fragments of her ancient sculptures.

Among the ruins of the Persian monarchy, which display themselves in melancholy state amid the deserts, is Persepolis. The fragments of sculpture that here remain are very rude, and give an idea of the mere infancy of art, though of gigantic dimensions. Such are those sepulchral monuments carved high in the rock mentioned by Flavio in these words: "He that heweth himself out a sepulchre on high, that graveth an habitation for himself in a rock."

The ruins of Persepolis present examples of Persian sculpture on the wall, and in the portals of its ruined palace, and also on the tombs of its kings. Their antiquity may be about the time when Ahabsaurus removed the seat of government from Babylon to Susa. We hear that Alexander took possession of Babylon, Susa, and Persepolis, the chief cities of the Persian empire, and burnt down the palace of Persepolis, of which the ruins now remain. They are hardly more ancient than that removal of the Persian government by Ahabsaurus, who is Darius Hystaspes.

Thus palace of Persepolis has its walls still remaining on three of its sides. The extent of the front comprehends fix hundred paces, from north to south; it is three hundred and ninety from east to west. On the west front are two magnificent flain-cases, confiting each of two flights of steps. On the top of these flain-cases are seen two grand portals, one fronting the west, the other eastward; between them are two magnificent columns, each fourteen feet in circumference and fifty-four in height; within the portals are carved, in stone, the heads and breasts, and front feet projecting beyond the portals, of two animals somewhat like sphinxes, twenty-two feet from the fore to the hinder legs, and in height fourteen feet and a half; they have the body of a horse, with the legs thick and short, like those of a lion: there is some appearance of their having had human heads, one of them having a crowned bonnet like a turrett. The other of these grand portals eastward has two somewhat similar animals, but these have wings on their shoulders, their dimensions being nearly the same with the former. And at the distance of a hundred and seventy feet from this portal are two flain-cases like the former. The walls which belong to these flain-cases are fix feet seven inches high, of which the lower stones make it evident that they were adorned with figures in low relief. The upper part of the flight is embellished with foliage, and the representation of a lion rearing a bull, much larger than life, and likewise in low relief. The stairs are seventeen feet in length, three inches high, and fourteen inches and a half in breadth.

What remain of this palace are chiefly pillars and porticoes, the pillars being fluted, having bases and capitals of uncouth ornament, of sometimes an animal's head and neck, and sometimes ornaments like Gothic arches. All the upper part of the building is entirely destroyed, and what remain of that below are only separate members, which have little connection with each other. Some of the columns are 70 feet high, and have been as numerous as 76 in a range, though comparatively few remain, and those terribly mutilated.

The other ruined portals are ornamented with figures carved in the sides of the jambs, of rude grandeur: on one portal is a man fighting with a lion; on another, a man fighting with a griffin or horned lion; and on a third, a figure like a king, with two figures behind him, one with a staff, the other with a sea horse's tail, which being fast to a gold handle, is fixed in Persia at the present time to drive away flies. Over his head, in the air, is a little figure of eagle's wings, perhaps a god or a genius. Another portal has a great many figures in different compartments, one above the other: in the top compartment is a figure sitting on a throne; on another portal, which was once the side of a door-way, is a figure sitting on a throne, and behind him an attendant; beneath, in three compartments, are many little figures much defaced. Other portals have had other ornament, and unknown characters of letters shaped, like the heads of arrows, disputed in different directions and in different combinations. The windows of these ruins, some of which remain, were ornamented also with sculptures in the same manner as the doors. One that remains has a man holding an animal by the horn, which is single and very long, and bending backwards; before them walks a figure of a man with something in his hand, like a fanning instrument: other windows have also the same unknown characters of letters engraved on their sides.

The flain-cases are half buried in the earth, and toward the top very much broken; they have each two flights of steps with landing places between, the walls of which, and of the flain-cases, have been ornamented with sculpture, in two ranges, one above the other. The first five figures at the entrance are smaller than the rest, and have large vellums with plaited sleeves, and a round bonnet rising in plains, and larger in the upper than in the lower part; they have hair and long beards; each holds a lance, and a quiver of arrows is fastened at their back with a strap carried over the shoulder. The figure which is next in order, precedes a train of others; he holds the next by the left hand, and grasps a fork with the right. It seems to represent an ecclesiastic at the head of a procession of others; he is likewise arrayed in a large robe, with a girdle hanging down very low. The three figures by which these are succeeded have shorter robes and sleeves, with upper and under velts, and pointed bonnets formed into five plates: these are properly the tics, called also reflexa, slumped into a curve backwards, contrary to the tics Prygias, which are bent forwards. Two of these figures hold a basin in each hand; a figure following him has two loops or circles in his hands. This is followed by two horses drawing a chariot, and by two other figures that place their left hands, one on the back, the other on the neck of the horses. They are all represented with hair and beards; the two left bare-headed, the other has a bandage or diadem.

Between each compartment of six or seven figures, is a kind of arch, and the two first figures always hold each other by the hand. A horse, led by the bridle, follows the two first figures in the second compartment; three figures following this, one of which bears something that resenbles a vellum: in the third compartment are five figures with little basins or buckets, and two others with bells or globes. These in the fourth compartment are not habitated to well as the others, having only a very straight staff, with a cincture, and long drawers, which are straight and plaited: three of these figures have also basins or little buckets in their hands, and are followed by a camel, having two hunches on his back, with a little bell hung round his neck, after the manner of the eastern caravans, that the sound may be heard at a distance, especially when they pass through narrow defiles; to give notice also to the inhabitants of the caravan's arrival: it is a signal likewise to those who have hid and enables them to join their companions. The last compartment is distinguished by a figure bearing a pole, with a pot appendent at each extremity; and in each of these pots are seen
seen little water vessels in an upright position: the habit of this figure is but indifferent. A mule, or an ass, is represented next, with two men armed with pikes, followed by another figure bearing two mallets. Several other characters appear next, and half of all a great lion encountering a bull, or some other animal, from whose forehead a single horn is extended.

There are forty-eight figures of men and beasts in this range, and as many in that above it, which consists of the following figures. The first six of these are merely habited; each of them has some vestment in his hand. Those that follow carry the fame, but are better arrayed. Most of them are greatly impaired by time. These are followed by an ox led with a halter. The only difference between this and the third compartment is, that in the latter, two rams are led, and each has a large crooked defected horn. After these appears a figure armed with a buckler, and another leading a horse by the bridle, followed by a third with two hoofs: the other three are habited like the preceding figures. Next comes a led ox, followed by a man armed with a lance and shield, behind whom appears two other figures, each with three lances, and their sleeves longer than their veils. The last figures that follow have very short veils, with drawers that are long and straight, which come down to their feet; they are armed with long bucklers hanging at the girdles of their waists; two of them have hoops in their hands, and a third a fork; they are followed by a horse led by the bridle.

Such are the figures on this fair-cave. Toward the west side, and toward the east side, are as follow. Twenty-eight figures, each grasping a lance with both hands; their veils are long and wide, and they are represented with hair and beards, and seem to be bare-headed, unless we may suppose them to wear a plaited bandage, or kind of diadem. These are succeeded by a number of other figures, armed with long bucklers, which are pointed and bent at one end, with a short broad dagger hung at their girdles: their veils are of unequal lengths; they are like the last figures in the drapery of their heads; they have also some ornament in one hand, and the other is placed upon their beard. This range consisted of sixty figures, the last of which are defaced. All these figures seem to represent some triumph, or procession of people bearing presents to the king, which was customary under the ancient monarchs of Persia, and is practised at this day.

A traveller counted 1300 figures of men and animals remaining in this great ruin.

There is another immense ruin in the defarts of the ancient empire, called Palmyra or Tadmor, said, in the Book of Kings, to be built by Solomon. The present ruins of this great city are very different from those of Persepolis, and indicate a much more modern construction; and that if Solomon originally built this city, the Roman emperors, and particularly Adrian, so far re-edified it as to leave no traces of greater antiquity.

As the remains of Palmyra, though vast and stately, are more properly architectural than sculptural, we shall refer the reader, to satisfy further curiosity concerning them, to the admirable work of Wood and Dawkins; for whatever remarks might be requisite on the sculptures of Palmyra, would more properly belong to observations on that subject in the section of Roman sculpture. See Palmyra.

Balbec, near the site of the ancient Damascus, is another ruin of the same description. (See BALBEC.) As for those great many cities mentioned by the Hebrew prophets as flourishing in their time in magnificence and riches, the places of some of them cannot be found, such as Teman, the capital of Edom, and the cities of Moab and Ammon, of Aethur and Aram; some are dwindled into little villages, and most have left no traces in the desert where they might be found.

With regard to Hezbon and Rabbath, and Bozra and Hamath, all the mighty cities described by Isaiah and Ezekiel, as filled with multitudes in power, riches, and magnificence; the coromant and the bittens pollute them, the wolf howls there, and the wild beasts inhabit those forsaken places, where ancient kings and their counsellors, and warriors, thought they had built an everlasting habitation; even Nisrach and Damalac are now indeed no more; they are, as the prophets said, "gone down into the nether parts of the earth," nor does history deign to tell their tale.

And of the ancient Tyre, and its Hercules of ancient Tyrian art, there are no remains. Herodotus says, "I failed to Tyre, in Phoenicia, because I heard there was a temple dedicated to Hercules. That temple I saw, enriched with many magnificent donations, and, among others, with two pillars, one of fine gold, the other made of a smaragdus, which shines by night in a surprising manner."

The Tyrian Hercules, or god of Tyre, is thus described by the prophet Ezekiel. "Every precious stone was thy covering, the sardius, the topaz, and diamond, the beryl, onyx, and jasper, the fapphire, the emerald, the carbuncle, and gold. The workmanship of thy tablets and pipes was prepared in thee in the day that thou was created. Thou art the anointed cherub that coverest, and I have fet thee fo; thou wast upon the holy mountain of God, and thou haft walked up and down among the fones of fire."

It looks as if there was some omission in the account Herodotus gives of this temple of Hercules, in Tyre. Herodotus, indeed, saw this temple after the ruin of Tyre by Nebuchadnezzar, consequently not in its glory, as Ezekiel had seen it; he has described the pillars as stones of fire, but he has not said any thing of the god; perhaps, in his time, the statue of Hercules had been taken away by mercenary cupidity, as the statue of gold in Babylon had been removed by Xerxes. Such is the melancholy picture of ancient times, the fulfilment of the denunciations against those ancient empires; "they utter a faint murmur out of the dust."

As there is a general resemblance in the early attempts at fine art in different nations; so there may be a likeness traced between the productions of Hindoo sculpture and the early productions of art in Egypt, Greece, and Etruria; however, we must always remember that the accurate observations made by the Greeks on beautiful nature, assisted by the regular progres of science, soon gave their productions a decided superiority over those of every other people.

The caverns of Elephants and Ellora are vast halls excavated in the rocks, equal in dimensions to the large temples of other nations.

That of Ellora is architecturally divided, by rows of columns, into aisles; the friezes, and pannels in the walls, are filled with sculpture, detached, or in feries, of the mythological personages, and acts of the Brahmin religion.

The sculpture of Elephants is of the same kind, with the addition, at one end of the temple, of a colossal bull of the triple-faced Braham.

The columns of these temples offer a continual variety of ornaments in their capitals, shafts, and bases; redundant and extraordinary for the application of the lotus, cames, and other vegetable and animal productions of the country, in which the human figure is occasionally introduced.

On the banks of the Ganges are continually seen such ancient works of sculpture in the living rock, of inferior dimenions, but of the same sacred character, obelisks magnificently adorned, the figures of oxen, horses, tygers, elephants, &c.

The necessity of hastening to the great object of our present
present enquiry, Grecian sculpture, makes it impossible to do more than refer to examples few, in the earlier period, as they are to be elegantly displayed by Mr. Daniel among the colossal statues of the East, which, in his exact representations, have not hitherto been cut out of any country, but have gottered every other of at least some merit.

Of Egyptian sculpture, the land of乏ance, was visited by the most wonderful of the Greeks in arts and letters, to whom we find more especially the names of Orpheus, Plato, and others of distinguished wisdom; all went to Egypt, as to the wisest nation of antiquity, for instruction. The earliest ancient, Herodotus, went also, and has given an account of the extraordinary country. He says, that in the time of their king Amasis, Egypt contained 79,000 populations.

The remains, at this present time, as described by the latest travellers, are more stupendous than those of any other country, with vast palaces and temples, in the age of ten, with their attendant sculptures and paintings; though devastated by the temple of war deluge after deluge, still the colossal power of Egypt has a remnant left to tell us what it once was.

Herodotus says, on the authority of the Egyptian priests, in his own time, from Egyptian records, that Menes was the first king of Egypt, after whom reigned three hundred and thirty kings: among these was a woman, named Nitocris. Of the acts of these kings, he was told, no record remained, except that Nitocris and of Menes, the last of these kings. He says, I shall, therefore, pass them by, to relate the memorable actions of a succeeding king, whose name was Sesostris. That he conquered all nations, and caused his image to be carved on stones in the countries that he subdued, which he describes thus. His figure is five palms in height, holding a bow in one hand, and an arrow in the other, and armed after the Egyptian and Ethiopian manner. On a line, drawn from one shoulder to the other, these words are engraved in the sacred letters of Egypt: “I obtained this region by the strength of these arms.”

After Sesostris reigned six kings. Statues made in the time of the last of these were in ruins in the time of Herodotus, which was about the year of the world 3400, a hundred years before Herodotus; so that 3000 years will remain to be occupied in Egyptian history; from Sesostris to Amasis; and within this time, those Egyptian buildings and works of sculpture, which the priests represented to Herodotus as to very ancient, might easily have been produced.

Thus a division is made between the fabulous and the historic ages, both in Egypt and Greece; and a decided era produced, which will not infringe on the truth of sacred scripture, nor on the credibility of authentic Gentile history; and by a comparison of the remains of those monuments, it may give some date to the early works of Egypt and Greece.

The remains of Egypt have been no less zealous to examine the remaining ruin of Earth, than the ancients to contemplate its ancient glories.

Of these works, these ruins of ancient knowledge, the late publications of Egyptian antiquities give majestic and awful ideas. Some of the drawings made by the French Institute in Egypt have been published, and they display Egypt, which once was.

The ruins of Egypt are contained in a compass of about 350 miles along the banks of the Nile, among pyramids, and pillars, and porticoes, and subterranean palaces hewn out for the dead.

The first objects of Egyptian sculpture that seize on the imagination are the colossal statues; among these are the sphynx, and the statues called Memnon or Olymmandus. The sphynx is situated near the pyramids of Giza, as to be exhibited, it is the appearance of one of those mafles of solid bulk, accompanied by other mafles of ornamented sculpture; and being divested of their gigantic accompaniments of intellectual labour, the pyramids are left alone, inexpressible monuments of lost wisdom as well as departed power.

The sphynx is thus described by Ripaud: the length of the rock, to which the form of this chimerical animal has given, is about 95 feet; its height from the base to the top of the head is 38 feet. The ancient very generally believed, that there was a passage in the body of the sphynx, which led by subterranean channels to the interior of the pyramid. It is still conjectured, that, beneath these subterraneous passages, caverns have been dug, which have supported to have been employed in the mysteries of initiation. On the face of the sphynx there is a hole five feet in depth; and it may even extend further. There are also appearances of another opening of the same kind on the back of the figure.
SCULPTURE.

The head of the sphinx bears the lineaments of a Negro. It is deprived of the nose.

Of this monument Denon says: although the proportions of the sphinx are colossal, the contours are free and pure; the expression of the head is fleet, graceful, and tranquil. It is the character of an African; the mouth and lips thick, with a softness in its movements, and a finesse in its execution, truly admirable: it is the flesh and the life. At whatever time this was produced, art was without doubt in a high degree of perfection. If there is wanting in this head that which we call style, that is to say, those forms, just and exalted, which the Greeks have given to their divinities; it is but justice to acknowledge, that there is no great and sweet character of nature which we cannot admire in this figure: if we are surprized at the dimensions of this monument, no less are we astonished at its execution.

The temples of Karnac and Luxor, on the right bank of the Nile, together with those of Medinet Abou and the Memnonium on the left bank, are supposed to occupy the situation of the ancient city of Thebes. The ruins of these temples are of vast extent. The palace of Karnac was in front 240 feet, and its depth near three-quarters of a mile. It consisted of four great courts of nearly equal dimensions, comprehended within a long square: the first court was occupied by four rows of columns; the second court had 150 columns, the largest 11 feet in diameter, the smallest 7 feet; the third court was adorned with obelisks 300 feet high, and colossal statues, surrounded by various royal apartments. On each side of the entrance to the fourth court was a falcon of granite: the rest of the space was occupied by porticoes, colonnades, and numerous chambers for officers and attendants. This palace, with four dependent structures of similar magnificence, but inferior proportions, was approached by four paved roads, bordered on each side with figures of animals, each 15 feet long. In one avenue were 90 lions; in another avenue, sphinxes; in another, rams; and in the fourth, lions with hawks' heads. From the ruined state of these avenues, we have no computation of the number of animals by which they were bordered; though it is almost certain that they were not fewer than 300, and it is possible they might be many more. In this palace 22 colossal statues still remain, and a great many statues of granite, and fragments of the size of nature; besides which, the walls were nearly covered within and without by faifo reliefs and pictures. The better structures in this group of buildings were adorned in the same manner, and communicated with the other temples of Luxor and Medinet Abou, as well as the Memnonium, which was the magnificent tomb of Olymmandae or Memnon.

The Memnonium looks to the east: it is a palace of the most ancient construction, and its dimensions also colossal. In one of its courts are seen the remains of the celebrated statue of red granite, which may be considered as that of Memnon. Its height was 64 feet, and its remains are scattered 40 feet around it. One of its feet is 55 feet more than the other, and one of its ears measured 30 inches in length. The excavations are still visible, where the wedges were placed which divided the monument, when it was thrown down by Cambyses.

Between the Memnonium and Medinet Abou, and distant about half a league from each of them, are the remains of a great number of colossal statues and traces of buildings, which indicate that these two places communicated with each other by structures which filled up the whole space between them. This mass of edifices appears to have composed, according to Diodorus Siculus, the tomb of Memnon or Olymmandae. We are confirmed in this conjecture, by the conformity which exists between the monuments in their prefered site, and the extensive as well as precise descriptions which that writer has left of pictures which are found in both palaces. They represent the sieges of fortified towns, hostile invasions, and victories obtained by the Egyptians.

The Memnonium has not been finished, as well as the greater part of Egyptian works, where, by the side of objects but roughly hewn, are seen examples of exquisite finishing. Between the Memnonium and the palace of Medinet Abou are the largest colossal statues which now remain in Egypt: these are the figures now called Memnon. They are both fitting, with their heads looking straight forwards; both their hands lying equally on their knees; their feet straight forward, and their legs in an upright position, and both alike. One of these, according to the descriptions in Diodorus and Strabo, and those who copy their writings, was the famous statue of Olymmandae, the largest of all the colossi. The height of them is about 58 feet. Three smaller female figures accompany each of the colossal statues, which are standing one on each side of the chair, and one between the legs of the principal figure: there are in the rotunda an expanse, and that on the pedestal or chair of the southern figure wants no charm of delicacy in the execution. It is on the leg of that figure, towards the north, on which the inscriptions are written of those illustrious ancient travellers who visited the statue of Memnon: there are innumerable inscriptions of names of all dates, and in all languages.

But Denon gives it as his opinion, which is also that of Ripaud, that the two statues now standing are the mother and son of Olymmandae; the figure of Olymmandae itself now lying in ruins, as was before described.

The great temples of Hermopolis; the great city of Mercury; of Tentyris, or Dendera; of Latopolis; of Karnac; of Apollinopolis, or Edfu; of the islands of Phile, and of Elephantine; are all now in ruins, covered with remaining examples of Egyptian sculpture, both in statues and in hieroglyphical representation, on the walls, and on the pillars and porticoes, within and without; many of which are works of great labour and care, as well as intelligence in art.

M. Ripaud says, the execution of the figures engraved on the exterior and interior walls at Dendera, is an example of the highest point of perfection to which the Egyptians attained. All the minuteness of their drapery is finished with a purity and delicacy most admirable, conferring the impracticability of the stone. The elevation of this temple is 72 paces in breadth, and 145 in length; the portico is 60 paces in length, and 30 in breadth. Its most remarkable decoration is the great zodiac, divided into two bands; it enriches the ceiling of the two last intercolumniations to the right and left. The colonnade is one to the portico, and is supported by 6x columns, whose capitals display four figures of Isis, with the ears of a cat. The compartments of the walls are decorated with pictures, in which is a great number of female figures.

On the terrace of the great temple is a small one, the columns of which are like those of the portico: this temple forms a square of nine feet, and is the portico of a chapel, of which there are no traces. In the inner part of the temple is an apartment, which is adorned with a zodiac; it is circular, and occupies one-half of the ceiling. The apartment appears to be consecrated to astronomy. It is separated from another astronomical sculpture by a female figure in bas relief, of a large size, occupying the whole diameter of the ceiling; it presents a contour easy, and of beautiful
beautifull proportions; its feet, well preserved, are in a beau-
tiful style; it does not prefix any attribute, except a cor-
ner, which is often seen on figures of IIs; the hair is parted,
and falls on each side of the face; and on each side of this
figure are hieroglyphical inscriptions.

At Luxor, which is part of ancient Thebes, are the re-
manus of a palace, having in its front two obelisks of granite;
their height is seventy feet above the earth. Near these are
two colossal figures hurled up to the breasts; and judging
from the size of what is above the earth, we may reckon
that thirty feet are buried, which gives a hundred feet to
these obelisks. They are in perfect preservation; the
hieroglyphics upon them are most laboriously traced: the la-
bour to cut them from the quarry must have been immense,
as well as to transport them to the place where they now stand.
The parts preserved of the two colossal are admirable pieces of sculpturc, and were finished in the most careful manner.
Behind these are two great moles, which formed the gate;
they are covered with sculptures representing chariots drawn
by two horses, each having only one conductor.

It is remarkable, that neither the colossal figures, nor the
monuments, are on a line with each other, nor with the gate:
also, they are so close together, that the distance between
the mole and the obelisks, comprehending the colossal fig-
tures between them, is but eleven paces; each of which ob-
exclus in an insalubrious position, would almost be beholder
with its fire.
The temple of Hermopolis was consecrated to Isis, whose
delivery from Typhon is sculptured on the walls in basso
relevo: it is a beautiful, elegant structure, but dreadfully
ruined.

Edfu, the ancient Latoopolis, has a temple, the portico
of which is in good preservation; it was dedicated to Jupiter
Ammon, as appears from a medallion over the gate in the
inner part of the ruin. The hieroglyphics and pictures rep-
resent a great number of sacrifices offered to this deity, and
to rams, his emblems: the most curious of these represent
the offerings made to crocodiles, and the worship of the
Nile. The triumphs of the signs of Leo and Cancer are
equally distinguished. Hieroglyphics are sculptured in relief
on the columns, very beautiful for their workmanship.
This temple is one of the most remarkable in Upper Egypt, as
well for the perfect preservation of the portico, and its parts
that still remain, and their fine execution, as for the very
interesting pictures, which relate to the banqueting of Egy-
pian worship, which are least known: here is also found one
of the remaining zodiacs. This is one of the most beautiful
monuments of antiquity; most perfect in proportion, and
beautiful in execution, of all the temples in Egypt.

Edfu, or Apollinopolis, is the most farrisuous as well as the
best preserved of all the Egyptian temples, and where the
Egyptian architecture displays itself with supreme magnifi-
cence. It was dedicated to Hermes, the Apollo of the Greeks.
Here it is that the huge materials have been employed with
the greatest care, though many of the stones have not been
placed perpendicularly on their capitals, and several of the
columns vary in their diameters. The drawing of the
figures is correct, and there is some appearance even of per-
fective in the statues of IIs, that decorate the frieze of the
portico.

The sculpture is particularly beautiful in the capitals of
the columns that decorate this temple, every one different,
but every one beautiful; they are totally original in the
composition of their ornaments, and perhaps equally ex-
cellent with the admired Corinthian, or Ionic.

The temples at Elephantine and Philae are by no means
inferior to any in Egypt; they are likewise adorned with
sculptures and paintings of the most perfect Egyptian work-
manship.

But the abodes of the dead were particularly descrip-
ted by the care of the ancient Egyptians. All the Lybian
mountain, which is half a league to the west of the Mem-
noum, and ends opposite to Medinet Abou, is formed
from its base to three fourths of its elevation, with a great
number of sepulchral grottoes: Those which are nearest the
surface of the ground are most spacious, as well as the most dec-
corated; those which are in the most elevated part of the
mountain, are much more rudely contrived and executed;
while such as hold the middle place bear an adjusted propor-
tion of space and ornament. Those which belong to the
poor are the most interesting, because they always contain
some representation of the arts which flourished, and the
trades which were practiced at that epoch. The plan of
these grottoes is in a great measure the same. A door open-
ing towards the cell displays a gallery of about twenty feet
in length, sometimes formed in a straight line; at other times
it runs off from the entrance in an angle: it is differently
supported by columns or pilasters. At the extremity of the
gallery is a well that leads to the catacombs, where the
mummies are deposed. The depth of these wells varies
from forty to fifty feet; and they are connected by long
subterranean passages rudely shapen in the rock, which
terminate in a chamber of about thirty feet square, whose
sidewalls are supported by pillars, and contain large remains of the
mummies. There are evident traces of numerous other
subterranean communications, which probably lead to other
chambers that are at present concealed.

In the upper gallery are sculptured in basso relievo, or
painted in fresco, a great number of subjects relating to
funeral ceremonies. The most interesting pictures which are
seen there, present a detail of circumstances connected with
the ancient inhabitants of the country. There are repre-
ented their first occupations, such as the chase and the
fishery. Thence we may trace the progress of civilization
in the employments of the fader, the cartwright, the potter,
the money-lender, the husbandman, and in the duties and
the punishments of the military life. Each grotto is adorned
with a ceiling painted with subjects of fancy.

The tombs of the kings are about six thousand four hun-
dred paces from the river. They have been formed in a
narrow valley in the centre of the Lybian mountain. The
ancient way thither is not known, and the spot is now gained
by an artificial passage. These sepulchres occupy a large
ravine, which is flanked by the bed of a torrent. The plan
of one of those tombs will be sufficient to explain the general
disposition of the cell.

Every grot communicates with the valley by a large gate,
which opens to a gallery hollowed in the rock; its breadth
and height are generally about twelve feet, and its length is
twenty paces to a second gate, which opens to another
gallery of the same breadth, and twenty-four feet in length.
To the right and left of this gallery are chambers of five feet
in breadth, and ten feet long. There are found paintings of
arrows of coats of mail, tygers' skins, bows, arrows, swords,
lances, and quivers. In other sepulchral chambers are found
household utensils, couches, chairs, stools, cabinets of ex-
quisite forms; and if the artist has copied what existed,
it is certain that the ancient Egyptians employed the wood of
India carved and gilded; there are also other utensils equally
elegant, as cups and vellies in all variety. Other funeral
chambers are consecrated to agriculture; others to the
utensils of the ploughman; others to instruments of music
elegantly executed. The detail of preparing food is also
there represented.
SCULPTURE.

It is in one of these chambers where are seen the two Harps which were copied by Bruce. A third gallery succeeds, of the same dimensions as the former, and leads to a chamber above the level of the other apartments, which is eighteen feet square; from this chamber is the entrance to a gallery of thirty-four paces in length. There is also an inclining gallery, whole length is twenty-eight paces. At its extremity is a corridor of sixteen paces, leading to a chamber of eleven paces, which is connected with another of the same size, by a gallery of six paces; a square portal then succeeds, supported by eight pillars; its length is twenty paces, and its breadth twenty; here is the sarcophagus which contained the mummy of the King. The Romans made some attempts to carry away this sarcophagus from the grotto where it is deposited; they had even tried to level the ground in order to facilitate its removal, but they very soon renounced the impracticable enterprise.

To the grotto of the sarcophagus another apartment succeeds, of twenty-five paces in breadth, and forty in length; the height of the tomb is seven feet, its length eighty, and its breadth fix; the total length of the gallery is two hundred and twenty-five paces. The tombs of the kings, throughout their whole extent, are covered with pictures, and hieroglyphics, but the greater part are painted in fresco, and represent the most pleasing subjects. The researches into Herculaneum have discovered a great number of paintings executed in a similar taste.

One of the most interesting of these grottoes contains a sarcophagus that is still entire, and in its place; its length is sixteen feet, and its height twelve, and its breadth fix; it still preserves the lid adorned with the figure of the king, which is a single block of granite. How this was transported across the mountain, and afterwards introduced through a subterraneous passage two hundred paces in length, we can have no conception.

From the time of Strabo there were reckoned seventeen tombs of kings; and we shall still find the same number, if we may comprehend in this enumeration a superb grotto, whose plan is equally large and beautiful with that of the sepultures of the Theban sovereigns.

This grotto is half a league to the north of the Memnonium, and is scooped out at the bottom of a mountain, whose enclosure contains many other tombs; the entrance of several of them is closed, but the greater part of them have been violated. It appears that thofe of the ancient Egyptians, who had remained faithful to their worship, endeavoured to conceal the knowledge of the sepultures of their kings from their conquerors, or from the profilers of other religions.

Two of these grottoes remain unfinished, and a third is altogether without sculpture; and some others offer to view several decorative objects in a very unfinished state.

The quarries of Sililis, in Upper Egypt, present a species of façade cut into door-ways of immense size, and porticoes, in which are other door-ways leading into tombs, in the chambers and passages of which are figures as large as life, cut in the native rock, often only rough hewn, and the walls are both sculptured and painted. On the borders of the Nile we find these porticoes, entablatures, and cornices covered with hieroglyphics cut in the rock. Beneath these are a great number of tombs, all cut in the rock. They are formed into galleries, at the end of which are funeral chambers of seven feet by ten and eight feet by twelve; these chambers, and the passages leading to them, are ornamented with hieroglyphics traced upon the rock, and finished with coloured fixtoo, representing offerings; the ceilings are also stuccoed with ornaments and scrolls; often they are arched with an elegant elliptical arch, and painted and sculptured in an exquisite style, displaying an agreeable assortment of colours, and an effect rich and graceful.

Most of the tombs are entered by a single door and gallery, and have only a single chamber, in which are one, two, or four figures as large as life, cut out of the rock, perhaps two brothers and their wives; the men sit in the middle and the women on the outside, with their hands posed under the arms of their husbands, who sit each with their arms crossed upon their bosoms. Some tombs have but one figure; perhaps of one who led a simple life; another has three figures, a man and two women; the man in the centre and the women on each side, with their hands posed under the arms of the man, who has his arms curled upon his bosom. The figures of men have little square beards, with head-dresses hanging down behind the shoulders; those of women have the same head-dresses, but hanging before their naked breasts. In some chambers the floor is cut into many tombs, of dimension and form to receive the mummmies, and in the same number as the sculptured figures. Sometimes the principal figure holds the flower of the lotus, an emblem of death. And on the side of the door-way, at the entrance, we often see the figure of a woman in some attitude of lamentation. Sometimes there are two galleries or entrance into a single tomb; and one tomb in these quarries of Sililis, the largest and best preferred of any, is 55 feet long in front and 15 high, with an entablature having five doors; the middle door is ornamented with an architrave covered with hieroglyphics; within the door is a gallery or passage 50 feet long and 10 wide, in the midst of which is another door-way leading to a chamber, at the further end of which are seven figures standing; and on the inside of the interior door are two niches, in each of which is a figure also standing; other figures are also in the passage or gallery, all cut in the rock. In the façade without the door are seven niches, three large with figures, the others smaller; those with the figures are all cut in the rock, the rest of the rock remaining in its primitive form.

Such are the ruins of a nation so celebrated, that it was the place where the wife men of that truly wise people, the Grecians, rejoiced to the school of science.

The universal and profuse employment of sculpture by the Egyptians, both in colossal and minute dimension, for public and domestic purposes, for the service of the living and the dead, all induce us to enquire into the principles and quality of their productions.

We have not only the written evidence of ancient authors, but the demonstrative evidence of remaining works, that almost the whole of Egyptian sculpture was faced, that is, representing divine qualities, attributes, and personifications, if we except the historical furies on their tombs and palaces.

The Egyptian statues stand equally poised upon the two legs, having one foot advanced, and the arms either hanging straight down each side; or if one arm is raised, it is at a right angle across the body. Some statues sit on seats, some on the ground, and some are kneeling; but the positions of their hands seldom vary from the above description. Their attitudes are of course simply rectilinear, and without lateral movement; their faces are flatish; the eyebrows, eyelids, and mouths formed of simple curves, slightly but sharply marked, and with little expression. The general proportions are something more than seven heads high; the form of the body and limbs rather round and effeminate, with only the most evident projections and hollows: their tunics or other draperies are without folds in many instances. Winckelmann has remarked, that the Egyptians executed quadrupeds better than human figures, for which he
Sculpture.

He gives the two following real facts: first, that as profusion in that country werebardorous, Greeks must be willing to represent the human figure in perfection; and, secondly, that profusion in reverence for the works of their ancestors prevented improvement. This is an amazing but well-told hypothesis, for there are statues in the capitals of nations with as great a breadth and choice of grand parts proper to the human form, as ever represented in their kings or other minor deities. In addition to the other observations on Egyptian statues, we may remark, that the form of their hands and feet are gods, they have no anatomical detail of parts, and are totally wanting in grace of motion. This last defect, in all probability, was not the consequence of a superstitious determination to perfect in the practice of their sculptors; it is better accounted for in another way: Pythagoras, after he had studied several years in Egypt, fascinated with joy of having discovered that a figure of the largest side of a right-angled triangle is equal to the two squares of the lesser sides of the same triangle; and thence it follows, the knowledge of the Egyptians could not have been very great in geometry at that time, which will naturally and sufficiently account for that want of motion in their statues and reliefs, which can only be obtained from observation of nature allied by geometry.

The date of Egyptian science in the time of Pythagoras being surmised, leads us to another consideration respecting the date of their architecture and sculpture. Most of their great works are mentioned by the ancients as done in the reign of Seoklos, and afterwards. Seoklos lived in the time of Rehoboam, king of Israel, about the time of the Trojan war, or 1000 years before the Christian era, which shows the arts of Egypt and Greece were in a progressive state at the same time. And from the Greeks refining with them to study of theology, philosophy, and science; from the great intercourse, political and commercial, between the two countries from the heroic times; from the Greeks being long settled in the city of Naukareis, and other parts of Egypt, we may fairly conclude their communication in arts was just as free as in other concerns, which seems the more likely, as there is a considerable resemblance in the features and contour of the early Greek and Egyptian statues.

The Egyptian baso reliefs are (generally but not always) engravings on the back-ground, being left with the highest part of the relief; for which practice two reasons may be assigned; first, that as many of these baso reliefs were cut in exceeding hard stones, basalt, and granite; as much time must have been consumed to clear away the ground about the figure, as had been employed to cut the figure itself; but besides the economy of time, when some thousands of figures were engraved on the sides of a lofty obelisk, or the walls of a temple: the far greater number of them were at a great distance from the eye 50, 60 feet or more; in this case the ground, being left perpendicular to the figure, the whole circuit of its outline, gave it a greater breadth of shadow and dimness to the spectator. These baso reliefs, which we comprehend in the general term hieroglyphics, or faceted gravings, represent different subjects, according to the place and purpose for which they were employed. On the walls of tombs they represent the professions, actions, and funerals of the deceased: in palaces, wars, negotiations, triumphs, processions, trophies, with civil, military, and domestic employment of kings. In temples, they were the symbolical registers of theology and faceted science. On obelisks, they express hymns to the gods, or the praises of their kings. Ammianus Marcellinus has preferred part of a translation by Hermannus the Egyptian, of the hieroglyphics on the obelisk which formerly stood in the centre of the Forum Maximus, as present the church of St. John Lateran in Rome. It imports, that the king, the lord of the country, goes to Rames the kingdom of Egypt, and descends all the earth in the city of Memphis. The temple was sufficiently pillared in the upper lines of the hieroglyphics, where a diversity is fitting; in the act of leaving a man, who kneels before him, stretching his hands to receive. In the following line the figure is seen on a pedestal, taking possession of an altar, on the side of which is the Amon, and on the top the sacred hawk, symbol of Osiris. This was the sacred symbol of Egypt.

The numerous works of Egypt have broken every foreign visitor with wonder and awe, to the members of the French Institute. However, few, one of their buildings is equal to many of the most considerable Greek buildings taken together, and M. Ribot observes, those works are so prodigious, they make every thing we do look little; and indeed, if we consider the execution of a statue 75 feet high, in so hard a material as granite, the boldest heart would be appalled at the incredible labour and difficulties of the work.

In the Egyptian sculpture we shall find some excellent first principles of the art. Their belt figures are divided into seven heads and one-third, or seven heads and one-half; the whole height of the figure is divided into two equal parts at the pubis; the rest of the proportions are natural, and not disagreeable. The principal forms of the body and limbs, as the breasts, belly, shoulders, breeches of the arm, knees, shin-bones, and feet, are expressed with a lively roundness, although without anatomical knowledge of detail; and in the female figures these parts are often puffed considerably, and give the greatest elegance and beauty. The forms of the female face have much the same outline and progression towards beauty in the features as we see in some of the early Greek statues, and, like them, without variety of character; for little difference can be traced in the faces of Isis, in her different representations of Diana, Venus, or Terra, or indeed in the face of Osiris, although sometimes understood to be Jupiter himself, excepting that in some instances he has a very small beard, in shape resembling a peg. The hands and feet, like the rest of the figure, have general forms only, without particular detail; the fingers and toes are flat, of equal thickness, little separated, and without distinction of the knuckles: yet altogether their simplicity of idea, breadth of parts, and occasional beauty of form, intrile the skilful beholder, and have been highly praised by the best judges, ancient and modern.

In their baso reliefs and paintings, which require variety of action and situation, are demonstrated their want of anatomical, mechanical, and geometrical science, relating to the arts of painting and sculpture. The king, or hero, is three times larger than the other figures. Whatever is the action—a figure, a battle, taking a town by storm, there is not the slightest idea of perspective in the place; or magnitude of figures or buildings. Figures in male action are equally destitute of parts, and other anatomical form, as they are of the balance and spring of motion, the face of a bow, or the just variety of line in the turning figure. In a word, their historical art was reducing the beholder, in the most manner they could, according to the rude characters they were able to make. From such a description, it is easy to understand how much their attempts at historical representation were inferior to their figure statues.

What has been hitherto said of Egyptian sculpture describes the ancient native sculpture of that people. After they
The Ptolemies, succeflors of Alexander the Great, were kings of Egypt, their sculpture was enlivened by Grecian animation, and refined by the standard of Grecian beauty. In proportions, attitude, character, and drefs, Obris, Isis, and Osiris, their three great divinities, put on the Macedonian costume; and new divinities appeared among them, in Grecian forms, whose characteristics were compounded from materials of Egyptian, Etafen, and Grecian theology and philosophy.

In the reign of the Roman emperor Adrian, a number of statues, in imitation of the ancient Egyptian, were made to decorate the Canopus in his magnificent villa of Tivol; several of which have been dug up, and placed in the Capitoline Museum. But Winckelmann has remarked of these, that they may be known from the ancient Egyptian sculpture, having so hieroglyphics on them. But, besides this distinction, they are entirely unlike the genuine Egyptian; as the drawing and character are Roman, in Egyptian attitudes and dresses.

The ancient authors, who give the most satisfactory account of Egyptian antiquities, are Herodotus, Diodorus Siculus, Josephus, Strabo, Clemens of Alexandria, Jamblichus, and Orus Apollo.

The best modern books on this subject are Pocceke's Voyages, Savary's Travels in Egypt, Norden's Egypt, Denon's Egypt; to which may be added, the most magnificent work of Ancient and Modern Egypt, now publishing in Paris, which will occupy twelve folio volumes, containing 840 plates, from the observations, researches, accounts, and drawings, of the learned men and artists of the French nation, who formed the French Institute.

Of Grecian Sculpture.—After Egyptian sculpture, the course of our subject naturally leads us to consider the fame art in Greece, which is thought by some to have received its first principle from Egypt, and certainly preferred the character of Egyptian sculpture in many of its works, down to a late date; as Plini observes upon the works of Egina.

In early times, the greater divinities were worshipped under the form of rude flones; and afterwards the lifeless representation of the human figure was attempted. with the eyes a little opened, the arms close to the sides, and the legs united in one common pillar for the support of the mass.

But about 1300 years before the Christian era, a sculptor appeared, whose works exalted the praise of poets, the speculations of philosophers, the record of historians, and continued to be perceived with zeal, and spoken of with respect, centuries after sculpture had reft to its zenith. This was Dædalus, the countryman and contemporary of Thæfeus, not inferior perhaps in fame and variety of adventures to that hero. Born of a royal race, the occasional friend and adversary of kings, admired for his works when living, and honoured with a chapel by the Egyptians after death; to him are attributed various mechanical inventions, fabulous and real: a fine portico to the temple of Vulcan at Memphis; the Cretan labyrinth, which was the copy of a hundredfold part of the Egyptian labyrinth. Diodorus Siculus speaks of his works in Sicily. Paufanias mentions those remaining in Greece in his time, nine in number, of which three may be particularly noticed: one a naked Her- cules of wood. The works of Dædalus are indeed rude, says Paufanias, and uncomely in aspect; but yet they have something as of divinity in their appearance.

Paufanias, besides the high character given of this statue, mentions it twice in his Grecian Tour; from which we must understand that it was held in considerable esteem and veneration. This would naturally lead us to hope we are not without some copy of it in gems, coins, or small bronzes, by which all the most famous works of antiquity were multiplied. In the British Museum, as well as in the other collections of Europe, are several small bronzes of a naked Hercules advancing, whose right arm, holding a club, is raised to strike; whilst his left arm is extended bearing the lion’s skin as a shield. From the style of extreme antiquity which characterizes these statues, the rude attempts at bold action, the peculiarities of Dædalus, the general adoption of this action in the early ages, the traits of favage nature in the face and figure expressed with little knowledge but strong feeling, by the narrow loins, turgid muscles of the breast, thighs, and calves of the legs, we shall find reason to believe they are copied from the above-mentioned statue.

The fame author says, the Gnothians had a chorus in white flone, made by Dædalus for Ariadne, which is mentioned in the 18th book of the Iliad, as youths and damsels dancing hand in hand. The most early Greek baso relieves and paintings represent choruses of the Graces and Hours in this manner.

Endæus, the disciple of Dædalus, made a statue of Minerva, which Paufanias saw in the Acropolis of Athens. The learned author of the Introduction to the volume of Sculpture, published by the Dillettanti Society, supposes the heads of Minerva, on the early coins of Athens, were copied from this statue, which seems very reasonable, when we compare the style and costume with other works of the highest antiquity. And here we must observe, that in the early times of which we are now speaking, the rude efforts were intended to represent divinities and heroes only. Jupiter, Neptune, and several heroic characters, have the self-same face, figure, and action, as the Hercules of Dædalus described above; the same narrow eyes, thin lips, with the corners of the mouth turned upwards, and pointed chin; the same narrow loins; turgid muscular forms of breast, thighs, and legs; the same advancing position of the lower limbs; the right hand raised before the head, and the left hand extended; and their only distinctions were, that Jupiter held the thunderbolt, Neptune the trident, and Hercules his palm branch or bow; as may be seen in ancient small bronzes and coins of Athens and Paflum, and on the most ancient painted vases. The female divinities were clothed in draperies, divided in few and perpendicular folds; their attitudes advancing like those of the male figures. The hair of both male and female statues or paintings of this period is drefled with great pains, collected in a club behind, and sometimes entirely curled, in the fame manner as practised by the native Americans, and the inhabitants of the South sea islands. Dædalus and Endæus first formed their statues of wood. Metal was also used for various purpofes of sculpture in the most ancient times, as we learn from Homer, Hecfod, and Plutarch.

Dipanous and Scyllis, the Cretans, were celebrated for their statues in marble, about 776 years before Christ; still retaining much of the ancient manner in the advancing position of the legs, the drawing of the figure, and the perpendicular folds of drapery, diversified in zigzag edges. Soon after elaborate finifhing was carried to excefs, undulating locks and spiral knobs of hair, like cockle-shells, as well as the drapery, were wrought with the most elaborate care and rigid exactness, whilst the tafteles and barbarous character of the face and limbs remained much the fame as in former times. This passion for high finifhing in sculpture, will reconcile to our reason a passage in Pliny (b. xxxv. c. 8), which has frequently been thought to difagree with the general history of ancient painting: he says, "that the picture of the battle of Magnete, painted by Bularchus, was paid for, with
with its weight in gold, by Candaules, king of Lydia, who was coeval with Romulus, and lived in the 26th Olympiad, or about 750 years before Christ: thus," continues Pliny, "proving the fame and perfection of the art." Now, according to the same author's account, the ancient painting did not arrive at its greatest perfection until after the time of Phidias or two hundred and fifty years later; and therefore it is likely that Bularchus's picture was chiefly valued for the fame high flattery we see in the earliest marble statues, of which the following are examples:—colossal busts of Hercules and Apollo, in the British Museum, most likely done by Dipoenus and Scyllus for the Sicyoniens:—very ancient statues of Minerva, and a priest of Bacchus, lately in the Villa Albani, published by Winckelmann in his Monumenta Inedita, and Storja dell Arte. To these might be added examples of extreme mutilation in early Greek picture and other bronzes. This observation on Bularchus's picture, and the sculpture of the same time, will naturally lead to another of more general comprehension, that the improvements in sculpture we have reason to believe followed those in painting according to the dates, as far as we are able to ascertain them in remaining works. Soon after this time may be reckoned the Amymone Apollo, described by Paufanias as very ancient. The throne, with the image fitting upon it, Paufanias conjectured at not less than thirty cubits; he enumerates the subjects sculptured upon it; they comprehend the history of the fabulous ages underneath. The base is the sepulchre of Hyacinthus, which is entered by a brazen door. In the sepulchre are many works of sculpture: The figure of Apollo, Paufanias describes as of very rude art. Paufanias also mentions a brazen Hercules of ten cubits, as the work of a disciple of Deldalus. Philocles the Egyptian, or Cleantus the Corinthian, is said first to have introduced the manner of the Greeks in the practice of which they were followed by Arides the Corinthian, and Telephius the Sicyonian, who used other lines within the outline, to express the marking of the body and limbs, also writing the names of those they painted, which agree with the earliest paintings on Greek vases, as their attitudes and peculiarities agree with early sculpture. Cimon Chiron invented cataphory, as the oblique representation of images, to give different views of the face, looking up, looking down, and looking backwards: he represented the veins, and the folds and plaits or wrinkles in garments. This Cimon is mentioned as living before the time of Phidias, which affords an additional argument for believing improvements in painting to have preceded those in sculpture; because oblique views of objects, and the veins of the limbs and body, seem not to have been attempted in sculpture before the time of Phidias.

Fortunately for us, the compendious history of painting and sculpture, left by Pliny, was selected from the writings of the best Grecian artists, and arranged, with attention to the several improvements, in chronological order, with such perspicuity and comprehension, that whenever, from the brevity of the work, we do not find all we wish for, yet by attending to the information before and after, we shall be enable to supply the defects from other writings or monuments of antiquity. In this manner we shall satisfy ourselves concerning the progress of sculpture, in the two hundred and fifty years which elapsed between the time of Dipoenus and Scyllus and that of Phidias. The better drawing of the figure, with a more careful attention to its parts, more precision and variety of attitude, a less elaborate curling of the hair, the forms of the figure better shown through the draperies, are all certain signs of a nearer approach to the age of Phidias. If we add to these observations the different ages of writing on works of sculpture, what better are wanting, and whether the inscription is in the Boeotothephen or ploughing manner, we shall not err much from the date of the work.

From the few historical observations now offered, it is evident that sculpture was eight hundred years from the age of Deldalus, to the time immediately preceding Phidias, in attaining a tolerable representation of the human form, which proves the slow growth of art perfected by manual labour in the infant state of science; whilst the means of subsistence are precarious, the rights of individuals undeemed, and the general attention of society employed on self-preference and defence, rather than on the increase of comfort or civilization of manners. Poetry and oratory, the more independent efforts of mind, appear in the earliest states of society, distinguishing man as an intellectual and rational creature, better the first feeds of knowledge, lay down theories for the government of future generations, expand the mind, and direct the power towards whatever is most useful and most desirable in the more perfect states of humanity.

The chief occurrences in the early history of Greece are, the Argonautic expedition; the war of Thebes; and the taking of Troy; in which particular heroism, or the united achievements of petty states, are interwoven with poetic fiction. Their consequences produced no considerable change in the manners of the people or the character of the country; but the battles of Marathon and Salamis, which destroyed the Perian army, whole myriads, like locusts, swarmed over the country, destroyed the Perian power, and gave a beginning to the Grecian or third great monarchy of the world. An event of so much importance has been conducted by changing fortune and transferring power in such a manner that a portion of the civilized part of mankind, raised the character of Greece, in proportion to the abatement of Persia. The Greeks, particularly the Athenians, the champions of the war, whose heroic ardour was increased by success, sought additional distinction by every great and praiseworthy exertion of body and mind in arts and arms. The accumulated wisdom of ages, and discoveries in science, were taught by their philosophers; their temples and public buildings were raised with a magnitude unknown before, and decorated with all the powers of art. Aechylus, Euripides, and Sophocles, ennobled the minds of the people by their dramatic poetry. The five exercises which formed the body to exertion and beauty, and the mind to fortitude and patriotism, were universally practised, cultivated, and honoured. In this general spirit of enterprise and improvement, sculpture appeared in the school of Phidias, with a beauty and perfection which eclipsed all former efforts.

About 450 years before the Christian era, Phidias flourished at the same time with the philosophers Socrates, Plato, and Anaxagoras; the statesmen and commanders Pericles, Miltiades, Themistocles, Cimon, and Xenophon, with the tragic poets above-mentioned. This period was as favourable in its moral and political circumstances, as in the emulation of rare talents, to produce the display and encourage the growth of genius.

The city and citadel of Athens had been burnt by the army of Xerxes; but the Greeks, being conquerors, raised more stately buildings in the room of those destroyed. Phidias was engaged by Pericles in the superintendence and decorations of the temple of Minerva, and other public works.

Superior genius, in addition to his knowledge of painting, which he practised before sculpture, gave a grandeur...
to his compositions, a grace to his groups, a softness to flesh, and a flow to draperies, unknown to his predecessors, the characters of whole figures were stiff rather than dignified; their forms either meagre or turgid; the folds of drapery parallel, poor, and representing geometrical lines, rather than the simple but ever varying appearances of nature.

The discourses of contemporary philosophers on mental and personal perfection, assisted him in selecting and combining ideas, which stamped his works with the sublime and beautiful of Homer's verse.

How this sculptor was esteemed by the ancients will be understood from the following short quotations. Pliny says, "Phidias was most famous through all nations." And when enumerating the most celebrated sculptors of antiquity, he says, "but before all, Phidias the Athenian;" and Quintilian says, that "his Athenian Minerva and Olympian Jupiter, at Elis, polished beauty which seemed to have added something to religion, the majesty of the work was so worthy of the divinity."

After such positive and magnificent testimony, there will be little room for our surmise, in the descriptions, fragments, and other authentic memorials, of some works only which he conducted and performed; such as the temple of Minerva, and the Acropolis of Athens, erected by Icacinus and Callocrates, under the direction of Phidias; and to him it is we likewise owe the compositions, figure, and character of the sculpture, in addition to much affinment in the drawing, modelling, and choice of naked figures and draperies, as well as occasional execution of parts in the marble.

Pliny says, the emulators of Phidias were Alcamenes, Critias, Nellocles, Hegias; and twenty years afterwards, Agelades, Callon, Polycletus, Phradmon, Gorgias, Lacon, Myron, Pythagoras, Scopas, Parnes. In this list we certainly have the names of the sculptors employed on the temples of Minerva and Thefeus; and as the styles of different hands are sufficiently evident in the alto and baso relieves, so there might perhaps be no great difficulty in tracing some of the artists by resemblance to others of their known works.

The two pediments of the temple of Minerva were each eighty-eight feet long, filled with compositions of entire groups, and statues from eight to nine feet high. The story of the western pediment related to the birth of Minerva, or rather perhaps represented her introduction among the gods. The eastern pediment was occupied by the contest of Neptune and Minerva for the patronage of Athens. Forty-three metopes were charged with combats of the Lapithes and Centaurs, and a frieze of three hundred and eighty feet round the wall of the temple, under the portico, was decorated with the procession of the Grecian states, in honour of Minerva, in chariots, on horseback, leading animals for sacrifice, bearing offerings, and presenting the sacred veil, in presence of the gods, sitting on thrones to witness the solemn ceremony.

The marquis Nanteuil had a drawing made of the western pediment of this temple, when the statues were all, excepting one, in their places; and notwithstanding some mutilations of parts, the whole was sufficiently entire for the composition to be perfectly understood from the marquis Nanteuil's sketch, carefully compared with the original fragments in the earl of Elgin's museum. In the centre, Jupiter sits holding his sceptre in his right hand, the thunder in his left; on the right of Jupiter, in an advancing position, Minerva takes possession of her car, while the reins are governed by Themis and Mars; from behind Themis, a genius leads Victory forward to attend the patroncnes of Athens; on the left of Jupiter, Vulcan stands by his mother Juno; Amphitrite sits next, whose feet rest on a dolphin; Latona succeeds, with her infant Apollo and Diana, beautifully implying that the maturity of divine wisdom was older than the sun and moon. The left group is Venus sitting on the lap of Ocean; the figures at each end of the pediment are not shewn, because they are mere contingents, spectators only; not partaking in the action.

The idea of this composition seems to have been suggested by Homer's hymn to Minerva, a short poem, but one of the author's highest flights; in which he describes Pallas in full figure, and completely armed, issuing from the head of Jove; Olympus, the whole earth, and surrounding seas, trembling at the vibration of her spear; the fun flaying his couriers in their race, and partaking in the fame amazement with the other immortals.

The statue of Minerva, in the Parthenon at Athens, one of the masterpieces of Phidias, is thus described by Pliny, Paufanias, and other ancient authors. It is in height twenty-six cubits, formed of ivory and gold, standing upright, her tunic reaching to her feet, holding a victory fix feet high in her right hand, and a spear in her left; the drapery is of gold; the uncovered parts of the statue are of ivory; the head of Medusa on the breast-plate of the goddess is of ivory; at her feet is her shield; in the convex part of her shield the Amazonian war; in the concave part is the war of the gods and giants; in the base Pandora's history: the gods are here pretent thirty in number; the Lapithes and Centaurs are sculptured on her sandals; a serpent at her feet admirably executed; a sphynx on the top, and a griffon on each side of her helmet. The quantity of gold in this statue was forty talents. Plato says the eyes were of precious stones.

There was also, in the citadel of Athens, another statue of Minerva by Phidias, thus described by Paufanias. Of the spoils taken at Marathon from the Persians, Phidias made Minerva's statue of brais, in whose shield the battle of the Lapithes and Centaurs was engraved by Myes, and painted by Parrhalus, the son of Evenor. The top of the spear, and crest of the helmet, might be seen by those who fall by Sucion.

But the great work of this great master, the allonishment and praisef of after ages, was the Jupiter at Elise; thus described by Paufanias. The god is seated upon his throne, made of gold and ivory, a crown of olive branch on his head; in his right hand a Victory, alof of ivory and gold; the heer a fillet, and is crowned; the left hand of the goddess holds a sceptre of various coloured metals, a eagle of gold sitting upon the sceptre; his garments are of gold, and on his garment are wrought animals and flowers, particularly the lily; his hands also are of gold; the throne is variously ornamented with gold and gems, and also with ivory and ebony: on it animals are painted in their proper colours, and sculptured with great labour. Four victories, as in the dance, are on the hinder feet of the throne, two on each side; and on the front the children of the Thébans taken away by the sphynx; and beneath the sphynxes, Niobe and her children slain by Apollo and Diana; on the frames that join the feet of the throne ornaments are carved; on that in front Hercules warring with the Amazons. Paufanias numbered upon them all together twenty-nine figures. Among Hercules' companions was alof Pallas. There were also pillars which adjoined to the feet supporting the throne, equal in size to the feet. There is not an entrance underneath the throne, as under that of Apollo at Amyclis. It is hollow, but the spectator cannot enter, because a wall includes the throne. Of this wall, that part which fronts the door is painted
SCULPTURE.

Alessander was celebrated for his Venus Aphrodite, to which Phidias is said to have given the last touches.

Praxiteles excelled in the highest grace of youth and beauty: Pliny says he not only excelled the ancients by his marly statues in the Cesaricu in Athens, but that the Venus was preferable to the rest, and all other statues in the world, to which many failed to add. This sculptor having made two Venus, one with dewy, the other without; the Caesars preferred the clothed figure, on account of its severe modesty. The fame price being let upon each, the Caesars decided for the Venus, and afterwards refused it to King Numa, who would have forgiven them an immense debt in return; being resolved, says our author, and with reason, to suffer any thing, so long as the statue of Praxiteles embodied Numa. The temple was entirely open in which it was placed; because every view was equally admirable. The figure is known by the descriptions of Lucian and Cebrenus; and it is represented on a medal of Caracalla and Plautilla, in the cabinet of France. This Venus existed in Gnidus during the reign of the emperor Caracallus, or about 400 years after Christ.

This statue seems to offer the first idea for the Venus de Medicis, which is likely to be the repetition of another Numa also the work of this artist, mentioned by Pliny.

On the reverse of the empress Lucilla's medals, is a clothed Venus, with an apple in her right hand; which from the grace of its attitude, and its resemblance to several antique marble statues, is likely to be the clothed Venus chosen by the Caesars.

Among the known works of Praxiteles, are his satyr, cupid, Apollo, the lizzard-killer, and Bacchus leaning on a fawn.

The celebrated Venus of Gnidus was found, about eighteen years since, in the neighbourhood of Rome, which was afterwards the property of Duke Brafides, nephew of the late pope Pius VI.

Polycletus of Sicyon, the fheolar of Agiledes, was particularly celebrated on account of his Doryphorus, or lance-bearer; and Diadumenus, or youth binding a fillet round his head. This statue was valued at an hundred talents. The Doryphorus was called the Rule by authors, from which they studied.

The Dicobolus of Myron is ascertained by an antique gem, and the description of Quintilian, who apologizes for its forced attitude. An ancient example of this figure is in the British Museum.

The Dicobolus of Naucydas is uniformly admired for its forms and momentary balance.

The wounded man, in which might be seen how much of life remained in him, was the famous work of Ctesilas, and perhaps is the fame as the statue commonly called the Dying Gladiator, but more properly a dying herald, or hero, according to Winkelmann.

Ctesilas, or D_NEWIUS, is known by his wounded Amazon. Pliny mentions the nine muses by Phileus of Rhodos; and the muses also, brought by Fulvius Nobilius to Rome. From one of these series must be the greater number of those formerly in the pope's museum, now in the gallery of France, of which the Comedy is remarkable for grace, and the Tragedy for grandeur.

The Hermaphroditic of Polycleus is one of the most delicate and graceful productions of antiquity.

The Apollo Phileus, or in love, by Cnachus, is witnessed by many fine repetitions in the different galleries of Europe.

The Ganymede, borne in the eagle's talons, is exactly descried by Pliny. An example of this work exists in the pope's museum.
SCULPTURE.

The Apollo Belvedere is believed, by the learned Vitconti, to be Apollo Alexicacos, the deliverer from evil, the work of Calamus; mentioned both by Pliny and Pausanias; and the history of its removal is given in the Museum Phum Clementinum. Only one small antique repetition of this statue is to be found; and indeed admirable and sublime in its beauty as it is, there is a reason which might render it less popular among the ancients than the moderns. Maximus Tyrius describes a statue by Phidias very similar to this, but in greater motion, either discharging an arrow, or preparing to do so. (Τεχν.) There are traces of this statue in some ancient baso-relieves; and it is possible the stronger expression of Phidias’s work, together with the authority of his name, might have diminished the public attention to Calamus in a comparative production.

The Venus de Medicis is fo popular a favourite among the Greeks and Romans, that a hundred ancient repetitions of this statue have been noticed by travellers. The individual figure is said to have been found in the forum of Octavia. The style of sculpture seems to be later than Alexander the Great; and the idea of this statue seems to have its origin from the Venus of Gnidos.

We may now notice some statues of great excellence, which Pliny has not mentioned. And no wonder they are omitted, when of more than 11,000 reckoned in his history, he professes to give a catalogue of about 500 only.

The colossal statues on Monte Cavallo in Rome we may fairly presume to be the works of Phidias and Praxiteles, as inscribed on their pedestals; because the animated character and style of sculpture seem peculiar to the age in which those artists lived; and because, in the frieze of the Parthenon there is a young hero governing a horse, which bears so strong a resemblance to those groups, that it would be difficult to believe it was not a first idea for them by one of those artists.

The heroic statue by Agasias the Ephesian, commonly called the Fighting Gladiator, is shewn by the ingenious and learned Abbate Fea, to be Ajax, the son of Oileus, as his figure is fo represented on the coins of Locris, his country.

The Hercules Farnefe was evidently one of the first favourites of antiquity, from its frequent repetitions in bronze and marble, gems and coins. Its history, according to the facts, seems to be this. The city of Prieneus was twice besieged by Philip of Macedon; the citizens, however, by the strengh of their situation, their own valour, and the intervention of friends, preferred their liberty. As their city was dedicated to Hercules, they represented him on their coins resting from his labours. The floating figure is the Hercules Farnefe, which, on the coin, was copied, as usual, from an honoured statue in the city; most probably from the work of Glycon the Athenian, whose country once delivered them from the oppression of Philip. The style is later than the time of Alexander.

We shall now proceed to those precious monuments of art, the ancient groups; in which we see the sentiment, heroism, beauty, and sublimity of Greece, existing before us.

The group of Laocoön, animated with the hope of agony of the father and sons, is the work of Apollodorus, Athenodorus, and Agelander of Rhodes. The style of this work, as well as the manner in which Pliny introduces it into his history, give us reason to believe it was not ancient in his time.

Zethus and Amphion, tying Dirce to the bull’s horns, an example of filial vengeance for a perfecuted mother, is as heroic in conception as wafhy in execution. The restorations of this group are fo bad, that they only become tolerable by something like an assimilation of spirit in their union with the ancient and venerable fragment. It is the work of Apollonius and Tauricus of Rhodes.

The group of Hercules and Antauris, in the Palace Pitti at Florence, may be a marble, from the bronze of which the copyist inferred the name of the original artist.

The groups of Atreus, bearing a dead son of Thyettæ; Orestes and Elektra; Ajax supporting Patroclus; are all examples of fine form, heroic character, and sentiment. There seems only to be one reason for their being omitted by Pliny, that they were too recent at that time to have obtained an equal rank in public estimation with the fine works of Phidias and Praxiteles, and their immediate descendants.

The group of Niobe and her youngest daughter, by Scopas, is an example of heroic beauty in mature age. The sentiment is maternal affection: the expotes her own life to shield her child from the threatened destruction.

The separate statues of the children all partake of the same heroic beauty, mixed with the passions of apprehension, dismay, or death.

To this series belongs that fine example of anatomical study, in difficult but harmonious composition, the group of The Boxers.

The beautiful and interesting group of Cupid and Psyche is not mentioned by Pliny, perhaps for the same reason that several other fine works are not noticed, because it was after the times of those great masters who were looked on as the standard of excellence in his days. It is most likely to have been produced after the reign of Augustus, when the Pythagorean philosophy was revived, from which its subject is taken.

From what has been said, it will appear sculpture did not arrive at its maturity until the age of Phidias, 490 years before the Christiant era; and Pliny’s catalogue of the most celebrated Greek artists continues 160 years later, or to 330 years before Christ. After which time, however, the Laocoön, and several of the finest groups and statues, seem to have been executed; nor can we believe, from the admirable busts and statues of the imperial families still remaining, that sculpture began to lose its grace until the reign of the Antonines; and, indeed, fo strong were the flaminium of Grecian genius in the art of design, that after the time of the Iconoclasts in the fifth and sixth centuries, when the noblest works were destroyed, when great works of sculpture were not required, even then, and until Constantinople was taken by the Turks in the 15th century, the Greeks executed small works of great elegance, as may be seen in the diptychs, or ivory covers to confular records, or faced volumes used in church service.

The works of sculpture, here enumerated, will also shew, that almost all the great and most valued productions were of marble, and not bronze, as fome have been inclined to believe. And although several of the statues mentioned by Pliny were bronze, from which we have marble copies, yet all the groups, with two or three exceptions only, are marble; and some of the most celebrated statues, as the Veneres, and the Cupid by Praxiteles, with many others.

The principal schools of sculpture were Athen and Rhodes. The sculptors of the Laocoön, and the Torus Farnefe, and the Colossi, were Rhodians; and it is almost incredible, that from this little island, only forty miles long, and thirteen broad, the Roman conquerors brought away 300 statues. But we shall more readily believe this when we recollect that the force and enterprize of these islanders were sufficient to conquer the navy of Antiochus, commanded by Hannibal.

Sicily had long been the work-shop of metals of all countries.
SCULPTURE.

countries. Eginia was also famous for bronze sculpture, and continued the Egyptian style.

Etruscan sculpture must be considered entirely the work of Greek columnists and their disciples.

The Sicilian sculpture is also Greek. Some of their finest works in particular are of the Corinthian school.

At the enterprise and taste of the present age have rejured two noble examples of Etruscan sculpture, the pediments of the temple of Jupiter Pancenum in the island of Eginia, and the frieze which surrounded the interior of the temple of Apollo Epeiros at Phrygilla, it may be proper to give some description of them in this place.

The figures, which were decorations of the east and west pediments of the temple of Jupiter Pancenum, were found among the ruins, nearly under the site in which they had been originally placed: their number was nine in the west pediment; that in the centre was the figure of Minerva; the rest seemed to be combatants, as well as in this pediment as in the six figures in the east pediment. On each side of an ornament, in the centre of the west pediment, were two female figures; and at each corner of the pediment the remains of a griffin. The statues were of fine small nature; and, according to Pliny's description, partaking of the Egyptian style of workmanship.

Among the ruins of the temple of Apollo Epeiros at Phrygilla, in the Argolis, were discovered, in many pieces, the frieze which adorned the interior of the temple. They represented the battle of the Athenians with the Amazons, and the Lapithæ with the Centaurs. The compositions are grand and energetic; the actions are natural, original, and elating; the lines of the bodies and limbs are beautifully variegated by the draperies, as flowing from the motion of the figures, or furnished in the air by impulsive wind; the beauty of the figures and countenances is heroic; and the general style and character of the work renown the after-locations in the temple of Theseus. The figures are about two feet high; and the whole extent of the different baso reserves, taken together, about ninety feet.

Of Roman Sculpture.—The earliest inhabitants of Italy, without doubt, practised the same kind of barbarous art, which is common in all early stages of society; but the accounts given by Herodotus, Diogoras Siculus, and other Greek writers of indisputable authority, concerning the emigrations of Greeks into Italy, who settled in that part which has been called Magna Graecia, comprehending nearly the whole western coast of that country, together with the evidence of nearly every work of art which has been discovered within those limits, prove satisfactorily, that all the earlier painting and sculpture, worthy to be called so, are properly colonial Greek, either the production of Greek artists themselves, or of natives who were their scholars.

We may observe upon their coins, that they all seem to have been derived from the earliest coins and weights of Greece. Their earliest coin money or weights, signed with an α, lead to a strong suspicion that they were imitations of similar weights alluded to by Homer, which had relation to the value of an α. Their coin casts or weights are also marked with the head of Janus, with two faces on one side, and the prow of a ship on the other; but it is to be observed that this double-faced Janus, when bearded, is only an imitation of the Greek heads of Jupiter, or the eastern Bacchus, who, according to the earlier systems of philosophy, was that which is past and that which is to come. When the head of Janus is without a beard, it sometimes seems to be a copy of the head of Hercules, and sometimes of Mercury; and in order to leave no chance of being deceived in the personage, he is represented with the pectus or hat upon his head, as well in the double as in the single head; besides which, all the divinities represented on such coins or cast weights, are but copies from well-known heads of the divine divinities, as Jupiter, Hercules, Mercury, Ceres, &c.; and by far the greater number of them from Greek heads of these divinities not earlier than the time of Phidias.

Concerning their painting, though it may be difficult to make the same allusion to politically and to extensively as that concerning their coins; yet we must assert that the subjects of those paintings, whether on walls or canvas, resemble Greek philosophies, Homer, personages, and stories; scenes from the Greek tragedies or Greek history; and that those representations in those paintings are written in Greek, expressing Greek names of the artists who painted, or the persons represented.

The sculpture also which has been called Etruscan has the same Greek characteristics with the paintings; to which we may add, in many instances, that it represents Greek arms and dresses.

The accounts given by Pliny of the figures of the Roman kings, and other illustrious personages of early times in the Capitol, together with the Terra Cotta figure of Jupiter Capitolinus, were from the Etruscan schools of art established in Etruria; and such were all the works of painting, sculpture, and architecture, executed for the early Romans, who do not appear to have polluted any works of magnificence or distinguished merit, before the Scipios introduced them to an acquaintance with Greek arts and letters.

After the enormous ravages and barbarities of Mummius at Corinth, and Sylla at Athens, the Romans ingrafted taste on rapine, and exhibited an inordinate curiosity and ostentation for works of fine art, which puffed in home instances for patronage. They filled their palaces, villas, temples, and public places with the spoils of Greece.

Although some general heads of Greek art have been already delivered in this dissertation, yet as Pliny the Elder's writings contain such satisfactory accounts of Etruscan, Italian, and Greek sculptur, it will be highly proper to give the English reader these accounts in his own words, which were collected from the writings and treatises of the ablest and most learned artists among the ancients. Pliny's Natural History, l. xxxiv. c. 7.

The flautary art was familiar in Italy in ancient times, as is shown by a Hercules consecrated by Evander, as it is said, in Foro Boario, which is called the Triumphal, by his having on the triumphal habit: besides the double Janus dedicated by king Numa, which expresses peace and war, and by its fingers signifies the number of days in the year, the god himself indicating the times and feasts of the year. There are also Tuscan statues dispersed very widely, which there is no doubt were made in Etruria; such were also believed to be their gods, except by Metrodorus Scipius, who offered it to the Senate and is said to have been by Brutus, of the ancient Romans, for two thousand statues, when the Volscians were conquered, were dispersed abroad. We have wondered to see the original statues of ancient Italy, of wood perhaps, or modelled in clay, the images of gods dedicated in temples until the conquest of Asia, from whence came luxury.

It will be proper to speak of the first origin of expressive likenesses in that kind which the Greeks call modelling, and that it was prior to flautary. This would extend to infinity in a work of many volumes, if any person should follow up the subject: every one does what he is able.

When Scipion was at Carthage, the statues were made in the scene of a temporary theatre. Mummius, when he conquered Achaea, filled the city; but dying, left his daughter without a dowry, which was insupportable. Lucullus brought many; from Rhodes there were as many as three thousand statues.

Mutianus.
SCULPTURE.

Mutianus, thrice consul, brought not fewer from Athens: from Olympia and Delphi, it is believed, a greater number.

What mortal can recount those which are most distinguis hed or noted for some reason or other; indeed, to have named the distinguished artists would be a pleasurable task. Their number also is infinite, when Lytippus alone produced to the number of 610 works, which were all famous; their number at his death, when his heirs opened his treasures; he was used, on receiving his payment, to deposit a golden denarius for every work. The art, in the success of its darnings, is elevated above human faith. One example of this fact we shall offer: the mutilation expressed is not of God nor of man. Our age four in the Capitol, before it was consacrared in the fire of Vitellius's times, in the chapel of Juno, a dog of brasses, licking his own wound, whose most wonderful and unequalled verisimilitude suggested the reason why it was dedicated: the life of its keepers was pledged for its safety. Innumerable are such daring examples of art: males have been deviued equal to towers. Statues which are called Colossus, such as Apollo in the Capitol, brought by M. Lucullus from Apollonia, a city of Pontus, of 30 cubits: its expence was 500 talents. Such, in the Campus Martius, is the Jupiter dedicated by Claudius Caesar, which is called the Pompeian, from its vicinity to Pompey's theatre. Such is that at Tarentum, made by Lytippus, of 40 cubits; admirable in this, the hand being stretched out and in danger of being broken by the stormy wind; the artift therefore provided, it is said, within a little interval, an opposing column, to prevent a great wind from breaking his work. Consequently, because of its magnitude, and the labour required, Fabius Verrucosus did not meddle with it at the time he brought from hence the Hercules which is in the Capitol. But above all, as objects of admiration, was the Colossus of the fun of Rhodes, by Chares the Lindian, the disciple of Lytippus before mentioned, 70 cubits in height. This statue, after 50 years, was thrown down by an earthquake, but lying prostrate it was still a wonderful spectacle; few could clasp round its thumb; its fingers were larger than whole statues. The vault caverns of its broken members were displayed within great mafles of fHONE, whose weight kept it fleadfast. Twelve years it was in making, at the expence of 300 talents, which were supplied by king Demetrius, being interrupted by the tediousness of delay. There are other less Colossus in this city, 100 in number, each of which would enable the place wherefore it was fixed. Besides these were those of the five gods made by Bryaxis, who made many Colossus in Italy, in particular an Apollo, which is seen in the Tuscan library of Augustus, 50 feet high, of fine brasses, and exquisite workmanship. Sp. Carvilius made a Jupiter, which is in the Capitol, from the breast-plates, helmets, and greaves taken from the Sammites, of an ampli tude to be seen from the temple of Jupiter Latiaris. The ref of the figures which are before the feet of the statue, are also from his file. Two heads also are admired in the fame Capitol, which P. Lentulus, the conful, dedicated, one made by Chares above spoken of, the other by Decius, overcome in the comparison to that degree, as feemed by no means probable, according to the works of the artift. But in statues of that kind, Zenodorus in our age has excelled. He made a Mercury in the city of Gallia Arvernus, the labour of ten years, which was afterwards so approved, that he was called to Rome by Nero, where he was defignated to make the colossal statue of that prince 110 feet high, which should be dedicated to the fun, by way of reverence, and which is among the atrocities of this prince. It is wonderful that in his workshop there does not remain any clay model of this work of a large fize, but there are many first sketches in small, like first attempts. This statue indicates that the art of founding in brasses is perfifyed.

Nero had prepared liberally both gold and filver, and Zenodorus in modelling and carving is not considered as inferior to any of the ancients. When he had finifhed the statue for the Arverians, Vbius Avitus, being the president of that province, two cups were sculptured by the hand of Calamis, which Germanicus Caesar highly valued, gave to his preceptor, Caius Syllaus, his uncle. As much as the excellence of Zenodorus was greater, so much may be found the decay in works of brasses. The statues which are called Corinthian are for the most part such as may be carried from place to place. Such was that of the Sphynx, which Hortenufus, the orator, received as a present from Verres, and occasioned a reply from Cicero. When Hortenufus faid, in altercation with him, "I do not understand your enigma;" Cicero replied, "You ought, for you have the Sphynx at home." Nero, the emperor, it is faid, took about with him a statue of an Amazon. And a little before our time, C. Cellius, the conful, always carried an image with him in the field of battle. Alexander the Great had a tent furlained by four fingle statues, of which two are now dedicated before the temple of Mars the Avenger, and the other two before the palace. The art is ennobbled by almost innumerable leffer statues. Before all, Phidias the Athenian made a Jupiter of ivory and gold. He also made statues in brasses. He floured in the 84th Olympiad, about 300 years from the building of Rome. In the fame period his emulators were Alcamenes, Critias, Neltocles, and Hegias. Afterwards, in the 87th Olympiad, Ageledes, Callon, Polyeletus, Phidias, Praxidias, Gorgias, Lacon, Myron, Pythagoras, Scopas, and Parehus. Among thefe, Polyeletus had for his disciples Argus, Alopolodorus, Alexis, Arrhikes, Phrynon, Dimon, Athenodorus, Damcas, and Myron. In the 95th Olympiad flourifhed Naucyes, Dionysus, Canachus, and Patrocles. In the 102d, Polyclus, Cephiadro fus, Leochares, and Hypatodorus. In the 104th, Praxitiles and Exuphranor. In the 107th, Echion and Theramachus. In the 148th was Lytippus, in the time of Alexander the Great; and at the fame time Lybiflatus and his brother Sthenis, Eu chronides, Sofratus, Ton, Silanion, who was admirable, none being more learned. He had for disciples Zeuxis and Jades. In the 120th Olympiad, Eutychides, Euthycrates, Dalippus, Cephiadora, Timarchus, and Pyromachus. The art then ceafed. And again, in the 125th, revived, though allowed to be inferior, yet approved; Antaues, Calibritis, Polycles, Athenanzus, Callixenus, Pythocles, Pythias, and Tumoles. We fhall pafs hastily over the moft distinguis hed of the celebrated artists in their distinct ages. A Venus was made with a kind of emulative contention, as formerly they made an Amazon, which was dedicated in the temple of Diana, at Ephesus; that work was approved which every artift judged to be next in merit to his own. This was the work of Polyeletus; the next was Phidias, the third Ctesfus, the fourth Cydon, the fifth Phra ridon. Phidias, beides the Jupiter Olympius, which no one attempted to rival, made also, from gold and ivory, Minerva at Athens, which stands in the Parthenon. Of brasses, also, before that Amazon just mentioned, he made a Minerva of supreme beauty, from which it received the name of Callimorphos. He made also Ciliduchus, or the key-bearer, and another Minerva, which Alexander Paulus dedicated at Rome in the temple of Jupiter. Also two figures clothed in the pallium, which Catullus dedicated in the fame temple, and another which was colossal, naked. He first discovered the art of alto relievo, and demonstrated its merit. Polyeletus of Sicyon was the disciple of Age ledes;
Sculpture.

Ladies; he made a statue of tender youth, called Diadumenus, from his binding up a garland, valued at one hundred talents. Also one called Doryphoros, from his carrying a spear, a youth in the vigour of his age. He made also what his art was called the Rule, seeking the loss of art from a certain low. He was the only man who made art its own judge. He also made a knight, and one throwing a discus and two bows at the darts, which are called Altagalzontes; they are in the emperor Titus's court. No work is judged to be more perfect than this. Also a Mercury, which belonged to Lycurgus, and Hercules slaying Antaeus from the earth; which is at Rome; also Artemon, an eminent voluptuary, who was called Periphetoros, from his being borne about in his couch. He was judged to have perfected the science. He was also highly skilled in alto relievo, which had been first discovered by Phidias. But what was peculiarly his own, he found out the balance of the figure on one leg; notwithstanding, as Varro reports, his figures were squared, and all imitated from one example. Myron, born at Eleutheria, the disciple of Agelades, was very famous for a heifer, prattled in celebrated verses, whereas many are commended more by the ingenuity of others than their own. He made a dog and Dicobulus; Perice, leamonters, and a fayry adorning the pipes; a Minerva; a Pentathlist, or master of the five exercises; a pancrastati or boxer; a Hercules alto, which is at the Circus Maximus of Pompey the Great. He made also the monument of a grafshapper and lacustris, to which Erina refers his verses. He made also Apollo, which the trunvour Antiox took away, but it was restored to Ephesus by Augustus, amassed for this purpose in a dream. No artist, for multitude or variety, surpassed Polycletus, or was more accurate in symmetry; but although he was so curious in the representation of bodies, he did not express the feeling of the soul. The hair also, and the pubes, he made like the rude ancient work. Pythagoras of Rhegium surpassed him in a Pancraatist, placed in Delphi; and also Leontinus, who made the pedestrian Affylon, which is shown at Olympia, with Libys, the boy holding tablets, and one bearing apples, naked; a Syracusan, also lame, the sufferers of whose ulcer affect the beholder; also Apollo the harper, the serpent slain with his arrows, which is called Dceus, which was taken from Thubes by Alexander. He first expressed the nerves and veins, and the hair also with accuracy.

There was another Pythagoras of Samos, at first a painter, whose statues of the seven goddesses naked, and an old man, are very much praised. This artist was said to have been indirminate in the likenesses of the face. The disciples of Rheiogus is said to have been his fellow's son, called Solfratus. Whereas Tully affirms, that Lytippus was his disciple, which Duris denies. He first became a worker in brases, from hearing the answer of Euompos the painter, who being questionned who should be followed of those before his time, answered, bowing a multitude of men, that nature should be imitated, not the artifit. It is said that he made more statues than others, being most proficic in his art; among which is a man using the trunqul, which Marcus Agrippa placed before his baths. This was very much admired by the emperor Tibcrius, who, not satisfied with it where it was, had it brought into his chamber, and another statue put in its place, at which the people of Rome were moved to revetment, and demanded it to be restored, which was done. Lytippus made a drunken piper, a hunting dog, and a charioteer and four horses, with the fun of Rhodes. He made also Alexander and Great in many works, beginning from his childhood, with a statue of whom the emperor Nero being very much delighted, commanded it to be covered with gold; but afterwards, when the art was discovered to be destroyed by it, it was taken off; and it was esteemed more precious with the cuts and lines remaining in the work to which the gold adhered. He made also Heracles, Alexander the Great's friend, which was 150 years before him. Also Alexander hunting, which is confconated at Delphi, and at Athens a crowd of satyrs; of Alexander's friends he made the strongest resemblance. Metellas, when he conquered Macedonia, brought them to Rome. He made also chariots with four horses, of many kinds. He added much to the art of statuary, expressed the baw, made the head less than the ancients, the body more flamer and dry than the ancients made theirs, by which the magnitude of the statues appeared enlarged. The Latins have not the word symmetry, which he most accurately observed, by a new and stiffer rule in changing the squared statues of the ancients; he had they made men as they are, he made them as they appear to be. He left tins and discipules very much admired artists, such as Dalippus and Bedas: but above all, Euthycrates, although he emulated rather the conftancy of his father than his elegance, and was pleased with the affuerite rather than the agreeable. Therefore he bell expressed the Delphian Hercules, and Alexander, Thephis the hunter, and Thephides, a battle of horsemen before Trophonius's oracle, chariots and four horses, many statues of Medea, hermes, and hunting dogs. His disciple was Tiberarri the Sicymon, the nearest to Lytipus of all his followers, in his works are more fully engraven and more vividly than those of Thelaen, an old man, king Demetrius, Peucelles, Alexander the Great's preferer, worthy of too much glory. Artificers, who have brought these things together in the volumes they have composed, celebrate Telephanes the Phocæan, unknown on other accounts, because in Thesaly, where he dwelt, his works are concealed; otherwise by the suffrages of others he is equal with Polycletus, Myron, and Pythagoras. His Larissa is praised, and his Wrtiter with the thorns, and his Apollo. Some think he had no other dement, but that he gave his workshops to Xerxes and Darius. Praxiteles was also particularly happy, and also celebrated in his works of marble. He made also in braes beautiful works; the rape of Propherine, the Sybil and propheteis, the drunken woman, Bacchus, and a most famous satyr, which the Greeks call Periboea; statues also before the temple of Felicity, and a Venus which was confumed in the fire of Claudius's palace; his marble, famous through the earth, was equalled by himself only. Also statues called Stephena, Philemon, Oeno- phorus, Harmodius and Arifton, the Tyrannides; which were taken by Xerxes, the Persian king, and were sent back to Athens by Alexander. He made also a youth, feeding upon a lizard, which he approaches to strike with an arrow; it is called Saurooten. He made two statues, expressing opposite effects, a mourning maeton, and a rejoicing harlot: they think this to be Phryne, discovering in her the love of the artifit, and the reward of the woman: this statue possesfes much grace. Calamines made a charioteer with four horses; in his horses are never found any defect, though he is thought to be defective in his men. The same Calamines made other chariots, both with four and with two horses, in which the men are not inferior. Nothing is nobler than his Alcmenes. The discipule of Phidias, Alcamenes, worked in marble; also in bras he made a Pentathlon, who is called Encrinomenos. But Aristotle, the discipule of Polycreteus, made chariots both with two and four horses. And Lucretius, by Iphocrates, is praised. Thus is the harlot who in the lyre and song was the familiar of Haremodias and Ariiftont, and partook of their counsel in the Tyrannicide. She was tortured to death, and did not betray them to the tyrant; wherefore the Athenians willingly hold her in honour, not that
that they celebrate her as an harlot, but they have made an animal of her name; and that the cause of the honour might be understood, they forbade the artist to add the tongue. Bryaxis made Aesclapius and Seleucus; Bedas made Battus adoring Apollo, and a Juno, which are at Rome, in the temple of Concord. Cteslaus made a wounded man fainting; in which might be understood how much life remained; and an Olympic Pericles, worthy of the sanction. He was admirable in his art, and noble men he made more noble. Cephisodorus made in the Athenian port an admirable Minerva, and an altar to the temple of Jupiter the favour, in the same port, with which few can be compared. Canachus made an Apollo Naked; it is called Phileius in Didymus: it is of the Eagean mixture of braies. Alca, a deer suspended in his steps, that a line might be drawn under his feet, retained only in the alternate bite of his hoofs and heel, so that turning about his teeth to both parts, he flarls from the repulse of his action by turns. He made also Cele- tizontes, or boys holding hatchets. Charreas made Alexander the Great and Philip his father. Ctesias, or Defilas, made a Doryphoros and a wounded Amazon. Demetrius made a Lythmachus, who was priest of Minerva sixty-four years. He likewise made a Minerva, which is called the Musfal; because the serpent’s in her Gorgan refound to the stoke of the harp. He also made Simonis, the horfeman, who first wrote on horsemanship. Dadasalus made, among his famous works, two boys uising the Irtigl. Dinomenes made Protefialus and Pythodemos the wrestler. Euphra- nor’s work is Alexander Paris, in which is praised what is intelligible at once; the judge of goddesses, the lover of Helen, and also the flayer of Achilles. His is the Minerva at Rome, which is called Catuliana, being dedicated in the Capitol by Quintus Lutatius Catulus; also the statue of Good Fortune; in his right hand holding a paste, and in his left a phylak of corn and a bowl. Allo Latona, the child-bearer, in the temple of Concord, sustaining in her arms Apollo and Diana. He made also a chariot with four, and another with two horses; also Clidunchus, or the key-bearer, of the most perfect form; also a Virtue, and Gracia, both of them cofalial; also a woman, admiring and adoring; and Alexander and Philip, in a chariot and four horses. Eutychides made Eurotas, in which many faw that art was more liquid than the river itself. Hegias made Minerva, and king Pyrrhus, highly prais’d, and Ceteizontes, boys; and Cal- tor and Pollux, before the temple of Jupiter the Thunderer. In the Parian colony is the Hercules of Iphidorus. Eleuthereus, the Lycian, was Myron’s disciple, who made (worthy of his preceptor) a boy, blowing the languid fire; and the Argonauts. Leochares made an eagle, who underfoot what he took away in Ganymede, and what he bore, fiercely touching the venr with his talons; also the boy Autolycus, victor in the Pancratium, on whose account Xenophon wrote his Symposium; Jupiter also, thundering in the Cap-itol, praised above all; also Apollo with a diadem. Ly- cicus made the boy Lagon, cunning, fable, and impudent. Lycus made a boy offering incense. Menechmus made one, with his neck bended, and his face preying his knee: this Mene- chmus wrote of his art. Naucyes made Mercury, and a Difcobolus; and, as it is thought, a person sacrificing a ram. Naucerus made a wrestler, drawing his breath. Niceratus made Aesclapius and Hygeia, which are in the temple of Concord at Rome. Pyramus made a chariot with four horses, governed by Alcibiades. Polyclees made a Her- maphrodite, a noble work; Pyrrhus, Hygeia and Minerva; Phoenix, the disciple of Lyuppus, Ephephers; Stipax, the Cyprian, one celebrated statue, an augur; here was the flave of the Olympic Pericles burning the entrails of a sacrifice, with a full mouth blowing the fire. Silanion made Apollodoros the most accurate among all in the art, and his own inimical judge, breaking the scarcely perfect statue, because he was unable to satisfy his own wishes in the art, and he was therefore surmamed the Madman; in this he expressed not the man made of braies, but rage itself; a noble Achilles he also made, and Epitale exercising the acrobatics. Styrigones made an Amazon, which, from the beauty of her leg, was named Eunemon; the emperor Nero always carried it with him; he also made a boy, whom the love of Brutus of Philippi rendered illuftrious with his name. Theodorus, who made the labryn- th at Samos, caft his own likenes in braies: besides the admirable resemblance, it is celebrated for the delicacy of its execution; the right hand holds a file and the left a square; it was taken to Preneile. He also compofed a car and driver, so small, that they might be covered with the wings of a fly. Xenocrates, disciple of Tificrates, or, as others say, of Euthyphores, excell’d, both in the number of his statues, and compofed volumes on his art. Many artifals made Attalus and Eunemon fighting against the Galatians. Tigionus, Pyromachus, Stratonicus, and Antigonus, compofed volumes on the art. Boethius, although more excellent in working silver, made a most beautiful infant frangling a goose. But of all the works I have mentioned (says Pliny), the principal were dedicated by the emperor Vespafian in the temple of Peace, and his other buildings, being brought together by the rapine of Nero into the city, and difpofed in situations in his golden house. Besides, there are other artifals equal in their merits, but none of their works are pre- eminent; Ariflon, who was ufed to work in silver; Cal/ades, Ctesias, Cantharos of Sicyon, Dinysodorus, disciple of Critias, Delades, Ephorion, Eunicus, and Heceatus. Among the sculptors in silver were Leiboeles, Prolorus, Pythoducus, Polypothus; these were not ufed alone among the sculptors in silver; Stratonicus and Scyraus, who was disciple of Critias. Pliny then enumerates those who made works of this kind, as Apollodoros, Androbulus, Alescle- dorus and Alevas, who made philofophers; Apellas made adoring females; Antigonus and Peryxionemon made the Tyrannicides above spoken of; Antimachus and Atheno- dorus made noble women; Ariftodemos made wrestlers, and a chariot with two horses, with their charioteer; philofo- phers; an old woman, and king Seleucus; his Doryphorus also is a graceful work. There were two of the name of Cepheidorus; the first made Mercury feeding the infant Bacchus; he made also an orator, with his hand raised up, but the perfon is uncertain; the other reprezented philofo- phers. Colotes, who worked with Phidias on his Olympian Jupiter, reprezented philofophers; also Cleon and Cen- cramis, and Challicides, and Cephis. Chalcothenes made a comedian, and an athleta; Daiphus made a trigilit; Dai- phon, Democritus, and Dæmon, the philofophers. Epigonus excelled almost all the relz already recorded, in his imitation of a trumpeter, and a mother piteouzly embracing her slain infant; and Eubolis counting by his fingers. Mycon made a beautiful Athleta; Menogenes a chariote and four horfes. Nor was Niceratus inferior to them all, reprezenting Al- cibiades in his attack; and Demaratus sacrificing; his mother lighting a lamp. Tificrates made a chariot and two horfes; Bithias placed a woman upon it; also he made Mars and Muccurus, which are in the temple of Concord at Rome. Perilus, whom none one prifes, more cruell than Phalaris the tyrant, made a bull, in which he promised that a man, by the power of fire, might be compelled to bellow, but he himfelf, by a more juft act of cruelty, was made to experience it. Thus a moft humane art was called away from the fim- litudes of gods and men. Was it for this that fo many la- bourzard to rear an art that it might become a torment?
Therefore one cause of preferring his work was that, who
soever should see it might hate the hand that produced it:
Sthenis made Ceres, Jupiter, and Minerva, which are at
Rome, in the temple of Concord, also matrons weeping,
and adoring, and sacrificing. Simon made a dog and an
archer. Scopas worked in all kinds; athletes, and fielders,
and Bacchantes, Batton, Bacchus, Gladiators, Heliodorus,
Hebe, Lysippus, Lycophron, Leon, Medardus, Mylboro,
Polykrater, Polydorus, Pythocles, and Protagoras, who
were famous in painting. Patrocles, Pufis, Pericles, who
also carved excellently in silver; they were Ephorini,
Pericleophanes, Philon, Sinemus, Tim monstrous,
Timarchides, Timon, Tritas, Thrasos; among all these
the most known and remarkable is Callimachus, always his
own calumniator; nor did he set any limit to his accuracy;
hence he was called Callimachus: he exhibited memorable
examples of his excessive attention. His are the dancing
Laec-diomedian females, an over-laboured work, in which all
the grace was taken away by the accuracy: he also, as
it is said, was a painter. One statue alone of Zeno, Cato
in his expedition to Cyprus, did not fail: not gratified with
the brafs, nor with the art; but because it was the portrait
of a philospher; this was obvcrse by the way, although
it may turn out an useful example. One statue was
mutilated and not passed over, the author is uncertain:
Near the Rilium at Rome, a Hercules, clothed in a
tunic of the Elean habit, with a frowning face, as
furious in the highest degree from the tunic. On this are three
inscriptions, L. Lucullus, imperator, from his spoils;
the other is the son of Lucullus, a minor, from fatitus con-
tum; the third is, T. Septimus Sabinus, a curule edile,
from his private property restored to the public. This
statue was thought worthy of such a distinction. Pliny,
l. xxxv. c. 19. &c.

Dibutades, a Sicyonian potter, first found the art of
making likenesses of clay, in Corinth, by the help of his
daughter, who being in love with a youth who was going
on a journey, feared lines round the shadow of his face
by a lamplight on a wall, which her father impressing
with clay, made a type, or cast, and with the rest of his
pottery placed to be hardened in the fire. It was pre-
ferred in the Nymphæum till Mummius overturned Corinth,
as it is said. There are those who say that Rhoces and
Theodorus first found out modelling in Samos, before the
Battledes were driven from Corinth. Demaratus fled from
that city, and in Etruria was the father of Tarquin, the first
king of the Romans; he was accompanied by Eucides and
Eugrammus, the modellers; by these modelling was first
brought into Italy. Painting them red, or making them
of red clay, was first practised by Dibutades; he is the first
who added marks to the extremities of tiles which threw
off the flowers, which at first were called protypes; after-
wards he made eptypes, or moulds of them; hence arising
unto the top of the temple, they were named models. The
likeliness of man was taken from the face itself in plaster;
and wax was produced in that form as poured into the plaster.
Lyfifrus, the brother of Lygippos the Sicyonian, improved
this invention; he first determinate the representation of
portraits; for before him, they endeavoured to make them as
handsome as possible. He did the like in his statues. Such
improvements were made that no statue was produced with-
out a model. It appears, therefore, that this art was more
ancient than calling in brases. Damophius and Gorfas
were very eminent modellers; they were also painters, who
executed both arts: in the temple of Ceres at Rome, and in
the Circus Maximus, there are verses inscribed in Greek,
which signify that the work on the right hand was that of De-

Sculpture.

nopolis, and on the left that of Gorfas: before this all the
work in this temple was Tuifus; as M. Varus says. From
this temple, when it was restored, the surface of the wall
being cut away, the pictures were included in frames, the
statues from the roofs also were dispersed. Cloudes
made several models at Athens, in a place which was called
Cereneus, from his workshop. M. Varus says that he
knew a man named Polis, who made at Rome statues of
grapes and apples, which could not be disdained from real
ones. He also extols Arethusa, the intimate friend of L. Aus
Lucullus, whose calls often sold for more than the other
works of his art; by him was made a Venus Genetrix, in
the former of Caesar; it was placed before it was finished,
from the battle of the dedocation. Afterwards by the same
hand, a statue of Felicity was to have been set up, but both
delights were frustrated by death. A cup was made for Octavius,
a Roman knight, the model of which is plaster cast a talent.
Patisteis is praised, who says modelling is the mother of
statuary, sculpture, and engraving. This art was very
much used in Italy, and chiefly in Etruria. Timnus,
being called from Cregillum by Tarquins the elder, made the
statue of Jupiter, to be dedicated in the Capitol: it was a clay
mould, and after cold, coloured red: he also was the model
on the top of the temple of a chariot and four horses, which
has often been spoken of. In this way he made a Hercu-
leans, which at this day in the city retains the name of its
material. Pliny, l. xxxv. c. 43. 45.

The first of all who were famous for marble sculpture, were
Dipenius and Scyllis, born in the island of Crete. When it
was under the dominion of the Medes, before Cyrus began
to reign in Persia, that is, about the 50th Olympiad, they betook
themselves to Sicily, which was a long time the workshop
for the metals of all countries. The images of certain
gods they publicly placed at Sicily, but before they had
finished them, the artificers, complaining of some injury, fled
to Eotia. Forthwith famine and barrenness invaded Sicily,
and direful afflictions. A remedy being asked from Apollo
Pythias, he immediately answered, "Let Dipenius and Scyllis
perfect the statues of the gods." They were intended to
do this with great rewards and liberal offers. These images
were Apollo, Diana, Hercules, and Minerva, which after-
wards were touched with lightning from heaven.

In their time there was, in the island of Chios, Malar,
a sculptor; then his son Nicciades; and then his grandson
Anthemus, a Chian, whose sons, Bupalus and Anthemus,
were famous in this science in the age of Hipponax, the
poet, who, it is certain, lived in the 60th Olympiad. If
this family had traced back their progenitors, they would
have found art to have originated with the commencement
of the Olympiads. Hipponax had a singularly ugly counte-
nance; wherefore his likenesses, produced in a vulgar joke,
was held up to public ridicule: at which Hipponax, indignant,
bore so hard upon them with the bitterness of his verses,
as compelled them to hang themselves. But this is an error,
for they made a great many statues afterwards in the
islands. In Delos, where the song was composed, they
could not escape the ceniture; but at Chios are the works of
Anthemus, the son; and there is shewn at Jafius a
Diana, made by their hands; and in Chios it is said there
is a Diana of their work, whose face is much above the
spectator's eye, and so contrived, that to those entering the
temple she appears severe, but to those going out she
appears exhilarating. At Rome their statues are on the Pal-
antine Hill, on the top of Apollo's temple. In their country
of Delos also are their works, and in the island of Lefbos
Dipenius has certain works at Ambracta, Argos, and
Cleone. All these artificers used the white marble that comes
from

VOL. XXXII.
SCULPTURE.

from the island of Paros; which Rome took the appellation of lychnites, because it was cut in the quarries by the light of the lamp, as Varro writes. Afterwards a much whiter kind was found; lately also in the quarries of Lunenum. But of the Parian a wonder is told: the fomy glebe, divided by the wedge, fell apart, and an image of Silenus appeared within. It must not be omitted, that these arts, both of painting and statuary, so anciently produced, were taken up by Phidias in the 83d Olympiad, 332 years afterwards: for Phidias brought forward the art of sculpture in marble. His Venus at Rome, which is in the forum of Octavia, is a work of the most beautiful perfection. He taught Alcamenes the Athenian, who, it is certain, is distinguished among the hero of the Athenians; whose works are at Athens, in many faced temples. Famed above the rest is his Venus without the walls, which is called Aphirodite in the Garden. It is said that Phidias put the finishing hand to this statue. His disciple was Agoracritus of Paros, so agreeable to that age; therefore many works are given about in his name. There was a trial of skill between the master and the disciple, in making a Venus. Alcamenes conquered not by his work, but by the suffrages of his city, which favoured him against a stranger. Under the condition that it should not be at Athens, Agoracritus fold it. It is furnamed Nemesis. M. Varro preferred it to all statues. There are in the temple of Magna Mater, in the fame city, works of Agoracritus. Phidias is undoubtedly famous through all nations, which have understood the fame of his Olympian Jupiter. That those may know how deferably to praise his works, who have not seen them; we fhall offer some arguments relating merely to his ingenuity; without comprehending the beauty of the Olympian Jupiter, and referring merely to the structure of the Athenian Minerva. It is 26 cubits, composed of ivory and gold: in her shield the Amazonian war is engraved; in the swelling part of the buckler, and in the concave part, the war of the gods and giants; in her hands the Lapiths and Centaurs, every minute particular put together with the greatest art. In the bafe is engraved the birth of Pandora. Here are gods produced, twenty in number: Victory is chiefly admirable. The skillful have admired the serpent, and, under the creft of her helmet, the fphyx of brafs. There are transient obfervations: the art can never be sufficiently admired, whilst it is known that he was no lefs distingu-ished by much magnificent, than by the smallest things. We have fpoken of Praxiteles, among the flaturaries of his age, as having excelled in the glories of marble, others, and alfo himself. His works are at Athens, in the Ceramicus. But before all, not only of Praxiteles, but on the whole globe of the earth, is Venus, which is viewed by multitudes who fall to Gnidos. He made and alfo fold two statues; one clothed, by means of which it was intended that there might be a preference. The Caesars took one at the fame price, confidering that as the more severe and modeld. That which was rejected was bought by the Caesars. Immense the difference in their fame! Afterwards king Nicomedes would have purchafed that of the Caesars, promising to pay the whole debt of the city, which was immense. But they rather bore all, nor without caufe, as long as the figure of Praxiteles ennobled Gnidois. Her little temple was wholly open, that the figure of the goddes might be viewed from all points; the goddes favouring them, as it was believed. No part was seen with less admiration than another. It is faid, a certain perfon was enamoured with the figure, and hid himself in the temple all night. There are in Gnidos other statues of marble, by illustrious artists: Bacchus, by Bryaxis; and another, by Scopas; and a Minerva. Neithet is there any other fpemcim of the work of Praxiteles more ex- ceellent than the Venus, that should be recorded among these by itself. Of the fame artift there is one a Cudip, objected by Cicero against Verres: it is that for which Thephia was visited. It is now in the Octavian Gallery. His is also another Venus, in a Parian colony of Propontis, like the Venus of Gnidos in noblenes and alfo in injury. At Rome are works of Praxiteles: Flora, Triptolemus, Ceres in the Servilius gardens, Good Fortune, and another statue of Good Fortune in the Capitol; also the Marsaeus, and those called Thyades and Caryatides; and Silenus in Afnins Pollio's monument, alfo Apollo and Neptune. Cephifforus was the fon of Praxiteles, and the heir of his art as well as of his elate; whole work of children embracing is at Bergam, a very much admired and a noble performance of art; the fingers seem to imprefl the body rather than the marble. At Rome his works are: Latona in a chapel of the palace, Venus in Afnins Pollio's monument, and in the temple of Juno, which is in Octavia's portico, Efeulapius, and Diana. The fame of Scopas contends with his: he made Venus, and Pothon, and Phaethion, which are worhipped in the faced ceremonies of Samothracea; alfo the Palatine Apollo. The fitting Vefa is very much praised in the Servilius gardens; two chariilayers or companions around her fitting on the ground. Two like them are in Afnins's monument; where is a canephorus, or man bearing a bafket, by the fame artift. But the greatest honour in Cn. Domitius's temple, in the Circus Flaminius, belongs to his Neptune and Thetis, and alfo Achilles; Nereides fitting upon dolphins, fea-monsters, and hippocampi; alfo triton, and a chorus of phorci and prikles, which are different kinds of fea-monsters, and many other marine fubjects, all by his hand. This was a moft famous performance, if it had been the whole work of his life. Now, besides what has been said above, we shall faak of things of which we are not certain. A Mars of his work, colorful, a fitting figure: it is in the temple of Brutus Callicus, in the Circus. Besides a Venus, in the fame place, furpassing the Gnidian, taking a preference to that of Praxiteles: it would have ennobled any other place. Rome, from its greatnes, has caufed that work to be forgotten; and the crowd of businesfs and offices draw away from obfervation, becaufe admiration is deferved only in things fitted to great silence and more lefler. Equal doubt is in the temple of Apollo Sobanes, whether Niobe and her children were made by Scopas or Praxiteles. Alfo Janus the father, which Auguftus brought from Egypt, and dedicated in his temple, but of whose hand it is fame does not tell us. Likewife in Curia Octavia, there is question concerning a Cupid holding the lightning; though at length it is afcribed to be the likeness of Alcibiades at that age. Many other things are in the fame gallery, which pleae, whose authors are unknown: four Satirs, with Bacchus, one of whom holds a flying garment over his shoulder; another fimilar Bacchus; a third quieting a crying infant; a fourth with a cup, satisfying the thirft of another with drink; two winds with flying vels. Nor is there lefs qefition who made Olympus, and Pan, and Chiron, with Achilles, in the Septis; particularly when their reputation has rendered them worthy of the pledge of their keepers' lives. Scopas had emulators in the fame age, Bryaxis, Timotheus, and Leochares, who are always fpoken of together, becaufe they wrought together on the Maufoleum. This was the sepulture of Maufolus, king of Caria, which his wife Artemifiia made for him, who died in the second year of the 106th Olympiad. It is a work reckoned among the seven wonders of the world, which these great artifts made. It is from fouth to north 63 feet, but shorter in front; its whole
SCULPTURE.

whole circuit is 441 feet, raised in height 25 cubits, surrounded with 36 columns. To the left it was flanked by Scopas, to the right by Hel docles, who both had a place on the first porch of the temple, as occurred from his work. Scopas placed at one of the piers, but at the elevation of their place, and his celebrated. All the work is in the temple, a Hercules, at which the Colossus stood for many years offered, therefore, the

It stands the ground, but the extra of the time leads to the statues of the Tuscan. There are standing the statues of the Thracians before the temple of Felicité, of which one was placed by a Roman noble, Junius Pecileicus, as a Roman noble; admired also, by Pausanias, who wrote five volumes on the noble works in the whole world. He was born at the Italian Greek town. Rich both in the city of Rome and its towns, he made a Jupiter of worr, in Metellus's temple, which looks over the fields. It beheld him, that in a step, in which were African wild beasts, forming at a den and carefully of leaving a den, which he meant to carpe, a painter broke off a head from another garden, not of flight peril to bring this art work. He made many works, as he is said; but of the which he made, the names are not reported. Arcebuchus also, very much praised by Varro, who himself had a marble honor, as he says, and wanded cupids (porting with her) of whom some held her bound, others force her to drink from horns, others kiss her with their fingers: all of one stone. He made also, for Coponius, fourteen nations, which are in Pompey's circus. I find Caenoxus (says Pliny) very much praised among the statues for works he made of marble. Nor must Sauron and Batrachus be forgotten, who made the temple of Octavia, included in the portico. They were Lauros and Amrasians. They are said to have been very rich, and they built this temple at their own expense; very carefully hoping to have an inscription, but it was denied them, notwithstanding they took another place and method to obtain it. There are, at this time, in the palaces of the columns, the inscription of their names carved; a frog and a lizard. In Jupiter's temple it is to be seen a picture, containing articles of dres; and all other things relating to women; for when the temple of Juno was completed, and they carried in the statue, they are reported to have changed the moveables; and that being guarded by religion, even as the seat partitioned among the gods themselves: in the temple of Juno is consecrated that which ought to be Jupiter's. Pliny, l. xxxvi. c. 4. Such is Pliny's account of ancient sculpture.

It is well known, from the testimonies of later authors who have written on the subject, as well as from the names of Greek artists found on their works, that all the noble productions of sculpture executed at Rome after the times we are speaking of, were the productions of Greek artists.

The busts of the twelve Caesars, from Julius to Domitian inclusive, are the first productions of portrait sculpture. The whole imperial series, both in busts and statues; are done to the emperors Balbinus and Pupienus, pofts the latest marus, and carried in that period the decline of art; but from the time of these emperors to that when Constantine fixed his capital at Byzaunium, the decline was so evident, that the life and beauty of former times were nearly lost in his productions.

Before we quit ancient Rome, we must notice in a general observation one of the great works of art still remain is that capital, which could not be properly introduced in the foregoing series.

The Trajan colonnade is one of the most beautiful monuments of ancient Rome, and the most superb column in L 2 the
the world. It was raised about the commencement of the second century, by the Senate and people of Rome; in honour of the Emperor Trajan, after the victory that he had obtained over the Dacians. This column is admirable for its height, and more still for the beauty of the base, with which it is ornamented; which represent the first and the second expeditions, and the victory obtained over king Decebalus. These bas reliefs are correctly designed, and most beautifully executed. There are numerous more than 2500 figures, all in different attitudes, without counting those of horses, elephants, arms, machines of war, and an infinity of others; altogether forming a variety of objects, which no one can see without admiration. Upon the capital of this column is a pedestal, on which was anciently a colossal statue of Trajan in gilt bronze. In the place of this statue, Pope Sixtus V. caused to be placed, in the year 1588, that of St. Peter the apostle in bronze, which was modelled by Thomao Porta. The same pope caused also to be cleared away the earth which encumbered the pedestal.

At the bottom of the pedestal, or base of the column, in one of the sides is a door, by which we mount to the top of the column. The flaire-cafe contains 185 steps, cut in the same blocks as the column: and to them are made 44 windows, which light the flaire-cafe; and there is on the top a balustrade, by which we may walk around and enjoy the prospect of the whole city of Rome. The height of this column is 118 feet, comprising the pedestal of the column and the statue on the top. The column alone, with its base and capital, is 92 feet; the pedestal of the column is 17, that of the statue 9; the lower diameter of the column is 7 feet 3 inches, the diameter of the upper part is 10 feet. This column is formed of 22 blocks of white marble, fixed with lead one upon another. The shaft of the pillar is in 23 pieces; the pedestal in 8; the capital 1; and the pedestal of the statue another.

The magnificence of this column answers to that of the ancient forum of Trajan, of which it occupied the centre. The Forum or Square of Trajan was surrounded by grand porticoes, and the edifices were built with the greatest magnificence after designs by the celebrated Apollodorus. These consisted of a temple or palace, where the consuls sat in judgment; the temple of Trajan, where was the Ulpius library, ornamented with statues of the learned; a superb triumphal arch with four equal faces, that the Senate caused to be built to the honour of the prince after his death; and a beautiful equestrian statue of Trajan, in gilt bronze: the statues, the cornices, the architraves, and the friezes which ornamented these edifices, were also in bronze. It would be difficult to describe all the magnificence of this superb square. Trajan caused a valley to be filled up, and levelled one part of Mount Quirinal, to make a level for this beautiful situation.

The Antonine column has given its name to the place of which it is the principal ornament. It was raised by the Roman Senate, and by the Emperor Marcus Aurelius Antoninus, in honour of Antoninus Pius, his father-in-law, whom he succeeded in the empire. His ashes were enclosed in a golden urn, and placed on the top, with his statue in bronze gilt; and because he had not obtained any one great victory in war, they caused to be sculptured around the column the victory over the Marcomanni. Time and various revolutions, and above all the fires, which had been anciently very frequent in Rome, have much damaged this column. Pope Sixtus V. caused it to be repaired in the year 1589, and the statue of the apostle Paul, in bronze gilt, to be placed upon its summit. This column is of white marble, surrounded by bas reliefs from the base to the capital. The artiff appears to have taken for his model the Trajan column; it is of the same style, though of inferior execution. The whole is composed of 28 blocks of marble: it is 15 feet in diameter, and 116 in height, without including the statue, which is 13; and the pedestal, on which it is placed, which is 9. The column contains a beautiful winding flaire-cafe of 100 steps, which conduct commodiously to the top; it is lighted by 41 windows.

The arch of Titus was raised by the Senate and people of Rome to the honour of Titus Vespasian, for his conquest of Judea and the taking of Jerusalem. It is of the most excellent workmanship, but has very much suffered from the injuries of time. It is ornamented with beautiful bas reliefs, and two fluted columns of the Composite order. Under the arch is seen the triumph of the emperor, drawn in a chariot by four horses, accompanied by his lictors; and in the triumph the famous candlestick of seven branches, the tables of the law, and other spoils of the temple of Jerusalem.

The arch of Septimius Severus was raised by the Senate and people of Rome, at the beginning of the third century, to the honour of that emperor, for having subjugated the Parthians and other barbarous nations. It is all of white marble, with three arches and eight fluted columns of the Composite order, ornamented with bas reliefs, of middle sculpture. It has suffered very much, and because it is partly buried in the earth, we cannot to well judge of its beauty; formerly there was an arch to the top of the arch, by a flaire-cafe in the interior; and there was placed upon its roof the Emperor Severus in a triumphal charriot drawn by six horses.

After the famous victory obtained over Maxentius by Constantine the Great, the Senate and people of Rome caused a triumphal arch to be raised to his honour: it is of the Corinthian order, having three arches; the two grand fronts are ornamented by eight fluted columns of yellow marble, and many bas reliefs of very different merit. Those that were made in the time of Constantine make us perceive the barbarity into which the fine arts were beginning to fall; the others, on the contrary, were taken away from the arch of Trajan, without such beauties, as indicate an age when sculpture was in high perfection. These are twenty in number, of which ten are of a square form, and are in the upper part; eight are round, above the side arches, and two others more large under the grand arch. All these bas reliefs, and the eight figures of Dacians placed upon the columns, prove themselves to belong to the expeditions and victories of Trajan.

The arch of Marcus Aurelius formerly stood in the Flaminian way, now called the Corso, or principal street in Rome; it was taken down by Alexander VII.; two fine remaining bas reliefs from which are at present in the Capitol; one of these is an apotheosis of the emperors Faustina, the other is an address of the emperor to the people of Rome. The figures are larger than life.

In general observations on the sculpture of the arches and columns here enumerated, we shall remark, that the earlist of them, the arch of Titus, must have been executed about the year 70 of the Christian era, consequentally when sculpture had lost much of its primitive ideal beauty; we shall of course find in these works less of fulness and more of conventional forms, consisting of subjects which were confined to battles, entanglements, triumphs, and acts immediately connected to them. The Roman general and soldiers, as well as the barbarians whom they fought with and conquered, are represented with an individual vulgarity of face and person, very different from the choice selection of beauty in the works of Greece. The dres and armour
armour are more complicated and divided than those of the ancient Greeks, added to the interior and exterior of parts, still augmented by the introduction of wings, bridges, poles of wood, battering rams, catapults and other military engines, &c., wholly omitted in the works of the last ages. The costrels are of the costest means, and of the most brutal forms, unlavished by any interference of supreme beings, and unexcelled by the beauty of the ancients. With such a character in the whole, the sculpture in the arch of Trajan, now the arch of Constantine, is superior to the rest of these works. Upon the whole, although the bas relief of the apotheosis of Faustina, formerly on the arch of Marcus Aurelius, is more sublime conception, the sculpture of the Trajan column has a great variety of natural attitudes, according to the situations in which the persons are placed, and the relieve has that general breadth, which is well fitted to show the outline of the column in all views. The figures and groups on the Antonine column are carved with a bolder relief; but such as deforms the shaft of the column by its irregular hollows, producing something of the appearance of rock-work to the whole outline. The sculpture on the arch of Severus is still more deteriorated in its style and conduct; and such of the bas reliefs on the arch of Constantine as were executed in the reign of that prince, have such a Gothicism and barbarity of execution, as would utterly exclude it from that class of sculpture, which has moderate pretensions to science, or any pretension whatever to sentiment.

We must not omit to mention some colossal statues, still existing entire or in parts in the city of Rome; i.e., two colossal statues of marble on Monte Cavallo, standing before the pope's palace, each nineteen feet and a half tall. The figures are in the prime of youthful manly beauty; the faces are of the highest class of Grecian beauty; the figures seem to breathe and move; their position is advancing; with one hand each holds his charger. They have been called Castor and Pollux, Achilles and Patroclus, Alexander and Hephestion, also Achilles, at the moment when his horse declares the will of Jupiter; on the authority of two coins of Nero and Adrian struck at Corinth, bearing on the reverse a hero holding a horse, much resembling this group; it has been called Bellerophon holding Pegasus. One of these statues bears the name of Phidias on its pedestal, the other statue seems to be this original, reverred by some other artist, to stand as its companion in some conspicuous situation.

In the cortile of the Capitol remains in marble of the colossal statue of Domitian, which appears to have been, when entire, about forty feet high; the head and neck to the bottom of the gutlet is of one stone, and above eight feet high; the feet are each six feet long; the knees, elbows, and some other fragments, are remaining. It appears to have been nearly naked, to have floor erect, to have had a chlamys hanging on the left arm; and is perhaps the same colossal of Domitian as that described by Philo Byzantion, according to his testimonies from different Latin authors. There is, in the same cortile, a head in bronze, believed to be that of the emperor Commodus, which from other remaining fragments was a colossal statue also.

The equestrian statue of Marcus Aurelius, considerably above the size of nature, in the centre of the Capitol, of noble workmanship, is sufficiently known to lovers of art by the prints of Perrier and other artists.

When Constantine removed the seat of empire from Rome to Byzantium, he and his successors are said to have taken from the ancient capital of the world, as many of the fine works of art as they could possibly remove. The Greek artists were employed in their own country to decorate the new capital, with the same magnificence indeed as in former times, and like their predecessors were employed in the cause of religion, not in emulation of Phidias' Jupiter or Praxiteles' Venus, but in the cause of that farce perniciously defaced, and of his followers who propagated the new delusion of mercy. The architects were employed in building Sancta Sophia and other great faced buildings in the city; and the painters and sculptors in the illustration of the Old and New Testament.

The controversies of religion and philosophy had been agitated with so much violence by the philosophers of Alexandria against the Christian divines, as induced the successors of Constantine to abolish the schools both of Athens and Alexandria; they also enrolled orders for the removal and destruction of the Pagan idols; and in the fourth and fifth centuries it is believed that the Olympian Jupiter at Eleusis was destroyed, either by imperial order or the ravages of barbarians. The Iconoclasts, and the irritations of the followers of Mahomet and other barbarous people, very nearly destroyed all the remains of the finest Greek sculpture in the East as well as in western Europe. This destructive fury against the arts and artists, continued with interruptions for two hundred years; still, however, the Christian Greek contributions from the Old and New Testament, from the time of Constantine down to the thirteenth century, were followed as examples of character and composition by the revivers of art in western Europe, down to the times of Michael Angelo and Raphael.

After the sacking of Constantinople by the Venetians, the only efforts of that feeble state were a few faint struggles for existence, previous to its destruction by the Mahometans.

To give some idea of the magnificent sculpture which adorned Constantinople, we shall insert the description given by Conitius, of those fine works which decorated this city, before it was taken by the Venetians.

The Roman conquerors, who were of an avaricious temper even to a proverb, practised a new method of rapine and plunder, unknown to those who had taken the city before them; for breaking open by night the royal sepulchres in the great grove of Heroum, they fearlessly rifled the coffers of those blest disciples of Jesus Christ, and carried off whatever was valuable in gold, rings, and jewels, which they found in these repositories of the dead. They spared neither the house of God nor his ministers, but stripped the great church of Sancta Sophia of all its fine ornaments and hangings, made of the richest brocades of ineffable value; but they no sooner cast their eyes on the brazen statues than they ordered them to be melted down. The fine statue of Juno in brass, which stood in the forum of Constantine, they chopped to pieces and threw into the forge. The head of this statue was so large, that four yoke of oxen could scarcely drag it. On the base of it was cut, in baffe relievo, the figure of Paris presenting Venus with the apple of discord. The noble quadrilateral pillar, supported by several ranges of pillars, and which by its height overlooked the whole city, and was both the wonder and delight of the curious spectator, shared the same fate. This lofty column was adorned with rural representations of all kinds of birds, folds of cattle, and of sheep bleating and lambs frisking and playing, &c. There was also engraved upon it a view of the sea and sea-gods, some of whom were catching fish with their hands, others ordering their nets, then diving to the bottom, while some in a
wanton manner were throwing balls to one another. This pillar supported a pyramid on the top of it, on which was placed the statue of a woman, which turned about with the wind, and was therefore called Anemone. This excellent piece was also melted down for coinage, as was also an equestrian statue, fixed upon a quadrilateral pedestal in the Taurus. This was a bold figure, of an heroic countenance, and surpfixing stature. He was said to be one of the spoils who were sent by Joshua, the son of Nun. With one hand he pointed sailward, with the other to the west. But this statue was generally reported to be Bellerophon sitting upon Pegafus; for the horse was without a bridle, as Pegafus is mostly figured, scouring the plain, deloping a rider, flying and driving about in a headstrong manner. This horse and his rider were also melted down; the barbarian soldiers expressing their utmost fury against the finest statues and most curious pieces of workmanship in the Hippocorn. The greatest statue of the Hellenic Hercules, which was fixed upon a magnificent pedestal, and clothed in a lion’s skin, which seemed to live and alright the spectators with his tremendous voice, felt the effects of military power. He was not armed with his quiver, his bow or his club; but stretching out his right leg and arm, he kneaded upon his left knee, and leaning upon his left elbow with his hand open, supported his head in a thoughtful manner, fesmning to lament his misfortunes. This figure was broad-shouldered, the shoulders large, the hair long, curled, and reaching to the waist; the arms were brawny, and as long as those made by Lytaeus, which was the original of this, and was the first and last masterpiece of his skill. In short, of such a stupendous size was this statue, that his writ was as thick as a man’s body, and his leg equal in height to any ordinary perfection. This noble statue did not elapse the rage of these mighty pretenders to virtue and honour. Besides this they also carried away the image of the afs and his driver, which figures were set up originally by Augustus Caesar at Aetium, of whom the story reports, that when he went out privately in the night time, to make a view of Antony’s camp, he met a man driving an afs, and asking him who he was and where he was going, the man answered, “my name is Nicon and my afs’s name Nieander, and I am going to Caesar’s army.” The statues of the hyena, and of the wolf which hung Romulus and Remus, underwent the same fate, and were coined into little bronze flaters. The severall statues also of a man fighting with a lion; of the horfe Nefios covered with scales behind; of an elephant with a moving proboscis; of the sphynxes, beautiful as women and terrible as beasts, which can occasionally walk or fly in the air; there was also the statue of a wild horfe, pricking up his ears, curvetting and prancing:—this and old Sylla were served in the same manner. She was figured like a woman to the waist, with a grim frightful look, just as she appeared when the sent her dogs to destroy Ulysses. There was also placed in the Hippocorn a brazen eagle, which was the invention of Apollonius Tyanes, and a celebrated monument of his forcour. This impostor being requested by the Byzantines to heal them of the bitings of serpents, which were then common among them, using charms and diabolical ceremonies placed this eagle upon a pillar. It was a pleasant light enough, and defend to be more narrowly inspected, for it made an agreeable harmony, and was dangerous than the Syrena. Its wings were stretched out as ready for flight, and it was quivering upon a serpent, which wreathed itself about the eagle. The serpent seemed to make the utmost effort to bite the eagle; the eagle looked brisk and lively, and seemed to have obtained the victory, and to be ready to bear him through the air in triumph, de-

noting that the serpents that tormented the Byzantines would hurt them no more, but suffer themtheselves to be handled and stroked by them. But these were not the only curiosities to be examined in this aquiline statue; for the twelve hours were engraved under his wings, under each wing fix, which flowed the hour of the day, by the sun darting through a hole in each wing made for that purpose. There was also a fine statue of Helen, whose charms led Troy in ruins; her fine proportions, in breathing braids, captivated all beholders; her habit fat loohe upon her, which discovered too great an inclination to gallantry; her long and delicate hair seemed to wave in the wind; it was braided with gold and jewels. Her robe was girt about her and falling down to the knee; her lips seemed like opening roses; you would fancy they moved; and such an agreeable smile brightened her countenance, as entertained the spectator’s eye with pleasure. There was also placed upon a pillar a more modern statue of a woman. Her hair hung down behind, combed close down from the forehead backwards, not braided up but bending, as if to the hand of the spectator. Upon the right hand of this statue stood a splendid statue of a woman; the horse stood upon one leg, the other bore a cup with liquor. The rider was of a large size; his body completely armed; his legs and feet covered with greaves; his air was manly, rough, and warlike. His horse was mettleome and high couraged, pricking up his ears as if he heard the trumpet; his neck was high, his look fierce, as eager for the battle, rearing up his fore-feet and prancing as a war horfe. Near this statue, hard by the eastern goal called Rufius, were a range of statues of charioteers, dextrous in driving the chariot and turning the goal. They were very busy in managing their bridles and fmaking their whips, and directing their horses, with their eyes fixed steadily upon the goal. There seemed to be describ’d in these figures all the tumult and fury of a chariot race, with the mott vigorous struggle for victory. But what excited the greatest admiration was a large pedeslal, having on it an animal call’d in bra’s large as an ox, with a short tail and a moderate dew lap, something like the Egyptian cattle; it had no hoofs; it held in its teeth, ready to brangle, another animal, clothed all over with scales that seemed impenetrable. This appeared to be a baflake; it had a mouth somewhow like a serpent’s. These figures seemed to represent an odd kind of fight, each of them furiously striving for victory. The creature which seemed to be the bafi- law was in colour like a frog, and was all over bloated from head to foot; he was casting out his venom upon his antagonist, to destroy him, while he was represented as bearing upon one knee and in a languishing state. There was also a figure of another animal, in whose jaws was repre- sented a smaller creature whose mouth was open, as almost choked by the teeth which held him, strugghing to get loose but to no purpose. His tail, which was very short, seemed to tremble; his shoulders, his fore-feet, and a part of his body, were hid in the mouth of his enemy and mailed by his jaws. This is the case with nations and kingdoms, which thus mutually destroy one another.

For further satifaction concerning the state of sculpture in the fourth and fifth centuries, a short decription of the column of Theodouis, erected at Constantinople, will be added.

This column was, in its general shape and fize, an imitation of that of Trajan in Rome; although, by the description of such travellers as saw it standing, it appears to have been larger, and formed of the same material, flatuury marble, decorated like that column, with a spiral base relief, from the bottom to the top of the shaft, surmounted by a statue of the emperor. The pedestal was covered with mi-

liary
SCULPTURE.

literary bas reliefs, on one side of which was the emperor,
leading, crowned by two victories, with a glory, raised
above the crown. The shaft of the column was by Gaius
Belien, the type, and the triumphal arch of Theodosi-
us, Arcadius, and Honorius, as it is believed, with the
emperor Gothic and Ledder Tartars; then id., kings,
trees, wagons, horses, draymen, elephants, and so on;
the captive multitude, with emblazoned figures, repre-
senting the city of Carthage, and the various figures of
the virtues, complementary to the emperors, particularly
related to their valor and elegance. Whoever desires to
be more particularly informed of the remains of ancient sculpture
which decorated Constantinople, may consult Glydullus
and Diti, and the Byantine writers.

Of Modern Sculpture. — From the fourth century the art
continued to decline, by the invasions, first of the Goths and
Vandals, and afterwards of the Saracens: and this decline
is manifest in fragments and ruins of the ages as they succeed
each other.

Theodoric, king of the Goths, established the seat
of his kingdom at Ravenna; his reign was long, and as he
very much loved building, he applied himself to his capital,
and at Rome, and in the principal places of Romani and
Lombardy, he built several palaces and churches, which are
yet to be seen; all of them, of a rude character, remote from
the principles of architecture, and the exact rules of the
ancients; he caused palaces to be built at Ravenna, Pavia,
and Modena, after a barbarous way; which were rather
great and rich than good of architecture. The same may
be said of the church of St. Stephen at Rimini, of St. Mar-
tin at Ravenna, and of the temple of St. John, built in the
famous city in the year 438, by Gallia Placidia.

The capitals of columns in buildings erected by Theodoric
and his family, are gross copies from the ancient Doric
Ionic, in which no attention is paid to the outline; the
leaves and volutes are without relief; the whole masses are
coarse, and without effect; the sculpture of baso relivo
on the sarcophagi of this king and his family at Rimini,
which represents our Saviour and his Apostles, is without
design, and of the rudest workmanship.

The church of St. Vitalis was built at Ravenna in 547.
Queen Theodolinda caused the church of St. John the Bap-
tist to be built at Monza, where was painted the history
of the Lombards; her daughter, queen Gundippiga, caused
a church to be built at Pavia. They are all of the ancient
Gothic style.

By the ancient Gothic is here meant a gross imitation of
the Roman buildings and Roman sculpture, without har-
mony, proportion of parts, or design, as nearly as these
unpracticed barbarians could imitate from the ruins of
Roman buildings, without any science, and with clumsy instru-
ments.

If the Gothic kings who embraced the Christian religion
had their painters, sculptors, and architects, they had also
to counteract these cruel wars to support against the barba-
rians, who still remained adverse to art and science; all Europe
was involved in such confusion, that little satisfaction can be
derived from the histories, and still less from the few barba-
rious remains of workmanship.

In the year 466, Clovis, king of the Franks, was con-
verted to Christianitv; he built the church of St. Peter and
St. Paul at Paris, which is now called St. Genevieve. The
fame rude workmanship is in the church of St. German,
built by Childebert, son of this king. Although these two
venerable remains of antiquity have been destroyed in the
French revolution, yet specimens of the sculpture are pre-
erved among the French monuments at the church of the
little Augustus; some of which, laid to be of that age,
appear to be much later, as the statue of the king, at the
portico of St. Germain des Pres, seems rather to have been
in the tenth century. The church in this direction of the city of Charlemagne, built from St. Denis, called La Ferté, there is in
it may be called, in its law, the model of all; it was with
every period of art, both of its own country, and it is not
with its feairs that we need deal; that statue
were a model for the rest of Europe.

What we have had in the State of Fiesole, in Tuscany,
will answer equally well for everything that was done in
England, Italy, Germany, and through at the east,
at this time.

In the year 825, Charlemagne built the church of the
Apostles in Florence, which has always been admitted by
architects of the greatest beauty, to that length which it
as a model so long afterwards as the year 1527.

In the eleventh century, when the territories of the Norman
invasion, in addition to that of the minor barbarians, had
pulled away, the governments began to be more regular and
established; agriculture and commerce began to revive; and
the crusades had diffused a very lively taste among the northern
nations, derived from the arts and literature of the East, so
that then the arts of design began that rapid course of
improvement which has been demonstrated in their works.

In 1016, the Pisans founded their great church, called
the Dome of Pisa. The commerce they had by sea, and
particularly into Greece, was a favourable means for the
establishment of architecture and sculpture. They brought
from thence several columns and fragments of ancient archi-
tecture, of marble, which they made use of in this church.

They brought together by these means several Grecian
sculptors into Italy, and also Grecian painters, who worked
after their own old methods, for using in their painting only
simple lines, which they coloured all over equally, without
any shading: their works were not very artificial, notwith-
standing these remains of art taught the Italians the practice of painting in water colours, or fresco and
mosaic.

But among all the artists of that time was Butchettu, a
Grecian of Dulichium. This cathedral of Pisa was built
under his direction; for besides the magnificence and fine
plan exhibited in this church, he used with great dexterity
those ancient pieces of Grecian architecture, and some of
them which they brought from Greece.

This great building excited in all Italy, and particularly
in Tuscany, those who had any genius for designing.

Thus the arts of designing began to be revived in Tuscany
before than were known in other countries; and very great
fabrics were reared in several cities of Italy. At Ravenna,
in the year 1384, Il Basso, a sculptor and architect, built
a great many palaces and churches; also at Naples
the castle of Capasso, now called the Vicarage, and Caltel
Dellomo; also at Venice he built the belfry of St. Mark.

In the year 1563, the IPS which the Pisans brought from
Sicily enabled them to add to the magnificence of their cather-
dral. The capitals and fragments of pillars they had brought
from Greece and Sicily, were employed in the cathedral
church and church of the bell tower; in which latter building
every capital almost is of fine ancient Greek workmanship.

The sarcophagi, chief preserved in the Campo Santa, formed
the school, in which Nicolo Pifano and his followers improved
their sculpture. The consequences of these improvements
are seen in the works of Nicolo Pifano, which are the pulpit
of Siena, the pulpit of the baptistery of Pisa, the bas relief
of St. Martin's at Lucca, the bas relief in the cathedral at Orvieto, and in other parts of Italy, in which his constant attention to the ancient bas reliefs is always observable. At this time the crusades had diffused such a spirit of piety, that magnificent churches were built all over Italy, in the designing of which, as well as the decoration with sculpture, Nicolo Pisano and his scholars were universally employed.

On the basement in the west front of the cathedral of Orvieto, there is a series of balto relieves, the work of Nicolo Pisano and his school, containing the most important subjects of the Old and New Testament, from the Creation to the Last Judgment, with separate figures of the prophets. The different subjects are contained in a running foliage, making the most rich and beautiful decoration to the four basements formed by the three doors in that part of the church. The figures are each about twenty inches high, very highly finished in flautary marble. There is in many of them a beautiful simplicity of sentiment, and in those of the Last Judgment, and the other bas reliefs that immediately relate to it, there are various striking instances of passion and terror. The pulpitos allo in the cathedral of Sienna, and in the baptistery of Pisa, which were before mentioned, are magnificent architectural designs, richly adorned with scriptural balto relieves by this artist.

At Pisa, in 1174, William Otramentano and Bonmamo, a sculptor, founded the fieceple of the dome. The royal gate of brafs in this church was made by Bonnann.

John Cimabue was born at Florence in the year 1211; he very much improved the art of designing; his disciple Ghiberto was both a painter and sculptor. Cimabue learned his art of Greek painters, who were employed in Florence. At the same time with Cimabue, flourished Andrea Tafi, a Florentine painter in mosaic; he went to Venice to perfect himself in his art; having learned that there were Grecian painters who worked in that way in Venice, he engaged Apollonio, one of them, to come and work with him in Florence, where they made several pieces. Tafi learned of this Grecian the art of making enamels and plalettes that would last a long time: he died in the year 1294.

About the year 1216 appeared Marchione, architect and sculptor of Arezzo, who worked much at Rome for the pope Innocent III. and Honorius III. he made the fine chapel of marble at St. Mary Maggiore, with the sepulchre of that pope, which is of the best sculpture of those times. But one of the first architects who began to reform in Italy, was a German named James, who built of stone the great convent of St. Francis; he dwelt at Florence, where he made the chief fabrics; he had a son, named Jacopo Amafio Lapo, who learned architecture of his father, and designing of Cimabue. He founded the church of St. Crof, at Florence, and several other buildings, the most considerable of which is the magnificent church of St. Mary del Fiore.

John Pisano was the son of Nicholas, and was also a fculptor and architect. In 1285 he was at Naples, and built there, for king Charles, the new castles, and several churches, and being returned into Tuscany, he made several pieces of sculpture at Arezzo, and also of architecture in that province, and died in the year 1320.

John Pisano deviated from his father's rigid imitation of antiquity, in giving a more waving line to his figures, and broader and less determined folds to his draperies, like the paintings and designs of Ghiberti. There is a general grace in the character of his figures; of which the bronze statues of a madonna and angels in the cathedrals of Orvieto and Florence are examples; there is no strong resemblance between the styles of these statues and those of queen Eleanor at Northampton, Geddington, and Waltham, on her crofles; as affords reason to believe they were produced by one of the ablest of John Pisano's scholars, if not from some flature or model by himself: nor is it here that the resemblance ceases, for this style is to be traced in most of the sculptures of Europe from this time to the reign of Henry VII. This sculptor had for pupils, Agolino and Andrea Sanso; they were, in the opinion of Ghiberto, the best sculptors of the time, which procured them the chief busnefs of Tuscany. They worked also at Bologna and Mantua, and bred up several ingenious pupils, and particularly carvers in silver, as Paul Arcino, a goldsmith, Maefiro Cione, and Jacomo Lanfranco, a Venetian, and Peter Paul, of the same city.

Ghiberto made designs for the brazen doors in the baptistery of Florence, which were engraved by Andrew Pisano, who also made several figures of marble in the church of St. Mary del Fiore. Andrew was as famous for sculpture as Ghiberto was for painting. The bas reliefs on the doors of the baptistery represent the life of St. John the Baptist, and possess great simplicity and grandeur for the age in which they were produced.

Stephen Florentin, Taddeo Gaddi, and Peter Cavallini, were scholars of Ghiberto, and in 1350 they formed at Florence an academy of designing, which was the first that had been formed since the revival of the arts. Taddeo Gaddi began to collect ancient sculpture for his studios, and there is a fine Greek body of a fain which belonged to him, which is kept in the Ducal gallery, and is known by the name of Gaddi's Torso.

This ingenious society was afterwards encouraged and affiliated by the princes of Medicis, which perfected at Florence the establishment of the arts of design, for there came out of that school a great number of painters, sculptors, and architects, who embellished that famous city, and all Italy, like another Sienon, where, in the time of the first ancients, the first academy of design had been established; this quickly shewed at Florence those great geniuses Lorenzo Ghiberti, Donzello, and Brunelieghi, and many other ingenious contemporaries.

Bartolocceo Cione was a sculptor in bronze, gold, and silver, and father of Lorenzo Ghiberti, who, besides following his father's profession, added to it the study of painting and architecture. He made the two fine brazen gates in the baptistery of St. John, one of which represents the history of the Old Testament, which Michael Angelo said was worthy to be a gate of Paradise; the other gate is adorned with the principal acts of our Saviour's life. Besides the beauty of the historical subjects in the panels, the architraves and friezes of those gates are of exquisite design, containing flowers, fruits, plants, and animals, so perfect that they seem to have been call from nature. He executed a figure of St. Matthew, in bronze, of a colossal size, in the church of San Michele, but this figure is inferior to his smaller works, from an attempt at excessive grace; the folds of drapery are too minute, curvilinear, and not well accounted for. He executed some bafio relieves in bronze, of the life of St. John the Baptist, on the baptismal font in the cathedral of Sienna; he also executed some painting in the same church when he was young. Ghiberti made also several curious figures, and a triple crown for pope Eugenius; it was of gold and jewels, valued at thirty thousand liras. Afterwards he became supreme magistrare of Florence, but till prattified architecture, managing for some time the building of the church of St. Mary del Fiore.

Donatello very much excelled architecture, managing for some time the building of the church of St. Mary del Fiore.
SCULPTURE.

and life of his designs, and in the character of nature in his statues, which are to be seen in Florence; he was born in 1443, and lived to be above 80 years old. His statue of St. George is a youthful pedestal figure, standing with his legs considerably apart, his two hands before him leaning on his shield. Michael Angelo admired the head of this figure to much, that he copied it in the monumental statue of Julian, duke of Nemours. Donatello designed some time the base of reliefs from the life of St. Anthony of Padua, which were executed by one of his pupils, and decorated the principal altar of the cathedral of Padua. He compos'd and executed the greater part of those noble reliefs from the life of Our Saviour, in bronze, round the two pulpits of St. Lorenzo, in Florence; the sentiment, passion, and composition of which, in parts, it seems impossible to exalt. He executed different statues of St. John, and crucifixes in wood, the characters of which are rather vulgar, and consequently very inferior to his bas reliefs. It was laid of this artiff, upon the Pythagorean idea of transfiguration, that either Michael Angelo's soul energized in his body, or his in Michael Angelo's. There is a bronze figure in the market of Florence, of Judith with the head of Holofernes, which, though, by his hand, has nothing striking in the attitude; and its drapery is confused. But there is another statue of a youth naked, about twelve or fourteen years old, in the ducale gallery, which is worthy to be ranked with the fine statues of antiquity.

Bramacichi, the friend of Donatello, was an excellent sculptor, goldsmith, and architect, and revived the true and ancient way by his indefatigable care. The remains of his sculpture are very few; there is an admirable crucifix, carved in wood by him, in the church of St. Mary Novella at Florence.

About the year 1450 appeared Andrea Verrochio and Donato Ghirlandaio, sculptors and painters in Florence. Verrochio was an excellent sculptor and engraver, not only in brass, but also in marble; he was also a good architect. He was esteemed of the first rank of sculptors, and preferred to Donatello and to Ghiberti, in making St. Thomas feeling our Saviour's side, which he constructed of brass for the oratory of St. Michael. He was the master of Pietro Pugnago and Leonardo da Vinci, and other excellent pupils. His last work was the famous figure on horseback of Bartholomeo Cogoleto da Bergamo, which is at Venice, in the square of St. John and St. Paul.

Donato Ghirlandaio was the master of Michael Angelo; he worked more in painting than in sculpture, particularly in mosaic for pope Sixtus IV. in the Vatican. He was particularly qualified as an instructor to that great man, from the delicacy of his genius as well as his original and copious invention.

But the progress of art was greatly accelerated by the progressive discovery of those miraculous productions of ancient Greek art, which had been buried so many ages, and were by degrees restored from the bowels of the earth. Poggio, the secretary to Eugenius IV., in the year 1429, particularly enumerated all the remains of ancient magnificence in Rome existing at that time, among which he reckons only five statues; two of them were the colossal statues by Phidias and Praxiteles, on mount Cavallo; the third the equestrian statue of Marcus Aurelius, at that time before the church of St. John de Lateran; the two others, perhaps, were the figure called Marforio, which is a recumbent statue of the Ocean, now in the Capitol; the other a fragment of the group of Ajax supporting the body of Patroclus, called Patroclus. The Laocoon was found in the year 1506.

In the year 1474 was born at Florence Michael Angelo Buonarroti; he was brought up to learn, but being himself always in private about designing, which his father desired, he put him to Damiano Ghirlandaio. In a little time Michael Angelo disdained to liken above his other disciples by the insipid beauty with which he designed. This great genius was very fortunately favored by prince Lorenzo de Medici, who, with great love to art, and a desire to assist men gifted and learned therein, established in the gallery of his garden an academy, which he filled with fine pictures and pieces of sculpture, both ancient and modern, and sought out at Florence those young designers who promised to do him service, to whom he allowed pensions to promote their studies. Those of the school of Ghirlandaio were chosen the first, and particularly Michael Angelo, who, having one day taken up a piece of marble, set about making a head, though he had never before handled a chisel, which so much surprised prince Lorenzo, and he conceived to great an affection for Michael Angelo, that besides allowing him the pension, he made him a companion at his table, and gave him a lodgment at his palace. After the death of this prince, his succesor, Pietro de Medici, continued Michael Angelo the same affection he had enjoyed from his father.

At Rome he made a marble statue of Bacchus, with several other marble statues. At his return to Florence, he applied himself with the same diligence, and made a David of marble, which was set up before the palace. Peter Soderini, the Gonfaloniere, and the citizens in general, were so charmed with the statue, that they required of him other works in bronze and in painting. The Gonfaloniere then ordered him to paint one half of the council-hall, and Leonardo da Vinci the other.

Michael Angelo in this work gave proofs of the excellence of his designing, both with respect to the composition of the subject, which was the war of Pyra, and in the correctness of his naked figures; and to have an opportunity to shew the better, he chose the time when the soldiers were bathing in the river Arno, to introduce the figures naked. Raphael, and the artistes his contemporaries, improved the grandeur of their design from that cartoon.

Julius II. being raised to the papal chair, sent for Michael Angelo to Rome, resolving to engage him in a mausoleum in St. Peter's, which was intended to flord under the centre of the dome, to be the most magnificent of the kind ever raised, and the principal object in the church. This work, however, was delayed till the pope died, and then one of its faces only, and upon an inferior scale, was erected by his nephew in the church of St. Peter in Vincole. The figures which decorate the architecture of this tomb are those of the pope, Moses, and allegorical virtues. Two statues of marble, which were to be part of this sepulchre, are now in the castle of Richelieu in France.

The execution of this monument was interrupted by Michael Angelo being at the same time employed by the pope to paint in fresco the arch of the church of the chapel of Sixtus IV., which so much raised his reputation, that besides the general applause that he received at Rome, the pope rewarded him also with several prebends. Julius II. being dead, Leo X., his successor, honoured Michael Angelo no less than he had done, employing him on the architecture of the front of St. Lorenzo at Florence.

After this, in the popedom of Clement VII., he designed the architecture of the vestibule, in the same church, for a mausoleum for the house of Medicis, and adorned the east and west sides with the sepulchres of Julian, duke of Nemours,  

Vol. XXXII. and
and the duke of Urbino, opposite to each other; with three
statues on the north side, the Virgin and Child, St. Peter,
and another saint. Both architecture and sculpture are
still admired among the finest productions of this art.

The fortification of the city of Florence was committed
to him: he fortified mount St. Miniati; but when the
wars of Italy in 1525 obliged the artists to leave Rome and
Florence, Michael Angelo was one of the number, and
going to Venice; where the doge Gritti employed him,
and he made the design for the bridge of Rialto, which
is one of the master-pieces of architecture. He painted in
that city sixe pictures, and among others that of Leda,
which he gave to the duke of Ferrara, who sent it to
Francis I.

The wars of Italy being ended, Michael returned to Rome,
and there finished the sepulchre of Julius II., after which
he painted, by order of Paul III., the great front of the
altar, whereon he represented the Last Judgment, it being
this only which was not finished of all the paintings in the
chapel.

The Last Judgment, and the ceiling of the Sistine chapel,
may be considered, together, as the noblest production of
modern painting existing in the world; and it is to be
doubted whether any work of antiquity could be compared
with it for grandeur of conception and power of execution.

He painted also, in the Pauline chapel, the Conversion of
St. Paul, in which the Saviour descends in the midst of his
heavenly ministers, as he addresses the fallen convert, who
is surrounded by flying harleions, and the on foot in dif-
ferent directions and inexplicable terror. The Crucifixion
of St. Peter, on the opposite side of the chapel, exhibits the
horror of the action, the patience of the saint, the grief
of attending friends, and the dolorous solemnity of the sur-
rounding multitude.

Michael Angelo, in his old age, applied himself more to
architecture than to sculpture and painting. After the
death of Anthony San Gallo, the pope appointed him chief
architect of St. Peter's, and of the apostolic chamber, al-
though he would have excused himself from it; but having
accepted the charge, he went to St. Peter's to examine
San Gallo's model, which not approving, on account of its
being a composition of parts, without sufficient reference
to a whole, he caused another model to be made, which not
only produced a much grander and more magnificent fabric,
but at one-eighth of the expense. And this great church
was finished according to the design of Michael Angelo,
excepting the front, which is not his. While he carried
on this building he made also several others, which constituted
part of the beauty of Rome: such as the palace of Farnefe
and the Capitol.

After he had arrived at the age of 80, and had withdrawn
himself from most works of importance, except the building
of St. Peter's, he gratified the pitty of his own mind, and
amused his leisure hours in working on one large block of
marble a group of four figures, representing the dead body
of our Saviour supported by Joseph of Arimathea, attended
by two of the Marys; a pathetic and noble composition,
which he did not live to finish. It is now to be seen on the
back of the high altar in the cathedral of Florence.

Michael Angelo died at Rome in 1564. He was almost
90 years of age. This great man, besides the affection of
seven popes, whom he served, is said to have gained very
great reputation among the following princes: Solymau,
emperor of the Turks; Francis I., king of France; the
emperor Charles V.; the princes of the republic of Venice;
and all the princes of Italy, particularly with the great
duke of Tuscany, who reigned when he died; for when his
body was in the church of the holy apostles, and the pope
was about to set up a fine sepulchre for him, this great duke
could not to be privately fetched away to be buried in
his capital city, and performed his funeral obsequies with
all imaginable pomp and splendour. This pomp was cel-
brated in the church of St. Crofs, at Florence, attended by all
the academy of design, who on that occasion gave sufficient
testimony of the esteem they had for their master by the
magnificent representation which the Italians call Catafalo,
and adorning the whole church with painting, and sculpture,
and lights. A panegyric was there pronounced over him
by Meller Benedetto Varchi.

Michael Angelo's character, as a man and an artist, was
equally honourable to painting, sculpture, and architecture:
his integrity is unimpeached; his generosity and gratitude
were princely; his piety and temperance were exemplary;
his studies were indefatigable; his genius was universal
and original; and his execution equally powerful, beyond
all thole who went before him and all his subsequent
imitators.

John of Bologna was a sculptor of great merit, both in
bronze and marble, who lived rather later than Michael
Angelo: his groups are remarkable for the good composition
and fine undulation of his lines, of which the Rape of the
Sabines, in the market-place of Florence, is an instance.
His statue of Mercury rising from the point of his toe into
the air is also justly admired. Many smaller works by this
artist partake in the same grace and beauty, and may be
studied with advantage.

Benvenuto Cellini, who was a goldsmith and sculptor in
metals, executed a fine colossal group, of Perseus holding
the head of Medusa in his left hand, with the sword in his
right, and standing on the body from which the head has
been separated: the pedetial is most whimsically adorned
with bas relief and chimerical figures relating to the subject.

After these artists, the Florentine school of sculpture
lindered into a state of infancy.

Bernini was employed in Rome by pope Urban VIII.,
and built the noble semi-circular porticoes of St. Peter's
church. His best work of sculpture is the group of Apollo
and Daphne: he designed and modelled inmumerable figures
for St. Peter's and the bridge of St. An-
geo; he executed the monuments of Alexander VII. and
Urban VIII. in St. Peter's; the colossal statue of St. Lon-
gius; and four doctors, which support the chair of St.
Peter.

This sculptor, whose works are fom numerou8, as he was
first a painter, and formed in the Lombard school, endeav-
oured to embody Coreggio's style of painting in sculpture,
forgetting the impossibility of representing flying draperies
and the extremities of hair in marble, which is to easily done
on canvas; and which, when universally attempted, remains
an equal testimony of the sculptor's want of judgment, and
the impossibility of the attempt. Although there are fine
ideas in the general conception of both the papal monu-
ments above-mentioned, by this artist; yet his allegorical
figures are affected in their attitudes, simpering and con-
ceived in their countenances; their forms are flabby and in-
correct, and their draperies confused: yet this style, de-
praved and flatly as it was, in spite of the beauties of
Nature, which continually appear before our eyes, and the
Grecian examples of rigid perfection which adorn the city
of Rome; notwithstanding thefe, it produced a train of
followers, Rafconl, Algardiz, Mosco, &c. &c. who continued
to be employed, till within these fifty years, in Italy,
SCULPTURE.

where the flimsy materials upon which they formed themselves were entirely worn out; and the human intelligence returning to the doctrine of art, which is the imitation of Nature, began the work anew, studied the principles of the ancients, and applied themselves with diligence to a representation of the human form divine.

This same mode of study has produced a new and better school, which promises something like a just emulation of the best days of Greece, in the works of that distinguished sculptor Mr. Canova, and some other sculptors, both natives and foreigners, in Italy.

The French nation, from its vicinity and intercourse with Italy, as well as from the friendship which the early kings of France cultivated with the emperors of Constantinople, always preferred a taste for fine art in that country, and supplied the means of its improvement, both in painting and sculpture. The large collections of fine Greek manuscripts, with their numerous beautiful illuminations, wereimitated by the French painters, and the nearness of the countries to each other, enabled the French artists to study sculpture and architecture in Italy, as well as the kings of that country to supply their great public works with architects and sculptors from Italy also. In the reign of Francis I., Leonardo da Vinci, Benvenuto Cellini, and Primaticcio, laid the foundation of a school of fine art, similar to that in Italy, as improved from the lately discovered Grecian works. The natives, who distinguished themselves most immediately after this period in sculpture, were Pilon, Counin, and John Gonjon, whose bas reliefs on the foundation of the innocent deserve admiration and praise. In them is an union of the elegance of Raphael's school, with the Grecian purity and delicacy. The genius and abilities of the people, added to national munificence, have kept up a respectable school of sculpture in France till the present time.

Whatever has been done in painting and sculpture in Spain, was also derived from Italy. The native powers and virtues of the Germans, which have contributed so largely to modern improvement in arts and letters, have not been deficient in the art of sculpture. Our present limits and object will not allow us to produce many examples; therefore we shall mention one which would be honourable to any nation, in any period. The monument of the emperor Maximilian, father of Charles V., stands in the church of St. Anthony at Innsbruck: it is in bronze, and was made by Alexander Collins of Mechlin, the sculptor. The idea of this monument is as extraordinary as the effect is pathetic. Maximilian lies in his imperial robes upon his tomb, elevated about five feet from the ground. There are, at the distance of two feet from the tomb, marble steps about two feet high. On one step stand eight colossal statues of his illustrious relations; and on the opposite step as many more facing them. They represent distinguished royal persons from the time of Godfrey of Boulogne, of whom he was one. The spectator is awed by this silent and imposing assembly, who stand in striking attitudes and solemn grief by their relation. The actions are bold and forcible; the armour is rich and elegant in the highest degree; but it may be objected that the ladies have something of muscular heroism in their characters.

There are several other fine statues in bronze, of inferior dimensions, representing German princes, in the same church. There is also a most noble monument by this artist in bronze, representing St. George, with one foot on the dragon, which he has just slain.

England, like the other nations of Europe, chiefly derived her arts and letters from her Roman conquerors. Altogether she is not without her obligations to Christian Greece as well as ancient Greece, for the arts and learning of the different ages. Those which were called Saxon architecture and sculpture, were in fact only barbarous imitations of the proved Roman arts. The Norman architecture and sculpture of this country were likewise an imitation of Roman art; but through the more diffused medium of the Norman French, subsequent improvements in the revival of arts were derived more or less remotely from Greek or Italian affinities; though, in justice to the genius of the English, it must be acknowledged that their progress in the art of sculpture, down to the Reformation, kept a respectable pace with their neighbours on the continent, as may be still seen by the sculpture on the west front of the cathedral of Wells, completed in the reign of Henry III.: in Exeter, Litchfield, and Salisbury cathedrals, but more especially in the sculpture in Henry VIIIth's chapel of Westminster Abbey: in also reliefs of scripture subjects, monumental sculpture, and figure statues, to be seen in different ecclesiastical structures throughout the kingdom. From the time of the reformation, when painting and sculpture were expelled from the native genius of the country, and left entirely without employment, and wherever painting was required for the decoration of palaces, or sepulchral sculpture for the churches, foreign artists were employed, and, with little exception, supplied the country with a degeneracy of French, Italian, or Flemish art. The belt of the foreign sculptors who have been employed since that time were Cibber, who executed the statues of Raving and melancholy maidens on Bedlam gates, the bas relief on the pedestal of the London column, the greater part of the kings in the Royal Exchange, and a multitude of other statues for different buildings in various parts of the kingdom: Roubiliac, who executed several monuments for Westminster Abbey, with much labour and attention to common nature, the compositions of which, however, are either conceits or epigrams, and the parts too often mean and vulgar. Scheemacher executed some of the statues on St. Paul's, and the bas relief in the pediment; but he is not distinguished for pre-eminence and ability.

Since the establishment of the Royal Academy, and the frequent employment of the sculptor's talents in public monuments, the art has been practised by natives, whose own industrv, studies in Rome and foreign countries, and the zealous exercise of their profession, have raised works equally creditable to the country and their own talents. Mr. Bacon's works have been much admired. Mr. Banks has left statues and baso relieves which might be ranked with some of the best works of antiquity: and some of the public monuments by English sculptors of the present day, might be compared with advantage with the ablest productions of the same kind on the continent.

In the general treatise on an art, we cannot pass over in perfect silence the productions of a great empire which has pretended to the highest antiquity in its cultivation; the ingenuity and beauty of whose finer manufactures and more delicate works have claimed universal attention, and have been admired and collected by most of the curious. The Chinese sculpture must be noticed; though, from the productions we have seen in Europe, and from the fact authenticated inquiries, we have great reason to believe that such of their paintings and sculptures as can lay any just claim to those titles, have received but little of their charms from European communication. There is great reason to believe that their smaller models and bronzes were improved from a very barbarous state. Among other branches of knowledge by Catholic
mansionaries who went over in the fourteenth century, their arts received a further improvement from the learned and ingenious Jesuits who visited them in the beginning of the seventeenth century; and again in the beginning of Louis XVth's reign, sixteen Chinese in the city of Paris were instructed in the European arts of designing, light, and shadow; optics, colour, and perspective; since which the painting and sculpture of China have become more nearly allied to the European practice of those arts than ever. These facts are attested by the known attainments of the several missionaries who have visited China; by the testimonies of the bolt writers who have written on that country; by the representation of European head-dresses and fashions in their works; and by Chinese subjects drawn and engraved by Jesuits who were resident in that country, and whose art of designing flew that the Chinese artists, of the same ages, formed their school of art upon the works of these men.

Motives for the Employment of Sculpture in Greece, and the Encouragement given to the Art.—The chief motive for the encouragement of sculpture in Greece was religion, which induced the several states and independent individuals to work with each other in employing the choicest talents of their countrymen for the production of the most beautiful and approved works, to adorn their temples and public places in honour of the different divinities, which they believed to be their more immediate patrons and protectors in that state of polytheism. This species of piety became more popular; and its effects became more general from another motive, the relation which most of the powerful families of Greece claimed with the several divinities and heroes, by dedicating their own genealogies from some one or more of them.

In a state of society where the families of all lived nearly in the same habits of simplicity, because the luxury and magnificence of private life created a jealousy among fellow citizens, likely to terminate in most tragical consequences; in this state of society the more wealthy employed their stores in building and equipping ships, raising troops of horse or foot, increasing the temples, placing in them magnificent tripods, beautiful statues, or other costly gifts; in strengthening the walls of their cities, and all such public works as provided for the safety, or increased the fame of their country.

Patriotism, in addition to religion, was another motive, not much less powerful than the former, for the encouragement of sculpture in Greece. The Olympic games, instituted at an early period in that country, encouraged the trials of skill to the utmost extent, which educated the human frame in the greatest habits of strength, activity, and promptness of exertion, for all the most useful employments of peace and war. They also publicly exhibited the finest forms and examples of personal beauty to the assemblies of Greece at the Olympic exercises, and by that means enabled the philosopher to analyse, the physician to enquire and deduce, the artist to form principles from nature for the perfection of his works, and the generality of spectators to judge of the phenomena of health, strength, activity, proportion, and pleasing parts of the human form, among those who were engaged in the exercises, and rendered themselves, by their prowess, ability, and fortitude, the objects of universal admiration and applause.

The immediate honours bestowed on the victor was an herbal crown, rendered equal in value to the richest diadem, by the approbation and congratulation of the whole state. The victor was likewise honoured with a brazen statue on the very ground where he had thrown himself properly qualified to be a defender of his country in war; and for prudence, activity, and fortitude, a valuable citizen in time of peace; and if any one obtained the crown three times in these exercises, he was not only honoured with a bronze statue on the spot, but that statue was made an exact portrait of him, not only in the face, but every part of his body and limbs. These general remarks on the religion and public institutions of Greece will sufficiently account for the immense sums expended in works of sculpture, and the prodigious multitude of these works produced in that country.

The statue of the Olympian Jove, made of ivory and gold by Phidias at Elis, was paid for by all the spoils taken from the Persians. If we might calculate a small part of this statue, only by the price of ivory at present, the covering of ivory only, which must have been perhaps the least article of expense in it, without the workmanship, could not have cost less than 2000. There were 8000. Hefting of gold in the statue of Minerva made for the Acropolis, besides the ivory, workmanship, and all other expenses.

We are beside told of another statue of the size of nature, valued at 10,000. gold, and of another, the Venus of Gnidus, which was refused to be given up for the payment of the debts of a whole city; and thus we cannot wonder that works produced from the noblest motives, and rewarded by the highest gifts that man could bestow on man, were of a supreme excellence, which have commanded the admiration and interest of all succeeding ages.

Concerning general Beauty in the ancient Works of Sculpture.—After a general view of the motives and circumstances which produced these works in public, we shall next enquire into the more private motives, attainments, and qualities which enabled the artists to produce such works, and here we must remember the observation of Socrates, that the dispositions of the mind may be expressed by the forms of the body; and as Socrates himself was a sculptor of no mean excellence, and a philosopher of the highest character also, what he says upon this subject cannot too carefully be attended to; and indeed it applies to the progressive improvement in this art from the most rude representation of the human form to the most perfect; and to the separate consideration of the mind and its qualities, by which the human form is animated.

As it has been observed in a former part of this article, the earliest attempts to represent the human form in all nations are almost equally barbarous and imperfect; we shall, therefore, begin our description of Grecian imitation, when, by a more general comprehension of science, her imitation of its archetypa was superior to such barbarous primitive attempts in general.

These attempts and their improvement have always succeeded best in those parts of the human figure which are nearest to our view, or present themselves to us most striking and important. In such representations, the features of the face are more accurately represented than any other part of the figure. The body, the arms, and legs attract the most general and less distinct notice; therefore the first improvements in the earliest statues of Greece remaining, approach only to something like a more tolerable proportion, express the arms in general meagre long forms, with the shoulders somewhat more round and prominent, and the fingers separated by nearly parallel channels. The body is distinguished by the paps of the breast, the line of the ribs, and the navel. The legs and thighs have little more of variety in their forms than a small knee-pan, and some projection of the calf of the leg, with feet and toes formed with as little attention to nature as the hands. In this state of improvement little variety of action will
wills conically be expected. Sufferings, illnesses, running, or
breathing, will nearly comprehend the whole extent of the
artist's activity in a single figure or his relief. In the late
state of improvement it is no wonder for experts to experi-
en any discrimination between the characteristics of gods and men; they were
all represented by the same forms: and Jupiter, Hercules,
Mercury, and Neptune were only known to each other by
the thunderbolt, the bow, the caduceus, or the trident.

According to the general improvement of taste, as the
observation of the surface of the heavenly bodies, the
divisions of land, and marking out the plates for building on
the ground, had introduced some practical application of geo-
metrical lines and figures, which must preclude observations
on the balance and motion of bodies; and as something more
like anatomical knowledge was obtained from the facsimile
of animals, or observations on the dead left on the field
of battle, or a human skeleton casually found; as these affl-
fances afforded light on the structure and movements of man;
the artist, applying principles as he became master of
them, copied his example with more accuracy, and repres-
tated the parts more in detail.

The next state of improvement we shall observe is a nearer
copy of ordinary nature, in which the hair, however, is
straight, the eyes full, the eyelids gently marked, the bottom
of the nose and the line of the mouth curved upwards at
the corners, giving a kind of smile to the face; the breast
a little more prominent; some indication of the muscles of
the abdomen by cross parallel lines; the hollow in the
hollow behind, and the general form of the blade-bones, more
natural; more distinction between the breadth of the upper
and lower portions of the thigh; the general forms of the
feet and hands, more accurate according to their angles and
divisions; and the biceps muscle marked in the arm, and
the elbow. Specimens of these different steps of improve-
ment may be seen on the Greek painted vases, particularly
those in which they have black figures on them. There are also many
small bronzes, which are demonstrations of the fame pro-
gress of improvement.

In the age of Phidias, when geometry had made con-
siderable advances, as we find by the writings of Plato, when
anatomical researches had been prosecuted with success by
Hippocrates, in addition to the advantages of seeing the
human figure in more perfection, from the establishment
of regular government, the more regular supplies of agricul-
ture for living; and other improvements in civilization most
favourable to the beauty of the human figure; — with these
advantages, the human figure was represented with the dis-
tinction of youthful beauty and elegant proportion, as well as
with the strength and agility which indicates a rather spare
diet and great exercise, of which the statue called Theefes
in lord Elgin's collection is an example.

It is remarkable, that personal beauty of countenance and
elegance of form frequently occur in works about the time the
Parthenon was built; although in the same works there is an
evident want of proportion and perspective in some of the
parts, with the most careful confusion of the drapery. But
we must remember that the course to excellence is progressive,
even to the greatest genius, and that all arts are perfected by
the accumulation of discoveries and long practice.

Having mentioned the first dawns of beauty in Greek
sculpture, this will be the place for some enquire concerning
that beauty which so eminently distinguished their best
works. A people long acquainted with the naked human
form, and the exertions of the human figure, would practi-
cally learn, that a particular make was favourable to a parti-
cular exertion, as long legs were favourable to walking and
running, broad shoulders and a full head were important
by this. The observed action of the parts would affect in
allowing the more convenient form of all other parts of
the body and hands for strength and grace, and the propor-
tions into the animal economy of the body, and the cir-
cumstances relating to health or hisiency, in the whole or
the parts, according to outward appearance. All this
would affect the artist in the determination of what he should
choose and what he should reject in his creation. The
bloom of youth, the prize of manhood, and the parts best
formed for all the uses and exertions of the body, would
become his standard example for the most fortunate attempts
of his art; and having proceeded thus far, he would be
able to more readily distinguish the usual character of
youth and manhood, the venerable form of advanced age, and
the graceful forms of female elegance.

But other distinctions and other characteristics still remain
in the artill to become acquainted with, to qualify him for
the extensive representation of gods, demi-gods, and heroes,
human creatures and infernal beings; and this could not be
done by the simple representation of common forms and
common expressions, such as controllingly proceeded themselves,
but by a selection from nature of whatever was most excel-
lent in form, accommodated to the highest qualifications
mind, to represent the higher orders of beings, and their opposi-
tions in those which are below humanity, and partaking of
animal and infernal nature.

More form, however harmonious in its proportions, or
beautiful in the smoothness and perfection of its boasted
surface, without the expression of sentiment and action, is but
bad, and no other than a corpse which has been quitted by
its immortal spirit; therefore the artist's great and most im-
portant interest, after he had obtained the geometrical forms
of body, was to watch the strongest and decided emotions
of mind in order to give animation to his works. It was
his concern to investigate and represent decidedly the
strongest affections, contemplation, parental, local, and
sexual; the sentiments of piety and religion; the incidents of
passion in their different degrees, whether of love or hatred; for
by these means only his works fastened on the kindred effec-
tions of the spectator, and obtained his esteem.

The Greek artists who gave these first mental improve-
ments to their works, sought for nobility of sentiment and
distinct characteristics of gods and heroes from the writings of
Homer; illustrated by the speculations of Pythagoras and
Plato upon the essential qualities of divinity, in their omni-
potence and extent, and the limited powers of humanity,
derived and finite.

From these they learned that all bodily perfection and
beauty were derived from mental beauty and perfection;
that as forms which expressed healthful bodies and their parts
were the most perfect, as far as form and animal power ex-
tend; so the expressions of the most perfect mental qualities
added the most perfect animation of beauty to those forms,
and gave the most perfect characteristics of magnanimity, jus-
tice, benevolence, and dignity to the faces and figures of their
divinities, and in an inferior degree to their heroes: and
whatever perfection of face or person they would express,
they found could only be done by the sentiment of this vir-
tue and beauty of men by which it was immediately caused.

Jupiter, the chief of their gods, was represented in the
most perfect human form; powerful in his make, benign in
his countenance, and of that mature age when wisdom is
united to the full development of the bodily powers. His
full beard and abundant flowing hair are collected with the
gratefully dignify the human head is capable of; and the hun-

Sculpture.

3
like hair and forehead decide the magnanimity of the character. The broad chest, the strength and proportion of the limbs, the whole solemnity of the person, at the slightest view, announces, according to the Homeric expression, the father of gods and men.

The next divinity in dignity to Jupiter is Apollo, whom we can readily believe to be the exact representation of his father, in the dignity of youth; his features are his father’s in youthful bloom and beauty; the form of his body and limbs partake of his father’s strength in youthful lightness and agility; his countenance is adorned by his flowing locks, according to his age, more light and varied than his father’s; his sentiment and employment are also suited to his age and more limited offices. Jupiter, seated on his throne, has little action or corporeal employment; his mental energy regulates the universe by his nod; and his single exertion is the discharge of his irresistible thunder. Apollo is seen in love, in meditation of immortal poetry to accompany his lyre, destroying Python, meditating the cure of diseases, or inflicting death by his arrows.

Bacchus resembles his brother Apollo so exactly, that they cannot always be distinguished one from the other; yet he frequently partakes of a more feminine nature, according to the Orphic description of his double sex.

Mercury, with the same beauty as his brother, and the same youthful resemblance to his father, has a more athletic form, approaching to heroic, as being the patron of gymnastic exercises, and messenger of the gods. His hair is short; he wears a small round hat or pafuas, which is winged; he has also wings to his ankles.

Mars differs little from Mercury in form or countenance, excepting that he is sometimes bearded, and frequently wears a helmet upon his head, or is drest in complete armour.

Neptune resembles his brother Jupiter, but his hair is more disturbed, and he is in general entirely naked.

Pluto also resembles Jupiter and Neptune, but his eyes are more flaring and spectre-like; his abundant hair falls more over his forehead, and gives a greater gloom to his countenance; he is clothed in a tunic and pallium, holds a sceptre in his left hand, and is attended by the triple-headed dog Cerberus.

The goddesses are drest distinguished from each other than the gods. The height of female beauty, in dignified figure, with noble mien, is common to them all.

Juno is represented with a regal diadem and sceptre, generally clothed in the tunic and peplum, or large veil; her countenance is lofty; her eyes and lips are full; her hair is turned up, and tied in a knot behind in simple majesty; her veil is sometimes over her head.

Minerva is distinguished by the serene austerity of her countenance, and the wisdom of her character. She is armed with a helmet and aegis, and bears a spear in her hand, but in other respects is drest like Juno.

Venus is distinguished by her tender softness and graceful action; she is represented as parting her hair and rising from the sea, modestly covering her person as returning from the bath; or drest in a light and thin tunic or veil, and engaged in those concerns of the toilette to heighten or preserve beauty. She is frequently attended by Love, who is represented as an infant divinity.

Vesta and Ceres have much the appearance of Juno; the first distinguished by her lions and myrtle drum; the other bears corn.

Diana has her hair collected on the top of her head; like her brother Apollo her tunic is Lucinæt, not reaching lower than her knees, its length being shortened by the tying of her zone; she wears buxkins, and is generally running, or in an attitude which relates to the chase.

Hercules, the first of their heroes, and who in early times was one of their greatest gods, was not represented with that irresistible strength and muscular force in the time of the first Greek sculptors, in which he was represented afterwards, and he changed his arms as well as his figure, for before the time of Eichylus his arms were a bow and sheaf of arrows; but as his labours became such as required more natural force, according to later mythologists his bodily powers were increased, and his arms changed from the bow to the club. His strength is proverbial, and his powerful form known to every one, by his numerous representations in sculpture and painting. It is well remarked by Winckelmann, that in the likenesses found in the antique statues between the faces of Hercules and Jupiter, there is a character of the bull given to the head of Hercules, by the short hair and the bull forehead. As a proof that this mixture of the bull in the head of Hercules is not fanciful, there are busts representing a mythological modification of the Herculean character, with the bull’s ears, horns, and dewlap.

We shall describe the fawns as one class, companions and minions of Bacchus; in this class we shall mention the Sileni, the foifer-fathers or nurses of Bacchus, one of which is a dwarfish figure, with a round belly, fat limbs, a somber merry face, a bald head, a long beard, undulated and divided; his body is more or less covered with hair. This Silenus is also occasionally called Ampelus. The other Silenus is a well-proportioned elderly man, rather a spare figure, with a philosophical countenance, and a head and beard bearing some distant resemblance to Jupiter. Both these Sileni are crowned with ivy, and have pricked ears.

The fawns have round faces, short noses, and a grinning expression; their hair is short, thick, and like that of a goat. Their bodies are strong, their muscles tender, like those of wild animals, and suited to the elasticity of their actions; they have short goats’ tails.

The satyrs have goat’s legs, their bodily conformation like the fawns, they have pricked ears, sometimes long goatish beards, and frequently faces resembling rams or goats.

The Titans and giants are Herculean figures to the waist; some of them have the lower limbs human, and corresponding to the upper part of their figures; others from the middle end in serpentine folds instead of human legs. Their heads have an Herculean character, fullen and terrific; there are serpents in their hands, perhaps relating to their infernal punishments.

Ocean and the divinities of seas are all Herculean figures, in countenance resembling the Saturnian family in youth or age; they are generally naked, though some are veiled downwards; and Ocean himself has a veiled head. The inferior divinities of the sea, as the family of the Tritons, and their various divisions, have hair, faces, bodies, and arms like the fawns, but with finer hair and gills, their lower halves ending in the tails of fishes, horses, bulls, &c.

The nymphs of mountains are robust figures, with solemn countenances, flowing hair and beards, crowned with pine, oak, &c.

The nymphs of Earth and Ocean are beautiful entire female forms, with hair sometimes flowing, sometimes tied in playful attitudes. The marine nymphs are frequently collected in affectionate groups, and employed in stretching out their flying veils to the wind.

The Three Graces are the beautiful female companions and attendants of Venus; they are represented as three beautiful
beauteous virgins, in the flower of youth, embracing each other.

The nymphs of Diana are habited like their patroness.

The Furies are handsome, but with a terrific expression of countenance; their hair dishevelled, wriggled, and with two small serpent-like heads, and on the tops of their heads; their dreads are shorn nearly short, and their limbs like Diana, and they have snakes and torches in their hands, to torment the wicked.

What has been said is sufficient to convey a general idea of the human figure in Sculpure, and to show what the sculptor should observe when the human figure is intended to appear in a sculptural work.

Concerning the Beauty of Parts in the Human Figure, its Balance and Motion.—The ancients have observed that the human figure is inscribed within the sphere and the circle; the square, when the feet are close together, the posture upright, and the arms extended in a parallel line; when the length from the extension of the opposite finger is equal to the whole height, from the crown of the head to the seat of the foot; the general observation leads to the determination, not only in the position of the body and limbs, but to the figure, by geometrical lines. The human figure being laid upon its back, the arms and legs, extended like the spokes of a wheel, may be inscribed in a circle, the centre of which is taken from the navel. When the figure stands upright, equally poised upon both feet, the centre of gravity falls in a perpendicular line from the gutters between the two ankles.

When the figure sits upon one foot, the centre of gravity falls from the gutter, perpendicularly on the bottom of the tibia bone of the leg on which it rests.

If the figure is in equipoise, the centre of gravity falls from the gutter between the legs.

In advancing from that point before the leg, and in swift running, it is at every interchange of step far before the foot which is next to be placed on the ground.

The figure, in bending sideways to balance itself, must still retain an equality of weight round the centre of gravity, to preserve its balance by stretching out the opposite leg or arm.

For further satisfaction concerning the motion of the human figure, consult Borrellus de Motu Animalium; Covent on the Muses; and Leonardo da Vinci on Painting.

To obtain a more positive idea of the form of the human figure, as well as its balance, together with the breadth of its parts, a reference to a geometrical figure is particularly useful. For instance, view it in profile, and we shall see that its column or general mass is not perpendicular, but consists of undulations, through the middle of which we may suppose the centre of gravity passed perpendicularly downwards. The head is thrown forward over the neck and the breast, to serve as a counterbalance with the breadth against the projection of the shoulders; and the projection of the eyes counterbalances that of the abdomen; so that the back-bone beginning from its uppermost joint, which immediately supports the skull, after being a little curved inwards, though nearly straight for the first seven joints, afterwards forms a bold curve outwards between the shoulders for the next twelve joints downward to the hips, partaking in the same hollow with the ribs, to contain the organs of the thorax.

The projection of the thighs in front is opposed lower down on the opposite side by the projection of the calves of the legs; not only for a counterbalance, but also for counteraction; and for the same reason the bending forward of the body from the head downward is determined by the length of the feet, and its solid weight for support.

The general view of the head in front is egg-shaped. The terminal character of the profile is that of the nose, little differing in straightness from the line of the forehead, the lips and chin making small projections, each about a quarter of a circle. This is the most general and simple idea of the human face, and that principle upon which all of the human ideal heads are formed. Force and passion are deviations from this principle by the application of curves in the outline more or less bold, and the face of infancy is determined by one portion of a circle forming the forehead, and another the cheeks, with a small hole between.

In the ancient sculpture, the most perfect necks for youth, beauty, and strength, are nearly circular, like the portion of a column. The breasts are elevated and broad; the line of the ribs is nearly a portion of a circle gently expressed, a little below the nearly straight line, which terminates the breasts above. The abdomen has a gentle curve below the pit of the stomach to the navel. The lower muscles of the abdomen to the os pubis are a little swelled and evenly plain. The sides of the ribs under the arms are marked with gentle divinations diagonally, tending downwards in front, which indicate the ribs and muscles which immediately cover them. The back of the trunk between the neck and the back is a curve outwards, as has already been decided; and the spine, or back-bone, which is the pillar of support to the upper part of the body, the arms, and the head, having behind an indentation between the two rounded portions of that back, on which the blade-bones and their muscles form a gentle and rounded flattened swell immediately below the neck. The commencement of the arms, as they are affixed to the body, has a hollow and rounded form, in the upper part of which is united the head of the upper arm-bone, to the end of the collar-bone before, and the blade-bone behind; the arm, beginning at the separation from the trunk and continued to the wrist, is a diminishing cylinder. The upper arm finishing at the elbow is broader, and sideways flatter than the lower arm. The lower arm is flattened the contrary way, and less than the upper part of the hum. The wrist is a rounded flattened form in youthful bodies full of flesh. The hand is hollowed within, and a little rounded without. The thumb extends to the end of the first joint, of the middle joint of the first finger, the middle finger is the largest; the next finger outwards is next in length; the finger between the thumb and the middle finger next in length; and the little finger shortest of all: they are less in bulk as they are shorter, and diminished downwards cylindrically. The male hand and finger has more of breadth and fatness; the knuckles are more square and defined even in youth. The female hand is more rounded and fleshly; the fingers are more perfectly cylindrical and tapered, the knuckles less decided, having little more distinction than gentle hollows in the more constricted portions of those knuckles, which unite the fingers to the hand. The nails in men are more squared, in women more rounded, long, and delicate.

The bones of the body are in the side view considerably curved in from the ribs, and project again in a gradual obliquity from the bottom of the ribs to the bottom of the nates. In the front of the figure, the trunk terminates at the os ilium or baron bone, which is marked immediately before the projecting muscles, which terminate the line of the
SCULPTURE.

From the bottom of the os pubis to the bottom of the patella, is the same length as from the bottom of the patella to the sole of the foot, two heads each; but we must observe, that the ancients generally allowed half a nofe more to the length of the lower limbs, exceeding the length of the body and head.

The arm, from the top of the humerus to the bend, one head and a half; and from the bend of the arm to the first knuckles, the same.

The female figure should not be too tall as the male. The shoulders and loins should be narrower, and the hips broader.

The proportion of the Hercules Farnefe and the Torso Belvedere are nearly one-fifth more in breadth than other statues.

But the ancients varied the proportion according to the character and age of the perfon. There are examples of the Silenus, and Hercules also, when he partook of the fame character, exceedingly dwarfish, not exceeding four or five heads in height; and there are examples on some of the Greek vases of figures nine or ten heads.

Draperies.—To introduce our observations on the draperies of the antique statues, we will first enumerate a few of those garments in which they are most generally clothed; and we will begin with the largest and coarsest woolen garment, called the pallium, which was a large piece of square, or taurish cloth, perhaps about seven feet long, but not so wide; this was generally worn by being folded over, perhaps one-third of the breadth; one end applied to the left side of the body, carried under the right arm, and thrown over the left shoulder in front; it formed broad and simple mafies before and behind, with a few bold and distinct folds, which left the body and limbs well accounted for beneath. It was, according to the convenience of the wearer, thrown in a variety of different manners: sometimes one arm was wrapped in it, sometimes the other, and sometimes nearly both; all the statues of philosophers, excepting the Cynics, are clothed in this manner.

There were other garments nearly of this kind, which are very commonly seen; particularly the manly peplus. The figures of Jupiter and Hercules are sometimes seen wrapped in the peplus, which appears to have no other distinction from the pallium, than that it is made of a finer texture, consequently produces fewer and more numerous folds, and its corners are sometimes ornamented with taffels, or knots.

The chlamys seems to have been a finer and lighter woolen garment than the peplus, much less, but, like that, of a long square; this garment is particularly appropriate to youthful heroes, and is seen on the colossal statues of Monte Cavallo, the Meleager, and many youthful heroic figures on Greek vases, and the young heroes in the frieze of Horfemen in the Parthenon at Athens.

The tunic, or kitos, was an under garment, also worn by men in early times; this had no sleeves, and hung over the left shoulder, leaving the right shoulder entirely bare, not to impede action; in after times it had short sleeves, was full in the body, and when not girded, hung down below the mid-
SCULPTURE.

The drapery, or web of drapery, such as that of the Flora Pomona, threw all the forms of the body and limbs with nearly the same distinctness as if they had been laid open, at the same time that the gentle and curving folds, upon a near examination, revealed the beautiful forms of the body by a variety of lines tenderly assimilated with the drapery, in such a manner as reduces the spectator to believe that the highest motion of the body would produce a different, and equally pleasing, effect in the folds of the drapery.

What has been said concerning drapery comprehends the principles of the subject; it was the intention in the first instance to produce a noble breadth by their drapery, as well as the figures, and to work out their most illustrious characters. In their more delicate characters they contrived the most beautiful forms by the most graceful display of lines in the drapery; and in all their classical statues they adorned the forms of the naked figure by perpendicular, circular, pendant, or zigzag folds, contriving the forms and adding quantity, but leaving the figure and its position perfectly intelligible.

In the figure of Bacchus in violet-leaf, the flying drapery becomes peculiarly ornamental; veering from the figure in undulating waves, which at its edges and extremities play upon the air in bulder forms, like the extremities of the poppy-leaf.

The Practice of Sculpture.—The first operation of sculpture, like that of painting, is design. The sculptor first makes his idea evident by a sketch or drawing; he then makes a small model, generally in clay, to try the effect of his lines, folds, and light and shadow, as well as the sentiment of his statue, or composition; but if the work requires the utmost accuracy and perfection he is able to give, he makes a model of the size in which the wood, marble, or bronze is to be executed.

He models his figure first naked in its just action and accurate in its forms; he then lays on his drapery either from studies made after the living figure, or drapery laid for the purpose on a clay figure, or manikin.

The clay model, if large, must be supported by a framework of iron; and the masses of clay may be kept together by a number of small wooden crosses attached to the iron frame-work, by wires of different lengths dispersed in different parts of the clay. This method is used by Mr. Canova, the celebrated Venetian sculptor.

The tools used by the modeller are made of wood, ivory, with ends pointed, rounded, square, or diagonal, with which he forms his models; marks out the hollows and dark parts; and does whatever he finds impracticable to perform with his fingers only.

When the clay model is finished it must be moulded and cast in plaster; which cast must also be well supported and secured by bars of iron well cemented, to prevent the rust of the metal from penetrating through the cast.

To copy the model in marble is performed in the following manner. A number of little black points must be marked upon the model, in every principal projection and hollow, to give the distances, heights, and breadth, sufficient to copy the marble with the greatest exactness from the model. The ancients performed this, by considering every three points on the figure as a triangle, which they made in the marble, to correspond with the same three points in the model,
SCULPTURE.

model, by trying it with a perpendicular line, or some other fixed point, both in the marble and the model.

The moderns perform this operation in another manner. After, by taking rough measures, they have found that the block of marble is sufficient to make the statue equal in size with the model, they then fix it on a base of flone, or a strong wooden bench, called a banker; in the front of which is a long strip of marble, divided into feet and inches. A strip of marble, divided exactly in the same manner, is placed in front below the model; and a wooden perpendicular rule, the height of the whole work, which is capable of being moved from the strip of marble or scale under the model, to the strip of marble or scale under the marble, at the workman's pleasure. This instrument being first placed upon the scale of the model, and the exact distance being taken, from its perpendicular, we will say, to the point at the end of the nose of the model, and the perpendicular rule being transferred to that scale on which the marble is placed; the workman cuts away the marble from the perpendicular rule at the same height, till he has arrived at nearly the same depth that the point of the model's nose was from the rule; and by this means, he finds the point of the nose exactly where it should be in the marble. He proceeds in the same manner with all the other parts of the figure; for example, the top of the head, the chin, the shoulder, and every other part of the body and limbs; until, by cutting down the marble at the same height and depth from the perpendicular line of the rule that he defines to transfer from the model to the marble, he finds a corresponding point to that he has taken from the model; and so goes on until he has obtained the general proportions of the whole work.

When this is done, the sculptor proceeds to work over his statue with a flat-ended steel tool, called a chisel, whose flat square end is about five-eighths of an inch broad. In the naked parts of the statue, and wherever there is a flat surface, he proceeds in this manner: for instance, we will say, upon the breast of the figure, he cuts away the rough surface from a given point in a straight line, to another given point at some distance; he then cuts away the surface from one given point to another, exactly parallel to the course of his chisel, as he worked on his statue; he then cuts the marble in a line at right angles with the former direction of his chisel. He continues to work over the surface in the same manner, continuing to cut it away in lines parallel to each other, leaving the space of about one-eighth of an inch between each course of his chisel; he afterwards cuts away the remaining rough surface of one-eighth of an inch between each two courses of his chisel; thus obtaining a beautiful flat surface to his work, which can be done by no other means, and may be afterwards varied with the curvatures and indentures of smaller parts at his pleasure.

This method of cutting the flone is followed, as much as possible, in all parts of the work; that is, as much as all the varieties of outline and hollows will permit.

When hollows are so deep or intricate, that they cannot be cut out with small chisels struck by the hammer, drills of different kinds are used to produce the rough hollows, which are afterwards finished with the hammer and chisel, or by long tools fixed in wooden handles, used by the hand only, without the hammer.

A particular dexterity is requisite in producing the different characters of the hair with the chisel, to make it look light and soft, whether curled, crisped, or plain; and this may be done by the hand of the practiced sculptor, with nearly the same effect as it can be by the painter, in laying on his colours with the pencil.

The finishing of flesh in imitation of the hues of muscle, the apparent pliability of the softer parts, the greater or lesser durability of tendons and bone, may also be represented on marble nearly to deception; but then the sculptor must be well acquainted with the structure and appearance of the parts he represents, and accurate in copying the object of his imitation. To inform the mafs with life and sentiment, whether it be of marble, bronze, wood, ivory, clay, or wax, is the very end and purpose of imitative art.

The last finish of marble, in the modern practice of sculpture, is performed by the use of rasps, and afterwards of files. The belts rasps for sculpture are those made in Italy; the teeth of these rasps being cut more sharply than those made in England, at the same time that the ends of these rasps and files are capable of being bent in any form, according to the use for which they are to be employed.

When a piece of sculpture is required to have an exceeding smooth surface, the pumice-flone is used after the file; and sometimes the whole surface is rubbed or ground carefully over with small pieces of grit-flone, accommodated to the various forms of the surface, as to flat spaces, rounds, and hollows of different depths. But the hair, in all cases, must be finished with the tool; and for this purpose, the edge of the tool must be sharpened with great accuracy and acuteness; and if it is required that the work should be very highly finished, the last edge of the tool must be given by an oiled Turkey-flone.

Chisels may be sharpened, for the different kinds of work, either on one side, or on both sides, horizontally, diagonally, circular, or pointed.

The sculptor ufed large square four-footed strong tools, with tops which turn round upon little balls of bronze iron, on which he places the marble flate on which the sculptor works. His tools are steel chisels of different sides and lengths; their ends being from an inch broad, and diminishing in succession, till they become perfectly pointed. These are worked with an iron-headed hammer, weighing from two to four pounds, according to the heaviness or lightness of his work. The first tools used in wearing away his marble are strong steel tools, sharpened nearly to a point; which, being struck with a heavy hammer obliquely, knock off the waite marble in much larger pieces than a broader pointed tool would do.

The practice of the sculptor also requires the frequent use of the flare and compasses, as his own ingenuity may direct.

There are some few fragments of marble statues, which have been found in different parts of Greece, especially where the works of sculpture have chiefly flourished, as Athens, Ægina, and Corinth, which appear to be the remains of very early attempts in this art; perhaps in an age when making the proper tools was either not known, or during the infancy of their invention. From these specimens, the edges of the tools, and the manner of using them, appear to have been equally imperfect: the course of the tool is infirm, indirect, and ragged; the surface it paied over, irregular. In the naked figure, the muscles are little determined, and the forms confused by the unpractised manner of working. In the draperies, the edges are undefined, and the hollows are few and shallow; a natural consequence of the workman's want of power over his material; and therefore, of his desire to produce his idea in the grofs, because he knew his incapacity to render a dainté and perfect detail.

High finishing in marble seems to have been a consequence of working in bronze, for two reasons: first, the working of metals requires a considerable knowledge in the
tempering of tools; and, secondly, the first high finished specimen of remaining sculpture seem to be imitations of bronze statues, from the hard parts of execution resembling that of metal, and the rectilinear wavy forms of hair and draperies. Whether this manner of finishing marbles was first introduced by Dipsas and Scyllis, according to our former supposition, or whether it was practised nearer the most distinguished epoch of art, it is certain that the working of marble with the greatest possible dexterity, such as distinguishing small folds from one another, by cutting the marble to a great depth between them, was practised considerably before the time of Phidias.

In the time of Phidias, it is certain the sculptor used chisels of all the different forms described above, of the most convenient forms possible for their works, and much perfectly tempered; of which we are assured, by tracing the forms of the several instruments in their execution, which is so free and characteristic of the parts imitated as could have been produced by the pen of the painter.

The Laecoon, the Apollo Belvedere, and the Venus de Medicis, appear to have been executed by the chisel only, without the assistance of the rasp or file, though there is, in the body and limbs of the Apollo, some appearance of a smoother surface having been obtained by rubbing with pumice-stone or wet grit-flour. Many others of the finest works of antiquity, statues, groups, and busts, appear to have been finished with the chisel only, and the use of rasps and files does not seem to have been very common in the practice of sculpture, till after the time of the twelve Caesars.

The execution of sculpture seems to have descended from perfection in the same steps by which it rose to it. In the age of Adrian and the Antonines, extreme high finishing was again in estimation; the surfaces were finished with a delicacy of smoothness which almost became a polish; the sculptor tried to make the extremities of his hair fly before the wind, and for this purpose laboured his marble with a delicacy of tooling, and a complication of drilling, that is almost miraculous; and there are examples of hair, so laboriously executed in that age, that the spectator is left in doubt concerning the possibility of paying the sculptor for his work, the time necessary to accomplish the undertaking, and for the instruments requisite to produce his effect. There are many examples of this kind in the portraits of M. Aurelius and Lucius Verus; particularly two colossal busts of these emperors lately existing in the Villa Borghese.

But the extreme attention to a polished surface, and extreme perfection of inferior pursuits, having withdrawn the artist's mind from nobler conceptions and sublime sentiment, he soon descended from the sculptor to the stone-cutter, and lost his distinction even as a mechanic, by adopting such a poverty of workmanship as was suited to his debased pursuits; and the age of Constantine exhibits the sculptor as incapable of following the noble conceptions of earlier times, as of shewing any skill in the mechanism of his art superior to the unmeaning and unsuccessful attempts of a barbarous age.

During the ages of the Roman emperors, when beautiful and expensive marbles were used to adorn their palaces and public structures, when the magnificence of effect was considered without relation to expense, porphry also was manufactured for columns, pannels, and other architectural purposes; it was also occasionally employed in sculpture, in defiance of the extreme difficulty and expense of the labour, of which we shall be enabled to judge from an instance mentioned in Winckelmann's History of Art: he says that a manaf was employed to fashion out a vase in the Villa Albani, the inside of which could not be above thirteen or fourteen inches deep, and eight or nine inches in diameter; he was ten months at work upon this, attending his labour regularly nine hours every day. Such a work as this, in England, as makers are paid at this time, would cost fifty five pounds; the payment of the journeyman sculptor should be reckoned at twice that sum.

There are fragments of drapery-figures executed in this material of fine taste and beautiful sculpture, the labour of which must be excessive; but the two greatest works remaining of this marble are in the pope's museum; one is the larcophagus of Constan dubious daughter of Constance; the other of Helena, his mother; which last is of enormous dimensions, and covered with alto relief of soldiers on horseback, and the heads of the emperor and his mother, angels, &c. Many parts of the alto relief on this larcophagus were broken when it was removed into the pope's museum, which were repaired by the following process. The pieces of porphry intended for the reliefs were first rudely shaped with a peening hammer, that is, one end of the hammer being pointed, the workman knocked the flume with repeated blows of this point, until he beat off little pieces, when it was reduced to the general form required; in this manner another instrument was used, called a snatching hammer, one end of the hammer being divided into four points, and being worked over with this instrument, the whole of the former very rough surface was made somewhat more regular; after this, pointed tools were used, struck by a hammer, to take off as much as possible the still remaining roughness of the surface, and to make particular hollows more exactly, the workman wearing spectacles all the while to prevent the splinters of the flume from flying in his eyes, which otherwise would blind him in the course of a few minutes labour. The tools for this work are temper, the handle of a razor, and of this more than four or five blows with the hammer before the points are broken. The last process is to grind the surface down with grit-flour and emery, till a smooth face is obtained; the whole being a process of immense labour and expense. The Egyptian obelisks, which are of red granite, with the hieroglyphics upon them, must have been wrought by a process somewhat similar to the manner of working porphry.

Of Wax-Modelling.—Wax-modelling is properly a branch of sculpture, inasmuch as it affords patterns and examples for very numerous articles of fine art in metals; although, from the nature of the material, a wax model of the Greek or Roman times has come down to us, they must have been almost innumerable during the best ages of Greece and Rome, judging only from their small figures of divinities in bronze, of which, perhaps, upon an average, every person rich and poor, might have half a dozen, so that the amount of these small images, from patterns of wax, would be nearly 15 times in number of the population of the civilized world at any one period.

Wax-modelling besides is required for the patterns of all goldsmiths' and chaser's ornamental work upon a small scale. All the fine medals of the popes were copied from small models in wax of the most distinguished sculptors.

To make the best modelling wax, take two cakes of Virgin's wax, break them in pieces, put them into a clean pipkin, and add the quantity of the smallest hazel-nut of Venice turpentine, and about double the quantity of flake white reduced to the finest powder; place the pipkin over a slow fire till the wax is melted, stir the composition together, and it is the best wax which can be used for modelling.

Models of different coloured wax may be made by putting pounded red, blue, yellow, &c. instead of flake white, according to the colour required.
Wax-modelling is performed, like the same art in clay, by pointed instruments of wood and ivory.

Sculpture in bronze and silver is practiced in the same manner by the model as Pliny describes it to have been done by the ancients, and is of three kinds. The subject is either cast from a model, or carved from the solid metal, or chased from a model upon a flat piece of metal, which is best hollow on the one side, to produce the relief, out of which the chased works the intended figure or figures on the other side. The instruments used in chasing are, for small works, a small hammer with a long elastic handle, which gives the blow a quick and artificial force; also chisels and points, something like those used in the sculpture of marble on a smaller scale.

The tools for carving in wood are so universally known to carpenters, upholsterers, and the different orders of wood carvers, that the description of them would be useless.

For further illustration of this article, the reader is referred to the engravings which are distinguished by the word Sculpture. These consist of select specimens of the sculpture of different ages and nations; particularly the finest examples of Greek and Roman sculpture.

SCULTEUS, or SCHULZ, John, in Biography, a distinguished surgeon, was born in the year 1595 at Ulm, where his father was a water-man. The latter was enabled to afford his son a good education, and sent him to Padua, where he studied medicine under Spigelius, and took the degree of doctor in philosophy, surgery, and physic, in the year 1621. On his return to his native city, he was admitted into the college of physicians in March 1625; and for twenty years he practiced his profession with great reputation. Being sent for to Stuttgart, to administer professionally to a sick gentleman of that city, Scultetus was there attacked with a fit of apoplexy, which terminated his life on the 1st of December 1645. He appears to have practiced surgery extensively, and to have been very bold in his operations, especially in those of bronchotomy, of the trachea, and for empyema. His principal work is entitled "Armedamentum Chirurgicum, 43 Tabulis articulca Ornamentum," and was published after his death, at Ulm, in 1653. It subsequently passed through many editions, and was translated into most of the European languages. Eloy Dict. Hist. de la Médecine.

SCUM, or Spume, Spuma, a light excrement arising from liquors, when briskly fired; called also foam or froth.

Scum is also used for the impurities which a liquor, by boiling, casts up to the surface; and also for those taken from off metals, when in fusion; these are also called fioria. Scum of Lead, is a kind of incrustation, of various colours, procured from melted lead.

Scum of Nitre. See Nitre.

Scum of Salt. See Salt.

Scum of Silver, is what we commonly call latharge of silver.

Scum of Sugar, in Agriculture, a substance sometimes used as a manure. See Sugar-Scum.

Scum, Sugar of the. See Sugar.

Scuma, a word used by some of the chemists for spuma, the scales of any metal, and particularly applied to the flakes flying off from hot iron under the hammer.

SCUOE, Skue, or Skue, in Geography, one of the Faroe or Feroe islands; 5 miles S. of Sandoe. See Feroe.

SCUI, in Ancient Geography, a town of Upper Media, in Dardania, according to Ptolemy.

SCUPPERS, in a Ship, are certain channels cut through the water-ways and sides of a ship, at proper distances, and lined with plated lead, in order to carry the water off from the deck into the sea. The scuppers of the lower deck of a ship of war are usually furnished with a leather pipe, called the scupper-hose, which hangs downward from the mouth or opening of the scupper. The intent of this is to prevent the water from entering, when the ship inclines under a weight of fall. Falcon.

SCUPPER Nails. See Nails.

SCUR, in Agriculture, a precipice faced with rock.

SCURCOLLA, in Geography, a town of Naples, in Abruzzo Ultra; 18 miles S. of Aquila.

SCURELLUR, in Ancient Geography, a town of India, on this side of the Ganges, between the Puelodome and the river Baris. Ptolemy.

SCURF, in Medicine, Furfur, small branny or powdery exfoliations of the cuticle, which occur after slight inflammations of the skin, a new cuticle being formed underneath during the exfoliation.

Scurf may be formed upon any part of the surface of the body; for wherever the skin is inflamed, the cuticle never fails to be separated and fall off. This exfoliation, when the inflammation is considerable, as in scarlatina, takes place in the form of large mafles, or of smaller scales; but in the minor degrees of inflammation, such as of the formation of pimples, or in slight erythematous affections, a mere scurfy skin ensues. In some cases of scurf, indeed, as in the bastard of infants, and in other forms of pityriasis, little or no inflammation is perceptible; but in other cases, as in the scurfy porrigo, affecting the heads of adults, the inflammation is often considerable, and accompanied by feverish itching. The scurf itself, instead, if it be permitted to accumulate, becomes the source of excitement to the inflammation, as well as to the itching sensations.

The first step in the treatment of scurfy affections is, therefore, the careful removal of the scurf, as it is formed; but this must be effected by gentle means, and by washes which do not augment the inflammatory action, where that is considerable. Hence ablation with simple water, or some flight farinaceous decoction, as of bran, is to be preferred to soaps and other irritants. This clearance of the surface having been effected, some gentle retentive lotion, such as lime-water, with or without a little of the liquor ammonia acetatis, or a weak solution of the salts of zinc, may be employed with advantage; or if the irritability of the parts be considerable, the faturnine substances may be preferable. See PITYRIASIS.

SCURFF, in Ichthyology, an English name for a species of salmon, called also in some places the bull-trout. It never grows to any great size, and differs plainly from the salmon of the common kind in this, that its tail is even, and not forked; its head is short and thick, and its flesh is less red than that of most of the salmon kind. See TRUTTA under the article SALMO.

SCURGULU, in Geography, a town of Naples, in Capitanata; 7 miles S.S.W. of Dragonera.

SCURGULUM, in Ancient Geography, a town situated in the most northerly climate of Germany. Ptolemy.

SCURRA, in Ornithology, a name by which the ancients have called the monedula, or common jackdaw. See CORVUS.

SCURRIZANO, in Geography, a town of Naples, in Capitanata; 5 miles N.E. of Alcoli.

SCURVOGEL, in Ornithology, the name of an American bird, called by some the abender-apea, and by the Brazilians jabiruguaçu. See MYSTERIA.
SCURVY.

SCURVY, in M. Liv., is defined, as follows:—It often falls on sea-men, and is attended by pain in the colon, and sometimes by a fever that lasts from ten days to a month or more. It is chronic in its nature, and belyed after its first attack. It is frequently accompanied with other disorders, such as ulcers, etc., which occur in leprosy, tuters, and other cutaneous disorders, usually called februlae.

This mistake requires correction, not merely as a matter of nomenclature, but because a great practical error results from it; namely, the admixture of antiscorbutic remedies in these cutaneous disorders, which cannot be cured, and are often aggravated, by them. The late Dr. Willan conferred a benefit on the profession, by his definite discrimination of these last-mentioned disorders. See Cutaneous Disorders.

The scurvy, properly so called, was first accurately described, and received its name, in modern times; and it is the subject of dispute, as to the cause of other diseases, whether it was known to the ancient physicians, or is a malady of more recent origin. The first specific accounts of the diseaee appeared in the early part of the sixteenth century, when the name of the malady seems to have been familiar among the vulgar: but the symptoms were not noticed by the early voyagers in the preceding century; for considerably more than half the crew, who accompanied Vasco de Gama, in his voyage round the Cape of Good Hope, in the year 1497, were destroyed by this disease. Olaus Magnus, in his history of the northern nations, published in 1555, has described the disease as of considerable length, and states that it was known to the inhabitants of the Baltic, under the name of feberluk, or februla; whence the Latin term februla, and our appellation scurvy. The term signified fever-mouth, and was probably applied to the disease in consequence of the piousy ulcerations of the gums, with hemorrhages, and loofening of the teeth, which are among the more severe symptoms of the complaint. Dr. Lind, however, suggests, with still more probability, that the name was derived from a Scavonian word, febr, signifying disease; the scurvy being endemic in the northern countries of Europe, from whence we borrowed the appellation.

Most of the continental writers have maintained that, although the ancients have not described the symptoms of scurvy, as a single distinct disease, they have, however, mentioned several concurring symptoms, which can scarcely be supposed to belong to any other malady: while Drs. Freind, Lind, Trotter, and some other authors of this country, contend, that the Greeks, Romans, and Arabians, residing in southern climates, and unpractised in long voyages, probably never witnessed the februla, and thence have no where accurately described it. The rarity of the disease, under such circumstances, will probably account for the imperfect descriptions which they have left; but sieges and
Scurvy.

limited experience, when they pronounced these symptoms as exclusively connected with enlarged spleen.

A disease is also mentioned by Strabo and Pliny, as occurring in the Roman armies in particular situations, which can only be referred to scurvy. In this disease, which Pliny ascribed to drinking the water of a certain well, when it occurred in the army of Germanicus while encamped near the Rhine, an affection of the gums, with a falling out of the teeth, is said to have been combined with a loss of muscular power in the lower extremities; the former affection being called *fomaccer* (quali *stomastik* vex, or *viti vitium*) and the latter *feletybrba*. (Plin. Nat. Hist. lib. xxiough they have been referred to the army of Julius Gallus, when in Arabia. (Geograph. lib. xvi.) Some authors, however, have denied that this *feletybrba* could be a feptic disease; because Galen has described *feletybrba* to be a kind of paralysis, in which the patient is unable to walk straight; but such a term might be sufficiently appropriate to that rigidity of the joints, which often occurs in scurvy.

On the whole, therefore, we are disposed to believe, with the early writers upon this subject, that the seconomy was known to the Greek, Roman, and Arabian physicians; although, from its comparative rarity in southern climates, it did not occur so often, or so extensively, as to claim their attention very strongly. That it may occur in any climate where there is a dearth of fresh food, is very obvious; for it is found equally at sea and on the land, in Greenland and in the great South Sea, in befieged towns, in frozen countries, and in ships, when fresh food is not to be obtained. Poupart has very correctly remarked, that the malignant seconomy of Paris bore a considerable resemblance to the pestilential *ignis facer*, described by Lucretius (lib. vi.); an opinion which Dr. Lind, confounding this *ignis facer* with the plague of Athens, confers on Thucydides, confiders as deserving no serious consideration. But the *ignis facer* was extremely different from the *true plague*, as well as from the pestilence described by Thucydides (see *Plague*); it seems to have been, like seconomy, the result of dearth, the *stomach malady*, of which we hear so much in ancient history; it had several symptoms in common with seconomy, but was a febrile disease; and has been ascribed in modern times to the use of corn, instead of the feacity and deficiency of that nutrient. See Ergot; *Ignis Facer*; Kriebel, Krankheit; &c. For the observations of Poupart, see Memoires de l'Acad. des Sciences, an. 1699.

Symptoms of Scurvy.—The first indication of the approach of seconomy is an averteron to any sort of muscular exertion; a lassiness, or strong inclination to fit still or lie in bed; which is accompanied with a spontaneous latitude, or a fence of heavinesses and pain throughout the body, and especially in the muscles of the limbs and loins, like that which arises from great fatigue; which soon becomes actual seelleness, so that the least exercise, especially in ascending or descending a declivity, induces fatigue and shortness of breath. With this aversion to motion and diminished power of exertion, there is also very early a change of the complexion, which becomes pale and bloated, or fawlow, especially about the lips and corners of the eyes, where there is a greenish tinge. These two symptoms, indeed, the diaphanisation to exertion, and the fallow countenance, often portend the approach of seconomy, while the patient eats and drinks heartily, and seems otherwise in good health; and the speedy latitude and difficulty of breathing upon motion, are among the most constant concomitants of the dilatation throughout its course.

As the disease advances, other symptoms appear. Among these the *fomaccer*, or morbid condition of the mouth, is one of the first that presents itself. The gums become hot and painful, and fawlow, growing soft and spongy, and of a livid hue, and afterwards extremely putrid and fungous, conflatuting one of the most disfiguring features of the disease. This occasioned a great terror of the breadth, and the loosening of the teeth, which become moveable in their sockets, and may be taken out without force or pain, and even fall out spontaneously. Hæmorrages also take place from the flighty prelure on the gums, or even without any apparent caue, as well as from the nofe; and ultimately from other parts of the body, where the cuticle is delicate, or the surface broken, in consequence of the apparent loss of cohesion in the folds, and especially in the vascular system.

From this cause the *fein* also exhibits some of the most striking characteristics of seconomy. It becomes dry, and spotted over with discolourations of a red, blue, yellow, and black hue, of various sizes, from the *petechiae*, or spots like flea-bites, to the most extensive *eczemyges*, of the size of a hand-breath, or larger, such as are produced by the feeverest bruises. These appear chiefly on the legs and thighs; but often also on the arms, breast, and trunk of the body; and sometimes, though more rarely, on the head and face. They confit, in fact, of effusions of blood under the cuticle, from the rupture of the small vessels. As the disease advances, this laxity and loss of cohesion in all the folds becomes still more manifest, by the frequent and profuse bleedings which are liable to occur from different parts of the body; especially from the nofe, gums, *fomach*, bowels, lungs, kidneys, and bladder, and from the ulcers and fungous excrences which arise on the surface. In some patients, the hæmorrages from the bowels are accompanied by severe pains and diarrhoea; while others, without either a purging or gripes, discharge great quantities of pure blood by the anus. Other marks of laxity appear in the edematous swelling which takes place in the legs, beginning first about the feet and ankles; which, however, is more painful than common anaæmies, and retain longer the impression of the finger. They appear remarkably also, in the great facility with which the flighty bruises and wounds degenerate into foul fungous ulcers, as well as in the spontaneous appearance of such ulcers, and the breaking out of long-healed sores, and even the divulsion of old fractures in bones. "Whatever former complaints," Dr. Lind observes, "the patient has had, epecially bruises, wounds, &c.; or whatever previous disorders he labours under, upon being afflicted with the feconomy, his old complaints are renewed, and his present rendered worse." Indeed the seconomy often first shews itself by the changes in diseased parts. "Thus, when a perfon has had a preceding fever, or a tedious sickeness, by which he has been much exhausted, the gums for the most part are first affected, and a latitude constantly attends; whereas, when one has been confined from exercize by having a fractured bone, or from a bruise or hurt, theye weak and debilitated parts become almost always first feborous. As for example, if a patient labours under a strain of the ankle, the leg, by becoming swelled and painful, and soon after covered with livid spots, gives the first indication of the disease. And as old ulcers on the legs are very frequent among leamen, in this case likewise the legs are always first affected, and these ulcers put on a feborous appearance, although the patient feemes otherwise perfectly healthy, and preserves a fresh good colour in his face." (Lind.) The effect of the disease upon former maladies is strongly depicted by the elegant writer of Lord Anfon's voyage. "But a moﬆ extraordinary circumstance," says that gentleman, "and
SCURVY.

and what would be scarcely credible upon any single evidence, is, that the scars of wounds which had been for many years healed, were forced open again by this violent distemper. Of this there was a remarkable instance in one of the midshipmen board the Centurion, who had been wounded above fifty years before at the battle of the Boyne; though he was cured soon after, and had continued well for a great number of years past, yet on his being attacked by the scurvy, his wounds, in the progress of his disease, broke out afresh, and appeared as if they had never been healed. Nay, what is still more astonishing, the callus of a broken bone, which had been completely formed for a long time, was found to be hereby disintegrated, and the fracture seemed as if it had never been consolidated. (A Voyage round the World in 1740-41, by Lord Anson, compiled by the Rev. R. Walter, chaplain to the Centurion, p. 102.) The ulcers, which occurred in the legs of the scurvy patients on this occasion, are said to have been "of the worst kind, attended with rotten bones, and such a luxuriance of fungous flesh, as yielded to no remedy." The edges of these scurvy ulcers are of a livid colour, and puffed up with the fungous excreta, which are most aptly called by the sailors, 'linden' leeder; from which substance, when boiled, Dr. Lind says, they bear a near resemblance, both in contumacy and colour. They often arise in the course of a night to a monstrous size, and although destroyed by cauteries, or the knife, (in which latter case, a copious bleeding commonly ensues,) are found at the next dressing as large as ever. Dr. Lind affirms, however, that "they continue in this condition a considerable time without tainting the bone." (Lind on Scurvy, pt. ii. ch. 2.) These scurvy ulcers, which are singular and uniform in their character, are distinguished from all others by being so remarkably offensive, bloody, and fungous.

In addition to these affections of the lower extremities, (to which however they are not exclusively confined,) in the advanced stage of the scurvy, the patients most commonly lose the use of their limbs, having a contraction of the tendons in the ham, with a swelling and pain in the joint of the knee. Indeed, a stiffness in these tendons, and a weakness of the knees, appear pretty early in this disease, generally terminating in a contracted and swollen joint. (Lind, loc. cit.) We have given this description in the words of Dr. Lind, in order to show how distinctly it answers to the account of the steele of the Roman armies, in conjunction with the flecre at.

In the progress of the scurvy, the patients commonly complain of pains, which are often moving from part to part. Some complains of a general pain in their bones, which is most violent in the limbs and loins, and especially in their joints and legs; and a pain, with tightness and oppression in the breast, is very common. The head is feldom or never affected, unless the patient is feverish, which is unusual; for, as Dr. Lind well observes, the disease is altogether of a chronic nature, and fever may be justly reckoned among its adventitious symptoms. It is remarkable, indeed, that in the worst stages of the scurvy, with all the severe symptoms above described, with painful spreading ulcers of the surface, with contracted limbs, hemorrhages, sponginess, putrid, flaking gums, over-run with sprouting flesh, and often deeply ulcerated, with inability to make the least muscular exertion, without fainting or perhaps dying; yet the patients, even in this stage, have a good appetite, with their fenes entire, and, though easily dejected and made low-spirited, yet, when in bed, they make no complaint of pain or sicknells, and appear to be in tolerable health. This singular characteristic of the disease is well depicted by the reverend author before quoted. "Indeed, the effects of this disease," he says, "were to amil every violent - wonderful; for many of our people, though closely in their hammocks, appeared to have no considerable state of health; for they eat and drank heartily, were cheerful, and talked with much seeming vigour, and with a loud strong tone of voice; and yet on their being the least moved, though it was only from one part of the ship to the other, and that in their hammocks, they have immediately expired; and others, who have confined in their seeming strength, and have refused to get out of their hammocks, have died before they could well reach the deck. And it was an uncommon thing for those who were able to walk the deck, and to do some kind of duty, to drop down dead in an instant, on any endeavours to act with their usual vigour; many of our people having perished in this manner during the course of this voyage." Lord Anson's Voyage, loc. cit.

Few of the authors, who have described the disease, have been very industrious in the examination of the bodies of those who have died. The most ample account of the different actions of scurvy patients has been given by M. Poupart, in his account of the disease, as observed at the hospital of St. Louis at Paris. The principal phenomena described by him were the results of the general extravasation of blood, and of the dissolution and separation of parts naturally united. Thus the bodies of the muscles were often found swelled and hard, from the blood fixed among their fibres, so that the limbs remained bent or contracted; and the epiphyses of the bones were found separated, the cartilages of the sternum were loosened from their union with the bony part of the ribs, and the ligaments of the joints were corroded and loose. He adds, that the melenic glands were generally obfuscated and enlarged, and the spleen three times bigger than natural, and fell to pieces as if it consisted of coagulated blood.

Causes of Scurvy.—The predisposing causes of scurvy, or those circumstances which produce a predisposition to the complaint, are various. Preceding diseases, whether of the acute or chronic kind, render persons more liable to the scurvy, where the exciting causes exist; and mevity and indolence greatly facilitate the attack of the malady. Those who are recovering from fevers, or who have been weakened by long attacks or relapses, most readily fall into scurvy; and the mariners on ship-board, who have less work, commonly suffer in a much larger proportion than the sailors. On the other hand, however, excessive fatigue and over-exertion, which exhaust the strength, as well as want of sleep, contribute to accelerate the attack of scurvy. An attention to this point was one of the most effectual means employed by captain Cook for the prevention of scurvy among his crews, as well as the avoiding of cold and moisture, from which much predisposition to the disease arises. A state of despondency and gloominess of mind contributes also materially to invite and aggravate the scurvy: it attacks the discontented and repining, while persons of more cheerful dispositions escape. Hence perhaps newly-impressed seamen are found to be particularly liable to it; and the inhabitants of besieged towns are observed to be very susceptible of its impregnations.

The principal exciting cause of scurvy appears to be the use of a certain kind of diet; and it is probable that every species of diet, which, either from being deficient of digestion, or from containing but little nourishment, fails to nourish the body, is capable of producing the disease under certain circumstances: we say, it is probable; for we shall have occasion to shew hereafter, that this notion is not entirely consistent with all the facts, and is somewhat inconsistent especially
presently with the nature of the remedies. As the disease is most frequently occasioned in modern times by a "fat diet," it has been ascribed to the use of "fatted meats;" but this opinion is altogether erroneous, and has been amply refuted by Drs. Lind, Milman, and others. It has occurred, indeed, to a great extent, where salted meats were not used; but it has been equally prevalent where the diet consisted principally of farinaceous or other unfermented vegetable matters, such as hard biscuits, peas, and beans, or of smoke-dried fish or flet; chese, &c. In some experiments, made by Dr. Stark in his own person, relative to the effects of particular articles of diet, symptoms of scurvy were induced by living a short time exclusively upon sugar. (See Stark's whole works, 4to. Lond. 1788.) And in the Russian armies, at the siege of Ateam, in 1736, and subsequently in their march to Ockakow, the scurvy prevailed to a great extent, although their diet did not consist of fat-provisions. They had little fuel to enable them to dress their victuals, and the fat indigestible fish of the river Don, being half-cooked, and their bread ill-baked, produced frequent sickness, and ultimately the scurvy. (See Dr. Nitzsch's account of this disease in the Russian armies, quoted by Dr. Lind.) The fame calamity occurred in the imperial army in Hungary, about the same period, although the army had fresh beef in plenty, but their other food consisted of a grose and vifeed bread, or other farinaceous matters, and especially of a sort of glutinous pudding, called rollatfchen, which was principally eaten by the Bohemians, who were indeed almost the only people who suffered from the scurvy. (See Geo. Hen. Kramer. Diff. epitolica de Scorbuto; which contains the sake of the imperial troops, addressed to the college of physicians at Vienna.) There is no doubt, therefore, if we examine the history of the malady, that persons predisposed to it, if they live upon any species of indigestible food, whether it be of an animal or vegetable nature,—whether preferred with fat, or not at all impregnated with it,—will be equally attacked with scurvy; and those persons are observed to suffer the most, who make the freest use of these indigestible substances. In all these instances, however, fresh vegetable substances did not probably constitute any considerable portion of the diet.

Other exciting causes, however, must co-operate with this diet to produce the scurvy, especially in its severe degrees. And hence whatever contributes to impair the health, and depress the mind, during the use of such food, materially accelerates the occurrence of scurvy; and we have already stated the effects of indolence, over-fatigue, and the depressing passions, in predisposing the constitution to take on this disease. Indolence and inactivity conduces to excrete the scurvy, because the hard and indigestible diet just alluded to requires a certain degree of exercise to subdue it in the stomach. The influence of exertion was curiously exemplified in the cafes of those persons who have wintered in high northern latitudes. The scurvy was the source of fatality which they had to dread; and it is singular, that those who went prepared to spend the winter in these frozen climates, and supplied with provisions, clothing, fuel, &c. have uniformly died of the scurvy; while those who have been accidentally left, without any provision, have escaped that disease and enjoyed good health. In 1653 two trials were made by the Dutch of establishing wintering-places at Spitzbergen and on the coast of Greenland, in latitude about 77° or 78°. Seven sailors were left at each, amply furnished with every article of clothing, provisions, and utensils. The thought necessary or useful in such a situation. The journals of both companies are preferred. The men at Greenland began to make a continual fire to fit by in October, served out their allowance of brandy, and now and then killed a bear: but in March they were all very ill of the scurvy; and on April sixteenth the first man died, and all the rest were entirely difabled, except one person. This poor wretch continued the journal to the last day of April, when they were praying for a speedy release from their miseries. They were all found dead. The men left at Spitzbergen killed but one fox the whole time. The scurvy appeared among them so early as November twenty-fourth, and the first man died January fourteenth: the journal ends February twenty-fifth; and these too were all found dead. Accident, however, soon afterwards gave rise to an experiment which had a very different result. For on the same fox of Spitzbergen, and in the same latitude, a boat's crew, consisting of eight Englishmen, who had been sent afoile to kill deer, were by some mistake left behind, and reduced to the deplorable necessity of wintering in that dreadful country, totally unprovided with any of the necessaries. Taking advantage of a large substantial wooden building, erected for the use of the cooper's belonging to the fishery, they rendered it warm and comfortable by building a smaller one within it, and by deer-skin beds, &c. They were tolerably supplied with fuel from old casks and boats, which they broke up, and, before the cold weather set in, they laid in a considerable flock of venison, having killed a good number of deer, the greater part of which they roasted, and flowed in barrels, referring some raw, which became frozen. This venison, with a few hares and bears which they killed from time to time, constituted their whole winter's provision, except a very unfavourable article, which they were obliged to make out with, at first two and afterwards four days in the week, which was whale's fritters, or the cerops of fat after the oil has been pressed out. Their only drink during the whole time was running water, procured from beneath the ice on the beach, till January; and afterwards snow-water melted by hot irons. The melancholy of their situation was aggravated by the absence of the fun from the horizon, from October fourteenth to February third, of which period twenty-two days were passed in total darkness. They contrived, however, to keep their fire and lamps continually burning during this period. At the approach of spring, they had the good fortune to kill several white bears which proved excellent food; and these, together with wild fowl and foxes which they caught, enabled them to dispense with their falling days on the mouldy fritters, and soon improved their vigour. Upon this simple fare, without spirits or fermented liquors, they were able to pass this rigorous winter, unafflicted by scurvy or any other disease: at the return of the ships on May twenty-fifth, they all appear to have been in health; and all returned in safety to their native country. (See Mem. of the Liter. and Philol. Society of Manchester, vol. i. p. 89, et seq.) Another still more striking illustration is related by Dr. Aikin, in the paper just referred to, in the cafe of four Russians, who were left at Spitzbergen, and also found a hut in which they refided above fifty years, living on the bears, deer, and foxes, which they caught, and drinking the running water in summer, and melted ice in winter. Three of them remained entirely free from the scurvy during the whole of their abode; but the fourth died of it, after lingering to the sixth year. This person, it is remarked, was of an indolent disposition, and could not conquer his avarice to drinking the rein-deer's blood. The continual exercise, required by the hunting of these animals, appears to have been the great source of health, and to have kept them at a distance from the scurvy, which is endemic in Lapland, Norway, Sweden, Russia, and in latitudes much less northerly than Greenland.
Other circumstances, both on ship-board and on land, by
injuring the aliment of the constitution, are to be
prevented by the sea. The science, however, is not to be es-
craved, as it is in particular places in Holland, where
the ship was on the coast of that country. From
Robinson, a very able and accurate writer, it appears,
that the sea is much more frequent in his ship,
Amsterdam, than in any other. He states, that the
sea was frequently damp, and the weather cold; but
Rousseau, the作者 of the voyage of the ship
upon which he passed, well aware of the state of
the climate, that have taken place in the condition
of the sea, and of the modes of living, the wealth of
Holland has increased, have rendered the disease much
less frequent, and have confined it almost exclusively to the
pursuit, who inhabit the low damp parts of the provinces,
and continue to live upon dried meat and coarse bread,
and to drink wholesome stagnant water.

The effect of certain devouring passions, not only in pre-
dispensing to the fever, but in exciting and aggravating it,
has been strongly manifested. Vander Mye exhibits a
curious and diversified picture of the operations of the pas-
sions of the mind during the famous siege of Breda, when
the feverish committed great havoc in that town. Upon
the report of bad news, it always spread_annuiously;
but it was in a manner whatsoever checked by the arrival
of agreeable intelligence. And the writer of Lord Anson's
voyage observes, "it was most remarkable in all our re-
iteration of experience of this malady, that whatever dif-
couraged our people, or at any time depressed their
hopes, never failed to add new vigour to the dissembler;
for it usually killed those who were in the latter flages of it,
and confined those to their hammocks, who were before
able of some kind of duty; so that it seemed as if alacrity
of mind and disagreeable thoughts were no contemptible prepa-
atives to its fatal malignity."

On the Prevention and Cure of Scurvy. — It is customary
in medical discussions, after stating the symptoms and causes
of any disease, to proceed to the means of alleviating or
prolonging the duration of it, as it is technically termed, of
the malady, before treating of the method of cure, which
would generally be deduced from the consideration of the
whole of these circumstances taken together. In this case,
however, we can scarcely discuss the nature of the proxi-
mate cause, without a previous knowledge of the means
by which the malady is prevented or remedied; since these
means tend to elucidate the nature of the symptoms which
they remedy. We shall, therefore, first detail the means
of prevention and cure.

The prevention of scurvy will consist chiefly in remov-
ing or counteracting the predisposing and exciting causes,
which have already been enumerated. Much is done, there-
fore, by preferring a due degree of general health in the
individuals exposed to the exciting causes; and especially
by avoiding cold and moisture, by means of proper clothing,
warm cabins, &c.; and by avoiding indolence and in-
activity on the one hand, and over-excitement, watching, &c.,
on the other. The effects of the former are exemplified in the
considerable exceptions that the petty officers in a ship of
war, while the crew suffer severely. "The Channel
shite," says Dr. Milman, "has often buried a hundred men
in a year; and landed a thousand more afflicted with
scurvy, and we among these there has not been a petty
officer. How does the condition of the petty officer differ
from that of the common sailor? The
officer is obliged to live on the ship's provisions. To
him, therefore, that the petty officer is often
burnt, but always they are sheltered from the extreme cold of the
water. He has the advantage of warm cabins, they are more warm,
and have a greater plenty of clean drink, that he is
liable to become wet, or to be frozen, the
common man." (Mey in on Scurvy, p. 4.) But the
supply from land, obtained by attention to the
rules of general health, was most strikingly exhibited in the
careful management of Captain Cook, by which he was
able to return to England, having had but two cases of scurvy on
his voyage. The special management of the
rules of general health with great fidelity, was
completed. He was especially careful to guard against
the too great fatigue of his men, and to secure them as
much as possible from the effects of cold and moisture.
In the first place, he divided them into three watches instead of
two, (except upon some extraordinary occasions,) by
which means they had eight hours rest for ten of duty,
and did not get the broken sleep, which men in their
situations have generally obtained. They had the time to
recruit their strength before they were summoned to return to
their labour, and they were likewise thus left exposed
to the weather, than if they had been at watch and watch.
If the men got wet, they had generally dry clothes
provided to shift themselves. Proper methods were taken
to keep the ships clean, and dry between decks. The
hammocks and bedding, every day that was fair, were
not only ordered upon deck, but each bundle was unfolded,
and spread out, that every part might be exposed to the air.
Besides the ordinary methods of washing and scraping the
decks, captain Cook had some wood put into a proper
loose, kindled, and carried successively to every part below
deck; which not only contributed to dry the ship, but by
heating the air above, and rendering it specifically
lighter than the common air, to make it rise and pass
through the hatchways into the atmosphere. In the tor-
rid zone, he floated his people from the leeward fan, by
an arm of water over his deck; while in his course under the
antarctic circle, he had a coat provided of a substantial
wooden stuff, with the addition of a hood to cover their
heads. The Russian hour, Dr. Milman remarks, seems
to be greatly inclined to simular means for his preservation
from the scurvy: for, though he lives in an extremely cold
climate, eats a good deal of salted meats, has no fresh vegetables
for six months of the year, and breathes during that
time the foul air of an unventilated apartment; yet, cloth-
ing himself in warm flannels, covering himself at night with
warm sheep-skins, providing for his crew with the
usual use of the warm bath, he is seldom afflicted with
this calamity.

Captain Cook also attended to the nutriment of his men.
Hard and salted meats required attention in their relation
and digestion in the stomach, and a plentiful supply of
water was always carefully provided by him. Salt-water,
indeed, may be rendered sweet by distillation, which
diminutio its false parts, and may be made more palat-
able by impregnation with carbonate of soda, or with rob
and acid juices. This method, however, was not known
to Captain Cook. In attending to the diet of his men, he
would not suffer the fat, which is boiled out of salted
and pork, to be given to his men, as a necessity. It did
not escape that sagacious officer's notice, that such greas-
undigestible matters has a great tendency to excite scurvy.

Vol. XXXII.
SCURVY.

Thus, then, by an attention to cleanliness and ventilation, by guarding against fatigue, cold, heat, wet, &c. and by providing at all times plenty of fresh water, captain Cook's seamen lived with impunity on their salt provisions. And a similar instance is mentioned by Dr. Trotter, in the case of the Intrepid, a ship of sixty-four guns, with a complement of five hundred men, in lord Rodney's fleet, which did not lose a man, except from wounds, for the space of two years and a half. "This ship was in a very sickly state when captain Molloy took the command of her; but by the complete mode of discipline, and attention to the cleanliness of the crew and ship, which he established, health was preferred in a climate reputed to be unwholesome; and that too, when exposed to the hardships which follow a state of frequent or constant preparation for action." (Trotter on the Scourvy.) Even where the exciting causes exist, therefore, the scurvy may be prevented by extraordinary and continued discipline in the care of the general health.

Something still further, however, has been attempted, in the way of prevention, by diminishing the extent of the chief exciting cause; although it may be questioned, whether much has been effected in this way. The Dutch were supposed to have preferred their seamen from scurvy by the use of four krait with their salt provisions, and this article was recommended to the British navy by Dr. Lind: but it is prepared by a fort of fermentation, which produces the acidity; and this fort of acid, the product of fermentation, does not appear to be a substitute for the acid of fresh vegetables. Dr. Trotter, however, is of opinion, that the virtues of this substance as an antiscorbutic are very trifling, and that it has cost the government in its preparation more than it is worth. Another substance has also been employed in the British fleet, as a substitute for fresh vegetables in preventing scurvy, on the recommendation of Dr. M'Brith, viz. the essence or extract of malt. It was recommended upon the hypothetic notion, that it contained much of the cementing principle, as he called it, or that principle which, when present in animal and vegetable substan ses, prevents the process of putrefaction; and that by retorting this principle to the blood, the diseased, which affe, like scurvy, from a putrid diathesis, (thus heaping hypothesis upon hypothesis,) would be prevented and cured.

The truth, however, is, that there is little or no carbonic acid in this substance; and the favourable accounts received at the Admiralty of its beneficial effects, which induced them to establish the use of essence of malt as a part of naval victualling, are to be ascribed rather to its being a wholesome, nutritious, and digestible substance, confinably of vegetable origin; that is, with any specific antiscorbutic properties. This appears to be the opinion of Dr. Trotter, and Dr. Lind speaks of it only as "a very nourishing liquor, well adapted for scorbutic patients." It does not appear, however, that these articles are sufficient substitutes for fresh vegetable productions; and they certainly do not prove the same powers, with the latter, of curing the scurvy, when it already exists. With the proper acids, which have been generally adopted since the time of captain Cook, they contribute to the support of the general health, and therefore to the prevention of scurvy.

There is another species of vegetable matter, however, which appears in some measure to supply the particular substance, which fresh vegetables afford, and which is used both as a preventive and a cure for the scurvy, namely, the acid of limes, lemons, and other similar fruits, which the art of chemistry has for some time supplied in a concrete state. These substances, we believe, are now considered as among the necessaries for a long voyage, and are probably much more efficient than the four krait, essence of malt, &c.

Cure of Scurvy.—When the preventive measures have been neglected, or ineffectually employed, and the disease has already appeared, it is very difficult to remove it, while the circumstances of diet, &c. remain unchanged. Where these circumstances, however, admit of a change, experience has shown that the cure is very simple, and often very expeditious. A pure, dry, warm air, with the ufe of fresh vegetables, almost of any fort, commonly proves effectual. The initiatory feelings of the sick, indeed, direct them strongly to the ufe of the chief remedy; for there is perhaps no defire fo intense as that which the scorbutive patient feels for the ufe of green vegetables, fruits, and acids; infomuch that the sailors of lord Anson's ships greedily devoured the grapes, which was the first vegetable matter obtained. The vegetables and fruits which contain the greatest proportion of acid, are the most effectual remedies for the symptoms of fcruscoury; whence more and fewer fpecies. But about all times, lemons, oranges, apples, currants, &c. act in a manner as specifics in relieving the disease. All succulent vegetables, and those especially which are of an aromatic nature, are useful, particularly when combined with the acid ones; whence fcurvyc, grafts, horfe-radifh, cresses, purslain, and the tetradyne, are ranked among the antiscorbutics, and numerous plants have been specified by different writers as posseffed of special virtues. On the whole, however, the acid juices appear to be most speedy and effectual remedies for scurvy, especially those which approach to the nature of the citric acid.

The testimonies in favour of the specific curative powers of these acids in fcurvy are fo numerous as to leave no doubt of the fact. Even Dr. Lind, with whole hypotlheses respecting the nature of the disease the fact was not quite compatible, admits, in his postscript, their striking efficacy. "To what has been already faid," he observes, "of the virtues of oranges and lemons in this disease, I have now to add, that in feemingly the moft depreffed cases, the moft quick and fensible relief was obtained from lemon-juice; by which I have relieved many hundred patients, labouring under almost ilterable pain and afliction from this disease, when no other remedy seemed to avail." As the acid is apt to operate violently upon the stomach and bowels of those who are much weakened, Dr. Lind recommends the addition of two or three ounces of brandy, to produce a Carl antiscorbutic, and was in the practice of ordering about four ounces and a half of lime or lemon-juice, and two ounces of sugar, to be put into a pint of Malaga wine, which was sufficient for any weak patient to take in twenty-four hours.

Dr. Trotter testifies the extraordinary cure of these scorbutic symptoms by the ufe of these acids, even though at the same time they produce a very lax or purging flate of the bowels, and some degree of emaciation; while, on the other hand, the ufe of fresh animal food, strong broth, and wine, produces comparatively very little benefit upon scorbutic persons, although debility is the most marked symptom of the disease. This diet and the Peruvian bark will often produce no favourable change upon scorbutic ulcers, and the most powerful stimulant applications will not alter the condition of these sores: yet in less than twenty-four hours after the ufe of lemon-juice, the livid complexion of the sores, with the black clot of blood on their surface, will often disappear, and they will put on a florid and healthy character. The farther effects of the lemon acid are thus described by Dr. Trotter. "The patient in the inveterate flage of the disease seems to gather strength even from the fight
Scurvy.

fight of the fruit, the juices are exhilarated by the table itself; and the juice is swallowed with emotions of the most voluptuous luxury. The gums are gradually hardened, and the teeth fixed in their sockets. The dull and listless looks in a few days put an end to the healthful complexion, which also extends to the whole surface of the body. The absorption of the effused blood in different parts goes on rapidly, and by marking the spots, you may calculate the progress of the absorption, and the cure of the disease. This absorption breaks a degree of stimulus communicated to the lymphatic system as well as the sanguineous, as soon as the blood has received a sufficient quantity of the vivifying principle. From the effects of the juice upon the bile, the colour of the fluids is changed, and a lax state of the bowels is the consequence. But it is to be observed, that this laxity of the intestines may be moderated by giving the fruit in smaller quantities; a speedy cure, however, demands that they should be given ad libitum, and the greater the number of lemons taken in a day, the recovery will be more rapid in proportion. Loccit. p. 142.

While, on the one hand, these fresh vegetables and vegetable acids speedily remove the symptoms of scurvy, experience has fully ascertained, on the other, that the medicines called tonics, such as the mineral acids, balsam of Peru, and the various vegetable bitters, which have also been considered as antitoxics, or antidotes of putrefaction, are incapable of affording any effectual relief. And wine, which has been found a valuable remedy in some low fevers, gives but a momentary stimulus; but it does not retard the disease, nor afford any permanent relief alone. It was clearly proved, too, in Lord Anson’s fleet and elsewhere, that abundance of fresh provisions of animal substances and fish, even with plenty of fresh water, did not tend to arrest the progress of the disease. The use of mercury appears to be injurious under every flag of the fevers.

In speaking of the predisposing causes of scurvy, we have mentioned the effect of the depressing passions in inducing and aggravating the disease; and we have now to mention, on the other hand, the remarkable effects of hope, and the exciting passions, in aiding the cure of the disease. The following striking example of this medicine of the mind is related by Vander Mye, in his account of the disease, when it occurred during the siege of Breda, spreading despair and death around. “On the 2d of May, 1625, when the prince of Orange heard of their distress, and understood that the city was in danger of being delivered up to the enemy by the soldiers, he wrote letters addressed to the men, promising them the most speedy relief. These were accompanied with medicines against the scurvy, said to be of great price, but of still greater efficacy; many more were yet to be sent. The effects of this deceit were truly astonishing! Three small phials of medicine were given to each physician, not enough for the recovery of two patients. It was publicly given out, that three or four drops were sufficient to impart a healing virtue to a gallon of liquor. We now displayed our wonder-working balsams. Nor were even the commanders let into the secret of the chest put among the soldiers. They flocked in crowds about us, every one heaping that part might be reserved for their use. Cheerfulness again appears on every countenance; and an universal faith prevails in the sovereign virtues of the remedy. The herbs now began to spring up above the ground; we of these made decoctions, to which wormwood and camphor were added, that by their prevalent flavour the medicines might appear of no mean efficacy. The fluff contracted limbs were anointed with wax melted in rape-seed, or linseed oil. The invention of new and stratified phials was speedily ordered; and amidst a defect of every necessary and salutary medicine, a fresh supply of drugs was constantly added. The effect of these remedies was truly remarkable; for every wound was speedily perfectly recovered. Such a hastened remission of pain before, we were informed by the captain of the regiment’s office, and at last with a final application of phials of opium and water. Many who declared that they had been treated worse by all former remedies, which had been unsuccessful, recovered in a few days, to their surprise, and to no let us general surprise, by the taking (either by their having brought to them) what we assured them to be their gracious prince’s cure.” This account of the curative influence of the pinnis is fully sanctioned by the statements in Lord Anson’s voyage, already quoted, and by a fact mentioned by Mr. Ives, in his journal. On the 30th of January, 1744, there were nearly seventy persons ill of scurvy in the Mediterranean fleet; yet the joy of approaching the enemy’s fleet, and the hope of beating them, had such an effect, that on the 11th of February following, when the engagement happened, there were not above five men not at their fighting quarters.

Many remedies have been mentioned by different writers, who have treated of scurvy, and many local applications and methods of curing particular urgent symptoms, such as hemorrhages, spongy gums, ulcerations, diarrhoea, stiffness of the tendons, &c. have been detailed; but it is unnecessary to repeat them, since the only effectual mode of alleviating particular symptoms is the radical cure of the constitutional disease. “Fomentations, the warm-bath, &c.” Dr. Trotter observes, “have been often tried for the rigid tendons, and hardness of the muscles, but without effect: stimulant applications have been equally unsuccessful. For the difficult breathing and tightness about the breast, blisters and the whole train of expectorants are insufficient to relieve them. Opium itself, our last and only refuge in other cases of acute pain, affords no refreshing sleep or ease to the scorbutic sufferer. We have heard much of sudorifics opening the pores of the skin and softening the surface; but this is trifling with the complaint. It is only the produce of fresh vegetation, that can administer to him the reviving cordial; and a few lemons will do more to allay his anguish than the whole art of pharmacy.” P. 231.

On the Nature of Scurvy.—Various hypotheses have been framed at different times, according to the prevalent pathological doctrines, to account for the phenomena of this singular and formidable disease; and like most other medical hypotheses, they have hinged chiefly upon two principles, by one of which they are referred to certain morbid conditions of the blood or circulating fluids, and by the other to morbid changes in the property of the living folds. If we take into consideration, however, the whole phenomena of the disease, its causes, and remedies, we shall find considerable difficulty in admitting either of these hypotheses exclusively, and not a little in giving any satisfactory view of the subject, even by allowing the partial truth of both.

All the older writers, being of the humoral school, maintained the doctrine of a morbid state of the fluids, as the proximate cause of scurvy. Boerhaave and his adherents referred the disease to an acrimony of the fluids, which they supposed would be of a different quality, according to the different causes which produced it; thus it would be an alkaline acrimony from salt and putrid provisions and foul water,
SCURVY.

water, and an acid acrimony from bad sorts of bread or vegetable gluten, combined with a sedentary life. (See Boerhaave, Aph. 1153.) Dr. Cullen, too, though he relinquished much of the humoral pathology, was of opinion that scurvy was the effect of "a preternaturally saline, and consequently diffused state of the blood," which was occasioned by a greater advance towards putrefaction, from the absence of the corrective of vegetable matters. (See First Lines, par. 1812—13.) And Sir John Pringle maintained a similar doctrine, that scurvy was the result of "a gradually accumulating putrefaction" in the blood, from the putrefacence of salted food, which he deemed the chief cause of the disease. (See his Obs. on Diff. of the Army, Appendix, p. xci.) In fact, the general opinion, for a long period, deemed scurvy the most characteristic example of a putrid disease. And this putridity of the fluids was inferred from the fetor of the breath, and of the ulcers; from the black colour and loose continence of the blood; from the extensive hemorrages; from the purple blotches on the skin, &c. But this is a gratuitous and erroneous inference: for we have no less authority than that of Dr. Lind, who made numerous experiments on the subject, affecting that blood, drawn from scorbutic patients, even in a putrid state, discovers no sensible taint of either acrimony or putridity, by the taste or the smell; that the serum of such blood is as tasteless as the white of an egg, and without odour; that it corrupts in the air no sooner than the blood of healthy persons; and that thin films of mucus,immerged in this serum, continued sweet and free from taint, as long as in the serum of persons in health. We know, indeed, from actual experiments, that if the smallest quantity of putrid matter be injected into the blood-vessels, it is followed by speedy death. (See a Diff. by Dr. Scobert, on the Putrefaction of the Blood, Philadelphia, 1793.) The ordinary secretions from the blood are not putreform, as has been asserted. Dr. Lind affirms, "the urine in this disease was not found to be more offensive to the smell, nor to corrupt sooner, than that of a peron in health; and their sweat is not fetid, or more disagreeable than when they are in health: the same may be said of their floggs." (Pott's Script., p. 515.) The same experienced physician justly observes, "the offensive smell from the mouth of scorbutic persons, when alive, seems to me to proceed solely from the corrupt state of the gums. For in their dead bodies I never perceived any unusual marks of putrefaction; they were neither more offensive, nor liable to corrupt sooner, than any other carrion." In a word, the notion of a putridity of the circulating blood is not only unsupported by actual evidence, but is refuted by all sober fact and observation; and the experiments of Dr. Lind prove that there is not even a proneness to putridity existing in either fluids or fluids.

Can we account, then, for the phenomena of scurvy upon the other hypotheses, which ascribes the malady to certain morbid conditions of the living folid? This view of the subject was ably advocated by doctor, now Sir Francis Milman, in one of the most elegant medical essays in the English language, published in the year 1782, (Enquiry into the Source of the Symptoms of Scurvy and Putrid Fevers, &c.) and, in fact, it afforded the most rational explanation of most of the symptoms of the disease, according to the physiological and pathological doctrines which modern inquiries have established. It is not at present, therefore, necessary for us to enter into any minute detail of the symptoms, with the view of explaining them upon the principle of a weakened and impaired condition of the nervous system, and of the muscular irritability. This has been accomplished at great length by Dr. Milman, taking this ample enumeration of Boerhaave, in his 115th aphorism, as the text, to which we refer the reader.

This view of the subject appears also to accord better, on the whole, with our knowledge of the pre-difposing and exciting causes of the disease above detailed. The various kinds of diet, under which scurvy occasionally originates, is ill calculated to produce any particular acrimony of the fluids; and the dry pulse and glutinous pudding of the Bohemians on shore could not have the same tendency to putrefaction as the salted animal diet of seamen. Yet all these substances might equally fail, from their indigibility, or from the defect of nutritious matter which they contained, to support the strength and vigour of the moving fibre, and would equally contribute, therefore, to produce that languor of the vital powers, which is so conspicuous in the progress of scurvy. The analogy of scurvy with the ignis facer; admirably described by Lucretius, which appears to have been commonly the result of famine, and often called pellencence, (whence M. Poupart was correct in comparing the epidemic scurvy of Paris with some of the ancient plagues) seems to support the same doctrine. (See Louis Facere.) And all the pre-disposing causes, on the one hand, which are principally debilitating causes, fatigue, indolence, want of sufficient sleep, cold and moisture, and the means of prevention, on the other, which are such as support the general vigour of the constitution, moderate exercise, sufficient sleep, fresh air, warmth, &c. concur in evincing the state of the moving fibre to be the source of the morbid symptoms. The same opinion is also farther supported by the extraordinary influence of mental impressions in producing and in preventing or curing the disease. These impressions cannot suddenly change the chemical condition of the fluids; but their influence upon the living folid, through the medium of the nervous system, is manifest both in health and disease, to a degree that unlearned persons will fearcely credit. (See IMAGINATION, Influence of, and IMITATION.) The discharges of blood from the relaxed and enfeebled orifices of the vessels, the gangrenous and consequent putrefacence tendency of the gums, and other delicate parts, the fainting and even dying on the slightest exertion, the dropical swellings, the labouring breath, the oppression about the heart, &c. &c. appear to be the result of diminished strength in all the muscles, and of enfeebled action in all the vessels, the consequences of a general failure of the vital or nervous power.

Such, then, appears to be the advantage, in point of argument and analogy, which the doctrine of diseased foids pollicyes over that of acrimony and putrefaction in the fluids. Nevertheless this theory is by no means satisfactory: it is in some measure, indeed, incompatible with the most striking and well ascertained fact, that the scurvy is not curable by those means which appear to contribute in general to the strength and activity of the solids, such as fresh animal food, wine, bark, soups, &c.; while it is speedily and certainly removed by the use of vegetable acids, which contain no nutritive quality, and are so far destitute of corroborating power, that they even induce emaciation, while they cure the disease. In truth, we can give no satisfactory theory of this disease: but our pollication of a certain remedy, and our knowledge of the means of prevention, may fairly supersede all hypothese upon the subject. In this, and in all other diseases, experience and observation are the only guides which the judicious physician will follow. The instinctive demands of the sick point out the source of relief, and hunger and thirst lead us to food and drink; and it is enough to have observed, that, by gratifying these demands, the
the disease is cured, I have observed sailors, that by the use of this plant, which is dried, and powdered, with a little oil, applied to the wounds caused by the bit of a horse, or any other cause, a most efficacious cure of the disease has been obtained. This plant is called in Europe, 'Sperma de Dragon.'

When I was on a voyage in the Mediterranean, we had a number of horses, and a very large number of sailors on board. The horses were constantly subject to the disease, and I have observed that by the use of this plant, which is dried, and powdered, with a little oil, applied to the wounds caused by the bit of a horse, or any other cause, a most efficacious cure of the disease has been obtained. This plant is called in Europe, 'Sperma de Dragon.'

Some confusion has arisen in the English denomination of the part in question, which is now generally called a field, in preference to Dillenius's word fauca, but well may all agree, surely, disapprove of the change. The source of the Latin fauca is faustum, a shield, and Linnæus, in his Flora, plus Botanica, appears to have intended using faustum, a little shield, instead of faustellus, a little dish. If he had kept to the former, our English word would indeed have been more strictly correct, but it is fully sufficiently to preserve any necessity of altering what is now generally adopted.

Sec. Cal. Cal. Perianth in favour, of one lobe, very short, tubular; rim almost entire, after flowering, cleft with a lid, persistent. Cal. of one petal, erect. Tuba very short, bent backwards; throat small, compressed. Upper lip concave, trunca: middle lobe concave, emarginate; lower ones flat, rather acute, lying under the middle one.
Lower lip broader, ensaginate. _Stam._ Filaments four, concealed under the upper lip, two of them longer; anthers small. _Pil._ Gynoecium superior, four-cleft; style thread-shaped, resembling the stamens in situation and length; stigma simple, incurved, pointed. _Peric._ none, except the clobed calyx, which is shaped like a helmet, triangular, burling at the lower margin. _Seeds_ four, rounded.

Ob. This genus is easily and sufficiently distinguishable from all others by the fruit alone, for the cloed calyx, containing the seeds, with its crest and lid, somewhat resembles a helmet.

Eff. Ch. Rim of the calyx nearly entire, cloed, and covered with a lid after flowering.

1. _S. orientalis._ Yellow-flowered Skull-cap. Linn. Sp. Pl. 834. Sm. Fl. Græc. Sibth. t. 580, unpublished. (Caflida orientalis, charmedyros folio, flore luteo; Tourn. t. v. 2. 159, with a plate.)—Leaves with deep parallel teeth; downy beneath. Spikes cylindrical, slightly quad-

2. _S. grandiflora._ Large-flowered Skull-cap. Ait. n. 2. Sims in Curt. Mag. t. 635.—Leaves heart-shaped, deeply crenate, downy on both sides, shorter than their flakas. Spikes very short, quadrangular. Corolla hairy, four times longer than the bracteas. —Native of Siberia, and introduced by Mr. Loddiges in 1804. It flowers in July. A hardy perennial, like the laf, of which indeed it may possibly be only a variety. The _spikes_ are shorter, and the _corolla_ is larger in proportion to the _bractea_, lilac-coloured, with a yellow palate. _Leaves_ rounder, lef downy beneath, but soft on both sides. Dr. Sims says it "approaches very nearly to the variety of _S. orientalis_ found in Georgia by Tournefort, and described in his travels."

6. _S. nervosa._ Ribbed Skull-cap. Pursh n. 2.—_Stem_ nearly simple, smooth. Leaves ferrate, ferrated. _Flowers_ in lateral clusters, small, blue, each partial flak bearing two tecteuous _bracteas_.

8. _S. halflolia._ Haft-leaved Skull-cap. Linn. Sp. Pl. 835. (Scutellaria folio non ferrato; Rivin. Monop. Irr. t. 77.)—Leaves quite entire; lower ones hafta; upper arrow-shaped. —Found on the shores of fresh waters, in Sweden and Austria, but not very common. It flowers in June and July. _Root_ creeping. _Stem_ generally simple. _Leaves_ blunter than in the preceding, not at all notched, cleft at the base. _Flowers_ axillary, foliary, in pairs, blue, larger than in the laf species, to which it is very closely allied, and of which both Linnaeus and Scopoli hint that it may be only a variety.

9. _S. minor._ Lesser Skull-cap. Linn. Sp. Pl. 835. Fl. Brit. n. 2. Eng. Bot. t. 524. Curt. Lond. face. 4. t. 43.—Leaves heart-ovate, nearly entire. _Flowers_ axillary. —Rather a scarce native of Britain, and the south of Europe, in a moist gravelly soil; flowering about August. _Root_ perennial, creeping. Whole habit much resembling _S. galericulata_, but the plant is about four times as small. _Stem_ branched at the base. _Leaves_ broader, rugose, nearly entire, sometimes toothed at the base, and as it were slightly hafted. _Flowers_ of a delicate pink colour, rarely blue; _lip_ white, spotted with red.

10. _S. umbilicus._ Dwarf Skull-cap. Brown Prodr. Nov. Holl. v. 1. 507.—Leaves of the same heart-shaped, coarsely crenate; dotted and rather downy beneath. _Flowers_ axillary. —Calyx smoothish, half as long as the corolla. —Found by Mr. Brown at Port Jackson, as well as in the fourth parts of New Holland. We received specimens, in 1793, from Dr. White. This agrees in size, and somewhat in habit, with the last, but the _leaves_ are smaller, more rounded, deeply notched, with curved brilily hairs about their ribs and margins. _Flowers_ solitary, opposite, spreading different ways.

11. _S. mollis._ Soft Skull-cap. Brown ibid.—"Downy, with capitate hairs. Leaves heart-shaped, oblong-ovate, deeply crenate. _Flowers_ axillary; their flakas as long as the foot-talks."—Gathered by Mr. Brown near Port Jackson.

13. _S. parvula._ Minute Skull-cap. Michaux Boreali-

Amer.
The text contains a list of plant descriptions, including their names, characteristics, and habitat information. The page is a detailed account of various plant species, their features, and their distributions. The text is quite extensive and requires careful reading to understand the full content. Without more context, it's challenging to provide a concise summary. The page seems to be from a natural history or botany text, discussing different plant species in detail. The text is quite dense and technical, typical of botanical descriptions.
almost as long as the leaves. Spikes somewhat aggregate, erect, dense, many-flowered, hairy, two or three inches long. Bracteas ovate, entire, longer than the calyx. Flowers all turned one way. Calyx covered with very long dense hairs, spreading in all directions. Corolla downy; its upper lip pale lilac; lower, as well as the tube, greenish-white.

24. **S.albida.** Pale Hairy-capped Skull-cap. Linn. Misc. VI. 248. Willd. n. 2. Sm. Fl. Græc. Sibth. t. 581, unpublished. (S. teucria face; Bauh. Hist. V. 3. 201.) — Leaves heart-shaped, serrated, downy as well as the item. Spikes elongated, unilateral. Bracteas two-ranked, ovate, flaked, nearly equal to the flowers. Corolla downy, its lower lip entire. — Native of the Levant; found by Dr. Sibthorp on Mount Olympus. Very nearly akin to the last, and not in the least resembling orientalis, to which Linnaeus, in his Systema Vegetabilium, by some unaccountable error, compares this species. It is, if possible, more strange that he should at one time have confounded albida with alpina, as appears by his herbarium. S. albida differs from peregrina in having broader, more coarsely serrated leaves, more crowded and numerous flowers, whose corolla is cream-coloured, downy, not clothed with long hairs; the edge of its lower lip even, instead of being entire, undulated, or notched. The calyx, on the contrary, bears much longer hairs than that of peregrina.

25. **S.albida.** Tall Skull-cap. Linn. Sp. Pl. 836. Willd. n. 16. Ait. n. 13. (S. Columata; Allion. Pedem. V. 1. 40. t. 84. f. 2. Willd. n. 14. Casriis; Column. Echpr. V. 1. 187. t. 189. C. orientalis albitetta, urticae folio; Tourn. Cor. 11.) — Leaves heart-shaped, serrated, acute, nearly smooth. Spikes elongated, unilateral. Bracteas ovate, acute, flaked, shorter than the calyx. — Native of Italy, Mount Caucaus, and the Levant. Miller cultivated it in 1731, and one of his own specimens, compared with those of Allion, have enabled us to verify the above synonymy, and to reduce two reputed species, of this difficult and confused genus, into one. The present differs from both the two last, in having leaves twice their fize, besprinkled with only a few minute flattered hairs, so as to appear nearly smooth. But its most essential character consists in the small leaves of the bracteas, whose points do not extend beyond the calyx. The spikes therefore appear almost naked, consisting of numerous purple downy flowers, whose calyx, like the flower-flake and bracteas, is rough with glandular villous hairs.

The last species in Linnæus, Willdenow, and Aiton, S. erecta, require to be expunged, being the very same plant as Teucrum Ardisini, Linn. Mant. 81, and announced as such in Sm. Prodr. Fl. Græc. Sibth. V. 1. 392. Its calyx and habit accord with Teucrum, not with Scutellaria.

Scutellaria, in Gardening, contains plants of the hardy, herbaceous, perennial kind, of which the species cultivated are; the entire-leaved skull-cap (S. integriloba); the Florentine skull-cap (S. peregrina); and the tall skull-cap (S. altissima).

Method of Culture. — These are all raised from seed, which should be sown in autumn or spring, but the former is the better season, in the places where they are to remain, or in a border to be removed afterwards. When the plants are up they should be properly thinned out and kept free from weeds.

They afford variety in the borders, clumps, and other parts of pleasure-grounds, when properly planted in them.

Scutellum, in Botany, a little shield, sometimes used for the fructification of Lichens, instead of Scultella, see that article.

Scutellum, or Erythronium, in the History of Infusoria, is the posterior part of the thorax; it is frequently triangular, and appears to be separated from the thorax by its intervening future, as in moll of the coleoptera.

Scuthinon, in Botany, a name given by the ancient Greeks to a yellow wood, called also thapsus, chryson, and Scythium lignum. It was of a beautiful colour, and was used in dyeing and in colouring the hair yellow, which was the favourite colour of that time.

The same authors have sometimes also called it cyphon, or cuthion: this is only the former word with the initial f taken away, as it was common with them to do in regard to many words; thus they called the similax milax, the simaragus, and fo of many more.

Scutiforme Os, in Anatomy, the chief bone of the knee, called also patella, mala, &c.

Scutiformis, Carditlagos, one of the pieces composing the larynx. See Larynx.

Scuttle, in Agriculture, the name of a shallow balket, or fort of wicker-bowl, much used in the barn and for other purposes. The large ones have handles, but the small ones are without them. They are often also employed for flitable purposes.

Scuttes, in Ship-Building, are square openings cut through the decks, much less than the hatchways, for the purpose of handing small things up from deck to deck. There are also scuttles cut through the ship's side, for the admission of air and light into the cabins, &c. between decks, and some between the ports of smaller vessels, through which the smoke is used to row the vessel along in calm.

Scuttle-Hatch, in a Ship, the little hatch that covers the scuttle.

Scuttlng, in Sea Language, the act of cutting large holes through the bottom or sides of a ship either when she is stranded or overfold, and continues to float on the surface. It is commonly devised for taking out the whole or part of the cargo, provisions, stores, &c. with all possible expedition.

The decks are scuttled sometimes to put pumps down to afflict the chain-pumps on emergency or failure.

Scuttock Hills, in Geography, hills of the United States of America, in the district of Maine; 8 miles N. of New Brifhol.

Scuttock Point, a cape on the coast of Maine. N. lat. 44° 18'. W. long. 67° 58'.

Scutula, in Botany, so named by Loureiro, from the shape of its berry, which resembles a little shield.—Loureiro. Cochinch. 235.—Clas and order, Oelandra Monogynia. Nat. Ord. ……

SCYBALA, σκυβάλα, in Medicine, an appellation given to the excrement of the bowels, when it is hard, dry, and formed into small maffes, or little balls, resembling the excrement of sheep. This form is always given to the bowels by their remora or delay in the intestines, and is sometimes merely the result of ordinary confinement, and is then probably produced in the cellular surface of the colon, or intestines; but in some cases, skubala are lodged higher in the canal, exciting great irritation in the bowels, and even violent purging of thin, slimy, mucus, together with much fruitless straining, or tenesmus; which constitute, in fact, one form of the dysentery, or flux. In these cases, it is obvious that, if astringents are given, with a view of checking the purging, the disease must be aggravated; for the enemy is thus closer locked up in the bowels; and that effectual cathartics must be administered by the mouth, to expel the accumulated excrement. Accordingly the appearance of skubala in the

SCYLANAX, in Ancient Geography, a river of Asia, in Pontus, which ran into the Iris, after this latter river had pursued an easterly course, and watered the town of Amaistra, according to Strabo.
SCY

SCYLDWIT, in our Old Writers, a mullet or fine for any fault.

It comes from the Saxon *seilde*, i.e. *delicium*, and *wit*, i.e. *parus*.

SCYLLITZA, John, *Cerophalates*, in Biography, a Greek historian, known for his abridgment of history from the death of Nicophorus Logothetes, in 811, to the deposition of Nicophorus Botaniates, in 1081. This history, from the year 1067, is the name that of Ceduncus, which has caused a delusion among the learned, which of the two was the plaguary. Scyllitz is thought to have been a native of Lefki Asia, and a prefect of the guards before he attained the dignity of eulopulates. A Latin translation of his history entire, was published at Venice in 1570; and the part concerning which there is no dispute was printed in Greek and Latin, at Paris, in 1647. Moretter.

SCYLLA, in Ancient and Modern Geography, a rock at the entrance of the Straits of Messina, about 200 feet in height, now cape Segio; which is. Scylla was famous in antiquity for the danger which it presented to navigators who approached it. The rock, personified by Homer in his Odyssey, and represented as a devoursing monster, has been destroyed by a late earthquake. Concerning its situation with regard to Charybdis, and other particulars, we refer to Charybdides.

SCYLLA, or *Scylla*, a town of Italy, in Bruttium.—Also, a defeat inflicted in the vicinity of the Thracian Chersonesus.

SCYLLAEA, in Natural History, a genus of the Vermes Mollusca clafs and order, whose generic character is, body compressed, and grooved along the back; the mouth contains a terminal toothless aperture; the tentacula or arms three on each side, and placed beneath. There are only two species.

*Pelagica.* The body of this species is fixed; the four extreme arms are alike; the middle ones papillous. It inhabits the ocean, and is generally found among floating seaweed. Independently of its specific character, it is decribed as having a roundish oblong body; broader behind, and obtuse; the mouth is placed at the end of the smaller extremity; the back is grooved with a crenulate hollow, by which it affixes itself to sea-weed; the extreme arms are smaller and rounded; the middle pair is oblong, foliaceous, bending over and sprinkled within with papillae.

*Compressa.* The body is detached; the first pair of arms is naked and hollow at the tip; the others have branched fibres within. The body is about an inch long, yellowish, with rusty brown dots; the back is flat, dotted with brown at the margins, with a row of blue dots down the middle; the tail is crenulated, with an elevated rounded back, and furnished on each side with small branched fibres; the abdomen is dotted with blue, and rough, with a row of five whitish papillae down the middle of each side; the first pair of arms is the longer, the rest are contiguous, with a denticulate margin.

SCYLLEUR Promontorium, in Ancient Geography, the promontory of Scylla, or of Skeldeo, that part of the Argolid which advances towards the south-east.

SCYMNITZA, a people of Attic Sarmatia, between the Sopotherne and the Amazons, according to Ptolemy.

SCYMNUS, in Ichthyology, a name used by Athenian, Appian, and many other of the old Greek writers, for the fish called *fleutus* by Aristotle. This is a species of the eels, called by Aristedi and others the eels, with the pinna ani placed in the middle, between the anus and tail: the *catulus vulgaris* and *catulus major* of authors.

SCYPHOPHORUS, in Botany, from ἑπάθεις, a large kind of drinking cup, and γυαῖς, bearings, alluding to the dilated cup-shaped stalks, refembling wine-glasses, borne by the leaves. On whose margins the fructifying tubercules are seated. This is the denomination of the 2111 tribe, or section, of the Lichenes, see that article, in the *Prodomus of Acharius*, which are well known to the vulgar, as well as the learned botanists, by the name of Cup-moils, or *Lichenes sydaxidi*. The above name is however stuck in that of Byzantia, in the *Methodos of that author*; though Michaux uses it generally in his *Flora Borzoi-Americana*, v. 2. 328.

SCYPHUS, among the Romans, a very large kind of drinking cup. The scyphus was called the cup of Hercules, as that of Bacchus, liberis patri, was named cantharus.

SCYPPIUM, in Ancient Geography, a town of Acha, Minor, in Ionia, on the confines of the country of the Colesphontians, according to Pausanias.

SCYRA, in our Old Writers, a fine imposed on such as neglected to attend the *fregemot court*, which all tenants were bound to do.

SCYRAS, in Ancient Geography, a river or stream of Laconia, which discharged itself into the gulf of Laconia. Near it was a temple of Apollo, and an altar of Jupiter. Pausanias, lib. iii. Lacon. c. 25.

SCYREGEMOT, or SCYREMO, in Ancient Cylons, a county-court held twice every year by the bishop of the diocece, and the caddorman, or sheriff; in which both the ecclesiastical and temporal laws were given in charge to the county.

In the time of Canutus the fregemot was held thrice every year. Edward the Confessor appointed it to be held twelve times in the year.

SCYRI, in Ancient Geography, a people of India, in the vicinity of Ariana.

SCYRIUM MARXOR, a name given by the ancients sometimes to a white, and sometimes to a yellowish marble, both used in the public buildings of the Romans, but seldom in flattery, not being capable of a high polish.

SCYROS, in Ancient Geography, an island in the Archipelago, situated to the E. of the isle of Euboea, and very near it. The ancients pretend that Achilles spent the first years of his life here, disguised as a female, in the court of Lycomedes. It was in alliance with Troy, as appears from Agamemnon's having made a conquest of it. See SCIRO.

SCYTALA, an island of the Arabic gulf.

SCYTALA, in Mechanics, a term which some writers use for a kind of radius, or spoke, standing out from the axis of a machine, as a handle or lever, to turn it round, and work it by.

SCYTALA Latanics, in Antiquity, a frigate, or device, of the Lacedaemonians, for the secret writings of letters to their correspondents; so that if they should chance to be intercepted, nobody might be able to read them.

To this end they had two wooden rollers, or cylinders, perfectly alike, and equal; one of which was kept in the city, the other by the peron to whom the letter was directed. For the letter, a thin of very thin parchment was wrapped round the roller, and on this the matter was written; which done, it was taken off, and sent away to the party, who, upon putting it in the fame manner upon his roller, found the lines and words, which were before its application to the roller confusedly disjoiined, and altogether unintelligible, in the very same disposition as when they were first written. Plut. in Vit. Lyfand.

This expedient they set a very high value on; though, in the
truth, artless and gross enough: the modern has improved vastly on this method of writing. See Cotton.

It should seem, that besides this variety, used for political and military purposes, private patrons made use of a commoner somewhat similar, to preserve deeds in contracts, but these were exactly like our talers.

SCYTALE, in Zoology, the same given by the Ancients to a species of apes, which was very long and thin, and equally big all along the body, so that the tail was not easily distinguished from the head.

Linnaeus mentions two animals under this title; one, a species of monkey or snake, and the other a species of the Eus; which tree.

SCYTALIA, in Botany, elegantly so named by Gartner, from scytos, a staff, or pole, and alia, a thing, in allusion to the heartly substance and colour of the skin of the dried fruit, as also to the little flesh-like tuberces, with which its outside is beset, resembling a coat of mail. Schreber has followed this author: but the same genus was published two years afterwards by Loureiro, under the name of Dimocarpus, indicating its double or twin fruit, which Willdenow has unawares retained, though in every respect less eligible. Hence the latter appellation is also adopted in the Hortus Kewensis, the plan of this book being, as much as possible, to follow Willdenow. Had we been aware that it would have done so in the present instance, we might perhaps have yielded our better judgment to convenience, and have given the history of the genus under the head of Dimocarpus; but this not being the case, we shall exhibit it here, acknowledging our preference for Scytalia.—Gent. See v. i. 197 t. 42. Schreb. Gen. 252. (Dimocarpus; Loureir. Cocih. 233. Willd. Sp. Pl. v. 2. 354. Ait. Hort. Kew. v. 2. 354. Euphoria; Juff. 247. Lamarck Histo. t. 356.)

Gen. Ch. Cal. Perianth inferior, of one leaf, very small, with five minute teeth. Cor. Petals five, small, reflexed, hairy on the inner surface, sometimes wanting. Stam. Filaments eight, sometimes but fix, awl-shaped, hairy, longer than the petals, dilated at the base; anthers heart-shaped, incumbent. Pd. Germen superior, two-lobed, somewhat flattened; style shorter than the filaments; stigma two, spreading. Peric. Berries two, ovate or globose, with a conicaceous warty coat, pulpy within, each of one cell. Seed solitary, large, elliptical, polished, obliquely cut away at the base, where it is inferted into the slightly elevated bottom of the pericarp.

Obf. Gartner has described as a flucky tunic of the feed, what is really only the dried pulp of the berry.

1. S. Litchi. Linn. or Apetalous Scytalia. (Dimocarpus Litchi; Ait. Hort. Kew. v. 2. 354. Loureir. n. 1. Litchi chinensis; Sonnerat Ind. Or. v. 2. 230 t. 129. Sapsindus edulis; Ait. ed. 1. v. 2. 356.)—Flowers with six filaments, and no petals. Fruit with prominent warts. — Nat. of China, Cochinchina, and Turquin. The celebrated governor Hastings is said to have sent this plant to England in 1756, and it is marked as flowering in the flowe at Kew, in May and June. The younger Linneus, however, appears to have obtained a specimen of the leaves, from the collection of the marquis of Rockingham at Wimbledon, during his stay in England in the spring of 1782. The Litchi is described by Sonnerat as a large tree, with a soft white wood, abounding in pitch. The leaves are alternate, stalked, abruptly pinnate, confiding of three or four pair

of species, tallied, elliptical, oblong, pointed, rosetted at the base, and furnished with a large, round, warty fruit, in the form of a thistle. Pericarion, a light, warty, with very round, echinate, and warty teeth. It is of an agreeable flavour, not so good as the fruits of the countries where it grows. I. Consider it in oven for expiatory. Scythia, which we have noted, England, contained a fine very good pears, at the table of tamarinds.

2. S. Longan. Licon, a Monkey-pod tree. (Dimocarpus Loureir. Ait. Hort. Kew. v. 2. 354. Loureir n. 2.)—Flowers with eight filaments and five petals. Fruit nearly smooth. — Nat. of C. A. Cultivated in the coast of Cochinchina, the East Indie, &c. This is also a large tree, with a few boisterous fruits, half the size of the last, more precociously ripened, and either quite smooth, or slightly leathery, not warty. The leaves are rather more numerous than in the former, shorter, blunter, and more elliptical, and held in our East Ind. p. curcas. In one from the ile de Bourbon, marked Longan, the leaves are oblique, or unequal, at the base, alternate, and taper-pointed. The fruit is quite smooth. We suspect this to be rather some Sapindus, confounded with the true Longan.

Loureiro mentions two more species unknown to us, one of which, his Dimocarpus inferius, seems to be the wild state of the Litchi, in the woods of Cochinchina. He speaks of the wood of all the four as of an excellent quality, heavy and hard, of a brownish-red. The same author relates, that the Litchi, being impatient of cold, as well as of great heat, is mostly cultivated in the southern provinces of China, and the northern ones of Cochinchina. As the fruit will not ripen at Pekin in the ordinary way of cultivation, trees in flower are sent thither by water, so as to yield ripe fruit, for the emperor's use, on their arrival. This is attended with great labour and expense.

SCYTHA, Scythe, among the Athenians, a designation sometimes given to the officers, more usually called hierarchi.

They had the name Scythia, because they were often natives of Scythia who were chosen hierarchi, as being brawny and flabby fellows.

SCYTHARION, in Botany, a name given by the ancient Greek writers to a tree, whose wood was of a fine yellow colour, and was used in those early times to dye things yellow: it was called also Scythium lignum, from its country, and chrysoyloan, or golden wood, from its fine yellow colour. It has been supposed that this was the same with the cotinus coriaria of the Romans; but this is an erroneous conjecture, since the wood of this tree dyed a yellow colour, and that a brownish-red, or a clear and pure red, according as the infusion was made more or less strong. This feytharian, therefore, could not be the same with the cotinus, but it certainly is the same with the thapous of the Greeks.

SCYTHE, in Agriculture, the implement used in mowing, being a crooked blade joined at right angles to a long pole, or handle. It is sometimes written ʃythe, or tythe. See Mowing.

Common scythes are of several different constructions and
Rhymnus, the is and that and a supposed, When and one to near and it had without and the tool, which is commonly furnished and fitted up differently for different purposes, as has been noticed under the heads to which they belong. See Mowing, Reaping, &c.

The fliff Flemith fcythe is in use in some places for cutting bean, and other flrong crops of the corn kind. It has the name of bean peck in some parts of Essex; and though it is thought by some to beat out the seed too much, in the hands of workmen who understand the use of it, very good clean work can be made with it, without any much mischief taking place, and they rid work in this way much faster than by the common tool and method.

In Cheshire, they make use of a strong tool of this fort, called the boddle-fcythe, the blade of which is about twenty inches in length, but curved in a different way to the common fcythe, the edge being nearly in one way of it, in a straight direction from the heel to the point; but the flat part of the blade forms a curvature, which varies about four inches from a straight line. The handle or shaft, to which the blade is fixed, is about three feet six inches long, and has one fcythe-like handle placed about eighteen inches from the top. When the work is performed, one hand is placed upon the top of the shaft or fneyd, and with the handle in the other, the crown of the ruff root is scooped out by the concave part of the blade, in consequence of a smart stroke being given by the tool. The early spring is considered as the most proper season for effecting this fort of busines; and it is advisable to carry off the ruff roots, and form a compost with them; the lod-holes, or cavities made by the tool, being filled level with the surface of the ground with some earthy material, and fown with hay or gras-ffeeds. This tool is yet but little known, except in the above district, where it has been used to considerable extent in many parts, with the most beneficial effects in clearing the lands from rufles; many scores of acres of low meadow and marshy lands having been in this way freed from them, and with the aid of gutters, rendered of more than double their former value.

Short floug fliff fcythes are made use of in moat places, for clearing away and removing all forts of shrubby plants from grounds, such as those of the broom, briar, furze, and several other limiar kinds.

SCYTHIA, in Ancient Geography, is a vast territory, which has been confounded by some geographers with Tartary or Tartary, of which it is only a part (see TARTARY), extended from the Ilter, or Danube, that is, from about the 25th to almost the 16th degree of E. longitude. It was divided into Scythia in Europe, and Scythia in Asia; including, however, the two Sarmatias, or Sarromatias, now the Circassian Tartary, which lay between and separated the two Scythias from each other. Sarmatia was also distinguished in European and Asiatic, divided from the European Scythia by the river Don or Tanais, which falls into the Palus Mazotis, and from the Asiatic by the Iva, now Volga, which empties itself into the Caspian sea. (See SARMATIA.) Accordingly the two Scythias were only parted by the boundaries of Europe and Asia, that is, by the river Tanais, descending, as it is supposed, from the Riphæan mountains into the Palus Mazotis. For, beyond those mountains northward, the Scythians did not advance into any of those remote regions; so that there were the proper confines of the Asiatic Scythia on the west. The northern boundaries reached to the Hyperborean or Frozen sea, called also by the ancients the Scythian sea, the Criotian, Amalian or Almalian, the Dead sea, and by some other names equally expressive of extreme cold and ice. On the east, they are supposed to have extended to the promontory of Tabis, and to have been bounded by the Caflian mountains, which parted Scythia from the kingdom of Sares, now Katai, Chahar, or Northern China; and even this last was by some of the ancients taken for part of Eastern Scythia; so that, on that side, it had no other boundaries, according to Ptolemy, than the unknown tracks beyond it; and on the south it was bounded by the Indian sea, by mount Caucasus, and the Caspian. As to the more northern parts of Scythia, it is, on account of its extreme cold, uninhabitable, except by wolves and other wild beasts; and hence they seem to have been unknown to the ancients beyond the 50th degree north. The territory beyond that degree was denominated Terra incognita. But the southern regions, better known to them, were divided into three parts, viz. Scythia within, and Scythia without, or beyond Imaus, and Sarmatia, which, as we have already said, lay between the former and the European Scythia, and which had been so blended with it, that the only difference between them was the name. Accordingly, Ptolemy bounds the Scythia on this side of Imaus on the west by Asiatic Sarmatia, by mount Imaus on the east, by the Terra incognita on the north, and on the south and east by the Sace, Sogdian, and Margian. The principal mountains in this part Ptolemy reckons to be the Alani to the east; the Rhyminni, from which flowed the Rhymnus into the Rha; the Norofni, from which sprung the Daix, the Afpifi, the Sauri, the Syebi, and the Ainaici. The rivers were the Rhymnus, the Daix, the Jaxartes, the Jaltus, the Polytimetus, and the Oxus. The inhabitants of this part, according to the same geographer, were, towards the north, the Alani, Sufobeni, and Agathyrri; and next to these, the Satiemen, the Maffi, the Syebi; near the Imaus were the Thases; near the eastern sources of the Rha, the Rhobacii, Azani, and Jordii; to the south, and near the river, was the country called Conadipfas regio; and near this, Cornphi, Orgazi, Iota, and Aoni; next to these, the Jaxartes, a considerable nation, on the river of the same name; to the south of the Satiemen were the Mologeni, and next to them the Samnitz; and below the Maffi and the Alani mountains were the Zaretæ and the Zasones; to the east of the Rhymnic mountains were the Tybiaca; and below them the Zaretæ, Tabeiæ, Jaltæ, and Machageni, near mount Norofni; above them were the Orofbes and Norofni; and more to the south, the Cachæfæ Scythe; to the east of the Afipifi, the Afipifi Scythe; and east of them, the Galatæphagi Scythez; and east of the Syebi, the Tapurei, and the Astantial Scythez. The Anaci lay to the south of the Agathyrri, and to the east of the Tapurei. The Afastance extended to mount Imaus; and near the Jaxartes, between the mouths of the two rivers, were the Ariace, the Sagaracuce, and the Rhibi, near the Oxus. The Scythia beyond Imaus, according to the same geographer, was bounded on the north by the mountains, on the east by Serica, on the south by part of India on this side of the Ganges, and on the west by the interior of Scythia and the Sace. The mountains of this part are the Auxacii, Caflii, and Emodi. The inhabitants were, towards the northern part, the Abi; to the south, the Hippophagi Scythez, thofe of the Regio Aucxatis, and the Regio Cafla, the Chatæ-Scythez; and near the Emodi, the Charauni.
Scythia. The towns were Auranica, Ilbodn Scythae, Chorazia, and Nauta; from which Melas alludes to the Scythians much in the same extent and boundaries. The Scythia Pharsica was called by the Greeks Mabilia.

The Aftate Scytha, therefore, comprehended in general Great Tartary, and Ruffia in Asia; and, in particular, the Scythia beyond or without Imaus, comprehended the regions of Bogdans, or Olaracon, and Tunguris. The Scytha within or on this side of Imaus comprehended Turkestian, and Mongul, the Utebek or Zagatai, Kalmuck and Nagayan Tartaris, besides Siberia, the land of the Samoedas, and Nova Zembla. The three last mentioned countries, not being so soon inhabited as the former, were wholly unknown to the ancients; and the former were peopled by the Bactrians, Sugdians, Gandari, Scace, and Massagetae. Sarmatia contained Albans, Iberia, and Colchus, which now constitute the Circassian Tartary and the province of Georgia. (See Circassia and Georgia.) The seas of Scytha, besides the Frozen and Indian ocean, were the Caspian, the Euxine, and the Palus Mecitis. The rivers, besides those already mentioned, or the Rhin or Volga, and the Tanais or Don, were the Ob, Lena, Amur, and Helum, all of which are in Great Tartary, to which we may add the Jaxartes and the Oxus, which discharged themselves into the Caspian sea; in which sea were islands called the Scythian islands. The most noted mountains were the Taurus, Imaus, and Caucasus.

European Scythia, whose confines were at first fixed at the Tanais, reached towards the south-west to the Po and the Alps, by which it was divided from the Celts, or Celto-Galla, and by the Rhine northward. On the south, it was bounded by the Iler or Danube, and the Euxine sea; which boundaries were continually changing, on account of the mutual encroachments of the Celts and Scythians; and as to its northern limits, which have not been accurately ascertained, they have been supposed to reach to the spring-heads of the Borylithes or Dnieper, and the Rha or Volga, and so to that of the Tanais. The ancients divided this country into Scytha Arimafaia, lying eastward, and joining to Afian Scytha, and European Sarmatia on the west; which were contiguous to each other, and stretching for some interval from north to south, without any perceptible line of separation. In Scytha, properly so called, were the Arimapia on the north; the Gete, or Dacians, along the Danube, and the Euxine; and the Neuris between these two. It therefore contained the European Ruffia, and the Iler or Crim Tartary, ethnically, and on the west, Lithuania, Poland, part of Hungary, Transylvania, Walachia, Bulgaria, and Moldavia. This Scythia had no other sea besides the Sarmatian, or Mare Scythicum, now called the Baltic, with the gulfs of Bothnia and Finland, and the White sea joining to the Northern ocean, all unknown to the ancients, if we except the Euxine and Palus Mecitis, which bounded it on the south. Its lakes were those of Ladoga and Onega in Finland, unknown to the ancient Sarmatians. Their chief rivers on the south were the Donetz or little Tanais, Borylithes or Dnieper, Bog, Tyra, or Dniefer, and the Iler or Danube, all which discharged themselves into the Euxine; and on the north, the Great or Little Dvina, which run, the first into the White sea, and the other into the Gulf of Finland, and therefore unknown to the ancients; and on the west, the Vitilia, which flowed into the Scythian sea, and divided Sarmatia from Germany.

The whole extent, therefore, of both Scythias, including the two Sarmatias, reached in longitude from the 20th to the 85th degree, or even beyond, and from the Alps to the promontory of Tuba, and hence of Asia; and by latitude, from Carnia to the Arctic sea, above 67 degrees. Herein it is said, that the Scythians were not of Scythian race, but another kind of people, some of whom were Aryan, others, of course, and others, with the Bald heads, or Argives, a wise and peaceful people, esteemed by all their neighbours: but he speaks of them merely by report, and with dilution; so that these regions were probably unknown, if not unoccupied. The five cities of Scythes, which we have mentioned, were probably built after the time of Herodotus, who writes no notice of any metropolis; though he mentions a considerable branch of Scythians, called Royal Scythians, whom he places along the banks of the Tanais; this river, as he says, dividing them from the Aftate Sarmatians. The original Scythians of Herodotus (l. iv.) were confined, by the Danube and the Palus Mecitis, within a square of 4000 Roman miles. Diodorus Siculus (vol. i. 1. p. 155. ed. Well.) has marked the gradual progress of the name and nation, from the mouth of the Danube to the sea of Japan (says Gibbon, vol. iv.), the whole longitude of Scythe is about 110 degrees, which, in that parallel, are equal to more than 5000 miles. The latitude of these extensive deserts cannot be so easily or so accurately ascertained; but from the 40th degree, which touches the wall of China, we may securely advance above 1000 miles to the northward, till our progress is stopped by the excessively cold of Siberia. In that dreary climate, instead of the animated picture of a Tartar camp, the smoke which issues from the earth, or rather from the snow, betrays the subterraneous dwellings of the Tungusse and the Samoyedes. The want of horses and oxen is imperfectly supplied by the ufe of rein-deer, and of large dogs; and the conquerors of the earth insensibly degenerate into a race of deformed and diminutive savages, who tremble at the sound of arms. Anc. Un. Hist. vol. iv. See Scythians and Tartars.

SCYTHIAN, a word used very often in the old Greek writers on the materia medica, to distinguish the peculiar fort of gum, or other drug, brought from the Scythians.

The Scythian and Indian drugs have been by many supposed different kinds of the same medicine; but this is an error; for it appears very obvious, on comparing the writings of Galen, Aetius, Aegius, and other of the later writers among the Greeks, with those of Dioscorides, Theophrastus, and the other old ones, that the words Scythis and Indian mean the same thing, and that those who old writers have called Indian, these have called Scythis.

The meaning of this is, that those things were called Scythis, which were brought from the country of Indo-scythia, or that part of Scythia which lay at the origin of the river Indus; but it is to be observed, that though the later Greek writers mean this by their term Scythis, yet the word is used in a very different sense by the Arabians, Avicenna, Serapion, and others; and that wherever they mention a drug under the name of Scythian, they mean that it comes from the northern parts of Scythia, on the confines of Europe. These authors having understood of this Scythia what the Greek writers have said of the other, have made no small errors in regard to the history of drugs, having given bdellium, and many other gums, the produce of only the Scythia of the Greek medical writers, to the frozen Scythis, before mentioned.

SCYTHIANS, in Ancient Geography, the inhabitants of Scythia, confided by some geographical authors as the same people with the Tartars, or, as they are more commonly,
monly, though erroneously, called, Tartars. (See Tar-
tars.) With regard to the etymology of the name of
Scythians we have many different conjectures. Pliny
foms to intimate, that this appellation is derived from Sacai, a
people known by a familiar name to the Greeks and Per-
hians. Bryant deduces it from Cuthia. Colonel Vallancey
traces its origin to words denoting navigation: others de-
rive it from the Greek word σκύθες, which expresses the
fierceafes of their countenance and natural temper; and
others again derive it from the Teutonic word *febolen or
fbuten, in which art this nation is said by Her-
dotus, Lucian, and others, to be fo expert, that the
name is given on that account, the word Scythian properly
signifying a great *booter or archer. As the Tartars and
Mufcovites called themselves Mogli, supposed to be an
abbreviation of Magogli, the fons of Magog; that of Scy-
thian might be either given to them by other nations, or
perhaps by the Celtes, whose language did not originally
much differ from the Scythian or Teutonic. Sir William
Jones observes, that neither Scythian nor Tartar is a name
by which the people now under our confideration have ever
distinguifhed themselves.

The Scythians have been confidered by some writers,
with regard to their antiquity and origin, as the fame
people with the Celtes, and as being the descendants of
Gomer, the eldest fon of Japhet. To this notion Her-
dotus, Ptolemy, and Justin have called the Scythians, who
emigrated into Asia, by fame names, and attributed fome
actions and places to them, which, upon closer exa-
famination, are found to have belonged to the Celtes or Gome-
rians, whom they had driven out of their European terri-
tories. Strabo informs us, that the old Greek hisfiorians
gave the name of Scythians and Celto-Scythians to all the
inhabitants of the northern regions, though it is plain that
many of them were properly Celtes or Gomeries. And he
also adds, that fome of thofe people who inhabited
beyond the Caffian fce, which fhoild be the Scythians,
were, by the fame Greek hisfiorians, called Saca, and
others Maffagetae, though the former of thofe names, at
leaff, belonged only to the Celtes. Hence many learned
men have chofen to reckon them as one people, branced
out into that variety of names and charaflers, under which
they are diftinguifhed in hisfory. See Celts.

Jofephus, who affirms the Scythians to be defcended
from Magog, the next brother of Gomer, has been fol-
lowed by many of the fathers, and by many moderns,
becaufe they could find no better authority. In the migra-
tion of thofe ancient tribes into Europe, if Gomer's de-
cendants turned towards the N.W., thofe of Magog may
be reasonably fuppofed to have spread themselves towards
the N.E. into both Scythia, where we find the ancient
Mufcovites or Tartarians; diftinguifhed by the name of
Mogli, corrupted or abbreviated possibly from Magogli,
the fons of Magog. To thofe conjectures it may be
added, that there is fcarceiy a nation under heaven, that
fo fully answers the fierce and dreadful charafler which the
Scriptures give us of Gog and Magog, as that of the
barbarous Scythians; though in fact this charafler was
too applicable to thofe neighbours in thofe early ages.

Sir Ifaac Newton is of opinion, that both the Celtes
and Scythians had spread themselves over Leffer Asia and
Europe, before the year of the flood 2220, that is, about
the latter period of the Israelith judges. How foon
the Scythians began to ftablish a regular government, and
what kind of government it was, it is impoffible even to
conjecture. It appears, however, from the testimony of
Herodotus, that one or two tribes at leaff, that is, the royal
and free Scythians, were under a kind of monarchy, and
that these two dijtinguifhed themselves more than all the
others. Herodotus informs us, that in process of time,
when the Scythians were likely to be invaded by Darius,
his king, dredging the invaders, invited all the Scythian
princes, viz. thefe of the Taurians, Agathyliaus, Ne-
rians, Androphagi, Melanchlemus, Budians, and Sarmat-
ians, to unite in giving him affifiance. All thefe tribes
fem to have been branches of the fame flock, but differing
much in their manners and customs. In confeguence of
this application, the three left named nations joined with
the king of Scythia, but the others refused to fuccour him,
alleging that he was the first aggressor. Hence we may
conclude, that they had emancipated themselves from the
yoke of the royal Scythians fame time before. As to what
the laws of the royal and free Scythian were, we may form
fome judgment from the excellent charafler that is given of
them by ancient hisfiorians. Justin (lib. ii. cap. 2.) gives
the following account of them. The Scythians were a
nation, which, though inured to labour, fierce in war, and
of prodigious strength, could nevertheless fo control their
paffions, that they made no other use of victories than to
increase their fame. Theft among them was reckoned fo
great a crime, and was fo fervely punished, that they could
not, in their numerous flocks wander from place to place without
danger of losing them. Thofe they defteemed their greatest
wealth, living upon their milk, and clothing themselves
with their skins. Instead of houfes, they used to convey
their wives and children about in covered waggons, drawn
either by horses or oxen, and made capacious enough to
carry all their other furniture. Gold, silver, diamonds,
pears, and other costly fones, were as much defpifed by
them, as they were esteemed by other nations, fo that they
could not covet that which was of no ufe. What is still more
wonderful, thofe virtues, which the Greeks in vain endeav-
oured to attain by learning and philosophy, were natural
to them, and they reaped thofe advantages from their igno-
rance of vice, which the others could not derive from their
knowledge of virtue. A nation of this charafler and way
of life could therefore want but few laws to secure their
property; fome others they had with relation to religion,
cultus, and polity, which forbade, under pain of death,
any alteration in either; which excluded their women from
the benefit of marriage, and every man from affilting at
their royal feast, till he had killed an enemy. Some other
of their laws we fhall have occasion to mention in the fequel.
Upon the whole, what appears of them feems wholly cal-
culated to prevent luxury, fraud, and covetousness, and to
cherish that martial spirit, for which they are fo juftly famed
in hisfory.

Some of the Scythian tribes, indeed, bear a quite dif-
ferent charafler, being repreffed by fuch fierce and cruel
depofition, as even to eat the flesh of their enemies. Thofe,
if under the fame government, were at fuch great diftance
from the centre of it, as to be out of the reach of its laws.
As the inclination of the air in thofe remote regions might
probably incline them to cruelty; fo the diftance and bar-
creness of their country might make them lefs heeded, and
probably more incapable of being restrained by the com-
mon regulations of society. However, it must be owned,
with respect to the warlike temper even of the true Scy-
thians, that it was not without a mixture of cruelty, if
they have not been wilfully misrepresented by the Greek
hisfiorians.

If we may reafon from fome fuccesfions we find men-
tioned in hisfory, it feems their crown was hereditary, and
yet
SCYTIANS.

Having reached the spot at which they had been left, two or three of their men, even the men of the guard, came up at their request. They returned to the same tent that they had pitched the night before, their horses being spread about it, the servants of the high priest, and some of his retainers, being within the temple. The temple was the same as that which was mentioned by Herodotus; it had before been burnt, and the king, when he undertook the task, told them that it was to be rebuilt. He himself, however, was the only one who could see it. This temple was dedicated to the god of war, who was supposed to be the same heathen god, the worship of which was prohibited by the religion of the country. The temple was a circular building, with a high, round, and solid roof, and was surrounded by a wall, which was made of stone. The temple was forty feet in diameter, and was built of stone. The sides were covered with slabs of stone, and the roof was covered with slabs of wood. The roof was supported by four columns, the tops of which were decorated with figures of horses. The temple was not large, but it was very fine. It was built of stone, and the roof was covered with tiles. The temple was dedicated to the god of war, who was supposed to be the same heathen god, the worship of which was prohibited by the religion of the country.

The temple was first built by the king, who had built it at his own expense, and who had dedicated it to the god of war, who was supposed to be the same heathen god, the worship of which was prohibited by the religion of the country. The temple was dedicated to the god of war, who was supposed to be the same heathen god, the worship of which was prohibited by the religion of the country. The temple was not large, but it was very fine. It was built of stone, and the roof was covered with tiles. veil, into which the contracting parties were to mingle some of their own blood, which they drew by a slight incision made in the finger, hand, or some other part of the body. They then dipped into the mixture the point of some warlike weapon, such as a scimitar, arrow, dart, javelin, or battle-ax. The parties then uttered some dire imprecations on the first breaker of the covenant, and, having each of them taken a draught of the liquor, they defined some of the most considerable among the bystanders to pledge them, and to be witnesses of the contract, which was reckoned so sacred, that they thought no punishment severe enough, either in this life or in the next, for those by whom it should be violated.

Their warlike temper and exploits were sufficiently known to the ancients; scarcely is there any nation to be met with in history, so famous for conquering wherever they carried their arms, even as auxiliaries, and themselves remaining still unconquered. Their frugal and simple manner of life, may indeed be supposed to have been a great preservative against such invasions, as other more opulent and luxurious nations were exposed to. But it is plain, this was not always the case, since we find they were once invaded by the king of Persia at the head of a most puissant army, from the power of which nothing but their valour and policy could have delivered them. Upon the whole, such were their strength and courage, whenever they entered into an offensive or defensive war, that, as Thucydidcs himself tells us, no nation, either in Europe or Asia, could equal them either for strength, valour, or conduct; nor could any thing reft their power, when they were unanimous among themselves.

Such care they took to cultivate this martial genius, that even their women were inured to it betimes, inso much that no woman could be admitted into matrimony till she had killed at least one enemy with her own hands. As for their youth, they were not without considerable encouragements to inspire them with martial valour, or rather ferocity, if we may rely upon the information of Herodotus, who tells us that they were wont to drink the blood of the first prisoner they took, and to present the heads of all the men they killed in fight to their monarch; these were either returned or registered, and the warrior enjoyed privileges in proportion to the numbers he had slain. They used to take the skins of the slain, to stretch, dry, and tan them, and then hang them at their horses' bridles, where they served both for trophies and napkins to the owner; he being always most esteemed, who had the greatest number to display. Their pride, or rather barbarity, went so far, that they took off and dress'd the whole skin of the slain, and covered both their quivers and horfes, and sometimes decked their own bodies with them; and used their skulls for drinking cups.

Had they only exercised this kind of savage pride against those who came to invade them, it might indeed admit of some excuse; but it doth not appear that they gave much better quarter to those whole territories they invaded.

In confluence of their living free from ambition and care, and eating plentifully of animal food, they acquired ruddy complections, and became so plump and fanguine, that, to prevent their growing too unwieldily, they not only used a great deal of exercise, but even cauterized their arms, shoulders, backs, and breasts, with a view to draw off superfluous moisture. They were remarkable for their fidelity and friendship, which they esteemed and gloried in above all things. They commonly confirmed their friendship by some such religious ceremony or oath, as we have lately mentioned, but a Scythian seldom diffused his attach-
number of dialects, from which most probably have sprung
the Meso-Greek, Salvanian, Polish, Danish, Swedify, Saxons,
and many others; between which one can but barely dis
cover affinity enough to evince their origin from the same
mother. A great number of words and phrases that are
found not only in these northern languages, but also in the
Latin, Greek, Arabic, and Persian, shew them to have been
so many dialects of the old Celtic. If these few relics of the
Scythian, which we have left in the names of their
kings, tribes, and districts, do not plainly appear to be
of the same extraction, we must remember they have put
through so many different hands, and have too often changed
their drefs, especially among the Greeks, that they may
be easily supposed to have quite lost their ancient form.
We may add, that some of them are perfectly Greek, or
translated from the Scythian into that language. Of this
kind is the name of the Oecus, a Scythian tribe, so called
in Herodotus, from their living upon the eggs of wild
fowl, and derived from the Greek οίκος. The Nomades
were so called from οῖκος, pαύβαρ. Of the same extraction
were the Hyppodes, Androphagi, and some others.
Their chief manufactures seem to have consisted mostly in
building waggon for their families and baggage, which being
covered with the skins of beasts, shews they must have
had some notion of tanning and dressing leather. We may
likewise reasonably suppose, that they fabricated their own
weapons, which were scimitars, javelins, axes, and epecially
bows and arrows, at which they are said to be so expert,
that their very children were trained to shoot at a mark,
even as they rode on horseback; insomuch that it became
a common proverb, "that the Scythians were as dextrous at
their bows as the Greeks were at their lyres." Hence
Cyaxares, king of Media, is reported to have sent his son
to be brought up under them, to learn the use of the bow.
They were so expert in horsemanship, as to have acquired
the epithet of ἐλθετονια, by Herodotus and Lucian.
Their women are affirmed to have been so well trained to riding
and shooting, that they did not fall short of the men in
those exercises. The ancients observe, that they had nei-
ther males nor slaves; and the reason they give is, that the
country was too cold for those creatures. Experience has
since shown the contrary, at least with respect to the latter;
but the true reason seems to be, that the horset, which
they bred in great numbers, could answer all the purposes
of the other two species, and at the same time be more swift
and expeditious.
As for agriculture, it doth not appear that they had any,
Herodotus indeed tells us of one province, whose inhabi-
tants called themselves Olbopolitians, and the Greeks Bo-
rythmians, as they lived on the north side of that river;
and these he likewise called husbandmen, because they
sowed grain, not for food, but for sale. But the rest of
the Scythians wholly neglected it, chusing rather to roam
where they found the best pasture for their cattle, and
containing themselves with the spontaneous products of
the earth, without being at the trouble of manuring it.
And this is in all likelihood the cause we read of so
many deserts, forests, and large uninhabited tracts of land
between tribe and tribe, in the writings of ancient historians
and geographers. How they disposed of the wool of their
flocks we know not, but, by their clothing themselves
with the skins of wild or tame beasts, we may conclude
they did not manufacture it into cloth; and as those skins
were of their own dressing, they wanted only the help of
foreign manufactures. Smiths they must have had, for
making their arms, waggons, and other necessary tools.
As to their arrows, darts, and javelins, if their heads were
made of copper, they were probably call in wood. They
used standards of a particular make, which, when blown
open by the wind, exhibited the figures of serpents and
dragons of several shapes, and these were commonly borne
by men on horseback.
Their chief riches and food consisting in their numerous
herds, they estrallated the care of them to the herdsmen, who
were a lower rank of Scythians, below the tribal men, though
they too had horses and captives in their service.
They used to move from pasture to pasture, with the
persons and families which were unfit to go to the wars. The
called lived upon honey, cheese, and milk, more especially
that of their mares, in which creature, if Herodotus
who was rightly informed, they had a strange way of faring
plenty of it, by blowing wind into the privies; but their
chief and choicest food was the vomit the killed.
What provisions the warlike Scythians made, when they were
absent from their flocks, we cannot guess; it is probable
when they came into an enemy's country, they fed upon
all the cattle they could meet with; and when that failed,
they had recourse to a composition they carried about them,
of which we shall speak presently.
From an allusive or two recorded of their kings, we
conclude, they allowed of polygamy, and were not over
strict in their marriages. Plato seems even to intimate that
they had their women in common, though, if any such cus-
tom prevailed among them, it must have been only among
the more savage part, for the royal and free men had wives;
and some of their kings we read of, who took them from
other nations, and of one of them who married his own
father's widow; but whether the same liberty was allowed
to private men we cannot affirm. The reason the Scythi-
ans gave for abhorring the Bacchanalian feasts of the
Greeks, namely, that it was absurd to suppose, that a god
should drive men to all the violent transport of madness,
seems to shew that drunkenness was not common among
them. And indeed we do not find that they were much
addicted to feasting. Plutarch, in his Banquet of the
Seven Wise Men, says, "that they neither had vines, nor
players on instruments, nor public games." One wine-feast
they kept however once a year in every district, for those
who had fastened themselves by killing one or more of
their enemies. Another we read of, which was used at
funerals. Some others they might have upon other occa-
sions not worth enquiring after; but in general, they were
remarkably abstemious, except in their intoxications for
their favourite women. They talked little, but conciliably
and nervously, especially about their warlike affairs. They
commonly travelled on horseback, or in their domestic vehi-
cles. When they had any rivers to cross, they laid their
horse's saddle and weapons upon a skin filled with cork,
and so well seen, that not a drop of water could get into
it; they then laid themselves down on it, and taking hold
of their horse by the tail, made him swim to the other side.
They carried with them a certain composition, in small
pieces like pills, one of which, upon occasion, would yet
afford sufficient nourishment for several days. Pliny adds,
that they used the like expedient with their hores, by means
of what he calls the Scythian weed, upon the strength of
which they could travel ten or twelve days without eating
or drinking.
When any person died, his nearest relations caused his
embalmed body to be carried in a chariot from house to
house among his friends and acquaintance, who received
and feasted them in their turns, setting part of the ban-
quet before the deceased. This ceremony was continued
forty days, after which the person was buried, and his at-
tendants...
tendent purifed themselves, not by any ablation, but by the
smoke of some hemp-feed peculiar to the country, which
being thrown upon burning stones, emitted a much
more agreeable perfume than the frankincense used in
Greece, and intoxicated the company, who concluded the
ceremony with hideous shrieks. This revered instead of
walking, which the Scythians never practized; not even
the women, who used instead of it to anoint their bodies
and face with a paste, made of cyprelps, cedar, and frankin-
cence, ground upon a rough stone, and soaked in water,
which paits being taken off next day, rendered their skins
clean, shining, and sweet.

Hitherto we have confined our chief attention to the
royal Scythians; but there were other tribes or petty king-
doms that demand some transient notice.

The Samaritans are affirmed by Herodotus to have been
the offspring of the Scythians and Amazons. These war-
like women, or as their Scythian name, Aior Patta, im-
ports, men-players, in their flight from the Grecians, having
landed near the precipices of the Palus Moesitis belonging
to the free Scythians, and having been persuaded to be
married to them, did in their turn prevail upon them to
leave that part of Scythia, where they pretended they could
not conveniently live with them, and to pass into the pro-
vince of Sarmatia on the other side of the Tanais. Hence,
our author says, the Samaritan women retained still the
Amazonian temper and way of life, being more warlike
than the rest of the Scythian females, and the language of
the country became a corrupt Scythian, because the Ama-
zons never could perfectly learn that language, but taught
it their offspring, corrupt as themselves spoke it. Here it
evidently was, that a virgin was unqualified for matrimony,
till she had dispatched an enemy in the field.

The Taurians had this input use custom, that they sacri-
fied to a virgin all that were shipwrecked, and all the
Grecians whom they caught upon their coasts. This
bloody offering was performed by knocking the person
on the head with a club, after many dire imprecaions, and
flinging his carcass down the hill on which their temple
was built, or as others told our author, by burying the
body, and referring only the head to be fluck on a pole.
The Taurians pretended, that the virgin demon whom they
thus worshipped, was Iphigenia, Agamemon’s daughter.
They lived chiefly by war and rapine, and were very cruel
to those who fell into their hands. The Agathyrians are
said to have had their women in common, in order to link
the men more strictly together, and to prevent jealousies,
and other ill effects of matrimony. The Neurian province
being infested with dangerous serpents, they were at length
forced to leave it for that of the Budians. They observed
the customs of Scythia in most particulars, only pretended
to greater skill in magic than they, and were reported to
be transformed into wolves for some part of the year, after
which metamorphoses, they refomed their own shape: an
allegory which is supposed to mean no more than their
wearing of skins with the fur outward during the cold
weather. The Neurians are mentioned also by Pliny, Mela,
and Steph. of Byzantium.

The worth of all were the Androphagi, or men-eaters,
who observed neither laws nor justice, and had nothing in
common with the rest, but their dreeds and occupation of
breeding cattle. The Melancheneans were so called for
afflicting to go always in black; they followed the Scythi-
ian customs, except that they fed upon human flesh,
which the free Scythians did not; nor indeed did any other
tribes use it, at least as common food, but only on some
particular occasions. The Budians were a populous nation,
famed for blue eyes, and red hair: in this province, above
all the rest, did they build them a city, and called it Gel-
on, whose houses and high walls were of timber, and
each side of the walls was three hundred stadia in length;
it had temples and chapels dedicated to the Grecian gods;
and here they celebrated the Bacchanalia triennially. The
people of the province differed from those in the city, in
that the former applied themselves to the rearing of cattle,
and the to tillage and planting gardens, living upon the
products of them, and of their corn fields; in a word, the
Geloniens were so much more civilized in their manners
than the Budians, that they seemed quite another people.
They are supposed to have been of Greek extract, and
to have been in time quite blended with the Budians, who
were of Sarmatian origin, and contiguous to them; and
Herodotus observes, that each preferred their own native
language. The Geloniens learned, among other things,
the custom of painting their bodies from the Sarmatians, whereto
verse in Virgil’s Georgics, xii. v. 115.

“Lique domos Arabum pictosque Geloni.”

This province abounded with otters and beavers, which
afforded skins for wearing, and cañfur for medicine.

The last two nations or tribes of the Scythians worth
our notice, were the Nomades, inhabiting the country on
the north-west of the Caspian Sea, and the Massagetes
on the west. For an account of the Amazons, we refer to
that article. The Nomades differed so little from the royal
Scythians, except in this appellation, that it is needless to
say more concerning them, than that they led a wandering life,
living no longer in one place than they found plenty of
pasture for their cattle; which being consumed, they re-
moved to fresh grounds; and, when called to the wars,
left their families and flocks, with their herds, till their
return. Pliny places them on the left side of the
Caspian Sea, and says the river Panticapes parted them
from the Georgis. Strabo adds, that they lived in waggons
instead of horses. (See Nomades.) For an account of the
Massagetas, see Massagetæ.

The following table exhibits the names and succession
of Scythian kings:

| 4. Sagillus, or Protothya. | 15. Ariphithes. |
| 11. Scholypethes, or perhaps rather Scythopetès. | |

Madyes was a warlike prince, and it was under his con-
duct that the Scythians, having driven the Cimmerians, or
northern Celts, out of Europe, and pursued them into Asia,
invaded the country of the Medes, and held the greater part
of Upper Asia in subjection for twenty-eight years. As
Scytha did not afford a sufficient supply of food for its
numerous inhabitants, they disfurnished the superfluous multitudes
towards the more fertile south; and having rapidly
passed into Asia, their victorious army was led into Egypt.
Here they made some incursions into the land of the Phi-
lities; and in this expedition they are said to have taken
the city of Bethule from the tribe of Manasseh, on this
side of Jordan, and to have called it, after their own name,
Scythopolis,
SCY

SCYTHICUM LIGNUM, in Botany, a name given by the ancients to a tree called *scytherium* by the later writers of the Greeks.

SCYTHOPOLIS, in Ancient Geography, a town of Syria, in a province called Decapolis.

SCYTHRANUS PERTUS, a port of Africa, in Marzaria, between Antipyrus and the Cataractum Promontorium, according to Ptolemy.

SCYTHROPS, in Ornithology, a genus of birds of the order Pioe. The generic character is, bill large, convex, sharp-edged, channelled at the sides, hooked at the point; nostrils naked, rounded at the base of the bill; the tongue is cartilagenous, split at the point; the feet are formed for climbing. This genus, of which only a single species is known, is nearly allied to the Ramphastus, from which it principally differs in the greater strength and stoutness of the bill, and in having the tongue entire at the sides, and bud at the tip.

Species.

**Pittacus.** This bird has obtained different trivial names. From the circumstance that it is found in New Holland; where, by the way, it is sometimes seen in small flocks, but more frequently in pairs, generally at trees, and uttering, during flight, a loud screaming noise, not unlike the crowing of a cock; it is called by some the Australian Channel-bird; by others, the New Holland Channel-bird; and by some, Pittacus Hornbill. By Dr. Shaw, it is specifically described as the lead-coloured channel-bill, with the tail-feathers barred with black and white. It is about the size of a crow, and measures in total length about seventeen inches, of which the bill measures four inches. The general

SEA

proportions of the head are what render it so much the more likely that it should be considered as of the family of the Ostrich, and as such it has been placed in the order of the Struthion in all the class-books. The tail is long and forked, and about parts of the body are of a purplish-brown colour; the bill tip is black, and other parts of the bill are a pale yellow. The egg is white, and has a black spot at the large end. The greatest length is about four feet, and the head and neck of a span. Dr. Shaw has described a figure of the bird, but we shall conclude, with respect to the measure, it is ascertainable from the head of it.

SCZEBRZESZIN, a town of Austrian Poland, in Galicia; 5 miles W. of Zamosc.

SCZELZEDROHORST, a town of Prussia; 60 miles S.E. of Breslau.

SCZUCZYN, a town of Poland; 35 miles S.W. of Sambor.

SDUR, a town of Arabia, in the province of Hira; 20 miles S.E. of Basra.

SE, or S.E., a county of China, of the second rank, in Honan, N. lat. 36° 35', E. long. 114° 14'.

S.E., or S.E., a sea, in Botany, is frequently used for that vast tract of water encompassing the whole earth, more properly called Ocean, which see.

For the cause of the saltiffs of the sea, see SALT.

Sea is more properly used for a particular part or division of the ocean, distinguished from the countries it washes, or from other circumstances.

Thus we say the Irjish sea, the Mediterranean sea, the Baltic, sea, the Red sea, &c., which sea respectively.

Till the time of the emperor Justinian, the sea was common and open to all men; whereas it is that the Roman laws grant an action against a perfon who shall prevent or molest another in the free navigation or fishing therein.

The emperor Louis, in his fifty-sixth year, first allowed such as were in possession of the lands, the sole privilege of fishing before their respective territories, exclusive of all others; he even gave a particular commission to certain persons to divide the Thracian Bosphorus among them.

From that time, the sovereigns of princes have been endeavouring to appropriate the sea, and to withdraw it from the public use. The republic of Venice pretends to be far nautical in her gulf, that there is a formal marriage every year between that signory and the Adriatic.

To confirm this right, those who contend for it have alleged the example of Uladinus, king of Naples, and the emperor Frederic III., and of some of the kings of Hungary, who requested the Venetians to permit them to pass through that sea with their vessels. That the empire belongs to the republic to a certain distance from the coast, in the places of which it can keep possession; and which it is of importance to hold in regard to its own safety, appears, says Vattel, to be incontestable; but he very much doubts, whether any power is at present disposed to acknowledge its sovereignity over the whole Adriatic sea.

In these last ages, the English have particularly claimed the empire of the sea in the Channel, and even that of all the seas encompassing the three kingdoms of England, Scotland, and Ireland.
Ireland, and that as far as the shores of the neighbouring states. In consequence of which pretension it is, that children born in these feas are declared natural Englishmen, as much as if born on English ground. The justice of this pretension is strenuously argued between Grotius and Selden, in the Mare liberum, and Mare clausum.

The use of the open sea consists in navigation and fishing; along its coasts it is likewise of use for the procuring of several things found near the shore, such as shell-fish, amber, pearls, &c. for making of fish, and, in short, for the establishment of places of retreat and security for vessels. The open sea is in its own nature not to be exclusively possessed, as no one is able to settle there so as to hinder others from passing. But a nation powerful at sea may forbid others to navigate it and to fish in it, declaring that it appropriates its dominions to itself, and that it will destroy the vessels that shall dare to appear in it, without its permission. Vattel, a highly approved writer on this subject, investigates its right to do this. It is evident, in the first place, that nobody has a right to appropriate to himself the use of the open sea; for he who navigates or fishes in it does no injury to any one, and the sea, in both these respects, is sufficient for all mankind. Nor does Nature give to any man a right of appropriating to himself things that may be innocently used, and that are inexhaustible, and sufficient for all; since, every one being able to find in its flete of communion what was sufficient to supply their wants, they might remain themselves sole masters of them, and to exclude all others, would be to deprive them, without reason, of the benefits of nature. Although the law of nature approves the rights of dominion and property, which put an end to the primitive manner of living in common, this reason could not take place with regard to things in themselves inexhaustible, which cannot therefore be justly appropriated.

If the free and common use of a thing of this nature was prejudicial or dangerous to a nation, the care of its own safety authorized it to submit, if possible, that thing to its dominion in order to permit the use of it, with such precautions as prudence should direct. But this is not the case with the open sea, in which people may fail and fish without the least prejudice to any person, and without putting any other people in danger. No nation then has a right to lay claim to the open sea, or to attribute the use of it to itself to the exclusion of others. The kings of Portugal have formerly arrogated to themselves the empire of the seas of Guinea and the East Indies; but the other maritime powers gave themselves little trouble about such a pretension. The right of navigating and fishing in the open sea being then a right common to all men, the nation which attempts to exclude another from that advantage does it an injury, and gives a sufficient cause for war: nature authorizing a nation to repel an injury; that is, to make use of force against any one who would deprive it of its rights. Besides, a nation which without a title would arrogate to itself an exclusive right to the sea, and support it by force, does an injury to all nations whose common right it violates; and all are at liberty to unite against it, in order to reprefh such an attempt. However, as each has the liberty of renouncing its rights, a nation may acquire exclusive rights of navigation and fishing by treaties, in which other nations renounced, in its favour, the right they derive from nature. They are obliged to observe their treaties, and the nation they have favored has a right to maintain by force the possession of its advantages. Thus, the House of Austria has renounced, in favour of England and Holland, the right of fishing vessels from the Netherlands to the East Indies. Many examples of like treaties may be found in Grotius, "De Jure Belli et Pacis," lib. ii. cap. iii. § 15. The rights of navigation, fishing, and others that may be exercised on the sea, are imperceptible; they cannot be lost for want of use; consequently, when a nation finds that itself alone has from time immemorial been in possession of a navigation or fishery in certain seas, it cannot, on this foundation, attribute to itself an exclusive right to them. But it may happen, that a want of use may be attended with the nature of a content, or a tacit pact, and thus become a title in favour of one nation against another. When a nation in the possession of the navigation and fishery in certain latitudes, pretends an exclusive right, and forbids any other interfering in it; if they obey that prohibition with sufficient marks of acquiescence, they tacitly renounce their right in favour of the other, and establish a right which the other may afterwards lawfully maintain against them, especially when it is confirmed by long use.

Nevertheless, the sea near the coasts may become property; so that the nation to which the coasts belong may appropriate to itself an advantage which it is considered as having taken possession of, and made a profit of it, in the same manner as it may pollefs the domain of the land which it inhabits. But if, so far from taking possession of it, it has once acknowledged the common right of other nations to come and fish there, it can no longer exclude them from it; it has left that fishery in its primitive freedom, at least, with respect to those who have been in possession of it. The English not having taken the advantage from the beginning of the herring fishery on their coast, it is become common to them with other nations.

A nation may likewise appropriate things, where the free and common use of them would be prejudicial and dangerous. This is a second reason for which powers extend their dominions over the sea along their coast, as far as they are able to protect their right. It concerns their safety and the welfare of the state, that the whole world be not permitted to come to near their possession, especially with men of war, as to hinder the approach of trading nations, and disturb navigation. These contiguous parts of the sea, thus subject to a state, are comprehended in its territory; nor can any one navigate them in spite of that nation. But it cannot refuse access to vessels not fabpleted, for innocent uses, without violating its duty; every proprietor being obliged to grant a passage to strangers, even by land, when it may be done without damage or danger.

It is not easy to determine to what distance a nation may extend its rights over the sea by which it is surrounded. Bodin pretends that, according to the common right of all maritime nations, the prince's dominion extends even thirty leagues from the coast. But this exact determination can only be founded in a general consent of nations, which it would be difficult to prove; each state may, in this respect, ordain what it shall think best, in relation to what concerns its citizens themselves, or their affairs with the sovereign; but between nation and nation, all that can be reasonably said is, that, in general, the dominion of the state over the neighbouring sea extends as far as is necessary for its safety, and it can render it respected; since, on the one hand, it can only appropriate to itself a thing that is common, as the sea, so far as it has need of it, for some lawful end; and, as to the other, it would be a vain and ridiculous pretension to claim a right that it was no ways able to cause to be respected. The fleets of England have given room to its kings to attribute to themselves the empire of the seas which surrounded that island, even as far as the opposite coasts. (See Selden's "Mare Clausum.") Selden relates a solemn act, by which it appears that this empire, in the time of Edward I., was acknow-
acknowledged by the greatest part of the maritime nations of Europe; and the republic of the United Provinces acknowledged it, in the same manner, by the treaty of Breda, in the year 1665, at least so far as related to the honours of the flag. But faithfully to establish a right of such extent, it is necessary to shew very clearly the express, or tacit, consent of all the powers concerned. The French have never agreed to this pretension of England, and in the same treaty of Breda just mentioned, Louis XIV. would not even suffer the Channel to be called the English Channel, or the British sea.

The banks of the sea belong incontestably to the nation that poises the country of which it is a part. The ports and harbours are manifestly a dependency, and even a part of the country, and consequently are the property of the nation. The same observation is applicable to the bays and straits. With regard to straits in particular, that serve for a communication between two seas, the navigation of which is common to all, or to many nations, he who poises the strait cannot refuse others a passage through it, provided that passage be innocent, and attended with no danger to the flote. Nothing but the care of his own safety can authorize the master of the strait to make use of certain precautions, and to require the formalities commonly established by the custom of nations. He has a right to levy small duties on the vessels that pass, on account of the inconvenience they give him, by obliging him to be on his guard; by the security he affords them in protecting them from their enemies, and keeping of pirates at a distance; and the expense he incurs by maintaining light-houses, sea-marks, and other things necessary to the safety of the mariners. As to the right of wrecks, see Wreck.

If the sea is entirely enclosed by the land of a nation, with only a communication with the ocean by a channel, or of that nation may take possession, it appears that such a sea is no less capable of being occupied and becoming property than the land; and it ought to follow the fate of the country that surrounds it. The Mediterranean was formerly included within the lands of the Romans; and these people, by rendering themselves masters of the strait that joins it to the ocean, might subject it to their empire, and add it to their domain. They did not by these means injure the rights of other nations; a particular sea being manifoldly designed by nature for the use of the countries and the people who surround it. Besides, in defending the entrance of the Mediterranean from all suspected vessels, the Romans secured at once the immense extent of their coast; and this reason was sufficient to authorize their possession of it. And as it has an absolute communication with none but their flote, they were at liberty to permit or prohibit the entrance into it, in the same manner as into any of their towns and provinces.

When a nation takes possession of certain parts of the sea, it enjoys the empire, as well as the domain. Those parts of the sea are within the jurisdiction of the territory of the nation; the sovereign commands there, he makes laws, and may punish those who violate them; in a word, he has the same rights there as at land, and in general all those given him by the law of the state.

It ought to be observed, however, that a nation may possess as property the domain of a state at land or sea without having the sovereignty; it may happen also that it may have the empire of a place where the property of the domain with respect to use belongs to some other nation. The English have never pretended to have a property in all the seas over which they have claimed the empire. Wattel's Law of Nations, b. 1. ch. 23.

The term sea is variously applied by sailors, to a single wave, to the agitation produced by a multitude of waves in a tempest, or to their particular progress or direction. Thus they say, a heavy sea broke over our quarter, or, we shipped a heavy sea; there is a great sea in the offing; the sea lets to the southward. He means a ship is liable to break the sea, when her course is exposed to the quarter or direction of the force of the seas. A long sea implies an interval and frequent motion of long and extensive waves; on the contrary, a flat sea is when they run irregularly, broken and interrupted, as frequently as hopp'd over a vessel's side or quarter.

SEA, General Motion of the. Mr. Dalib of Paris, in a work published about a century ago, has been at great pains to prove that the sea has a general motion, independent of winds and tides, and of more consequence in navigation than is usually supposed. He affirms that this motion is from east to west, inclining toward the north, when the sun has passed the equinoctial northward, and that during the time the sun is in the northern signa; but the contrary way, after the sun has passed the south equinoctial southward; adding, that when this general motion is changed, the diurnal flux is changed also; whence it happens, that in several places the tide comes in during one part of the year, and goes out during the other, as on the coasts of Norway, in the Indies, at Goa, Cochinchina, &c., where, while the sun is in the summer signa, the sea runs to the shore; when in the winter signa, from it. On the most southern coasts of Torguin and China, for the summer months, the diurnal course runs from the north with the ocean; but the sun having re-passed the line toward the south, the course declines also southward. Phil. Trans. N° 135.

SEA, Bays of the, Fundus mari, a term used by geographers, and other writers, to express the bottom of the sea in general.

Mr. Boyle has published a treatise on this subject, in which he has given an account of its irregularities and various depths, founded on the observations communicated to him by mariners.

The ingenious count Marigli has, since his time, given us a much fuller account of this part of the globe, mostly from his own experiments in many places, particularly along the coasts of Provence and Languedoc. The entire bason of the sea is of such immense extent, and covered in many places with such an unfathomable depth of water, that it is not to be expected that it can be traced in every part; but as the whole may be guessed at, from some part of it, and as its general figure is of no consequence in a search of this kind, the observations of this curious author are of great value, in forming a judgment of the whole.

The materials which compose the bottom of the sea, may vary rationally be supposed, in some degree, to influence the taste of its waters; and Marigli has made many experiments to prove, that fossil coal, and other bituminous substances which are found in plenty at the bottom of the sea, may communicate in great part its bitterness to it. See Saltiness.

We are not, however, to judge hastily, that there are not so many beds of these at the bottom of the sea, as would be necessary for such a purpose, or to judge too hastily against the existence of any other substances there, because we do not find proofs of them by the plummet, which in sounding brings up other substances, and not these; for the true bottom of the sea is very often covered and obscured from us by another accidental bottom, formed of various substances mingled together, and often covering it to a considerable depth.

The entire gulf of Lyons, situated between Cape Quiez and
in Rouflon, and Cape Croisit in Provence, forms a bank above the surface of the water at the shore, of the exact and perfect figure of an arch; and within this there is formed another such arch, making the bottom of the sea in that place for a very great way from shore, which is of different depths in various places, but usually between fifty and seventy fathoms. See Sea-Shore.

It is a general rule among sailors, and is found to hold true in a great many instances, that the more the shores of any place are steep and high, forming perpendicular cliffs, the more deep the sea is below; and that, on the contrary, level shores denote shallow seas. Thus the deepest part of the Mediterranean is generally allowed to be under the height of Malta. The observation of the strata of earth, and other fossils, on and near the shores, may serve to form a very good judgment as to the materials which are found in its bottom.

The veins of salt and of bitumen doublets run on the fame, and in the same order in which we see them at land; and the strata of rocks, that serve to support the earth of hills and elevated places on shore, serve also, in the same continued chain, to support the immense quantity of water in the bason of the sea. It is probable also, that the veins of metals, and of other mineral substances, which are found in the neighbouring earth, are in the same manner continued into the depths of the sea. The particles of metals in this case, are probably carried off into deep water, and funk among the softer matter of the bottom, but some of the lighter minerals seem to have given colour to those beautiful crufits, which are found upon many sea substances, and which lose their lustre in the drying. The subterranean rivers, and currents of water, make great changes in what would be the natural surface of the bottom of the sea, where they arise, each having a peculiar bason of its own. We are informed by numerous instances of subterranean currents, and as we see them break out in rivers on the surface of the earth in some parts, so in others we may be well assured that they break up the bottom of the sea, and empty their fresh waters into the salt mafs.

In this cafe, the rushing up continually of such a body of water makes a roundish cavity, and its running some one way, lengthens and carries on that cavity, till by degrees it is lost, as the fresh water by degrees becomes blended with the salt. Thus every river that arises in the bottom of the sea, alters the form of its surface, and makes a bason for itself, in which it runs a considerable way. Many seas near the shore, and when the water is tolerably clear, we see the traces of these currents to the naked eye from the surface, and the water taken up from them is found more or less fresh.

The coral fisheries have given us occasion to observe, that there are many, and those very large caverns, or hollows in the bottom of the sea, especially when it is rocky; and that the like caverns are sometimes found in the perpendicular rocks, which form the steep sides of those fishery. These caverns are often of great depths, as well as extent, and have sometimes wide mouths, equal to their largest diameter in any part, but sometimes they have only narrow entrances into large and spacious hollows. It is the common opinion of the people about the place, that these caverns are prepared by nature for the circulation of the sea-water; but that operation, however necessary, may be performed as well without, as with these caverns, and they seem in reality to be only accidental.

We daily meet with immense hollows and caverns, naturally made in rocky mountains; and as this part of the bottom of the sea is almost all rock, and its sides of the same nature, it is no wonder that the same accidents should happen, and like hollows be found, though with no particular intent of Providence in their use. Nay, there is this further reason to expect them in the rocks buried under the sea than in those in hills, that the latter are in a flat of rock and quiet, whereas the former are in continual reach of water, which will infinate itself into every crack or crevice nature has left in them, and may be easily fupposed to have burrowed its way in a small hole made by nature, till it has formed of it a very large one.

From such observations he infers, that the bason of the sea was at the creation, or at its second formation after the universal deluge, covered with or composed of the fame substances, as the surface of the rock of the earth is, that is of rocks, clay, and sand, and other such substanaces. Over these there is an artificial bottom formed of muddy tartareous incrustations, dead weeds, broken shells, and other bodies of the same kind, cemented together into a firm mafs or crust; and in those places where this crust has never been formed, or where it has been broken, the bottom of the sea is of the same nature with the strata of the earth.

The bottom of the sea is covered with a variety of matters, such as could not be imagined by those who have examined into it, especially in deep water, where the surface only is disturbed by tides and storms, the lower part, and consequently its bed at the bottom, remaining for ages perhaps undisturbed. The soundings, when the plummet first touches ground on approaching the shores, give some ideas of this. The bottom of the plummet is hollowed, and in that hollow there is placed a lump of tallow; this being the bottom of the lead, is what first touches the ground, and the soft nature of this fat receives into it some part of those substances which it meets with at the bottom; this matter, thus brought up, is sometimes pure sand, sometimes a fort of sand made of the fragment of shells, beat to a fort of powder; sometimes it is made of a like powder of the several forts of corals; and sometimes it is composed of fragments of rocks; but beside these appearances, which are natural enough, and are what might very well be expected, it brings up substances which are of the most beautiful colours.

Things of as fine a scarlet, vermilion, purple, &c. as the finest paint could make them, and as yellow as a solution of gamboge, are common; and sometimes, though not so frequently, the matter brought up is blue, green, or of a pure snowy whiteness. These coloured matters sometimes seem to have made up the whole bottom or mafs of the surface, but more usually they have been formed upon other things, as upon the mud, or upon larger pieces of shells, corals, and the like, in the manner of tartareous crusts, and those in some degree resembling the crustaceous coats of some of the sea plants. The colours of these substances are not merely superficial and transient, but many of them are so real and permanent, that they may be received into white wax melted, and poured upon them, or kept in fusion about them; and when thus examined, they seem as if a proper care might make them of great value, as paints of the finer kinds, where little is to be used.

The same coloured matters that thus coat the substances, found at the bottom of the sea in these places, are also sometimes found extended over the surface of marine substances of the harder kind, which are found in deep water. They are always, in this case, in a fort of liquid form, being lodged within, or embodied among a fort of jelly or glue of a transparent substance, which in these cases perfectly coats over the whole. In this state it gives the naturalist, who is present at the fishing up of his treasures, a transient prospect of
of a very elegant kind, but this variega white is alone at
it. A piece of coral, or other hard substance, is thrown
over, and rises to the surf ace of the water, or
delicate green, blue, or purple; but when taken out of
water it is found that this piece is actually of a mass
of glass or jelly which covers the coral; and when it is
washed, the color remains with it, and the coral
flings off its own native tint. I add it to no purpose to attempt
the preserving of it, by buffeting this glass to dry upon the
water, for the colour flies away by degrees, as the moisture
crystallizes, and the coral, &c. whatever it be, is only so
much the less beautiful, than it naturally would have been,
as it is covered with a dry yellowish dirty looking
matter. These are the cavities in the hard rock, therefore, which can only be seen by those who venture out
in order to take them up.

The small quantities of these elegant colours, which we
thus find spread over the surfaces of marine bodies, as we
approach deep water, may give a rational idea of what
we should find, were we able to examine the bottom of the sea
in its deep and natural state reclines. It is easy to con- 
ceive, that in these places we should find great quantities of
the most beautiful tubuliferae. M. Marfigh, Hill Thyt. de la
Mer.

Dr. Dossi, an Italian work, containing an essay to-words a natural history of the Adriatic sea, printed at
Venice in 1750, has received many curious observations on this
subject, which confirm the above account of Marfigh; 
having carefully examined the rock and productions of the
various countries that surround the Adriatic sea, and com- pared them with those which he took up from the bottom
of the sea, he found that there is very little difference
between the former and the latter. At the bottom of
the water there are mountains, plains, valleys, and caverns,
similar to those upon land. The soil consists of different
shells, placed one upon another, and for the most part parallel
and corresponding to those of the rocks, islands, and near- 
bordering continents. They contain it now of different forms,
minerals, metals, various purified bodies, pumice-stone
and lavas formed by volcanoes.

The adjacent countries, as well as the bottom of the
Adriatic sea, consist of a mass of a whitish marble, of
an uniform grain, and of almost an equal hardness; and this
marble, in many places under both the earth and sea, is
intercepted by several other kinds of marble, and covered by
a great variety of bodies, such as gravel, sand, and earth
more or less fat. To this variety of soils, he ascribes the
varieties observed with respect to the nature and quantity of
plants and animals found at the bottom of the sea.

One of the objects which most excited his attention, was a
crull, which he discovered under the water, composed of
crustaceous and tectaceous bodies, and beds of polyopes
of different kinds, confusedly blended with earth, sand,
and gravel; the different marine bodies, which form this
crull, are found at the depth of a foot or more, entirely petrified
and reduced into marble; these, he supposes, are naturally
placed under the sea when it covers them, and not by means
of volcanoes and earthquakes, as some have conjectured.

On this account, he imagines, that the bottom of the sea
is constantly rising higher and higher, with which other
obvious causes concurred; and from this rising of the
bottom of the sea, that of the level of the water naturally
follows; in proof of which this writer recites a great number

SEA, Dead. Dr. Perry made several experiments on the
water of the Dead sea, in order to find what particles it
contained. Upon making some scrapings of galls in it, it

SEA.
tioned, being fainter and stronger in different places, might be owing to this cause; and that certain circumstances of weather, &c. might invite them to the surface, on which, in a calm, they might sport themselves and glow, or in storms, being forced up, make the same appearance.

Mr. Folier, in his account of a voyage round the world with captain Cook, in the years 1772, 1773, 1774, and 1775, describing this phenomenon as a kind of blaze of the sea, and having attentively examined some of the illuminated water, expresses his conviction, that the appearance was occasioned by innumerable minute animals of a round shape, moving through the water in all directions. One of these luminous sparsks, which stuck to his finger while he was stirring his water with his hand, was examined by the common magnifier of Mr. Ramfden's improved microscope, and was found to be globular, transparent like a gelatious subsistence, and somewhat brownish; by means of the greatest magnifier, the orifice of a little tube was discovered, which entered the body of the animal; within which were four or five insectile bags connected with the tube. He imagines that these animals may be the young fry of some species of medusa, or blubber, and considers them as possessed of the power of shining, or of withholding their light at pleasure.

M. Dagelet, a French astronomer, falling into the bay of Antongil, in the island of Madagascar, observed a prodigious quantity of fry, which covered the sea above a mile in length, and which he at first took for banks of sand, on account of their colour; they exhibited a disagreeable odour, and the sea had appeared with uncommon splendour some days before. On another occasion, having perceived the sea to be remarkably luminous in the road of the Cape of Good Hope, during a perfect calm, he remarked that the oars of the canoes produced a whith and pearly kind of lustré; when he took in his hand the shining water, he discerned in it, for some minutes, globules of light as large as the heads of pins; upon pressing these, they seemed to be a soft and thin pulp, and some days after the sea was covered, near the coasts, with whole banks of these little fish in num-

merable multitudes.

M. Dagelet, in his return from the Terra Australis in 1774, brought with him several kinds of worms, which shine in water when it is set in motion; and Mr. Rigaud affirms, that the luminous surface of the sea, from the port of Breit to the Antilles, contains an immense quantity of small, round, shining polypuses.

M. le Roi, after giving much attention to this phenomenon, concludes that it is not occasioned by any shining insects, especially as, after carefully examining with a microscope some of the luminous points, he found them to have no appearance of any animal; and he also found, that the mixture of a little spirit of wine with water just drawn from the sea, would give the appearance of a great number of little sparsks, which would continue visible longer than those in the ocean; the same effect was produced by all the acids, and various other liqours. M. le Roi is far from affainting that there are no luminous insects in the sea; for he allows that the abbe Nollet and M. Vianelli had found them; but he is satisfied that the sea is luminous chiefly on some other account, though he does not so much as offer a conjecture with respect to the true cause.

Other writers, equally dissatisfied with the hypothesis of luminous insects, for explaining the phenomenon, which is the subject of this article, have ascribed it to some subsistence of the phosphoric kind, arising from putrefaction. The observations of F. Bourzes, above referred to, render it very probable, that the luminoiusnes of the sea arises from slimy and other putrefact matter with which it abounds, though he does not mention the tendency to putrefaction, as a circumstance of any consequence to the appearance.

The correspondent of Dr. Franklin, part of whose letter has been already recited, observes, that several gentlemen have been of opinion, that the separated particles of putrid, animal, and other bodies, floating on the surface of the sea, might cause this appearance, for putrid fish, &c. will cause it; and the sea animals which have died, and other bodies putrefied in it since the creation, might afford a sufficient quantity of these particles to cover a considerable portion of the surface of the sea; which particles being differently dispersed, might account for the different degrees of light in this appearance; but he adds, this account seems liable to an obvious objection, viz. that as putrid fish, &c. make a luminous appearance without being moved or disturbed, it might be expected that the supped putrid particles on the surface of the sea should always appear luminous, when there is not a greater light; and, consequently, that the whole surface of the sea covered with these particles should always, in dark nights, appear luminous, without being disturbed, which, he says, is contrary to fact. Franklin's Experiments and Observations, p. 274, &c.

This difficulty is, in a great measure, removed by the experiments of Mr. Canton, recited in the Philosophical Transactions, vol. lix. p. 446, &c. which have the advantage of being easily made, and leave no room for doubt, that the luminousnes of the sea is principally owing to putrefaction.

Having put a fresh whiting into a gallon of sea-water, neither the whiting, nor the water when agitated, gave any light; Fahrenheit's thermometer, placed in the cellar where the pan was placed, standing at 54°; the following evening, that part of the fish which was even with the surface of the water was luminous, but the water itself was dark; however, on drawing through it the end of a flick, the water appeared luminous behind the flick all the way, but gave light only where it was disturbed: when all the water was stirred, the whole became luminous, and appeared like milk, yielding a considerable degree of light to the sides of the pan, which it continued to do for some time after it was at rest. The water was most luminous when the fish had been in it about twenty-eight hours, but would give no light by being stirred after it had been in it three days. He then put a gallon of fresh water into one pan, and an equal quantity of sea-water into another, and into each pan he put a fresh herring, of about three ounces; the next night the whole surface of the sea-water was luminous without being stirred, but much more so when put in motion; and the upper part of the herring, which was considerably below the surface of the water, was also very bright; while at the same time, the fresh water, and the fish that was in it, were quite dark.

There were several very bright luminous spots on different parts of the surface of the sea-water, and the whole, when viewed by the light of a candle, seemed covered with a greasy film. The third night the light of the sea-water, while at rest, was very little, if at all, less than before; but when stirred, its light was so great as to discover the time by a watch, and the fish in it appeared as a dark subsistence. After this its light was evidently decreasing, but was not quite gone before the seventh night; the fresh water, and the fish in it, were perfectly dark during the whole time. The thermometer was generally above 60°. Having made artificial sea-water, determined by an hydrometer to be of the same specific gravity with the sea-water, by adding four ounces avoidupois of salt to seven pints of water, wine measure, he put into a gallon of this water a small herring; and another into a gallon of water, in which two pounds of salt had been dif-
folved. The next evening, the whole surface of the artificial sea-water was luminous without being stirred, but gave much more light when it was disturbed, and exhibited the same appearances with the real sea-water in the preceding experiment; while the other water, which was almost as flat as it could be made, never gave any light. The herring which was taken out of it the seventh night, and weighed from its fall, was found firm and sweet; but the other herring was very flat and putrid, much more so than that which had been kept as long in fresh water. If a herring, in warm weather, be put into ten gallons of artificial sea-water, a head of one, the water, Mr. Cantor fuses, will still become luminous, but its light will not be so strong.

These experiments confirm an observation of Sir John Pringle, that the quantity of light contained in sea-water is less putrefaction; but there is little probability of fact which promotes putrefaction in the mud, is less than that which is found in sea-water, it is probable, Mr. Cantor observes, that if the tides were less salt, it would be more luminous. See PUTFRECTION.

Mr. Cantor observed, as Mr. Ait. Martin Swed. Ab. hand. vol. xxxii. p. 215. had done, that several kinds of river-fish could not be made to give light, in the same circumstances in which any sea-fish became luminous. He says, however, that a piece of carp made the water very luminous, though the outside, or fatty part of it, did not shine at all. See this subject farther discussed under the article Exhibition of Light from Living Animals.

SEA. Perils of the, in Marine Injunmce, denote, in a large sense, all the accidents or misfortunes to which persons engaged in maritime adventures are exposed; but it has been found convenient to distinguish the losses to which ships and goods at sea are liable, by the "immediate causes" to which they may be ascribed. Accordingly the perils of the sea mean only such accidents or misfortunes as proceed from mere sea damage, that is, such as arise from frcs of weather, winds, and waves, from lightning and temnels, from rocks and sands, &c. A loss by the perils of the sea are therefore happen, by the ship's foundering at sea, in which case it must generally be total; or, 2dly, by the ship's being driven on shore by the winds and waves, or voluntary, where she is run aore either to prevent a worse fate, or for some fraudulent purpose: this stranding may be followed by shipwreck, which occasions a total loss, and if the ship be got off in a condition to prosecute her voyage, the damage foundered and the expenses incurred will incur only a partial loss of the nature of a general average; or, 3dly, by the ship's striking against a sunken rock, or something else under water, which may occasion the springing of a leak, or absolute shipwreck. If a ship be not heard of within a reasonable time, she shall be presumed to have foundered at sea. In some countries there is a limitation of time for this presumption: thus in Spain, if a ship has not been heard of for six years from her departure on a voyage to or from the Indies, she is deemed lost; but in France, after a year from the ship's failing, in common voyages, and two years in distant voyages, the injured may abandon and demand payment, without other proof of loss. In England there is no such limitation of time. When an interval, thought to be reasonable by those who are conversant in maritime affairs, has elapsed, a liberal underwriter will pay his loss; and if there be any ground for doubt, he may either demand security from the injured to refund the money, or refuse the ship should afterwards arrive safe, or he may trust to his remedy by action, for recovering it back. If a ship be driven by frcs of weather on an enemy's coast, and be there captured, this is a loss by capture and not by perils of the sea, for which the injured may recover upon a policy against capture only; and yet it has been held, that capture is a loss by the perils of the sea, as much as if it were occasioned by shipwreck or tempest. If a ship be thrown overboard, on account of a scarcity of water, occasioned by the captain's misjudging his course; this is not a loss by the perils of the sea. The case is the same, if the ship be for want of food, occasioned by the extraordinary length of the voyage. And if a ship be destroyed by worms, the loss is not attributable to perils of the sea. As to the case of throwing slaves overboard in order to lighten a ship and preserve it in a storm, the practice has been generally repudiated by seamen. Every thing on board, however precious, as he humanly and rationally observes, should be thrown into the sea sooner than the manikal slave. [Rev. 19:16] The law of nations, moreover, under pretense of saving the ship, shall throw men into the sea, whether they be freemen or slaves, and whether it be done by or without, or guilty of any such unwarrantable act, in order to save his own life, has a right to take away the life of any other human being, who does not attack him.

If, by some extraordinary accident, as the violence of the winds or waves, it becomes necessary to ship a cable, or a cable be broke, and an anchor lost, or a sail or yard be carried away, this is a loss by the perils of the sea within the policy. Also, if animals be injured, their death, occasioned by temnels, by the shot of an enemy, by jettison in a storm, or by any other extraordinary accident, is a loss within the policy; but it is other wise if their death be owing to diseafs. The injury occasioned by one ship's running foul of another at sea, is a loss within the policy, unless it be imputable to the misconduct of the master or mariners of the ship injured. In such case, however, this misconduct would, as seafarers conclude, amount to bartray, and the injured would be liable for the loss; but an action would lie against the master of either ship, to whom the misconduct is imputable, for the loss which he has occasioned. A loss occasioned by an accidental fire, not imputable to the fault of the master or mariners, is a loss within the policy; and in many places the injured is held to be liable, even when the fire happens by the fault of the master or mariners; but in France the injured is not held answerable in such case, unless, by the policy, he be liable for bartray. For every loss occasioned by capture, whether lawful or unlawful, and whether by friends or enemies, the injured is liable. Marshall on Insurance, vol. ii. See Recapture, Risk, and Salvage.

SEA-Adder, in Ichthyology, an English name for a sea-fish of the acus kind, called by Willughby the new luminosiformis. See ACUS and SYNGNATHUS.

It is a small fish of a cylindrical shape, without scales, and of a greenish-brown colour, with some admixture of a reddish-yellow.

Their fin is long and hollow, and the mouth opens upwards at its end; the eyes are small, and their iris red; the gills are four on each side, but are covered by a membrane, and the whole body divided into rings like the common earth-worm; it is usually about three or four inches long, and of the thickness of a goule-quill; it has but one fin, which is situated on the back. The anus is much nearer the head than the tail, and under the inut there is always a fleshy tubercle.

The fin is common on the coast of Cornwall. Willughby.

SEA-Army. See Navy Army.
SEA

SEA-Astronoe. See ASTROLABE.

SEA-Banks. (See Bank.) Maliciously destroying sea-banks, by which lands may be overflowed, is made felony without benefit of clergy by 6 Geo. II. c. 25, and Geo. II. c. 32.

SEA-Bat, in Ichthyology. See CHETODON Vespertilio.

SEA-Bear, in Zoology, the Phoca Ursina of Linnaeus, called also by some writers the sea-cat, and by Pennant the uprine seal, inhabits together with the sea-lion and manati, from June to September, the isles that are scattered in the seas between Kamtchatka and America, in order to copulate, and bring forth their young in full security. In September they quit their lation in a very unacated state; some returning to the Asiatic, and others to the American shores, but, like the sea-otters, they are confined to those seas between latitude 50° and 56°. These animals are also common about New Zealand, Staten Island, New Georgia, and the Falkland Islands.

The urine seals, during the three months of summer, a very indolent life; they are confined for several weeks to the same spot, sleep the greatest part of their time, eat nothing, and are totally inactive, the employment of the females in suckling their young excepted. They live in families, each male having from eight to fifty females, which he guards with jealousy; and though they lie by thousands on the shore, each family, consisting sometimes of one hundred and twenty, keeps itself separate from the rest.

The old animals, which are deserted by the females, live apart, and are exceedingly sullen and quarrelsome, very fierce, and so attached to their old haunts, that they would die sooner than quit them; in defending these, discord is sometimes spread through the whole shore. The other males are also very irascible, and the caucuses of their disputes are generally such as these; an attempt to seduce any of their females, the intrusion of one upon the lation of another, and interference in their mutual quarrels. Their battles are severe and bloody, and when they terminate, the combatants throw themselves into the sea, to wash away the blood.

The males are very fond of their young, of which the female generally brings but one at a time, and never more than two: but they are very tyrannical towards the females, which, on the other hand, are very fawning and submissive.

The sea-bears swim very swiftly, at the rate of seven miles an hour; when wounded will seize on the boat, bear it away with impetuosity, and sometimes sink it. They can continue a long time under water. When they want to climb the rocks, they fall down with the fore-paws, and draw themselves up. They are very tenacious of life, and will live for a fortnight after receiving such wounds as would immediately destroy any other animal.

The males of this species are much larger than the females; their bodies are of a conical form, thick before, and tapering to the tail; the length of a large one is eight feet, the greatest circumference five feet, and near the tail twenty inches; the weight Scolops; the nose projects like that of a pug dog, but the head ripes suddenly; the nostrils are oval, divided by a septum; the lips thick, and in the infide red and ferrated; the whiskers long and white; the teeth, which are thirty-five in number, lack into each other when the mouth is closed; the tongue bifold; the eyes are large and prominent, and capable of being covered at pleasure with a fleshy membrane; the ears are small and sharp-pointed; the length of the fore-legs is twenty-four inches; the feet are formed with toes, but covered with a naked skin, to as entirely to appear a shapeless mass; the hind-legs are twenty-two inches long, and fixed to the body behind, but capable of being brought forward, and the feet are divided into five toes; the tail is only two inches long; the hair is long and rough, under which is a soft down of a bay colour; the general colour of these animals is black, but the hairs of the old ones are tisp with grey. The females are cincereous. The skins of the young, cut out of the bellies of their dams, are useful for clothing.

The fat and flesh of the old males are very naineous, but the flesh of the females resembles lamb, and the young ones reared as good as sucking-pigs. Pennant's Hist. Quad. vol. ii. p. 526, &c. See Phoca Ursina.

SEA-Bijker. See BISKEET.

SEA-Bent, in Naval Language, a vessel that bears the sea firmly, without labouring heavily, or straining her masts or rigging.

SEA-Branches, a term used by the farmers to express the overflowing of their low lands near the sea by the fresh water.

SEA-fall, moderately used, is a great improvement to all lands, but too much of it kills all sorts of vegetables, except such as nature has intended to live among it. See SALT.

The sea breaking in upon lands thus, injures them greatly. The owner is to stop the breach by which it entered with all possible diligence, and then trenches and drains must be cut through all parts of the land to carry the salt-water into some one low place, from which it may be emptied by means of an engine; or if it be small in quantity, it may be laded out by hand over the bank; or if yet less, the sun and winds may dry it away; but in either case, the place where it was suffered to rest must be covered with a large quantity of fresh earth, to take off from the too great fatness of the other; and the whole land should be ploughed for three or four years, to let in the rains and air to frethen it.

SEA-Bream, in Ichthyology, the English name for the fish called by the generality of authors the pagus and phagrus. According to the new system of Arcted, it is a species of the sparsi, and is distinguished by the name of the red sparus, with the skin carried into a finus at the roots of the back fins, and the pinna ani. See sparus.

SEA-Buckthorn, in Botany. See Hippophae.

SEA-Brief, in Marine Insurance. See SEA-Letter.

SEA-Cabbage, in Gardening, the common name of an useful garden plant. See Brassica and Crambe. See also SEA-Kale.

SEA-Calf, Phoca vitulina in the Linnaean system of Zoology, is the common seal, with large black eyes, large whiskers, oblong nostrils, flat head and nose, tongue forked at the end, two canine teeth in each jaw, fix cutting teeth in the upper jaw, four in the lower, no external ears, body covered with thick short hair, short tail, and toes furnished with strong sharp claws; its usual length is from five to six feet; the colour various; dulfky, brindled, or spotted with white or yellow. This species inhabits most quarters of the globe, but is found in greatest number towards the north and south; they swim near the Arctic circle, and the lower part of South America, in both oceans near the southern end of Terra del Fuego, and among the floating ice as low as lat. 60° 21' S.

They are also found in the Caspian sea, in the lake Aral, and lakes Baikal and Orau, which are fresh waters, but there are less, and more fat than those of the salt-water. Seals bring forth two young at a time in autumn, which are for a short time white and woolly, and fuckle them till they are fix or seven weeks old in rocks or caverns, when they take to sea; as they cannot remain long under water, they
they frequently rise to take breath, and erect their

in New Holland, they leap on rocks or sand banks: if pursued, they plunge into the sea, and when at a distance from the land, with their long feet, and make a plunging movement, which they can repeat alow, and if they are overtaken, will defend themselves with their teeth and feet; they are then killed by a gun shot bow on the nose, otherwise they will in a very few minutes.

These animals swim with great strength and speed, and in their own element sport without fear about ships and boats, which, says Mr. Pennant, may have given rise to the belief of sea-nymphs and syrens. They are the chief food: they feed on all sorts of fish; are like good food, and eat by voyageurs: they are killed for the sake of the oil made from their fat, of which a large bowl will yield eight gallons; their bladders are useful in making washeats, covers for trunks, and other convivial casks; and they are the wealth of the Greenlanders, supplying them with every necessary of life.

We have a draught of one animal in the Phil.-topical Transactions, N° 469, by Dr. Parison, who observes, that Aldrovandus, Johnson, Rorderus, and Gofner, have made several mistakes in the figures of this creature, so as to convey no just idea of it.

Upon dissecting one of these animals, the stomach, intestines, bladder, kidneys, ureter, diaphragm, lungs, great blood-vessels, and pudenda, were all covered of the cow; the ears of the whales were very heavy and clear; the spleen was two feet long, four inches broad, and very thick; the liver consisted of six lobes, each hanging as long and as slack as the spleen, with a very small gall-bladder. The back was long and flabby in its texture in general, having a large clavicles ovale, and very great columna carnose. In the lower stomach were about four pounds weight of flinty pebbles, all sharp and angular, as if the animal chose them of that form for eating the food. The uterus was of the usual kind, each of the cornua being thicker than the body or duct leading to them: the ovaria were very large, being granulated on the surface with the ova, under a very thin membrane; and the opening into the tubes leading to the cornua is a great hole.

The authors who have treated on this animal, are Aristotle, Pliny, Aldrovandus, Roderus, Gofner, Wolfgangius, and Johnston.

This animal is viviparous, and suckles its young by the mammary, like quadrupeds; and its flesh is curious and muscular. That dissected by Dr. Parson was seven feet and half long, though very young, having scarcely any teeth, and having four lobes regularly placed about the navel, which in time became papillae. (See Piscis, Vitalinars.) See a description of other species of seal, with figures, by Dr. Parson in Phil. Trans. vol. xlvii. p. 109, &c. and Pennant's Hist. Quad. vol. ii. p. 518, &c.

Sea-Chart. See Chart.

Sea-Charts, in Agriculture, a muddy sort of clayey matter found on the shores and borders of the sea, which is blackish or bluish appearance, and often of a very stiff tenacious quality, not easily mixing with earthy soils. It mottly lies underneath the fandy ouzy matters that are collected in such situations. See Sea-Sand.

In Lancashire they make use of a fat sort of seal-clay, which is dug out close to the shore on the left and right shores of land, when in the flat of fallow for wheat, in the proportion of about 200 single horse cart-loads to the acre, and believe it to answer better than the common sea-clay, or even sandy mud. It may probably be of a marly nature.

Sea-Coy. See Coast.
whale, it has no voice, and, like that animal, has an horizontal broad tail, without even the rudiments of hind feet. It inhabits the seas about Bering's, and the other Aleutian islands, between Kamtschatka and America.

In calm weather these animals swim in great depths near the mouths of rivers; when hurt, they swim out to the sea, but soon return again. They live in families near one another, each consisting of a male, female, a half-grown young one, and a very small one; the females obligate the young to swim before them, while the other old ones surround, and, as it were, guard them on all sides. The affection between the male and female is very great, for if she is attacked, he will defend her to the utmost, and if she is killed, will follow her carcase to the very shore, and swim for some days near the place where it was landed.

They copulate in the spring, in the same manner as the human kind, especially in calm weather; towards the evening; the female swims gently about, the male pursues, till tired with wantoning, the flings herself on her back, and admits his embrace; the ureine and urine seizes copulate after the same manner on shore. Steller says, they go with young above a year, and bring forth one at a time, which they suckle by two teats, placed between the breasts. They are very variegated and glutinous, and feed not only on the loci that grow in the sea, but such as are flung on the edges of the shore; and when they are filled, they fall asleep on their backs. Their back and sides are generally above water, and as their skin is infested with a species of lefore peculiar to themselves, numbers of gulls are continually perching on their backs to pick out the infects.

They continue in the Komschatkan and American seas the whole summer, but in winter are very lean. They are taken by harpoons fastened to a strong cord, but after they are struck, it requires the united force of thirty men to draw them on shore. When one is struck, its companions repair to its help, some will endeavour to overturn the boat, by getting under it; others will press down the rope, in order to break it; and others strike at the harpoons with their tails, with a view of getting it out, in which artifice they sometimes succeed. Their noise is like the snorting of a horse, which is occasioned by hard breathing. They are of an enormous size, some being twenty-eight feet long, and eight thousand pounds in weight; the head is small, oblong, and almost square; the nostrils filled with short bristles, the lips double, and the mouth, near the junction of the jaws, full of white tubular bristles, which serve to prevent the food from running out with the water; the lips are also furnished with bristles, which serve instead of teeth to cut the roots of the sea plants; in the mouth there are no teeth, only two flat white bones, one above and another below in each jaw, with undulated surfaces, which answer the purpose of grinders. The eyes are small; instead of ears there are two small orifices; the tongue is pointed and small, the neck is thick, and the head always hangs down. Near the shoulders the circumference of the body is twelve feet, about the belly twenty, near the tail four feet eight inches; the head is thirty-one inches, and the neck nearly seven feet; which dimensions render the animal extremely deformed. Near the shoulders are two feet or fins, two feet two inches long, without fingers or nails; the tail is thick, long, and horizontal, ending in a flat black fin, slightly forked. The skin is thick and black, and full of inequalities, and so hard as scarcely to be cut with an ax, without hair; beneath the skin is a thick blubber, which tastes like oil of almonds. The flesh is coarser than beef, and will not soon putrefy. The young ones take like veal; the skin is used for shoes, and for covering the sides of boats. Pennant's Hist. Quad. vol. ii. p. 536. &c.

The sea-ow, or sea-cow of the gulf of St. Lawrence weighs from fifteen hundred to two thousand pounds, and produces from one to two barrels of oil, which is boiled out of a fat substance that lies between the skin and the flesh; it carries its young about nine months, and seldom bears forth more than one at a time. The skin is cut into slices of two or three inches wide, and exported to America for carriage- traces, and to England for glue. The teeth afford an inferior fort of ivory, which very soon turns yellow. Philos. Trans. vol. lxxv. part 2. p. 249, &c.

The sea-ow is also a name given by Edwards to the cut-water of Catesby and Pennant, and to the black skimmer of Latham. See Rynchus Niger.

Sea-Cow, in Ornithology, a name given by the common people of many counties of England to the pewit; which see.

Sea-Cow, in the Vernum Zoophyta, a name given by Ellis to the Sertularia Cypressea; which see.

Sea-Saffidi, in Botany. See Pancratium.

Sea-Decil, in Ichthyology, an English name for the rana piscatrix, or lobius piscatorius of Linnæus; a very remarkable species of fish, of a middle nature between the cartilaginous and bony fishes. See Lophius Piscatorius.

The bronchial holes are three on each side, which are situated deep in the mouth, and open into marupia or faculi on the side of the head, the fides of which are the branchioleges, having several long slender cartilaginous bones, running longitudinally for their support, analogous to the branchiagal or fides of other fishes; and these facks, Dr. Parfons conjectures, may answer two ends, first, to form the membrane branchioleges; and, secondly, to make a convenient receptacle for the young till they are able to shift for themselves. If this be the case, it was not to be answered, the branchie might have been terminated near their origin in the mouth, as in other fishes. If this fish does not bring forth its young perfect, Dr. Parfons thinks there can be no use aigned for these facks; but if they are viviparous, then the young may probably be harboured in them, being capable of crawling into them, as we may see by the pectoral webs on the under side; besides, as these fishes crawl on the bottoms of deel places, watching and aluring their prey, the young must be protected by the parent, till they are able to provide for themselves, which may probably be when they grow too large to enter into these marupiae.

This fish has either no no덤s, or else they are hid within the head, and has a fort of membranous rim running all round the commissures of its fides and belly. Its flesh, when boiled, tastes like that of the frog. Wilughby's Hist. Pisc. p. 85. Phil. Trans. vol. xlvii. p. 126, &c.

Sea-Dragon, or Draco marinus, a species of Trachinus; which see.

Sea-Dragon, among Marinors, is such things as hang over the flap in the sea, as shifting, coats, and even the boat, &c. when towed.

Sea-Eagle, Agula marina, in Ichthyology, a species of the raia, with a smooth body and a long tereated spine on a finny tail. See Raia Agula.

Sea-Eel. See Eel and Murena.

Sea-Egg, or Sea-apple, the name of the roundish centronia, with crooked or feiculated spines. See Centronia and Echinus.

Sea-Fins and Sea-feathers. See Gorgonia and Spongia.

Sea-Faring, denotes the condition of a mariner.

Sea-Fight. See Engagement and SIGNAL.

Sea-Fir, a species of Seriolar:; which see.

Sea-Fox, in Ichthyology, an English name for a fifth of the ficals kind, called also the sea-ape; both names being given
The old Greek writers have called it _pelagia_, and the
later _aegea_, _marina_, and _hypo marina_, where the names
fish, and _sape_. See Senv and Squalls _Vulgaris_.

See also _Attitude_ and _Gage_.

Sea-Fowl, at Sea. When two threes are aboard one another,
they swim on a wave or blow, the feathers fly, they are aboard
with a feather together.

See _Gos._, in _Gos._, the _Ant. Eruption_. See _Deck_.

Sea-Goose, in _Betta_. See _Coccoloba_.

Sea-Goose, in _Betta_, an English tame given to the
fish eaten by the generality of writers. See _tamer_,
and the _gelder_.

Artedi, who has made a genus of the pelman, excludes the
common _gallina_, or _gallina azurea_, from it, but he admits
this fish as a genuine species of it.

Another tells us of three kinds of gallina, the black,
the yellow, and the white. This seems to have been very
plentifully the black _gallina_ of that author. Solenian, in the
figure of this fish, has given three feet on the back, but it
really has only two. See _Galina Nera_.

Sea-Hare, a species of _Stellata_; this fer.

Sea-Hare, in the _High._ of _Lyras_, the name of the
lenus_; a species of the _Amphor_, and also of the _Phylus_
which fer.

Sea-Hin, in _Ornithology_, a name given by some to the
larin, a web-footed bird, common on our coasts, and
called the _guinnaea_, or _kildaw_. See _Columbus Tribe_.

Sea-Holly, in _Botany_. See _Eryngium_.

Sea-Horse, in _Ichthyology_, the English name of the _hippo-
campus_; a species of the _neos_, according to the older writers,
and one of the _fungus_ of Artedi. See _Syngnathus_.

The many idle tales reported of this salt amphibian
creature, such as his method of bleeding himself when
dtempered, his vomiting fire when enraged, and the like,
have made people, in almost all ages, desirous of feeding the
Romans were fond of exhibiting it in their flos of
wild beasts, and the deferta Phyn gave it of it from thene,
was all the world knew of the creature for many ages.
That author's account, however, of its feeding on grases on
the banks of the Nils, no way agrees with the teeth we find its
mouth furnished with.

The skeletons of these animals, as rare as they are with us
at present, in their recent states are not found so frequently,
in part least, buried under ground, and that at great depths.
The bones of the head are different from those of any other
cnown animal, and when found in some parts of France, had
always puzzled the wits of the naturalists there, who had in
various times compared them with those of oxens, horses, &c., but at
length none of the heads of these animals being sent over to
France, cleared up the whole difficulty. The two jaws of
this weighed forty-five pounds, and were two feet long, a foot
deep, and a foot and half wide.

It is easy to conceive from this, that the accounts we have
of the size of the animal are not fabulous, these bones cor-
responding very well with them. Mem. Acad. Par. 1724.

Sea-Horse is also a name sometimes, but improperly, given
to the river horse, or _hippopotamus_.

Sea-Horse is also a name given to that species of seal called
walrus.

Sea Kale, in _Gardening_, the common name of a highly
nutritious and palatable culinary vegetable. It is an early
every plant, the young shoots of which are used somewhat
in the manner of asparagus, and may, if laid, be grown,
by the method of cultivation which is given hereafter, to a size
and of a delicacy of flavour greatly superior to that which
is commonly brought to the table. See _Kale_.

In addition to what has been offered under that name, it
may be observed that the plant grows naturally the blood
a tea family, or one which is of a honey gravity, quite
by the leaves of the tea. In the cultivation of the garden, the
proper method which is lately laid down, is, that of preparing
the ground to it by trenching it and a half deep, about the edge of the year or at the
beginning of it: when the tea is deeply, and at a
ight quality, it is to be transplanted by artificial means, such as the applanator of a tunnel, or portion of free white land,
and very rotten vegetable earth; if the ground be wet in the winter leaves, it should be partly drained, that the
water may drain in from the bottom of the cultivated
mound, as the strength of the plant depends upon the
roots and rhizoids of the bottom loam. After which the
ground is to be divided into beds, four feet in width, with
always of eighteen inches between them, then, at the dis-
tance of every two feet each way, five or six feet are to be
formed into a circle of about four inches diameter, to the depth of
two miles. This beds should be performed in a
rather regular and exact manner, as the plants are afterwards
to be covered by means of pots for blanching them,
and the health and beauty of the crops equally depend upon
their standing at regular distances. If the beds which were
low were found and perfect, they will come up and the
materials in the last spring or beginning summer month;
which as soon as they have made three or four leaves, all
but three of the strongest and best plants should be taken
away from each circle; planting out those which are pulled
up, which, when done by a careful hand, may be performed
to as for them to have the whole of their tap-root is a
spare bed for extra forcing, or the repairs of accidents. The
turnip fly and wire worm are to be carefully guarded against,
the latter by picking them by the hand from out of the
ground, and the former by the use of lime laid round the
young plants in a circle. When the summer months prove
dry the beds should be plentifully watered. As soon as
the leaves decay in the autumn they should be cleared away,
and the beds be covered with light earth and sand to the
thickness of an inch; the compost thus having laid some
fume in a heap, and been turned several times, to be as
free from weeds, and the sort of infects as well as grubs.
Upon the sandy loam dressing, about six inches in depth of
light loose litter to be applied, which completes the work
of the first year.

In the spring of the second, when the plants are begin-
ing to push, the stable litter is to be raked off, a little of
the most rotten being dug into the alluvies, and another inch
depth of loam and sand applied. Cutting this year is to be
restrained from, notwithstanding some of the plants may
rise strong, and the beds managed exactly as before during
this winter season.

In the third year, a little before the plants begin to fur,
the covering laid on for the winter is to be raked off, and an
inch in depth of pure dry sand or fine gravel now laid on.
Then each circle of plants is to be covered with one of the
blanching-pots already aluded to, pressing it firmly into the
ground, so as to exclude all light and air, as the color and
flavour of the shoots are greatly injured by exposure to
either of them. When the beds are twenty feet long,
and four wide, they will hold twenty-four blanching-pots;
with three plants under each, making five and twenty plants in a bed. They are to be examined from time to time, the
young items being cut, when about three inches above the
ground, care being taken not to injure any of the remain-

ing buds below, some of which will immediately begin to swell. In this way a succession of gatherings may be continued for the space of six weeks, after which period the plants are to be uncovered, and their leaves suffered to grow, that they may acquire and return nutriment to the root for the next year's buds. When seeds are not wanted, the flowers should be pinched off by the finger and thumb, as long as they appear. Where the expense of blanching-pots is objected to, the beds must be covered with a large portion of loose gravel and mats; but the saving is trifling, when the time and trouble of removing and replacing the gravel, for the cutting of the crop and securing the plant, are considered. By this mode of management, sea-kale is said to have been cut which measured ten, eleven, and even twelve inches in circumference, and that each blanching-pot on the average afforded a dish of it twice in the feaon.

The blanching-pots for this use are somewhat of the fame shape and size as the large bell-glafls commonly employed in market gardens for raising tender vegetable crops, but made of the same materials as the common earthenware, having a handle at the top. They may be about a foot and a half in diameter at the rim where they apply to the ground.

Forcing Sea-Kale.—It is supposed that no vegetable can be so easily and cheaply forced as this, or require so little trouble; as the dung is in the finest state possible for spring hot-beds, after the common crop has been cut and gathered. The principal circumstance necessary in this business, is that of being very attentive and particular in guarding against too great a heat. The temperature under the blanching-pots should constantly be kept as near fifty-five degrees of Fahrenheit's scale as possible, and on no account higher than fixty at any time. In this intention, in either of the two concluding months of the year, as the sea-kale may be wanted more early or late, a suitable quantity of fresh flable dung should be collected and prepared, to cover both the beds and the alleys from two to three feet in height; as in the quantity to be laid on, a great deal must always be left to the judgment of the gardener, as well as to the state of the feaon as to mildness or severity.

It should invariably be well penned down between the blanching-pots, heat-flicks being placed at proper intervals, by the occasional examination of which the heat below will be readily known. When the dung has remained in this situation four or five days, the pots should be examined to see the state of the shoots. It not uneventually happens that worms spring above the surface, and spoil the delicacy of flavour in the young shoots. In order to prevent this, it is best to cover it with dry sea-coal ashes, which have been fitted either very small or very large. Salt has also the power of destroying them in an effectual manner, without injuring the sea-kale.

The crop, it is said, will be ready to cut and gather in three weeks or a month from the first application of the heat; but as much danger and mischief are the consequence when this is violent, it is advised to begin soon enough, and to force slowly, rather than in too quick a manner. It is likewise necessary to cut the leaves off a fortnight or three weeks before they decay, in those plants which are intended to be forced at a very early period.

It is also suggested that the blanching-pots used in forcing should be made in two pieces, the uppermost of which should fit like a cap upon the lower; as the crop might then be examined at all times without disturbing the hot dung. See Transactions of the Horticultural Society of London, vol. i. p. 13.,

Sea-Lark, in Ornithology. See Saxicarius Hircicus, and Emberiza Muscicola.
SEA

Sea-lions, *Phocoena phocoena*, a not to the Mo-1

Sea-lions, in the History of India, the English name of a species of seals.

**SEA-MARK.**

Sea-Mark, a point and conspicuous place distinguished at sea. See LAND-MARK, BEACON, and BUOY.

**SEA-MARK**

See Coralline and Conparya.

**SEA-MEIOE, in the History of India, the English name of the aphrodisiac.

**SEA-MUD, in Agriculture, that sort of muddy deposition, which is often taking place on the shores and coasts of the sea, and which occasionally forms a constituent part of the body of the land in such neighbourhoods. It is so called, because it is of a mucky, muddy quality, but in the other it is partly taken of a clayey, productive nature, either by that which is of a loam, chalk, or clay, or by so dull, or brown, or mud. The sea-mud is by much the ruddiest, and thickest as it is the blackest and all black, and the best calculated for application in this way, where it can be procure

It is sometimes employed in preference to marl, though that subtilice may be reserved to itself, and the proportion of about three parts to the quantity of marl, being laid on the lower ground in autumn, that is to be broken up in the following spring months. It is mostly got by digging it up only one foot depth and the surface. After being spread out, and well broken down and reduced, it is turned down into the soil by the plough. It is useful for oats, barley, potatoes, and wheat crops, producing a large return. It is also very durable as a subtilice of this nature, lasting longer even than marl, and being never liable to injure grasslands. The sort of rich sea-mud is mostly met with on the hanks or shores near the mouths of large rivers which empty themselves into the sea, but in other places its fertilizing properties are often lost to be depended upon.

The muddy matter which is combined with sandy materials on the sea-coasts in some districts, is also found of great utility as a manure.

**SEA-Nettle.** See NETTLE.

**SEA-Oak.** See WHEAT, and FEEDS.

**SEA-OFFICER.** See OFFICER.

**SEA-Union, in Botany.** See SCILLA.

**SEA-OUTER.** See OUTER.

**SEA-Outs, in Agriculture, a rich sort of mud or deposition, raised from the sea-shores in different parts of the kingdom, and which has been found in many cafes of much use as a manure. It might probably be found good, and in large quantities, in many situations on the sea-coasts, where it has not yet been thought of by the farmer. As there can, however, be no doubt of its possesing a highly enriching property, it should be diligently provided in all places where it can be had. It is stated, in the Norfolk Agricultural Survey, that Mr. Peckham, at Colchester, uses much sea-outy mud scraped up by the beach from the bottom of Yarmouth Haven. He lays on forty loads per acre, and has thus manured seventy acres; the improvement is very great. It was found material that it is a calcareous outy-mud; and that on scalds or burning-places, and sand or gravel, it forms a cold bottom, and is an effectual cure. Fifty loads per acre of sea-out are often used on the upland loams of Warham and other parts of the country for what is termed *crabs*, *sulphus*, and *sulphur*. It is stated by the writer examining it, to be obviously the ruins of a forest of large trees, the roots and roots covering, in such a state of decay, that with a spade be dug into the centre of many, and might have done of all, with as much facility as into a mass of butter. Where the fluming are not found on digging, a black mass of vegetable fibre, apparently combining of decayed branches, leaves, leaves, flags, &c. is turned up: to what depth this vegetable stratum extends, has not been ascertained, but at some years.

**SEA-ROOR.** See ROOR.

**SEA-ROOR, in Agriculture, a rich sort of mud or deposition, raised from the sea-shores in different parts of the kingdom, and which has been found in many cafes of much use as a manure. It might probably be found good, and in large quantities, in many situations on the sea-coasts, where it has not yet been thought of by the farmer. As there can, however, be no doubt of its possesing a highly enriching property, it should be diligently provided in all places where it can be had. It is stated, in the Norfolk Agricultural Survey, that Mr. Peckham, at Colchester, uses much sea-outy mud scraped up by the beach from the bottom of Yarmouth Haven. He lays on forty loads per acre, and has thus manured seventy acres; the improvement is very great. It was found material that it is a calcareous outy-mud; and that on scalds or burning-places, and sand or gravel, it forms a cold bottom, and is an effectual cure. Fifty loads per acre of sea-out are often used on the upland loams of Warham and other parts of the country for what is termed *crabs*, *sulphus*, and *sulphur*. It is stated by the writer examining it, to be obviously the ruins of a forest of large trees, the roots and roots covering, in such a state of decay, that with a spade be dug into the centre of many, and might have done of all, with as much facility as into a mass of butter. Where the fluming are not found on digging, a black mass of vegetable fibre, apparently combining of decayed branches, leaves, leaves, flags, &c. is turned up: to what depth this vegetable stratum extends, has not been ascertained, but at some years.
creeks on the very edge of the sea at low water, there is a very fine loamy sea-oule at two or three feet depth: the extent of this once fertile region, which every common tide now covers, can scarcely be left, in one place only, than from five to six hundred acres. There is not an appearance of any tree lying at present from the flump, as if blown down; but after falving the branches, there is a forest cut down in half, the flints cleared and hurried away, leaving the branches to rot; but this is mere conjecture. It is remarkable that there is not, as he is informed, any mention of this ruined forest in the old historians of the county; nor does tradition offer the least conjecture or report on the subject. Trees, roots, and flumps, are very common in bogs, wherever found; but here is not the trace of any thing like a bog, the earth is solid, and all a fine oule, or sea-clayey mud. It is added that Mr. Reighton viewed these relics with the eye of a farmer; for experiment, he sent his carts down for fome, and spread ten loads per acre of it, for turnips: it answered perfectly, and on comparison equalled his yard-dung, and also rape-cake. In another experiment, he measured two acres for wheat, with a compoit, confiding of nine loads of this weed, (or oule,) and three chaldrons of lime mixed; one acre with yard-muck; one acre with tallow-chandlers’ graves, sixteen bushels, and the reft of the piece with rape-cake; the graves were, in effect, far beyond all the rest; between which the difference was not very perceptible. The expense only 1s. per load; but if a barge was floated to the spot, and anchored when the tide was in, for loading at low water, it might be procured at a much cheaper rate. And it is suggetted, that this ingenious cultivator has opened a real mine to fuch farmers as shall have the fagacity to dig it in; it appears astonishing, but he thinks, that none of them should long ago have made the fame experiment, and consequently have profited by fo beneficial a vicinfty.

Without doubt, by proper examination, other situations might be found to afford fubstances that might prove useful as manures.

Sea-oule, in Ichthyology, a name given by many to that fish which we more ufually call the lump-fish, the lumpus of Willughby, &c. and the cyclopetrus of Arsted. See Cy clopetrus lumpus.

Sea-pee, in Botany. See PISM.

Sea-Pearch, in Ichthyology. See PERCA.

Sea-Pen. See Sea-PEN.

Sea-Pheasant, in Ornithology, the name of a bird of the duck kind, but differing from all the other species in the shape of its tail, which has two long feathers standing out beyond the rest; and terminating in a point. It is called more generally the cracker. See DUCK.

Sea-Pie. See Pica marina, and Hematopus ostralegus.

Sea-Pigeon-pee, in Botany. See SOPHORA.

Sea-Pike, in Ichthyology. See ESox bolese.

Sea-Pink, in Botany. See CERASTIUM.

Sea-Plants, a denomination comprehending thofe marine productions which are formed by insects, and which properly belong to the animal kingdom; however, they fo much reftemble vegetables in their form, that they have been long taken for plants called by this name, and called under the vegetable kingdom.

Count Marigli, who was at indefatigable pains to collect the various sea-plants of feveral places, divides all thefe productions, which he referred to the rank of vegetables, into three classes. The first class contains the soft or herbaceous ones; such are the algae, called sea-wrecks, the fuwices or sea-oats, the sea-maffes or conferves, and the different species of sponges: the second class comprehends thofe that are ligneous, or of a woody hardnefs, which were called lithophya by the ancients, as if their hardnefs approached to that of flones; thofe, Marigli says, confist of two subftances, a cortical and an internal; the cortical part, while in the fea, is foft, but in drying becomes as hard as chalk, and in cutting; but after falving, it fhews; the internal fubftance fows more of the nature of horn than of wood; when burnt it throws out a fpume, or froth, like that which horns or feathers of animals yield in the fire, and their smell in burning is of the fame kind; the branches of thofe are very pliable, bending in the manner of whalebone, and giving the fame reftance to a knife in cutting. The third class comprehends thofe plants which are of the hardnefs of flone, and which fhould properly be called the lithophya: thofe are the feveral species of coral, madrepora, and the like.

Marigli endeavours to explain the differences of thofe feral fubftances, and to account for the manner of their receiving nourifhment, agreeably to the fystem which prevailed in his time, and which appropriated them to the fads of vegetables. Marigli, Hift. Phyf. de la Mer. Mem. de l’Acad. Par. 1710.

By later experiments and obfervations, it has been sufficiently demonftrated by M. Peyssonnel, Bernard de Juffieu, Donati, &c. that thofe marine fubftances which Marigli thought to be plants, are the work and habitation of animals. See on this fubjeét the articles CORAL, and CORALLINES.

Dr. Lifter apprehends, that thofe fubftances, which in his time were thought to be sea-plants, ferve to render a great deal of the fea-water freh, and give it in mifts to the clouds, whence it again falls on the earth; this is easily proved by experiment, thus, if a quantity of fea-water be put into a long glass body, and into it there be put a large and vigorous sea-plant, fuch as the common fhipreck, and the head placed on the glafs, and a receiver fitted for it without cutting the joints, there will daily diflip into the receiver, without giving any fire below, a clear and fweet water, freh and potable, and without any difagreeable or unwhofeome quality. The quantity is but illmalt that is obtained in this way, but it is evident, that in the fame manner a very immene quantity of the fea-water is every hour made freh, and railed up into the air from the infinite number of plants that grow in it. Dr. Lifter even thinks that the tropic winds, which blow conftantly one way, may be owing to this fort of caufe. Philof. Tranf. N° 156. See TROPIC winds.

Sea-Peaches, in Botany. See ATRIPLEX.

Sea-Quadrant. See BACK-flufh, and QUADRANT.

Sea-Room, denotes a fufficient distance from the coaft, as well as from any rock and shallows, by which a ship may drive or foud without danger of fhipwreck.

Sea-Salt. See SALT.

Sea-Sand. See SAND, and Common SALT.

Sea-Sand, in Agriculture, that fort of sand which is thrown up in the creeks and other places on the coafts of the sea, and which is often very ufeful as manure. The fheafand, which is thrown up in creeks and other places, is very rich and proper for this purpofe. In the western parts of England, which lie upon the fcoafts, very great advantage is made of it. The fragments of fca-shells, which are always in great abundance in this fand, add to its virtues; it being always the more elfeemed by farmers, the more of these fragments there are among it. The fand of this fort, which is used as a manure in different parts of the kingdom, is of three kinds: that about Plymouth, and fome other of the southern coafts, is of a blue-grey colour, like ashes, which is probably owing to the fheils of mufcles, and other fifth.
of that or the like colour, being look'd and mixed with its great quantity. We land near the Land's End, the sand is very white; and about the islands of Scilly it is very white, with small patches of red. On the coasts of the North Sea the sand is yellow with brown, or red sand, and it is a great quantity of its most of little sand; it is not to be easily computed at. That part of the sand is said to be well suited, which is of a reddish colour in the water in value to the sand, and the water in the sea. This kind of sand is in the sand taken up from under the water, or from sand-banks, which are covered by every tide. And it is remarked, that the small-grained sand is the most utilized in its operations, and it is therefore sold for the tenant who is only to take three or four crops; but that the earthy, or large-grained sand, is much better for the land; the good it does lasts many years. Where sand is dredged out of the sea, it is usually much dearer than where it is taken from sand-banks.

In the northern parts of Lancashire, and in Cornwall, the more light parts of sand in the vicinity of the sea-shores, are in many cases much improved by the application of sea-sand upon them. The practice is to lay it on in a pretty thick layer, so that it may be well incorporated with the soil, by the plough, before the wheat is sown. In the way the crops are often afforded, and the effects of the dressing last several years. It is likewise found very beneficial when applied thinly over the surface of grass-lands or pastures, being at all times more and more extensively made use of than has hitherto been the case. See Sand, Shelly.

This sort of sand is considered as a vast treasure by the farmers in some parts of the county of Cornwall, as has been already hinted at, especially on the sea-coast in the vicinity of the sea. It is supposed to be a substance that feeds the corn, as well as pule-crops and roots, and which is highly useful on pasturage-land; it being material to the value of the corn whether they are near to or remote from it. It is, however, procured from great distances in some cases. Its goodness greatly depends, however, upon the quantity of calcareous and animal matter which it contains, in addition to the mechanical effects which it affords; with some kinds of it, fomy, earthy, ligeous, vegetable and animal matter, are combined, in which case it is denominated bog or boggan, and thought of great value for potatoe crops. The large-sized coral sand is supposed the most lasting in its effects; but the smaller grained and shelly forts are extensively used in some places.

When this sort of sand is applied alone, either on tillage or grass-land, it is called clean sanding; but it is more usually laid on in mixture with earth and dung in the way of a manure. It is employed in all the proportions from three hundred to thirty sacks of sixteen gallons each, to the customary acre of that district. Its utility depends much on the nature of the lands, being much improved on the moory and the thinner forts of soil, than on the deep marly kinds.

It is computed that more than 54,000 cart-loads of it are taken from the harbour of Padstow alone, and that the expense of land-carrige for this article only, for the whole district, is more than 30,000l. a year.

In some of the northern parts of the county of Lancashire, sea-sand was formerly much more reckoned to on tillage and other land, as has been seen above, but it has lately been little employed. They apply it from 80 to 300 or 400 single horse cart-loads to the customary acre, every ten or twelve years, mostly for the wheat crop. The dry sea-sand was formerly made of, but very little is used, mostly, of that described above, in the north, and is said to be much better. It is a great sort of sand to be brought here for land, and various crops then the customary acre, in land, and the same is done in the same manner and various crops. It is very useful for farming purposes, and small tracts made with it by the Rev. Mr. Looe, however, are of little utility. He had two fields on this principle, or rather planted, with the quantity of sea-sand, converted to the customary acre, in land, and the same is done in the same manner, to the same purpose in every part of them. It is, however, remarked, in the report of the Surveyor of the North Riding of York, that many cases in the vicinity of the sea, where the land is well made, as a measure with excellent effects, and that for the districts of Chelwood, and the coast where the wet adhesive clay want draining and breaking, and in most parts of which it might be easily procured, it would be equally useful. It is supposed to be there disregarded in consequence of its great plenty, and being capable of being provided with at pleasure. See Sand, Shelly.

Sea-Scorpion, See Scorpio.

Sea-Serpent, See Sea Snake.

Sea-Shells, in Agriculture, such as are formed and dug from the creeks and bays on the sea-coast. They are constantly very beneficial in improving land in all situations where they are met with in sufficient quantity. But the great use of marine shells is more shown in the following passage in the Statutory account of the parish of Kirkmae-brick, in Galloway. The principal manure used there for improving land is sea-shells, of which there is an almost inexhaustible quantity, not only within the high-water mark on this side of Wigton bay, but also in the dry land, several hundred yards from the shore. These shells are sold at five per cent, twenty-five of which are sufficient for an acre; and prove a cheap and excellent manure, preferable to either lime or marle. Many thousand tons of these shells are annually carried (by vessels constantly employed in the busines) all round the coast, and sometimes even to the Isle of Man. These shells have been used with great advantage in the improvement of barren land, innumerable, that many hundreds of acres in this parish, originally not worth more than 2r. per acre, have been made worth from 10s. to 15s. per acre. Yet this, like every other advantage that is easily attained, is not duly prized; for upwards of one thousand acres in this parish, though capable of cultivation, lie in a state of nature, covered with heath, and almost good for nothing. A little calculation might serve to shew landlords, that in nothing could they lay out their money to so much advantage. As for a tenant, where he has only a lease for nineteen years, and perhaps his encouragement not great otherwise, it cannot be expected he should do much in the cultivation of barren land. The tenant, however, might well lay these sea-shells on land already cultivated. This hint should be duly attended to by the cultivators of such lands, in situations where such manures can be readily provided. It is observed, that in Loch-Tartar there is an immense number of oyster-shells, almost unmixed with any sand, when the thin strata above them is removed: the extent of this allomining mass of shells is unknown, but it is probable it can never be exhausted. A vast tract of improvable moorish land in the neighbourhood, may, some time or other, shew that Providence did not place this fund of manure in vain to rear it. For such moorish heathy ground, these sea-shells are the fittest ma-
and treasures, but their use ought not to be confined to it. In order to make the carriage lighter, and the effect the quicker, perhaps it would be worth while to burn them itself, as it is sometimes done to marle. The kiln might be made with one or two eyes, running into it about half way at the bottom, with some flaps or flues rudely arched over them, the kiln then filled with shells, and fed with fire for a day or two, as might be found necessary. Lime is burned in this way in the space of two or three days, and shells already in a mouldering state, would take much less of both time and fuel. The operation would not be hindered by the tides, as these shells are found also under the surface beyond the sea-mark. Strata of these oyster-shells are also to be found at the head of Loch Caolies port; but there (so flow is the progress of the improvement!) they have not yet begun to use them as manure; probably the time is not distant when these sea-shells will become an article of commerce, and be carried at least along all the shores of Kintyre.

And it is stated by the author of the Agricultural Report of Norfolk, that in East Winch and Wallis Blinks, and scattered for ten miles to Wallington, there is a remarkable bed of oyster-shells in sea-mud; the farmers use them at the rate of ten loads an acre for turfrips, which are a very good dressing; they are of particular efficacy on land worn out by corn. Mr. Forster several years ago laid twenty loads an acre on some worn-out land, and they had an amazing effect in producing grass, when laid down in beds, giving a deep luxuriant hue like good dung: the benefit very great at the present time. They are found within two feet of the surface, and as deep as they have dug, water having stopped them at sixteen or eighteen feet deep. They are used again and again on the same land, and with the same effect. At East Winch, Mr. Crowe has acres together of this most valuable manure. They fall to powder on being stirred. All sea materials of this nature should conflagrantly be well attended to, and collected when wanted to be employed as manure by the farmer. Where they are in a solid state, they only require to be in some measure broken down into a coarse powder. See Sand and Shells.

It may be noticed, that in the first mentioned district, the price of the shells is now higher than it was formerly.

SEA-SICHENS is said to be prevented by drinking sea-water mixed with wine.

SEA-SIDES-GRAPE, in Botany. See Coccobola.

SEA-SPLINTER, or Polyphy, a name given by Ellis to the Sertularia secchennastra.

SEA-SUN-CRUCER, American. See American, &c.

SEA-SCALLOWS, in Ornithology, the name of the ferna birwada, common on our coasts. See STERNA.

SEA-TAMARIK, a name given by Ellis to the Sertularia tamarike.

SEA-TANGLE, in Agriculture. This is another name by which the sea-weed which is usually made use of as a manure is known in some districts, especially those of the north, where it is sometimes collected, and applied, either in its simple state, or when made up into compost with some sort of earthy substance. See SEA-Weed.

SEA-TURTLE DVE. See SEA-Turtle Dove.

SEA-WALL, in Rural Economy, that fort of wall or defence which is thrown up and provided against the sea on the different coasts of the kingdom. It is formed of various kinds of materials, according to the nature of the situation and circumstances, such as those of earth, rocks, shells, strong gravel, and many other matters, to as to constitute a fort of embankment. See Embankment and Embanking.

Walls or banks of this nature should constantly have a good degree of slope backwards, whatever the nature of the materials may be which are employed in their construction, as this form always affords great safety and protection to them. The bases or foundations of them should likewise be securely laid, and well guarded and protected by every possible convenient means which their situations and circumstances will admit of; and the internal parts have a sufficient weight of earthy or other matter thrown up and laid against them, in order to counteract the weight of the water during the time of the tides. In Essex, Mr. B. Dudley is said to have endeavored to give a new direction to a shifting bank of shelly, as a guard to a sea-wall, which had been newly repaired and was much exposed, and by that means to convert it into this fort of defence and security, which he accomplished in the following manner; a flag-stone hedge was made in the ounce, in order to retain the stall land, which being found to have taken effect, a second was formed. The shelly bank, it is said, shifted, though slowly, according to his intention, and that he laid the rational expectation of fully availing himself of it to strengthen his wall, at little more expense than that of thinking. It is urged, that opportunities of this nature frequently present themselves, but are wholly neglected and turned to no account.

It might not be an object unworthy of attention, it is supposed, to have a general commissional of fewers, &c. for the repairs and preservation of sea-walls along the coast, which protect lands the most capable of improvement from the destructive inundations of the sea-water, which leave such fatal well-known effects behind, that the ground is not worth the tillage for some years after being overflowed, and, besides, the expense and trouble that may have been laid out upon it are mostly for ever lost. As the matter now stands, it is common for the owners of the land to manage their own walls according to their own discretion, by which means the neglect or inattention of an individual may cause, not only ruin to himself, but many of his more careful neighbors, and spread a general distress around him. This is the fate of the cause in the above county, and in others it is probably much the same, where they border on the sea.

SEA-WARES, in Agriculture, a term frequently applied to the weed thrown up by the sea in many situations, and which is collected and made use of as a manure, and for other purposes. It is the quercus marina, and has often the names of sea-wreck, sea-tangle, &c. See SEA-Weed.

SEA-WATER, that briny bitterish fluid which constitutes the sea. See Water, &c.

SEA-WATERS, in Agriculture, that which is brought by the sea, and much impregnated by saline matters. It is suggested in the Argyleshire Agricultural Survey, that as it is known that salt is beneficial as a manure, sea-water, which is found to contain it in the proportion of about a bushel to a ton, may also be recommended in the same view. And that, from its promoting putrefaction, it may be applied to peat-earth, dung-heaps, and composts, with much advantage in many situations. This fort of water, where it flagnates for any length of time on land, is, however, found to be very injurious. See SALT-Water.

SEA-WEEKS, in Botany, The Submerged Alga of some scientific writers, are such cryptogamic plants as grow under water, in the sea, fixed by their base, originally, to some rock, flume, or shell, but often found floating without any attachment. Their seeds are, in many instances, known, but the economy of their fructification has not yet been satisfactorily explained, notwithstanding the labours of Rau-mer, Gmelin, Gautier, Corens de Serra, Velley, Turner, and others. See CONIFERA, FUCUS, ULVA, &c.

SEA-Weed, in Agriculture, the wreck or weed thrown up by the water on the sea-coasts, and sometimes cut from their sides.
It is the plant known by the name of quercus marina. And it is a material much used as a manure in the districts, as those of Kent, and the northern counties, as well as in the islands of Jersey and Guernsey. It is found to be tender and easily reduced by remaining some time in heaps, and taking on the process of fermentation. It is thoroughly impregnated with lime matters, and of course proves a beneficial application for land.

It has been found, in the practice of Mr. Rudd in Yorkshire, to a better and more complete union with keimp, ashes, than from the alum-works, and lime, the whole being mixed up with earth. But in many places it is made use of in its simple state, after having undergone a degree of fermentation, or after being incorporated with yard-dung. In the Agricultural Survey of Argyleshire it is stated, that along all the coasts it is much used as a manure, though not always valued as much as it ought. Its effects are not so lasting as that of dung, nor is it so great when laid on in winter as in April or May, when it is riper, and more impregnated with faits. What comes afloat during summer after the ground is frozen, the more careful farmers gather into heaps, or spread on lay-grounds. In either way it turns to little account. Much of the heaps melt away, and much of what is spread dries and shrivels to nothing. If mixed with earth, mofs, fern, weeds, etc., in a compost, it would produce a quick and strong fermentation, and all its juices would be preferred. This is the way to make the most of this great gift of Providence, and the farmer and cottager both should thus increase their store of manure wherever it can be done.

It is likewise noticed, that in the above islands, where this weed has been long employed, it is cut twice in the year, the first cutting in February or March being applied as a manure on the pasture grounds, nurseries, and those towns with barley. It is used in the proportion of two cart-loads, weighing two thousand pounds each, with six cart's of stable dung to a 1000 feet square. The second cutting, which is performed in July, is laid to dry on the sea-shore, and afterwards made use of as fuel; the ashes of which are found an admirable manure, especially on turf land. It is spread over the surface of the land in the winter season, or early in the spring, in the proportion of about half a bushel to the perch. It is said to have a great effect in giving a full ear to the grain, and to prevent its being laid.

But it has not yet been ascertained upon what sorts of land the weed in its simple state has the most effect. It is found to afford great vigour of growth to plants in all kinds. It has generally been supposed to have little effect beyond the immediate crop; but when duly blended and incorporated with other proper earthy or other materials, it has been found to be more lasting in its effects, and to be more proper in this application. See Manure.

The plants of this fort, however, which are made use of as manure on the sea-coasts of this country and Ireland, consist of many distinct species of fuel, algae, and conifer, according as they prevail in different parts. Sir Humphrey Davy found by different processes, in the common fucus, which is commonly the most abundant of any on our sea-coasts, in one mode one-eighth of gelatinous substance similar to mucilage, and in treating it another way, nearly four-fifths of its weight of water, but no ammonia; the ashes contained sea-salt, carbonate of soda, and carbonaceous matter. The gelous matter was small, and chiefly carbonate acid, galeous oxide of carbon, and a little hydro-carbonate.

This manure is laid to be transient in its effects on land, not lasting more than a single crop, which may be readily accounted for from the large proportion of water, or the elements of water, which it contains. It decays, on exposure to the atmosphere, without any heat being produced, taken to melt down as it were, and drive away. A large heap has been known to be wholly reduced in a little while, matter in less than two years. The fresh part of a farm being set down in a mar with itself with a hot fire, became much shrivelled, and the sides of the pitted very dewy, the air being found to have lost oxygen, and to contain carbons and gas.

The suffering of this sort of weed to ferment before it is used, is thought wholly necessary, as there is a fibrous matter rendered soluble in the process, and a portion of the manure is left. The practice of the best farmers in the western parts of this country, is to put it that of which it can be laid, and that the results of this method are exactly in conformity to the theory of its operation. "The carbonic acid formed by its imperfect fermentation may be partly dissolved by the water let free in the same process, and thus become capable of absorption by the roots of plants." That the effects of this weed as a manure must chiefly depend upon this carbonic acid, and the soluble mucilage it contains; and it has been found that "some fuels which had fermented as to have lost about half its weight, afforded less than one-twelfth of mucilaginous matter, from which it may be fairly concluded that some of this substance is destroyed in fermentation."

There is unquestionably a great lost sustained in this and perhaps other ways, where earthy matters are not used with it.

**SEA-Wilows**. a name given by Ellis to the *Gueorgia* anceps.

**SEA-Worms**. See Worms.

**SEA-Worthy**. See Worms.

**SEA-Worthy**. In Marine Insurance, a term applied to a ship, denoting that she is "tight, staunch, and strong, properly manned, and provided with all stores;" so as to be in all respects fit for the intended voyage. In every insurance, either on ship or goods, there is an implied warranty that such is the state of the ship, so that the insurer may gain the premium for indemnifying the insured against certain contingencies; for if the ship is incapable of performing the voyage, there is no possibility that the insured should gain the premium; and in that case, the contract, on his part, would be without consideration, and consequently void. The insurer undertakes to indemnify the insured against "the extraordinary and unforeseen perils" of the sea; and it would be absurd to suppose that any man would insure against those perils, but in the confidence that the ship is in a condition to encounter the "ordinary perils," to which every ship must be exposed in the usual course of the voyage proposed. In France every ship is surveyed, before the commencement of her voyage, by officers appointed for that purpose, who make their report; but the report upon such survey was not sufficient proof of seaworthiness, and it still rested with the insurers to shew the contrary. A ship should be presumed not to have been seaworthy, unless it be made to appear that her disability arose from sea-damage, or other misfortune. It is a wholesome rule, all circumstances considered, says Jesuys Marshall, that the insured shall be held to pretty strict and cogent proof of the ship's being seaworthy, fit for performing the voyage insured, with the proposed cargo on board, and in all respects fit for the trade in which she is intended to be employed. It is also a wholesome rule, that this proof shall not only be cogent and strong to shew the ship's sufficiency at the time when she sailed, but also that the insured shall bring forward all the evidence which he has upon this subject, particularly what relates to the state she was in when the loss happened,
or when she was condemned as unfit to proceed on the voyage. If any thing should be withheld, which the injured might have produced, it will always throw great suspicion on the cause. If, on the other hand, it appears from the facts of the case, that the loss may fairly be attributed to sea-damage, or any other unforeseen misfortune, but yet the insurers mean to allege that the ship at her departure was not sea-worthy, the onus probandi will lie on them. This seems to be the simplest rule; and the simplest rules are always the best, particularly in matters of commerce. If it be clearly ascertained that the ship, at the time of her departure, was not in a condition to perform the voyage insured, neither the innocence nor ignorance of the insured, nor any precautions he may have taken to make her seaworthy, will avail him against the breach of his implied warranty. If the ship be not seaworthy, the policy will be void, though both the insured and the captain believed her to be seaworthy; and though the insurers knew the plat she was in as well as the owners. Where the goods insured have sustained a damage in the voyage, from the insufficiency of the ship, the question, whether the owner or master of the ship liable to make good the loss, depends on the question whether the ship was in a condition to perform her voyage at the time of her departure, or became defective from fires of weather and the perils of the sea. But it is sufficient if the ship be seaworthy at the time of her failing. She may cease to be so in twenty-four hours after her departure, and yet the underwriters will continue liable. The question, however, in such cases, will always be, whether her disability arose from any defect existing before her departure, or from a cause which occasioned it afterwards. But if a ship, within a day or two after her departure, become leaky and found at sea, or be obliged to put back, without any visible or adequate cause to produce such an effect, the natural presumption is, that she was not seaworthy when she failed; and it will then be incumbent on the insured to show the plat she was in at that time.

It is unnecessary to make any representation of the condition of the ship to the insurer, previous to the effecting of the policy; for it is a rule that no representation need be made of matters relating to the risk which are covered by a warranty. But a ship, to be seaworthy, must not only be tight, staunch, and strong, and provided with all necessary stores for the voyage proposed; it is, as has been already observed, a condition or warranty, implied in the contract, that the ship shall be properly manned, by persons of competent skill and ability to navigate her. And therefore, if she be suffered to fail in a river, or other place of difficult navigation, without a pilot properly qualified, the underwriters will be discharged; for this is a breach of the above condition. Marshall's Treatise on Insurance, vol. ii. See SIR and WARc.

SEA-WRACK, the name by which the sea-weed, collected and prepared for manure, is known in some places. See SEA-Weed and WRECK.

It is said to be fed upon by sheep and black cattle, in some places; eating it from the rocks on which it grows, in its fleshy flake, during the ebbing of the tides. As a manure, it is often used fresh with earth and sand in a fort of compost, without any lofs.

SEA-Yoke. See YOR.

SEA, Head. See HEAD SEA.

SEA, High. See HIGH.

SEA, Lie under the. See LING.

SEA, Pacific. See PACIFIC.
the structure of the germ and intuition of the embryo.

SEA

ST. AGAN, in G. Grapt., a town of Persia, in the province of Irag: 3 miles E.N.E. of Harabad.

ST. AGARIM, a name sometimes given to a troubled red wood. S. Raymond.

STE, in J. Noyes., a manner of capacity containing six cabs. S. Cain and Measure.

SEA-HORSE, an island, an island in Hudson's bay. N. lat. 84°. W. long. 89° 50'.

SEA-HORSE, a cape on the east of a peninsula in Hudson's bay. N. lat. 74°. W. long. 82° 10'.

SEAKONNET ROCKS, rocks on the coast of Rhode Island, in the strait of Narragansett bay.

SEAL, a print, a piece of metal, or other matter, usually either round or oval, on which are engraved the arms, device, &c. of some prince, state, community, magistrate, or private person, often with a legend or inscription; the impression of which in wax serves to make acts, instruments, &c. authentic.

The king's great seal is that by which all patents, commissions, warrants, &c. coming from the king are sealed: this consists of two impressions, one being the seal itself, with the effigy of the king flamped upon it; the other has an impression of the king's arms in the figure of a target, for matters of smaller moment, as certificates, &c. that are usually sealed: S. pede seali.

The keeping of this seal is in the hands of the lord high chancellor, who is hence also denominated lord keeper.

The office of lord chancellor, or lord keeper, whose authority by 3 Eliz. c. 18. is declared to be exactly the same, is with us at this day created by the mere delivery of the king's great seal into his custody, without writ or patent.

The king's privy-seal is a seal usually first set to grants that are to pass the great seal. See PATENTS.

The use of seals is very ancient, an instance of which occurs in Daniel, chap. vii. 17. But seals are still older than this; for Jezabel, in 1 Kings. chap. xxi. seals the orders for Naboth's death with the king's ring. See also Jerem. xxxii. 16.

In effect, as the ancient seals were all engraven on the collet, stones, &c. of rings, and as the original use of rings, it is inferred, was only to be in readiness for the sealing of acts, instruments, &c. seals should seem to be as ancient as rings themselves.

These sealing rings, called annuli signatarum, signillares, cipographi or cipographae, is fast by ancient authors, were first invented by the Lacedemonians, who, not content to flout their churls, armories, &c. with keys, added seals to them; and to this end, at first they made use of worm-eaten wood, the impressions of which they stuck on wax, or soft earth; but they at length found the art of engraving figures, or rings, the impressions of which they took in the same manner. This, however, must be granted, that even in Moses's time, the art of engraving, not only on metals, but also on precious stones, was known.

Indeed, it does not appear that the ring had any other use among the primitive Jews besides ornament; but at length it was used to seal instruments, contracts, diplomas, letters, &c. instances of which we have in the first book of Kings, xvi. & Esther, viii. 10. Xenophon, Hellen. lib. i. Qunt. Cist. lib. vi. Just. lib. xiii. cap. iii. where we learn, the keeping of the emperor's seal was become a particular office. Lucan adds, that Alexander gave his seal to Perdicas, thereby appointing him his successor.

They observe, that in his time there were no seals used any where but in the Roman empire. At Rome, it seems, they were because of old-time custom, intended that a testament should roll with the testament, and the seals of seven witnesses; but it is certain appears that the Romans had no such thing as holy seals: nor that their seals and contracts were sealed, as is the custom in the times of the emperors.

In France the quality of this was, instead of signing their municipal acts, &c. by their seals, they signed from a box of their charters, which were not fixed at all; the rest of which was, that in those days very few people were able to write; hardly any body, indeed, could read and write but clerks:—the custom continued when learning made its way among them; though this reason for doing it had ceased.

In England, the first sealed charter we have extant is that of Edward the Confessor, upon the landing of Wulfran the Abbot; yet we read of seals in the MS. history of King Offa.

And Sir Edward Coke relies on the influence of King Edw. in the making use of a seal about a hundred years before the Conquest; though some have doubted the authenticity of this charter, because it is certain that sealing was not then in common use.

Before the time of William the Conqueror, the English did not seal with wax, but only made a golden cross in the parchment, and sometimes an impression on a piece of lead, which hung to the grant with a filken string, and was termed an abundant authorizing of the grant itself, without either signing or witness.

This practice of affixing the form of the cross proceeded from their inability to write; which is honestly avowed by Caedwalla, a Saxon king, at the end of one of his charters:—"propr. manu pro ignorantia litterarum signum facta, crucis expressi et subscripsi." The fame circumstance is related concerning the emperor Julian in the Eafi, and Theodone, king of the Goths, in Italy.

The colour of the wax with which William's grants were sealed, was usually green, to signify that the act continued for ever fresh; and of force. The usual impression on all laymen's seals, till the year 1218, was a man on horseback, with a sword in his hand; afterwards, they began to engrave their coats of arms on their seals; only the archbishops and bishops, by a decree of cardinals Ottone, who was legate here in 1237, were to bear in their seals their title, office, dignity, and even their proper names.

Du Ctehe observes, that none below the dignity of a knight had any right to a pendant seal, called authentica.

The emperors long sealed all their acts of importance with a golden seal; and the golden bull of Charles IV. for the election of an emperor, takes its name from the gold seal hanging to it, which is called bull.

The pope has two kinds of seals, the first used in apostolical briefs, and private letters, &c. called the fibermann's ring. This is a very large ring, on which is inscribed St. Peter drawing his net full of fishes.

The other is used in bulls, representing St. Peter's head on the right, of St. Paul on the left, with a cross between the two; on the reverse are sometimes the pope's name and arms.

The impressions of the first seal are taken in red wax; but those of the second, always in lead.

Theod. Hopper, a German lawyer, has furnished the world with a learned and curious work on the subject of seals, printed in 1642, at Nuremberg, in quarto, under the year.
SEA

title, "de Sigillorum prisco & novo Jure, Tractatus Practicus," &c. We have another work of the like kind by Heiniccius, in folio, printed at Frankfort and Leippic in 1709, under the title, "de Veteribus Germanorum alienum Nationem Sigillis, eorumque Usu & Praelationis, Syntagma Historicorum."

SAI is also used for the wax or lead, and the impression thereon, fixed to the thing sealed.

The manufacturers' seal, frequently applied to their stuffs, &c. is to be of lead. That of knights, by the French law, is to be of hard wax; that of agents, of soft wax.

Some seals are stamped on the paper or parchment itself, others hung by silk strings.

The French seal their edicts with green wax; arrets with yellow wax; expedients for Dauphiné with red wax. And the letters of the French academy are sealed with blue wax. See Wax.

Seal, Hermetrical. See Hermetical.

Seal, Lady's, in Botany, a species of Bryony.

Seal, Solomon's, or lily of the valley. See Convallaria.

Seal, in Zoology. See Phoca, and also Sea-Bear, and Sea-Calf.

Seal, Hair of, in Agriculture, is a substance made use of as a manure, in the way of top-dressing, in combination with rabbits' dung and lime, but which can seldom be provided in any sufficiently large quantity, nor is it found very beneficial for the purpose. See Manure.

Seal, in Geography, a small island near the coast of Donegal, Ireland, called in Arrow-smith's map Flasheedy; it is near the entrance of Strabaghy bay, and about four miles south of Malin Head.

Seal Island, an island near the S.W. coast of Nova Scotia. N. lat. 43° 25'. W. long. 66°.—Also, an island in the Atlantic, near the coast of Maine. N. lat. 43° 50'. W. long. 65° 40'.—Also, a small island W. of King George the Third's Sound, on the S. coast of New Holland; 3 miles N.W. of Baldhead.

Seal Islands, a cluster of small islands in the Atlantic, near the coast of Maine. N. lat. 44° 45'. W. long. 67° 46'.—Also, a cluster of small islands near the east coast of Labrador. N. lat. 53° 15'. W. long. 55° 10'.

Seal Key, a small island in the Spanish Main, near the Mosquito shore. N. lat. 12° 54'. W. long. 82° 40'.—See also Lobos.

Seal River, a river of North America, which runs into Hudson's bay.

Sealcote, a town of Hindooftan, in the country of Lahore; 50 miles N.N.E. of Lahore. N. lat. 31° 44'. E. long. 73° 50'.

Sealer, an officer in chancery, appointed by the lord chancellor, or keeper of the great seal, to seal the writs and instruments there made in his presence.

Sealing, in Architecture, the fixing of a piece of wood or iron in a wall, with plaster, mortar, cement, lead, or other solid binding.

For staples, hinges, and joints, plaster is very proper.

Sealing-Wax. See Wax.

Seam, or Same, in Rural Economy, a term applied to tallow, grease, hog's lard, before it is rendered and formed into lard, &c. in some places.

Seam, a term applied to a horse-load of three hundred weight. In Cornwall, a team of four weighs two hundred weight. The team also differs very much in the weight of different articles of other kinds. It likewise varies in different districts of the kingdom.

Seam, Monk's. See Monk.

Seam, Round, of a sail, is so called, because round like the common flem.

Seamen. See Mariners and Navy.

Seamer, in Geography, a river of England, in the county of York, which runs into the Ure.

Seamer's Lake, a lake in America, in the state of Vermont. N. lat. 44° 53'. W. long. 71° 55'.

Seamle, a town of Hindooftan, in the circar of Schaurnpourij; 36 miles S. of Schaurnpourij.

Sea Otter Sound, a bay on the W. coast of North America. N. lat. 55° 40'. W. long. 133° 45'.

Sea-Pye's Keys, a cluster of small islands in the gulf of Mexico. N. lat. 29° 56'. W. long. 89° 5'.

Seal, in Rural Economy, a term applied to dry or rotten wood, in opposition to that which is green.

Seara, in Geography, a town of Brazil, in the government of Marahoa. S. lat. 3° 30'. W. long. 39° 30'.

Searc. See Suer.

Search-Warrant, in Law, a kind of general warrant signed by justices of peace, for searching all suspected places for stolen goods; and there is a precedent in Dalton, requiring the confable to search all such suspected places, as he and the party complaining shall think convenient, but such practice is condemned by lord Halse, Mr. Hawkins, and the local authorities. However, in cases of a complaint, and oath made of goods stolen, and that the party suspects that the goods are in fuch house, and shews the cause of such suspicion, the justice may grant a warrant to search in those suspected places mentioned in his warrant, and to attach the goods, and the party in whose custody they are found, and bring them before him or some other justice, to give an account how he came by them, and to abide such order as to law shall appertain; which warrant should be directed to the constable, or other public officer, who may enter a suspected house and make search.

Searcher, an officer in the customs, whose business it is to search and examine ships outward bound, if they have any prohibited or uncustomed goods on board, &c. 12 Car. II. There are also searchers of leather, &c. See Alnager.

Searcher, in Artillery, an iron socket with branches, from four to eight in number, a little bent outwards with small points at their ends; to this socket is fixed a wooden handle, from eight to twelve feet long, of about an inch and a quarter diameter. This searcher is introduced into the gun, after it has been fired and turned round, in order to discover...
cover the cavities within; and after their distances are marked on the outside with chalk, they make use of another barbed instrument which has only one point, about which a mixture of wax and talcum is put, to take the impression of the holes; and if there are any a number of such deep, or of any considerable length, the gun is rejected as unsafe for the government. The gun is thus proved and searched twice.

SEARCHING, in Rural Economy, an implement used for boring in search for coals &c. See Borer.

SEARCHING, the operation of boring or sinking into the bowels of the earth, for the discovery of the different materials which it contains. For the detection of marbles, coals, or other similar substances, the use of the barren must be carefully avoided. But where difficulties are in performing it in this way, from the obstruction of stones, &c., a narrow shaft, such as a well, may, Mr. Marshall thinks, be carried down, without much expense, to the depths at which it can be wrought with advantage. See Borer and Marble.

SEARCHING of Neutral Ships, in Political Economy, a practice authorized by the law of nations, in order to prevent the exportation of contraband goods, or such commodities as are particularly useful in war, and the importation of which to an enemy is prohibited. Accordingly Vattel, and other writers of the same description, maintain that there is a right of searching. Some powerful nations have indeed at different times refused to submit to this. But what a neutral ship refusing to be searched, would from that proceeding alone be condemned as lawful prize. But to avoid inconveniences, there is, and every other irregularity, the manner of the search is settled in the treaties of navigation and commerce. According to the present custom, credit is to be given in certain cases and bills of lading, produced by the master of the ship, unless any fraud appear in them, or there be good reasons for suspecting their validity.

SEARCHING for the Stone, called also Founding, denotes, in Surgery, the operation of introducing a metallic instrument, named a found, through the urethra into the bladder, with a view of ascertaining whether a stone is really lodged there or not. In this manner, the surgeon actually makes the instrument strike against any calculus which may be present; and the collision produces such an impression on the fingers of the surgeon, and on the ears of every bystander, as leaves no doubt respecting the matter of the case. Sounding is in fact the only infallible way of learning that the bladder contains a stone. The symptoms of the complaint resemble those of several other diseases, and may deceive us (see Lithotomy); but when we both hear and feel the collision of the instrument against the calculus, we obtain that kind of information which does not admit of error.

The most advantageous posture for sounding is that, in which the patient reclines back upon a sofa, or couch. A chair of large size, with a back that can be made to fall backwards to a convenient distance, is sometimes used, and may be seen in most of our hospitals.

As the stone is generally situated at the lowest part of the bladder, the extremity of a found is usually not so curved as that of a catheter, in order that it may more easily touch anything situated immediately behind and below the neck of the bladder. The found is only a particular kind of probe, and as its chief use is to convey information through the medium of the organ of touch, its handle should be smooth and highly polished, so that as many points of its surface as possible may come into contact with the fingers.

The found is introduced exactly in the same manner as the silver catheter, either with the concavity or convexity of the instrument towards the abdomen. When the last method is preferred, as is the case when the patient is recumbent in the presence of the surgeon, it is to be kept in mind that the found is not to turn the concavity of the instrument towards the patient, previous to its passage through the membranous and prostate portions of the urethra. This is the case which the French surgeons have called "l'operation du banc." When the extremity of the found is in the bladder, it is to be pushed downward for the purpose of ascertaining whether the stone lies beneath its convexity, or as commonly the case where one is present. If the extraneous body should not be felt in this manner, the back of the instrument may be turned first to one side of the cavity of the bladder, then to the other. Should the calculus not be touched by these movements of the found, the instrument may be drawn forward, for the purpose of learning whether the stone is more anteriorly situated. Frequently the stone cannot be felt till the whole of the urine has been expelled, and the bladder has become contracted. Sometimes, the found may be made to lie the finger, by introducing the finger into the rectum, and thus bringing the extraneous body upward. In this way, the calculus may often be plainly felt by the finger.

We shall conclude this short article, with carefully cautioning surgeons never to perform lithotomy, unless they can distinctly feel the stone with the found, or touch, immediately before the operation.

SEAR-CLOTH, or Creecloth. The word fearcloth is supposed to be a corruption of cerecloth, and to be derived originally from the Greek σαρανθα, a world.

In Surgery, it denotes a form of external remedy, somewhat harder than an unguent, yet softer than an emplastro, though it is frequently used both for the one and the other.

The fearcloth is always supposed to have wax in its composition, which distinguishes it, and even denominates it. In effect, when a liniment or unguent has enough wax in it, it does not differ from a fearcloth.

Fearcloths are a kind of substances to friction, and are sometimes used for other purposes; the bell arc compound of resolvent drugs, as fenum, myrrh, and as, incorporated with wax and galls, as albanum, gum ammoniac, and fagapenum; the whole tempered with wine.

SEARSBURG, in Geography, a township of America, in Bennington county, Vermont; 12 miles E. of Bennington.

SEASE, Season, or Season, in a Shop. See Sease.

SEASONING, in Ship-Building, a term applied to a ship kept standing a certain time after she is completely timbered and dubbed out for planking, which should never be less than six months.

Seasoned timber or plank is such as has been cut down and converted, or felled out in one season at least, particularly when thoroughly dry, and not liable to shrink.

Seasoning of Timber. See Timber.

SEASONINGS, in the West Indies, a kind of ashen dillenmper, which foreigners are much subject to at their first coming.

SEASONS, in Cemography, certain portions or quarters of the year, distinguished by the signs which the sun then enters, or by the meridian altitudes of the sun; consequent on which, are different temperatures of the air, different works in tillage, &c.

The word is formed from the French saisons, which Menage derives from the Latin stas, whereas the Italians have formed stagioni; Nicot derives it from stasio, tempus stasines, following time.
The year is divided into four seasons, spring, summer, autumn, and winter; the beginnings and endings of each of which, see under its proper article.

It is to be observed, the seasons anciently began differently from what they now do; witness the old veris:

"Dat Clemens hymen; dat Petrus ver cathedratus; 
Æfniu a Urbanus; aautumnat Bartholomew."

SEAT, in Astronomy. See Scheat.

SEAT, in the Moneys, is the posture or situation of a horseman upon the saddle.

To seat a horse upon his branches or hip, see Put.

SEAT, in Ship-Building, the scarp or part trimmed out for a chock, &c. to lay to.

SEAT-Transom, that transom which is fayed and bolted to the stern-timbers, next above the deck-transom, at the height of the port-fills.

SEATING, that part of a floor which fays on the deadwood; and of a transom which fays against the poop.

SEATNESS, in Geography, a cape on the S.W. coast of Shetland. N. lat. 59° 46'. W. long. 1° 56'.

SEATON, a small sea-port town in the hundred of Colyton, county of Devon, England, is situated at the distance of three miles S. from Colyton, and 156 S.W. from London. This place is called Suetetone in Domesday book, and was undoubtedly the Moridunum of the Iter of Antoninus. Ridson fays it is "memorable for the Danish princes landing there in the year 937, as also for the attempt of the inhabitants of Colyton to make a haven there, which they had feomnly named Collyton haven, and procured a collection under the great feal of England for the levyng of money to eft the fame, of which work there remained no monument, only a remembrance of fuch a place among strangers that know not where it fands."

At presente Seaton is chiefly noted as a well frequented tea-bathing village. The church is an ancient building of free-stone, dedicated to St. Gregory, and contains a very elegant monument in memory of W. Walrond, esq. and his lady. According to the parliamentary returns of 1811, the parish of Seaton comprifed 323 houses, and 1524 inhabitants. The History of Devonshire, by the Rev. Richard Polwhele, three vols. folio, 1797. The Chorographical Description or Survey of the County of Devon, by Tritram Ridson, 8vo. 1714, 2d edit. with additions, 8vo. 1811.

SEATON, or Port Seaton, a small sea-port of Scotland, in the county of Haddington, in the Frith of Forth; 5 miles W.N.W. of Haddington. N. lat. 55° 58'. W. long. 3° 59'.

SEATON Nook, a cape of England, on the E. coast of the county of Durham, at the mouth of the Tees; 5 miles S.S.E. of Hartlepool.

SEATON Shakes, a fuiue which opens into the German fea, on the coast of the county of Northumberland.—Allo, a town of England, called "Seaton Delaval," in Northumberland, deriving its name from an artificial harbour constructed by Sir Ralph Delaval, in the 17th century; 10 miles N.E. of Newcastle. N. lat. 55° 6'.

SEATON, a river of England, which rifes near Leathward, and runs into the English Channel, three miles E. of Looe, in Cornwall.

SEAVES, in Rural Economy, a term used to signify rufhes, especially the loft rufhes.

SEAVY Ground, such ground as is covered or over-run with rufhes.

SEAVUM, in Geography, a town of Hindeoofan, in Lahore; 18 miles W. of Rahoon.

SEA-WOLVES ISLAND, an island in the gulf of St. Laurence, near the W. coast of Cape Breton. N. lat. 46° 21'. W. long. 61'.

SEBA, Albert, in Biography, a native of East Friesland, was by profession a druggist at Amsterdam, and a member of the Academy Naturalis Curiatorium. He published a descriptive catalogue, in Latin and French, of the vast collection of objects in natural history which he had brought together, in four vols. folio, illustrated with a great number of engravings. He likewise communicated several papers to the Ephem. Nat. Curiof.

SEBACA, in Geography. See Marindt.

SEBACEOUS GLANDS, in Anatomy, small glandular bodies in the skin, secreting the unctuous matter which covers the surface of the body. They are particularly manifest about the aiz of the nofe, and in the folds of the external ear. See Integuments, Ear, and Nose.

SEBACIC Acid, in Chemistry, is an acid produced from the decomposition of animal fat, particularly hog's-lard. The acid fumes which are evolved during the burning of fat at a heat short of inflammation, was formerly considered as a peculiar acid, which was called the acid of fat, and afterwards the febacic acid. From the experiments of Thenard it has since been proved not to be a peculiar acid, but the acetic acid digested with some other product of the decomposition. During these refearches, however, he found that by the dilution of tallow, he obtained an acid having peculiar properties, which he still called the febacic acid. "The following is the procefs he recommends. Dilift hog's-lard from a retort, by a heat which will decompose the fat; carbonic acid and carburetted hydrogen first come over, and a yellow fluid containing acetic acid, but fyll no febacic acid. This receiver muft now be removed, and a new one adapted; the heat being continued, an oily matter comes over of the confommee of butter. It is in this fubfance that the febacic acid is found. It is separated by firld boiling it in water, and evaporating the liquid till the febacic acid falls down in cryftals. This depofition is increased as the liquid cools. He alfo recommends, instead of getting the cryftals by evaporation, to add acetate of lead to the water in which the oily matter has been boiled; a falty precipitate is formed, which is the feton of lead, and which is to be well wafted and dried. When to this fubfance sulphuric acid is added, and heat applied, a fatty liquid floats on the top, which is to be collected; this being difloved in hot water, forms cryftals of pure febacic acid, which are deponited on cooling. The lard affords but a very small proportion of the acid. Rofe informs us that it requires a pound of lard to produce forty grains of acid.

Sebamic acid, thus obtained, is in the form of a cryftalline mass, of a white colour. It has no smell, but its tafe is agreeably four, and fightly bitter; like most other acids it changes fome vegetable blues to a red colour.

When heated, it melts like fat into a tranparent fluid, but on cooling it re-allumes its whitefens and its cryftalline form. It is fald to be volatile by heat, still retaining its properties, but a strong heat decomposes it.

It is sparingly foluble in cold water, and boiling water diffolves about one-fourth its weight; it affords cryftals on cooling, which are in the form of prifms. Alcohol diffolves it in considerable quantity. It is alfo foluble in oils. From the laft, and fome other properties, it bears a fharp refeonblance to the benzoic acid. This laft analogy has been pointed out by Berzelius. He found alfo that the farts formed by this acid have a fharp refeonblance to the benzoaet.

Thefe facts go far to fhew fo fharp an analogy between the two
two sides, as almost to establish their identity. See Ben- 
net, and

SEBACOOK, or SEBANA, in Geography, a pond or 
lake of America, in the state of Maine, equal in extent to 
two large two-masted ships, and covered with ice, from the 
N. W. by Sec. 4, T. 3, R. 11 W., in latitude 12°, 20' 
N., and longitude 70° 50' W., being a distance of 35 miles 
from N.W. to S.E.; 18 miles N.W. of Portland.

SEBAA, in Sasan, 1 a name adopted by Mr. Brown, 
from Dr. L. de l'Eclat's, a memory of Albert 
Seba, an apothecary of Amsterdam, who prepared a 
sketchy description, with plates of his own making, in four 
four folio volumes, which came out between the years 1734 and 
1765. The author indeed died in 1746, so that his three 
letters were published posthumously. Many Cape 
plants were here engraved, and several of them one of the perfect 
genus. Yet Seba does not deserve to rank as a scientific 
botanist; nor did Linnaeus, who knew him, and by whose 
recommendation he employed Artedi to arrange his figures, 
ever think him worthy to be commemorated in a genus. 
If, however, we compare him with numbers who have been 
so much more conspicuous, we will not appear to so much 
dishonour; for as a collector he stands rather high. Brown 
Prodr. Nov. Holl. v. 1. 451.—Claus and order, Tetrandria 

Gen. Ch. Cal. Perianth inferior, of one leaf, deeply 
divided into four ovate, acute, keeled, slightly spreading, 
segments, folding over each other at the base. 
Cor. of one petal, withering, salver-shaped; tube swelling, 
the length of the calyx, contracted at the upper part; limb 
in four deep, elliptical, spreading segments. Stam. 
Filaments four, thread-shaped, inserted into the tube, projecting 
out of its mouth; anthers erect, shorter than the limb, 
oblong, budling longitudinally, subsequently recurved and 
callosus at the tip. Peti. German superior, roundish, filling 
the tube; style thread-shaped, erect, the length of the 
filaments; stigma two, oblong. Peric. Capsule roundish, 
with a furrow at each side, comprised, of two cells and 
two valves, the length of the calyx; partitions from the 
inscribed margins of the valves, inserted into the edges of the large 
central receptacle, from which they finally separate. Seeds 
umerous, minute.

Obi. The flowers in some species are five-cleft.

Eff. Ch. Calyx deeply four-cleft, keeled. Corolla salver-
shaped, with an inflated tube. Anthers budling 
longitudinally; finally recurved and callosus at the point. 
Capsule with two furrows, two cells and many seeds; 
the partition from the inscribed margins of the valves. Stigmas two.

Mr. Brown has separated the present genus from Exacum, whose genuine species, according to him, are E. fijjile and 
pedunculatum of Linn. Sp. Pl. with which the albus and 
cardioatum of the Supplementum are, in the last-mentioned 
work, confounded. (See Exacum.) Perhaps also, as 
Mr. Brown conceives, E. punctatum of the last work may 
made a third, and a nonderivitum Ded India one in his 
pollination a fourth, species. He considers as essential to Exacum 
a leafless, deeply divided calyx; anthers without a callosus tip, 
bursting by a pore, or short slit, and continuing straight 
afters the flowers fade; style declining; an undivided stigma; 
and receptacle of the seeds connected with a partition 
originating from the middle of each valve.

1. S. albus. Whitish Sebaa. (Exacum albus; Linn. 
Suppl. 123. Wildd. Sp. Pl. v. 1. 674, but not E. pedun-
culatum, Sp. Pl. 163. Centauream subrotundata folio, 
floraibus comitis; Burm. Afr. 207. t. 74. f. 41; excluding 
the reference to Plukenet.)—Flowers in the upper forks of 
the stem fijjile.—Gathered by Thunberg, Sparrmann, and 
Vol. XXXII.

others at the Cape of Good Hope. The root is small, 
sclerotic, or five, at times, much broadened, 
reportedly in a. 1750, 1781, with four 4, 5, cari 
bead; supra, is slightly 
and slender, about 11. in length, the pedicels, 
2 centim. — In a second place, we add, that 
in the same island, but on the opposite side of the 
short, the flowers were large. We are 
remarkable publication. CH. 1. Such 
third, 
636. 4. (Exacum 
Willd. 
Vol. 
S. albus, 
Burm. 
Plukenet.

2. S. suavea. Yellow Sebaa. (Exacum suavea; Linn. 
Centauream suavea, floribus numerosis, xerophaac; Pl. h. Almag. 
t. 275. f. 3.)—All the flowers small. Gathered by 
Sparrmann, at the Cape of Good Hope. About half the 
size of the last in every part. Flowers yellow, 
borne each on a slender quadrangular stalk, even from the uppermost, 
as well as the lower, forks of the stem. Linn. 
636. 4. is evidently 
recalls Plukenet's figure, though he had originally, in Sp. 
Pl. cited that synonymously under his E. fijjile, 
a widely different plant. It is remarkable that he 
describes the calyx in the Supplement 23 of five leaves, whereas it 
has only four, as it ought, the corolla being five-cleft.

3. S. cordata. Heart-shaped Sebaa. (Exacum 
But not E. fijjile, Sp. Pl. 163. Gentianas exacondes; Linn. 
Sp. Pl. 332. Centauream perfoliatam, forum calyce mem-
branaceum ventriculos; Burm. Afr. 208. t. 74. f. 5. 
C. perfoliatum xerophaacum, floribus exiguis listercitibus, 
albus magnis quadrilateralibus crustis; Pluk. 
Almag. 94. t. 275. f. 4. "C. capnle minus, capsula 
quatuor alibi donata; Sp. Pl. v. 1. t. 22. f. 7.)— 
Flowers five-cleft. Segments of the calyx with a 
dilated, half-heart-shaped, veiny keel. Leaves heart-shaped.— 
Native of the Cape of Good Hope. The size and habit agree 
with the first species, but the flowers are larger, apparently 
yellow, with a longer tube, and five-cleft limb. Calyx 
distinguished by the dilated veiny keels of its segments, which 
are five, not (as Plukenet and Seba say,) four only. 
All the flowers have partial stalks, though shorter in the upper 
ones than the lower. The whole history of these three 
species, in the Supplement, was written by Linnaus 
himself, not by his son, who only described the fourth, Exacum 
pentatum.

ovoatam; Labill. Nov. Holl. v. 1. 38. f. 52.)— 
Flowers five-cleft. Segments of the calyx simply keeled. Leaves 
ovoatam.—Gathered by M. Labillardiere at Cape Van Diemen, 
and by Mr. Brown at Port Jackson, New South Wales. 
Taller and more slender than the foregoing, being about a 
span high. Such of the upper flowers, as grow from the 
forks of the stem, are nearly tellal, like those of S. albus. 
Segments of the calyx lanceolate, with a simple, not dilated, 
crenated with a small, short, five-cleft limb; nothing 
is recorded of its colour.

SEBAGENA, in Ancient Geography, a town of Cappa-
docia, in the prefecture of Cilicia. Proleny.

SEBAIA, in Geography, a town of Arabia, in the pro-
vince of Hedjes; 33 miles S. of Medina.
SEBAKET BADROH, i.e. the lake of king Baldwin, a narrow lake of Egypt, near the Mediterranean, about fifteen miles long; 2 miles E. of Catech.

SEBALA, a town of Arabia, in the province of Hadsjas; 27 miles S. of Medina.

SEBAMA, or SEBAR, in Ancient Geography, a town of Palmas, on the other side of the Jordan, in the tribe of Reuben, according to the book of Joshua.

SEBANZARRO, in Geography, a town of Abyllinia; 80 miles E.N.E. of Axum.

SEBAR, or CEBAR, in the Materia Medica, a name by which the Arabians call the *liquum abie*, or *aloe-wood*, a perfumed aromatic drug.

SEBARIMA, in Geography, one of the mouths of the river Oroonoco.

SEBASTACOOK, a river of America, in the state of Maine, which rises in lakes nearly N. from its mouth, and after receiving, in the windings, many tributary streams, joins the Kennebec at Taconsett Fall, where Fort Halifax was erected, in 1754; the fall is 18 miles from Fort Western, which was constructed in 1752. Its numerous streams abound with small fish.

SEBASTE', a miserable deserted village of Syria, the depopulated remains of Samaria, which acquired its new name in honour of Augustus Caesar; 34 miles N.N.E. of Jerusalem. See SAMARIA.

SEBASTE, in Ancient Geography, an island and town of Cilicia Propria, on the other side of the promontory of Corycus. Strabo says that this town was called Eleusa, and that Archelaus made it the place of his residence, when Augustus gave him Cilicia Trachea.—Alfo, a town of Afa Minor, in Phrygia.

SEBASTIAN, in Biography, king of Portugal, was the pollihumous son of the infant John, by Joanna, daughter of the emperor Charles V. He succeeded to the crown at three years of age, on the death of his grandfather, John III., in the year 1537. By his education he acquired an extravagant admiration for valourous exploit, and an enthusiastic zeal against all the foes of the Christian religion. Under the influence of this passion, he, at the age of twenty, undertook a sudden expedition to Africa, in which, however, he performed nothing of any importance; but availing himself of the application for aid of Muley Hamet, king of Fez and Morocco, who had been dispossessed of his crown by his uncle Muley Mochof, he resolved to renew the attempt against the Moorish monarch with all the force he could bring together.

In vain was he dissuaded from the enterprise; he was inaccessible to all admonitions. Having flippred his country of its military strength, and the flower of the nobility, he fell in the summer of 1578, and proceeded to Arzillia. There he was met by a much more numerous army, with Muley Mochof in person, who was fo debilitated by sickness that he was carried in a litter. In the battle that ensued, the onset of the Portuguese army was so furious that nothing could withstand them, and Muley, in rallying his men, was so much exhausted that he died in the attempt. Sebastian, who was not less dexterous in the use of arms than brave, fought till two horses were killed under him, and most of his attendants were slain by his side. At length, however, he disappeared, nor was it ever known, with any degree of certainty, what became of him, though a body, supposed to be his, was received as such from the Moors, and interred at Belem. But in a slaughter so dreadful, that not more than fifty of the Portuguese army are said to have escaped, it is no wonder that a single body, and probably flippred, should not be recognized. Such, however, was the attachment of the nation to a prince, whose romantic valour had revived in their minds the heroic times of Portugal, that they refused to give credit to his death, and long entertained the full expectation of seeing him return from his supposed concealment. Of this opinion many importers availed themselves, who allowed him character, and obtained a portion of respect due to their favourite sovereign; for more than a century it was believed that he would be again seated on his throne.

SEBASTIAN, St., in Geography, a town of Spain, and the most important of the district of Guipuscoa, situated on the coast of ancient Cantabria, now Biscay, between two arms of the sea, which form a peninsula of it, and at the mouth of the little river Urumea, or Gurumera, which was the Menaceum of the ancients. On the sea-side there is an eminence which serves as a dike. This town, flanked with bastions and half-moons, appears defended by a castle or citadel of little importance, placed upon an almost circular and tolerably high mountain, which is bare, without trees, almost smooth, and ascended by a spired road. St. Sebastian has a small harbour inclosed by two moleS, that leave a very confined space for the passage of ships, which are afterwards protected from the winds, on arriving at the bottom of an eminence of rocks which covers this harbour, where there is a large square tower; it holds at most five and twenty or thirty vessels. The town is very airy; it contains twenty streets, several of which are straight, long, and broad, and all paved with large smooth stones. There are from six hundred and fifty to seven hundred houses in it, and many of them are pleasant enough. It is the residence of the governor of the province, who had the title of captain-general until the beginning of the present century. It has a governor, a king's lieutenant, a major, an aide-major, a small garrison, and a naval academy; two parishes, and a third in the suburbs, which are very populous; two convents of monks, three convents of nuns, and an hospital. There are in this town and its suburbs five manufactories of hides and leather, some tanning-yards established in the faubourg St. Martin, a manufactuary of anchors for the royal navy in the faubourg of St. Catalina, and rope-walks, where cables are made.

Saint Sebastian has always carried on a considerable trade. In 1728, the Philippine company was formed by Philip V., with which that of the Caraccas was afterwards united. This company was very servile, as it procured for Spain a lucrative branch of trade, which was in the hands of the Dutch. In consequence, however, of mal-administration, and the loss of 1,500,000 piastres, which it sustained at the commencement of the war between England and America, this company sunk and was suppressed. However, a trade with the province of Caraccas was continued by private merchants from this port, and the cocoa, tobacco, and leather which are from thence imported, form no inconsiderable branch of trade with the interior and the other parts of Spain, and a still more important one with foreign countries. Hence its harbour is very much frequented by English, Dutch, French, and other ships. It receives the produce of foreign industry, and returns, in exchange, iron anchors, cables, leather, wool, and sometimes cotton. This trade attracts a considerable population to the town, which is estimated at 13,000 inhabitants.

The port of St. Sebastian, though free, is not what is called *abitato*. This word means a privilege to fend merchandise directly to America.

The environs of St. Sebastian are pleasant, though the soil is sandy; we enjoy at the same time a view of the sea and of the Pyrenees. Those who love the country, take pleasure in visiting the pleasant valley of Layola. We go...
SEBASTIAN, del Opo. See La Plata.

SEBASTIAN, St., or St. Sebastian, a town of the island of Tenerife, situated between mountains, about half a mile distant from the sea.

SEBASTIAN, St., or St. Sebastian, a town of Portugal, in Algarve; 6 miles N.W. of Loule.

SEBASTIAN, St., a town of Mexico, in the province of Chihuahua, on the Mazarra; 35 miles N.W. of Chihuahua. N. lat. 23° 34'. W. long. 106° 37'.—Alto, a small island in the Atlantic ocean, near the coast of Brazil. S. lat. 23° 45'.—Alte, a town of South America, in the province of St. Vincent, 10 miles W. of Los Reyes. Alto, a bay of the Indian sea, on the coast of Africa. S. lat. 32° 22'.—Alto, an island of Mexico, in Nayarit, with a town near the E. coast. N. lat. 11° 48'. W. long. 87° 5'.—Alto, a river of Mexico, which runs into the Pacific ocean, N. lat. 25° 20'.—Alto, a town on the E. coast of Guatamala, one of the Canary islands. N. lat. 25° 41'. E. long. 17° 12'.—Alto, a town of Terra Firma, on the E. side of the gulf of Darien.

SEBASTIAN, Cape St., the eastern point of the gulf of Darien, on the coast of the Spah Main, 10 leagues from the western point of Cape Tiburon. The city which formerly stood here has been abandoned, on account of its unhealthy situation. Alto, a cape on the coast of California. N. lat. 43° W. long. 107°. Alto, a cape on the N. coast of Madagascar. S. lat. 17° 20'. E. long. 54° 44'. Alto, a cape on the E. coast of Africa. S. lat. 22° E. long. 35° 20'. Alto, a cape of Spain, on the E. coast of Catalonia. N. lat. 51° 52'. E. long. 5° 0'.

SEBASTIAN, St. Louis, a town on the Mississippi, in the State of Missouri. N. lat. 39° 40'. E. long. 93° 31'.

SEBASTIAN, New, St., town of South Carolina. N. lat. 33° 40'. E. long. 81° 0'.

SEBASTIAN, Fort, St., at the mouth of the Mississippi, in the State of Louisiana. N. lat. 30° 40'. E. long. 90° 10'.

SEBASTIAN, New, St., town of South Carolina. N. lat. 33° 40'. E. long. 81° 0'.

SEBASTIAN, Castle, St., on the coast of South Carolina. N. lat. 33° 40'. E. long. 81° 0'.

SEBASTIAN, St., in the town of South Carolina. N. lat. 33° 40'. E. long. 81° 0'.

SEBASTIEN, St., See St. Sebastian.

SEBASTIAN, del Opo, See La Plata.

SEBASTIEN, St., a town of Portugal, in Algarve; 6 miles N.W. of Loule.

SEBASTIO, or Dionysius, in Ancient Geography, the name of one of the principal towns of that part of the Colchide which was to the right of the Phasis. Alto, a town of Asia Minor, in the Cappadocian Pontus, on the road from Pavia to Sebastia.

SEBASTOPOLIS, or Diumenias, in Ancient Geography, the name of one of the principal towns of that part of the Colchide which was to the right of the Phasis. Alto, a town of Asia Minor, in the Cappadocian Pontus, on the road from Pavia to Sebastia.

SEBASTOPOLE, in Geography. See SEBEATOPOLE.

SEBAT, in Chronology, the fifth month of the civil year of the Hebrews, and the eleventh of the ecclesiastical year, answering to part of our January and part of February.

SEBATS, in Chronology, a genius of fables, formed by the union of the Sibylline and the problematical sages. For an account of these, see the different fables: for instance, for lebt of him, see LIMUS; and so on for any other.

SEBBA Rous, or Seven Capes, in Geography, a cape or headland on the coast of Algiers, the vicinity of which is occupied by persons of a brutal and ferocious description, who live in caves scooped out of the rocks. Their people, called "Kabyles," rush in crowds to the coast when any vessel in distress, or in the course of sailing, approaches it, and vociferate their horrid wishes, that God would deliver it into their hands; and probably the name of "Boujore," or "Catamites," was first given by the Italian navigators to these capes, on account of the savage disposition of their inhabitants. N. lat. 37° 8'. E. long. 6° 32'.

SEBAH, a town of Africa, in the country of Fezzan, T 2 60 miles.
60 miles N. of Mourzouk. Here the large remains of an ancient castle, built upon a hill, and of other venerable ruins, that, in point of extent, are compared to those of Lebida, impress on the mind of the traveller the melancholy idea of departed greatness; while, on the other hand, the humble dwellings of the modern inhabitants, and the rich vegetation of their neighbouring fields, present to his eye an ample store of all that is requisite for the fulness of man. Dates, barley, Indian corn, pumpkins, cucumbers, fig-trees, pomegranates, and apricots, and for meaner purposes, the white thorn and Spanish bean, are described as but a part of the numerous vegetables that reward the industry of the people. The animals in which they most abound are the common fowl, and the brown long-haired and broad-tailed sheep. At the distance of two days' journey from Sebbah is "Goddoua," a town of similar produce; and in two days more the traveller arrives at Mourzouk.

SEBEDA, in Ancient Geography, a port of Lycaia, according to the Periplus of Arrian.

SEBEL, an Albanian name for the disorder of the eye usually called a pannus.

SEBEN, in Geography, a town of the bithropic of Brixen, on the site of an ancient town named "Sabiona," destroyed by Attila; eight miles S.W. of Brixen.

SEBENDUNUM, in Ancient Geography, a town in Spain, in the Tarragonensis, the country of the Castristani. The inhabitants were destroyed by the Salian Franks.

SEBENICO, in Geography, a sea-port town of Dalmatia, situated on the Kerka, near the Adriatic; one of the strongest towns on the coast, with a large harbour, defended by four citadels; erected into a bithropic in 1298. It is said that the city was founded by a number of banditti, who lived on the rock which is the present site of the castle, and who plundered any vessels that approached the coast. In the course of time they built some colleges, and encloosed them with a kind of palisades called "fibula," whence was formed Sebenico. The city was enlarged by an increase of robbers; and afterwards, when the ancient city of Scardon was destroyed, its inhabitants reftored to Sebenico. The inhabitants, oppressed by the king of Hungary, who was then sovereign of Dalmatia, surrendered themselves in 1412 to the republic of Venice. This city, whatever may have been its origin, is the most pleasantly situated of any in Dalmatia, and also the best built, containing the greatest number of noble families, next to Zara. On one side it is defended by a castle on a hill; and towards the sea, upon a narrow channel at the mouth of the harbour by another fort, a noble work of Sannichels, whose gate resembles that of Verona, by the same celebrated architect. Among the buildings of Sebenico, the dome or cathedral deferves particular notice, on account of its general fabric, and more especially of its roof, which is composed of large pieces of marble, connected together. In the sixteenth century the arts and sciences flourished here more than in any other city of Dalmatia. It has several buildings in good style of architecture, and it has produced many eminent men; 25 miles N.W. of Spalatro. N. lat. 44° 30'. E. long. 16° 15'.

SEBENNYTES NOMUS, in Ancient Geography, a name of Egypt, between the branches of the Nile, called the Pharnuthiac and Athribitic, and near their mouth. Ptolemy divides this nome into the Upper and Lower.

SEBENNYTICUM OSTIANUM, the name of one of the seven mouths of the Nile, E. of that called the Bolbitic. Ptolemy.

SEBENNYTUS, a town of Egypt, in the Delta, and capital of the Sebennytic nome.
Female, Calyx of four leaves. Corolla rose. Petals ten, filiform. Leaves many, S. subtile

1. S. fistulosa. In the botany of the Genesee, &c., E. A. Smith of the Clarke. Nature of the woods of China and Ceylon. A large tree, with spreading branches. In Asian countries, made into china, etc. Males as well as her malus lateralis, or male unferocious, thus: two, or three, or four.

Birch, oak, larch, tamarack, etc., may well be used for parks and borders. The branches and leaves extend a distance of 100 yards, and the fruit is easily reached by plowing or tilling, to an extent that it is as sure and durable. A great quantity of thick, white, paper is extracted from the bark of the male, as well as the paper of the female, but of a miserable kind.

We cannot further refer this account to any plant different from trees; and yet the tree should be well known in this country.

SEBINIKVAR, in Geography, a town of Transylvania; 6 & 8 S. of W. of Táj.

SEBIUS, or泗比), an Augean, in Geography, the name of a family which was distinguished at Strafsburg by the celebrity of the physicians whom it produced, and who were chiefly sacred to the professional chair in that city for the space of 134 years, without interruption, in the persons of four individuals only. The first, second, and fourth of these physicians were named Melchior; the third, John Albert; and all, with the exception of the first, succeeded their fathers in the chair. The first Melchior Sebius was, the son of George Sebius, a doctor of laws, and chamberlain of the duke of Châlons. Melchior Sebius was born in 1539, in Falkenburg, in Silesia, and was at first intended for the profession of the law; but in 1565 he changed his plans, and began the study of medicine. For this purpose, as was the custom of the times, he began his travels to different universities: he was at Montpellier in 1566, and three years afterwards went to Italy; and subsequently visited France, where he took the degree of doctor at Valence, in Dauphiné, in August 157. On his return to Germany, he practised his profession first at Hagenau; and having gone to Strafsburg in 1574, he determined to settle there. His talents soon raised him to the rank of professor, and he practised with great celebrity until his death, which took place in June 1625, in the eighty-sixth year of his age.

Sebius, Melchior, the son of the preceding, was born at Strafsburg in 1578. He began his education under his father, and is said to have studied in twenty-seven universities, among which he chose that of Bâle as the place of his graduation in 1610. So early as the year 1612, his reputation raised him to the professional chair, which his father resigned, or rather, perhaps, he became his father's colleague at that time. His increasing reputation obtained him the favour of the emperor Ferdinand II., who created him a count palatine in 1636. But no dignities could seduce him from the practice of his profession, or the duties of his chair, and during the space of sixty-two years, while he taught, and was rector of the faculty at Strafsburg, he examined one hundred and sixty-three candidates, and imposed the doctoral cap on fifty-five physicians. Enjoying uninterrupted health and a long life, never using spectacles, and suffering no infirmity except a slight deafness, he lived to the age of ninety-five, and died in January 1674. He was the author of numerous works, especially anecdotal dissertations, in which there is more learning than originality or discovery; whence Haller pronounced him "crudatus vita, perversus perennis experimentum." He wrote a pamphlet on the death of the title of his works.

SEBRETT, John Albert, fought for the Reformers, father, in the professional chair. He was educated at Oxford in 1645, and graduated in 1659 at the universities of Bâle, Montpellier, and Paris. In 1652 he was appointed to the position, and became within two years dean of the faculty. He died on the 16th of March, 1674, in the 71st year of his age. He was the author of four works in 4 vols. 8vo, and a treatise on "Eucharistic practices," relating to the eucharist in the head and church.

SEBEIN, Melchior, the son of John Albert, was born in 1664. After Bâle he went to Paris, then returned to Strafsburg, and took the degree of doctor in 1698; and in 1704 he received the title of professor. He held this office, however, but three years, and died in 1707, being at that time rector of the university. See also Del. H. de la Medecine.

SEBENITZ, in Geography, a town of Saxony, in the margravate of Mecklenburg. E. S. E. of Dr. B. N. lit. 50° lat. 59°. E. long. 14° 15'. Alto, a river of Saxony, which runs into the Peile, two m. N. of Scharnau.

SEBOIM, in Ancient Geography, the name of one of the four towns of the Pentapolis, which were enclosed by the city of heaven, with Sodom, Gomorrah, and Admah. Eusebius and Jerome speak of a town of this name which subsisted in their time, and which was situated on the western coast of the Dead Sea. The town must therefore have been rebuilt.

SEBOL, in Geography, a town of Hungary, in the province of Beszterce; 12 m. N. N.W. of Bécs.

SEBOO, or SeBO, a river of Africa, which passes by the city of Fez, and runs into the Atlantic a little below Marrakech.

SEBORZ, a town of Bohemia, in the circle of Boleau; 3 m. S.E. of Melnik.

SEBOU, a small island near the N.W. coast of Cape Breton.

SEBRAJEPOUR, a town of Bengal; 13 m. W. N.W. of Delhi. Alto, a town of Bengal; 13 m. S.E. of Koonda.

SEBRAIPA, in Ancient Geography, a town of the African Sarmatia, on the banks of the river Varusus. Profem.

SEBRITHITES, a name of Egypt, from which king Vaphres sent to Solomon 1000 men for building the temple, according to Eusebius.

SEBRUD, in Geography, a river of Persia, in the province of Khurasan, which runs into the Tigris, 6 m. S.E. of Zaweh.

SEBU. See SIBR.

SEBUH, a feast among the ancient Samaritans, when St. Ephraem accuses of changing the time expired in the law, for the celebration of the great annual feasts of the Jews.

Serrarius conjectures, that they were thus called from their celebrating the feast of the Pasch on the seventh month, called by the Hebrews יְבֵא, יְבֵא, week. Drusius rather takes them to have been denominated from שָׁבָא, the leader of a feast among the Samaritans. Scaliger derives the name from the Hebrews יְבֵא, week, because of its celebrating every second day of the seven weeks between Easter and Whitsun tide.

SEBUH.
SEBÚE, in Geography, a town of Abiylinia; 90 miles S. of Mina.

SEBUNTA, in Ancient Geography, a town situated in the interior of Arabia Petraea. Ptolemy.

SEBURAI, SEBURAI, a name which the Jews give to each of their rabbins or doctors, as lived and taught some time after the finishing of the Talmud.

The word is derived from יד, sařer, I think; whence יד, sařera, opinion, sentiment; and thence יד, sebar, or sebbar, opinatores.

The reason of this appellation, say the rabbins, is, that the Talmud being finished, published and received in all the feasts, and synagogues, these doctors had nothing to do but dispute for, and against, the Talmud, and its decisions. Others say, it was because their sentiment were not received as laws or decisions, as those of the Milkine and Gemaric doctors were; but were held as mere opinions.

Others, as the author of Schallhelethes Hakkabalah, or chain of tradition, tell us, that the perfections the Jews underwent in those times, not allowing them to teach quietly in their academies, they only propounded their opinion in the composition of the Milkine. The first and chief of the Seburai was R. Jofi, who began to teach in the year 787 of the era of contracts; which, according to R. David Gaultz, falls on the year of the world 4236, and, who, according to R. Abraham, was thirty-eight years president of the Jewish academy.

The era of contracts is the name with that of the Sebucide, the 787th year of which falls on the year of Christ 476, which, of consequence, is the era of the origin of the Seburai, whose reigns did not hold long: Buxtorf says, not above fifty years; R. Abraham, and others, say not fifty: The last of them was R. Simon. They were succeeded by the Gaons or Geonim.

SEBURG, in Geography, a town of France, in the department of the North 35 miles E. of Valenciennes.

SEBZAR, See Kesh.

SEBZVAR, a town of Persia, in the province of Khorasan; it was taken, in 1581, by Timur Bosc, but upon its revolting and being again reduced, he caused 9000 of the inhabitants to be piled in a heap, with mortar and bricks, and thus buried alive; 180 miles N.W. of Herat. N. lat. 36° 11'. E. long. 69° 14'.

SECA, LA, a town of Spain, in the province of Leon; 24 miles S.W. of Valladolid.

SECACUL, in the Materia Medica of the Ancients, a name given by Avicenna, Serapion, and others, to a root which was like ginger, and was brought from the East Indies, and used as a provocative to venery.

The interpreters of their works have rendered this word ingle, and hence some have supposed that our eryngium, or eryngos, was the root meant by it; but this does not appear to be the case on a strict enquiry, and there is some reason to believe that the famous root, at this time called gingfer, was what they meant.

SECALÉ, in Botany, a name in Pliny, which some etymologists, among whom is De Theis, derive from the Celtic gegal. This, he says, comes from gea, a sickle in the Latin language, and thence gea, the Latin appellation of all grain that is cut with a similar implement. Those who have looked no further for an etymology than the Latin geo, to cut or mow, have come to the same conclusion. —Rye. —Linn. Gen. 39. Schreb. 53. Willd. Sp. Pl. v. 1. 471. Mart. Mill. Dist. v. 4. Ait. Hort. Kew. v. 1. 178. Jull. 32. Lamarck Hilar. t. 49. Genr. t. 81.—Clafs and order, Triandra Digyna. Nat. Ord. Gramina.

Gen. Ch. Cal. Common receptacle toothed, elongated into a spike. Glume containing two flowers, and consisting of two opposite, ditant, erect, oblong, pointed valves, smaller than the corolla. Flores fertile. Cor. of two valves; the outermost hardest, tymid, pointed, compressed, fringed at the keel, and ending in a long awn; the inner flat, lanceolate. Nectary of two lanceolate, smooth, fringed scales, tymid on one side at the base. Stam. Filaments three, capillary, hanging out of the flower; anthers oblong, forked. Pfli. Gramen superior, turbinato; styles two, reflexed; stigma cylindrical, feathery. Peric. none, except the permanent corolla, which finally opens, and lets the seed escape. Sted solitary, oblong, somewhat cylindrical, naked, pointed. Ost. There is sometimes a third floret, scarcely perfect, forked, between the other two. It is very difficult to distinguish this genus from Triticum.

Edl. Ch. Calyx of two valves, solitary, two-flowered, on a toothed elongated receptacle.

1. S. circé. Cultivated Rye. Linn. Sp. Pl. 124. Wildl. n. 1. Ait. n. 1. Purv. v. 1. 90. Holt Gram. Auflr. v. 2. 35. t. 48. (Secale; Matthis. Vagr. v. 1. 364. Camer. Epit. 190. Ger. Ex. 68.)—Glumes of the calyx bordered with minute parallel teeth. —The native country of this, so generally cultivated, grain, is hardly to be guessed. Mr. Purv. says it frequently occurs, apparently wild, in North America, flowering in June. For its agricultural history, and mode of cultivation, see Rye. The root is fibrous and annual. Herbage somewhat glaucous. Stem jointed, slightly branched at the bottom, smooth. Leaves linear, rough towards the point. Spike terminal, erect, three or four inches long. Axena erecta, straight, rough, four or five times the length of the glumes.

2. S. villosum. Tufted Rye. Linn. Sp. Pl. 124. Wildl. n. 2. Sm. Fl. Græc. Sibth. v. 1. 77. t. 97. (Gramen spicatum ficalum, glumis villosis in arilis longifilis definitibus; Tourne. Infl. 518. G. ficalum maximum; Park. Theatr. 1144. G. ericinicum ficalum, glumis ciliariis; Tourne. Cor. 39. Buxb. Cent. 5. 21. t. 41.)—Glumes of the calyx wedge-shaped, abrupt, fringed with tufts of hairs.—Native of the south of Europe, and the Levant. Gathered by Dr. Sibthorp in the fields of Crete and Zante. The root is fibrous and annual. Stems numerous, erecta, twelve or eighteen inches high, leafy, smooth; their lower joints bent. Leaves spreading, flat, hairy on both sides, with soft smooth sheaths. Stipula very short, blunt, crenate. Spike about as long as the former, but twice as thick. Calyx bordered with remarkable tufts of fine hairs. This should seem to be cultivated in the above-mentioned islands, but we know nothing of its agricultural merits.

3. S. orientale. Dwarf Oriental Rye. Linn. Sp. Pl. 124. Wildl. n. 3. (Gramen orientale ficalum, spicâ brevi et latâ; Tourne. Cor. 49.)—Glumes of the calyx ovato-lanceolate, strongly ribbed, taper-pointed, hairy all over.—Native of the Archipelago, in a sandy soil. Root annual, with white downy fibres. Stems about six inches high, slender, smooth, often zigzag. Leaves linear, narrow; the upper one shorter, with a long, smooth, inlathed sheath. Spike hardly an inch long, thick and broad, composed of closely imbricated, two-ranked spikes, whose glumes are rigid, deeply furrowed, uniformly hairy, each tapering into a short, straight, rough point or awn, not so long as the glume itself.

4. S. etricum. Tall Cretan Rye. Linn. Sp. Pl. 125. Wildl. n. 4; excluding the synonym of Tournefort, which belongs to Hordeum bulbofum. (See Hordeum.)—"Glumes of the calyx externally fringed."—Native of Crete. Obf. We have never seen a specimen. Descientes affirms that this is distinct from Hordeum bulbofum of Linnaeus, his Seriacum, which
E. From Geography, That line... to another, or divides it into two parts. Sec. Line. &c.

The term AM (P. X. III. Geom. 4. 4.) denotes a tangent of the circle A D E, A, and cuts the circle in B. It is demonstrated by geometers : 1. That if several rays, M A, M N, M E, &c., be drawn from the same point M, that passing through the centre, M A, is the greatest; and the rest are all less than the half, as they are more remote from the centre. On the contrary, the rays of them without the circle M D, M O, M B, are to each other as the greater, as they are farther from the centre. The least is that of M A, which passes through the centre.

2. That if two lines, M A and M E, be drawn from the same point M, the secant M A will be to M E as M D to M B; or M E to M D, M A, M B is the square of a tangent to the circle drawn from the point of concurrence M.

The secant of the arc A H, which is the complement of the former arc to a quadrant, is called the co-secant, or secant of the complement.

The sine of an arc, A D, being given, to find the secant of F C, the rule is, as the co-fine D C is to the whole fine, so is the whole fine, or radius, A C, to the secant F C; or the secant is a third proportional to the co-fine and radius. See Sine.

To find the logarithm of the secant of any arc, the sine of the complement of the arc being given, multiply the logarithm of the whole line by two, and from the product subtract the logarithm of the line complement; the remainder is the logarithm of the secant. The reason of which operation is obvious; because

\[ \log D C = \log C F = \log E C. \]

From the nature of logarithms, twice the log. of E C = the log. of D C = the log. of C F.

**Secant.** Line of. Sec. Sector.

**Secans.** In Geography, a cluster of small islands in the Pacific ocean, near the coast of Vera Cruz. N. lat. 8° 20'. W. long. 83° 16'.

**Secatibas.** A town of Asiatic Turkey, in the province of Durrhakir; 75 miles S.W. of Moful.

**Secca.** A small island near the coast of Iliria. N. lat. 49° 52'. E. long. 14° 31'.

**Secche.** A small island near the coast of Iliria. N. lat. 45° 14'. E. long. 13° 45'.

**Secchia.** A river of Italy, which rises into the Po, at 3 miles N. of Quistello, in the duchy of Mantua.
SECEDES, formed from the Latin word secedo, to separate or withdraw, in Ecclesiastical History, an appellation comprehending those who are dissenters from the established church of Scotland. This kind of secession took place in the year 1727, when John Glass, disapproving every establishment of a national church, maintained that all churches ought to be congregational; or, in other words, that no general church should be formed for a nation, but that each religious society in a kingdom or state should be self-constituted, and controlled only by itself. For this and some other opinions he was suspended from his ministerial functions; and, for continued contumacy, deposed from the rank of minister, fut by the synod of Dundee, afterwards, viz. in 1730, by the general assembly of the Scots church. Perilling, however, in the propagation of his sentiments, both by preaching and writing, he formed several congregations, of which the most numerous was that of Dundee. The secession of Mr. Glass and of his immediate disciples was followed by that of several other divines, who, on different grounds, determined upon withdrawing from the establishment. The two brothers, Ralph and Ebenezer Erskine, enlisted, about the year 1730, in this number, and contributed very much to give reputation and influence to their cause. The seceding ministry alleged various infringements in the constitution of the kirk; but as they depaired of redress, they resolved to establish new congregations. They complained of the laws of patronage, and wished for a popular election of ministers; they pleaded that the right of protest against the proceedings of the assembly had been invaded, and that the rulers of the kirk not only acted arbitrarily, butuffered its doctrines to be corrupted. For the freedom of their animadversions on these points, four ministers were suspended from their parochial functions in 1733; and though they were reinstituted by the assembly in the following year, the ground of complaint remained, and they refused to rejoin the establishment. From the clergy and laity they gained an accession of strength, more particularly after they had published a second "Itinere of the Reasons of their Secession." Upon a citation to appear before the assembly, the jurisdiction of which they refused to acknowledge, they were debarred, in 1740, from the exercise of all clerical functions in the church, and excluded from all its emoluments. The Seceders are rigid Calvinists, strict and severe in their discipline, and somewhat zelote in their manners.

When the secession had formed three presbyteries, a division took place among them, in 1747, in consequence of an oath, which some of them deemed inconsistent with the sentiments avowed in their "Testimony." This was the ordinary oath of a burgher, in support of the true religion established by law. We cannot, said one party, called "Antiburghers," conscientiously honour with that appellation the establishment from which we have seceded; while the other members of the synod, denominated "Burghers," contended that the oath might safely be taken, as the religion of the state was full the true faith, though many of its offenible votaries had departed from its principles, or hoefely professed it. The Antiburghers prevailed in the contest, and obtained a vote, that the oath was incompatible with the testimony; and they even excommunicated the members by whom it was vindicated. This dispute long continued to maintain the separation of the Seceders in distinct synods. Of these two claus, the Antiburghers are said to be the most confined in their sentiments, and least disposed to associate with any other body of Christians.

Under this article we may mention another party in Scotland, who quitted the establishment, and assumed the title of the "Reformed Presbytery." Lamenting the defection of the national rulers, and the majority of the people, from the true principles of the reformation, a party of religious malecontents denounced all connection with the "reformation kirk," and under the guidance of Mac-Millan and Nairn, formed a seceding presbytery. By these ministers, others were selected for the same functions; and the secession has been continued to the present time. Besides the congregations of this complexion in North Britain, there are several in Ireland, and some in North America. The members profess to follow the scripture as their principal guide, and the ordinances of the Westminster assembly in the next place. They disapproved the high authority assumed by the state over the church of Christ, as the result of worldly policy, rather than a claim justified by the genuine spirit of religion. Yet they submit peaceably to the higher powers, and do not indulge in the clamours of sedition, or the murmurs of disaffection. Their public worship is conducted much in the same manner with that of the dissenters in South Britain.

Another considerable sect departed, in the year 1753, from the Seces establishment. A minister named Gilkiepe, who opposed the reception of a new minister, whose appointment was not agreeable to the majority of the inhabitants of Inverkeithing, was expelled from the church in which he officiated; and he was soon joined by others, who, like himself, wished pastors to be elected by the people; and they formed a congregation in Dunfermline. The "Presbytery of Relief," in allusion to the defined relief from the arbitrary rigour of the laws of patronage, was the denomination assumed by this body of seceders. More liberal than the generality of Presbyterians, they were willing to admit into their communion all those who seemed worthy of being called Christians, however they might differ with regard to particular points. Their congregations multiplied; and about the close of the last century, the allocation professed above fifty places of worship. Both classes of the "Seceders" and "Relief" include about 300 ministers, who are strict Presbyterians, though they secede or dissent from the established church of Scotland. Adams's Religious World displayed, vol. iii. Cooke's edition of Milhem's Ecc. Hist. vol. vi.

SECERRÆ, in Ancient Geography, a town of Spain, in the Tarragonensis, upon the route from the Pyrenees to Caftulo, between Aquae Voconiae, or Voconia, and Prætorium, according to the Itinerary of Antonine.

SECESPITA, among the Romans, a knife with a round ivory handle, adorned with gold and silver, which the flavens and priests used at sacrifices.

SECHELLES, in Geography, a cluster of rocky isles in the Indian sea, composed of a reddish granite, and generally low. On these are found some marine animals and vegetables, with different species of palm-trees. S. lat. 4° to 5°.

SECHES. See Secas.

SECHI, —, in Biography, an excellent performer on the hautbois, in the service of the elector of Bavaria, in 1772, who, if we had never heard Fischer, would have delighted us much more than the spirit of parallel would allow. However, in a duet with Rheiner, a performer of great merit on the bamboo, we were reminded of the two Bezazzis at Turin; for as their ingredients, so their genius and abilities seemed made for each other, there being a like correspondence in both.

SECHIEN, in Geography, a town of Perisia, in the province of Kerman, on the north coast of the Persian gulf; 141 miles S. of Sirjan.
SECHEIUM, in Romance, a name given by Dr. Patrick
Brown to this genus, and most probably derived from
the name of a fruit, the fruit being used in Jamaica to
fuel lamps. In this case, however, says professor Martyn,
it should have been called Scehium. — Brown, Jan. 355.
Dict. v. 4. 51, Lamarck Dict. v. 3. 65. — Cif

Gen. Ch. Male. Calyx tenuiflorus, of 5 leaves, tubu-
lar, ten half way down; tube bell-shaped, spreading;
segments of the limb large, flat, widely spread.
Calyx of one petal; tube the same size and figure of
the calyx, and adheres to it; limb divided into five, flat,
these parts, the segments, nearly twice as long as the calyx,
and much spreading. Nectary consisting of ten cavities in
the upper part of the tube of the corolla. Stam.
Filaments five, formed into an erect cylinder, five-cleft at the top, spreading;
anther one on the top of each filament, all the five
together forming a capsule, undulating, polliniferous
leaf. Female on the same plant. Caly. as in the male,
but placed on the germen, deciduous. Cor. 5 in the male,
but with larger cavities in the nectary. Pet. German, sepals,
leaves, ovate, five-furrowed; leaf cylindrical, erect,
the length of the calyx; stigma very large, peltate, reflexed,
five-cleft at the margin. Per. Apple very large, ovate,
turbinate, five-furrowed, theca, unequally gibbous at the top,
fruits with harmless prickles, one-celled above.
Seed foliolary, nearly ovate, flat or compressed, flabby,
obtuse at each end.

Nectary ten cavities. Filaments five, forming a cylinder.
Female, Calyx and Corolla as in the male. Style five-
cleft. Fruit minute, single-seeded.

Oec. 1150. (Sieges edulis; Jacq. Amer. 258. t. 163.) —
Native of the West Indies, where it flowers and fruits in
September. Root annual. Stem herbaceous, climbing or
premature, greatly divided, roundish, irregular, smooth,
theke. Leaves alternate, flat, angulate heart-shaped,
external, round-bent, toothed at the margin, rough on
the upper side, rough beneath, often a span long. Tendrils
opposite to the leaves, horizontally, very long. Flowers
mo
cocious, bell-shaped, yellow, scentless.

Jacquin informs us that the Chocho Vine is used by the
inhabitants of Cuba in their soups and puddings; and that
it is served up as a vegetable with boiled meats.

SECHURA, in Geography, a town of Peru, in the
province of Truxillo, and jurisdiction of Piura, situated
on the banks of the river Piura, about a league from the
Pacific ocean. The town contains about 200 houses, con-
structed of cane, and a handsome brick church. The inhabitants,
who are all Indians, compose nearly 500 families, and are
employed chiefly either in fishing or driving of mules. The
defence of Sechura is a waste of land, extending 30 leagues,
of difficult and dangerous passage; 180 miles N.W. of
Truxillo.

SECHIUM, among the Romans, a term used to signify
everthing the pears cut with the knife facipora, as the
Pom. placenta, &c.

lity of Han. 175; 7 miles W. of H. 3.

SECKENDORF, Freih. Linne, 1620-1698, a celebrated
German, was born in Saxony, near Nittenburg, in the year 1620. His father having attended
him to school, he was left chiefly to himself,
where he had the advantage of a few
books, and the tuition of a faithful master in the Latin tongue. At this period he began to study Latin, Greek, and
Hellenic languages; and still further to improve the studies of that age. He was four years
introduced to the court of Ulm, duke of Wurtemberg, where
he remained about a year, and the entitled him to the
studies at the academy of Göttingen. After two years, by
the assistance of a friend, succeeded to the studv of Stralau, which
was at that period celebrated for the charity of its professors;
and here he made such a rapid progress, that he surprised
in knowledge almost all his contemporaries.

1645 he returned to Erfurt, and resided near to
Gotha, where he met with a very warm reception from duke
Ernst. At this period he was found to have a taste for the study,
language, perhaps, not of eight languages, viz. the Lat., Gr., Hebr.
ues, French, Italian, Spanish, Danish, and Swedish. He had,
moreover, acquired a very deep insight into Old Testament
history, theology, philosophy, and feudal law, with
mathematical sciences. By these means, and a facility
rarely surpassed, he became not only a great translator,
but one of the brightest ornaments of the republic of letters.
At the end of two years the prince made him a gentleman of
his bed-chamber, and he was employed in various
important missions. In 1656 duke Ernst gave him the
management of a part of his revenues; and in the same year he
accepted the place of judge in the tribunal of Jesus,
which was conferred on him by the duke of Altenburg.
In 1663 he was nominated chancellor, a member of the
council of state, and director of the confabulary, and of
the chamber of justice. The labours attached to these offices
were too much for his strength was equal to, and in the follow-
ing year he resigned the greater part of them. After
this he was appointed by Maurice, duke of Sax-Zeitz,
to be his chancellor, and president of the ecclesiastical senate.

John George II., elector of Saxony, nominated him in
1669, to be one of his counsellors; and that he might
declare himself with more attention to this new office, he
required that which he held at Jena; for he was so strictly
conscientious, that he was ever cautious of undertaking
any thing that he did not believe he should be able to per-
form.

On the death of duke Ernst, he was held in no less esti-
uation by his son Frederic, who gave him an important
office; and in 1680 the duke of Altenburg entrusted him
with the management of a large part of his revenues.
He now found the interruption of his pressing up
private, reformed his employments, and in 1682 retired from public life.

After a residence of seven years on his country estate,
Frederic III., elector of Brandenburg, invited him to be
ecclesiastical counsellor; and soon after chancellor of the
university of Halle, which he had founded. He accepted
the offer, and removed to Halle in November 1692; but he
did not long enjoy his new offices, as death in a few months put
an end to his labours, having attained to his 65th year.
One of the most striking features in the character of Scken-
dorf was a rational and sincere piety, which was manifest
not only in his writings, but in the whole tenor of his life;
and to this mutual be ascribed his fidelity to his employers, and the uncommon probity which he displayed in the management of public affairs. He polished great acuteness and discernment, which enabled him to extricate himself from many embarrassments; and by his indefatigable application, he found means to arrange and go through labours, which would have overwhelmed almost any other person. His works are very numerous, but the most important and considerable is his "Commentary on Lutheranism," which was undertaken with the view of confuting Maimbourg. Duke Ernest had solicited him to write the History of the Reformation, or at least that part of it which related to Saxony; which, in 1682, he agreed to undertake. So highly were his talents esteemed, that as soon as his intention was known, most of the German princes opened to him their libraries and archives, and furnished him with such documents as might be useful to his project. A part of the work came out in 1698; but it was not till 1692 that the whole of it was given to the public, under the following title, "Commentarius Historicorum et Apologeticorum de Lutherismo, sive de Reformacione Religiosae ductu D. M. Lutheri in magna Germanica, alique Regionibus et speciatim in Saxonia recepta et stabilita," sec. 2 vols. fol. This work was received with great applause by the learned of all parties. Bayle, in speaking of it, says, "Whoever is desirous of being thoroughly acquainted with the history of that great man (Luther), needs only to read the extensive work of Seekendorf. It is, of its kind, one of the best books that have appeared for a long time."

Among the other works of Seekendorf, those most deserving of notice are, "The State of the Princes of Germany;" "A Defence of the Relation concerning Antoinette de Bourignon, or a Refutation of that female Fanatic;" "Historical and Apologetic Differentials on the Doctrine of Luther in regard to Mafs, published by Caspar Saggiaturius;" "The State of the Chriftians, in which Chrifiannes is examined in itself, and defended against Atheists." Gen. Biog.

SECKENHEIM, or SoHRENHEIM, in Geography, a town of the duchy of Baden; 4 miles E. of Manheim.

SECKER, THOMAS, in Biography, a celebrated archbishop of the church of England, was born in 1603, at Sibthorp, in Nottinghamshire. His father was a Protetant difenter, who lived upon a small paternal estate, and who was enabled to give his son an excellent education. He was first placed at a school at Chelfield, whence he was removed to an academy at Attercliffe, near Sheffield, intended for the education of young men designed for the ministry among difenters: after this, he was sent to a similar institution in the neighbourhood of Tewkbury. When he was about the age of 19, he had attained to a good knowledge of the classics, the Hebrew language, and of those branches of the mathematical sciences which were taught young men as preparatory to their studies in theology. From this time, till he was about 23 years of age, he pursued his theological course with great vigour; when, for some reasons with which we are unacquainted, he determined to abandon his plan and study physic, and after attending lectures two years in London, he went to Paris for farther improvement, and carried his attention to all the branches of medicine, including surgery and midwifery. During this period he kept up a close correspondence with Mr. (afterwards bishop) Butler, who had been a fellow-student at Tewkbury. His friend had already conformed, and persuaded Secker to follow his example, affuring him of the patronage of bishop Talbot. Secker now began to think seriously of those prospects which were held out to him in the established church. He was already amply provided with theological knowledge, and he had expressed a dissatisfaction with the divisions existing among the dissenters, and with the authority too frequently assumed by the heads of their congregations; he therefore closed with the invitation held out to him. It was thought right by his friends that he should have a degree from Oxford, with this view; and in order to expedite the process, he took the degree of M. D. at Leyden, in the year 1721, on which occasion he did himself great credit by a thesis which he delivered on the occasion, "De Medicina Statica." He then entered himself a gentleman-commoner of Exeter college, Oxford, and in a few months obtained the degree of B. A. in that university. He was ordained by Dr. Talbot, at that time bishop of Durham, and preached his first sermon in March, 1723. The prelate now took him into his family as chaplain, in which office he had Dr. Rundle for an associate. In 1724 he was presented to the valuable rectory of Houghton-le-Spring, in Durham; and being in a situation to maintain a family, he married the sister of Mr. Benfon, afterwards bishop of Gloucester; and Mrs. Talbot, the widow of the prelate, by whose advice Secker had conformed, came to live with Mr. and Mrs. Secker, from whom she received, to the end of life, the most affudious attentions, in return for the services he had received from her late husband.

Secker now set himself down seriously to the duties of a country rector; but the place in which he lived did not agree with the health of Mrs. Secker, and he exchanged Houghton for a prebend of Durham, with the rectory of Ryton. He continued to reside in the north till 1732, when, being nominated one of the chaplains of the king, he came to the metropolis, and in the following year he was presented with the rectory of St. James. Upon this occasion he went to Oxford, to take the degree of doctor of laws, not being of sufficient standing for that of divinity, when he preached what was denounced an act sermon, "On the Advantages and Duties of Academical Education," which was regarded as a master-piece of sound reasoning and good composition. It was printed at the desire of the heads of the houses, and passed through several editions; and the reputation derived from it was thought to be the principal means of his advancement to the episcopal bench, which took place in January, 1734—5, when he was consecrated bishop of Bristol, Dr. Benfon, his brother-in-law, being at the same time consecrated to the see of Gloucester. In his high office as prelate he exhibited the most striking proofs of a conscientious attention to all parts of his duty. He now delivered, twice a-week, in his parish church, a course of lectures on the church catechism, which were afterwards published, and which were generally regarded as admirably adapted to give a connected view of the principles of the Christian religion as profess'd by the church of England, and as established by law.

In 1737, Dr. Secker was translated to the see of Oxford, which he held more than twenty years, and no one could perform with greater affability and earnestness the essential duties of his function; his exterior deportment likewise was grave, dignified, and perfectly adapted to the importance of the character which he maintained. In 1748, Mrs. Secker died, leaving no issue, and the bishop did not marry again. In 1750 he exchanged his prebend of Durham and rectory of St. James for the deanship of St. Paul's; and in 1758 he was raised to the archbishopric of Canterbury. His original education among the dissenters did not render him less zealous in the interests of the church to which he had conformed: he even went farther than most of his contemporaries.
Ozanam, but if the one auntil Kirlrotl W. Uf* (own town J. Ihr cilr, oratory leaturr, Ihr 'I friidnefs name; a uj, to the the 1768, -la Tlir they Latin the 4 the Voltoii, and put ftiiirr frirr hour, cxtnliTr Orography, nearly the On The of Irvc*r! 1 and uf&. Of a worms, cient Candidates and those on those to the political party in which he exerted his chief degree. He bellowed in the project to further our Canada.

During the time that archbishop Secker held his high per- performer, the Methodists made very rapid strides in the propagation of their principles: some of the bishops had declared against them; but Dr. Secker acted with his usual prudence, and recommended to his clergy moderation and kindness in their behaviour towards those whom he wished to consider as his future friends, but whom others were disposed to treat as enemies.

The archbishop had for many years been a great sufferer from the coast, which latterly brought on severe local pains. They were at first confined to the thigh, and terminated in an extensive caries of the thigh-bone; one of the fatal consequences of which was a sudden fracture of that bone upon the mere raising him up on his couch. Shortly after this he died, Aug. 3, 1768, in the 75th year of his age.

To the many benefactions for useful and charitable pur- poses which he bestowed in his lifetime, he made large additions by his will. Besides his "Lectures on the Church Catechism," he was author of "Eight Charges delivered to the Clergy of the Dioceses of Oxford and Canterbury; with Instructusions to Candidates for Orders, and a Latin Speech, intended to have been made at the opening of the Convocation in 1761;" "Fourteen Sermons, preached on several Occasions;" and "Sermons on several Subjects," in four volumes, published after his death by his chaplains, Drs. Porteus and Stinton. The various works of this able prelate have established his character as one of the most useful and rational preachers among the English divines.

Their style is simple and without ornament: they have no pretence to oratory and fine writing; but they display more knowledge of the human heart, and the real motives of action, than is usually found in those kinds of compositions. They are truly didactic, and "come home to men's businesfs and bofoms" in a remarkable degree.

He was attached to those political principles which placed the house of Hanover on the throne; and on the breaking out of the rebellion in 1745, he exerted himself most con- spicuously in support of government. He enlisted himself under the banner of no flat party; but his chief parlia- mentary connections were with the duke of Newcastle and lord Hardwice. Life of Secker, prefixed to his Sermons.

SECKINGEN, in Geography, a town of Baden, on the Rhine, the waters of which surround it; 4 miles W. of Laufenburg. N. lat. 47° 34'; E. long. 8°.

SECKVELT, a town of the flate of Utrecht; 13 miles W. of Utrecht.

SECLA, a name by which some authors have called wormwood.

SECLIN, in Geography, a town of France, in the de- partment of the North, and chief place of a canton, in the district of Lille; 4 miles S. of Lille. The place contains 2500, and the canton 18,579 inhabitants, on a territory of 1244 kilometres, in 26 communes.

SECO, a town of Africa, in Karto; 65 miles N. of Kenne. - Alto, a river of Peru, which rises on the Pacific side, S. lat. 7° 6'.

SECOANU, in Asia, Geography, a town of Afghanistan, Syria, mentioned in the mountains, S. of the Mediter- ranean, and W. of the river Orontes, in the territory of Apam.

SECOMBI, in Europe and Asia, the name of a genus of plants of the class of the Jepami; the characters of which are, that they are herbs of a decumbent habit, divided into parts, or portions of a spiral manner, into several smaller or his regular portions, of a moderately fine texture, not giving fire with flesh, but forming with and matters, and easily calcining.

The tepretan of this genus are, of all others, the most common, and are what have been known by the little expor- tive, or in a manner, the common name of the common vein, or dumb Holmsen. We have many species of these bodies coming among us. Of the whitish or brownish kinds we have thirteen; of the yellowish, five; and of the ferruginous ones, four.

SECOND, in Anatomy. See Secondi generi.

SECOND, in Geometry, Astronomy, &c., the sixteenth part of a prime, or minute; either in the division of circles, or in the measure of time.

A degree, and an hour, arc each divided into sixty minutes, marked thus '; a minute is subdivided into sixty seconds, marked thus ; a second into sixty thirds, marked thus ; &c.

We sometimes say, a second minute, a third minute, &c. but more usually, simply, second, third, &c.

A pendulum, three feet three inches and two-twentieths of an inch long, vibrates seconds, according to Sir Jonas Moore's reduction of Huygens, three feet eight and a half of Paris measure to English measure. See Pendulum.

Second, in Music, denotes one of the musical intervals; being only the distance between any found, and the next found, whether higher or lower.

As in the compass of a tone there are reckoned nine sensible different sounds, which form those little intervals called commas, one might in strictness say there are eight kinds of sounds.

There are three kinds of seconds occurring in practice, the lesser, the greater, and the superfluous second; to which, if the enharmonic genus were reformed, we might add the diminished second. The lesser second is the teton major, and is nearly equal to five commas. The greater second is the tone, which being either major or minor, there must also be two great seconds; one nearly equal to five commas, and the other to nine commas; but practitioners usually found these two. The superfluous second is a tone major, and femitone major; the other superfluous second, arising from the tone minor, and femitone minor, is not in use. Lastly, the diminished second is a femitone minor less than the lesser second; that is, equal to the diatonic interval. Thus, between E and F, or between A and B, would be a diminished second, as also between G sharp and A. This last has been practised by Mr. Handel, in the oratorio of Samp- ton, in the second part of the song, to Return, return, O God of Hosts." See Interval.

Some authors, as Ozenan, call the femitone minor by the name of diminished second, but this is contrary to the analogy in like cases, where diminished is usually applied to intervals a femitone minor less than a true diatonic interval.
Thus the diminished seventh is a semitone minor less than the flat seventh, or seventh minor.

SECOND, Diminished. See DIMINISHED SECOND.

SECOND de l’Oreille, in Anatomy, a name given by Vieuftens and others to a muscle of the ear, called by Cowper and others fistulaceus, and fistulida muscleus; and by Albinus fistulidus. Winiflow calls it the muscle of the petriou.

SECOND Captain. See CAPTAIN.

SECOND Cause. See CAUSE AND EFFICIENT.

SECOND Deliverance, Secundo deliberation in Law, a judicial writ that lies after nonuit of the plaintiff in replevin, and a return bakado of the cattle replevied, adjudged to him that distrained them; commanding the sheriff to repley the same cattle again, upon security given by the plaintiff in the replevin for the re-delivery of them, if the diftreb be justified. It is a second writ of replevin, &c. F. N. B. 68.

SECOND Flank, Notion, Order of Curves, Rate. See the substantives.

SECOND Sight, an odd qualification, which many of the inhabitants of the Western islands of Scotland are said to be possessed of. The thing is attested by many credible authors (among whom is Mr. Martin, author of the natural history of these islands, and a member of the Royal Society); and, notwithstanding the strangeness of it, many have fledfully believed it.

The second sight is said to be a faculty of seeing things to come, or things done at a great distance, represented to the imagination as if actually visible and present.

Thus, if a man be dying, or about to die, his image, it is pretended, shall appear distinctly in its natural shape, in a shroud, with other funeral apparatus, to a second-frightened person, who, perhaps, never saw his face before; immediately after which, the person fo seen certainly dies.

The quality of second-frighteneds, they say, is not hereditary; the person who has it cannot exert it at pleasure; nor can he prevent it, or communicate it to another; but it comes on him involuntarily, and excrcises itself on him arbitrarily; and often, especially in the younger second seers, to their great trouble and terror.

There is a great number of circumstances said to attend these visions; by observation of which, the particular circumstances, as to time, place, &c. of the death of the person, &c. are learnt. The method of judging of them, or interpreting them, grows into a kind of art; which is very different in different persons. Second-frightened is held a discredit in the country; so that none, they say, will counterfeit it; but that many conceal and dissemble it. See Johnson’s Journey to the Western Islands of Scotland, p. 248, &c.

SECOND Surcharge, Writ of, in Law. See SURCHARGE.

SECOND Terms, in Algebra, those where the unknown quantity has a degree of power less than it has in the term where it is raised to the highest.

The art of throwing these second terms out of an equation; that is, of forming a new equation, where they have no place, is one of the most ingenious and useful inventions in all algebra.

SECOND Title. See TITLE.

SECONDARY, or SECONDARY, an officer who acts as secon, or next to the chief officer.

Such are the seconday of the courts of king’s bench and common pleas; the seconday of the compters, who are next the sheriffs of London in each of the two compters; two secondays of the pipe; secondays to the reembrancers, &c.

Secondary is more frequently used in an adjective sense, by way of opposition to primary, or principal.

SECONDARY ADORS. See ACTORS.

SECONDARY AFFECTIONS. See AFFECTIONS.

SECONDARY Circles of the Ecliptic, are circles of longitude of the stars; or circles which, passing through the poles of the ecliptic, are at right angles to the ecliptic. See CIRCLES OF LATITUDE.

By the help of these, all points in the heavens are referred to the ecliptic; that is, any star, planet, or other phenomenon, is understood to be in that point of the ecliptic, which is cut by the secondary semicircle, which passes through such star, or phenomenon.

If two stars be thus referred to the same point of the ecliptic, they are said to be in conjunction; if in opposite points, they are said to be in opposition; if they be referred to two points at a quadrant’s distance, they are said to be in a quadril aspect; if the points differ a sixth part of the ecliptic, they are said to be in sextile aspect.

In the general, all circles which intersect one of the six greater circles of the sphere at right angles, may be called secondary circles. As the azimuth or vertical circles in respect of the horizon, &c. the meridian in respect of the equator, &c.

SECONDARY COLATERAL POINTS. See COLATERAL.

SECONDARY CONVEYANCES, in Law. See DERIVATIVE.

SECONDARY DIOLS. See DIAL.

SECONDARY FEVER, is that which arises after a crifis, or the discharge of some morbid matter; as after the declension of the small-pox, or mealls. See FEVER, SMALL-POX, &c.

SECONDARY Motion. See Motion.

SECONDARY PLACE. See PLACE.

SECONDARY PLANETS, those moving round other planets as the centres of their motion, and along with them round the sun. See PLANET.

SECONDARY QUALITIES, RAINBOW. See the substantives.

SECONDARY USE, in Law. See USE.

SECONDIGNY, in Geography, a town of France, in the department of the Two Seves, and chief place of a canton, in the dilliric of Parthenay; 6 miles W.S.W. of Parthenay. The place contains 1405, and the canton 6140 inhabitants, on a territory of 172½ square leagues, in seven communes.

SECONDINE. See SECUNDINE.

SECORA, in Geography, one of the branches of the river Darsh, which joins the main stream at Timiskilt.

SECOTAN, a town of Candahar; 150 miles S. E. of Candahar.

SECOUSE, DENYS-FRANÇOIS, in Biography, was born at Paris in 1691. He was one of the earliest pupils of the celebrated Rollin, and being brought up to the bar, he was for some time a pleader. This profession, however, he quitted in order that he might devote himself entirely to literature, in which the study of French history was his principal object. In 1723 he was admitted into the Academy of Inscriptions and Belles Lettres. The office of censor-royal was conferred upon him, and he was appointed, in 1746, to examine the public documents preferred in the newly conquered towns of the Low Countries. He died at Paris in 1754. His publications were, the Collection of Royal Ordonnances, from the second to the ninth volume inclusive; “Mémoires pour servir à l’Histoire de Charles le Mauvais,” two vols. 4to.; an edition of the “Mémoires de Condé,” six vols. 4to., in conjunction with the abbé Lenglet, and several dissertations in the “Mémoires de l’Académie des Inscriptions.”

SECOZANO, in Geography, a town of the county of Tyrol; 13 miles N.N.E. of Trent.

SECRETARIUM, among the Romans, a reclusiae room, where
The secretaries of state have the custody of that seal, properly called the signet, and the direction of the great office; in which there are four chief clerks and three deputies employed, who prepare all things as to pass the signet, in order to the pry or great seal. All grants, signed by the king, are returned thereto, which, transferred, are carried to one of the principal secretaries of state, and sealed, and then called dispatches; which, being directed to the lord privy-seal, are his warrant.

On the secretaries of state is likewise dependent another office, called the paper office; in which all public proceedings, papers, matters of state, &c. are preferred.

All the under secretaries and clerks are in the choice of the secretary of state, without reference to any person; the under secretaries receive orders and directions from them, for writing dispatches, foreign or domestic, which they give to the chief clerk, who distributes them to the under clerks.

The secretary at war belongs to the war-office, and has under him a deputy secretary, with his private secretary, and a number of clerks and other officers.

SECRETARY OF AN EMBASSY, is a person attending an ambassador, for the writing of dispatches relating to the negotiation.

There is a great difference between the secretary of the embassy, and the ambassador's secretary; the last is a domestic, or mental of the ambassador's; the first a servant, or minister of the prince.

SECRETION, in Physiognomy, is that vital procex, in which some substance, either designed to answer a purpose in the animal economy, or to be thrown out of the body as useless or injurious, is separated from the blood by an organ of glandular structure. It agrees with nutrition, with the exhalations from the skin, membranes, adipous and lymphatic cells, in being the separation of something from the blood; but it is distinguished from these processes by the circumstance of its being performed by glands. The word secretion however is often used more loosely by medical writers, in application to any living process, by which matters are separated from the blood. The organic structures, in which secretions are carried on, the material agents of these processes, and the powers by which they are executed, are considered under the article GLAND.

SECT, two collective terms, comprehending all such as follow the doctrines, or opinions, of some famous divine, philosopher, &c. For the scriptural meaning of the term sect, see HEResy.

The sects of philosophers among the ancients, particularly in Greece, were numerous: as the Pyrrhonians, Platonists, Epicureans, Stoics, Peripatetics, Academics, &c. See each under its proper article.

In later times, the sects of philosophy have been chiefly reducible to three; viz. the Cartesians, Peripatetics, and Newtonians. See Cartesian, &c.

In theology, the sects are much more numerous; yet the ancients had many legions, now extinct; as Machinists, Gnostics, Montanists, &c.

The principal now on foot are the Lutherans, Calvinists, Anabaptists, Arrians, Socinians, Arminians, and Unitarians. The rife, progress, and fate, with the distinguishing characters and opinions of each, see under LUTHERAN, CALVINIST, &c.

SECT, Ionic. See IONIC.

SECT, Hellenic. See HELLENIC.

SECTS OF HINDOOS. It has been long known that the Hindoos are divided and subdivided into a number of sects, tribes, or calls. Under our articles BRACHMANS, CAST, and GENTOOS, we have given the substance of what has been communicated.
SECTS OF HINDOOS.

Communicated by early and later travellers to eastern regions on the subject of these distinctions. In common with these writers, we have also used the term cafia, or cafie, though we are not aware of any classical authority for the word. We are disposed to think it introduced by the Portuguese; and it is now, and has been for many years, as common in the mouths of natives as of Europeans, especially on the coast of Coromandel. We do not affirm that the word is not of Sasanian origin, and in truth it sounds very like it: but we have never met with the word in eastern writings, nor heard it used by natives beyond the reach of European colloquial influence.

In considering the division and subdivision of the numerous race of Hindoos, we are disposed to separate them into theological, civil, and philosophical classes or tribes. Theologically we find two grand divisions, the Saivas, who worship Siva, and the Vaishnavas, who worship Vishnu: these are numerously subdivided, as we shall notice presently, as are the many sects which essentially or trivially differ from both, and are probably numerically equal to both, under the general denomination of Buddhists or Baudhins, and various specific varieties. The civil grand divisions are four, viz. Brahman, Kshatriya, Vaisya, and Sudra. As the two former theological grand divisions comprise the whole race of Hindoos (leaving for the present the sects into which the Saivites have divided themselves), so do likewise these four civil tribes or grand divisions: either of the four may be theoretically a Saiva or a Vaishnava, as his parents may have taught, or his feelings led him. These four civil grand divisions are subdivided into almost innumerable distinctions and varieties. Here follows a brief outline of the distinctions of these four great civil tribes.

1. Brahman. This is a small tribe in point of number; but in power paramount. Intellectual is power; and, with a few exceptions, the intellectual wealth of India is confined to the Brahmanical treasury. As among the Jews all priests were taken from the tribe of Levi, so with the Hindoos the tribe of Brahman exclusively furnishes the priesthood. All Hindoos priests are therefore Brahmins, but all Brahmins are not priests. Ministers and public officers of state are very commonly Brahmins, even in Mahomedan governments; and they are occasionally merchants, and even soldiers. In both the British and native armies of India, are many Brahmins. The two Maharrat generals whose names are best known in England, Purfemaran Bhan and Hurry Punt, were both Brahmins. A Brahman is pointedly prohibited from becoming a king: royalty appertains to the second tribe. (See Peshwa.) In the Gita, a work profoundly venerated by numerous sects, the duties of the four tribes are very concisely and plainly stated. "The natural duty of the Brahman is peace, self-restraint, zeal, purity, patience, rectitude, wisdom, learning, and theology," Gita, p. 130. (See Mahabarata.)

2. Kshatriya, usually pronounced Keri, or Kheri, is the second civil grand division. It is the warrior tribe; comprising all soldiers, who alone can lawfully become kings. (See Peshwa.) All the other tribes, however, furnish soldiers; and, indeed, princes too, if the ambitious individual can effect it. "The natural duties of the Kshatri are bravery, glory, fortitude, rectitude, not to flee from the field, generosity, and princely conduct." (Gita, ib.)

This grand division is very numerous. Some hundreds of different sects might be enumerated as belonging to it, and many hundreds would still be omitted. The Ayin Akerly flates, (vol. iii. p. 87. Calcutta ed.) that of the tribe of Kshatri, there are upwards of five hundred subdivisions, fifty-two of whom are in Europe, and twelve particularly so. Of one of these subdivisions, that of Rajput, the same authority says there are upwards of a thousand different sects. The term Rajput, or rather Rajaputra, means offspring of kings: a title assumed by various warrior tribes in the north of India; individuals of which are pretty numenously spread in the southern and other provinces, wherever good pay invites their services.

3. Vaisya, vulgarly called Vai, or Blye, is the tribe next in rank to the military. This is a very numerous tribe, comprising merchants, traders, and cultivators. In this, that is, practising its avocations, are found many individuals of the three other. "The natural duty of the Vaiya is," according to the Gita, "to cultivate the land, tend the cattle, and buy and sell." (Ibid.) This tribe is numerously subdivided like the others. It contains a great proportion of wealthy individuals. The subdivision of Varna, or Bania, called by the English Banya, belongs to this class, and has been comprehended eighty-four different sects: it being only itself a tribe of this third grand division, or of Vaiya.

4. Sudra. In this is comprised mechanics, artisans, and labourers of every description. In the protection of the Sudras' avocations, individuals of the leonid and third tribes or classes will be found; and occasionally, though comparatively but rarely, of the first. Many mechanics and artisans are of the third class. "The natural duty of the Sudra is servitude," Gita.

This arrangement into castes or sects, tribes or grand divisions, is, as before noticed, of very early origin. In the Institutes of Menu, (see Menu) we find it laid down as of the remote antiquity; and, as is usual with every thing relating to the Hindoos, traced to a mythological source. "That the human race might be multiplied, he (the supreme lord, or Brahma) caufed the Brahman, the Kshatriya, the Vaiya, and the Sudra, (so named from the scriptures, protecting, wealth, and labour,) to proceed from his mouth, his arm, his thigh, and his foot." Ch. i. v. 31.

In early times it is probable that these distinctions of castes were kept up and observed with considerable strictness, both in respect to intermarriages and avocations. These times were, however, anterior to the Institutes of Menu, who gives names to the spurious offspring of sectarian intermarriage; wisely endeavouring to correct, what his authority would prove unequal to prevent, or materially restrain. Denunciations, however, against these illicit practices, sexual and handicraft, abound in the books of law; and absolution from the sin thus incurred is doubted even, and
SECTS OF HINDOOS.

The principal sects are distinguished who worship exclusively as deities. Three are: The Siva, who worship Siva. 1. The Vishnu, who worship Visnu. 2. The Shakti, who worship Devi. 3. The Satea, who worship Parvati. 4. The Ganesa, who worship Ganapati. 5. The Siva, who worship Siva. But if we examine closely the relation which they respectively bear to each other, we shall find the fourth and fifth to be ramifications of the first, or sect of Siva; of which may be traced these distinctions. 1. Siva himself, generally supposed to include both the worshippers of Siva only, or of Brahma and Parvati jointly. (See Siva.) 2. Linga, the adorer of Siva under his phallic emblem called Linga. (See Linga and Siva.) 3. Sakti, the adorer of Parvati, under her symbol the Yoni. (See Sake and Yoni.) 4. The Ganapatias, worshippers of Ganesa, son of Parvati and Siva. (See Polleman.) These four sects, and many divisions and sects of them, may be deemed as comphended in the first named, Siva, or Sivaibakt. The worshippers of Baghesa, or Siva, are sometimes called Soma Suddhanta.

The second great sect of Vaihna is also variously divided and subdivided. Two principal divisions or branches are the Gokulavis and Ramavir, or worshippers of Visnu, in two of whose grand incarnations of Krihna (one of whose names is Gokul), and of Rama. These two principal sects of Vaihna are each divided into three. The Gokulavis are 1. Those who exclusively worship Krihna as Visnu himself; and this sect is extensively considered as the true and orthodox Vaihna. (See Krihna and Vaihna.) 2. Those who exclusively worship Krihna as Krihna of Rama. (See Krihna and Vaihna.) This sect is sometimes called Radha-baliabibi. 3. The worshippers of Krihna and Rama conjointly. The three divisions of Ramavis are 1. Those who worship Rama only. (See Rama and Ramane.) 2. Those who worship Siva only. And 3. Those who worship both Rama and Siva conjointly. See Siva.

The sect of Ganapatias we have considered as a division of that of Siva; and the sect of Sura, worshippers of Sura, or the sun, we are disposed to class under that of Vaihna; for although Siva be the sun as well as Vaihna, yet the other, and more particularly in his incarnation of Krihna, is more generally reckoned the archetypal of the solar deity; or, what amounts to the same thing, the sun, a symbol or type of Vaihna. Individuals of several sects of Sura do doubt mix their adoration with the solar worship; as do also many sects of the Vaihna. See Sura.

Under our article Sakti we have observed that the Hindu mythology has portrayed the abstract and attractive powers of the divinity, and ascribed lores to these mythological personages. The Sakti, or energy of an attribute of God, is female, and is fabled as the comfort of that performed attribute. Hence has arisen such a series of fictions, comprehending all natural and moral phenomena, obscured by myth, and felt for all purposes, as it is fairly possible, in the case of Krihna, Parvati, and other Asuras. Religion, the Siva, in that, is worshipped in a spiritual form, or as the mind-like embodiment of the universe. In the sect of Krihna, that now is worshipped by the lower classes, the Sakti is considered as the energy of the heathen divinity. The sect of Ramavis is portrayed as the worship of a eternal life, the Sakti, or the soul, is represented as existing for ever as the energy of the universe. (See Sakti.) And the sect of the Siva worshippers, in which the Sakti is worshipped, as well as a multitude of other divinities of similar kind, who are supposed to exist as the energy of the universe and to possess the attributes of the Sakti.

There is another very numerous sect of Vaihna, called Bhagavatas, of more modern origin, than the others. Their tenets and practices are grounded on the eighteenth Puranas, which is chiefly a history of the life, adventures, and doctrines of Krihna, and is entitled Saivagara, which see. The work is ascribed to Vapadeva, who endeavored to reconcile and unite all sects, by recognizing the deities of each, but as subordinate to the Supreme Being, or as attributes or manifestations of God. This is, in fact, the doctrine of the Gita; but that work, as well as the Sri Bhagavata, while professing to uphold a unity in the deity, claims that pre-eminency for Krihna; and although the sect of Bhagavata is very numerous, and includes individuals of or from many other sects, still a purity of doctrine is far distant from all, while a mythological paraphrase is given to the attributes or the Amritak. For all the other sects, or at least a portion of the most enlightened and learned individuals among them, are sufficiently ready to profess a belief in the unity of the deity, if their claim of that awful designation for the object of their own adoration be conceded. See Krihna, Sama, and Siva.

The Bhagavatas, while recognizing the five divinities worshipped by the other sects respectively, and even paying them in turn their daily adoration, and on particular occasions extending it to other deities, still deny the charge of polytheism, and repel the imputation of idolatry. It may be easily imagined that but few, we may almost say none, of the numerous followers of this sect can fully comprehend the doctrines they profess. They incline much to real polytheism, but do at least reject the derogatory notions of the deity which the other sects seem to have adopted. The practice of adoring images of celestial spirits, they justify by arguments similar to those which have been elsewhere employed in defence of image-worship. (See Gentious and Idolatry.) If the doctrines of the Vedas, and even those of the Puranas, be closely examined, the Hindu theology will be found consistent; notwithstanding, though it contains the seeds of polytheism and idolatry. See Purana and Vedas.

Modern Hindoos seem to have misunderstood the numerous texts in their sacred books, which declare the unity of the godhead,
SECTS OF HINDOOS.

godhead, and the identity of Viṣṇu, Śiva, the Sun, &c. Their theologians have entered into vain disputes on the question of which, among the attributes of God, shall be deemed characteristic and pre-eminent?

Sankaračārya (see the article under his name) the celebrated commentator on the Veda, contended for the attributes of Śiva, and founded or confirmed the sect of Saiva, who worship Śiva as the supreme being, and deny the co-equal or independent existence of Viṣṇu and other deities. Madhava and Vallabha, both also furnamed Ācārya, denoting literary dignity, have in like manner established by their comments the sect of Vaiṣṇava, who adore Viṣṇu as God.

Under the article Saraswati we have noticed, that there is now no sect, who exclusively or principally worship Brahma; no one hath hitherto been discovered named after him, denoting the creative power to be the object of exclusive adoration. Still by some legends he is described as the Almighty; leading us to infer, that he was once factually addressed as the other two members of the triad now are. His faksi, Saraswati, is described in some passages as all-productive, all-powerful, and all-wise. It may be reasonably inferred, that there are many more sects among the Hindoos than have hitherto been ascertained. Most of the sects, however, approach or melt into each other on closer inspection; as may in all such cases be supposed, when they mutt all have originated in one common source. This union is with the Hindoos marked with their usual extravagant sexual mythology. Śiva and Parvati, they say, had a contest on the question of the comparative potency or eminence of their several worship; in other words, the worshippers of their symbols, the Linga and Yoni, contended the point. To appease this physiological difference between the god and his consort, Viṣṇu interposed, and his novel, or rather as times, came at length to be considered as the same with the Yoni; confounding the Vaiṣṇavas with the Yonis; but we must refer to our article Yoni, and the other articles and the works therein mentioned, for further particulars on this point.

In the early part of this article, we have adverted to the numerous šāstras, under the generic term of Baudhas, followers of the doctrines of Buddha or Boooth. (See Boodh.) These, under various dénominations, we are diffused to clafs as heretical Vaiṣṇavas, worshipping Viṣṇu under one of his avatars or incarnations, that of Buddha; as the Gokalathas and Ramanujas do under others; those of Gokal, or Krishna and Rama. "In respect to the number of followers," the author of the Hindoo Pantheon observes, "and the extent over which they have spread, the doctrines of Buddha have probably obtained greater dominion than those of any other religious persuasion. Although now comparatively trampling on the continent of Hither India, his doctrines and followers are still found, differing in externals, and divided into sects, throughout China and its tributary nations; in the great empires and states of Cochinchina, Cambodia, Siam, Pegu, Ava, Afam, Tibet, Budan or Boatun, (see these several articles) many of the Tartar tribes, and generally all parts east of the Ganges; including those vast and numerous islands in the seas southward and southwestward of the farther Indian promontory, whose inhabitants have not been converted to Islamism. In these great and distant parts of the globe the tenets of Buddha, distinguished by various apppellations, may be recognized as forming the religion of the people; an extent exceeding that either of the Mahomedan or Brahmanical superstition, and outnumbering perhaps, the followers of the religion of Jesus Christ."

Buddhism, like other distinctions of faith among Hindoos, is divided into sects. If it be reckoned the grand generic fact, we may deem the sects of Jainah and Mahahmoh sects of specific varieties; and there appears no good reason why they should not all be clad with the other sects, who adore exclusively one of the avatars or incarnations of Viṣṇu, under the comprehensive denomination of Vaiṣṇavas. Of these avatars see under the article Visnu; and for some account of the heresy of Buddha and its subdivisions, see Boooth, Jainah, Sakyah, and the other articles hence referred to in this work. Most oriental people seem to have prized themselves on distinguishing their deities by a great many names. Those names are, however, mostly, perhaps all, significant and characteristic; of which early enquirers were of course ignorant. The prevalence of this pride will be seen in our articles Parvati, Śiva, and others. In the infancy of Buddha, another proof might be exhibited of the same feeling. He is distinguished by different names in the same and in different parts. Boooth, Budha, Butta, and others of nearly similar found, are mere varieties, in different parts of India, in orthography and pronunciation; and so perhaps is the Bud, or Wud, of the ancient Pagan Arabs. Pout in Sienn; Poti, or Poti, in Tibet; and But in Cochinchina, are the same; the Chinese having, it is said, no B or D in their alphabet, and their language being monosyllabic, fastened his name into Fo, or Fo-e. (See Fo.) They call him also Xa-ka; a variation, perhaps, of the Sanscrit Sakyah. (See Sakyah.) That the Toth of the Egyptians, and the Woden of the Scandinavians, and other northern nations, is the same name and deity, is upheld by some; but the supposition is denied by others: some, indeed, will not recognize him in the Fo of China. A Buddha, whether the ninth incarnation of Viṣṇu or not may be disputed, has been deemed to answer in character with Mercury; so has the Gothic Woden. Each respectively gives his name to the same planet, and to the same day of the week. Buddha is, very extensively in India, whether among Baudhah, Śivah, Vaiṣṇavas, or Mahomedah, the same with Dies Mercurii, or Woden's day; whence some have derived our Wednesday.

The common reproach of the Brahmans is that the Baudhas uphold the dangerous dogma of the eternity of matter and the perifhability of the soul. But we ought to receive accounts of the tenets of a heretic sect with caution; and of the Baudhas and Jainah we have yet but little else. Like the Jainah, their worship is confined to deified images; and the name for the chief of them is, as flatted in another place, derived from the Sanscrit word bodha, to know; hence Buddha is philosophy; and hence has been the Saxon and English verbs bodian, to bode, forebode, &c.

The Jainah, or votaries of Jainah, are probably the most ancient of Hindoo sectaries. They reject, like the Baudhas in general, the authority of the Vedas; and are the most scrupulous of any sect in their cautions against the even accidental extintion of animal life. (See of this under our article Jainah.) In the Vedas the slaugther of animals is not only allowed, but on some occasions enjoined. (See Vedah.) The adoration of the Jainah is exclusively offered to deified mortals, or rather, as they affirm, through them to the deity; and in the clafs of deified mortals may be included many of the gods of the Hindoos, although they profess to reject the polytheism and incarnations of the latter. The doctrine of transmigration is found among the Jainah; how extensively it is not ascertained; the belief of a future state of rewards and punishments, and an extensive portion
SECTS OF HINDOOS.

portion of the Puranic history, is common to them with the orthodox Hindoos. Formerly powerful and widely disseminated, this sect is supposed to have suffered great diminution from the extension of the modern heresy of Buddhism. And at present its more opulent members are said to find it convenient to reform the orthodox persuasion, which may be done without much difficulty, and will greatly tend to a diminution of its members and respectability.

Several of the sects noticed in the articles of this work named after them, are described as distinguished by marks on their foreheads, arms, and breasts. The forehead mark is the chief distinction, and when horizontal or parallel with the eyebrows, it is understood to designate a Sava, while a Vahinava is recognized by its perpendicularity. One, two, or three of these lines, red, white, or yellow, accompanied by circles and dots, differing in position and colour, together with many other symbols and hieroglyphics, afford an infinite variety of indications of the sectarian bias of the individual so decorated. When convenient, and no special objection exists, it is said to be held necessary, that these marks be daily renewed; and, of course, by the hand of a Brahman. One of that tribe cannot perform his daily offices, ablutions, &c. without the completion or contemplation of this distinction; and it is held irreverent in one of an inferior tribe to approach a holy man, or to ask his blessing, without, or in view of, this sectarian decoration. The second plate of the Hindu Pantheon contains some figures of these mysterious symbols. To that work, page 400, &c. we refer fuch of our readers as desire further information on this point, for a curious variety of the distinguishing marks, and a full explanation of their sectarian application.

Another sect, who worship fire, or the perfunctory in Agni its regent, is noticed under the article SAGNIKA, (which see). This is referrible to the grand division Sava, Agni being of that line of parentage. See PA-

VAKA.

Having, under the article PHILOSOPHY of the Hindoos, given the names of the principal sects, or schools; and referred for a brief explanation of the several doctrines to the articles of this work, under which they are respectively noticed, we shall not, in this place, offer any thing farther thereon. For some of the particulars of this article we are indebted to Mr. Colebrook's Essay on the Religious Ceremonies of the Hindoos, in the ninth volume of the Asiatic Researches, and to the Hindoo Pantheon.

From what precedes it will appear, that an individual of either of the four civil tribes may profess his own theological sect: a Brahman, or a Sudra, is at liberty to choose what form of worship he may think proper, and to what deity he will offer it: observing, of course, due consistency and conformity with the ritual. He may thus, without offence beyond incurring some displeasure, perhaps, from his trailer family, and Guru, or pator, change from a Lingi to a Yonja, or associate one with the other; or from a Saura to a Ganapatyia; or he may combine all, and more; and, being all in Krishna, become a Bhagavata; he may, without incurring sin, or, as the idea is better understood in Europe, without losing caste, turn from a Sava to a Vahinava. All these are prevalent, and admit of caste expiation. He is still under the spiritual dominion of the same priesthood, and while he observes the ordained fasts and feats, performs pilgrimages, is liberal in alms, and conforms to the externals that serve to meet the mental cravings forg'd for him by the Brahman, all is well. He may also study, and, under certain limitations, believe and profess, whichever philosophical doctrines he prefers. It would not, perhaps, be thought decorous in a Brahman, especially if he were a priest, to make any dissertation display of the doctrines of a free-thinking Brahman, who prescribes border on a denial of the existence of the mythological beings, reverence to which is the basis on which rests the spiritual faculty of his own tribe. But there are still many individuals among the Brahman who think deeply; and who, in relaxing on the gross eres and obscurities of these mythological legends, cut themselves. See VEDANTA.

It is in the civil distinctions that the Hindu law is guarded against innovation. Here every possible care has been taken to keep the tribes apart; and sexual intercourse, the principal apprehended cause of confusion, is regulated and legitimated with great precision. These regulations vary in minute particulars in different tribes and countries, but agree pretty nearly in the main point of degrading the offspring of forbidden intercourse. Such degradation does not, however, necessarily reflect. Rich delinquents can assert immediate ecclesiastical censure; and the lape is soon forgotten. With the poor such things are of little moment; exciting perhaps little else than the passing scandal of the neighbourhood; unless in cases where the Brahmanical dignity or purity may be implicated in a manner too gross or notorious to be overlooked. Formication or adultery between a male Sudra and a Brahman would be deemed of this nature. So would eating or drinking together of individuals of remote or different tribes. But the latter, if not frequent or wilful, admit of expiation; expensive and vexatious in proportion to the wealth of the offenders, and the degree of enormity in the offence.

Some writers have told us of the cace with which the Hindoos, and even the Brahmanas, seem to change their religion: "with as much facility," say they, "as their garments." The theological change of fect as above noticed, is not attended with much difficulty: they are still Hindoos, and can find priests of their new persuasion, who will afford them the consolations and benefits of religion, such as they are. But the work of conversion altogether from that religion, and liberation from the trammels of prieres, have ever been, and ever will be found, a task of much greater difficulty: to be accomplished only by the potency of continued persuasion, superadded to the aid of example in the preceptors.

In concluding this article on the sectaral divisions of the Hindoos, we may observe that there is strong reason to believe many of them to be of modern origin. The Veda, the scripture of the Hindoos, affords no authority for such extravagancies as worshipping deified heroes, female powers or indelent symbols, or avatars. See VEDA.

We shall here subjoin a brief account of Saniafay, omitted in its proper place. Saniafay denotes an order of Hindoo mendicants, who arrive at this distinction by divers acts of persevering penance and suppoosed piety. We are not aware of any material distinction between this description of saints, and the so-called Yogi and Yati by different sects. In the Gita, as translated by Mr. Wilkins, Krishna declares him to be both a Yogi and a Saniafay, who performeth that which he hath to do independent of the fruit thereof. Saniafay, or a forsaking of the world, is declared to be the same with Yogi, or the practice of devotion. He who can bear up against the violence produced from luft and anger in this mortal life, is properly employed, and a happy man. The man who is happy in his heart, at rest in his mind, and enlightened within, is a Yogi, or one devoted to God, and of a godly spirit. The soul of the placid, conquered spirit, is the same in heat and cold, in pain and pleasure, in honour and disgrace. To the Yogi, gold, iron, and lumes are the same. The man is distinguished whose resolution, whether amongst his companions and friends, or in the midst of his enemies; with those wha
who love and with those who hate; in the company of saints or sinners, is the fame. The Yogi constantly exerciseth the spirit in private. He is a recluse of a subdued mind, free from hope, and free from perception. He planteeth his own feat firmly on a spot that is un değerlendir, and sitteeth upon the sacred grails, kusas, covered with a skin and a cloth. (See Kusa.) There he, whose busses is the restraining of his passion, should sit, with his mind fixed on one object alone, in the exercise of his devotion for the purification of his soul, keeping his head, his neck, and body steady, without motion, his eyes fixed on the point of his note, looking at no other place around. To be a Sanavis, or recluse, without application, is to obtain pain and trouble.

This divine discipline is not to be attained by him who eateth more than enough, or lesse than enough; neither by him who deepeth too much, nor by him who deepeth not at all. A man is called devout, when his mind remaineth thus regulated within himself, and he is exempted from every luft and inordinate desire. The Yogi of a subdued mind, thus employed in the exercise of devotion, is compared to a lamp standing in a place without wind, which waweth not. He becometh acquainted with that boundless pleasure, which is far more worthy of the understanding than that which arises from the senses; depending upon which, the mind moveth not from its principles; which having obtained, he refpecteth no other acquisition so great as it; on which depending, he is not moved by the severest pain. Supreme happiness attendeth the man whose mind is thus at peace; whose carnal affections and passions are thus subdued; who is thus in God, and free from sin. The Yogi is more exalted than the Tapafwi (see Tapas); the zealot who harasses himself in performing penances, is respected above the learned in science, and inferior to those attached to moral works.

The above passages from different pages of the Gita, may serve as a specimen of that extraordinary work; supposed to have been composed by Veya, many centuries before the Christian era. See Vyasa, Jaina, Yati, and Yogi, for some farther notice of Hinduoo penance and devotion; and Tapas, for instances of their authority.

Individuals calling themselves Saniassys and Yogis, are still found wandering about India; sometimes stark-naked; rubbed over with ashes, especially if of the sect of Sarva (which see); the god Siva being represented to powdered. Sometimes they have, like him, a tiger's skin to fit on: and at others, carry one of Vishnu's emblems, the chakra, of which see under Vishnu and Vajra. In the latter cafe, the individuals are probably of the sect of Vijaya-vanu, which see.

Secta, in Law. See Suit.

Secta Hundred. See Hundred Suit.

Secta ad curiam, a writ which lieth against him who refetheth to perform his suitor to the court county, or court baron.

Secta curia. See Suit of Court.

Secta facienda per illum quam habet amicam partem, a writ to compel the heir that hath the elder's part among co-heirs, to perform service for all the coparencers.

Secta falde. See Faldage.

Secta ad sulphatum faciendum, is a service which a man is bound to perform by his see.

Secta molendini, a writ lying where a man by uffage, time out of mind, &c. has ground his corn at the mill of a certain perfon, and afterwards goes to another mill with his corn, thereby withdrawing his suitor to the former. And this writ lies especially for the lord against his tenants, who hold of him to do suit at his mill. This is now generally turned into an action of the cafe.

Secta regalis, a suit by which all perfon were bound twice in a year to attend the sheriff's town, and was called regalis, because the sheriff's town was the king's seat; wherein the people were to be obliged by oath to bear true allegiance to the king, &c.

Secta unica tantum saccia pro pluribus h Persistence, a writ that lies for an heir who is distrained by the lord to do more suits than one, in respect of the land of divers heirs defended to him.

Sectilia, among the Romans, pavements laid with flowers cut into various forms. Suctonius distinguishes them from those that were tessellated.

Sectineus, in Anatomy, a small, flat, and pretty long muscle, broad at the upper part, and narrow at the lower; situated obliquely between the os pubis, and the upper part of the os femoris.

It is commonly a single muscle, but it sometimes found double. It is fixed above by fleshy fibres to all the sharp ridges, or critia, of the os pubis, and to a small part of the oblong notch, or depellation, on the fore part of the critia, in which the upper extremity of this muscle is lodged; and thence it runs down obliquely towards the little trochanter, under, and a little behind which it is inserted obliquely by a flat tendon, between the anterior part of the muscle's insertion, and inferior portion of the triceps secundus, with which it is united. Windlow.

Sectio Cesarea. See Cesarian Section.

Section, Section, formed from secare, I cut, a part of a thing divided; or the division itself.

Such, particularly, are the subdivisions of chapters, by others called paragraphs, and sometimes articles. The mark of a section is §.

The ancients neglected to divide their books into chapters and sections: that was a talk left for future editors and critics.

Section, in Geometry, denotes a side or surface appearing of a body, or figure, cut by another; or the place wherein lines, planes, &c. cut each other.

The common section of two planes is always a right line; being the line supposed to be drawn by the one plane in its cutting or entering the other.

If a sphere be cut in any manner, the plane of the section will be a circle, whose centre is in the diameter of the sphere. The sections of the cone are five, viz. a circle, triangle, parallelogram, hyperbola, and ellipse. See each under its proper article. See also Cone.

Sections, Conic. See Conic Sections.

Section, Axis of a Conic. See Axis.

Section, Centre of a Conic. See Center.

Section, Diameter of a Conic. See Diameter.

Section, Tangent of a Conic. See Tangent.

Sections, Following, Sections Successive, in Conics, may be thus conceived: suppose two right lines, as A B, C D, (Plate XIII. Analysis, fig. 5.) mutually intersecting one another in E, which point E is supposed to be the common centre of the opposite hyperbolic sections F, G, H, I, and whole common asymptotes, the proposed lines A B, C D, also are. In this case, the sections G, F, and H, I, are called sections successives; because they are placed following one another in the contiguous angles of two intersecting right lines.

If the determinate diameter, H G, of one of the sections successives (which is coincident with the supposed indeterminate diameter of its opposite) be equal to the vertical tangent K L, applied between the asymptotes in the point G, of the diameter G F; then Apollonius calls such sections, conjugated sections. See Gemin of the Hyperbola, under Conic Sections.

Sections, Opposite. See Opposite.
SEC

**Sections.** The nature of the problem, or a description of the various parts, if any, on the plan, or if the object is not described, to determine the whole.

**Sector.** (or.) The figure, or the length of the arc, and the other side directed to the centre.

**SECT.** The figure, or the length of the arc, and the other side directed to the centre.

**SECTOR.** A part of a circle comprehended between the radius and the arc.

The mixed triangle ACD (Plate XIII. Geometry, fig. 5) comprehended between the radius AC and CD, and the arc AD, is a sector of the circle.

It is demonstrated by geometricians, that the sector of a circle is equal to a triangle, whose base is the arc AD, and whose altitude is the radius AC.

If from the common centre of two concentric circles be drawn two radii to the periphery of the outer, the two areas included between the radii will have the same ratio to their peripheries; and the two sectors, the ratio to the areas of their circles.

To find the area of a sector DCE, the radius of the circle CD, and the arc DE, being given. To 100, 314, and the radius DC, find a fourth proportional number; this will be the semiperimeters: then to 180 degrees, the given arc DE, and the semiperimeter just found, will give the fourth proportional; which will give the arc DE in the same measure in which the radius DC is given: halfly, multiply the arc DE into the semiperimeter, and the product is the area of the sector.

In order to find the area of any sector of a circle, Dr. Hutton, in his "Menfuration," has given the two following rules:

**Rule 1.** Multiply the radius by half the arc of the sector, and the product will be the area, as in the whole circle.

For the demonstration of this, see the article Circle. Putting r = the radius of a circle, d = the diameter, a = the area of a sector of it, u = the length of the arc of the sector, b = the degrees in $\frac{1}{2}$ of $\frac{1}{2}$, x = half the chord of the arc a, or the line of $\frac{1}{2}$ a, and $\nu = \sqrt{\frac{2}{2}}$; then, by multiplying the radius by half the arc, by a variety of rules which Dr. Hutton has stated, we shall have,

1. $a = \frac{1}{2} dr = 174532.7 r r r$. 2. $A = r \sqrt{\frac{1}{2}} \nu \times$

$3. A = \frac{1}{2} dr + \frac{1}{4} d^2 r$. 4. $A = \frac{1}{2} \sqrt{\frac{1}{2} \nu}$.

5. $A = \frac{1}{2} \nu \times \nu$. 6. $A = \frac{1}{2} \nu \times \nu$. 7. $A = \frac{1}{2} \nu \times \nu$.

**SECT.** The number of the parts of the circle included in the figure, or the number of its sides, but the terms above are in the manner of the circle.

Redhill. As one of the degrees, or the arc of the sector, for the whole area of the circle is the area of the sector.

SEC. A sector of a triangle, or the area of the sector, for the whole area of the circle is the area of the sector.

**Double.** The figure, or the length of the arc, and the other side directed to the centre.

**Doubles.** The figure, or the length of the arc, and the other side directed to the centre.

**Double.** The figure, or the length of the arc, and the other side directed to the centre.

**Decimals.** The figure, or the length of the arc, and the other side directed to the centre.

**Double.** The figure, or the length of the arc, and the other side directed to the centre.

**Double.** The figure, or the length of the arc, and the other side directed to the centre.

**Double.** The figure, or the length of the arc, and the other side directed to the centre.
The manner in which these scales are disposed of on the
sector, is best seen in the figure.

The scales of lines, chords, fines, tangents, rhumbs, longitudes, hours, longitude, incl. merid. may be used, whether the instrument is shut or open, each of these scales being contained on one of the legs only. The scales of inches, decimals, log. numbers, log. fines, log. versed sines, and log. tangents, are to be used with the sector quite opened, part of each scale lying on both legs.

The double scales of lines, chords, fines, and lower tangents, or tangents under 45 degrees, are all of the same radius or length: they begin at the centre of the instrument, and are terminated near the other extremity of each leg; viz. the lines at the division 16, the chords at 60, the fines at 90, and the tangents at 45; the remainder of the tangents, or those above 45 degrees, are on other scales beginning at one-fourth of the length of the former, counted from the centre, where they are marked with 45, and run to about 76 degrees.

The secants also begin at the same distance from the centre, where they are marked with 10, and are from thence continued to as many degrees as the length of the sector will allow, which is about 75 degrees.

The angles made by the double scales of lines, of chords, of fines, and of tangents, to 45 degrees, are always equal. And the angles made by the scales of upper tangents, and of secants, are also equal; and sometimes these angles are made equal to those made by the other double scales. The scales of polygons are put near the inner edge of the legs, their beginning is not far removed from the centre, as the 60 on the chords is. Where these scales begin, they are marked with 4, and from thence are figured backwards, or towards the centre, to 12.

From this disposition of the double scales, it is plain, that those angles which are equal to each other, while the legs of the sector were close, will still continue to be equal, although the sector be opened to any distance it will admit of.

The scale of inches is laid close to the edge of the sector, and sometimes on the edge; and contains as many inches as the instrument will receive when opened: each inch being usually divided into eight, and also into ten equal parts. The decimal scale lies next to this: it is of the length of the sector, when opened, and is divided into ten equal parts, or primary divisions, and each of these into ten other equal parts; so that the whole is divided into a hundred equal parts: and if the sector admits of it, each of the subdivisions is divided into two, four, or five parts; and by this decimal scale, all the other scales, that are taken from tables, may be laid down. The length of a sector is usually understood when it is shut; and, therefore, a sector of five inches makes a rule of twelve inches when opened; and a foot sector is two feet long, when quite opened. The scales of chords, rhumbs, fines, tangents, hours, longitudes, and inclinations of meridians, are such as are described under Plane Scale.

The scale of logarithmic or artificial numbers, called Gunter’s scale, or Gunter’s line, is a scale expressing the logarithms of common numbers, taken in their natural order.

For the construction of this scale, and also of those of logarithmic lines, logarithmic tangents, and logarithmic versed sines, see Gunter’s Line, and Gunter’s Scale.

We shall here observe, that all these scales should have one common termination to one end of each scale, i.e. the 10 on the numbers, the 90 on the fines, the 0 on the versed sines, and the 45 on the tangents, should be opposite to each other: the other end of each of the scales of lines, versed sines, and tangents, will run out beyond the beginning (marked 1) of the numbers; nearly opposite to which will be the divisions representing 35 minutes on the lines and tangents, and 168$^\circ$ degrees on the versed sines.

The double scales are constructed in the following manner.

The line of lines is only a scale of equal parts, whole length is adapted to that of the legs of the sector; thus, in the six-inch sector, the length is about 5$^\frac{1}{2}$ inches. The length of this scale is divided into primary divisions; each of these into ten equal secondary parts; and each secondary division into four equal parts. The accuracy of the division may be determined by taking between the compasses any number of equal parts from this line, and applying that distance to all the parts of the line; and if the number of divisions be contained between the points of the compasses in every application, the scale may be received as perfect. The line of fines is constructed by making the whole length of this scale equal to that of the line of lines; and from this line, taking severally the parts expressed by the numbers in the tables of the natural lines, corresponding to the degrees, or to the degrees and minutes, intended to be laid upon the scale; and then by laying down these several distances on the scale, beginning from the centre. In scales of this length, it is customary to lay down divisions, expressing every 15 minutes, from 0 degree to 60 degrees; between 60 and 80 degrees, every half degree is expressed; then every degree to 85; and the next is 90 degrees. The length of the scale of tangents is equal to that of the line of lines, and the several divisions upon it (to 45 degrees) are laid down from the tables and line of lines, in the same manner as the former; observing to use the natural tangents in the tables. The scale of upper tangents is laid down, by taking $\frac{1}{4}$ of each of the natural tangents above 45 degrees, as are intended to be put upon the scale. The beginning of this scale, at 45 degrees, though the position of it on the sector respects the centre of the instrument, is distant from the centre $\frac{1}{4}$ of the length or radius of the lower tangents.

The distance of the beginning of the scale of secants from the centre, and the manner of laying it down, are the same as those of the upper tangents: except that in this the tabular secants are to be used.

For the scale of chords; its length is to be made equal to that of the fines; and the divisions, which are twice the length of the fines of half the degrees and minutes counted from the centre, express every 15 minutes from 0 degrees to 60 degrees, to be laid down as in the scale of fines.

The scale of polygons usually comprehends the sides of the polygons from fix to twelve sides inclusive. The divisions are laid down by taking the lengths of the chords of the angles at the centre of each polygon, and laying them down from the centre of the instrument. When the polygons of four and five sides are also introduced, this scale is constructed from a scale of chords, where the length of 90 degrees is equal to that of 60 degrees of the double scale of chords on the sector. Instead of none of the double scales above described, there are found other scales on the old sectors, and also on some of the French ones, such as scales of superficies, of solids, of inscribed bodies, of metals, &c.; but these are left out to make room for others of more general use. See CALIBER.

In describing the use of the sector, the terms lateral distance, and transverse distance, often occur. By the former is meant the distance taken with the compasses on one of the scales only, beginning at the centre of the sector; and by the latter, the distance taken between any two corresponding
SECTOR.

The transverse distance of the sectors of the same name, the legs of the sector being in an angular position: but in taking their transverse distances, it is to be observed, that each of the sectors hath three parallel lines, and it is which the divisions of the scale are marked, and that the points of the compasses must be always set on the inside line, or that line nearest the inner edge of the leg, which is the only line, in each scale, which runs to the centre.

For the use of the logarithmic scale of numbers, see

Gunter's Line.

1. To divide a given line into any number of equal parts: e.g. 9. Make the length of the given line, or some known part of it, a transverse distance to 9 and 9; then will the transverse distance of 1 and 1 be the 4th part of it; or such a submultiple of the 4th part, as was taken of the given line, or the 4th part will be the difference between the given line and the transverse distance of 8 and 8.

2. To make a scale of a given length, to contain a given number of equal parts: e.g. let the scale to the map of a survey be 6 miles long, and contain 140 poles, and let it be required to divide the scale into the several parts, so that a corresponding scale may be taken from the line of miles. Make the transverse distance 7 and 7 (or 50 and 50, vs. 14) equal to 3 inches (-\frac{1}{3}); and this position of the line of miles will produce the given scale.

3. To divide a given line (e.g. 5 inches) into any affixed proportion, as of 4 to 7. Make 5 inches, the length of the given line, a transverse distance to 9 and 9, the sum of the proposed parts; and the transverse distances of the affixed numbers, 4 and 5, will be the parts required.

4. To two given lines, vs. 2 and 6, to find a third proportional. Take between the compasses the lateral distance of the second term, viz. 6; set one point on the division expressing the first term, viz. 2, on one leg, and open the legs of the sector till the other point fall on the corresponding division on the other leg; keeping the legs of the sector in this position, take the transverse distance of the second term, viz. 6, and this distance is the third term required, which distance, measured laterally from the centre, will give 18, the number required: for 2 : 6 :: 6 : 18.

Otherwise, take the distance 2 laterally, and apply it transversely to 6 and 6, the sector being properly opened; then the transverse distance at 2 and 2, being taken with the compasses, and applied laterally from the centre of the sector on the scale of lines, will give the third term, when the proportion is decreasing; for 6 : 2 :: 2 : 7.

If the legs of the sector will not open far enough to let the lateral distance of the second term fall between the divisions expressing the first term; then take \frac{1}{2}, \frac{1}{4}, or any aliquot part of the second term, that will conveniently fall within the opening of the sector, and make such part the transverse distance of the first term: then, if the transverse distance of the second term be multiplied by the denominator of the part taken of the second term, the product will give the third term.

5. To three given lines, vs. 5, 7, and 10, to find a fourth proportional. Open the legs of the sector, till the transverse distance of the first term, 3, be equal to the lateral distance of the second term, 7, or some part of it: then will the transverse distance of the third term, 10, give the fourth term, \frac{3}{10}, required; or such a submultiple of it, as was taken of the second term; for 3 : 7 :: 10 : 23.

Otherwise, set the lateral distance, 7, transversely from 10 to 10, opening the sector accordingly; and the transverse distance, at 3 and 3, applied laterally, will give \frac{7}{5}; for 3 : 7 :: \frac{3}{5}.

6. To diminish a line of four inches, in the proportion of 8 to 7. Open the sector till the transverse distance of 8 and 8 be equal to the lateral distance of 7, with the point, where four inches, and lateral distance, taken from the centre, reaches; and the transverse distance taken at that point will be the line required. If the line should be too long for the legs of the sector, take \frac{1}{2}, \frac{1}{3}, or \frac{1}{4}, &c. part of the given line for the lateral distance, and the corresponding transverse distance, taken twice, three, or four times, &c. will be the line required.

7. To open the sector, so that the two scales of lines shall make a right angle. Take the lateral distance from the centre to the division marked 5, between the points of the compasses, and set one foot in the division marked 4, on one of the scales of lines; and open the legs of the sector till the other foot falls on the division marked 5, on the other scale of lines, and then will those scales stand at right angles to one another; for the lines 3, 4, 5, or any of their multiples, constitute a right-angled triangle.

8. To two right lines given, e.g. 40 and 50, to find a mean proportional. Set the two scales of lines at right angles; find the half sum of the given lines, vs. 65, and the half difference, vs. 25, and take with the compasses the lateral distance of the half sum, 65, and apply one foot to the half difference, 25, the other foot transversely will reach to 60, the mean proportional required: for 40 : 60 :: 60 : 60.

9. To find the Scale of Chords on the. 1. To open the sector so that the two scales of chords may make an angle of any number of degrees, e.g. 40. Take the distance from the point to 40, the number of degrees proposed on the scale of chords; open the sector till the transverse distance from 60 to 60, on each leg, be equal to the aforementioned lateral distance of 40: then do the scales of chords make the angle required.

2. The sector being opened, to find the degrees of its aperture. Take the extent from 60 to 60, and lay it off on the scale of chords from the centre: the number, where it terminates, shews the degrees of its opening. By applying sights on the scales of chords, the sector may be used to take angles, as a surveying instrument.

3. To project or lay down an angle of any given number of degrees. 1. Let the number of degrees be less than 60, vs. 40. At any opening of the sector, take the transverse distance of 60 and 60 on the chords; and with this opening describe an arc: take the transverse distance of the given number of degrees, 40, and lay this distance on the arc described, marking its extremities: from the centre of the arc, through these extremities, draw two lines, and they will contain the angle required.

When the degrees given are more than 60, vs. 148; describe the arc as before; take the transverse distance of 7 or \frac{1}{2} of the given degrees, 148, e.g. 7 = 49\frac{1}{2} degrees; lay this distance on the arc three: and from the centre draw two lines to the extremities of the arc thus determined, and they will contain the required angle. N.B. If the radius of the arc or circle is to be of a given length, then make the transverse distance of 60 and 60, equal to that affixed length.

4. To find the degrees which a given angle contains. About the vertex describe an arc, and open the sector till the distance from 60 to 60, on each leg, be equal to the radius of the circle; then taking the chord of the arc between the compasses, and carrying it on the legs of the sector, see what equal number, on each leg, the points of the compasses fall on: this is the quantity of degrees the given angle contains.

5. To take an arc, of any quantity, from off the circumference of a circle. Open the sector till the distance from
from 60 to 60 be equal to the radius of the given circle; then take the extent of the chord of the number of degrees, on each leg of the secto, and lay it off on the circumference of the given circle. By this use, may any regular polygon be inscribed in a given circle, as well as by the line of polygons: e.g., in a circle whose diameter is given to describe a regular polygon of 24 sides. Make the given diameter a transverse distance from 60 to 60 on the scales of chords; divide 360 by 24, and take the transverse distance of 15 and 15, the quotient, and this will be the chord of the twenty-fourth part of the circumference. In order to prevent errors, where the distance is to be repeated several times, it will be best to proceed thus: with the chord of 60 degrees divide the circumference into 90 equal; in every division of 60 degrees lay down, first, the chord of 15 degrees, and next the chord of 30 degrees, and then the chord of 45 degrees, beginning always at the same point. Thus the error in taking distances will not be multiplied into any of the divisions following the first.

**sector. use of the line of polygons on the.** In a given circle to inscribe a regular polygon, e.g., an octagon. Open the legs of the secto, till the transverse distance of 6 and 6 be equal to the given diameter, then will the transverse distance of 8 and 8 be the side of an octagon, which may be inscribed in the given circle. In like manner may any other polygon be described, the number of whole sides does not exceed 12, be inscribed in a given circle.

2. On a given line to describe a regular polygon, e.g., a pentagon. Make the given line a transverse distance to 5 and 5; at that opening of the secto, take the transverse distance of 6 and 6; and with this radius, on the extremities of the line, as centres, describe arcs intersecting each other; and on the point of intersection, as a centre, with the same radius, describe a circumference passing through the extremities of the given line; and in this circle may the pentagon, whose side is given, be inscribed. By a like process may any other polygon, of not more than 12 sides, be described on a given line.

3. On a right line, to describe an isosceles triangle, having the angles at the base double that at the vertex. Open the secto till the ends of the given line fall on 10 and 10 on each leg; then take the distance from 6 to 6; this will be the length of the two equal sides of the triangle.

**sector. use of the scales of sines, tangents, and secants on the.** By the several lines disposed on the secto, we have scales to several radii: so that, 1, having a length, or radius, given, not exceeding the length of the secto when opened, we find the chord, sine, &c. thereto: e.g., suppose the chord, sine, or tangent, of 10 degrees to a radius of three inches required. Make three inches the aperture, or transverse distance, between 60 and 60 on the scales of chords of the two legs; then will the same extent, from 45 to 45 on the scale of tangents, and from 90 to 90 on the scale of sines, on the other side: so that to whatever radius the line of chords is set, to the same are all the other sines. In this disposition, therefore, if the aperture, or transverse distance, between 10 and 10, on the scales of chords, be taken with the compasses, it will give the chord of 10 degrees; if the transverse distance of 10 and 10 be in like manner taken on the scales of sines, it will be the sine of 10 degrees: lastly, if the transverse distance of 10 and 10 be in like manner taken on the scales of tangents, it gives the tangent of 10 degrees to the same radius.

2. If the chord, or tangent, of 70 degrees were required, for the chord, the transverse distance of half the arc, viz., 35, must be taken, as before; which distance, being repeated twice, gives the chord of 70 degrees. To find the tangent of 70 degrees, to the same radius, the scale of upper tangents must be used, the other only reaching to 45: making, therefore, three inches the transverse distance between 45 and 45 at the beginning of the scale; the extent between 70 and 70 degrees, on the same, will be the tangent of 70 degrees to three inches radius.

3. To find the secant of an arc, make the given radius the transverse distance between 0 and 0 on the line of secants; then will the transverse distance of 10 and 10, or 70, on the said lines, give the secant of 10 degrees, or 70 degrees.

The scales of upper tangents and secants do not run quite to 76 degrees; but those of a greater number of degrees may be found by the secto in the following manner. Thus, the tangent of any number of degrees may be taken from the secto at once; if the radius of the circle can be made a transverse distance to the complement of those degrees on the lower tangent. E.g., to find the tangent of 78 degrees to a radius of two inches. Make two inches a transverse distance of 12 degrees on the lower tangent; then the transverse distance of 45 degrees will be the tangent of 78 degrees. In like manner the secant of any number of degrees may be taken from the fines, if the radius of the circle can be made a transverse distance to the cofine of those degrees. Thus, making two inches a transverse distance to the fine of 12 degrees, then the transverse distance of 90 and 90 will be the secant of 78 degrees. Hence it will be easy to find the degrees answering to a given line, expressing the length of a tangent or secant, which is too long to be measured on those scales, when the secto is set to the given radius. Thus, for a tangent, make the given line a transverse distance to 45 and 45 on the lower tangents; then take the given radius, and apply it to the lower tangents: and the degrees, where it becomes a transverse distance, give the cotangent of the degrees answering to the given line. And for a secant, make the given line a transverse distance to 90 and 90 on the fines: then the degrees answering to the given radius, applied as a transverse distance on the lines, will be the cofine of the degrees answering to the given secant line.

4. If the converse of any of these things were required, that is, if the radius were required, to which a given line is the fine, tangent, or secant, it is but making the given line, if a chord, the transverse distance on the line of chords, between 10 and 10, and then the secto will stand at the radius required; that is, the aperture between 60 and 60, on the said line, is the radius.

If the given line were a fine, tangent, or secant, it is but making it the transverse distance of the given number of degrees; then will the distances of 90 and 90 on the fines, of 45 and 45 on the lower tangents near the end of the secto, and of 45 and 45 on the upper tangents towards the centre of the secto, and of 0 and 0 on the secants, be the radius.

5. If the radius, and any line representing a fine, tangent, or secant, be given, the degrees corresponding to that line may be found by setting the secto to the given radius, according as a fine, tangent, or secant, is concerned; taking the given line between the compasses, applying the two feet transversely to the scale concerned, and sliding the feet along till they both rest on like divisions on both legs; and the divisions will shew the degrees and parts corresponding to the given line.

For the method of determining the degrees answering to any tangent, or secant, that cannot be thus measured, see above.

6. To find the length of a vered sine to a given number of degrees, and a given radius. Make the transverse distance
tance of 90 and 90 in the frixes equal to the given radius; take the trancverse distance of the true complement of the given degrees; if the two degrees are less than 90, the difference, but if greater, the half of the true complement and divide by the given radius.

3. To give the sides of the fides from the corresponding double scales of lines, wherein, 1°, take, each of them, a right angle. On the lines, make the lateral distance of the given length, and 6 on the other leg; on the line, make the lateral distance 90 a transverse distance of 45 to 45, or from 90 to 90, or from 90 to 90, or from the line of any degrees to their complement; and, as the distance of 45:2, transverse distance of 12.5.

Sector. 1. The base and perpendicular of a right angled triangle being given, to find the hypotenuse. Suppose the base BC (Plate Triang. nom. fig. 5.) 40 miles, and the perpendicular AB 32; open the fector till the two scales of lines make a right angle; then, for the base, take 40 parts on the scale of lines on one leg; and, for the perpendicular, take 32 on the same scale on the other leg; then the extent from 40 to 32 on the other, taken in the compass, will be the length of the hypotenuse; which line, applied to the scale of lines, will be found 50 miles.

2. The perpendicular AB of a right angled triangle ABC being given, 30, and the angle BCA 37 degrees; to find the hypotenuse BC. Take the given side AB, and let it over, on each side, on the line of the given angle ACB; then the parallel distance of 90 and 90 or radius, will be the hypotenuse BC; which will measure 50 on the scale of lines.

3. The hypotenuse and base being given, to find the perpendicular. Open the fector till the two scales of lines be at right angles; then lay off the given base on one of the scales from the centre; take the hypotenuse in your compasses, and letting one foot in the term of the given base, let the other fall on the scale of lines on the other leg; the distance from the centre to the point where the compasses fall will be the length of the perpendicular.

4. The hypotenuse being given, and the angle ACB; to find the perpendicular. Make the given hypotenuse a parallel radius, i.e. make it the extent from 90 to 90 on the scales of lines; then will the parallel line of the angle ACB be the length of the side AB.

5. The base and perpendicular AB given, to find the angle BCA. Lay off the base AB, on both sides the fector, from the centre, and note its extent; then take the given perpendicular, and to it open the fector in the terms of the base given; the parallel radius will be the tangent of BCA.

6. In any right-lined triangle, two sides being given, with the included angle; to find the third side. Suppose the side AC (fig. 6.) 20, the side BC 30, and the included angle ACB 110 degrees; open the fector till the two scales of lines make an angle equal to the given angle, viz. 110 degrees; lay off the given sides of the triangle, from the centre of the fector, on each of the scales of lines; the extent between their extremities is the length of the side AB sought.

7. The angles C A B and A C B given, and the side C B; to find the base A B. Take the given side C B, and turn it into the parallel face of its opposite angle C A B; and then the parallel line of the angle A C B will be the length of the base A B.

8. The three angles of a triangle being given; to find the proportion of the sides. Take the lateral lines of the several angles, and measure them in the scale of lines; the numbers answering to which give the proportion of the sides.

9. The three sides being given; to find the angle A C B. Lay the sides A C, C B, along the scale of lines, from the center, and let over the side A B in the terms, in the fector opened, in their lines, to the quantity of the angle A C B.

10. The hypotenuse A C (fig. 7.) of a right angled parallelogram triangle A B C, given, e.g. 43 degrees, and the angle C A B 29 degrees; to find the side C B. The rule is, as radius A to the line of the given hypotenuse, is 43 degrees, so is the line of the given angle 29 degrees to the side of the perpendicular C B. Take the 29 degrees from the center, along the scale of lines, in your compasses, and let the extent from 0 to 0 on the two legs; and the parallel line of 43 degrees, the given hypotenuse value, will, when measured from the center on the scale of lines, give 13. 36", the side required.

11. The perpendicular B C, and the hypotenuse A C, given, to find the base A B. As the true complement of the perpendicular B C is to radius, so is the true complement of the hypotenuse to the true complement of the base. Therefore make the radius a parallel line of the complement of the given perpendicular, e.g. 47, then the parallel line of the complement of the hypotenuse, e.g. 47, measured on the scale of lines, will be found 25. 1", the complement of the base required; consequently the base itself will be 40. 35'.

Sector, in Geometry. &c. particular use of the. 1. To make a regular polygon, whole area shall be of any given magnitude. Let the figure required be a pentagon, whose superficial area is 125 feet; extract the square root of 5 of 125, it will be found 5. Make a square, whose side is 5 feet; and, by the line of polygons, as already directed, make the isosceles triangle C G D (Plate XII. Geometry, fig. 8.) so as C G being the semi-diameter of a circle, C D may be the side of a regular pentagon inscribed in it; then let fall the perpendicular G E. Then continuing the lines E G and E C, make E F equal to the side of the square before made; and from the point F, draw the right line F H parallel to G C; then a mean proportional between G E and E F will be equal to half the side of the polygon sought, which, doubled, will give the whole side. The side of the pentagon thus had, the pentagon itself may be described, as above directed.

2. A circle being given, to find a square equal to it. Divide the diameter into fourteen equal parts, by the scale of lines, as above directed; then will 12 of those parts, found by the same line, be the side of the square sought.

3. A square being given, to find the diameter of a circle equal to it. Divide the side of the square into eleven equal parts, by means of the scale of lines; and continue that side to 12.4 parts; this will be the diameter of the circle required.

4. To find the side of a square equal to an ellipsis, whose transverse and conjugate diameters are given. Find a mean proportional between the transverse and conjugate diameters; which being divided into fourteen equal parts, 12, of it will be the side of the square required.

5. To describe an ellipsis in any given ratio of its diameters, the area of which shall be equal to a given square. Suppose the proportion of the transverse and conjugate diameters be required, as 2 to 1; divide the side of the given square into eleven equal parts; then, as 2 is to 1, to is 11 x 12 = 14 to a fourth number; the square root of which is the conjugate diameter sought. Then, as 1 is to 2, is 2 the conjugate diameter to the transverse. Now.

6. To describe an ellipsis, by having the transverse and conjugate diameters given. Let the two diameters A B, C D,
CD, bisect each other at right angles in E (Plate XIII. Geometry, fig. 9.) Make AE a tranverse diameter to 90 and 90 on the lines; and take the tranverse distances of 10°, 20°, 30°, 40°, 50°, 60°, 70°, 80°, successively, and apply those distances to A E from E towards A, as at the points 1, 2, 3, 4, 5, 6, 7, 8; and through these points draw lines parallel to EC; make EC a tranverse distance to 90 and 90 on the lines; take the tranverse distances of 80°, 70°, 60°, 50°, 40°, 30°, 20°, 10°, successively, and apply those distances to the parallel lines from 1 to 2, 2 to 3, 3 to 4, 4 to 5, 5 to 6, 6 to 7, 7 to 8, and so many points will be obtained, through which the curve of the ellipse is to pass. The same work being done in all the four quadrants, the elliptical curve may be completed. In the construction of solar eclipses, instead of using the lines to every ten degrees, the lines belonging to the degrees and minutes corresponding to the hours and quarter hours, are to be used.

7. To describe a parabola whose parameter shall be equal to a given line. Draw a line to represent the axis, in which make AB (fig. 10.) equal to half the given parameter; divide AB, like a line into ten degrees, as at the points 10, 20, 30, 40, 50, &c. and through these points draw lines at right angles to the axis A B. Make the lines A a, 10 b, 20 c, 30 d, 40 e, &c. respectively equal to the chords of 90°, 80°, 70°, 60°, 50°, &c. to the radius A B, and the points a, b, c, d, e, &c. will be in the curve of a parabola; and a smooth curve line drawn through those points, and the vertex B, will represent the parabolic curve required.

N. B. As the chords on the secter run no farther than 60, those of 70, 80, and 90, may be found by taking the tranverse distance of the lines of 35°, 45°, 55°, to the radius A B, and applying those distances twice along the lines 20, 10 b, &c.

8. To describe an hyperbola, the vertex A, and asymptotes BH, BI, being given (fig. 11.) The asymptotes BH, BI, being drawn, the line BA bisection the angle I BH, and the vertex A taken, draw A I, A C, parallel to BH, BI. Make AC a tranverse distance to 45 and 45, on the upper tangents, and apply to the asymptotes from B so many of the upper tangents taken successively as may be thought convenient, as B D 50°, B E 55°, B F 60°, B G 65°, B H 70°, &c. and draw D d, E e, &c. parallel to AC. Make AC a tranverse distance to 45 and 45, on the lower tangents; take the tranverse distances of the cotangents before used, and lay them on those parallel lines; thus, make D d = 40°; E e = 35°, F f = 30°, G g = 25°, H b = 20°, &c. and through the points A, d, e, f, g, b, &c. draw a curve line, which will be the hyperbola required.

Sector. In Surveying, Use of the. The bearings of three places, as A, B, C (Plate VII. Surveying, fig. 1.) to each other, i.e. the angles ABC, BCA, and CBA, being given; and the distance of each, from a fourth standing among them, as D, i.e. B D, B C, and A B, being given; to find the distances of the several places A, B, C, from each other, i.e. to find the lengths of the sides A B, B C, A C. Having drawn the triangle EFG similar to ABC, divide the side E G in H, so that E H may be to H G, as A D to D C, after the manner already directed; and after the like manner must E F be divided in I, so that E I may be to I F as A D to D C. Then continuing the sides E G, E F, E F, as E H - H G is to H G, so is E H + H G to G K; and as E I - I F is to I F, so let E I + I F be to F M; which proportions are easily wrought by the scales of lines on the secter. This done, bisection H K and I M in the points L, N; and about the said points as centres, with the distances L H and L N, describe two circles, intersecting each other in the point O; to which, from the angles E, F, G, draw the right lines E O, F O, and O G, which will have the same proportion to each other, as the lines A D, B D, D C. Now, if the lines E O, F O, and O G, be equal to the given lines A D, B D, D C, the distances E F, F G, and E G, will be the distances of the places required. But if E O, F O, O G, be less than A D, B D, D C, continue them till P O, O R, and O Q, be equal to them; then the points P, Q, R, being joined, the distances P R, Q R, and P Q, will be the distances of the places sought. Lastly, if the lines E O, F O, O G, be greater than A D, B D, D C, cut off from them lines equal to A D, B D, D C, and join the points of section by three right lines; the lengths of the said three right lines will be the distances of the three places sought.

Note, if E H be equal to H G, or E I to I F, the centres L and N will be infinitely distant from H and I; that is, in the points H and I there must be perpendiculars raised to the sides E F, E G, instead of circles, till they intersect each other; but if E H be less than H G, the centre L will fall on the other side of the base continued; and the same is to be understood of E I, I F.

The sector is of especial use for facilitating the projection of the sphere, both orthographic and stereographic.

See on the construction and use of the secter, Bion's Construction, and Mathematical Instruments, by Stone, p. 54, &c. edit. 1. and Robertson's Treatise of Mathematical Instruments, &c. p. 50, &c. edit. 2.

Sector of a sphere, is composed of a segment less than a hemisphere, and of a cone having the same base with the segment, and its vertex in the centre of the sphere. The secter of a sphere, generated by the revolution of the secter of a circle C A E (Plate III. Geometry, fig. 12.) about the radius A C, is equal to a cone, whose base is equal to the portion of the spherical surface generated by the arc A E, or to the circle described with the radius A E, and whose height is equal to CA the radius of the sphere. Arch. de Spher. et Cyl. Maclaurin's Fluxions, Intro. p. 15. See Sphere.

SECUL, in Geography, a town of European Turkey, in the province of Moldavia; 5 miles S.W. of Niemecz.

SECULAR, something that is temporal; in which fene the word faneus opposed to ecclefojical.

Thus we fay, fecular power, fecular arm, fecular jurifdiction, &c.

Secular is more peculiarly used for a person who lives at liberty in the world; not shut up in a monastery, nor bound by vows, nor subjected to the particular rules of any religious community.

In which fene the word faneus opposed to regular.

The Romish clergy is divided into regular and fecular.

The regulars pretend, that their fte is much more perfect not than that of the feculars. Secular priests may hold abbeyes and priories both fimple and conventual, though not regularly, but only in commendam.

It is a maxim in their canon lairl, feneularia feneularius, i.e. feneular benefices are only to be given to fecular perfons; regular only to regular.

Secular Corporation. See Corporation.

Secular Games, Ludi Seculares, in Antiquity, were four games held among the Romans, once in an age; or, in a period deemed the extent of the longest life of man, called by the Greeks, and by the Latins, sexaevum.

The fecular games were also called Terentius games, ludi Terentini, either because Manius Valerius Terentius gave occasion to their institution; for having been warned in a dream,
dream, to dig in the ground in a place near the Campus Martius, called Termeum, he there found an inscription referring to Dido, to Plato and Proserpine: upon which, as he had heard him in his dreams, three of his children, born blind, obtained their sight; and he, in gratitude, performed another rite, the same day. In the Tyber, three days and three nights, a fish only. Or, heaps, he found here was an altar of Pluto; and deep under ground, the bottom of the Tyber, three times, he entered into the depth of this place.

The first games held three days, and as many nights; during which a time sacrifices were performed, the oil, the cubs, the birds, and other fruits and flowers; and all those games were executed, withebus, sports, etc. in the Circus.

Their origin and institution are delivered at length by Val. Max. 13; the occasion of which, according to this writer, was to flogh the prospects of a plague. The first who had them celebrated at Rome, was Valerius Publicola, the first consul created after the expulsion of the kings; in the year of Rome 245. The ceremonies to be observed in them were found prescribed in one of the books of the Sibyls; in which was contained a prophecy to this effect, viz.: that the Romans at the beginning of every age should hold solemn games in the Campus Martius to the honour of Pluto, Proserpine, Juno, Apollo, Diana, Ceres, and the Parcae; their city should ever flourish, and all nations be subjected to their dominion. Accordingly, they were very ready to obey the oracle, and in all the ceremonies used on this occasion conformed to its directions.

At the time of the celebration of the secular games, heralds were sent to invite all the world to a solemnity which nobody had ever yet seen, nor was ever to be seen again.

They were introduced with extraordinary preparation, under the direction of the quindecemviri; who distributed to the people flambeaux and sulphur, and wheat and other grains; for an offering. On the first day after they had offered sacrifices to the above named deities at the Capitol, they returned to the Campus Martius, where they had assembled, and held sports to the honour of Apollo and Diana. On the second day, at the hour appointed by the oracle, the noble matrons went to the Capitol to sing hymns to Jupiter; and on the third day of the feast, twenty-seven boys, and as many girls, sung in the temple of Palatine Apollo hymns and versets in Greek and Latin, to recommend the city to the protection of those deities, whom they particularly honoured by their sacrificies.

Authors are not agreed as to the number of years in which these games returned; partly because the quality of age or feculum, among the ancients, is not known; and partly on other accounts; some will have it, that they were held once every hundred years; and that the feculum, or age, was our century. This Varro and Livy seem to express in very plain terms; yet others will have it, that feculum comprehended a hundred and ten years; and that the secular games only returned in that period; that is, at the beginning of every 11th year; which opinion is countenanced by Horace, in his Secular Poem, ver. 21.

Be this as it will, it is certain they sometimes did not stay for the 11th, nor even for the 100th year, for the celebration of these games. The first were held A. U. C. 245, or 298; the second, A. 505, or 408; the third, A. 518; the fourth, either A. 605, or 608, or 618. Augustus held them in the year of Rome 735, and Claudius again in the year of Rome 800, and of Christ 38, viz. sixty-four years after the former; and Domitian, again, in still less time; viz. in the year of Rome 841, or of Christ 79, at which Tacitus alludes in quality of quindecimvir, as he himself tells us, Annal. lib. xi. cap. 11. and this was the seventh time that Rome had seen them from the first institution. The

ch., 38. 8. 102.

emperor Sev. el extended them the eighth time, that is, the hundred and seventh year after the death of Domitian. The day it was the last, but in a year, in the year of Rome 822, that is, fifty years after the death of the emperor Philip, the first celebration was greater than ever had been known. These that were celebrated by permission of the emperor Hadrian, after he had received the gift of the victory of Sertorius from Augustus, were held under his authority. Zosimus states the number of the victory of the fift games among the Romans. We find them represented by many deities.

Secular Poem. S. SEV. CARP. EORAM.

Secular Year, the same with Secular.

Secularis, Carpen, Secularis, a poem long, or reformed, at the funeral games.

Of this kind we have a very free piece among the works of Horace; it is a satirical ode, which éludes care at the end of his epistles. In some editions, the two last lines of the first book is also called "Carmen Secularis." Secularis, the act of secularizing, or of converting a regular person, place, or ceremony, into a secular one. Almost all the cathedral churches were anciently regular, i.e. the canons were to be religious, but they have been since secularized.

For the secularization of a regular church there is required the authority of the pope, that of the prince, the bishop of the place, the patron, and even the consent of the people. And in France all this must be confirmed by parliament.

Religious that want to be released from their vows, obtain briefs of secularization from the pope.

Secul., in Antiquity. See Age and Secular Games.

Secunda Aqua, among Chemists, &c. See Aqua Secunda.

Secunda super operationis pastura. See Surcharges.

Secundani, in Ancient Geography, a people of Gaul, who inhabited the town of Arauio, situated in the interior of the country.

Secundans, in Mathematici, an infinite series of numbers, beginning from nothing, and proceeding as the squares of numbers in arithmetical progression, 25 0, 1, 4, 9, 16, 25, 36, 49, 64, &c.

Secundaria in Geography, a town of Hindoostan, in the subah of Delhi; 25 miles S.E. of Delhi. N. lat. 28°32'. E. long. 78°17'.

Secundary, or Secondary. See Secondary.

Secunderpoure, in Geography, a town of Hindoostan, in Benares, on the Ganges; 35 miles N.E. of Gazypour.—Also, a town of Hindoostan, in the circuit of Jeynagar; 15 miles S.E. of Parsafoo.

Secundi Generis, in Anatomy, a distinction among the lactic vessels. There are two kinds of lactic; one primary, or those of the first kind, primum generis; and se- fundi generis, secondary, or of the second kind.

The first carry the chyle from the intestines into the glands, dispersed in great numbers throughout the mesentery. The second carry it from these glands, after its being diluted there with lympha, into the common receptacle. See Lacteals.

Secundi internodi pollicit esterior. See Extensor.

Secundans, in Ecclesiastical History, a sect of Val- estrians in the second century, whose chief, Secundus, one of the principal followers of Valentine, maintained the doctrine of two eternal principles, viz. light and darkness, from
whence arose the good and the evil that are observable in the universe.

SECUNDINES, in Anatomy and Midwifery, the placenta, umbilical cord, and membranes including the fetus, which, being expelled from the uterus after the fetus, constitute the after-birth. They are described under the article Embryo.

Dr. Grew, in his Anatomy of Plants, applies the term fecondine to the fourth and last coat or cover of seeds; because this performs nearly the same office in plants, that the membranes, investing the fruit, do in animals. And indeed Pliny, Columella, Apuleius, &c. have used fecondine in the same sense.

SECUNDO. Proposito de Secundo adjacente. See Proposition.

SECUNDRA, in Geography, a town of Hindooistan, in the circum of Sirkhand; 90 miles E. of Sirkhand.—Alto, a town of Hindooistan, in Doob; 15 miles W. of Canoge.

SECUNDUS, Johannes, in Biography, is the literary name of John Everard, a celebrated Latin poet, the son of Nicholas Everard, an eminent jurist, and prebend of the council of Mecklin under Charles V. He was born at the Hague in 1511, and at an early age fled the law at Bourges. He, however, shewed a decided attachment to polite literature in preference to jurisprudence, and contracted intimacies with some of the most distinguished Latin poets of his time. He travelled into Italy and Spain, and was made secretary to cardinal Tavera, archbishop of Toledo. He followed Charles V. in his expedition against Tunis, but the delicacy of his constitution not permitting him to undergo the fatigues of war, he returned to the Low Countries, where he died at the early age of twenty-five. Few modern Latin poets have possessed more facility and sweetness than Secundus. A volume of his elegies, epigrams, odes, and miscellaneous pieces, together with a narrative in prose of his different journeys, was published. Of all his poetical works, the “Biaia” have been the most popular, on account of their diction, and the delicate volupitousness of their painting. They are still read, and new editions are frequently printed. Johannes had two brothers, who were also eminent Latin poets, known by the names of Nicolas Gradius, and Adrian Marius. They have united in an affectionate commemoration of their deceased brother, annexed to his poems. Secundus himself practised the art of engraving, and to his volume is prefixed a portrait of a female, with the following inscription: “Vatis amatoris Julia sculpta manus.”

Secundus, in Botany, a term not very easy, in the technical sense of Linneaus, to translate. One ranked may generally express its meaning. This term is applied to a racemosus, or cluster, whose flowers are all turned to one side, as in Pyrola secunda. Engl. Bot. t. 517.

Secundus Mulle, in Anatomy, a name given by Duverney, and some others, to one of the muscles of the ear. It is the internus auris of Cowper and others, and is most properly named by Albinus tenor tympani.

Secundus Occlum Movens, a name given by Velalius to that muscle of the eye, called by Riolanus and others superculus, and elevator oculi, and by Albinus the subducitor, one of his four muscles recti of the eye.

Secundus Poronexus. See Poronexus.

Secundus Scalenus. See Scalenus.

Gen. Ch. Cal. Perianth inferior, small, deciduous, of three, ovate, colored leaves, the uppermost of which is opposite to the standard, the others accompany the keel. Cor. papilionaceous, of five petals: wings much spreading, very obvtule; standard of two leaves, oblong, straight, united to the keel at the base, reflexed at the tip; keel as long as the wings, nearly cylindrical, its border dilated, bearing a little, obvtule, plaited appendage. Stam. Filaments eight, combined at the bottom; anthers oblong, erect. Pifl. German superior, ovate, terminating in an awl-shaped fylle; stigma flat, dilated, toothed at the tip. Peric. Legume ovate, of one cell, ending in a ligulate wing. Seed solitary, oblong.

Obf. In habit this genus is very nearly allied to Polygala, but it is polypetalous, and the fruit has only a single cell, resembling the capsules of Banifleri.

Ed. Ch. Calyx of three leaves. Corolla papillonaceous: the standard of two leaves within the wings. Legume ovate, of one cell and one seed, ending in a tongue-shaped wing.

2. S. volubilis. Climbing Securidaca. Wilth. n. 2—(S. scandens; Jacq. Amer. t. 183. f. 83—Spartium scandens, fructu crisitato et alato, flore rubro; Plum. Ic. t. 247. f. 1.)—Stem twining. Leaves oblong, acute.—Native of South America, and the West Indies. Found in Jamaica by Browne, and at Carthagena by Jacquin.—A twining fbrus, whose younger, leafy branches are changed into very strong tendrils. Leaves alternate, oblong, pointed, scarcely flalked. Flowers in loaves, lateral clusters, red, ficientes.

3. S. virgata. Wand-like Securidaca. Wilth. n. 3—Swartz Prod. 104.—(Spartium alterum scandens, fructu alato, flore variegato; Plum. Ic. t. 144. f. 1.)—Stem twining. Leaves roundish, very obtule.—Native of Jamaica and Hifpaniola. Swartz is of opinion, that Browne’s first species in his Hiory of Jamaica, must be this, and not S. ericeta, as Linneaus supposed. We know of no further description of this species than what is quoted above.

For Securidaca of Tournefort, Miller, and Gartner, see Cornusilla.

Securinega, so denominated by Commerson, from securis, a hatchet, and nega, to deny, or refuse to yield; in allusion to the extreme hardiness of the wood, called Bois dur by the French, in the Ille de Bourbon. Some also call it, according to Commerson’s manuscripts, Bois de Tres, and others Quin-quin. The English, who rest with this tree in Otaheite, named it, from the appearance of the leaves, Otaheite Myrtle.—Juff. 388—Wilth. Sp. Pl. v. 4. 761—Point in Lamarck Dict. v. 7. 631—Ait. Hort. Kew. v. 5. 583—Clas and order, Dioecia Pentandria; (or rather Monadelphia.) Nat. Ord. Euphorbiaceae, Juff.

Female, on a different tree, Cal. Perianth as in the male, inferior, permanent. Cor. Nectary as in the male; permanent. Pifl. German superior, nearly globular, three-sided; fylles
instance, a few spines as in the male, permanent.

Cymodoceum, Oct.* 3, three-celled.

S. C. M. A., Calix, in five deep segments. Petals

N., a peculiar ring on the outside of the

Tarsus, Calyx, and calyx as in the male, permanent.

Cymodoceum, Oct. 3, three-celled.

S. C. M. A."

SECURIS, John, in Biography, an English physician

of considerable character in his day, was born in Wiltshire,

and studied with great reputation in New college, Oxford,

in the reign of Edward VI. From thence he went to Paris,

where he diligently pursued the study of astronomy and med-

dicine, the latter under the celebrated professor Sylvius.

On his return, he settled at Salisbury, and was much referred
to on account of his skill in the practice of physic. He

published annual tracts, which he called "Prognostics!"

and which appear to have been a kind of almanacs, accom-

panied with astronomical predictions and medical precepts.

Andrew Wood had been two of them, for the years 1579

and 1580. To the latter was added, "A Compendium, or

brief instructions how to keep a moderate diet." Securis

was likewise the author of "A Detection and Queremony

of the daily Enumorities and Alphabets committed in Physic,

concerning the Three Parts thereof." Lond. 1566.

This is a little treatise, written with learning and pithiness,
on the often repeated complaint of the intrigue of irregularly

educated persons into the practice of physic, and the per-

sistence of surgeons and apothecaries in taking upon them

to act the physician. A peroration in verse, addressed to the

two universities, is subjoined. This work was thought to be

so much meritorious, that it was reprinted in 1662, and

published along with Recorde's "Judicial of Urines." The

author is not named in the title-page, but is called "A Doc-

tor of Physick in Queen Elizabeth's Days." In this tract

there is a reference to one which Securis had published about

the year 1554, with this odd title: "A great Galley lately

come into England out of Terra Nova, laden with Physi-
cians, Surgeons, and Apothecaries." See Atkin's Biography.

Memoirs of Med.

SECURITATE PACIS, in Law, a writ which lies for

one who is threatened with death or danger, against the

person who threatens him. It is taken out of chancery, di-

rected to the sheriff. See Peace and Security.

SECURITATEM, serious factum quod non divisatur ad

paetis extra finem legis regis, an ancient writ lying for the

king against any of his subjects, to stay them from going

out of this kingdom into foreign parts; the ground whereof

is, that every man is bound to serve and defend the common-

wealth, as the king shall think fit.

SECURUM, Si tine fuerit. See Si tine fuerit.

SECUTOR, VR. 2, 6, an army officer designated

for the purpose of fire, fire, and for the

SECUTORIES, in Anglia, a kind of sea, among the Romans, well described by the return

The word is taken from the verb to set, to bring; hence the levellers used to plant the return, when they

took to cast the net, or, of those on their head; and they were two miles on their head. Some considered the return

with writs, because both had nearly the same

Weapon.

Secundus was also the name given to two glorifiers as

took the place of those killed in the combat; or who

fought the conqueror. The part was usually taken by

the ancient mountaineers we also meet with secutor triumvir, se-

cutor duumvir, secutor Cesaris, sec. who were officers attending

the tribunes and generals; perhaps like our aids-de-camp.

SECEZENIAGA, in Geography, a town of European

Turkey, in Dobroua Tartary, on the Dismoe; 20 miles N.

of Kirfova.

SEDA, a town of Portugal, in Alettejo; 6 miles W.

of Altor do Chao.

SEDAB, in History, a name given by the Persian

physicians to the wild, or mountain rae, a plant common

in Syria, Greece, and other places. Avicenna supposes the

gum, which he calls gentum, or gentum, to be produced from

this plant, but very erroneously, that gum being obtained

from the roots of the thafia, or deadly carrot.

SEDAINE, Michel Jeann, in Biography, a French

dramatic writer, was born at Paris in 1719. His father, an

architect, having left his family entirely destitute, the sub-

ject of this article was obliged to work for a common mason,

to maintain his mother and two younger brothers. By his

ludicrous industry he became a master mason, but his fond-

ness for the theatre having led him to make some attempts at

dramatic composition, which were attended with a con-

siderable portion of success; he was, in 1754, engaged by

Monet, director of the comic-opera, to devote himself to the

service of the stage. His talents were so well exerted,

that he brought full audiences to that theatre, which had,

before his time, been nearly deserted, and he passed many

years in this employment, generally beloved and esteemed

by the literary characters of the time. He died in the year

1797, in the 78th year of his age. Sedaine was the author

of a great number of pieces, chiefly of the light kind, and

accompanied by music. Some of them were eminently suc-

cessful; the "Le Deferent" was represented one hundred

times. He had a perfect knowledge of stage effect: his
dialogue was easy and natural, though extremely incorrect;

hence his works were more adapted to the stage than to the

closet.

SEDAKI, in Geography, a town of Japan, in the island

of Nippon; 40 miles N.W. of Nambu.

SEDA, a town of France, and principal place of a

district, in the department of the Ardenne, situated on the

Meuse; strongly fortified, and reckoned one of the keys of

France. It is divided into the north and south parts: the

former contains 5984, and its canton 11,471 inhabitants, in

14 communes: the latter has 4563, and its canton 13,724

inhabitants, in 22 communes. Both comprehend 320 kilo-

metres. This town has a manufacture of cloth; and before

the revocation of the edict of Nantes, it had a flourishing

protestant university; 131 polls S.S.W. of Liege. N. lat.

49° 42'. E. long. 5° 1'.

SEDAN CHAIR. See Chair.
SEDANG, in Geography, a town on the N.W. coast of the island of Borneo. N. lat. 2° 15'. E. long. 116° 45'.

SEDAREE, a town of Persian Armenia; 30 miles S.E. of Erivan.

SEDASHYCUR, a town of Hindoostan, in Canara, on the coast; 6 miles N.W. of Carwar.

SEDASIER, a town of Hindoostan, in the country of Coorga, where a battle was fought in 1799, between the troops of Tippoo Sultan, and the British under general Stuart, in which the former were defeated; 7 miles from Periapatam.

SEDATIVE, in Medicine, from sedare, to still, or allay, a term which was used by the older writers, nearly in the same acceptation with anodyne; namely, to denote such medicines as were calculated to allay pain. But among the moderns it has been employed in another sense, and stands in opposition to stimulant. In the modern pathology, all the actions of the animal frame are ascribed to the agency of the nervous power; and whatever increaees or excites that power, or its actions, is thence called a Stimulant; and those agents, on the contrary, which diminish or retrain that power, or its actions, are therefore denominated sedatives. Of the former class, wine, alcohol, camphor, ether, aromatic substances, &c. may be enumerated as examples; of the latter, tobacco, digitalis, fugar of lead, opium, &c. In the school of Brunswick, however, which the word stimulant is in constant use, the existence of a direct sedative is absolutely denied; for the Brunonian hypothesis maintains, "that life is the result of the action of stimulants on the principle of excitability, and, consequently, that every thing which acts must be stimulant."

(See Excitability.) It further maintains, that a sedative action is not real, but apparent; or rather, is not direct, but indirect; that is, it is the result of the previous stimulation; and therefore, that an actual sedative is a non-entity. But this argument, like many others of the Brunonian school, is an obvious petitio principii in logic: it is founded upon two unproved propositions; first, that life is solely the result of excitement; and, secondly, that a previous excitement occurs, where it is not cognizable, as in the case of digitalis, and the superacetum of lead, and some other narcotics, which appear to influence directly the action of the heart and arteries, and to depress the whole nervous power. The use of sedatives for medicinal purposes, is principally confined to the regulation of the arterial system, as in cases of hemorrage, especially from the lungs, in defeces of the heart, &c.

SEDATIVUM SAL. See Sedative Salt.

SEDAU, in Geography. See Seyda.

SEDBERGH, a market-town in the west division of the wapentake of Staincliffe and Evercros, Well Riding and county of York, England, is situated in the parish of Sedbergh, at the distance of 27 miles N.W. by N. from Settle, and 27 miles N.W. by N. from London. This place, which, according to the late population returns, contained 344 houses and 1865 inhabitants, is chiefly indebted for its support to the manufacture of iron articles. The market is held on Wednesday, weekly; and there are fairs annually on the 20th of March, and the 29th of October. Here is a free school, but neither it nor the church is in any way remarkable. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1813.

SEDE, a lake of Egypt, separated from the Mediterranean by a neck of land, which extends from Aboukrik to within a mile or two of Alexandria. It communicates with the sea by a narrow opening, and wetherly the British army opened a channel to form a communication with lake Marcots; it is also called the "lake of Aboukrik."—Also, a lake of Egypt, producing natron; 55 miles N.W. of Cairo.

SEDEANA, a town of Italy, in Friuli; 10 miles W.S.W. of Udina.

SEDEF, a town of Egypt, on the left bank of the Nile; 7 miles S. of Abutigé.

SE DEFENDENDO, in Law, a plea for him who is charged with the death of another; alleging, that he was forced to do what he did in his own defence, the other so assailing him, that he had not done as he did, he must have been in danger of his own life. See SELF-defence, HOMICIDE, and MANSLAUGHTER.

SEDELLA, in Geography, a town of Spain, in the province of Grenada; 12 miles N. of Velez Malaga.

SEDEM ATTOLLENS, in Anatomy, a name given by Vefalus and others to the mucule, now more generally known by the name of levator ani.

SEDENTARIUM Os, a name given by some anatomical writers to the protuberance of the os coxendicus, on which the whole weight of the body rests in fitting.

SEDER OLAM, in Philology, a Hebrew term, literally signifying, order of the world; being the title of two chronicles in that language.

They are both very short, though the one more so than the other; for which reason the one is called feder olam roabb, that is, the great feder olam; and the other, feder olam wata, i.e. little feder olam.

SEDER OLAM, the Great, commences at the creation of the world, and comes down as low as the war of the plessed-messiah Barcochesha, under Adrian, fifty-two years after the destruction of the temple of Jerusalem; and by conquence to the hundred and twenty-second year of Christ. It is almost all taken from the Scripture, excepting the end. It is the work of R. Jofa, son of Hillepeta of Tipperior, who lived in the second century, about the year 130, and was master of the famous R. Juda Hakkadoth, the compiler of the Mishna.

SEDER OLAM, the Lesser, is an abridgment of the former, brought down as far as Mar Sutra, who lived 450 years after the destruction of the temple, or 522 years after Christ. F. Morin, continually bent upon diminishing the antiquity of the principal books of the Jews, endeavours to prove this to have been written about the year of Christ 1124, as indeed it is expressed in the beginning; but R. Dav. Gantz has overthrown this opinion in his Tienmaiah David, and shewn that the date in the beginning is an interpolation.

These two chronicles were first printed at Mantua in 1514, 4to. 5 again at Baffy, by Probenius, in 1580, 8vo. at Venice, in 1545, 4to. and at Paris, with a Latin version of Genebrard, in 17mo. They have been since reprinted at Amsterdam, in 1711.

SEDERON, in Geography, a town of France, in the department of the Drôme, and chief place of a canton, in the district of Nyons. The place contains 614, and the canton 7334 inhabitants, on a territory of 375 kilometres, in 18 communes.

SEDFE, a town of Egypt, on the left bank of the Nile; 3 miles S. of Bata.

SEDGE GRASSES, in Agriculture, a title given to various sorts of grases of the poor hard carnation kind, which are very hardy in their nature, and prevail much in most crude heavy land. They are scarcely ever touched by live- stock, being what may be called the fag end of herbage. See CAREX and WEEDS.
SEDGEFIELD, in County, a market-town in the north-east division of Stockton, was on 15 Jan.[1] late of Durham, England, is situated at the distance of 11 miles S. by E. from Durham, and 255 N. by W. from London. The position of this town is one of the finest that can be imagined, being that of the summit of a gentle hill, surrounded on all sides by a country in the highest state of cultivation. On the north and south-east is a delightful prospect of Clark's, Reckaby, Toppesfield, and a large range of pretty hills, with the borders of the river Tees, drawn to the German sea; on the south-west is a beautiful country decked with a variety of fine woods; and on the south and south-west appear the towns of Bishop Middleham and Pickburn and Thornton. The celebrated Dr. Abraham called Sedgefield the Montpelier of the north of England, and very frequently recommended his patients to it for the benefit of the air. In the centre of the town is a spacious market-place ornamented with a handsome clock. On one side of it stands the church, which consists of a nave, transept, chancel, and three aisles, with a lofty tower rising from the intersection of the nave and transept. The pillars of the interior are clustered, and support light pointed arches. Between the nave and the chancel is a rich screen of oak woodwork, having three arches on each side, divided by beautiful light columns, and covered with canopies. The whole chancel is wainscotted with oak, panelled, and ornamented with cherubs. In this church were formerly two chantries, one dedicated to St. Catherine, and the other to St. Thomas; also a guild, dedicated to St. Mary. Here are numerous monuments; and among others two curious brasses, representing skeleton figures in winding sheets.

Sedgefield became a market and fair-town in 1312, by grant from bishop Kellaway. The market-day is Friday, weekly; and the fair is held on the eve of St. Edmundo. Here is an hospital, founded by the truckers of Thomas Cooper, surrog of this place, who died in 1703; also a free grammar-school, situated near the church. According to the parliamentary returns of 1811, this town contained 247 houses, and a population of 1307 inhabitants. The History and Antiquities of the County Palatine of Durham, by William Hutchinson, F.A.S. vol. ii. 410. 1794.

SEDGEPOOK, a village of Patagonia, which runs into the Strait of Magellan. Its water is excellent, and on each side are very fine trees, which Commodore Byron says were supplied the British navy with the best masts in the world; some of them being of a great height, and more than eight feet in diameter. Among these woods are many parrots, and other birds of most beautiful plumage. Geese, ducks, and fish, and fresh provisions are abundant. The traces of wild beasts were perceived in the field, but none were seen. Many huts and wigwams were seen, but no Indian was observed. The mouth of this river is in the W. part of Port Famine.

SEDGMOOR, a large tract of English land, in the county of Somerset, memorable for the defeat of the Duke of Monmouth in the year 1685; situated between Somerset and Bridgewater.

SEDGWARA, a town of Hindeoostan, in Guzerat; 20 miles E. of Surat.

SEDGWICK, a town of America, in the state of Maine and county of Hancock; on Naugatuck Point, which bounds Persiffor on the N.E., extending to the town of Penobscot, and distant 155 miles E. from Boston. It contains 1735 inhabitants.

SEDHOU, a town of Hindeoostan, in the circuit of Cuddapa; 6 miles N.E. of Cuddapa.

SEDILIO, a town of the land of Song, 36 N.E. of Oranges.

SEDIMUMENT, learned from the Latin, signifies, which Matthew Sylvanus derives a state or furnishing, or dress of any thing; or that part, way, or field body was, up a winding, leads to the L of the world.

Some physicians live hard, and few to deliver, in the nature of the disease, from the hand of man. Dr. Woodward testifies, that, at the decline, the whole terrestrial globe was divided into two departments, that the new world, among others, was: chiefly explored, and without any inequalities, consisting of several states, which the earthy element gradually produced, as it drained.

SEDINA, in the Maturi Medici, a word highly used by the writers to express dragon's blood.

SEDINI, in Geography, a town of the island of Sar- dina; 10 miles S.E. of Cotel Ansepolis.

SEDATION, among Graecians, is used for an irregular commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of society. See Revolition.

This offence is of different kinds: some seditions are immediately threatening the supreme power, and the subversion of the present constitution of the state; others tending only towards the redress of private grievances. Among the Romans, therefore, it was generally punished, according to its end and tendency threatened greater mischief. (See lib. i. Cod. de Seditionib, and Matth. de Crum's lib. ii. n. 5. de Lacta Majellate.) In the punishment, the authors and ringleaders were justly distinguished from those, who, with less wicked intention, joined and made part of the multitude.

The same distinction holds in the law of England, and in that of Scotland. Some kinds of sedition in England amount to high treason, and come within the stat. 25 Edward III. as levying war against the king. And several seditions are mentioned in the Scottish acts of parliament as treasonable. (Baye's Crim. Law of Scotland, p. 33, 34.) The law of Scotland makes riotous and tumultuous assemblies a species of sedition. But the law there, as well as in England, is now very much regulated by the riot act made 1 Geo. I., only it is to be observed that the proper officers in Scotland to make the proclamation thereby enacted, are sheriffs, lieutenants, and bailies of royalities, or their deputies; magistrates of royal boroughs, and all other inferior judges and magistrates; high and petty constables, or other officers of the peace, in any county, city, or town. And in that part of the island the punishment of the offence is death, and confiscation of moveables: in England it is felony. See Riot.

SEDELEY, Sir Charles, in Biography, a dramatic writer, born in 1639, was son of Sir John Sedley of Ayleford, in Kent. He was educated at Wadham college, Oxford, and after leaving the university, he passed his time in retirement till the restoration. On that event he came to court, and was one of the licentious circle round Charles II. His first efforts in writing were some amatory poems, chiefly distinguished by their voluptuous cast. At this period of his life he was guilty of some public indecency, on account of which he was fined 500£. Sir Charles's fortune being impaired by this course of life, he got into the house of commons, and he sat in three parliaments during that reign, in which he was frequently speaker. In the following reign he took a patriotic part, which would have been highly to his credit, if private pique
had not been the principal motive of his conduct. It appears, notwithstanding the laxity of his own morals, that he was much offended with James II. for taking his daughter for a mistress, in which quality she was raised to the title of countess of Dorchester, an elevation that, as her husband indignantly said, only rendered her infamous the more conspicuous. Sir Charles joined the earl of Dorset in a steady opposition to the design of keeping up a standing army after Monmouth's rebellion, and he concurred in all the measures which produced the revolution. For the latter he gave the honourable reason, that as the king had made his daughter a countess, he would in return do all in his power to make his majesty's daughter a queen.

Sedley long continued to be regarded as a fine gentleman, a lively companion, and a judge and patron of poetry, in which last capacity he was instrumental in bringing Charles Montague, afterwards earl of Halifax, into notice. He is supposed to have lived to beyond his eightieth year. His works, in two vols. 8vo., consist of poems, speeches in parliament, and a number of dramatic pieces, none of which are retained on the stage. Biog. Brit.

SEDLEZANY, in Geography. See SELTSCHAN.

SEDLITZ, or GREAT SEDLITZ, a town of Saxony, in the margrave of Meissen; 2 miles S.W. of Pina.— Alto, a village of Bohemia, in the circle of Sazt, where Hoffmann, in the year 1724, discovered a medicinal spring, from which is prepared a purgative salt, near Moft.

SEMDA, a word used by some as a name for the lapus hamaticus.

SEDNEVO, in Geography, a town of Russia, in the government of Tchernigov; 24 miles N.E. of Tchernigov.

SEDORP, a town of the duchy of Holstein; 8 miles N.E. of Segerborg.

SEDSÁ, a town of the island of Corfica; 12 miles N.W. of Corte.

SEDOSCHEROI, in Ancient Geography, a people of Pontus, in the vicinity of the river Cohibus, according to Tacitus.

SEDr, or SEDRE, the high priest of the sect of Ali, among the Persians.

The fdr is appointed by the emperor of Persia, who usually confers the dignity on his nearest relation.

The jurisdiction of the fdr extends over all effects defined for pious purposes, over all mosques, hospitals, colleges, felpuches, and monasteries. He dispenses of all ecclesiastical employments, and nominates all the superiors of religious houses. His decisions, in matters of religion, are received as so many infallible oracles; he judges of all criminal matters, in his own house, without appeal; and is, without contradiction, the second person in the empire.

The fdr, however, has not any indelible character, but frequently quits his post for another purely secular one. His authority is balanced by that of the mudschich, or first theologe of the empire.

SEDRE PASSAGE, in Geography, a narrow channel of the East Indian sea, on the N. coast of Sumatra, between Pulo Nancy and King's Point.

SEDIULUS, CATHÓLICUS, or ZEOLIUS, in Biography, a priest and poet, who flourished about the year 250. He is known only by his writings, of which the principal is a Latin poem in heroic verse, entitled "Paehala Carmen," in five books, the first of which relates to the histories recorded in the Old Testament, and the last four to the life and miracles of Christ. This work is chiefly esteemed for its subject, though the style is flowing, and, for the age in which it was written, is tolerably pure. It has been printed several times, and is contained in Mattaire's "Corpus Poetarum." An edition of it was printed in 1704. A prose work of the same writer is extant, entitled "Paehala Opus."

Ell. Ch. Calyx five-cleft. Petals five, with five nectariferous scales at the base of the germen. Capsules five, superior.

The herbage of this genus is succulent, and mostly, though not invariably, smooth. The flowers are either of a yellow, white, or reddish colour.—Willdenow enumerates twenty-nine species, which are divided, after Linnaeus, into two sections, Planifolia and Tereifolia; the former including such as have flat leaves, the latter such as have round, or cylindrical ones. To these however we have several to add, some of which are Brit. As a collection from the whole genus, the following are the most remarkable.

Seet. 1. Planifolia.—Leaves flatish.

S. Telephium. Orpine or Live-long. Linn. Sp. Pl. 616. Engl. Bot. t. 1319. Curt. Lond. fisc. 3. t. 25.—Leaves flatish, serrated. Corymb leafy. Stem erect. Found in dry fields, about hedges, and on bulbous hills in Britain and most parts of Europe, on a gravelly or calcareous soil, flowering in August.—Root perennial, tuberous, fleshy, white. Stems two feet high, erect, simple, leafy, round, smooth, purplish. Leaves scattered, fleshy, ovate, fleshy, flat, toothed in a serrate manner, rather glaucous, smooth. Flowers purple, occasionally white, forming terminal, many-flowered, crowded, leafey tufts. This species is found to vary in the colour of its flowers and the serrature of its leaves, as well as in the size of all its parts.

S. Anacamperos. Evergreen Orpine. Linn. Sp. Pl. 616. Curt. Mag. t. 118. (Anacamperos minor, rotundire folio, sempervirens; Tournef. 264.)—Leaves wedge-shaped, attenuated at the base, nearly fleshy. Stems succulent. Flowers corymbose.—Native of the south of France, mostly in the crevices of rocks. It flowers in July and August.—Root perennial, fibrous. Stems redish, trailing at their base, more upright and glaucous towards the top. Leaves numerous, alternate, or scattered, ovate, fleshy, dotted at the tip of a blue-fish-green colour. Flowers deep lilac or purple, rarely white, in compact, leafy, terminal tufts.

SEDUM.

Auga. — 
Stems tuberculate, erect, a little wavy, spreading, about a foot in height, frequently of a bright red color. **Leaves alternate,驿站, on length stalks, slightly leathery, turning of a brownish-red colour, fleshy.**

In habit and appearance this plant greatly resembles Sarcocaulon rotundifolium.

S. rotundifolium. Starry Stonecrop. Linn. Sp. Pl. 617. "Fl. Græc. t. 434." Leaves flat, angulated. Flowers lateral, solitary, little — Native of France, Italy, and the mountains of Greece, flowering in June and July. **Root annual, with spreading fibrous. Stem upright, thick, waxy, pink coloured at the base, brownish at the top. Leaves scattered, wedge-shaped, angulated with about seven teeth, very fleshy, with yellow dots, finely fringed. Flowers solitary, terminal, of a delicate white colour; each petal marked longitudinally with a pink line.**

S. tetraphyllum. Four-leaved Stonecrop. Sm. Prod. & Fl. Græc. Sibth. n. 1048. "Fl. Græc. t. 448." — Leaves in fours, spatulate, entire, obtuse. Found by Dr. Shibthorpe in Peloponnesus, and also in Sicily. **Root annual, fibrous, white. Stem upright, hairy, branched at the base; the branches rather decumbent. Leaves four together, numerous, fleshy, club-shaped, fibrous, fringed with hairs. Flowers in long, terminal, leafy spikes, white, tipped with a pink rib. The whole plant is of a yellowish-brown hue, dotted with red, and thickly beft with hairs.**

S. angustus. English Stonecrop. Sm. Fl. Brit. t. 171. Engl. Bot. t. 171. — Leaves thick, ovate, gibbous, and loose at the base. **Cyme of two branches. Native of Great Britain, but not a common plant. It has been gathered near Dumbarton castle, on the fanny downs near Yarmouth, and other maritime and mountainous localities, flowering in July.**

S. aequal. Flowering in July. — Roots and stems. **Leaves** crowded at the base, flat, leathery, red. **Roots** frequently occur, rising, very thick, fleshy, ovate, slightly green, with a few tubercles at their base. **Stems** red, thickly covered, afterwards in red; red, petal white, with a red rib, and generally dotted with red at the tips. Capillary membranous, two-ribbed.**

S. aequal. Bitsy Stonecrop. Wall. Wood. Sp. Pl. 619. Engl. Bot. t. 857. Curt. Lond. Isæ. 1. t. 8. — Wood. Sp. Suppl. 5. 231. — Leaves entire, short, thick, fleshy, gibbous, fixed to the stem by their root in the base. **Cyme three-ribbed, leafy.** — The flowers are compact in an hour or two in some time afterwards, with red, and dry, red, or a fancy ground, which it sheds as it rises with a clasp of gold, in distance of course and most for charming air.**

S. pentim. Pentim. — Leaves tufted, branched, decumbent, smooth, round, leafy. Leaves alternate, fleshy, erect, spreading, gland, green, scarlet, pretentious at the back. Flowers erect, golden-coloured, its terminal, three-ribbed, leafy. — The whole herb is annual, leaf and bunching to the tailer, whence its common name.

S. pentim. Bitsy Stonecrop. Wall. Wood. Sp. Pl. 620. Engl. Bot. t. 1926. Curt. Lond. Isæ. 4. t. 53. — Leaves in five or seven rows, few, flat, ovate, red, fleshy, spreading, fixed to the stem by its root in the base, the base. **Cyme three-ribbed, leafy.** — Occasioned to be met with in dry, leafy places, about wells, flowering in June and July. In hills this is general, so it resembles the last species, but it is generally red rather. The leaves are more cylindrical, not ovate, about three together in alternate whorls,1 distant in the whole leafy stem or branch five or seven or eleven rows. **Cyme terminal, of two larger branches, and a small one. Flowers pellucid yellow.** The foliage frequently turns red. The whole herb, though unpleasantly bitter, is of the most elegant pungency of flavour.

S. hians. Mountain Stonecrop. Willd. n. 16. Wiggers Hol. t. 35. "Fl. Græc. t. 450." Fl. Dan. t. 59. — Leaves scattered, convex on one side, flat on the other, obtuse, loose at the base. **Stem branched, decumbent.** — Native of rocky mountains in Norway and Switzerland, also in Greece, flowering about June. **Root annual. Stems** woody, five inches high, branched, diffuse. **Leaves** distinctly alternate, fleshy, bright green, the lower ones sometimes turning red. **Flowers** fleshy, solitary, hanging on one side of the branches, yellow.

S. villifolium. Hairy Stonecrop. Linn. Sp. Pl. 620. Engl Bot. t. 354. Fl. Dan. t. 24. — Stem erect. **Leaves** flatish, slightly hairy, as well as the flower stalks. **Native of mountains and damp pastures, and the most fibres of rocks, flowering in July.** — **Root perennial, fibrous, stem erect, leafy, downy towards the upper part, branched at the base. Leaves alternate, linear, fleshy, often pink-coloured, rough at the back with vied hairs. Flowers cyme or paniculated, on vied stalks; their petals white or rose-coloured, with a red rib. Capillary pointed, red, purplish.**

S. aequal. Petal white, with a red rib. Capillary membranous, two-ribbed.**
SEDUM.

a span high, round, leafy, branched, smooth, decumbent at the base. Leaves scattered, spreading horizontally, rather glaucous, fleshy, and extremely juicy. Panicle terminal, rather cymose, many-flowered, smooth. Flowers white or reddish.

S. achroleucum. Pale Stone-crop. Sm. Prod. Pl. Græc. Sibth. ii. 1825. Sm. in Trans. of Linn. Soc. v. 10. 6. (Sempervivenia fediformis; Jacq. Hort. Vind. t. 81.)—Leaves glaucous, scattered, acute; the lower ones round; upper elliptical, deprested. Segments of the calyx rather acute. Found on walls, rocks, and banks, as well as about shady culverts, in the south of Europe. It flowers in July. An interesting account of this species is given by Sir J. E. Smith, in the volume of the Linnean Transactions above quoted, where it is shown to be the Anargon to which Diocleides, who describes it thus: "Several slender stems spring from one root, thickly encompaßed with little, round, succulent, sharp-pointed leaves. It throws out, moreover, a stem towards the middle, about a span high, with an umbel of slender (greenish or) pale yellowish flowers?"

This plant, when potted, is used at Athens as a cooling cataplasm to bruises or gouty limbs.

S. glaucum. Glaucous Stone-crop. Engl. Bot. t. 2477. (S. reflexum β; Sm. Pl. Brit. 490. S. minus hematoides; Ger. Em. 512.)—Leaves glaucous, awl-shaped, scattered, loosened at the base; those of the branches thread-shaped. Flowers in a cyme. Segments of the calyx lanceolate. —Native of this country, flowering in July and August. It differs from the last (of which it has till lately been considered but as a variety) in its more glaucous hue, and more slender leaves, especially those of the branches.

S. Forsterianum. Forsterian Stone-crop. Engl. Bot. t. 1852.—Leaves thick, awl-shaped, clustered together in many rows, spreading, loose at the base. Flowers in a cyme. Segments of the calyx short and rounded. Gathered by E. Forster, jun. eqv. near the Devil's bridge, Cardiganshire, in 1856. It flowers in July. This species has hitherto been confounded with rugosum, from which however (fays the author of English Botany) it differs in having the leaves of the barren branches spreading in a rostrate form, not clove-pressed or erect, and especially in the want of a glaucous hue in the leaves, stem, and calyx. The petas also are more elliptical and blunt.

SEDUM, in Gardening, contains plants of the hardy herbaceous succulent kind, of which the species cultivated are; the orpine Stone-crop (S. telephium); the evergreen Stone-crop (S. anacampseros); the yellow Stone-crop (S. aizo on); the poplar-leaved Stone-crop (S. populifolium); the hairy Stone-crop (S. flaccidum); the purplish-leaved Stone-crop (S. cepa); the thick-leaved Stone-crop (S. dasyphyllum); the rock Stone-crop (S. rupestris); the Spanish Stone-crop (S. hispanicum); the white Stone-crop (S. album); the biting Stone-crop, or wall pepper (S. acre); the infundibular Stone-crop (S. fexangulare); the English or mild white Stone-crop (S. anglicum); and the annual Stone-crop (S. annuum).

In the first fort there are several varieties, as with purple flowers, with white flowers, with broad leaves, and the greater orpine.

In the sixth fort there is a variety which has the fln more erect, and the lower leaves in threes or fours, the next opposite, and the uppermost alternate.

The seventh fort, when introduced into a garden, propagates itself freely upon walls, in wall places, and about garden pots; and no plant is better adapted to the purpose of decorating rock-work, as it grows without any trouble, in any aspect, multiplying very much by young shoots, and always looks beautiful.

The ninth, as well as the preceding fort, are cultivated in Holland and Germany to mix with lettuces in fallads.

The eleventh fort is eaten by fome as a pickle.

Method of Culture.—These plants are all raised without much difficulty, by proper care and attention to have the soil dry, and of the poor sandy kind.

Culture in the Orpine Sorts.—These may all be readily increased by planting cuttings, during the summer months, in light mould in a shady situation, or in pots placed in similar situations. The plants in the open ground, as well as those in pots, should be kept clean from weeds, and be watered frequently when the weather is dry. They may likewise be raised by pitting the roots, and planting them in a similar manner in the spring or autumn. When the plants are once well established, they spread rapidly, and require little or no care.

These plants are sometimes cultivated for medicinal use.

Culture in the Stone-crop Kind.—These are raised without much trouble, by planting out their trailing flanks in the spring or summer feason, which readily take root. They thrive most perfectly on old walls, buildings, or rock-works. Where cuttings or roots of the perennial kinds are planted in some soft mud, placed upon such situations, they quickly take root and spread into the different joints and crevices, covering the whole in a very short time.

The seeds of the annual sorts also, when sown soon after they become ripe in such situations, soon come up and support themselves without further trouble.

Most of the perennial sorts are kept in the nurseries in full plants, fit for setting out in the borders, pots, &c. either in the spring for flowering the same year, or in the autumn to flower in the following year. These plants may be planted out in any dryish light soil, in borders, beds, and other places, and in the sides of dry banks, or in any elevated rubbishy soil, as well as in pots to move to different parts occasionally; or also some of the evergreen kinds, to introduce in their pots among winter plants under shelter, to increase the variety. In most sorts, they may also be introduced as rock plants, to embellish artificial rock-works, ruins, and other similar places in pleasure-gardens. The Stone-crops and other low trailing kinds may also be made to occupy the tops of any low walls, pent-houses, hedges, or other low buildings.

And further, the twelfth and thirteenth sorts may like-
wife be diffused in patches towards the fronts of borders. As they spread thick and thinly close to the ground, and flower all day, they being plated in pots, are proper to place in the out of doors, copy as of low walls, and rich, dark, and ever-varying, in color, with other low fancy plants: they will secretly overspread the surface, and flower profusely as far as they extend in such situations.

Sedum Aber, Walled Grass, or Little Bittercress in Murraya Medicus, a common British plant, growing on banks, walls and gravelly banks, is in 13 cent hirt, extremely acid, like the hydraper; and, therefore, it taken in large doses, it acts powerfully on the plasma, proving both emetic and cathartic, and applied to the skin, as a cataplasma, it frequently produces venules and erosions. Boerhaave, therefore, imagined that its internal employment must be unsafe; but experience has discovered, that a decoction of this plant is not only safe, but of great efficacy in scorbutic complaints; for which purpose, a handful of the herb is directed by Below, a Swedish physician, to be boiled in eight parts of beer till they are reduced to four; of which three or four cures are to be taken everyday, or every other morning. Milk has been found to answer this purpose better than beer. Not only ulcers, simply scorbutic, but those of a scrophulous and even cancerous tendency have been cured by the use of this plant, of which Marquet relates several instances. He likewise found it useful as an external application in destroying fungous flesh, and in promoting a discharge in gangrenes and carbuncles. Another effect for which this plant has been esteemed, is that of stopping intermittent fevers.

Sedum Majus. See Semprevivum.

Seduni, in Ancient Geography, a people of Gallia Narbonensis, in the vicinity of the Nantuates and Veragari, who jointly occupied the country that lies between the Allobroges and the higher Alps.

Sedunova, in Geography, a town of Russia, in the government of Iekutski, on the Lena; 12 miles N. of Ork Lange.

Sedusius, in Ancient Geography, a people of Germany, who fought under Ariovistus against Caesar.

Sedziszow, in Geography, a town of Poland, in the patrimoine of Sandomierz; 35 miles S. of Sandomierz.

See-Amol, a small island in the East Indian Sea, near the eait coast of Borneo. N. lat. 5° 25'. E. long. 118° 48'.

Seeassee, a small island in the Soooloo Archipelago. N. lat. 5° 25'. E. long. 120° 50'.

Seexur, a river of Hindoostan, which runs into the bay of Bengal, near Pondicherry.

Seebach, a town of Austria; 1 mile S.S.W. of St. Jergen.—Also, a river of Saxony, which runs into the Mulda, 2 miles S. of Eulenburg.

See-Bangol, a small island in the East Indian sea, near the east coast of Borneo. N. lat. 4° 11'. E. long. 118° 24'.

Seebergen, a town of Germany, in the duchy of Gota, in which is a celebrated observatory, erected by the late duke; 4 miles E.S.E. of Gota.

Seebugung, a town of Hindooftan, in Bengal; 12 miles S. of Goragot.—Also, a town of Hindooftan, in Bengal, on the left bank of the Ganges; 5 miles N. of Nagpore.—Also, a town of Bengal; 45 miles N.E. of Purasch.—Also, a town of Bengal; 40 miles N.W. of Nattore. N. lat. 25°. E. long. 87° 32'.

Seebu, the largest river in Well Barbyr: it rises in a piece of water situated in the midst of a forest, at the foot of Atlas, eastward of the cities of Her (Iz), trench (Mogador), and west of the town, between the town of Belloul and the town of Bouch. Another branch, passing over the hills in the north of this city, and distending itself to this river. This river is navigable to the inhabitants of sea, and supplies the town with water, that it is called "Well El Juir," the river of pears, according to its vegetation. Some secondary streams, proceeding from the territory of Terra, fall into the Seebo in Laco, on the pedl between the 20th of December and 20th of January inclusive. This river is navigable, except in boats, or on rafts. At Macluna, or Moctrail, where it enters the ocean, it is a large, deep, and navigable river; but the port being vacated, revenue commerce is a diluted and little flippany has been admitted here. The Portuguese settled the place. This river absorbs more than any other in that rich and delicate soil called blackburb. If this country afforded any encouragement to industry, corn might be conveyed up the Seebo river to live at a very low charge: whereas it is now transported to that populous city by camel, the expense of the hire of which often exceeds the original cost of the grain. Jackson's Account of the Empire of Morocco.

Seebbour, a town of Bengal; 12 miles N. of Hoogly.

Seeburg, a town of Prussia, in the province of Ermeland; 55 miles S. of Konigberg. N. lat. 53° 31'. E. long. 20° 40'.—Also, a town of Weipplin, in the counties of Mansfield; 5 miles E. of Eifelbean. N. lat. 51° 31'. E. long. 11° 51'.

Seed, Jeremiah, in Biography, a learned divine of the church of England, was born at Chilton, in Cumberland, and educated at Queen's college, Oxford, where he took his degrees in the arts, and obtained a fellowship. He was afterwards presented to the rectory of Ashburn, in Hampshire, where he died in 1747. His sermons, which are very highly esteemed, are published in 4 vols. 8vo.

Seed, Siemen, in the Animal Economy. See Seem and Generation.

Seed, in Brittany, is that most important organ in the fructification of vegetables, the perfecting of which is indeed the sole object of all the other parts: so that rud they are subervient either in forming, perfecting, or dispersing it. A seed is composed of many essentia parts. See Embryo, Cotyledones, Albumen, Vitellus, Testa, Hilum.

Besides these, there are various accessory parts, or appendages, to seeds, which come under the following denominations. See Pellucula, Arillus, Parfus, Calyx, Rostrum. To these we must add Alas, which our predecessors have neglected to describe as a seminal appendage, in its proper article. (See that article.) The Alas, or wing, is a dilated membranous appendage to seeds, serving to waft them along in the air; it is commonly foliary, except in some umbelliferous plants. Seeds are occasionally furnished with spines, hooks, scales, crested appendages, particularly a little gland-like part sometimes called Straminum, and situated near the Hilum. The various modes by which seeds are dispersed, in order to accomplish their germination, cannot fail to strike an observing mind with admiration. Indeed this is a most amusing branch of the science of vegetable economy. See Intro. to Bot. ed. 3. 210—232.

Seeds, Ethinate. See Ethinate.

Seeds, Naked. See Naked.

SEED-DOWN. See PAPPUS.
SEED-FIELD. See Pericarp.

Seed, in Agriculture, the grain or other product of a plant, whereby the species is propagated, upon its being sown or put into the earth.

It may be observed, that the choice of the seed intended to be sown, is an object of greater importance than many farmers seem to imagine. It is not sufficient that the finest grain be chosen for this purpose, unless it be likewise clear from weeds. In procuring feed, it should, therefore, be a rule with the farmer to purchase or reserve such as is the most full, plump, found, clean, and healthy, whatever the fort may be; as it is perhaps only in this way that crops of really good corn can be ensured. And this practice is still more obvious, from the circumstance of its being in some measure the same with plants as with animals, that the produce is in a degree similar to that from which it originated. It is not, however, merely on this principle that such grain as is small, shrivelled up, and imperfectly fed, should be rejected as improper for feed, but as containing a smaller proportion of farinaceous matter, and being thereby less proper for affording that degree of nourishment which is necessary to the young plants, during the period of the first stage of their growth. Where shrivelled-up and imperfectly ripened feed is sown, in general a little of it vegetates; and that which does, mostly sends forth plants of a weak and feeble kind, that afford only a lean and feeble sort of crop. Besides, there are other circumstances which ought to be taken into the account, in providing of feed corn; such as that it be new, and recently threshed from the thraw, and that the skin be clear and thin; for it is found that grain which is fresh, and only just threshed out, is in a much more proper state for quick vegetation, than such as has been long kept, consequentley less liable to perish in bad seasons; and that where the rind or skin is of a bright colour, and thin, a much larger proportion of fine farinaceous or mealy matter is yielded from the fame quantity of grain, which renders it of course more valuable to the cultivator. This is particularly the case in wheat, and the same thing probably takes place in other sorts of corn.

And the writer of the Synopsis of Husbandry has shewn, by some experiments, that wheat, after being kept fix or seven years, though there may not be any perceptible difference in its appearance from such as is new, is wholly unfit for being made use of as feed, on account of only a small portion of it being capable of vegetating; a circumstance that may probably, in many cases, be owing to the grain being more disposed, under such conditions, to take on the putrefactive fermentation, or become rotten, than to the absorption of oxygen, which is believed to be essential to the procceds of vegetation in the early stage, as stated by Mr. Gough in the Manchester Transactions; and besides this effect, where the moisture and juice of the grain is much taken away, as is the case in keeping it for a great length of time, the plants that are produced from it may even be less vigorous and luxuriant, as happens in gardening to some kinds of feeds, as that of the melon, which is frequently kept for several years, in order to effect this purpose in a more perfect manner.

On these accounts, therefore, it must be evident that, on such principles, grain, in order to secure perfect vegetation, should not be placed too much out of the influence of the atmosphere; and that the bed of mould, or earth, in which it is deposited, be in as fine a powderly state as possible; as, under such circumstances, the air is more uniformly admitted, and the feed, from being in a more equal temperature, and more equally supplied with moisture, is exposed in the most favourable circumstances to the combined effects of the causes that have been found to promote the sprouting, growth, and prosperity of the young corn plant, as has been fully shewn by Mr. Gough, in his excellent paper on the vegetation of feeds. And there should likewise be a constant attention, that no such grain as is in any way diseased should ever be made use of as feed corn; as the fowing of this sort of feed, though it may have been advised by some cultivators, who have not been sufficiently cautious, or who have placed too much confidence on the efficacy of steeped, can only disappoint the views and hopes of the farmer, by propagating more widely such maladies, or producing scanty crops of good grain.

A great many different methods have been pursued, in the view of securing such grain as is healthy and proper for the purpose of fowing; but that which is the most readily executed is probably that of selecting from among the corn plants, while they are growing in the fields; as in this way an opportunity is afforded of choosing such heads or ears of the plants of different kinds as are the most perfect, the most forward, and most vigorous in their growth, and which contain such feeds as are the most plump, and full, and the beet ripened. These benefits or advantages may likewise, in some measure, be attained in the most valuable sorts of grain, by having them picked over by hand, after being threshed out; but this is a tedious practice, and not so certain of having the feed from the most healthy and best ripened plants, as the above and some others: therefore, to have the most perfect sorts of feed, and at the same time the most healthy and proper for vegetation, the most vigorous plants should be selected, as well as such as are the most forward and early in respect to the season; and that these, while they are growing, be so preferred, that they may not be injured by having weaker plants of the same kinds near them; as the art of having good feeds does not, it is contended by an experienced farmer, depend so much upon obtaining new feeds from places at a considerable distance, as upon collecting and referring the best feeds or roots of our own production. Dr. Priestley, in a paper in the first volume of Communications to the Board of Agriculture, has remarked that this method of practice has been hitherto, in consequence of its having been found that though vegetables of all kinds are extremely liable to changes, in respect to the times of their maturation, or ripening, and other properties, the best feeds never fail to produce the best plants. It is likewise remarked, in addition, that in the preferring of feed grain, by collecting it in the ears from the sticks or sheaves, there may, however, be disadvantages in the way of lengthening the produce, by choosing the largest ears, which have rarely more than one upon it, and by taking such as become ripe at different periods.

It is observed that many different modes have been proposed for ascertaining the goodnefts of grain or feed-corn; but the farmer generally depends upon the appearances that it exhibits, preferring such as is full, plump, and well fed, and that has a certain brightness and cleanliness, without any shrivelling or thinking in the husk or external covering. But it may perhaps be ascertained with greater accuracy by other means, as the weighing of a certain measure or quantity; and from its being well known that grain or feeds, on being immerced in fluids, leave the more light and imperfect floating on the surface, while the better and more perfect sink to the bottom; solutions well saturated with saline substances, from their gravity being much increased, become useful in ascertaining the goodnefs of the corn, as none but such as are perfectly found sink in them. And the
SEED.

the author of the Philosophy of Gardening observes, that the weight of a given measure of grain may be a determinately certain method of discovering the quantity of bulk or
branch contained in it; as that grain which is cut too early, or which is otherwise not quite ripe, as happens in wet seasons, thrashed in the barn or granary, and becomes wrinkled, and has thus a greater pro-
portion of skin or bran than that which has been more perfectly ripened, and weighs lighter in proportion to its
bulk. And another method, which he supposes may be had
recourse to in order to distinguish light from heavy grain, is
that of winnowing, as the surfaces of light grains, from their
being greater in proportion to their solid contents, may be
carried further by the current of air afforded in the opera-
tion; of course in passing them through a screen, the heavy
grains may be liable to run further out on the floor from
their being more propelled by their greater gravity, without
the resistance of the air on their surfaces being increased,
and be consequently more proper for feed-corn in general.
See Change of Seed.

But lately, however, a very different notion from the above
has been entertained by Sir Joseph Banks, though we do not
find it supported by the tell of experiment in the field.
The result of a single trial, made under the circumstance of
a hot-house, can never be satisfactory to the farmer. He
thinks, that although the foods of wheat may be rendered by
the exhausting power of a fungus so lean and thrivelled,
that fearcely any flour fit for the manufacture of bread can be
obtained by grinding them, these very foods will, except in
the very worst cases, answer the purpose of feed-corn as
well as the finest and plumpest samples that can be obtained,
and in some respects better; for as a bushel of finely thrushed
corn will contain one-third at least more grains in number
than a bushel of plump corn, three bushels of such corn will
give as far in sowing land as four bushels of large grain. And
that the use of the flour of corn in furthering the process
of vegetation, is to nourish the minute plant from the time
of its development till its roots are able to attract food from
the manured earth; for this purpose one-tenth of the con-
tents of a grain of good wheat is more than sufficient. The
quantity of flour in wheat has been increased by culture and
management calculated to improve its qualities for the benefit
of mankind, in the same proportion as the pulp of apples
and pears has been increased by the same means above what is
found on the wildings and crabs in the hedges. Further, that
though it is customary to set aside or to purchase for feed-
corn the bold and plumpet samples that can be obtained,
that is, those that contain the moulder flour, this is unnecessary
waste of human subsistence: the smallest grains, such as are
lifted out before the wheat is carried to market, and either
consumed in the farmer's family or given to his poultry,
will be found by experience to answer the purpose of propa-
gating the form from whence they sprang as effectually as
the largest. Every ear of wheat is composed of a number of
cups placed alternately on each side of the straw; the
lower ones contain, according to circumstances, three or four
grains nearly equal in size; but towards the top of the ear,
where the quantity of nutriment is diminished by the more
ample supply of those cups that are nearer the root, the
third or fourth grain in a cup is frequently defrauded of its
proportion, and become thrivelled and small. These small
grains, which are rejected by the miller because they do not
contain flour enough for his purpose, have nevertheless an
ample abundance for all the purposes of vegetation, and as
fully partake of the sap (or blood, as we should call it
in animals,) of the kind which produced them, as the full
and fullest grain that can be obtained from the bottoms of
the lower cups by the walled proofs of beating the sheaves.
But, however further and more numerous experiments may
establish this doctrine, the best practice of the farmer is
probably, at present, to take care to have good well ripened
grain, clear from all adulteration of feeds of the weed kind;
without any blackheads about the extremities of the grains,
being free from that dark-brown colour that indicates its
having been heated too much in the stack; and that it have
no signs of mouldiness from being badly secured, or of
shrinking from being cut in too green a state. It has also
been lately suggested by Mr. Lerti, who has been engaged in
many interesting experiments on the subject, not by any
means to procure feed grain from a soil north of that on
which it is to be sown, but from a district south of it; as
he considers it a general rule, that the product of feed improves
in going from the south to the north, but decreases in virtue
in paling from the north to the south.

And with respect to the proportion of feed that may be
proper to be sown on different soils and situations, attention
will not only be necessary to their peculiar nature, and to
the periods of sowing or putting the feed into the ground,
but also to the nature of the faion, and the mode in which
the fowing is executed in it. For crops in general, the strong,
woody, and fiffer sorts of land will demand a larger quantity
of feed than such as are more mellow, thin, and light; for
coarse strong wet loams, and stiff retentive clays, will require
more feed than light mellow loams, and sandy gravelly
or even thin chalky lands. But where lands of the rich loamy
kinds have been well reduced and broken down by the op-
erations of tillage, it is observed, that if the feed be not
sown in too great a proportion, an opportunity is afforded
for the plants spreading themselves from the roots, many
items often issuing from the same root, in consequence of
which the crops frequently become, even when thinly
sown, extremely thick upon the ground; and from the
great nutritive power of rich soils, or what is moily
termed strength by the farmers, would be greatly too much
so, if a large proportion of feed were at first put in.
And that in the case of root crops, whether such as are formed
upon or within the soil, where such lands are in a sufficiently
mellow and friable state for producing them, the feeds or sets
should not on the same account be sown or put in too
great a quantity, or too thickly. While in the strong, fluff,
woody, retentive clays, from the plants seldom retiring, or
branching off much from the roots, except in particularly fa-
vourable circumstances of weather, a much greater proportion
of feed will be necessary, in order to secure such full crops as
lands of this kind are capable of supporting and bringing to
maturity in moli cafes.

But where the soils are light and thin, a less quantity of
feed will be sufficient, according to Mr. Donaldson and
others; as, if a large proportion be put into such kinds of
ground, from their potelling much less strength the crops will
rarely, except in particular faions, be well formed in the ear,
or have the grain plump and well fed. It is likewise a prac-
tice in the best grain districts, on all sorts of land to sow
smaller proportions of feed on lands of the same quality,
in the early periods of the feed time, than in those of the
latter. The reason of this, according to the above writer,
is, that grain sown early in the season takes deeper root, and
has more time to branch out additional floutes, than that
which is later sown, which, when the soil is not very free as
well as fertile, generally runs up into one tingle flalk, so
that if a liberal quantity of feed be not allowed, the crop,
however luxuriant in respect to the plants, must be scanty in
the
the article of grain or produce. And for this there may also be other reasons, as where the feed is put in at a later period, especially in the spring, it will not have time fully to establish itself in the soil, before it becomes retarded by the hot and dry summer weather, unless a large quantity of seed be employed so as to afford protection by the closeness of the growth of the plants. And in the late autumnal sowings, the grain may not become well fixed and rooted in the soil before the frosts begin to affect them; and on that account a larger proportion of seed be required than under other circumstances would be necessary. Something may likewise depend on the state of the weather in sowing or putting feed into the ground; as where the season is very dry, and there is but a small proportion of moisture in the soil, more of the feed may fall in vegetating, than where the contrary is the case; which also shows the propriety of sowing and putting in the feed in such dry seasons, immediately after the plough has performed its work.

And it must likewise vary according to the manner in which it is deposited in the earth; as where the grain is scattered over the whole of the land, in some measure at random, as in the common broadcast method of sowing, a much larger proportion of seed must be sown, than where the grains are deposited with equality and exactness, but only on certain portions of the land, as in drilling and dibbling. And as some disadvantage may attend the first method, in respect to the vegetation of the feed, a larger proportion may also be requisite on that account. It is consequently evident, that the quantity of seed must vary according to different circumstances, and that it is a matter of much difficulty to fix upon a proportion that may be suitable to all the circumstances and sorts of soil. It is, however, commonly supposed, that from two and a half, to three and a half bushels to the acre, may be the proportion that may be the most proper both in the spring and autumn sowings. Mr. Middleton has suggested, that for sowing wheat broadcast about the latter end of September, two bushels and a half is the most advantageous quantity on soils of medium quality; but that for every fortnight later, four quarts of seed should be added to that proportion. But the tabular view given below of the proportions that have been found to answer well in practice in an extensive midland district, on soils of different qualities, may afford a more satisfactory notion of the nature of sowing soils of different kinds and qualities.

It may be necessary, before inserting this however, to shew the quantities in use in a great southern grain district with wheat. In Norfolk, in practice of the belting farmers, the proportions of feed-wheat usually made use of, according to the late Agricultural Survey of that district, are about Walton, when dibbled, six or seven pecks, in the practice of some; but with others, when sown before Michaelmas, two bushels, afterwards two and a half. Also near Dereham, the quantity is four bushels broadcast, and when dibbled, from ten pecks to three bushels. At Wiston ten pecks dibbled, and three bushels broadcast; and at East Bilney, and the adjoining parishes, only from two and a half to three. But in the practice of Mr. Henry Blythe of Burnham, seven or eight pecks are drilled per acre; but the common quantity broadcast, from ten to twelve. And in the clays of Marpham, from five to six pecks are sown broadcast. And about Wymondham they dibble in from six to eight pecks, but in the broadcast method few three bushels. In some situations they however complain of loss from too thin a plant in this sort of crop.

The exact proportion of feed that may be required, however, under different states and circumstances of land, in order to afford the most full and productive crops, cannot by any means be ascertained, much constantly depending on the judgment of the feedman, who must always decide in respect to the necessary proportion for the particular circumstance, having a due regard to the nature and quality of his feed, as well as the time and manner in which it is put into the ground, as well as other circumstances. See Sowing.

The most usual quantities and proportions of feed that are made use of in all the different forts of field-crops, are mentioned under the particular heads to which they belong. See the particular crops. The writer of the work on "Agricultural Chemistry," thinks...
SEED.

thanks that, in the general selection of feeds, it would seem that those arising from the most highly cultivated varieties of plants, are such as give the most abundant, but that it is necessary from time to time to change, and, as it were, to cross the breeds, which may easily be done by proper means. Mr. Knight has found great advantages to arise from it in wheat, merely by sowing the different sorts together; and states, that in the years 1805 and 1806, when almost the whole crop of corn in the island was blighted, the varieties obtained by crossing these, especially in the field, and in very different situations. By crossing two varieties of peas, a large fine pea has also been produced, which may probably be cultivated by the farmer with great benefit."

The feeds which are the most perfect, and healthy in their nature, are always found to sprout and grow in the best manner as crops, as may be more fully seen under their proper heads. See Germination and Vegetation.

It is concluded, from a great number of experiments detailed in a paper in the third volume of the Transactions of the Highland Society, "On the Influence of Fruit, &c. in Ripening Corn," that barley and oats in every period of their growth may be exposed to much variety of bad weather, without being destroyed, and that they even continue to acquire additional weight, although frequently exposed to severest degrees of cold, and occasionally even to frost. That when the leaf is dry, they not only suffer little from it, but often continue to fill; yet, where moisture prevails with it, they are soon wholly destroyed. But that although this may be the case, exposure in this way renders them very unfit for feed: as while every feed of good corn will vegetate and thrive when properly placed in the soil, where it is good, a great proportion of those which have been thus exposed never appear above the surface, and the plants of those that actually grow are so weak, that the crop is not only small in quantity, but the corn of inferior quality. That, though it seems in using well-ripened corn for feeds, the crop which it yields depends, in a considerable degree, on the weight of it, yet this does not happen in every evident degree with corn that has suffered from frost, as the plants arising from corn that has been exposed to much of it are constantly weak, and the produce small, even although the feed be of the common weight. That frost appears still more hurtful to pulse crops as feed, and in other ways, than to those of the grain kind, as well as to grasses. That no corn which has been thus exposed to frost should ever be used as feed; but that which is for this purpose, should always be procured from southern situations, where there is no danger of this fort. That, on the score of economy, the feed which has been so exposed should never be employed; as nearly twice the quantity of it will be required; while the quantity as well as the quality of the produce will be vastly inferior. That this sort of grain is easily distinguished from the common, the latter being plump, full, and of a peculiar healthy appearance, and mostly free from chalk, while the former is curled and pinched in, and never entirely full, being bleached and chalky. Where these marks are not present, the mere vegetation of the feeds as it is laid, by no means sufficient, though often depended upon. That, when light feed is made use of, the crops more readily suffer with blight and other diseases, and it would seem that many morbid affections of plants, especially such as give rise to the generation of insects, are particularly apt to spread and communicate the contagion to others that are weak; which, like animals in a state of debility, do not to readily resist it, or the formation of those vermin by which they are most liable to be destroyed, as those plants which are found to be as species that in the same manner as the beans are used for feed, and that it can be equally made into meal for human food. Great advantage is also seen in the use of the weak part of the late corn for horse, and all the best of it in round rolls. It is also seen great advantage, in the proper preparation of rapeseeds that are both small in quantity and of very poor quality. That, for the present, we shall leave it to be seen, but the bell feeds of every kind should be laid. That, with this view, farmers should not only procure feed that has been well ripened, but such as will be well kept, and never injured by frosts, snows, or rain. That it would also be much for their interest, to wait the whole feed of corn, or as much of good brine; not only the winter but the barley and oats, as well as their beans, peas, and beans, as the wheat corn to fit for feed as the season, when properly done: as it not only carries all the bell feeds, but all the feeds of a great many weeds which cannot in any other way be so completely separated from it.

That it is thought, that the preference mostly given to new corn for feed, is not well founded; as it was found that the produce of old corn was equal, both in quantity and quality, to that of the bell corn newly raised. This is the case too with all the grassy feeds that are commonly known. One of the best crops of hay, which is not moulded to have been feem, was produced from a mixture of red, white, and yellow clover, ryegrass, and hay-grass, which, by accident, had been neglected, and kept for five years. An acre, or thereabouts, was found with this mixture, while the rest of the field was sown with the feed of the preceding year, and the crop was equally good over the whole. That it is here advised, that in dry warm seasons, when all the grassy feeds are commonly good, such farmers as have it in their power should provide a large quantity of those that they usually sow, to make use of when they are scarce and bad, which constantly happens after cold or wet season. That it is on this principle, of the seeds of plants retaining their power of vegetating for a long time, that we account for the sudden appearance of many of the grasses, and other plants, where they had not grown for a long period of time before. After the great fire in London in 1666, broom and clover, it is said, appeared on the site of almost every houset in the space of a few months, although the whole had been occupied with streets for several centuries. We daily perceive, it is said, in Scotland and other parts, that white clover appears almost as soon as the heath or other matters are destroyed, with which lands had been occupied before; and it is thought probable, that corn, pulse, and grassy feeds, where they have been and good at first, and properly kept afterwards, will be found quite fit for feed, even when a good many years old. See the Paper.

Second, in Gardening, the small grains or other differently formed bodies, which are produced by plants, trees, or shrubs of almost all kinds after flowering, and which contain in them the little embryo, or efflorescence of the future plants, of each particular fort, which consist of several different parts, but the principal of which are these: the corolla, the little heart, the point of life, or essential point or part from which the future vegetable is to be produced, and which is the small point or speck that is placed in the centre of each feed, between what are called the stigmata or the lobes of it, and which is attached thereto, being distinctly visible in most of the bean kind, as well as in almost every other sort of leguminous feeds. It consists of two parts, the
the rottum and the pluma; the former of which constituting the radical or descending part, which strikes downwards into the earth, or foil, and becomes the future root; the latter, which becomes the ascending part, or that which shoots upwards, and constitutes the item, branches, and other parts of the future plant. This point, or spot in the seed, is likewise sometimes termed *punctum vitæ*.

The cotyledons, or fide-lobes, are the perifhal fide-lobes, or parts of the seed, which involve, contain, and for some time nourish and support, the corculum, or embryo plant. These fide-lobes are for the most part two in number, which are very clearly seen in the bean kind of seeds, as well as in most others derived from the leguminous tribe of plants, especially when they have been previously laid a short time in earth or water. When the seed has been committed to, and deposited in the ground or foil, the corculum, or point of life, if the seed be good, is seldom long before it begins to sprout or germinate and exert itself in it, but the exact length of time which is necessary, is somewhat different in different cafes, circumstances, and kinds of seeds; the cotyledons expand, burbling open the outer coverings, and rise in a gradual manner out of the earth or foil, in the form of blades or leaves, which are commonly, in most forts, termed the *feel-leaves*, in which displaying the filr, or primary visible foundation and rudiments of the infant plant; accompanying it for some length of time after its eruption or first breaking from the ground, as until the stiff proper leaves are formed in the centre of the vegetable, and advanced a little in their growth, when the lobes or seminal leaves becoming useless, they wither, decay, and are destroyed. See Germination.

In general, plants are furnished with two cotyledons, or seed-leaves, especially almost the whole of the tribe of herbaceous-rooted plants, all trees and shrubs; but there are some which have only one cotyledon, as is the case in most of the bulbous plants of the liliaceous tribe, which rise out of the ground in the manner of a thistle; and there are some seeds which have no cotyledons at all, for instance, such as the ferns, mosses, flags, and fungiaceae. The other parts of seeds are the ale, or wings, and the corollse, or crowns; in the former, many of which are winged, or furnished with a thin membranous web or film, by which means they fly and are diffused in being dispersed about, as in the birch, maple, ash, elm, hops, and a great number of other forts; and in the latter kind many of the seeds are covered, and form surrounded with a pappose substance, or a fort of feathery or hairy down, especially in many of the compound and other descriptions, which serve for the purpose of their dissemination, being thus framed for flying, in a somewhat familiar manner to the shuttlecock, so as to be easily carried and transported by the wind to very considerable distances from their natural situations, examples of which are to be met with in hawk-weed, groundsel, dandelion, and many other plants: this, however, is not much the case with garden-seeds of the common kinds. But there are still numerous forts of seeds which are perfectly simple, having neither any thing of the wing or pappose substance about them; as in most of those employed by the gardener. It may likewise be observed, that the number, form or shape, fize or dimensions, and the fubtile or solidity of different seeds, are extremely various, as produced by different kinds of garden plants. In respect to the particular number, it may confit of from one, to several hundreds, or even thousands, in a single feed-veffel, according to the particular plant from which it is taken: for though some plants do not afford more than one or two, others three or four, there are many which have very numerous of seeds, and are of amazing fertility; as, for instance, in the tobacco-plant, one simple feed-veffel frequently contains not less than about one thousand feeds; and in that of the white poppy plant it is often not lower than eight thousand: the whole produce of one single tobacco-plant is certainly upwards of forty thousand; but some have sufficed it to be more than three hundred thousand; and that of one single flake of spenwort is conceived from calculation to be above one million of seeds. This is mostly the cafe in flower and other plants, but rarely in the culinary forts.

In regard to what concerns the forms of garden feeds, they are, in general, either round, oval, kidney-shaped, heart-shaped, angular, flat, or some other form approaching to some of these. And in relation to the sizes and dimensions of such seeds, they are very different according to the plants from which they are taken, varying from the magnitude of the large nut kind, down to the very minute feeds of cresses, and others, which are still much smaller in their sizes. With respect to the fubtile and solidity of seeds they vary greatly, some feeds are soft, pulpy, fleshy, others hard and firm without any fleshy matter, some megalonymous, others hard and long in their nature, which is the cafe in all the different kinds of the nut tribe, as well as in the ilones of many forts of berries and other stone fruit.

Seeds of the garden fort are likewise either covered or naked; the covered feeds are all such as are contained and concealed in some veffels either of the capfule, pod, berry, apple, pear, cherry, or some other fimal kinds; the naked feeds are all those which are not contained in any veffel, but lodged in their receptracles, or in the bottoms of the cups belonging to the different plants or flowers.

There is an almost endless variety in the modes which nature has provided for the diffeminating and dispersing the feeds of plants, which is truly wonderful, though of but little confequence in garden culture; in a very great many plants, the fruit or veffels containing the feed, are raised above the ground, either by erect firm items, or by climbing ftalks, so that the fruit being elevated from the ground, it may be more readily and easily shaken by the wind which blows the feeds not unfrequently to a great distance; for the fame reason also, that description of feed-veffels which is called capfule, in some instances, opens at the top, in order that the feeds may be more fully and completely, as well as more readily, dispersed or thrown about. And from a great number of feeds being winged, as has been forementioned, they are in that way spread far and near by the winds, and find their paflage into different fols and territories. Besides, some seed-veffels are endowed with a remarkable degree of elaticity, by means of which they dart and throw their feed with great force to a very confiderable distance; of this kind are the plants called touch-me-not, and the spitting cucumber, as well as some others. There are many feeds and feed-veffels too, which are armed with a fort of hooks, hairs, &c. by which they attach themselves to different kinds of animals, or other matters, and are thereby dispersed; such for instance, as in the feed of the carrot, hemp, agrimony, burdock, &c. Further, the feeds of many forts that are devoted by bird, being carried and voided by them in an entire and perfect flate in different parts, often at a very great distance, not unfrequently take root and grow. In berries, as well as other pulpy fruits, which have been eaten as food, the feeds and kernels of many kinds of which pafs through the body unhurt, and falling to the ground, likewise not seldom take on a growing flate. Seeds are also very frequently carried, diffeminated, and dispersed by brooks, rivers,
rivers, torrents, and all sorts of running waters and tiles to a great number of leagues distance from their native soils and expostures, where, after being left in such different grounds and climates, they, however, not unfrequently elude and render themselves familiar and agreeable in such new situations. These circumstances are necessary to be known to the gardener, in order that he may guard against the introduction of weeds, \\

The duration of laving of seeds, in so far as respects their powers or properties of vegetating or producing new plants, is very considerable indeed; as for instance, those of the cucumber, melon, and gourd, not seldom retain their powers of vegetation for eight, ten, or twelve years; and it has been sufficiently ascertained that those of the muscard, or lentive plant, will retain or preserve the principle of life or growth for thirty or forty years or more; while, on the other hand, a far greater number of seeds will not keep good, or in a germinating state, for more than one or two years; and many, or indeed the greatest part of these, will not vegetate properly, if more than one year old, nor fome even when kept the shortest time. There are fome indeed which require to be sown or put into the ground foon after they become ripe, or they will not grow until the succeeding year; others, until they are fown immediately after they have been gathered, will not grow at all, as is not unenquently the cafe with the berries of the coffee-plant. It has, however, been remarked, that almost all forts of feeds which have been sown the firt year after being collected or gathered, in general rife much sooner, and a great deal stronger, than fuch as have been kept for a greater length of time; for which reason it is principally advised to have recourse to new feeds, or such as are, not more than one year old, wherever it can possibly be done; except in the particular cafes of cucumbers and melons, in which feeds of two or three years old, or more, are often more to be preferred, as the plants of this kind, when raised from new feeds, are liable to run or grow much too vigorously to items or falks, without becoming either tolerably expeditiously fruitful, or producing fruit in any fufficient quantity.

In regard to the keeping of garden feeds, all fuch as are produced in dry capsules, or other dry feed-vessels, are found to keep much better and longer in fuch vessels than if taken out of them; but it is probable that most kinds of feeds will keep and retain their germinative property the longest and most perfectly in the bawfes of the earth, when they have been accidentally deposited and buried to a confiderable depth, and out of the reach of the influence of the fun and the air or atmosphere. For it has been noticed respecting the feeds of corn fallad in particular, which have been buried by accident to the depth of three feet or more in the ground for thirty years or more, that on the foil being turned up that depth to the top, they began to vegetate and have grown freely. The fame thing has likewise been remarked of many other kinds of feeds, which have by chance been deposited in the earth to the depth of several feet; and in the bottoms of wells, vaults, ponds, ditches, and many other similar fittations, and which have not been furred for many years, as is evident from the circumftances of the cafe; as when occasion has required the foil or earth to be thrown to the top of the surface, and to be exposed to the fun and air, many feeds have vegetated and plants rifen, which had not been remembered to have been fown in fuch places any time before, or at leaft for a very great length of time. Most forts of garden feeds should therefore be kept confantly in the capsules, huffs, and other parts in which they are inclosed.

It may also be remarked, that molt forts of feeds, if fown too deep, remain inactive, and fame never exert their vegetative properties at all, while others, insomuch as they preserve their powers of vegetation and growth, and whenever the ground or foil is again fresh furred, or newly turned up, fuch of them as happen to approach towards the upper part, will frequently throw themselves, and come up, which fully demonstrates the power and effect which the fun and free air have, in promoting and bringing forward the vegetation of feeds as well as plants. On this account, therefore, it is advised that feeds of this fort should never be fown too deep in the ground, but constantly, in fome measure, in proportion to their fize, or the quantity of matter which they contain; as from about a quarter or half an inch deep, in the smaller forts, to about one, two, and sometimes three inches in the middling and large kinds. See Sowing of Seeds.

In relation to the vegetation, germination, or growth of feeds, after they have been regularly fown or deposited in the earth or foil to a proper depth, it is very quick in fome forts, while in others it is slow, as for instance, the feeds of cresses, millard, turnips, and many other feeds, vegetate and come up in a few days; fome other feeds in one, two, or three weeks; as in molt of the efcellent kinds of the kitchen garden, and a great many others of the herbaceous class; but the feeds of parsley and fome other kinds of plants often remain in an inactive state for a month or fix weeks, and there are ftil fome other feeds which will one or two years or more in the ground before they germinate and rife in plants.

With respect to the feeds of shrubs and trees, there are fome which will rife in the coufe of a month or fix weeks, or even in a much shorter time, while others require two or three months to vegetate and grow, and there are fome kinds which he a whole year or more, before they begin to vegetate and grow, as in the cafe of the hawthorn, the holly, and molt others of the very hard-long-feeded kinds.

On the whole, these feeds are the decifive parts of the vegetables to which they belong, each of which includes the rudiment of a new plant, and is endowed with a vital or living principle by means of the sprinkling of the pollen or male dust, which they are capable of retaining for a very confiderable length of time when properly kept and preserved.

It is of great importance in the practice of gardening, to be careful in collecting feeds from the best forts and varieties of the different kinds of plants, to preserve them in a proper manner, and to put them into the ground with due attention to their nature and qualities. Much advantage may like-fife be gained in fome cafes, by feping them in a fufiable manner, and by producing a change in them, from the mixing or combining of different varieties of the fame plants, in faining thole from which they are taken. Peace have been very greatly improved in this way.

With proper precautions, and with a zeal in any degree refembling that of the late Dr. Solander, of Mr. Blake, who had formed a plan of procuring the feeds of all the vegetables produced in China, which are used in medicine, manufactures, or food, or are in any way serviceable to man-kind, and to forward to Europe not only fuch feeds, but the plants producing them (see Kippis's edit. of Brit. Brit. art. Blake); and of Sir Joseph Banks; we might obtain a great variety of curious and useful plants now uncultivated in this country.

The feeds of fruit-trees, it is faid, should not be chozen from thofe that are the molt fruitful, fo much as from the molt solid and fair; nor are we to covet the largest acorns, but the molt weby, clean, and bright. Porous, infipid, or fweet feeds, are to be fown as soon as ripe; hot, bitter feeds, ought to be kept a year before they are fown. See Seminary.
The shape and weight of seeds direct how they are to be set; most of them, when they fall, lie on one side, with the small end towards the earth; which shows that pollute to be left to fall any flone or nut in; if they be heavy, low them the deeper. Acorns, peaches, &c. are to be fown two or three inches deep. See *Seminat*ion.

There is a common method of trying the goodness of many sorts of feed, which is by putting them in water; and those which sink to the bottom are esteemed good, but those that swim on the surface are rejected. This rule, Mr. Miller observes, is not universal; for having sowed the seeds of melons which floated on the surface of water, they were washed from the pulp, and keeping them two years, they grew very well; but the melons produced were not so thick-flushed as those which he obtained from heavy seeds of the same melon. The lightness of many sorts of seeds he ascribes to their not having been sufficiently impregnated by the farina fpecundans; and, therefore, care should be taken that this operation be properly performed, by not excluding plants that are in flower from the external air, or even by affilting nature in conveying the farina of the male flowers to those of the female. Miller’s Gard. Dictionary, art. *Seed*.

*Seed, Change* of, a term used by the farmers to express the common, and, as they suppose, necessary custom, of changing among one another the feed of their lands, as wheat, and the like; it being a received opinion, that the feed produced on one land will grow better on another than on that which produced it, though the same species of plant be fown.

Seeds, in their natural climate, do not degenerate, unless culture has improved them; they then indeed are liable, upon omission of that culture, to return to their natural state again. Whatever benefit arises to the farmer from the changing of the seed of the same species, is from causes which are themselves the effects of different climates, such as heat and moisture, which may vary very much in the same neighbourhood.

Lauremburgius has carried this notion of degeneracy and change from the soil, so far as to affirm that wheat will, in some places, degenerate into rye; and in other places, rye will be exalted into wheat by the soil; but those who are acquainted with botany know, that a horse might as soon be changed into a bull by feeding in an improper pasturage, as one plant degenerate into another by fault of the soil. Tull’s *Husbandry*, p. 116. See *Change of Seed*.

*Seeds, Steeping* of, in prolific liquors, is a practice that has occasionally prevailed, and it is not of modern invention. The Romans, who were good husbandmen, have left us several receipts for steeping of grain, in order to increase the powers of vegetation. In England, France, Italy, and in all countries where agriculture has been attended to, a variety of liquors has been recommended for this purpose. The practice is founded on a preumption, that, by filling the vesicles of the grain with nourishing liquors, the germ, with its roots, would be invigorated. On this subject Dr. Hunter observes, that all his experiments demonstrate, that steeped have no inherent virtue; having fown more than once the same feed, steeped and unsteeped, all other circumstances being alike, he never found the least difference in the growth of the crop. When, indeed, the light feeds are skimmed off, as in the operation of brining, the crop will be improved, and diseases prevented; but these advantages proceed from the goodness of the grain sown, and not from any prolific virtue of the steep. In this opinion many rational farmers, determined by their own experience, concur. Duhamel speaks in the strongest terms against the practice of steeping, so far as it supposes an impregnation of vegetative particles.

Dr. Hunter, having sprouted all kinds of grain in a variety of steeps, alters the farmer, that the radicle and germ never appeared to vigorous and healthy, as when sprouted by elementary water; whence it appears, that the feed requires no alluence.

Upon the whole he concludes, that as no invigorating or fruitifying liquor, however ponderously introduced, has ever equalled the two fair and correct experiments, it may be laid down as an established truth, that plump feeds, clear of weeds, and land well prepared to receive it, will seldom disappoint the expectations of the farmer; and upon these he should rely for the goodness of his crop. Hunter’s *Evelyn’s Silva*, p. 15, &c.

*Seeds, in Pharmacy*, &c. The medicid seeds, especially those imported from the Indies, Levant, &c. are severally described under their respective articles; which see. Among those used with us, the principal are, the four *greater hot*, and the four *greater cold* seeds, as they are called. The first are those of anise, fennel, cumin, and caraway; the latter, those of gourd, citrul, melon, and cucumber.

The chief use of the four cold seeds is for the making of emulsions, cool refreshing drinks, pastes for the hands, and oils used by the ladies for the complexion.

*Seeds, in Agriculture*, a term applied to young gralles, or to lands newly laid to grans, in many cases.

*Seed-Furrow*, the furrow or ploughing on which the feed is sown, or put in. It is usual, in the last ploughing before fowing, to have the furrow left turned than in other cases. See *Ploughing*.

*Seed-Grafs*, a term used to signify cultivated herbage, or grans, raised in opposition to natural grans. See *Artificial Grasses*.

*Seed-Lip*, a sort of bafket, in which the fower carries his feed, in order to sow it. It is sometimes written *feed-lap*, or *feed-lip*.

A great improvement has lately been made on the common fowing-bafket, by a farmer at Malvern, in the county of Elex. He has contrived it in such a manner, that the bottom is a wire-fieve, which sifts out the seeds of weeds from the grain, in the motion of fowing; a cloth bag being attached beneath, for the purpose of catching them.

*Seed-Room*, the room or place where garden feeds are kept and preferred in, either for the purpose of sale, or future use in fowing and raising crops. Rooms for this purpose should have but little fun, be perfectly free from all forts of moisture, and be fitted up with every kind of convenience for receiving, hanging, and keeping all descriptions of feeds.

In the arrangement with other garden buildings, the feed-room should have a place as near the hot-houfe and fruit-room as possible; but where there are no other buildings, it may have any situation which is ready and convenient for depositing the feeds.

*Seed-Seam*, the interface between two plats, as left by the plough; also the channels made by floating, drillling, &c.

*Seed-Weeds*, such weeds as arise from the fowing or dispersion of their feeds, and which do not propagate themselves by the roots. See *Weeds*.

*Seed, Amber, Anife, Luc, Line, Muslard, Worm*. See the respective articles.

*Seed of Pearl*. See *Pearl*.

*SEEDLINGS*, among Gardeners, denote such roots of gigiflowers, &c. as come from feed fown. Also the young tender shoots of any plants that are newly fown.

*SEEDLY,*
SEEDLY, in Geography, a town of Morung; 55 miles N.W. of Amersfoort.

SEEDINESS, in Agriculture, provincially used for feed

SEEDSMAN, a term applied to the labourer or person who selects, dispenses, or puts the feed in or on the ground, in feeding for different sorts of crops, before it is covered. Certain peculiarities of steep and full are requisite in good feedmen, which are only to be acquired by time, practice, or experience. Expert feedmen are, of course, but rarely to be met with among farm labourers, though they are of very material importance, so far as the success, goodness, and beauty of the crops are concerned, as well as in having much expense in the feed, and other ways; consequently the farmer who does not perform this part of business himself, will find it to be greatly his interest to have constantly the best, most able, and experienced men of this kind procured for executing the work of feeding; as he will thereby have not only considerable immediate saving, but the advantages of a more certain and favourable appearance, and much greater produce in his crops. It is hardly to be conceived, except by those conversant in the matter, how great the waste and injuries are, which are committed by feedmen who are not well acquainted, experienced, and expert in the business of feeding. They are, besides, in many instances, incapable of getting on with the work with that expedition which is necessary; which is a very great inconvenience and less to the farmer at this very busy season of the year, when every thing of this sort ought to be in the greatest activity. See Seed and Sowing.

It is also a term which is made ufe of to dignify the person who keeps a flour, or other place, for the sale of feeds, either to the farmer, or the gardener, or any other persons. These feed-dealers have sometimes the name of garden feeders. The London feed-dealers are a very considerable class of men, who do much business in the disposing of all sorts of feeds which are necessary to be employed in the practice of farming and gardening, as well as in different other ways.

The garden feedman is commonly the gardener himself, other persons being never, or very rarely, employed in feeding any sort of garden crop.

SEEDY, in the Brandy Trade, a term used by the dealers to express a fault that is found in several parcels of French brandy, and which renders them unpalatable. The French appoife that these brandies obtain the flavour, which they express by this name, from the weeds which grew among the vines, from whence the wine, of which this brandy was made, was preixed.

However it be, the thing is evident, and the taste not of any one kind; but some pieces of brandy shall taste strongly of aniseed, some of caraway seed, and some of other of the strong flavoured feeds of plants, principally of the umbelliferous kind; so that it shall be rather taken for aniseed, caraway, or some other water, than for brandy.

The proprietor of such brandies is always at great trouble to get them off, and usually is reduced to the necessity of mixing them in small quantities with pieces of other brandies, as to drown and conceal the taste; and where he has not opportunities of doing this, he is obliged to sell them on very disadvantageous terms.

The business of rectification of spirits is very little understood abroad, though much practised with us; and a man in France or Holland, who could take off this taste from these brandies, might get great advantages by it. There is no doubt but that the fame means, which we ufe to rectify malt spirits, that is, to clear it of its nauseous and vol. xxxii.

flaking oil, which always males with it to the first definiton, would also be able to purify these brandies, and by leaving the extraneous oil behind, render them as well tasted as any other; since there is no quefion, but that the oil of malt, which is a principle of the fame ingredient with the spirit, is more freely united to it than that flavoured oil in the brandy, which are not the product of the grain, but of some foreign matter, only accidentally mixed with it. See Brandy and Spirits.

It is a mistake to imagine, that all brands made in France are so free from all which we meet with on the quays of London; on the contrary, there are many brandies pieces made every year, which are badly flavoured as our coarse malt spirit. But the oil is this, they feed the bell brandy, and the bell wine, to England, where they can get the best prices for them. In Holland, on the contrary, the mart of goods of all sorts, it is sometimes difficult to find one piece of good brandy out of fifty, the general run of them being either feedy, or muddy, oily, or otherwise infected with some unnatural and disagreeable flavour; and these are the sorts which in France they deliver of curing by redilution, or bringing to the state of three-fifths, or tres cinquieme, as they express their stronger brands. Shaw's Eflay on Distillery.

SEEDY Abdul Abbass, in Geography, a town of Tunis, anciently called "Multi," 16 miles N.E. of Kefl.

SEEDY Abdulinsamen, a town of Algiers, in the province of Tlemcen, on the coast of the Mediterranean, having a good road for ships. It derives its name from a celebrated prophet, whose tomb the inhabitants hold in great veneration; 4 miles S.W. of Mejerda.

SEEDY Abdallah, a town of Morocco, on the coast of the Atlantic; 30 miles N. of Mogador.

SEEDY Abdinik, a town of Algiers, in the province of Tlemcen, at the confluence of the Arhew and the Sheref, held as a sanctuary; 30 miles E. of Multiyanni.

SEEDY Bofsanain, a town of Tunis; 40 miles S.W. of Kefl.

SEEDY Bujeridon, a town of Morocco, on the coast of the Atlantic; 10 miles N. of Mogador.

SEEDY Douie, a town of Africa, in the kingdom of Tunis, at the north extremity of the peninsula of Dukk, surrounded with the ruins of the ancient Mifs. Its present name is derived from Douie, or David, a Moorish saint, whose sepulchre, as they flew it, is five yards long. But, according to Dr. Shaw (in his Travels), this is really a fragment of some Roman praetorium, as it led to conjecture from three tesselated or mosaic pavements, wrought with the most exact symmetry; and executed with all the artful wreatheings and variety of colours imaginable, and with an intermixture of figures of horses, birds, fishes, and trees, curiously inlaid, so that they appear more gay and lively than many tolerably good paintings; 10 miles S.W. of Cape Bou.

SEEDY Esfel, a town of Algiers, anciently called Sava; 25 miles S. of Boujeish.

SEEDY Medleuh, a town of Africa, in the kingdom of Tunis; 20 miles N. of Gabes.

SEEDY Nedja, a town of Algiers; 16 miles E. of Burg Hamza.

SEEDY Ouda, a town of Africa, in the province of Zaaeb, famous for a tomb of an Arabian general of that name, and for that of Seedy Lezear, its tutelar saint; 15 miles S.E. of Bifcar.

SEEFEIJD, a town of Austria; 6 miles W. of Laab.

SEEHAUSEN, a town of Brandenburg, in the Old A

Mark,
Mark, on the river Aland, which almost surrounds it; 40 miles N.W. of Brandenburg. N. lat. 52° 53'. E. long. 11° 39'. - Also, a town of the duchy of Bremen; 3 miles W. of Bremen. - Also, a town of Welfphalia, called "Sommerschenburg," in the duchy of Magdeburg; 18 miles W. of Magdeburg.

SEEHANUSZ, a citadel of Germany, in the lordship of Schwarzenberg, on a lake; 6 miles S. of Scheinfeld.

SEE-HOO, or Si-nou, a lake of China, on the borders of which stands the wealthy and extensive city of Hang-choo-fou, or Hang-tcheou-fou; which see. This lake, with the surrounding scenery, is accounted one of the grandest, as well as most beautiful, spots in all China. The Lu-fang-ta, or tower of the thundering winds, standing on the point of a promontory, jutting into the lake, forms a bold object. It is said to have been built in the time of the philosopher Confusius, who lived centuries before the Christian era. The vale of tombs has an almost infinite variety of ornaments. Naked coffins in great abundance lie scattered upon the ground, and the tides of the hills that rise from the vale are thickly fet with groups of sarcophagi, in the shape of small houfes, arranged in such a manner as to have the appearance of so many Lilliputian cottages. In the plates annexed to Staunton's Voyage, we have an interesting view of this lake.

SEEHUrah, a town of Hindooflan, in Gurry-Mundella; 25 miles N. of Gurrah.

SEEING, the act of perceiving objects by the organ of sight; or, it is the sense we have of external objects, by means of the eye.

For the apparatus, or disposition of the parts necessary to seeing, see Eye. For the manner in which seeing is performed, and the laws of it, see Vision.

Our best anatomists differ greatly as to the cause why we do not see double with the two eyes. Galen, and others after him, ascribe it to a coalition, or decucation of the optic nerve, behind the osphenoides. But whether they decussate or coalesce, or only barely touch one another, is not so well agreed.

The Barthesines and Vesalius say expressly, they are united by a perfect confusion of their substance; Dr. Gibbion allows them to be united by the closest conjunction, but not by a confusion of their fibres.

Alhazen, an Arabian philofopher of the 12th century, accounts for single vision by two eyes, by supposing that when two corresponding parts of the retina are affected, the mind perceives but one image.

Defecrates, and others, account for the effect another way; viz. by supposing that the fibrillae constituting the medullary part of those nerves, being spread in the retina of each eye, have each of them corresponding parts in the brain; so that when any of those fibrillae are struck by any parts of any image, the corresponding parts of the brain are affected thereby.

Somewhat like which is the opinion of Dr. Briggs, who takes the optic nerves of each eye to consist of homologous fibres having their rife in the thalamus nervorum opticorum, and being thence continued to both the retinae, which are composed of them; and farther, that tho' fibrillae have the fame parallelism, tension, &c. in both eyes; consequently, when an image is printed on the fame corresponding sympathizing parts of each retina, the same effects are produced, the same notice carried to the thalamus, and fo impaft to the soul. Hence is that double vision ensuing upon an interruption of the parallelism of the eyes; as when one eye is deprived by the finger, or their sympathy is interrupted by disease: but Dr. Briggs maintains, that it is but in few subjects there is any decucation; and in none any conjunction more than mere contact.

Dr. Briggs's notion is by no means confonant to facts, and is attended with many improbable circumstances.

It was the opinion of Sir Isaac Newton, and of many others, that objects appear single, because the two optic nerves unite before they reach the brain. But Dr. Porterfield thought, from the observation of several anatomists, that the optic nerves do not mix, or confound their substance, being only united by a close cohesion; and objects have appeared single, where the optic nerves were found to be dijuncted. To account for this phenomenon, this ingenious writer supposes, that, by an original law in our natures, we imagine an object to be situated somewhere in a right line drawn from the picture of it upon the retina, through the centre of the pupil; consequently the fame object appearing to both eyes to be in the fame place, the mind cannot diftinguish it into two.

In answer to an objection to this hypothesis, from objects appearing double when one eye is distorted, he says, the mind mistakes the position of the eye, imagining, that it had moved in a manner corresponding to the other, in which case the conclusion would have been just; in this he feems to have recourse to the power of habit, though he disclaims that hypothesis. This principle, however, has been thought sufficient to account for this appearance.

Originally, every object making two pictures, one in each eye is imagined to be double; but, by degrees, we find that when two corresponding parts of the retina are impreffed, the object is but one; but if those corresponding parts be changed by the distortion of one of the eyes, the object must again appear double, as at the first. This seems to be verified by Mr. Chefelden, who informs us, that a gentleman, who, from a blow on his head, had one eye distorted, found every object to appear double, but by degrees the most familiar ones came to appear single again, and in time all objects did so without amendment of the distortion. A similar case is mentioned by Dr. Smith.

On the other hand Dr. Reid is of opinion, that the correspondence of the centres of two eyes, on which single vision depends, does not arise from custom, but from some natural constitution of the eye and of the mind.

M. du Tour adopts an opinion, long before fixegged by Gaffendi, that the mind attends to no more than the image made in one eye at a time; in support of which he produces several curious experiments; but as M. Buffon observes, it is a sufficient answer to this hypothesis, that we see more distinctly with two eyes than with one; and that when a round object is near us, we plainly see more of the surface in one case than in the other.

With respect to single vision with two eyes, Dr. Hartley observes, that it deferves particular attention, that the optic nerves of men, and fuch other animals as look the fame way with both eyes, are united in the fella turcica in a ganglion, or little brain, as it may be called, peculiar to themselves; and that the affociations between synchronous impressions on the two retinas must be made fonner, and cemented firther on this account; and that they ought to have a much greater power over one another's images than in any other part of the body. And thus an impression made on the right eye alone by a single object, may propagate itself into the left, and there raise up an image almost equal in vividness to itself; and, consequently, when we see with one eye only, we may, however, have pictures in both eyes.

It is a common observation, fays Dr. Smith, that objects seen with both eyes appear more vivid and stronger than they do to a single eye, efpeditiously when both of them are equally good.
the S. coast of the island of Buchar, with which it forms a good inner and also outer harbour.

ST. ELBURG, or STENFELD, a town of the duchy of Courland, on the Dvina, where the bishops of Sventoki, formerly resided, and who, on that account, were called bishops of Sventoki; 50 miles S.E. of Riga.

SEELING, a horse is said to feel when he begins to have white eye-brows, that it, when there grows on that part about the breadth of a farthing of white hairs, mixed with that of his natural colour, which is a mark of old age.

It is said a horse never feels till he be fourteen years old, and always does before he is sixteen. The light foiled and black foored feel than any other.

Horse-jockies usually pull out those hairs with pinces: but if there be so many that it cannot be done without making the horse look bald and ugly, then they colour their eye-brows, that they may not appear old.

SEELING, in Falconry, is the running a thread through the eye-lobes of a hawk, when first taken, to make her endure the hood the better.

SEELING, at Sea, is used in the same sense nearly with heeling: when a ship lies down confusedly, or heavily, on one side, the seamen say she feels; and they call it feeling, when the tumbles on one side violently and suddenly, by reason of the sea forstaking her, as they call it, i.e. the waves leaving her for a time in a bowling sea. When a ship thus tumbles to leeward, they call it lee-feel: and in this there is not much danger, even in a Bora, because the sea will presently right her up again; but if the rows or feels to windward, there is fear of her coming over too short or suddenly, and to by having the sea break right into her, be either foundered, or else have some of her upper works carried away.

SEELINGAN, in Geography, a small island in the Sooboo Archipelago. N. lat. 6° 4'. E. long. 118° 15'.

SEELKEN, a town of Prufia, in the province of Nautangen; 9 miles W.N.W. of Liel.

SEELOW, a town of Brandenburg, in the Middle Mark; 10 miles W. of Culdin.

SEEAN, or SEEAN. See SEEAN.

SEE-MA-KOANDO, in Biography, a Chinefe mandarin and philopher of the nineteenth century, who enjoyed the favour of the emperor, and had several important places, which he resigned and retired to a solitary place, where he wrote a history of China, commencing at the 403d year before the Christian era. He was author likewise of some moral treatises.

SEEMO, in Geography, a town of Africa, in Kaffon. N. lat. 14° 25'. E. long. 8° 45'.

SEENEENDOONG, a small island in the East Indian sea, near the N. coast of Borneo. N. lat. 7° 48'. E. long. 117° 45'.

SEENGHOO, a large town of the Birman empire, situated on the Irrawaddy, having in its neighbourhood, and for a great distance along the eastern bank of the river, small temples built close to the water; 10 miles S. of Pagah.

SEERO, a town of Hindoostan, in Malwa; 50 miles E.S. E. of Shajahanpour.

SEEPARKAN, a small island in the East Indian sea, near the east coast of Borneo. N. lat. 4° 5'. E. long. 118° 25'.

SEER, Principality of, a petty soverignty of Arabia, extending from Cape Mullendom along the Persian gulf. The Perisans call it the country of Djoflar, another name near Mullendom. The Europeans also call the inhabi-
S E F

abitants the Arabs of Djuflar. The other Arabs call it Seer, from the town of the same name, which has a good harbour, and is the seat of the feicheik. He formerly possessed and still retains the title of Schahredje, with some considerable places upon the opposite side of the gulf, among which are Kunk and Lundje. This country not long since acknowledged the sovereign authority of the Imam; but it has withdrawn itself from this condition of dependence; and the feicheik often goes to war with his old master; but without sufficient, he is not able to defend himself. He takes care, however, to live upon good terms with the other independent feicheiks, especially with the feicheik of Dejen, whose dominions he was forced from Oman. The prince of Seer makes some figure among the maritime powers in these parts. His navy is one of the most considerable in the Persian gulf. His subjects are much employed in navigation, and carry on a pretty extensive trade. N. lat. 25°. E. long. 54°. 38'. Niebuhr's Travels into Arabia, vol. ii. Eng. ed.

SEERD, a town of Asiatic Turkey, in the province of Diarbekir; 55 miles E. of Diarbek.

SEERKA, a town of Bengal; 25 miles E. of Patamow.

SEERPUR, a town of Bengal; 18 miles W. of Moorshedabad.—Allo, a town of Bengal; 25 miles N.E. of Nattore.—Allo, a town of Hindooitan, in Allahabad, on the Ganges; 40 miles E. of Gazzypoor.—Allo, a town of Hindooitan, in the circuit of Sumbul; 40 miles S. of Ndijhabad.—Allo, a town of Hindooitan, in Bahar; 15 miles W. of Patna.—Allo, a town of Hindooitan, in Bahar; 9 miles N. of Arrah.

SEERSY, a town of Bengal; 40 miles S.S.W. of Burdwan. N. lat. 22°. 39'. E. long. 87°. 35'.

SEERWAY, a town of Hindooitan, in Myfore; 10 miles N. of Cheena Balabaram.

SEES, a town of France, in the department of the Orne, and chief place of a canton, in the district of Alençon, before the revolution the see of a bishop, suffragan of Rouen; 24 miles N. of Alençon. The town, situated on the Orne, contains 5471, and the canton 18,484 inhabitants, on a territory of 210 kilometres, in 18 communes. N. lat. 48°. 36'. E. long. 0°. 15'.—Allo, a river of France, which runs into the sea near Mount St. Michel.

SEESEEN, a town of Welfphalia, in the principality of Wofenbottle; 4 miles E. of Ganderheim.

SEESKAR, a small island in the gulf of Finland. N. lat. 60°. 5'. E. long. 25°. 11'.

SEESUCANDA, a town of Africa, in Woolly. N. lat. 13°. 25'. W. long. 12°. 54'.

SEETACON, a town of Hindooitan, in Bengal; 18 miles N. of Itlamabad.—Allo, a town of Bengal; 15 miles N. of Curruckpore.

SEETAPON, a town of Bengal; 20 miles N.N.W. of Itlamabad. N. lat. 22°. 37'. E. long. 91°. 48'.

SEETRUNGE, a river of Hindooitan, which rises in Guzerat, and runs into the gulf of Cambay; 4 miles E. of Sultaneppour.

SEETUL, a town of Bengal; 13 miles N. of Maul- dah.

SEEVE, a river which runs into the Elbe, near Harzburg.

SEEWAH. See Siwa.

SEEWALD, a town of Pruffia, in the province of Oberland, near Deutsch Eylau.

SEEWEEBAY. See Seeve.

SEFAKIN, a town of Arabia, in the province of Yemen; 60 miles S.E. of Lohia.

SEFATIANS, a sect of Malometans, who held the opposite opinion to the Moatazalites, with respect to the eternal attributes of God, which they affirmed, making no distinction between the essential attributes, and those of operation; and hence they were named Sefatians, or Attributes. See Moatazalites.

The doctrine of the Sefatians was that of the first Morometans, who were not yet acquainted with these nice distinctions; but this sect afterwards introduced another species of declarative attributes, or such as were necessarily used in historical narration, as hands, face, eyes, &c. which they did not offer to explain, but contented themselves with saying they were in the law, and that they called them "declarative attributes." At length, by introducing various explanations and interpretations of these attributes, they divided into many different opinions; some, by taking the words in the literal sense, fell into the notion of a likeness or similitude between God and created beings, to which it is said the Karaites or Caraites among the Jews, who are for the literal interpretation of Moses' law, had thrown them the way:—others explained them in another manner, saying that no creature was like God, but that they neither understood, nor thought it necessary to explain the precise signification of the words which seem to affirm the fame of both; it being sufficient to believe that God hath no companion or similitude.

The sects of the Sefatians are, 1. The "Assharians," or followers of Abu'l Hafan al Affaari, who allowed the attributes of God to be distinct from his essence, yet so as to forbid any comparison to be made between God and his creatures; and who, as to predetermination, maintained that God hath one eternal will, and that he willeth both the good and evil, the profit and hurt of men, and who have even said, that God may even command man to do what he is not able to perform; and as to mortal sin they taught, that if a believer guilty of such sin die without repentance, his sentence is to be left to God, whether he pardon him out of his mercy, or whether the prophet intercede for him, or whether he punish him according to his demerit, and afterwards, through his mercy, admit him into paradise; but that it is not to be supposed he will remain for ever in hell with the infidels:—such were the more rational Sefatians, who were very different from—2. The "Mohabbities," or "Affilimitors." (See Mohabbities.) 3. The "Keramians," called also "Mojallamenies," or "Corporaliasts," who declared God to be corporeal. (See Keramians.) 4. The "Jabarians." (See Jabarians.) 5. The "Morgians," said to be derived from the Jabarians, who teach, that the judgment of every true believer that hath been guilty of a grievous sin, will be deferred till the resurrection, and that disobedience with faith is not injurious, but, on the other hand, that obedience with infidelity doth not profit. The Morgians are distributed into four species; three of which, according as they happen to agree in particular dogmas with the "Kharejites" the "Kadarians," or the "Jabarians," are distinguished as Morgians of those sects, and the fourth is that of pure Morgians, and this species is subdivided into five others. The opinions of Mokatel and Batar, both belonging to a sect of Morgians, called "Thaubians," are as follow. The former asserted that disobedience hurts not him who professed the unity of God and is endowed with faith, and that no true believer shall be cast into hell; he also taught that God will of himself punish all transgressors. The latter declared that a disobedient believer will be punished at the resurrection, on the bridge laid over the midst of hell, where the flames of hell-fire shall catch hold on him, and torment him in proportion to his disobedience, and that he shall
all then be admitted into paradise. The latter held, that if God do call the believers guilty of grievous sin into hell, yet they shall be delivered there, for they shall have been sufficiently punished; but that it is neither possible nor consistent with justice, that they should remain there for ever.

Sale's Karon—Prel. Dutc.

SEFIDROU, in Geography, a town of Peræa, in the province of Farfaia; 114 miles S.W. of Scras.

SEFROI, a town of Africa; 2 miles S.E. of Fez.

SEFURA, a town of Africa, in Fouta. N. lat. 10° 35'. W. long. 10° 25'.

SEG, in Rural Economy, the name of a cultivated barley.

SEGACHEE, in Geography, a town of the Birman empire, on the Irrawaddy; 6 miles from Denerhow.

SEGALLA, a gold mine of Africa, in the dominion of Barnabuk.

SEGAR, Sir William, in Biography, garter king at arms, was author of "Honour Civil and Military," folio, 1602. He was imprisoned for granting the royal arms of Arragon, with a canton of Brabant, to George Branden, the common hangman, but it being very evident that he had been imposed upon he was released. He died in 1633. Edmundson's Baronsage is said to have been principally taken from Segar's MSS.

SEGAR, in Geography. See SADSHAI.

SEGARDEE, a town of Hindoostan, in Goleconda; 30 miles N.W. of Hydрабad.

SEGARQUIM, a town of Thibet; 52 miles S.W. of Zungga.

SEGBORG, a town of the duchy of Holstein, the name of which is derived from a castle built there by the emperor Lutharius in the year 1137, of which few vestiges now remain; 18 miles N.W. of Lubeck. N. lat. 50° 58'. E. long. 10° 19'.

SEGED, a town of Nubia; 30 miles S. of Sennaar.

SEGEDA, in Ancient Geography, a very celebrated town of Spain, in Buxea, in the interior of the country, between the coast of the ocean and the river Tabor, according to Pliny.—Also, a large and powerful town of Spain, in Celtiberia, belonging to the people called Belis, according to Appian.

SEGEDIN, in Geography. See SECEDIN.

SEGEDUNUM, in Ancient Geography, a town on the confines of Dacia, on the river Tibiscus, which belonged to the Jazgyes.

SEGEDUNUM, one of the eighteen stations on the wall of Severus, is English "Comins-house," being the first station reckoning from east to west, three miles five furlongs and one and a half chain from the next station to the west of it. See STATION.

SEGHERAD, in Geography, a town of Norway, in the province of Christiana; 24 miles W. of Christiana.

SEGELOCUM, in Ancient Geography, a town of the Isle of Albion, in the 8th Iter of Antony, between Lincoln and Dartmouth. All our antiquaries agree in placing Segelocum, which is called Agelocum in 8th Iter, at Littleborough, between Lincoln and Doncaster, where Roman coins, altars, and other ancient remains have been found.

SEGELSBERG, in Geography, a town of the duchy of Bremen; 5 miles E. of Bremen.

SEGERA, a town of Arabia, in the province of Hadjas; 5 miles S. of Medina.

SEGES, or SECHERS, GERARD, in Biography. This eminent painter was born at Antwerp in 1532. He was first a pupil of Henry van Balen, but afterwards entered the school of Abraham Janssens, and had made considerable progress in the art when he went to Italy. On his arrival in Rome, he attached himself as a disciple to Bartolomeo Manfredi; and from him adopted a style for the expression of Michael Angelo Caravaggio. To the strength of contrast, which he thus adopted, he added force and beauty to the tone and colour; he had brought with him from his native country: producing the powerful effect of candle-light, though often falsely applied in subjects which appear to the naked illumination of the day. By skilful productions of this nature, he acquired a very considerable fame, and was at length invited by the cardinal Zanone, the Spanish ambassador at Rome, to accompany him to Madrid. He accepted the invitation, and was preferred by the cardinal to the king, who received him in the most gracious manner, and engaged him to his service, with a considerable pension. He employed himself at Madrid in painting several historical subjects, and some musical conversation pieces, which were greatly admired; but after remaining there some years, the desire of revisiting his native country induced him to request permission to retire. His renown had reached Flanders, and his fellow-citizens were impatient to pull from his productions; yet, when he had arrived there, and executed some paintings in his strong manner, they, whose eyes had been accustomed to the pure brilliant hues, and clear contrasts of Rubens and Van der Weyde, were unable to yield him that harvest of praise to which he had been accustomed, and he was obliged to change his manner, and adapt a more tender and agreeable style. The facility with which he effected this change, proves his power over the materials of the art, and his judgment in its principles; and many of his latter pictures bear evident testimony in support of his general ability. His most esteemed productions is one of the principal altar-pieces in the church of the Carmelites at Antwerp, the subject of which is the Marriage of the Virgin. Vandyke painted his portrait among the eminent artists of his country, which is engraved by Pontius. He died in 1651, aged 62.

SEGES, DANIEL, was the younger brother of Gerard, and born at Antwerp in 1590. His taste leading him to design fruit and flowers, he was placed as a disciple with J. Brughel. At the age of 16 he entered the society of the Jelants, and abandoned painting during his novitiate, but when that term expired, he obtained permission of his superiors to visit Rome, where his brother was then flourishing with distinction; and he also acquired considerable celebrity, by the fidelity and skill with which he imitated the beauty and variety of those objects of creation, as flowers, plants, and insects, which he chose for his models.

His productions were sought with anxiety, and his talents were not unproductive even to his convent, which received valuable tributes in return for those ingenious and entertaining treasures of art. He appears, indeed, to have painted more for the benefit of the wily society to which he had attached himself, than for his private advantage; and when he had produced his most celebrated picture, at the command of the prince of Orange, it was presented to that monarch in the name of the society, which was magnificently recompensed in return. He frequently painted garlands of flowers, as borders for pictures, which were filled up with historical subjects by the first painters. He died at Antwerp in 1665, aged 70.

SEGESTA, or AGESTA, in Ancient Geography, a town in the interior of Sicily, W. of Panormus. It had a harbour and gulf of the same name. The harbour was called "Segelatorum emporium," according to Ptolemy.

Thucydamides represents it as a maritime town, and speaks of the navigation at Agesta. This ancient name is said to
have been given to the place by Egelius the Trojan, who is said to have been one of its founders; but the Romans pretended that it was founded by Æneas. Its ruins are still visible. The mineral waters of this place were called "Segesta aigua:" and they are placed in the Itinerary of Antonine on the route from the Lilybean promontory to Tyndaris, between Drepanum and Parthenium.

_SEGESTA._

The fabulous mixed circle, Twenty-five E. a.m. or afternoon Liguria, proved the town demontirated, Spain, northern town from E. the aot. a visible. empire. uninhabited. describable. Segesta, a town of Italy, in the interior of Liguria, towards the east. It was anciently considerable. 

_SEGESTAN, or SEJSTAN, in Geography, a province of Perista, formerly called "Nimofoe," from a fabulous tradition that it was once under water, and that it was drained in the short space of half a day by the Genti, comprehends part of Ariana and the country of the Sarangans, and is bounded on the N. and N.W. by Khorasan, E. by Canda- har and Zableftan, and S. and S.W. by Mekran and Kerman. The greater part of this province is flat, sandy, and uninhabited. A wind blows for a hundred and twenty days, during the hot months, with such violence as to overwhelm with clouds of sand, houses, gardens, and fields. Although Segesta is now reduced to a depopulated condition, it once rivaled in prosperity the most flourishing provinces of the empire. The noble river Heermund (the ancient Eymander), navigable for boats from Boll to Zarang, flows through the extent of it, from the mountains of Hazara, beyond Cabul to the lake of Zerah. Capt. Chirkie, who travelled in 1810 through the heart of Segesta, reports that from Noofsky, in northern Mekran, to the banks of the Heermund, the country was a mere desert, intersected with sand-hills, and that he did not see a single town, or even village, in the way; the only inhabitants of this wild being a few Balouque and Patan shepherds, who lived in tents pitched in the vicinity of the springs. He reached the Heer- mund in N. lat. 32° 24'. E. long. 64° 16', and followed the banks of that river for about seventy or eighty miles. Its course lies through a valley, varying in breadth from one to two miles, the desert rising on either side in perpendicular cliffs. The valley, irrigated by the waters of the river, is covered with verdure and bruffwood. Our traveller found an astonishing number of mixed towns, villages, and at one of these, Kula, an island in a tolerable state of preservation. The remains of a city, called "Poolkee," he describes as immense. The Heer- mund is four hundred yards wide, very deep; the water being remarkably fine, and the banks cultivated for half a mile on each side. The present capital of Segesta is "Dooh- shak," supposed to be the same with the ancient Zarang, and now the residence of the prince of Segesta, situated in N. lat. 31° 8'. E. long. 65° 10'; about eight or nine miles from the river. It is small and compact, but the ruins cover a vast extent of ground. It is populous, has a good bazar, and the inhabitants, dressed in the Persian manner, appeared more civilized than the other natives of the province, who are either Patan or Balouque shepherds, men of wandering life, and pitching their tents under the ruins of ancient palaces. The country in the vicinity of the town is open, well cultivated, and produces wheat and barley sufficient for exportation to Herat; the palturage also is good and abundant. The revenues of the chief of Segesta amount to no more than 50,000 rupees, and he can bring into the field about 3000 men. Twenty-five miles N. of Doohshak are the ruins of a very large city, called "Pehahuwan," and a few miles beyond that the remains of another, called "Jouen." Ferrah, or Ferah, is distant fifty-five miles from Doohshak, and it is described as a very large walled town, situated in a fertile valley, on a river which flows into the lake of Zerah, or Zara, and nearly half-way between Candahar and Herat.

Segesta is, at present, divided into a number of small independent states, governed by chiefs, who live in fortified villages, situated principally on the banks of the Heermund. About ten days' journey from Doohshak is the city of Kub- beer, situated in the midst of the desert, fifteen days' march from Kerman and sixteen from Yezd. The whole of the inter- mediate space is an arid waste, intersected with one or two ranges of mountains. Through this desert is a path, by which Caffids, or couriers, can go from Kerman to Herat in eighteen days; but the risk of perishing is so great, that a peron of that description demands 200 rupees for the carri- essage of a letter. Kimner's Mem. of the Persian Empire.

_SEGESTE; in Ancient Geography, a town of Ithria, be- longing to the Carni, according to Pliny. Strabo places it in Pannonia, at the confluence of several navigable rivers, so that the Romans estahlished their magazines in it, during their war with the Dacians.

_SEGESTI, a town of Italy, in Liguria, S.E. of Portus Delphi.

_SEGESVAR, in Geography. See SCHESBURG.

_SEGETICA, in Ancient Geography, a town of European Mydia, or of Moasia, of which Crailus gained possession, according to Dion Cassius.

_SEG EZ, in Geography, a river of Ruffia, which forms a communication between the lakes Sig and Vig, in the government of Olenetz.

_SEGGARS, in the Manufacture of porcelain and pottery, are cafes formed of coarser clays, but which are capable of retaining the required heat without fusion; in which different kinds of earthenware are baked. See PORCELAIN and POTTERY.

_SEGGERA, in Ancient Geography, a town of Africa Propria, according to the Itinerary of Antonine.

_SEGIDA, a town of Spain, in Celtiberia, Steph. Byz. and Strabo.

_SEGILMESSA, in Geography. See SUCULMESSA.

_SEGISA, in Ancient Geography, a town of Spain, in the Tarragonensis, in the interior of the country of the Bar- rilani.

_SEGISAMA, and Segisma Julia, a town of Spain, in the Tarragonensis, depending upon the Vaceans, according to Ptolemy. It was situated S. of Loc brigas, and E. of Pallentia.

_SEGLINGE, in Geography, a small island in the Baltic, near the coast of Finland. N. lat. 60° 14'. E. long. 20° 30'.

_SEGLORE, a town of Sweden, in West Gothland; 25 miles E. of Gothenburg.

_SEGMENT of a Circle, in Geometry, a part of a circle, comprehend between an arc and its chord; or, it is a part of a circle comprehend between a right line less than a semi-diameter, and part of the circumference.

Thus the portion AFBA (Plate XIII. Geometry, fig. 13.) comprehend between the arc AF and the chord AB, is a segment of the circle ABFD, &c.; fo is also ADBA a segment comprehend between the arc ADB and the chord A B. As it is evident every segment of a circle must either be greater or less than a semicircle, the greater part of the circle cut off by a chord, is, e. the part greater than a semicircle, is called the greater segment, as AFB; and the lesser part, or the part less than a semicircle, the leffer segment, as ADB, &c.

The angle which the chord AB makes with a tangent L B, is called the angle of a segment. It is demonstrated, that
that the angle included by a tangent to a circle and a chord, drawn from the point of contact, is equal to the angle in the alternate segment.

Some theorems on mixed angles are explained. The segment is the See segment.

The height of a segment is defined as the perpendicular from the base to the line parallel to the base.

If the area of the greater segment BFA were required, the triangle ABC must be added to the segments ACF and BCF. For other methods of finding the area of a segment of a circle, we refer to Hutton's Method, p. 133, &c.

Segment of a sphere is a part of the surface terminated by a portion of its surface, and a plane which cuts it off, passing somewhere out of the centre. This is more properly called a section of a sphere.

The base of such a segment, it is evident, is always a circle whose centre is in the axis of the sphere.

The solid content of a segment of a sphere is found by multiplying the surface of the whole sphere by the altitude of the segment, and then dividing the product by the diameter of the sphere, and to the quotient added the area of the base of the segment; or, if it be less than a hemisphere, then take the altitude of the segment from the radius of the sphere, and by the difference multiply the area of the base of the segment, and subtract this product, from that which will arise by multiplying the semi-axis of the sphere into the square of half the altitude of the segment; then divide the remainder by 3, and the quotient is the solidity sought.

The latter method supposes the axis of the sphere to be given; if not, it may be found thus: let the altitude of the segment be called $h$, and its semidiameter, $r$, then will $h^2 = h^2 - 2ah$; add $a^2$ to $a$, and that shall give the axis found.

See Frustum and Sphenum.

Segment is sometimes extended to the parts of ellipses, and other curvilinear figures.

Segments, Line of. On Gunter's sector there are usually two lines, called lines of segments; they are numbered with 5, 6, 7, 8, 9, 10, and lie between the lines of segments, and those of superficies. They represent the diameter of a circle, so divided into one hundred parts, as that a right line drawn through those parts, and normal to the diameter, shall cut the circle into two segments, of which the greater shall have that proportion to the whole circle, which the parts cut have to one hundred.

Segment of leaf, a denomination given by botanists to those leaves that are cut and divided into many shreds, or pieces, as fennel, &c.

Segmentum, among the Romans, an ornament of lace used by the women on their shoulders, which, according to fume, refembl'd our shoulder-knots.

Segmenta were likewise a kind of tesselated or Mosaic pavement, made up of pieces of vari-coloured stones, but which had no name of their own.

SEMIOSDAI, Valonia, in Austria, are little villages of the plains. The arable land is well plowed, and the gardens are fertile.

SENGA, in Geography, a small town of Brabant, on the sound of the Adria, declared a free port, and erected into a bishopric by the emperor Leopold II., in the year 1783. It is a free town, under the protection of Austria. The city is still built, walled, and fortified. It lies on the bank of the sea, on a foundation of concerete ground, at the mouth of a narrow valley, surrounded by mountains. Sengia supposed to have been originally situated about three miles farther from the sea, on a spot where are found traces of ancient habitations and burial monuments. The sea seems to have covered the bottom of the valley as far as the city, which rested on the side of a hill, and formed a tolerable harbour. The walls of this city were not constructed before the 16th century; and thus, together with other circumstances, affords a further proof that Senga does not occupy the site of the ancient Sinia. The wind from the mountains sometimes blows with such violence, that it is dangerous in winter to encounter it in the street. Horses loaded with salt are frequently thrown down in the market-place of Senga; and the roofs of houses, though covered with heavy stones, are removed. When hurricanes occur, the ships that happen to be in the harbour run the greatest risk of being lost; nor are they preferred without great labour and expense. The sea in the mouth of the channel of Senga, opposite to the valley, is hardly ever calm; but notwithstanding all these perils and disasters, the inhabitants had, about the beginning of the last century, fifty merchant-ships at sea; and they acquired wealth by exporting the corn, wood, wax, honey, tar, and iron of the Turkish state, on which they border, as well as the timber felled in the ancient forests of Vilebiach; and by importing, besides many other articles of merchandise, salt, oil, and wine, for the supply of the interior. At length, however, the inconvenience of their situation disconcerted their marine and commercial enterprises, so that at present Senga has but few ships belonging to it. Another damage was sustained by this city, in consequence of the regulation made by the court of Vienna in 1741, which deprived it of 60,000 florins a-year in money, 40,000 ells of cloth, and 100,000 measures of grain, given yearly by the emperor to the inhabitants of Senga, who were a warlike people, and formed a kind of barrier against the Turks on that side. When the Austrians took the country of Lika from the Turks, and formed all the inhabitants into militia, Senga lost its importance. The soil is so unproductive, that, with the utmost labour, it supplies scarcely provisions sufficient for two months in the year; and they are under a necessity of procuring water from a spring at the distance of twelve miles. The population of Senga is at present computed at less than 7000; and yet the people, amid all their disadvantages, manifest a civility and politeness of manners, which are not met with in any other place of the Austrian coast, nor even among the Venetian subjects of these parts. N. lat. 45° 4'. E. long. 15° 3'.
turning to Florence, he was employed in public affairs by the republic, and by duke Cionio, who in 1541 sent him on an embassy to Ferdinand, king of the Romans. He was, in 1542, appointed consul of the university of Florence, then in very high reputation. He wrote a history of Florence from the year 1527 to 1555, which in every respect is considered as one of the best productions of the age. It was seen by no one during his life, and was not printed until the year 1713, when it appeared, together with a life of Niccolo Capponi, gonfalonier of Florence, Segni's uncle. This writer likewise translated into the Italian language several treaties of Arrilottre, which were printed at Florence in 1549–50. He died in 1559.

SEGNI, in Geography, a town of the Campagna di Roma, the fee of a bishop, under the pope. Organs are said to have been invented in this town; 25 miles S.E. of Rome.

SEGNI, in Ancient Geography, a people of Gaul, who are supposed to have occupied a territory, which is the feite of a small town, called "Sinei," or "Signei," on the frontier of Namur, and to have founded it.

SEGINITZ, in Geography, a town of the duchy of Wurzburg, on the Maine; 12 miles S.E. of Wurzburg.—Alfo, a town of Germany, in the principality of Anspach; 4 miles S.W. of Maynbernheim.

SEGNO, It. 1, in Majic, a sign or mark of reference, for the repetition of any strain, or portion of a strain. It is usually an S, the initial of figura or figlio, dotted on each fide, thus $S$; of more use in rondells than in any other movements. The sharp $S$, natural $S$, and flat $b$, are accidental figus, as is the diesis $\times$, or double sharp. The paufe, or corona $\circ$, is a figo di silentio, as well as a final terminating sign. (See all these terms under their several heads.) The $S$ is likewise used in canons and catches written on one line, to mark the places where the several parts come in.

SEGO, in Geography, a city of Africa, and capital of the kingdom of Bambara, situated on the Joliba or Niger. Mr. Park, whose death we have now reason to lament, arrived at this city in his first African expedition; and to him we are indebted for the following account of it. He says, that it confined, properly speaking, of four divisions or quarters, two on each side of the water, and each of them surounded by a mud wall; so that they exhibited the appearance of four dillinct towns. The two divisions on the north side of the river are called "Sego Korró" and "Sego Boo"; and those on the south bank are called "Sego See Korró" and "Sego See Korró." The houfes are built of clay, and have flat roofs; but some of them have two stories, and many are white-washed. Besides these buildings, Moorish mosques are seen in every quarter. These objects, with the numerous boats on the river, a crowded population, and the cultivated flat of the surrounding country, formed altogether a prospect of civilization and magnificence, which our traveller little expected to find in the bofom of Africa. From the chief inquiries he could make, he had reason to believe, that Sego contained altogether about 30,000 inhabitants. The king of Bambara comittantly refides in the largelst quarter of the city, called Sego See Korró; he employs a great many slaves in conveying people over the river; and the money thus obtained, though the fare is only ten cowries for each person, furnishes a considerable annual revenue to the king. The boats on the Niger are of a circular construction, each of them being formed of the trunks of two large trees, rendered concave, and joined together, not fide by fide, but lengthways; the junction being exactly across the middle of the boat. They are, therefore, very long, and disproportionately narrow; for Mr. Park observed in one of them four horses and a great many people, croufing from a ferry. It was at a village near this city that Mr. Park was ordered by the king to take up his abode; but the inhabitants being indifferently, either from averion or from fear, to accommodate him with lodging and entertainment, he was under a necessity of sheltering himself, in a storm of thunder and rain, under a tree. For an account of the hospitable treatment he received on this occasion from a poor Negro woman, fee the article AFRICA. When he received, on the third day of his abode, an order from the king to depart from the vicinity of Sego, Manfeng (the king) wishing to relieve a white man in distress, sent him 5000 cowries, to enable him to purchase provisions in the course of his journey. The messenger added, that if Park's intentions were to proceed to Jenne, he had orders to accompany him as a guide to SanFanbing. Sego is situated in N. lat. 14° 10' 30". W. long. 2° 26'.

SEGOBRIKA, in Ancient Geography. See SEGORBE.

SEGODUNUM, a town of Gallia Celsita, belonging to the people called "Rutani," or "Ruteni," according to Ptolemy. In the Peutingerian Tables, it is called "Segudum"; and it afterwards took the name of "Rutenus," or "Ruteni," and at length that of Rodon.

SEGOLTA REM, one of the Hebrew accents, usually answering to our semicolon, and marked with three points over a letter, thus (•••) or (•••).

SEGONTIA, in Ancient Geography, a town of Spain, in the Tarragonensis, upon the route from Emerita to Saragozza, between Cafta and Arcobrega, according to the Itinerary of Antonine.

SEGONTIA Paramica, a town of Spain, in the Tarragonensis, belonging to the people called "Varduli."

SEGONTIACI, a people of the ile of Albion, who inhabited with the Trinobantes, and were of the number of those who submitted to Cesar.

SEGONZAC, in Geography, a town of France, in the department of the Charente, and chief place of a canton, in the dioclet of Cognac; 6 miles S.E. of Cognac. The place contains 2549, and the canton 12,386 inhabitants, on a territory of 2223 kilometres, in 19 communes.

SEGOR, in Ancient Geography, a town of Paleitine, in the Pentapolis, at the southern extremity of the Dead Sea. It escaped the destruction of the four other towns of the Pentapolis. Its first name was "Bala;" but Lot having obtained permission to flee from Sodom, called it Segor, or the little town.

SEGORBE, in Geography, a town of Spain, in the province of Valencia, with the title of duchy, agraciously situated in a very fertile vale, abounding in grain and in fruit, on a river of the same name, which there takes that of Murviedro or Morviedro. Its population consists of 13000 families, or about 66000 souls. Some people relying on the similarity of names, pretend that this is the ancient "Segorbera," which we find on many Roman medals; others, on the contrary, place that ancient town in Catifile; and others in Aragon. Segorbe is the fee of a bishop, suffragan to Valencia, the diocese of which comprehends 42 parishes. The clergy of its cathedral are composed of four dignitaries, ten canons, twenty-four benefactors, and thirty-three chaplains. The town has four convents of monks, a convent of nuns, a seminary, a hospital, five hermitages, oratories or chapels; a provost, who is at once official and vicar-general of the diocese; nine gates, and fix squares. It abounds in fountains, three of which are public, and about forty in private houses. It was taken from the Moors in 1245; by James I., king of Aragon. The
The cathedral church has some paintings of the school of Jacques, and of that of Riblita. The church of the con-
vent of numerous good architecture, and has some good
paintings. The bell-tower is kept in the ancient house of the
judges, Antonio Xumay, a poet in the commencement of the
17th century, and Juan Valera, a dramatist of the be-
ginning of the 17th century, were born in the town. At
a quarter of a league from Segorsa stands the Christian
monastery of Vel de Casa, founded by the domin cun
Marin, son and successor of Peter IV., king of Aragon.
Here are four good paintings by Veygara, Caramon, Da-
freda, Juanita, and Orarte. The monks have established
a paper manufactory at Altura, a village of about 1500
inhabitants, which belon to them, and which is at a quar-
ter of a league's distance between their monastery and Segoresa.
N. lat. 39° 58'. W. long. 39'.

SEGORIALACTA, in Ancient Geography, a town of
Spain, in the Tarragonenses, which belonged to the
Aurewac, Poeleny.

SEGOSA, a town of Gaul, marked in the itinerary et
Autonne between Aqui and Bourdeaux. It is now the
place called "Eusofile.

SEGOSTAEVE, in Geography, a town of Russia, in
the government of Koliva; 44 miles W. of Kralnoard.

SEGÖVELLAUNI, or SEGOSATV, in Ancient Geo-
ography, a people of the interior of Gallia Narbonensis,
in the vicinity of the Rhone.

SEGOSI, a town of Hither Spain, south of Casta;
rous for its aqueduct, said to have been constructed in the
time of Trajan.

Segovia, in Geography, a town of Spain, in Old Castile,
which in the arrangement of its buildings exhibits the
figure of a ship, with the stern to the sail, and the prow
to the wave, commanding an immense rock, and appearing
buried between two deep valleys, one lying to the north,
and the other to the south. The river is watered by a
stream, called Clameses, which forms a junction with the
Esquiura, that waters the left, on which are five handson
bridges. This river, whose boats are clothed with wood,
formerly bore the name of Areva, whereas the appellation
of Arwati was given to the inhabitants of these valleys.
The city is surrounded with walls; and a range of towers,
at equal distances, is planted on the ramparts. The number
of houses has been estimated at 5000, but the population
does not exceed 11,000 souls. The streets are almost all
narrow and crooked, and irregularly paved. The four
suburbs are on more even ground, and contain several manu-
ufactories. Segovia is the see of a bishop, suffragan of the
archbishop of Toledo, where diocese includes the cathedral
chapter of Segoriel, the collegiate chapter of St. Hefelento,
and 438 parishes. The cathedral chapter is composed of
38 dignitaries, 37 canons, 7 prebends, and 13 sub-prebends;
and besides these, 23 chaplains are attached to the church.
In Segovia are reckoned 24 parishes, a chapel of ease,
and 21 convents for both sexes. This city is the residence of
the metropolitan of the district, which assumes its name;
and under the superintendence of a regidor, an alcalde, and
a fixed number of regidores. Here are a statirical society,
the members of which assume the title of "friends of the
country;" and a military school, defined for the instruction
of young engineers. Segovia was once a commercial and
opulent town, eminently distinguished for its cloth and
woollen manufactures; and it has been calculated, that
44,160 quintals of wool were consumed in the looms of this
town, and that 34,199 persons were employed by them;
but its manufactures and trade declined, so that, in the
18th century, the manufacture of stuffs and cloths employed
no more than 120 hands, in which only 2318 grains of
waffed wool were consumed. Between 49 and 59 years
ago, this town lost its trade, and in 1670, when 3186
looms, which employed 5000 hands, wool, and afforded or spun 2542
silk threads. This city has still a town council of 300, but is of little
importance. An aqueduct has been built to convey the rain,
producing as perfect only water, and is a handsome building, erected in the 15th century by
Henry IV., and restored by Juan II., and additions are carried on by hydraulic machines; there
are the Capuchins, with four convents of nuns, the convents of the Carthusians, the town hall, the church of
the Conception, with a double tower; and the cathedral, with two towers, the church of San Juan Atonal,
- the cathedral church, which exhibits the ruins of Gallic and Christian architecture, the church of St.
Francis, bearing the character of a noble antiquity, where Alphina, the Wife crowned his attributes,
tables, and in which are apartments treated with marble
work, still fresh; and a large of 52 statues of painted wood,
and each bearing an appropriate inscription. The relief
mantel of Segoriel is its aqueduct, which has been re-
ferred by some writers to a very remote antiquity, and
attributed to the architects who built the Egyptian temple
of Serapis; but which much more probably originated with the
Romans, at an uncertain period, but perhaps with the
authority of Lucullus, Lacedem, or Trajan. The ma-
terials are of rough freestone. It commences at a large
byashelf, (about 50 paces from the town,) from whence
it receives the water, which it conveys through an open
channel towards the south. At its origin the fabric is erected
on a long range of 75 arches, of which the first is 14 feet
6 inches in height; the last, which is at the convent of St.
Francisco, is 33 feet 6 inches. At this point begins a
double row of arches, supported one over the other, which
run in the direction of isle and well, and cross the valley
and the place of Azoqueo; of these the greatest elevation
is 80 feet 10 inches. The whole range comprehends 159
arches, supported on pilasters, most of which measure 6 feet
11 inches in the front surface, and 9 feet 4 inches in the
interior side. The aqueduct terminates at the alcazar, after
having distributed the greater part of the water through
the different quarters of the town. In modern times, the noble
work of Roman architecture has been disturbed by the
erecion of several houses on its pilasters, a disposition highly
injurious to the majesty of the original edifice. It is built of
square stones, which are placed one on the other, without
any appearance of cement. Segovia was the native place
of Alphonso de Ledesma, a good poet, who flourished at
the commencement of the last century; of Domingo Soto,
the son of a gardener, who published an essay "De Juris
et Juro, two books "De Natura et Gratia," and Com-
nentaries on St. Paul's Epistle to the Romans. At Seg-
ogia was also born the Jesuit Francia Ribera, who died at
Salamanca in 1591, well known for the erudition and wise
men displayed in his Commentaries on the major prophets.
Segovia is distant 46 miles N.N.W. of Madrid. N. lat.
41° 3'. W. long. 4° 1'.

SEGOSIA, Nueva, a town of the island of Lucon,
founded in 1593, the see of a bishop, defended by a fort and
a garrison; situated near the N. coast of the island; 250
miles N. of Manila.—Alto, a town of Mexico, in the pro-
VoL XXXII.
vice of Nicaragua; 70 miles N.N.E. of Leon. N. lat. 13° 30'. W. long. 89° 56'.—Alfo, a town of South America, in the government of Caracas, and province of Venezuela, founded by the Spaniards in 1552; 130 miles S.W. of Caracas. N. lat. 8° 57'. W. long. 68° 16'.

SEGRA, a river of Spain, which rives in the N. part of Catalonia, and joins the Ebro, on the borders of Aragon, near Mouquene.

SEGRAIS, John Regnault de, in Biography, a man of letters, was born of a good family at Caen, in 1624. He was intended for the church, but a courtier, charmed with the spriteliness of his conversation, carried him to Paris when he was about twenty years of age, and placed him with Mademoiselle de Montpenier, who first gave him the title of her amanuensis in ordinary, and then of her gentleman in ordinary. He became known to the literary world by his lyric and pastoral poetry, and in 1656 he published a collection of pieces of this kind, together with some little stories called "Nouvelles Françoises," by which he obtained considerable reputation. He was thought to have been particularly happy in his Eclogues, in which he attempted to unite elegance with the simplicity appropriate to his subject. He aimed at a higher strain in his metrical translation of Virgil's Æneid, which was well received by the public, though it was not free from faults, which were heavy drawbacks on its merit. Thereropment of Segrais gave him admission, in the year 1662, into the French Academy. In 1672 he quitted Mademoiselle de Montpenier, and was domiciled with Madame de la Fayette, whom he affiliated with his advice and correction in the composition of her romance of "Zayde," and he engaged his friend the learned Huet to prefix to it his Differtation on Romances. He at length retired to his native city, and married a rich heiress, who was his cousin. Being now at his ease, and somewhat incommode with deafness, he declined engaging in the education of the duke of Maine, observing that experience had taught him that at court both good eyes and good ears are requisite. He collected the difpermed members of the academy of Caen, and gave them an apartment to meet in. He died in 1701, at the age of 76. After his death, there appeared his translation of Virgil's "Georgies," and a mifcellany of anecdotes and literary opinions.

SEGRE, in Geography, a town of France, and principal place of a district, in the department of the Maine and Loire; 18 miles N.W. of Angers. The place contains 558, and the canton 9247 inhabitants, on a territory of 205 kilomètres, in 14 communes.

SEGREGATA, POLYGAMIA, in Botany, the laft order of the clafs Symphyta, in which the flowers are doubly compound, each floret, or assemblage of florets, having a partial calyx.

SEGRO, in Geography, a town of Naples, in Capitanata; 10 miles N.E. of Manfredonia.

SEGS, in Rural Economy, provincially the name applied to fedges, or fedge-grafs.

SEGSTADT, in Geography, a town of the duchy of Wurzburg; 5 miles E. of Hafurt.

SEGUATANEO, See CHEQUETAN.

SEGUE, in Italian Music, is often found before aria, sero, alleluja, amen, &c. to acquaint performers that such movements immediately follow the last bar of the preceding piece, over or after which such notice is written. But if the words fi place, or ad libitum, are added, they imply that such movements may be performed or not, at pleasure.

SEGUENZA, Ital. in Ecclesiastical Music, is a kind of hymn sung in the Roman church, generally in prose. The Seguence are generally sung after the Gradual, immediately before the Gospel, and sometimes in the vespers before the Magnificat. They were formerly more used than at present. The Roman church has retained three seguence, called by the Italians, li tre seguene dell' anno: which are, "Lauda Sion salvatorum," &c.; "Vittima pacli laudes," &c.; "Veni Sancte Spiritus." These are sung, in many places, to figurative music. There is also one beginning "Dies irae, dies ille," in the funeral service, which has been admirably set by all the great composers a cappella of Italy, and among the Catholics of Germany.

Gen. Ch. Cal. Periaphis inferior, spreading, permanent, of five, oblong, coloured, concave leaves. Cor. bore. Stam. Filaments numerous, capillary, spreading, longer than the caly whole; anthers oblong, flatish. Pist. German superior, oblong, comprefed, membranous at the top, thicker on one side; style very short, at the thicker side of the germen; stigma fimple. Peric. Capule oblong, augmented by a very large wing, thicker on the straight side, with three smaller wings on each side at the base, of one cell, not gaping. Seed solitary, oblong, smooth.

1. S. americana. American Seguireria. Linn. Sp. Pl. 747. Jacq. Amer. 179. "Pict. 1. 82."—Stem climbing, prickly. Leaves lanceolate, margarinate. Clusters branched, leafy.—Native of South America, especially in woods and coppices about Carthagena, flowering in September. The flom of this shrub is generally twelve feet in height, with very long, round, green flowering branches, by which it is supported. Leaves alternate, falked, ovate, entire, flowering, with recurved prickles. Flowers in terminal clusters, with whitish, smelly disagreeably. The unique fruit is said to resemble that of Securidad.

SEGUIN ISLAND, in Geography, a small island on the coast of Maine, in Cacofo bay.

SEGUAM, one of the Fox islands, in the North Pacific ocean. N. lat. 53° 35'. E. long. 187° 50'.

SEGUINTIA CULTIBERUM, in Ancient Geography, a town of Spain, in Celtiberia. Livy.

SEUR, in Geography, a town of France, in the department of the Correze; 12 miles W. of Uzerche.—Allo, a town of France, in the department of the Aveiron; 12 miles E.S.E. of Rhodez.
SEGURA, a town of Spain, in the kingdom of Andalusia; 34 miles N. of Saragossa.—Alli, a town of S. of the S. of Saragossa.—Almor, a town of S. of the S. of Saragossa, about 13 miles S. of Saragossa, and the length of N. and S. of Saragossa, near the river of Saragossa.—Alma, a town of S. of the S. of Saragossa, about 16 miles of of Saragossa.—Alma, a town of S. of the S. of Saragossa, about 18 miles S. of Saragossa.—Amposta, a town of the province of Lerida, near the E. of Spain; 7 miles N. of Barcelona.—Amposta, a town of the province of Lleida, near the E. of Spain; 7 miles N. of Barcelona.

SANTA CRUZ DE TENERIFE, a town of the island of Tenerife, in the province of Tenerife, built by Cortez; 50 miles S. of Tenerife.

SANTA CRUZ DE LA SIERA, a town of Spain, in the province of La Sierra; 60 miles of Chiutlla.

SEGUSO, a town of France, in the department of the Upper Perigord; 4 miles N. of Angouleme.

Segus, in Ancient Geography, a river of Germany, the banks of which were inhabited by the Sicambri, according to Caesar and Tacitus.

SEGUI, a town of the island of Madera, inhabited by the natives of the island of Madera, and the length of S. of the island of Madera, near the E. of the island of Madera.

SEGUIN, or Seguins, a people of Gallia Celtica, or of Lyons. To the N. were the Caei and Seguins, to the E. and N. the Allebroges, and to the W. the Arverni. Pliny says, that these people were dependent on the Caei in the time of Caesar; but that they rendered themselves independent under the empire of Augustus.

SEGUSIO, a town formerly not inconsiderable, in Transpadana Gaul, among the mountains, on Duria Minor. Under the Romans it obtained the title of municipal. In later times, its rulers were designated by the title of marquis. At present it is included in Picardy.

Among other things found in this place is the triumphal arch on which were inscribed the appellations of the people who were subject to Cottius in the time of Augustus. See Segusian.

SEGUSTERO, Sitges, a town of Gallia Narbonensis. From its Celtic name we are led to presume that it existed, or at least that its territory was inhabited, before the Romans came into Provence. Some have thought that this town depended on the Avantici.

SEGWAH, in Geography, a town of Hindostan, in Baghala; 20 miles S. S. E. of Damascus.

SEHALOUR, a town of Hindostan, in Mysoo; 36 miles N. of Serampur.

SEHUN, a town of Arabia, in Yemen; 3 miles W. N. W. of Doran.

SEHARUNKOUR, a town of Hindostan, and capital of a circuit, to which gives name, between the Jumnah and the Janghe, in the subah of Delhi; 86 miles S. of Delhi.

SEHARUNKOUR, a town of Hindostan, and capital of a circuit, to which gives name, between the Jumnah and the Janghe, in the subah of Delhi; 86 miles N. of Delhi.
but for a time he concealed his fpicicous in his own breath, and even while under the fear of danger, he conferred upon his minister additional marks of his favour, making him his colleague in the confulship. He however gradually withdrew from him the tokens of his confidence, and finding that the symptoms of this change had greatly diminished the crowds that attended his levees, he proceeded, though with much caution, to the meafures for his deftitution. He now appointed another commander of his praetorians. Sejanus, knowing the extent of his own guilt, began to be alarmed: he called together his friends and followers, and held forth to them the most flattering promises, and having increased the number of his partifans, formed a bold conspiracy, resolved by any means to feize the sovereignty. A powerful league was formed with ftunning rapidity, and great numbers of all defcriptions,fanétors as well as military men, entered into the plot. Among thefe, Saturnius Secundus was the confident friend and prime agent of the minister, who, for reasons that are not known, resolved to betray his master. For this purpose he addreffed himself to Antony the triumvir, the widow of Drusus, and the mother of Germanicus. When this illustrious woman, who was highly esteemed by the people, as well as honoured by the court, heard the particulars, she feft dispatches to the emperor by one of her flaves. Tiberius was allotted, but not at all dismayed: the danger preferred, and he determined to take decisive meafures. He feft Macro to Rome with a special commiffion, and giving him ample powers that might be adapted to all emergencies. Early in the morning of the 15th, before the kalends of November, a report was spread, that letters had arrived at Rome, with the view of augmenting fift another the honsours of Sejanus. The fenate was summoned to meet in the temple of Apollo, near the imperial palace. Sejanus attended without delay, and a party of praetorians followed him. Macro met him in the veftibule of the temple. He approached the minister with all demonstrations of profound respect, and taking him aside, told him not to be surprifed that he had not received a letter from the emperor himself, but, fays he, I am this day to deliver the emperor’s orders. Sejanus, elated with joy, expefting fome unlooked-for dignity, entered into the fenate-houfe, and Macro followed. He opened his commiffion by reading a long letter in the fenate to the confuls from Tiberius, which concluded with an order to feize his perfon: infantly the whole assemby loaded with inful tions and reproaches the man at whom they lately bent, and the people began to throw down and treat with every indignity the ftatures before which they had been accustomed to offer Sacrifices. His perfon was feized, and thrown into prifon, and being accufed of high treafon, he was condemned without a fingle defender. On the fame day he was executed, and his body thrown into the Tiber. A maffe of his relations took place, and even his infant children were inhumanly flaughtered. This catastrophe took place in the year 31 of the Christian era, and it firmed to Juvenal a fine infine of the mutability of fortune, of which he took advantage in his tenth fatire.

SEIBERSHOLTZ, in Geography, a town of Bavaria, in the principality of Aichfatt; 3 miles N. of Aichfatt.

SEIBERSTORF, a town of Audria; 8 miles N. E. of Ebenfurth.

SEIBO, or ZEYO, a town of the island of Hispaniola; 50 miles E. N. E. of St. Domingo.

SEIBUSSE, a river of Algiers, which runs into the Mediterranean, near Bona.

SEICHES, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the diocife of Marmande; six miles N. E. of Marmande. The place contains 1351, and the canton 13,546 inhabitants, on a territory of 250 kilometres, in 20 communes.—Alfo, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the diocife of Bauge; nine miles W. of Bauge. The place contains 1364, and the canton 9966 inhabitants, on a territory of 240 kilometres, in 13 communes.

SEID GENDER, a town of Peruia, in the province of Lariflan; 25 miles N. of Lar.

SEIDE. See Saida.

SEIDENBACH, a town of Germany, in the principality of Culmbach; 9 miles W. S. W. of Bayreuth.

SEIDENBERG, a town of Lufatia, in which are manufactures of cloth and knit flrockings; 8 miles S. S. E. of Gotlitz.

SEIDENSCHWANZ, a town of Bohemia, in the circle of Boleflau; 8 miles N. of Turnau.

SEIDENSTETTEN, or SEITENSTETTEN, a town of Austria; 9 miles N. N. W. of Waidhoven.

SEIFERSDORF, a town of Bohemia, in the circle of Boleflau; 5 miles S. of Krottan.

SEIGH, a town of Hindoolfan, in Bahar; 15 miles S. of Bahar.

SEIGHN, a town of Hindoolfan, in Bahar; 31 miles N. of Hagypour.

SEIGN, a forfets of Dalmatin, in the territory of Spalatro; 16 miles N. E. of Spalatro.

SEIGNELAY, a town of France, in the department of the Yonne; 6 miles N. of Auxerre.

SEIGNEUR, or SEIGNOR, Lord. See SIRE, SIEUR, MONSIEUR, LORd, &c.

SEIGNIOY, DOMINIM, in our Las, is used for a manor or lordship.

SEIGNORAGE, or SEIGNORAGE, a right or due belonging to a feigneur, or lord.

SEIGNORAGE is particularly used for a duty belonging to the prince for the coining of money, called also coinage (which fee), and in the bolder Latin monetagium. See REMEDY for the Master of the Mint.

This duty is not always the fame, but changes according to the peculfure of the prince, and the occasions of flate. It is in some measure for the discharge of this duty that alloy was invented; that is, the mixture of other metals with gold and silver.

Under our ancient kings, for every pound of gold brought in the mafs to be coined, the king’s duty was five fhillings; one fhilling, and sometimes eighteen pence, of which went to the master of the mint. Under Edward III. the feignorage of every pound weight of silver was eighteen penny weight, which was then equivalent to a fhilling. Under Henry V. the king’s feignorage for every pound of fiver was fifteen pence. At prefent, the king claims no feignorage at all, but the subject has his money coined at the public expence; nor has the king any advantage from it, but what he has by the ally.

In France, under Philip Augulfus, the feignorage was one-third of the profit made by coining; St. Louis fixed it at one-sixteenth part of the value of the money coined: king John, at three livres the mark of gold; Charles VII. by reafon of the defire of his finances, raised it to three-fourths of the value; Louis XIII. fixed it at fix livres the mark, or eight ounces of gold, and ten fols the mark of silver. Louis XIV. took away the right of feignorage in 1679, though it was re-established in 1689, on the foot of seven livres ten fols the mark of gold, and twelve fols fix deniers the mark of silver.
SE1

It must be observed, that for the levying of this duty of 450 francs, the full value of the money is augmented by the value of the duty.

SE1IAN DIST. in Gallia, a mount of Taurin

SEINHEIM, Markt, a town of Germany, and capital of a lordship, united to the country of Schwarzenberg; 18 miles S.E. of Wurzburg.

SEIONT, a river of North Wales, which runs into the Menai near Caernarvon.

SEIR, in Ancient Geography, the name of mountains which lay to the E. and S. of the Dead sea, appropriated to them before the establishment of the Israelites in the land of promise.—Alto, a mountain on the frontier of the tribe of Juda and that of Dan. Josh. iv. 10.

SEISACHTHEIA, Σείσαχθεία, in Antiquity, a public sacrifice at Athens, in memory of Solon's ordinances, by which the debts of poor people were either entirely remitted, or at least the interest due upon them, cancelled, and the creditors prevented from feizing upon the persons of their debtors, as had been customary before that time.

The word signifies the flashing of a burden.

SEISENBURG, or Sieonenberg, in Geography, a town of Carniola; 11 miles S.E. of Weixelburg. 

SEISENSTAIN, a town of Austria, on the Danube; 2 miles N.E. of Ips.

SEISIN, Seisina, in Law, signifies possession. In this sense we say, primer feisin, for the first possession, &c.

Seisin is twofold, seisin in faid, and seisin in law. The former is when an actual and corporal possession is taken: and the latter, when something is done, which the law accounted a seisin, as an enrolment.

This in law gives a right to lands and tenements, though the owner be by wrong dispossessed of them. He who hath an hour's possession quietly taken, hath seisin de droit, &c., of which no man may dispossess him by his own force or subtlety, without process of law. See DISSEisin.

The civilians call the latter civitatem possessoriam, and the former naturalem.

SEISEN, Livery of. See LIVERY.

SEISANA habendo, quae non habuit annum, diem et vasum, a writ that lies for delivery of seisin to the lord of lands or tenements, after the king, in right of his prorogative, hath had the year, day, and wafe, on a felony committed.

SEISENAM habere faciam. See HABERE.

SEISOR. See DISSEISR.

SEISSAN, in Geography, a town of France, in the department of the Ges; 9 miles S. of Auch.

SEISSEN, a town of Saxony, in the circle of Erzgebirg; 18 miles S.S.E. of Freycyberg. N. lat. 50° 35'. E. long. 13° 27'.

SEITAN, a name given by Avicenna, and other of the Arabian writers, to a species of prickly tree, often recommended in their prescriptions.

The word is sometimes also written setan, seten, setab, or setun.

Pliny mentions this as a wood remarkably durable. He says it grew midst plentifully in Egypt, and that it remained uncorrupted in waters. It is called by him, and others of the old Latin writers, fecina nigra, the black-thorn; and the durable nature of our common holly-tree, or blackthorn, growing on our hedges, has tempted some to believe it to be the same with the setan, or scavina nigra of the ancients; but this is overthrown by the common account of Pliny, and others, of ships being built of this wood, the small size of our black-thorn rendering it wholly impossible to put it to such uses.

Theodotion is to be understood of this wood, when he speaks of the setab, or acanthina.

It is plain, from Avicenna, that this setan, or setan, is no other than that species of acacia, which, from its producing our gum arabic, is called the gum arabic tree.

SEITIL, in Commerce, a wine measure at Vienna; 168 seiles = 70 kopien = 40 maflies = 4 vertius = an eimer; and 30 eimers = a dreyling, and 32 eimer = a fuder of wine. The contents of a maal is 71/2 French cubic inches, or 86/5 English ditto, or 3 English pints nearly; so that one eimer is = 15 English gillons.

SEITSAARI, in Geography, an island of the Baltic, five versts long, and about half as much in breadth, distant 95 versts from St. Petersburg, and 75 from Vyborg. The land-banks here reach as far as to the Petersburg channel, and, being invisible from their lying under water, are dangerous in dark nights, that in this place alone not fewer vessels have been lost than in all other parts of the gulf of Finland together. The land is every where unfruitful; though in some of the marshes there is a slight crop of hay. Great numbers of eels and itone perch are caught here. The herring and sea fisheries are also considerable. The inhabitants compose about 20 families. Here is a light-house.

SEITTENHOFF, a town of the duchy of Carniola; 3 miles N. of Weixelburg.

SEITZ, a town of the duchy of Stria; 6 miles N.E. of Cilley.

SEIJUR, a river of Syria, that rives a little N. of Antab, and after a course of about 30 miles through a plain deriving its name from it,loses itself in the earth.—Alto, a town of Syria; 15 miles S. of Antab.

SEIX, a town of France, in the department of the Arriege; 7 miles S. of St. Girons.

SEIZE, Seaze, or Seife, Te, in Sea Language, is to join two ropes, or the two ends of one rope, together, &c., by several close turns of small rope, line, or spun-yarn, round them, with two or more crois-turns.

Throat-fezing, is the first feizing clapt on where a rope or ropes cross each other; see RIGGING, Plate N° 11. fig. 16, at 5.

Middle-fezing, is a feizing between a throt and end-fezing, as at 6.

End-fezing is a round feizing near the end of a rope, as at 7, on the same plate.

Eye-fezing, is a round feizing next the eye of a hrood, &c. RIGGING, Plate II. fig. 15, at 3.

The feizing, feasing, or seafing of a boats, is a rope tied to a ring or little chain in the fore-lip of the boat, by which means it is fastened to the side of the ship.

SEIZING, in Falconry, is when an hawk gripes her prey, or any thing else, full between her claws.

SEIZURE, in Commerce, an arrest of some merchandise, moveable, or other matter, either in consequence of some law, or of some express order of the sovereign.

Contraband goods, those fraudulently entered, or landed without entering at all, or landed at wrong places, are subject to feizure.

In feizures among us, one half goes to the feizor, or informer, and the other half to the king. In France, half the painted linens, &c. feized, used to be burnt, and the other half lent abroad; but in 1715, by an arret of council, the whole was ordered to be burnt.

SEKI, in Geography, a town of Japan, in the island of Niphon; 20 miles S.S.W. of Izo.

SEKIALE, a town of Arabia, in the province of Nedjs; 300 miles E. of Madian.

SEKIDO, a town of Africa, on the Gold Coast, in the district of Agouana, which has an English factory.

SEKIN,
The text contains references to various places and species, discussing their geography, morphology, and uses. It includes detailed descriptions of plants and their habitats, mentioning terms like 'Corymb', 'Leaves', 'Fruits', and 'Flowers'. The text is rich with botanical terms and geographic references, providing a comprehensive overview of the subject matter. The extract is from a larger document that appears to be a natural history or botanical reference.
and sometimes on all of them, and an orange spot at the
mouth of the tube. Bracteas alternate, ovate, large. It is
valuable not so much on account of its beauty as its fra-
grance. Linnaeus described it under the name of Lippia
ovata from a dried specimen which may account for its
faying the flowers are of a dark-violet colour. M. L'He-
ritier first referred it to Selago; in doing which, Mr. Curtis
observes, it would have been better to change the specific
name to Bracteas, its floral leaves or bractees confinuting
the most prominent feature of the plant.

Selago, in Gardening, furnishes plants of the thrubby
and under-thrubby kinds, of which the species cultivated
are; the fine-leaved selago (C. corymbosa); the linear-
leaved selago (S. ipurila); and the ovate-headed selago
(S. ovata).

Method of Culture.—These plants may be increased by
cuttings and layers. The cuttings should be made from the
young under-thruits, and be planted out during the summer
months in a bed of fresh earth, covering them close with
a bell or hand-glafs, shading them from the sun, and refresh-
ing them and rising them with water. They should be gra-
dually hardened, and then transplanted into small pots,
placing them in the shade till they have taken root. The
layers may be laid down in the autumn or spring, and when
well rooted be taken off and planted out in pots, as above.
The plants should afterwards be placed out with other hardy
greenhouse plants, and about the end of October removed
into the dry stove. They only require protection from frost,
being treated in the same manner with the harder fort of
greenhouse plants.

They afford much ornament and variety in greenhouse
collections, among other fimilar plants.

Selah, in Scripture Criticism, a word which occurs no
less than seventy times in the Hebrew text of the Psalms,
and which has occasions great difficulty to the critics.
The Septuagint renders it διελθαμα, g. d. a pause in finging :
and this, it must be owned, was greatly wanted before the
Psalms were divided into verses.

Selam, in Geography, a town of Egypt, on the left
bank of the Nile; 6 miles N. of Siut.—Alto, a town of
Mexico, in the province of Yucatan, near the coast; 45
miles N.W. of Merida.

Selame, an island, or rather cluster of small islands,
near the coast of Arabia, at the entrance into the gulf of
Perfia, near Cape Mecandum.

Selamum, a town of Egypt, on the W. branch of the
Nile; 48 miles N.N.W. of Cairo.

Selanieh, or Zelanien, a town of Egypt, on the E.
branch of the Nile, opposite to Damietta.

Selanian, in Botany, a name by which some fcholars
have called the common crocus vernus, or the garden spring-
flower, which we call the crocus.

Selb, in Geography, a town of Germany, in the prin-
cipality of Culmbach; 14 miles S.E. of Hof.

Selbe, a river of the Isle of Man, which runs into
Ramsey harbour.

Selberg, a mountain of Austrian Swabia; 4 miles
W.N.W. of Schonau.

Selbistan, a small town of Perfia, in the province of
Farfitan, at the distance of 18 furlands from the capital
of the province, containing about 4000 inhabitants, situated
at the foot of a hill, on the banks of a small stream, which
is mostly abордин in the irrigation of the gardens and fields
adjoining the town.

Selbitz, a town of Germany, in the principality of
Culmbach; 3 miles S.S.E. of Lichtenberg.—Alto, a
river of Germany, which rifes in the principality of
Calabach, and runs into the Saal, 2 miles N.E. of Lichten-
berg.

Selboe, a town of Norway, in the diocese of Dron-
theim, where a copper-mine was discovered in the year
1712; 40 miles S.E. of Drontheim.

Selbosoe, a town of Norway, in the province of
Drontheim; 16 miles S.S.E. of Drontheim.

Selby, a market-town partly within the liberty of
St. Peter of York, and partly in the lower division of the
waspente of Barkleton Awe. West Riding and county of
York, England, is situated on the south bank of the
river Ouse, at the distance of 14 miles S. by E. from
York, and 181 miles N. by W. from London. This
town is of great antiquity, having been known in Saxon times
by the appellation of Selbage. In the year 1070, William
the Conqueror erected a monastery at Selby; and having shortly
after visited his new foundation, along with his queen, the
latter was here delivered of a son, who succeeded to the
throne by the title of Henry I. From these circumstances
this place derived considerable celebrity; and was endowed
with various privileges. Many of these, however, are now lost,
but it still retains a market, held on Monday weekly,
and three annual fairs, held on Easter Tuesday, the 22d of
June, and the 10th of October. Here also are holden the
petty fessions for the waspente of Barkleton Awe.

Selby abbey flour on the west side of the town. It was
dedicated to the honour of St. Mary and St. German; and
was filled with monks of the Benedictine order. King
William Rufus gave the patronage of it to the archbishop
of York and his successors, in lieu of the claim they had to
some part of Lincolnshire. Previous to the disfolution its
revenues were valued at 729l. 12s. 10d. per annum, accord-
ing to Dugdale; and at 819l. 22. 6d. according to Speed;
which, with the abbey itself, were granted by king
Henry VIII. to Sir Ralph Sadler. Since that period the
buildings of this monastery have been appropriated to various
uses; and most of them are now demolished, except the
church, which appears to have been a very spacious and ele-
gant pile. From the various styles of its architecture, no
doubt can be entertained of its having been erected at dif-
ferent periods. The oldest divisions are the body and nave,
which evince an early Norman origin, and are probably
eoecal with the foundation of the abbey. The western
front, though extremely irregular, is exceedingly curious,
both with respect to structure and ornaments. The entrance
on this side, and likewise the northern porch, are particularly
worthy of observation. The form of this church is that of
a clops, the shaft of which measures 269 feet in length, and
its transept 100 feet. From the centre of the whole pile
rises a massive tower, which was rebuilt in 1702. On each
side of the choir are twelve ancient falls, similar in form and
workmanship to the prebendal falls in York cathedral.
In the windows are considerable remains of flained glafs,
representing the armorial bearings of Thomas, earl of Lan-
caster, and other distinguished characters of the fourteenth
and fifteen centuries. Here are likewise several ancient
monuments, and a great variety of modern date, i. e. created
since the church became the parochial place of worship about
the year 1660.

According to the parliamentary returns of 1814, Selby
parish contains 742 houses, and 3363 inhabitants. The
principal trade of the town consists in ship-building, and
in the manufacture of leather, fail-cloth, and iron articles.

Five miles to the northward of Selby is the village of
Cawood, remarkable for the ruins of its ancient c<lale,
which is said to have been erected by king Athelstan
in the year 926, and which afterwards became a palace of the
archbishops.
archbishops of York. The flattering entrance or gateway is still remaining, on the summit of which cardinal Wolsey used to sit, and enjoy the view of the surrounding country. Oxburgh castle continued in all its splendour till the commencement of the civil war in 1642, when it was seized upon, and garrisoned for the parliament. It subseqently, however, fell into the hands of the king's party, and filled a siege of ten months before it was retaken by the parliamentary troops, when it was ordered to be demolished. The history of Selby, by James Mountain, 12thmo. York, 1833. Beauties of England and Wales, vol. xi. by John Bigland, 1814.

SELCH, Skerne, one of the smaller Orkney islands, a little N. of North Ronaldshay.

SELCHA, or Sellaqua, in Ancient Geography, a town of Judaea, situated in the half tribe of Manasseh, on the other side of Jordan, according to Joshua.

Selden, John, in Biography, a very distinguished scholar, and an eminent political character, called by Grotius "the glory of England," was born at Salvington, in Sussex, in 1584. He was educated at the free-school at Chichester, whence he was sent to Hart-hall, Oxford, where he resided about four years. He then removed to London, for the study of the law, and with this view entered himself in Clifford's-inn, and about two years after he removed to the Inner Temple, where he soon acquired great reputation by his learning. He had already made himself known by some works of great merit, and this year he wrote verses in Latin, Greek, and English, upon Mr. William Browne's Britannia's Palaesias.

Having been called to the bar, he occasionally pleaded, but was much more employed as a chamber counsellor. The first object of his private studies was the history and antiquities of his own country, and in 1607 he drew up a work, entitled "Analecten Anglo-Britannicum," which was a chronological summary of English history down to the Norman conquest. This work was followed, in 1610, by "England's Epinomis," and "Jani Anglorum Facies Altera," a Latin and English treatise on the origin and progress of English law. By these compositions he became known as a diligent enquirer into the early history and constitution of his country, and acquired the esteem of several eminent literary characters, among whom were Camden, Spelman, and sir Robert Cotton. He was also on familiar terms with Ben Jonson, Drayton, Browne, and other poets of that period, who seem to have regarded his learning and talents with great respect, though his genius appears to have been inclined to poetry. In 1614 he published his largest English work, a treatise on "Titles of Honour," in which he displayed a vast extent of reading, directed by sound judgment. It became a standard authority with regard to all that concerns the degrees of nobility and gentry in this kingdom, in which light it is still referred to; and it abounds in historical information concerning the origin of such distinctions as he traced through other countries. In the year 1617 he entered upon a wider field of literature, and made himself known to the learned throughout Europe, by a celebrated work "De Dies Syris." The chief or leading object of this performance was to treat on the heathen deities mentioned in the Old Testament, but he extended it to an enquiry into Syrian idolatry in general, with occasional illustrations of the mythology of other nations. This work was received with great applause by the learned world, and a new and improved edition of it was printed at Leyden, under the care of Daniel Heinsius.

Hitherto Selden had failed his life in the tranquillity of a man of letters, engaged in subjects not liable to debate; but his next publication, being "A History of Tyre," printed in 1618, subjected him to many severe opprobria, and brought upon him, says his biographer, "a burn for a quarter which has always proved dangerous to free enquirers." In the work alluded to, he had considered the question of the divine right to that republic, advanced by the clergy, and now beginning to be maintained by the bishops of the church, and though he only treated of it as a matter of history, without arguing for or against the right, yet the lamp of his authority had ill-naturally inclined the balance to the negative side of the question, some of the clergy took offence at his freedom, and made an accusation against him before king James. That sovereign, who was fond of interfering in theological disputes, and who was always desirous of keeping on good terms with the church, sent for Mr. Selden, and gave him a lecture on the subject, and being afterwards called before the archbishop of Canterbury, and some other members of the high commission court, he was induced to deprive himself, as to sign a declaration at his sorrow for what he had done. He, however, cautiously avoided retracting his opinion, or contradicting the facts which he had produced. Several answers to Selden's work were published, to which he was not permitted publicly to reply, though he circulated some remarks among his friends. This incident unquestionably confirmed him in his hostility to civil and ecclesiastical tyranny which ever after marked his conduct. Selden was next to shine in the character of an advocate for constitutional liberty, with which his name is now so closely allied. The parliament which James's necessities had obliged him to convocate in 1625, was soon at issue with him on the point of their powers and privileges, all of which the king asserted to have been grants from his predecessors and himself, while they maintained them to be an inheritance from their ancestors. Selden being referred to by the parliament as the ablest antiquarian of his time, for information relative to the ancient privileges of that body, spoke so freely before them against the practices of the court, and was so instrumental in drawing up their spirited protestations, that he was selected as one of the victims to the royal resentment, and committed to custody. His imprisonment was not rigorous, and he was soon discharged upon his own petition. Refusing now his antiquarian studies, he edited, in 1723, the historical work of Edadm, a monk of Canterbury, with learned notes relative to the laws and customs established by William the Conqueror. In the following year he was elected to the new parliament, as one of the representatives for Lancaster, but nothing occurred to call forth his exertions during that session. He was again a member in the two first parliaments of king Charles, in the second of which he was appointed to support some articles of impeachment of the duke of Buckingham. He afterwards took up the cause of sir Edward Hampden, who had been imprifoned for refusing to contribute to a forced loan; and in 1628 he was the person whom the house of commons employed to produce matter of record to justify its resolutions in favour of the subject's right to his liberty and property. These useful and very honourable labours did not fit entirely engross his attention, but that he found time, in 1629, to draw up his learned treatise, entitled "Marmora Arundeliana," the occasion of which was the importation by the earl of Arundel of some very ancient Greek marble columns. In this work he collected the evidences of great value in the study of history and chronology. This was another obligation conferred upon Selden, in the learned world, which was received with due gratitude.

On the dissolution of the parliament, on account of its vicious proceedings against the measures of the court, Sel-
Selden was one of the eight members of the house of commons who were thrown into the prison of the Tower, on a charge of sedition. Their application to be released on bail was only assented to by the judges, on condition of giving security for future good behaviour, which they refused to do, as repugnant to the dignity of parliament, and the rights of Englishmen. Being brought up by virtue of the habeas corpus act to Westminster-hall, the condition was again proposed, and again rejected, and both parties seemed to part in their determination: of course the term of imprisonment was indefinitely protracted. Its rigour was, however, softened, and shortly after became very lenient. Selden being removed, first to the Marshallea prison, and then to the Greenhouse, was at length ordered to go at large on bail, as were the others likewise, till the beginning of 1644, when bail was no longer required, and they were fully liberated. Their firmness was much applauded by the parliament party, and Selden was distinguished among them as being their spokesman, when the point was argued before the judges. During the imprisonment of Selden, his mind was not inactive; his studies were turned to Jewish history and antiquities, and the first fruits of them were shewn in a work entitled "De succedalionibus in bona defuncti ad leges Ebraeorum," which was published in 1631, and reprinted in 1636, with the addition of a treatise "De succedionibus Pontificatum Ebraorum." Selden had long employed his great talents in a work which was intended to allert and justify the maritime prerogatives of this country, in opposition to the principles advanced by Grotius in his work entitled "Mare Liberum." Selden's treatise was, after it had long lain on the shelf in MS., read and approved by King James: and the subject, in 1635, having become very interesting in consequence of some disputes with the Dutch, his majesty commanded its publication. It was therefore fitted by him for the press, and appeared in that year under the title of "Mare Clamium seu Dominio Maris." In this performance, the author first attempts to prove, by reasoning and example, that the sea is capable of dominion: and then to establish historically the British right over the circumjacent, or, as they have been denominated by others, the narrow seas. (See Campbell's Lives of the Admirals, vols. i. ii.) This author, speaking of Mr. Selden and his Mare Clamium, says in which, "he has effectually demonstrated, from the principles of the law of nature and nations, that a dominion over the sea may be acquired, and from the most authentic histories, that such a dominion has been claimed and enjoyed by several nations, and submitted to by others for their common benefit: that this was, in fact, the case of the inhabitants of this island, who, at all times, and under every kind of government, had claimed, exercised, and constantly enjoyed such a dominion, which had been confirmed by their neighbours frequently, and in the most solemn manner. All which, with learning, industry, and judgment superior to praise, this great man hath fully and unquestionably made out to the satisfaction of foreigners, as it is the design of this work to impress the same sentiment on the minds of all sensible Britons, viz. "that they have an hereditary, uninterrupted right to the sovereignty of their seas, conveyed to them from their earliest ancestors, in trust for their latest posterity."

Selden's work was, in truth, acceptable to all parties, and the king in council ordered copies of it to be kept in the council-chest, the court of exchequer, and the court of admiralty, as faithful and strong evidence to the dominion of the British seas. Several following years of Selden's life seem to have been chiefly occupied in Hebrew studies, of which one of the principal products appeared in 1640, under the title "De Jure Naturali et Gentium juxta disciplinam Ebraorum:" Lib. septem. This work is a copious digest of Jewish laws and institutions, as well from the rabbinical writers, as from the writings of the Old Testament, which is generally esteemed a valuable repertory of all the matter afforded by history or tradition relative to the subject.

This year, 1640, the long parliament met, and Selden was chosen one of the representatives for the university of Oxford. His name appears in several committees appointed for the correcting of the abuses, and restraining the oppressions of the reign, which parliament was, at this period, resolved to pursue. One of its strong measures, viz. the imprisonment of Lord Strafford, he did not concur in, not considering that this measure was warranted by the law of the land. Nor did he seem willing to proceed further in the reformation of religion, than to check the usurpation of ecclesiastical power, to which he was a most decided enemy; and he had no wish whatever to abrogate the episcopal form of church government, which he preferred to the presbyterian. So well affected was he, upon the whole, to the exiling constitution in church and state, that after the king had withdrawn to York, there was a design of appointing him keeper of the great seal. When the differences between the king and parliament were manifestly tending to an open rupture, Selden opposed the attempts of both parties to gain possession of the power of the sword, hoping that the strong arm of the law might prove sufficient to settle the contest, and when his efforts had proved fruitless, he withdrew, as much as he was able, from public business. He remained, however, in parliament, and was one of the yönod which met at Westminster for the establishment of church government. In 1643 he was appointed by the house of commons keeper of the records in the Tower, and in the next year he subscribed the Solemn League and Covenant. It is mentioned to his honour, that he constantly employed his influence, in these contentious times, for the service and protection of learning and learned men; and the university of Oxford, on different occasions, expressed its gratitude for the good offices which he performed for it in times of its distress. He likewise befriended the ladder university, in which he was regarded with so much veneration, that he was elected to the mastership of Trinity-hall, though he thought it right to decline the office. His learned labours were still unimpaired, and new works were occasionally flowing from his pen. Of these, the most considerable were, "Eutychii Egerius Orientalis Ecclefsiae leges," translated from the Arabic; "De Antiqua Civili Veterum Ecclesiae"; "Uxor Ebraica," which contained an account of all the Jewish rites and institutions relative to marriage; an edition of the ancient work entitled "Fleta;" "De Synedriis Veterum Ebraorum," being a copious account of the juridical courts of the Jews. His concluding work was "Vindictae de Scriptione Mari Chaua," the object of which was to controvert a malignant imputation of an English author, that he had composed his Mare Clamium in order to please King Charles, and obtain his liberation from imprisonment. Selden died in November 1654, having completed his seventieth year. He was interred with great solemnity in the Temple church, and on this occasion the learned Usher pronounced a funeral discourse. Selden was always in affluent circumstences, and had intended, at his death, to bequeath his valuable library and museum to the university of Oxford, but owing to some offence given to him, he left it to his executors, who, however, restored them to their first destination, and they now make part of the Bodleian library. After his death, his manuscripts printed a collection of Selden's sayings, entitled "Table Talk,"
"Selena," in Geography, a river which rises in Chalcedony, and traversing the countries of Ruffia, runs into the Balkan lake, 36 miles W. N. W. of Varchesul Ursinz.

SELENGIN, a town of Ruffia, in the government of Irkutsk, at the confluence of the Selenga and Chalok. It was made an o(trog in the year 1666, and about 22 years afterwards, the fort, which is now standing, was built, and to this the place owes its prosperity. The town lies parallel to the river, and contains two churches, and about 150 houses, inclosed within the fortifications. This is defended by five pieces of brass cannon, and many iron guns; and the garrison consists of a regiment of fielders. The inhabitants are nicknamed "Peromik," from the great quantities of sand found in these parts. The whole adjacent country is mountainous and barren, but a few miles below there is a good arable land. The country about Selenginsk yields a great quantity of rhubarb, incomparably as much as the Siberr Want exported from Ruffia grows in these parts; 54 miles. S. E. of Irkutsk. N. lat. 51°. E. long. 166° 44'.

SELENIACON, a mine for a kind of smelted Form for the epitypus.

SELENITE, in Mineralogy, crystallized gypsum. See Gypsum, and Sulphate of Lime.

SELENIZ, in Geography, a mountain of Carnithia; 10 miles S. of Clagenfurt.

SELENOGRAPHY, formed from σέλες, moon, and γραφή, description, a branch of cosmography, which describes the moon, and all the parts and appearances of it, as geography does those of the earth.

Since the invention of the telescope, selenography is very much improved.

We have now distinct names for most of the regions, mountains, &c. visible in the moon's body. The first who attempted, but in a very rude manner, to make a map of the moon's surface, was Riccioli. Hevelius, a celebrated astronomer, who was a burgess-mater of Dantzig, and who published his selenography, represented the appearance of the moon in its different phases from the new to the full, and from the full to the new, and named the several places of the moon from those of the earth, which figures Mayer prefers; but Langenus and Riccioli named them afterwards, from the names of the celebrated astronomers and philosophers, assigning the largest spots to those of the most celebrated characters, which distinction is now generally followed. Thus, what the one calls mons Porphyrites, the other calls Arcturus. What the one calls Alba, Sinai, Aiters, Acanthus, Sec. the other calls Copernicus, Poedonius, Tyche, Gallenus, &c. A map of the moon, as it appears when full, drawn by Cathini, who published a work entitled...
entitled "Instructiones Selene". The late Mr. Rulicke, a painter of eminence, made excellent drawings of the moon; but the most accurate and complete that have yet been published, are those of the celebrated Schroeter, who has given highly magnified views of most parts of the moon's surface. Dr. Brewer, in his improved edition of Ter- 
gul's Astronomy, has given several tables of the lunar spots. The first of these tables is formed from the observations of Lambert, and contains the longitude and latitude of 207 spots, with the names given them by Rulicke and Hevelius, together with remarks on their position, appearance, and structure. The second table contains the longitude and latitude of 89 lunar spots, as determined by Tobias Mayer, with general remarks. This third table exhibits the new names which have been given to the anonymous lunar spots by J. Schroeter, with their positions, as determined by the editor, from a comparison of Schroeter's plates with Mayer's engraving of the moon, and his table of the lunar spots. Our limits will not allow of our insertion of either of these tables, and they are incapable of abridgment.

SELENTI, in Geography, a town of Aasian Turkey, in Caramania, at the mouth of the river Selenti, which here runs into the Mediterranean; 45 miles E. of Alanieh. N. lat. 30° 32'. E. long. 29° 18'.

SELENS, one of the smaller Shetland islands. N. lat. 60° 48'. W. long. 1° 22'.

SELESTRIA, a town of Aasian Turkey, in Caramania; 50 miles S.W. of Tarsus.

SELETZKAIA, a town of Rullia, in the government of Archangel; 80 miles S. of Archangel.

SELEUCIA, in Ancient Geography, a famous city of Aas, built by Seleucus, one of Alexander's generals, and situated on the western bank of the Tigris, about 45 miles N. of ancient Babylon, was the capital of the Macedonian conquests in Upper Aas, and is said to have been the first and principal cause of the destruction of Babylon. Pliny reports, that the intention of the first of the Seleucids was to raise, in opposition to Babylon, a Greek city, with the privilege of being free. The ramparts and telle of this Greek city are said to be nearly opposite to the ruins of Ctephion (which fee); and in process of time Seleucia and Ctephion became united and identified, under the name of Al Modain (which fee), or the two cities. For the precise situation of Babylon, Seleucia, Ctephion, Modain, and Baghdad, cities often confounded with each other, we refer with Gibson, to an excellent geographical tract of M. d'Anville, in Mem. de l'Académie, tom. xxx. Many ages after the fall of the Macedonian empire, Seleucia retained the genuine characters of a Grecian colony, arts, military virtue, and the love of freedom. The independent republic was governed by a senate of 300 nobles; the population consisted of 600,000 citizens; the walls were strong; and as long as concord prevailed among the several orders of the state, they viewed with contempt the power of the Par- thians; but the madness of faction was sometimes provoked to implore the dangerous aid of the common enemy, who was poaching almost at the gates of the colony. The Par- thian monarchs, like the Mogul sovereigns of Hindoostan, delighted in the pastoral life of their Scythian ancients; and the imperial camp was frequently pitched in the plain of Ctephion, on the eastern bank of the Tigris, at the distance of only three miles from Seleucia. (See Strabo, lib. xiv. p. 743.) By the influx of the innumerable at- tendants on luxury and despotism, who retired to the court, the little village of Ctephion infenibly swelled into a great city. Under the reign of Marcus, A.D. 165, the Roman generals penetrated as far as Ctephion and Se- leucia. They were received as friends by the Greek colony; they attacked as enemies the seat of the Parthian kings; and yet both experienced the same fate. The fall and conflagration of Seleucia, with the massacre of 300,000 of the inhabitants, tarnished the glory of the Roman triumph; though it has been alleged in their favour, that the citizens of Seleucia had first violated their faith. Seleucia, already exhausted by the neighbourhood of a too powerful rival, sunk under the fatal blow; but Ctephion, in about 33 years, had sufficiently recovered its strength to maintain an obstinate siege against the emperor Severus.

Browne (Travels in Africa, p. 91.) identifies Seleucia with Suades, the port of Antioch, about four hours dis- tant from it. Its former possessors, he says, took immense pains to render it convenient for traffic; but it is now rendered useless, by the negligence of its present masters. A large gate, says this traveller, yet remains entire; it ap- proaches to the Doric order. The rock near it has been excavated into various apartments. A port exists of the thick and substantial wall which defended Seleucia towards the sea. The port must have been commodious and secure, though small, as it was formed by a mole of very large stones. Although it be at present dry, the sand in the bottom appears no higher than the surface of the sea. A little to the north is a remarkable passage, cut in the rock, leading, by a gentle descent, from the summit of the moun- tain towards the water. It is about 600 common paces long, from 50 to 50 feet high, and above 20 broad. In the middle of it is a covered way, arched through the rock, but both the ends are open. A channel for water runs along the fide, conveying the pure element down from the mountain to Seleucia. The whole rock above is full of artificial cavities, formed for some purpose now unknown. A Greek inscription of five lines is visible on the S. fide of the cavern. Towards the sea are some catacombs, ornamented with pilasters, cornices, and mouldings.

Jackson, in his "Journey from India," considers Bagdad as the fite of the ancient Seleucia, and he fays that feveral of the coins of Seleucia are found in Bagdad. The gold coin is worth about two guineas; it bears as strong an impression of the head as the ancient Roman coins, but has a long beard.

SELEUCIA, a town of Aas Minor, which was anciently in Cicia; but in the 4th century of the Christian era, the province of Hauria was made to constitute a part of Cicia; and this city became the metropolis of the pro- vince. The Notitia of Hierocles represents Seleucia as founded by Seleucus Nicanor, and as being one of the largest and richest towns of the East. The river Calycadnus was navigable near this city, and facilitated the commerce of the country. In the year 116, Seleucia threw off the Roman yoke; but Trajan sent hither a body of troops in the beginning of the year 117, who reduced it to subjec- tion. However it again recovered its liberty, as we learn from a medal of Gordian and another of Philip, on which it is denominated eclethera, or free.

SELEUCIA, a large town of the Perible, in the territory of Elymais, on the river Edyphaste, according to Strabo. It was also named Solae.—Alfo, a town of Aas, in Pi- lidia, according to the Notitia of Hierocles. Appian re- lates that it was one of the nine towns built by Seleucus Nicanor, who gave it his own name.—Alfo, the name given to the town of Trallus, in Lydia. Pliny.—Alfo, an episcop- eal town of Aas, in Pamphylia.

SELEUCIA PIERIA, a town of Aas, in Syria, situated on the coast of the Mediterranean sea, N.W. of the river Orontes.
Seleucus, and near it, and S.W. of Antioch. According to Pliny, it was a free city.

Seleucia, the name which Seleucus gave to a town of Gadara, situated to the E. and beyond the sea of Tiberias. — Also, a town of Judea, in the half tribe of Manasseh, on the other side of Jordan.

SELEUCIANS, SELEUCIUS, in Eusebius' History, a foot of ancient heretics, called all Hellenists.

Seleucus and Hermon taught, that God was corporeal; that the elementary matter was material with him; and that the human soul was formed by the angels of fire and air. They also denied, that Jesus Christ sat at the right hand of God; asserting that he had quitted the right, and had removed his throne into the sun.

SELEUCIDES, in Chronology: era of the Seleucides, or the Syro-Macedonian era, is a computation of time, commencing from the establishment of the Seleucides, a race of Greek kings, who reigned as successors of Alexander the Great, in Syria, as the Ptolemies did in Egypt.

This era we find expressed in the book of Maccabees, and on a great number of Greek medals struck by the cities of Syria, &c.

The rabbins and Jews call it the era of contrariety, because, being then subject to the kings of Syria, they were obliged to follow their method of computing all contracts.

The Arabs call it terbiik dikarmin, era of two horns, which some say signifies the era of Alexander the Great; because that prince bore two rams' horns on medals, in imitation of Jupiter Ammon, whose horn he would needs be; but others understand it much better of the two kingdoms of Syria and Egypt, which were now cloven or divided, and of one single empire parted into two monarchies.

The grand point is to know the year in which the separation was made; or, which is the same thing, when Seleucus Nicanor, one of Alexander's captains, and the first of the Seleucides, established his throne in Syria.

Without detailing the various sentiments of various authors, it may suffice to observe, that, according to the best accounts, the first year of this era falls in the year 311 or 312 before Christ, which was twelve years after Alexander's death. See Epoch.

Seleucia, in Ancient Geography, a country of Asia, in Syria, which took its name from the city of Seleucia. It was also called Tetrapolis, on account of four celebrated towns contained in it, according to Strabo. This country extended southwards as far as Phoenicia.

Seleuco Beth, a town of Asia, in Syria; situated towards the river Orontes, W. of mount Belus, about N. lat. 35° 40'.

Seleucus, a town of Asia, in Syria, in the vicinity of Apamea.

Seleucus I, in Biography, surnamed Nicator, king of Syria, was son of a Macedonian named Antiochus, a captain under king Philip. Seleucus entered, when young, into the service of Alexander the Great, by whom he was raised to an important command, and, after the death of that conqueror, he was placed by Perdiccas at the head of the cavalry. On the division of the provinces made by Antipater, the government of that of Babylon was entrusted to Seleucus, in which situation he opposed the advance of Eumenes against Antigonus. When, however, that leader, after the death of Eumenes, marched to Babylon, he found such a hostile disposition in the people, that the latter thought it necessary to take refuge with Ptolemy, king of Egypt. Upon the defeat of Demetrius, the son of Antigonus, by Ptolemy, Seleucus recovered his government of Babylon, and added to it Media and Susiana, which he wrested from Nicanor, the governor, his Antigonus. Defeating afterwards Seleucus from Babylon, he returned, and durably established his authority. He then prepared with a powerful army to the East, conquered and took Nicator, and marching through Persea, Bactria, and Hyrcania, invaded those countries, and the other provinces which had formed part of Alexander's empire on the side the Indus. From his important victories he assumed the name of Nicator; and the other Macedonians, who had shared the title of kings in the year 306 B.C., he followed to example. The historical era of the Seleucides, however, commenced six years earlier than this, even in the year 312 B.C., when he recovered Babylon. He now marched to regain the districts of India Proper, conquered by Alexander, but he was opposed by to large a force, that he thought it expedient to leave him in possession, on condition of being supplied by him with 500 elephants. One reason of his making this treaty was the necessity of joining with Callander, Lyphimachus, and Ptolemy, in order to reduce the overgrown power of Antigonus, which menaced the independence of them all. This purpose was effected by the great battle of Ipsus, in which Antigonus lost his life.

His dominions were shared by the four confederate monarchs, previously to which Seleucus had terzed the province of Upper Syria, and founded the famous city of Antioch. He also built other cities in the same province, to which he gave family names, as Seleucia, from himself; Apamea, from his wife; and Laodicea, from his mother; and as he was a great founder of cities in all his territories, he filled Asia with places bearing the names of his family.

After this, he built Seleucia on the Tigris, which became one of the most famous cities in the East, and was the caesare of the defterion and ruin of Babylon. In many of his new cities he settled colonies of the Jews, whom he endowed with ample privileges, and to him was owing their establishment in the African provinces to the west of the Euphrates. When he was advanced in years, he is said to have resigned to his son Antiochus, his wife Stratonice, and with her he resigned to the prince all the provinces of Upper Asia. Seleucus and Lyphimachus were now the only survivors of Alexander's captains, and a domellic tragedy having taken place in the family of the latter, some of its members took refuge in the court of Seleucus, whom they urged to make war upon Lyphimachus. He accordingly invaded, with a very powerful army, the territories of Lyphimachus in Asia Minor. That prince crossed the Heliopolis to protect them, and a most bloody battle was fought between the rivals in Phrygia, in which Lyphimachus was slain, in the year B.C. 281. Seleucus took possession of his dominions, but did not long enjoy the fruits of victory, for as he was marching into Macedonia, seven months after, he was treacherously murdered by Ptolemy Ceraunus, one of the fugitives from the court of Lyphimachus. Seleucus died in the 43d year from the death of Alexander, and in the 71st year of his age. He was a prince of splendid qualities, mild and equitable in his government, and a patron of letters and learned men. Univer. Hill.

Seleucus II., surnamed Callinicus, succeeded his father Antiochus Theos, in the year 246 B.C. His mother Laodice having cruelly put to death Berenice, the second wife of Antiochus, and her son, Ptolemy Euergetes, the brother of Berenice, marched into Syria, led by Laodice, and took possession of great part of the Syrian empire. After his return to Egypt, Seleucus recovered part of his lost dominions; but being defeated by Ptolemy, he applied for aid to his brother. This union brought about a truce with Ptolemy, but the two brothers then quarrelled, and Seleucus was defeated.
feated by Antiochus in a great battle at Ancyra. The war between them was carried on with great inveteracy, while the empire was invaded on one side by Eumenes and Attalus, kings of Pergamus; and on the other, Arfas, founder of the Parthian monarchy, was making a progress in Hyrcania.

Seleucus was at length delivered from the hostility of his brother, who was detained captive in Egypt, whether he had fled, and he then turned his arms against Arfas, but in a great battle that was fought he was defeated and taken prisoner. He died in Parthia, in consequence of a fall from his horse, in the year 226 B.C.

Seleucus III., furnamed Cerasanus, eldest son of the preceding, succeeded him on the throne. He was a weak and incapacious prince, and after a reign of three years he was poisoned by two of his chief officers, while engaged in an expedition against Attalus.

Seleucus IV., furnamed Philopator, succeeded his father Antiochus the Great, in the year 187 B.C. He was favourable to the Jews during the greatest part of his reign, but near the close of it he employed Heliodorus to carry off the treasuries of the temple at Jerusalem, as is mentioned in the second book of Maccabees. He was afterwards poisoned by Heliodorus, who usurped his throne. This event occurred in the year 176 B.C. There were several other kings of the name of Seleucus, but they did nothing worthy of notice.

Selezneva, in Geography, a town of Russia, in the government of Irkutsk, on the Ilim; 28 miles S. of Ulimsk.

Self-Abuse. See Self-Pollution.

Self-Defence, in Law. With regard to the defence of one’s self, or the mutual and reciprocal defence of such as stand in the relations of husband and wife, parent and child, master and servant, it is observed, that in these cases, if the party himself, or any of these his relations, be forcibly attacked in his person or property, it is lawful for him to repel force by force; and the breach of the peace, which happens, is chargeable upon him only who began the affray.

Self-Defence, therefore, as it is justly called the primary law of nature, so it is not, nor can it be in fact, taken away by the law of society.

In the English law, particularly, it is held an excuse for breaches of the peace, nay, even for homicide itself; but care must be taken, that the reluctance does not exceed the bounds of mere defence and prevention, for then the defender would himself become an aggressor. Blackoff. Com. vol. iii.

Self-Examination. See Examination.

Self-Heal, in Botany. See Prunella.

Self-Heal, in the Materia Medica. The greater self-heal, with an undivided leaf, grows wild in pasture grounds, and flowers in June and July. It has been reckoned among the vulnerary plants, and is accounted serviceable in all sorts of wounds and putrid ulcers. It is refreshing, and good for inward bleedings, and making bloody water; and has been much used in gargles, for ulcers in the mouth, throat, or gums, either in juice, or in a strong decoction.

Its virtues do not appear to be very great; its astringent or bitterish tincture is more sensible in the flowery tops than in the leaves; though the latter are generally directed for medical use.

Self-heal is also a name given to faneile.

Self-Love, in Ethics, is that principle, or passion, which leads a man to defire and pursue his own happiness. It is contradistinguished from benevolence. See Mental Philosophy.

Self-Opens, a term used by the miners in the north of England to express certain natural cavities, or chambers, which are frequently met with, some near the surface, some at very great depths, some small, and others very large.

These are of various figures, and often run into strange shapes. Dr. Lister, in accounting for the origin of earthquakes, supposes the whole crust of the earth to be more or less hollowed in this manner; which he also argues for, from the phenomena of waters which arise in large quantities from the fides of mountains, and must have communication with these self-opens, and supplies from them.

These natural hollows the doctor thinks to be the means of continuing, and propagating earthquakes; the first cause of which he attributes to the breaks of the pyrites, which he also says is the pyrites itself tota subflantia. This he observes takes fire of itself, on being exposed to the air in our flight, and may do so, from various other causes underground. The sulphurous smell of the air and waters before and after earthquakes, in the places where they happen, seems a proof that they owe their origin to some such sulphurous matter as thus flows; and the rolling and defulory noise of an earthquake seems also to shew that it is not expanded every way at once, but is propagated through a chain of these subterranean hollows.

It is not necessary that we should suppose a continued chain of them, from the place where the earthquake begins to be felt to the spot where it ends; but if there are many of them irregularly scattered about the earth, the force of the explosion will be sufficient to burst through the solid parts between, and open a passage from one to the other, which may continue open no longer than the force continues, and after the shock is over, close together again, so as to leave no trace where it was.

Our miners not only find the natural caverns, but they also find them often full of what they call “fire domps,” which are inflammable vapours, of the very nature of those which he supposes to occasion earthquakes; and when fired make the same explosions, and cause the same effects in a certain degree. These sometimes require a candle, or other actual fire, to come in contact, in order to kindle them; but sometimes they are found kindled of themselves, and glading on the surface of the waters, in the bottoms of the pits, or at the suffures of the coal. Phil. Trans. No. 157.

Selga, or Selge, in Ancient Geography, a considerable and well-peopled town of Asia, in Phidias. It was colonized from Lacedaemon.

Selgenfelt, in Geography, a town of Prussia, in the circle of Natangen; 3 miles S. of Konigberg.

Seleuthal, a town of Germany, in the circle of the Lower Rhine; 3 miles N.W. of Burken.

Selgoe, in Ancient Geography, a people of Britain, fented to the west of the Gadeni, in the countries now called Elkhdale, Annandale, and Nithdale, lying along the shores of the Solway Frith, which is believed to have derived its name from that of this ancient Britton nation. Mr. Baxter supposes that the name of these people was compounded of the two British words Sel Gui, which signify salt waves, alluding to the Solway Frith, with which the coasts of their country were washed. But Dr. Macpherson thinks it more probable, that the name was derived from the British word Sealg, which literally signifies hunting, and metaphorically theft. The Selgoe became first acquainted with the Romans, when Agricola marched his army through their country into Caledonia, in the second or third year of his government in Britain; at which time they made their submission to that victorious general. From that period they were alternately under the dominion of the Romans, or enjoyed freedom, as that people extended or contracted the limits of their empire in this island. The Romans had several stations and camps in the country of
of the Seljuks, of which some vestiges are still remaining.

SELY, or SELICO, in Geography, a town of Africa, on the north side of the Gambia, in Mandingo.

SELIGNASTRT, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, formerly imperial, on the Main; 12 miles E.S.E. of Frankfort on the Main. N. lat. 49° 59'. E. long. 8° 46'.

SELIENTHAL, a town of Germany, in the county of Henneberg; 3 miles N. of Smalkalden.

SELER, a lake of Ruilla, in the government of Tver; 80 miles W.N.W. of Tver.

SELIGONION, in Botany, a name by which some authors have called pinyon.

SELM, in Ancient Geography, a town of Palatine, in the tribe of Judah, on the southern side along the frontiers of Edom, according to Joshua. This was afterwards comprehended in the tribe of Simeon. See SALEM.

SELM I., in Biography, a Turkish emperor, was the second son of Bajazet II. In 1541, being governor of Trebizond, he rebelled against his father, and marched to Constantinople, where he was defeated and obliged to seek his safety in a precipitate flight. The janissaries, however, favouring him, Bajazet was forced to resign his crown to him, and soon after died, probably by poison. Selim ascended the throne in 1512, being at that time about 46 years of age. His first step was to proceed against his eldest brother Achmet, who was at the head of some troops in Afa. He defeated and put him to death, which was soon after the fate of another brother. Selim then invaded Persia with a numerous army, and defeated Shah Ismael in a great battle, entered the city of Tauris. He afterwards annexed Diarbekir to the Turkish empire; and one of his officers recovered Dabnia, which had been conquered by the Hungarians. In 1515 Selim turned his arms against the sultan of Egypt, and obtained a victory over him near Aleppo, the sultan being slain in the engagement. Aleppo and Damascus submitted to Selim after this event, and he prepared to march into Egypt. Arriving in the neighbourhood of Cairo, a very bloody battle ensued between him and Tuman Bev, which terminated in a total defeat of the Mamelukes. Cairo, after a desperate refitishment, was taken, and all Egypt submitted. Selim returned to Constantinople, and, elated with his success, made a vow that he would not lay down his arms till he had put an end to the Perilian empire. His career was, however, stopped by disease, which terminated in his death at a village in Thrace, in 1520. Selim was one of the most able and vigorous of the Ottoman sovereigns, and made greater additions to the Turkish empire than any one of his predecessors. He was, at the same time, unprincipled in his projects of ambition, and had all the ferocious cruelty of an eastern despot.

SELM II., Turkish emperor, son of Soliman I., succeeded his father in 1566. Being of an indolent disposition, and extremely intemperate, the actions of his reign are

tho' of his vices, and greed. Of these the principal was the capture of Cyprus, then belonging to the Venetians, which, after a vigorous resistance, was rendered to the European powers, who had combined for its recovery in the same year, the famous naval battle of Lepanto, which nearly ruined the Turkish marine. Nevertheless this success, the Venetians were obliged to make peace with the Turks in 1574, upon very disadvantageous terms. During the remainder of Selim's reign, the affairs of the Ottoman empire were prosperous. Selim died at the age of 52, probably of a remission. He had many good qualities, but was foppish and foppish.

SELEMABA, in Geography, a town of Hindooostan, in Bengal; 12 miles S.S.E. of Burdwan. N. lat. 24° 5'. E. long. 87° 48'.

SELEMBRIA. See SELIVRA.

SELIME, a village of Nubia, on the route of the Soudan caravans from Allnut to Darfur; 42 miles S. of Sheb.

SELEMPOUR, a town of Bengal; 24 miles N.W. of Burdwan. N. lat. 23° 23'. E. long. 87° 35'.

SELINOS, a town of Africa, in the kingdom of Galam; 15 miles S. of Galam.

SELINA, in Ancient Geography, Ilium-Adassa, or Ille of Serpents, an island of the Euxine sea, near the mouth of the Danube: called Paralithius, or Paralitium. Some authors have denominated it Melitha.

SELINAGUR, in Geography, a town of Hindooostan, in Oude, on the Ganges, opposite to Furruckabad.

SELENCOURT, a town of France, in the department of the Somme; 18 miles W. of Amiens.

SELINE, a river of Spilea, which runs N.W. into the Is, 7 miles S. of Breifian.

SELING, a town of China, of the second rank, in the province of Quang-Si. N. lat. 21° 55'. E. long. 106° 20'.

SELINGUE. See SELINGA.

SELINO, a province of the island of Crete, south of that of Kifamos, which takes its name from that of a small town, built on the south coast of the island, in the situation formerly occupied by Lissa or Lixus, a place of small importance, mentioned by Ptolemy. It is entirely mountainous, but very fertile. It furnishes a little silk, honey, wax, and a tolerably large quantity of fruits, such as cherries, apricots, peaches, pears, and oranges. Thus is the only province in which the chestnut-tree is cultivated, and it thrives well on the semitile hills and mountains of this country. The chestnuts are carried to Canea, Retimo, and Candia. A quantity is also annually exported to Syria. Oil, however, is the principal commodity of Selino; and it is reckoned better than any other in the island. The merchants of Canea generally establish their speculations in the quantity and quality of the oils of Selino. Wine, wheat, and barley, are not plentiful. The population of the Turks is estimated at a fourth or fifth of the inhabitants.

SELENUM, in Botany, an ancient generic name of Theophrastus and Dioscorides, whose Selenum is said to be derived from χέλυνος, χέλυνος, on account of its growing in mud, whence Homer's ἐλεφυτής στέφανος. Dr. Thunberg says that Selenum is derived from χέλυνος, the moon, because of the shape of its growing seeds; and that it is the foundation of many other compound names of umbelliferous plants among the Greeks, as χελυνία, χελυνίας, &c.—Linn. Gen. 153. Schreb. 184. Wildl. Sp. Pl. v. 1. 330. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 303. Ait. Hort. Kew. v. 2. 131. Pursh 127. Juss. 225. Lamierek II. l. 202. Garret. t. 21. —Class and order, Pec-
Selinum, in Ancient Geography, a town of Egypt, in the Thebaid, on the other side of the Nile, between Panum and Anten, according to the itinerary of Antonine.

SELINUS, or SELINUNTUM, a town of Sicily, south-east of Mazara, on the southern coast. It was founded by a colony from Hybla, another town of Sicily, 100 years before the destruction of that city by Gelon. In its vicinity were many palm-trees, where arose the epithet of palmata given to it by Virgil. It was destroyed, a little before Himera, by Hannibal, who took it by storm, and treated the inhabitants with great barbarity, massacring a great number, and carrying the rest into captivity. The inhabitants had conferred to the Olympian Jupiter a treasure, in which, among other rarities, was a statue of Bacchus, the face, hands, and feet of which were made of ivory. It appears to have been destroyed in the year of Rome.
In this case, the page contains a passage about the life of Alexander Selkirk, a Scottish sailor who lived on Robinson Crusoe Island for four years. The passage is a natural text representation of the content on the page.
fine poem by Mr. Cowper, with which all our readers are no doubt well acquainted. B I o g. B r i t.

SE L K I R K, in Geography, a royal borough town, and a parish, in the county of Selkirk, Scotland. It derived its name from the Celtic word Scheleckgreich, which signifies the kirk in the wood; expressing thus in one word the situation of the place itself, and the state of the surrounding country, which in former times was one continuous forest. From the circumstance of its being placed on the summit of a considerable eminence, Selkirk enjoys an extensive prospect in all directions, especially up and down the river Ettrick. The inhabitants boast greatly of the spirit displayed by their ancestors at the celebrated battle of Flodden. Of a hundred citizens of Selkirk, who followed the fortunes of their prince on that occasion, it appears that several survived the conflict, and even carried off some spoils and trophies. The English, in resentment, reduced their town to ashes. But, on the other hand, king James V. granted to them a thousand acres of the forest; the trees for rebuilding their houses; and the property as the reward of their heroism. These borough lands are now worth about 150l. per annum, and are divided into a great number of small properties; a circumstance which tends to damp that spirit for commerce and manufactures, by which the inhabitants of towns are in general dilugisified. On the day on which the magistrates annually survey this tract, a standard, taken from the English in the field of Flodden, is carried before the corporation of weavers, a member of which was the captor. It may be added, that the sword of William Brydon, the town clerk, who led the citizens to the battle, and who is said to have been knighted for his valour, is still in the possession of a citizen of Selkirk, his lineal descendant.

Selkirk has a weekly market held on Tuesday, and six annual fairs; two in March, and one in July, Augest, October, and December. As a royal borough, it unites with Lanark, Linlithgow, and Peebles, in sending one member to parliament. The corporation consists of two bailies, a dean of guild, treasurer, and ten counsellors, and polleys a revenue of about 300l. per annum, drawn from that portion of the borough lands which has not been alienated in fee to private individuals. The parish, which is about ten miles square in extent, lies partly in Selkirkshire and partly in Roxburghshire; and, according to the parliamentary returns of 1811, contains 440 houses, and a population of 2466 persons, of whom about 1000 are resident within the borough.

The principal object of interest in this vicinity is Newark castle, situated on a peninsula, formed by the stream of Yarrow, which has here cut its turbid course through a deep gulf of rugged rocks, enclosed in wood, and presenting a most "fantastically wild scene of grandeur and beauty." The castle is now in ruin, but enough of it yet remains to evince its ancient strength and importance. It is generally suppos'd to have been the birth-place of Mary Scott, the flower of Yarrow. Beauties of Scotland, vol. ii. Svo. 1805. Statistical Account of Scotland, by Sir John Sinclair, vol. ii. 1792.

S E L K I R K S H I R E, one of the southern counties of Scotland, is situated between 55° 22' and 55° 43' N. lat. and between 2° 50' and 3° 20' W. long. from the meridian of Greenwich. It is bounded on the W. by the county of Dumfries; on the E. by Mid-Lothian and Roxburghshire; on the S. by the county last mentioned; and on the N. by that of Peebles. Its greatest length, from the source of Ettrick water to the junction of Gala and Tweed, is 27 miles, and its greatest breadth from Borthwick brae to Glenfaxburn, about 17 miles. Taking, at a medium, 20 miles for its length, and 12 for its breadth, its contents may be calculated at about 240 square miles, or 153,600 acres. The proportion of arable land actually occupied in husbandry may be computed at about 6880 Scotch acres.

General Aspect of the County.—With the exception of a few vallies, the whole of Selkirkshire is mountainous, and presents elevations of considerable height, Mead, in the parish of Galafhie, being 1480 feet above the level of the sea. In the parish of Ettrick, the most remarkable hills are the Ward Law and Ettrick Penn: the former rises 1000 feet above the level of the sea, the latter 2200. In the parish of Yarrow, the hills are in general steep and towering; the most remarkable is thole called "Blackhouse heights." The highest point of elevation above the level of the sea measures 2370 feet. For the most part, the mountains exhibit a green appearance; though upon some few there is a considerable quantity of heath. Toward the source of the waters of this county, that is, on its western extremity, the hills are more green, and are covered with long coarse grasses. Towards their junction with the Tweed, they have a greater mixture of heath, and the grass is shorter. On the north side of the Tweed, some of the hills are covered with loose stones, but none of them are very rugged or barren of herbage, or interrupted by mosses. Bordering on Minichmoor, over which was the old road from Peebles to Selkirk, their aspect is bleak and barren, and forms a striking contrast with the green hills on the opposite sides of the Yarrow and the Tweed.

Rivers and Lakes.—The Tweed, Ettrick, and Yarrow, flow through this county. The Tweed enters it near the ancient seat of Elbank, and flows through it for nearly ten miles, along a well-cultivated and fertile but narrow valley. At the eastern corner of the county it receives the Gala, a small water, which rises in Mid-Lothian, and which forms the boundary of Selkirkshire for five miles. Yarrow water rises near the western extremity of the county, and flowing through the Loch of Lows, and St. Mary's Loch, augmented by many smaller waters, joins the Ettrick about a mile above Selkirk. From the nature of its source, lochs, and from the circumstance of its receiving in its course many additional streams from the hills, the Yarrow, in time of high winds and rain, is rapidly flooded, and rendered impalpable; but, from its rapid descent, it as rapidly subsides. The Ettrick also takes its rise in the western angle of the forest, and running in an almost parallel direction with the Yarrow, unites with it about a mile above; they fall into the Tweed three miles below Selkirk, after a course of 30 miles. These waters, as they pass through this county, form many beautiful windings. Near their source they are hemmed in on each side by high towering hills; but as they approach their confluence with the Tweed, the expanse between the hills becomes wider and more open; and they flow through fertile vallies, in a broader channel, with a lefs rapid stream. For a considerable way above their junction, they are finely fringed with natural and artificial wood; but the extensive forests which once beautified and adorned their banks, and from which the country obtained the appellation of Ettrick forst, are now almost entirely destroyed. Every stream abounds with trout; and for a considerable way up the Ettrick and Yarrow, salmon are caught in large quantities. Ale water takes its rise from the Kingmoor loch, but only runs in this county for a short way; in some places palling out of it into Tewitdale, and in others forming its boundary. Borthwick water also constitutes part of its boundary. The hills are every where intersected by small streams.
the medium of heat 43 degrees. This hill, as Wool may be taken as a pretty full the land of the county, as at eight miles above Selkirk, on the waters of the Ettrick and Yarrow. There are few places, even in the highest part of the country, so very mild in Langholm; though, in proportion as it rises, there is a greater quantity of rain. The hill becomes colder and more penetratively cool, and the rains more gently and feebly felt, and how lies deeper and colder. The rays of the sun, reflected by the surrounding mountains on some values 600 feet above the ocean, exist a degree of heat that brings the crop very quickly to maturity.

The number of springs that are obstructed in their course, forms marshes more or less deep and extensive. There are many morasses, some of them of an unknown depth; a good deal of marshy land; and several lakes. The moisture exhaled from the soil quantity of water collected in their, greatly increases the dampness of the atmosphere, and produces frequent mists and showers. Nor can this necessity be effectually obviated by the numerous drains which are daily making, though these may doubtfully contribute to moderate the climate. The general course of the weather and seasons is much the same as in Roxburghshire.

Selkirkshire.

Mineralogy.—There are no metals, coal, limestone, or free stone, in any part of this county. But there is abundance of whinstone and granite. Moles, formed of decayed wood and other vegetables, are made into peat for fuel. Some of them are of considerable extent and depth; and those towards the south-east, in the parishes of Selkirk, Roberson, and a corner of Yarrow and Altkirk, cover large beds of excellent shell-marl. In the rills by which some of them are fed, many small lakes are found; some of them overspread with a glorious substance, others incursored with matter very similar to that of which the shells are composed; others again with shells in every progressive state of formation; and a few with the animals alive, in shells completely formed, but of different degrees of consistence and hardness.

To account for this incrustation of shells with calcareous earth, in a county where no lime is known to exist, and to determine whether it comes from some rock as yet unexplored, from loose fragments or particles scattered among other fluctuations, and washed away by streams, or from pulverized shells, or from any other matter found in the neighbourhood, would require a scientific and accurate examination of the surrounding mountains, and the different strata of which they are formed. On the supposition of the incrustation proceeding from a rock, or detached pieces of lime, it may become a question how far this salubrity is necessary or useful to the animals in rearing their shells, and on the other supposition, of its being occasioned by pulverized shells, it is of equal importance to ascertain the materials from which these shells are constructed.

Agriculture.—The agriculture of such a county as this, cannot be a very interesting subject. In the lower parts of the county, the best practices in agriculture are successfully pursued, as in Roxburghshire and Berwickshire; but in the upper part of the county, or foreland, as it is called, where the arable land is not fenced off, and the disadvantages of an unfavourable soil and climate occur, little can be done. In this situation, the small portion of arable land on the skirts of the hills is chiefly cropped with oats, which are the grain best adapted to the nature of the climate, and the wants of its inhabitants, both as a part of their food, and for the support of their horses. In these situations, the principal improvement that can be adopted, consists in rendering the arable land suitable to the support of sheep, which form

D d 2
the great object of the farmer's attention. Accordingly, green crops, such as turnips and hay, &c. are raised on many of the farms, from which very great advantages are derived, being food to the sheep in storms. Little wheat is produced in the county. Both barley and bean or bigg are grown. The return from barley is, at an average, from seven to eleven-fold. The return from bean is nearly the same, but the weight and market price are greatly inferior. Artificial grasses are very generally found. Pea is less cultivated than formerly, the preference being given to turnips.

Line Stock.—Sheep are the staple animal of this county, and their number is estimated at 118,000. There are two sorts, viz. the original breed, which are black-faced, and the white-faced, which are generally of the Cheviot breed. The former, being about one-third of the whole number, are to be found in the upper or western part of the county, and the latter mostly in the lower districts of the shire. The different qualities and value of these two breeds should seem nearly balanced, for though, of late years, a preference has been given to the Cheviot sheep, on account of their superior fleece, and even the opinion of their being less hardy than the black-faced sheep has been disproved. Yet it is admitted that the white-faced lambs, when very young, are much barer in wool, and therefore less protected from the weather, than the black-faced; and in an inclement lambing season, nearly four times more of them die than of the black-faced kind. The mutton of the latter is likewise accounted more delicate. The practice of making ewe-milk cheese is nearly abandoned, from an opinion that it weakens the ewe. The few herds requisite for cultivating the arable district, are of the Lanarkshire and Northumberland breed. Swine are reared only by a few gentlemen for their tables, and by millers for the market. Vatt quantities of poultry are raised by the farmers, who fend cart-loads of eggs to Berwick, which are bought by "egglers," who sell them again for the London market.

Inclusions.—Inclusions are not very generally used, unless round gentlemen's feats, and on the farms in their own possession. The reader is referred to what is mentioned in the account of Roxburghshire, as to the kind of inclusions used.

Towns, Villages, Roads, Fairs, and Manufactures.—Selkirk is the capital of the county. (See SELKIRK.) Galashiels, so called from its being situated on the banks of the water Gala, is a thriving village. It has been long known for its manufactures of woollen cloth, which was at first coarse, and of a grey colour, and was called "Galashiels' grey;" but the cloth now manufactured are of various kinds and colours. In consequence of an act of parliament obtained in 1764, a road of twelve miles was made from Croflee toll-bar, on the confines of Mid-Lothian, through Selkirk, to Haremos toll-bar, with a branch of three miles to Galashiels. Part of the road from Kello to Peebles, of about six or seven miles long, also runs through this county from Galashiels' bridge to Buthope burn, beyond Hollis' toll-bar. The expense of these roads, and of a substantial bridge over the Tweed, was $5,000. There are two considerable fairs held at Selkirk; four leff fairs are likewise held there, and three at Galashiels for various purposes. The chief manufnctures are woollen cloth, stockings, tanned leather, and different implements of husbandry, or wood blocked out for making them.

Antiquities.—There are but few remains in this shire of British or Roman antiquities. There are the remains of some British strengths in the eastern division of the shire, which were erected upon heights, and were constructed generally in a form between the circular and the oval. There is also a Roman camp in the midst of several of these strengths, in the parish of Roberton. But the most remarkable remains of the Britons in this shire, is the "Catriall," or battle fence, consisting of a large folle, with a rampart on either side. Its length is 28 miles. This wall war-fence can only be referred, for its construction, to the romanized Britons, who, after the abdication of the Roman government, had this country to defend against the intrusion of the Saxons on the call, during the fifth century, the darkest period of our history. The modern antiquities of Selkirkshire conflict chiefly with ruined callies and moss-grown towers, erected, some of them, in the twelfth century, but the greater number of them in subflebute ages of foreign holllities or domestic feuds.

Historical Events.—Like other counties of Scotland, Selkirkshire has its share of family feuds, fanatical conflicts, wars, and battles, which would occupy too large a portion of our pages to recount. Selkirk became a royal burgh on an occasion that reflects high honour on the loyalty and spirit of this ancient town. When James IV. was marching forward to his fate at Flodden field, a hundred townsmen joined him under the town clerk. They fought stoutly; they almost all fell in the field rather than flee. On the 10th of September 1545, was fought the decisive battle of Philiphaugh. This is one of the last civil conflicts which itained the forests of Selkirkshire with human gore.

Eminent Natives.—This shire puts forth a fair claim to rank in its annals many characters of celebrity. The Doughills, the Scotts, the Murrays, and Patrick Ruthven, who had learned the art of war under the great Gustavus, and was created lord Etterick, are names conspicuous in history. Andrew Pringle, who was placed in the female house on the 14th of June 1759, by the title of lord Alemoor, as a lawyer was distinguished by his model and eloquence, and as a judge for his dignity and knowledge. It produced an eminent soldier in colonel William Rufiel, of Affylfit, who distinguished himself amongst the warriors of India. Mary Scott, the flower of Tarrow, is still remembered by the "cold-blooded murderers of Etterick forest." She is celebrated by Ramsay in amorous rant:—

"With success crown'd, I'll not envy
The folks, who dwell above the skye;
When Mary Scott's become my marrow,
We'll make a paradise on Yarrow."

Population.—This county has seven parishes, and a portion of two others, containing a population of 5889 persons. Selkirkshire, as a county, sends one representative to the united parliament. Beauties of Scotland, vol. ii. Svo. 1805. Chalmers' Caledonia, vol. ii. 4to. 1810.

SELL, in Building, is of two kinds, viz. ground-fell, which denotes the lowest piece of timber in a timber building, and that on which the whole superstructure is raised. See Ground-Plates.

SELL, Window, called also window-fell, is the bottom piece in a window-frame.

SELL-Bed, in Joining, a term used in some parts of England to express some particularly rich parts of the vein of ore.

In Cornwall they sometimes find the tin-ore so pure, that it requires only bruising to dress it, without the washing and separation by grates, launders, and the like means; they call these collections of ore the fell-beds of tin; and it is observed, that these never have any filings illuing from them, as the other lands have. Philos. Transf. No 60.

SELA, in Ancient Geography, a river of Messiah, N. of the isle of Oenussa.

SELLA, in Geography, a town of Africa, in Benguela.
SELLART, in Geography, a town of Naples, in Calabria; 16 miles of Bova.

SELLASIA, in Ancient Geography, a town of Latium, S.W. of Olympia, on the river Ganus. It was destroyed in the time of Paulus, when C. Quintus Flaminius pulled into the Peloponnessus in 193 B.C., to deliver Greece from the yoke of the tyrants who oppressed it. It is a junction near this place; but a little after the time, it was destroyed by Arratus, the conqueror of the Lacedaemonians. Towards the N.W. was a mount, which bore the name of Mount Othrys. The latter battle of Sellaia, in the year 122 B.C., was fought between this town and Evia. At this time, a band of Macedonians, was led by the king of Macedonia, Rhysson, king of Sparta, commanded the Lacedaemonians. This bulk, having been captured, returned to Egypt by way of Ptolemy Philadelphus.

SELLAY, in Geography, a small island of the Hibernian, in the district of Harris and county of Inverness, Scotland. It is about a mile in circumference, and yields excellent pasture for sheep.

SELLÉ, a town of France, in the department of the Canton; 6 miles S. of Avrilée. — Alus, a river of France, which runs into the Scheldt, about six miles above Valenciennes.

SELLÈRE-BLOT, a town of France, in the department of the Loiret; 7 miles N.E. of Montargis.

SELLÈRE, a town of Hindostan, in Guzerat; 25 miles S.E. of Mahommedabad.

SELLÉ, a town of Persia, in the province of Isfak; 110 miles E. of Ipahan.

SELLÈS, in Ancient Geography, a river of the Peloponnesus, in Aegypt. Strabo places the village Ephyrus on the bank of this river.—Alus, a river of Ætolis, in Aegypt, according to Strabo.—Alus, a river of Aisia Minor, in the Troade, which watered the town of Arbus, according to Homer, cited by Strabo.

SELLÈMPOUR, in Geography, a town of Hindostan, in Oude; 42 miles S.E. of Goorapour. N. lat. 26° 35' E. long. 84° 12'.
of disadvantage arising from suffering mere men of the law to intermeddle in the purchases of lands, before the preliminaries of agreement have been adj usted, that no apology is due to the profession for the observations which he has thrown out in the above cases.

But in purchasing by private contract, the particulars which may be required to be furnished by a seller, are, he says, the quantities of the several pieces of land on sale, together with the maps, or rough draughts of the same; the tenure under which they are held; some assurance as to the title of the seller, and his right of alienation; the tenancy under which the several farms are let; and, if on lives, the ages of the nominees; if for a term of years, the number unexpired; if at will, the notices (if any) which the tenants have had; and an abstract of the covenants under which they are let; particularly those which relate to taxes and repairs, to the expenditure of produce, to the ploughing of grass-lands, &c.: the existing rents and profits receivable; whether for tenant lands, appurtenances, or abstract rights; with the estimated value of the demeine, and the wood-lands, in hand; together with the estimated value of the timber growing upon the estate on sale; as well as of the minerals and fossilis which it may contain: the outgoings to which the estate is liable; the proposed time of the delivery of possession; the price and the mode of payment expected for the same. And in the next place, he considers it as proper to set down the particulars of instructions to be given to a surveyor, or other valuer, of an estate to be purchased. But it will be right, however, he thinks, to premise, that much, in this respect, depends on the probability of purchasing; and on the time allowed for making the estimate. In cases of sale by public auction, where there can be no certainty as to purchase, and where the time for valuation is limited, a rough estimate of each farm, and a general idea of the value of the timber and other appurtenances, may be all that can be prudently ascertained. While in a sale by private contract, where the refusal of an estate is granted, and time allowed for deliberate survey, a more minute investigation may be proper, especially when there is every reason to believe that a bargain will take place. For the former report will not only serve as a guide to the purchaser, but will become a valuable foundation on which to ground the future management of the estate. And he urges, that for these and other reasons, a purchaser by private contract is most to be defined by a gentleman, who is not in the habit of personally attending public sales, and is unacquainted with the business of auction rooms. But, he says, it does not follow that a sale by auction is equally ineligible for a seller, who may gain the advantage ground by this mode of disposition: provided he can frustrate the combinations of public Sales. The auction duty, however, and the heavy expenses of public sales, are objections to this method of making a bargain; as the money thus expended must necessarily come out of the pocket of the buyer or the seller.

And in regard to the particulars to be required from a surveyor or surveyors, they are principally these. The rental value of each field or parcel of land, with the rate in which it lies, as to arable, meadow, pasturage, or wood-land. The value of the timber, and other appurtenances. The characteristic, and the state of the management, of each farm or tenement; with the eligibility of its occupier; together with the state of repair of buildings, gates, fences, water-courses, and roads; the amount of the incumbrances and outgoings; and, lastly, the probable value of the improvements of which the estate may appear to be capable, in different ways. And it is also added, that these several particulars of information being procured, the subjects of treaty are few. The two statements having been duly compared, so that no misunderstanding can take place between the parties, the price, the times and mode of payment, are the principal matters of agreement. A clear understanding respecting the custody of title deeds, and the expences of conveyance, require, however, to be enumerated among the preliminaries of the purchase before any thing is finally settled.

But in what relates to the business of the negotiation, it is best carried on by letters; which become vouchers of facts. Whatever is done by interview requires to be reduced to writing, and to be read by or to the parties before they separate, that no possibility of misconception may arise. And in addition to these precautions, it is proper, in large purchases, and when abstracts of intricate title deeds are to be made out, and examined, that a legal contract, or memorandum of agreement, should be entered into for the mutual satisfaction and surety of the parties. This contract, and the deed of conveyance, (namely, the instrument which is legally to transfer the property from the seller to the purchaser,) may be said to conclude and ratify the business of the purchase, and in this part of it, legal assent is essentially necessary; to examine existing deeds, and see that the seller has a legal right and clear title to the land, and a legal power to dispose of it; as well as to draw up, or examine, the fresh deed of conveyance, and see that it is sufficient to transfer the property, legally and adequately, to the purchaser of such landed estate or property.

See Valuation of Land.

SELLIUM, in Ancient Geography, a town of Spain, in Lusitania, S.E. of Callippo and N.E. of Scalabis.

SELMAST, a town of Perfia, in the province of Adirbeizan or Azerbaijan, situated in the most picturesque, and at the same time, the most flourishing division of the province, lying along the N. and W. border of the lake of Uruanca, from Tabruz or Tabris, to the confines of Armenia. The town contains about 2000 inhabitants, principally Nestorian Christians, and is famed for its lofty poplars and delightful gardens; 75 miles W.S.W. of Tobrez. N. lat. 37° 45'. E. long. 45° 30'.

SENNITZ, a town of Bohemia, in the circle of Chrudim; 16 miles N.W. of Chrudim.

SELO, a river of Naples, which runs into the Mediterranean, near Pelti.

SELOCZOW, a town of Austrian Poland, in Galicia; 40 miles E. of Lemberg.

SELOGORAR, a town of Hindoustan, in Berar; 20 miles N. of Nateurgon.

SELOKOI, a town of Russia, in the government of Tobolik, N. lat. 63° 8'. E. long. 76° 14'.

SELOMMES, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Vendôme; 6 miles S.E. of Vendôme. The place contains 624, and the canton 4396 inhabitants, on a territory of 215 kilometres, in 16 communes.

SELO, a town of Hindoustan, in the Carnatic; 10 miles S.W. of Tiagar.

SELOONDA, a small island in the East Indian sea, near the N. coast of Cumbava. S. lat. 8° 51'. E. long. 117° 34'.

SELONGEY, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Dijon; 4 miles N. of Is sur Tille. The place contains 1878,
of corrosive sublimate, precipitates a yellow powder or turbid liquor, and mixed with another of tartar, gives it a reddish color, and mixed with salt amon, to a purplish tint, while a great deal of this water, let it, with presence of spirit, and finely evaporated, will form a thin and a half of salt, not differing much from that of pure tartar. This is mixed with water, or kept to lip and be corrupted by keeping, and that if it be left for a day or two in a warm vessel, it will yield tartar crystallined, and table, only like water, in which all of tartar had been mixed.

From all these observations it appears, that this water is abundant with an astringent liquor of a much greater quantity than any of the other mineral waters, with a tendency to contain a pure and perfect spirit of bittership, which is the common ingredients of the other mineral waters; on this account, it adds, that it does not purify, but generally pass off by means. Hoffman recommends it as one of the mildest and most innocent of all the mineral waters, and old posts that it may be taken by person of the weakest constitution.

From the experiments of Dr. Brockley on Seltzer-water, we learn, that upon drops of twelve drops of very highly coloured syrup of violet into a small glass of it, the very first drop that fell of a purple hue, but upon their minute into the whole charge into a beautiful green: that the same quantity of oil of tartar per diemum dropped into a glass of sparkling fresh clear water, quickly turned the whole milky, and after lingering a fine pearl-coloured powder fell to the sides and bottom of the glass; on adding an equal number of drops of pure dephlegmatized spirit of vitriol to a glass of this water, a light cloud was seen floating towards the middle of the glass, and numerous air-bubbles rose from all parts of the water, and the sparkling might be renewed by adding one or more drops of the acid, and making the glass; and the like ebullition was more readily produced by a solution of fugar and Rhenish wine, or vinegar with the same and the same appearances were exhibited by dropping any vegetable or mineral acids into this water, as are observed when alkalies and acids are mixed together; a volatile caustic alkali, in half an hour after it had been dropped into this water, produced at first a cloud and afterwards a precipitation. Lithium lanplanum so far decomposed a glass of Seltzer-water, that a cloud instantly appeared in the middle of it, and the air-bubbles emerging from the lower part of it were greedilly absorbed by the caustic alkali, which is known to imbibe fixed air, whenever it comes into contact with it. This water, says Dr. Brockley, purifies into a glats, separates more air-bubbles than any other water which he had tried, and continues longer to do so in the open air, but its sparkling may be renewed by adding any sub-acid vegetable, and a little fugar, as sharp cider and Rhenish wine and fugar; but, he adds, that the best Seltzer-water here will not perfectly curdle milk, nor laugh with soap, and that with powder of gall-nuts no further change of it appear than in pure water. By evaporating twenty-four ounces of the best Seltzer-water, he obtained thirty glats of a caustic residual; and the greatest quantity he could ever get from a pint, wine measure, was less than thirty glats.

Ten drops of strong spirit of vitriol, poured on as many grams of salt of Seltzer-water, caused great and instant ebullition, and suffocating steam, which tinged blackness a silver spoon held in them, and gave to its polished surface a bitter taste.

Having dissolved sixty-six grains of pure white salt, obt
tained from this water, in distilled water, and filtrated it, he thereby obtained seven grains of a calcareous earth, perfectly soluble in all weak acids; but by several different modes of trial he was led to conclude, that this water contained no ferrugious principle. Finding that the salts and earths contained in Seltzer-water are too inconsiderable, both in quantity and quality, to promise any very material medicinal effects, he proceeded to investigate what might be ascribed to the great quantity of fixed air, which this water constantly discharges, in a heat not exceeding that of the human body; and the result was, that the factitious air yielded by a bottle full of water, containing exactly fourteen ounces seven drachms, in a heat never exceeding 116° by Fahrenheit's scale, amounted to a quantity which occupied a space, that required two ounces two and a half drachms of water to fill it; or allowing two hundred and sixty-five grains of common water for a cubic inch, the whole water amounted to twenty-seven cubic inches, and that which would fill the space occupied by the air four ounces and one-fifth; and so large a quantity of interstitial air, he says, was generated in a heat not incompatible with life in any part of the world, as the fever-heats in all climates testify, and less than the heat which is often experienced without insalubrious prejudice, in some tropical climates.

However, this generated air soon began to be re-absorbed into the body of the water, and in about eight hours, the space occupied by the remaining air did not exceed one-fifth of what it had formerly done.

From another experiment with the falt of Seltzer-water, he found that this ferves to have let go much the greatest part of its fixed air, and probably thereby lost most of the virtues inherent in the pure fresh water itself.

From such experiments Dr. Brocklefby infers, that Seltzer mineral water contains, besides the mere elementary water, a very small quantity of calcareous earth, and a much greater portion of a native mineral alkali, together with some acid retained a while within the water, but which either evaporates into the open air, or else is fon combined with the mineral alkali: and he thinks it probable, that the active virtues of this water depend more on this cleftic matter, or fixed air, which it contains in such uncommon abundance beyond other mineral waters, than in any combination of its saline and earthy contents, which are found in such small quantities, as to be incapable of any material service, though this water is known to be exceedingly beneficial.

This account of the analysis of Seltzer-water is closed with the history of some medical cafes, in which the use of this water completed a cure, after a great variety of other remedies had proved insufficient.

The operation of this water, as Hoffman observes, is chiefly by urine, for it has no purgative virtues. It corrects acidities, renders the blood and juices more fluid, and promotes a brisk and free circulation; and, therefore, it is good in obstructions of the glands, and against grosfs and vilef humours. It is of great use in the gravel and stone, and other disorders of the kidneys and bladder.

It is also excellent in gouty and rheumatic complaints, especially when mixed with milk, or improved by the addition of Rhenish wine and a little fugar. It is drank with great success in scorbutive, cutaneous, and putrid disorders. It relieves the heart-burn, and is an excellent homoeopathy. On account of its diuretic quality, it is serviceable in dropical complaints; and mixed with afles' milk, it is much recommended in consumptive cafes, and in disorders of the lungs; with or without milk, it is in great esteem in nervous disorders, and also in hypochondriacal and hysterical complaints, and in obstructions of the meatus, accompanying the use of it with proper exercise.

It is also administered with success in purging and fluxes arising from acidity in the bowels; and it is said, if drank by nures, to render their milk more wholesome and nourishing, and to prevent it from turning four on the romachs of children. See on the subject of this article Hoffman, Oper. vol. v. p. 144. London Med. Observ. vol. iv. p. 7, &c. Elliot's Account of the Principal Mineral Waters, p. 194, &c.

**Seltzer-Water, Artificial,** may be prepared by adding one scruple of magnesia alba, fix scrupules of foffil alkali, and four scrupules of common falt to each gallon of water, and saturating the water with fixed air, in the manner directed under **PYRMONT-Water.**

**SELVA,** in Geography, a town in Spain, in Catalonia, on the coast of the Mediterranean, 35 miles N.E. of Gerona. N. lat. 42° 20'. E. long. 5° 2'.

**SELVA,** a small island in the gulf of Venice, separated from Ulbo by a narrow channel; it is rocky, and the soil fo poor, that the olives feldom come to perfection: the vines produce bad grapes, and the corn is still worse. The fhone that abounds here is chiefly hard whitiff marble. N. lat. 44° 38'. E. long. 14° 5'.

**SELVAGE,** in Sea Language, a fort of hank or flein of rope-yard tied together at several distances. It is used to fatten round any ropes, as a fhroud or flay, fo that a tackle may be hooked in it, to extend the faid fhroud or flay, which is called fitting it up.

**SELUCHUSA,** in Ancient Geography, an island near the Pelponnefus, being one of those which were situated on the coast of the promontory of Spirafteum. Pliny.

**SELUCIA,** in Geography, a town of the Arabian Irak, 160 miles N.W. of Ballora.

**SELVE, L.A,** a town of France, in the department of the Avyron, and chief place of a canton, in the district of Rodes or Rhodex; 14 miles S. of Rhodex. The place contains 840, and the canton 6738 inhabitants, on a territory of 242½ kilometres, in 15 communes.

**SELVIG,** a town of Denmark, on the W. coast of the island of Samfoc. N. lat. 55° 52'. E. long. 10° 36'.

**SELUNE,** a river of France, which runs into the sea, near mount St. Michel.

**SELUR,** in Ancient Geography, a town of India, on this side of the Ganges, in the interior of the country of the Caracens, according to Ptolemy.

**SELYMBRIA, SELYTRA,** called also by Suidas Olybria, a town of Thrace, on the coast of the Propontide, between the mouth of the river Athyras and Perinthus, or Heraclea. Its name signifies the town of Selys, bria signifying town in the language of the Thracians. See Selytra.

**SELBACH,** in Geography, a river of France, which runs into the Rhine, 7 miles below Fort Vauban.

**SEM,** a river of Ruffia, which rifes in the E. part of the government of Kurfc, and paffing by Kurft, unites with the Dena, near Solnitza, in the government of Novgorod Sieverkoe.

**SEMAMPLEXICAULE LEAF,** in Botany. See Leaf.

**SEMENA,** in Geography, a town of Hindooftan, in the fubah of Delhi; 25 miles S. of Sirhind. N. lat. 29° 23'. E. long. 75° 33'.—Also, a town of Japan, in the island of Nippon; 125 miles W. of Meaco.

**SEMAO,** an island of the Eaft Indian sea, about 24 miles long from N. to S., and from fix to ten broad; sepa-
SEME

ESE. or SEEM. See SEAM.

SEMECARPUS, in Botany, derived from semicus, to mark, and ἅρπας, a fruit; a name evidently derived from the use that is made of its nut, in the East Indies, to mark table linen and articles of apparel. If these are put over the nut, and pricked, the juice exuding will make an indelible

Gen. Ch. Cal. Persicariae, inferior, of one leaf, bell-shaped, clover half way down into five, heart-shaped, acute segments. Gen. Petals five, lanceolate, bordered, obtuse, larger than the segments of the calyx. Stam. Filaments five, oval-shaped, shorter than the corolla, inserted into the receptacle; anthers oblong, small. Pet. Germin superior, globular, flattened; styles three, unarmed, situated on the germ and shorter than it; stigmas club-shaped, retuse. Pers. more, except the receptacle, which is erect, fleshy, pear-shaped, smooth. Seed, a nut resting upon the receptacle, heart-shaped, flattened on both sides, smooth and shining.

Obl. Dr. Roxburgh has observed some trees of Seme- copas with male flowers only, on which account profluous Martyr has described the genus as belonging to the class and order of Polygamia Divisa.

1. S. Anacardium. Marking-nut tree. Linn. Suppl. 182. Roxb. Coronaedul. v. 1. 3. 3. 1-8. —Native of mountainous, dry woods throughout the East Indies, flowering in May and August. Rooting its feed in January and February. A handsome lofty tree, whose bark is rough, ashy-coloured and glutinous with mucus. Branches numerous, spreading, rather hairy. Leaves alternate, on shortish stalks, wedge-shaped, rounded at the tip, entire, firm, nearly smooth above, whitish and a little rough beneath. Flowers in large, terminal, erect panicles, composed of numerous, small spikes, of a dirty-greenish-yellow colour. Brachii numerous, small, deciduous. Receptacle yellow, as large as the nut, which is black, containing a corrosive red juice, at first of a pale milk colour, but turning black.

The wood of this tree is fleshy, containing an acrid juice. The fleshy receptacles when roasted have the flavour of apples, and are eaten by the natives. The green fruit, pounded into a pulp, makes good bird-lime; when ripe, its black acrid juice is highly esteemed by the Telangas physis- cians, as a remedy for various disorders.

SEMIRENDA, in Geography, a town in Africa, in the kingdom of Hansa, on the Niger, near a lake called by Ptolemy Libya Palus. N. lat. 15° 25'. E. long. 6° 29'.

SEMEIOTICA, Sp. Gr. H.V. or symptom, that part of medicine which considers the signs or appearances of diseases, which are the sole guides to the physician, by which he can ascertain the seat and nature of diseases, and their probable termination. It includes, therefore, the art of diagnosi and geographis, and ophaloe, or the art of arranging diseases in methodical order. See these words respectively.

SEMELA, in Geography, a town of Africa, in Tripoli; 145 miles S. of Mefurada.

SEMELE, in Mythology, the mother of Baco.

SEMELITANI, in Ancient Geography, a people who inhabited the interior of Sicily, according to Pliny.

SEMEN, in Botany. See SEED.

SEMEN, in Physiology, an animal fluid secreted by the male, the contact of which is necessary to render the germ formed by the female prolix. See GENERATION.

SEMEN SANCTUM, or Santonium. See Wurm-Seed.

SEMEN CAN, in Geography, a town of Grand Bu- chan; 100 miles S.E. of Balka. See SEMEN.
SEMENDERY, a town on the S. coast of the island of Java. S. lat. 7° 11'. E. long. 106° 52'.

SEMENDRIA, a town and fortress of Servia, on the S. side of the Danube; 20 miles S.E. of Belgrade. N. lat. 44° 52'. E. long. 20° 41'.

SEMENGHE, in Music, an instrument used in Arabia by those wandering musicians who accompany the dancing women. It is a sort of bad violin, joined with a drum. The body is commonly a cocoa-nut shell, with a piece of skin extended upon it; three strings of catgut, and some times of horsehair, are fitted to it; and it is played with a bow, not being awkward in its form than the Greek lyre.

SEMEANGH, in Geography, a town of Persia, in the province of Segeftan; 132 miles S. of Kin.

SEMEJAN, a town of Grand Bucharas; 70 miles W. of Anderah. N. lat. 36° 22'. E. long. 65° 50'.

SEMMENDY, a town of Egypt, on the E. branch of the Nile; 8 miles S.S.W. of Mandora.

SEMEKOV, a town of Ruffia, in the government of Nizni-Novgorod; 36 miles N. of Nizni-Novgorod. N. lat. 55° 30'. E. long. 44° 14'.

SEMENOVSKO, a town of Ruffia, in the government of Vologda; 44 miles N.N.W. of Vologda.

SEMENTINAE, in Antiquity, feals held annually among the Romans, to obtain of the gods a plentiful harvest.

They were celebrated in the temple of Tellus, or the Earth, where solemn sacrifices were offered to Tellus and Ceres.

The time of the celebration was about feed-time, usually in the month of January; for Macrobius observes, they were movable feals. They had their name from femis, feed.

SEMEROH, in Ancient Geography, a royal town of Judæa, in the tribe of Zebulon, according to the book of Joshua, whither, it is said, Jabin sent a messenger to demand succour of the king of the city, and which he accordingly obtained, together with that of several other kings, to attack the Israelites; but they were all defeated and slain in the combat.—Also, a mountain of Judæa, in the tribe of Ephraim, E. of Sichem; called also the mountain of Samaria.

SEME, SUMMETS, or SUMMITS, in Botany, are used by Dr. Grew and others, for the apices of the stature of plants.

SEMI, a word borrowed from the Latin, signifying half; but only used in composition with other words, as in the following articles.

The French, instead of semi, frequently use demi, the Greeks hemi.

In music, semi has three several usages: first, when prefixed to the name of a note, it expresses a diminution of half its value, as in semi-breve, &c.

 Secondly, when added to the name of an interval, it expresses a diminution, not of half, but of a lesser semi-tone, or four commas, in the whole compass, as in demi-diapente, &c.

Thirdly, in old music to the end of the 16th century, it implies imperfection in the value of notes, as a semi-circle, or circulo meszo; the whole circle then implying perfection, or triple-time. O three breves, or three times three semi-breves, without a point. C common time, or, as it was then called, imperfect, or dual measure. See Musical Characters, and the first Time-Table.

SEMIARIANS, in Ecclesiastical History, a branch of the ancient Arians, confuting, according to Epiphanius, of such as, in appearance, condemned the errors of that heresiarch, but yet acquiesced in some of his principles, only palliating and hiding them under softer and more moderate terms. See Arians.

It is true, they separated from the Arian faction; but yet could never be brought to acknowledge that the Son was homousios, that is, consubstantial, or of the same substance with the Father; they would only allow him to be homoiouss, that is, of like substance with the Father, or similar to the Father in his essence, not by nature, but by a peculiar privilege. See Homousios, &c.

Though, as to expression, they only differed from the orthodox by a single letter, yet yet that, in effect, of the opinion of the Arians, as they placed the Son in the rank of creatures. It did not avail their teaching, that there was no other creature of the same class with him, since by denying him consubstantial with God, they effectually precluded him from being truly God.

Yet some, even among the orthodox, use the word homoiouss, in speaking of the Son; applying such an idea to it as it seems is consistent with orthodoxy.

But the name Semi-Arians is also given, by the second general council, to another branch of Arians, who believed orthodoxy of the Father and Son, but denied the deity of the Holy Ghost; thus rejecting that part of the Arian fyltem relating to the Son, but still retaining that which related to the Holy Ghost.

As the zeal of the Arians was chiefly levelled against the second perion in the Trinity, that of the Semi-Arians was bent against the third; whereas, as the former were sometimes called Νόμιμοι, the latter were denominated Νομιμοιοι.

Macdonius, bishop of Constantinople, made an innovation in this sect in 360, and gave rise to a new branch of Macedonian Semi-Arians, or Pneumatomachi; who allowed the Son not to be of the same substance, but of like substance with the Father; and at the same time openly affirmed the Holy Ghost to be a creature. This hereby was condemned by the eleventh general council held at Constantinople in the year 381. See Macedonians.

SEMBREVE, O = f, half a breve, in Music. See the Time-Tables.

SEMICIRCLE, in Geometry, a figure comprehended between the diameter of a circle, and half the circumference.

Two semicircles can only cut each other in one point.

SEMICIRCLE is also an instrument in Surveying, sometimes called the graphometer.

It consists of a semicircular limb, as F, J, G, (Plate VII. Surveying, fig. 3.) divided into one hundred and eighty degrees, and sometimes subdivided diagonally or otherwise into minutes. This limb is subtended by a diameter FG, at the extremities of which are erected two sights. In the centre of the semicircle, or the middle of the diameter, is fixed a box and needle. On the same centre is fitted an alidade, or moveable index, carrying two other sights, as H, I. And the whole is mounted on a staff, with a ball and socket.

The semicircle, then, is nothing else but half a theodolite; with this only difference, that whereas the limb of the theodolite, being an entire circle, takes in all the 360° successively; in the semicircle the degrees only going from 1 to 180°, it is useful to have the remaining 180°, or those from 180° to 360°, graduated in another line on the limb within the former.

To take an Angle with a Semicircle. Place the instrument in such manner, as that the radius CG may hang over one leg
SEM

The text is a compilation of various entries, likely from an encyclopedia or a similar work. It covers topics such as anatomy, semicircular canals, and astronomical terms. Each entry is labeled with a heading in bold, followed by a definition or description of the term. The text is dense and technical, typical of an encyclopedia entry for students or professionals in the field.
SEMILUNAR Cartilages of the Knee-joint, are two small portions of cartilage situated in that articulation. See Extremities.

SEMILUNAR Portion or Edge of the Fasce Lata. See Fascia.

SEMILUNARES COCCHEAE, in Natural History, the name of a genus of fucells, so called, from their having semilunar mouths. See Conchology.

The characters of the genus are these. They are univalve shells of a compact body, with a flat semilunar, and often dentated mouth; the columnella, or inner lip, running diametrically across it in a straight line. Some of the species have exserted spicula, and some depressed; these are nearly globose shells, and the turban is never much produced, but lies flat or level with the bottom.

There are many distinctive and specific characters in the several species of this genus, which arrange together considerable numbers of the species under each. Thus the nerita, which are of this genus, are some of them umbilicated, and others have teeth and a kind of gums. The inal kinds, distinctively so called, that fall under this genus, are very different from the neritas, in that they have no teeth, no gum, and no palate. The term semilunares coeccae was invented by Rumphius to express their mouths, being of the shape of half a circle.

All the species of the semilunares shells have few convolutions, and have the extremity of the voluta small, and usually flauding a little out.

The species of the semilunare coeccae are these, as arranged under the two general divisions of dentated neritas, and umbilicated coeccae; viz. the dentated nerita, commonly called the gum-shell; the bloody-tooth nerita; the ox-palate nerita; the inflated and punctuated nerita; the canaliculate, the furrowed, the thrush, and the partridge nerita.

Of the neritas which have no teeth, we have ten species; viz. the jasper with a long beak; the jasper with an operculum; the lemon-coloured pea; the yellow pea; the prickly; the reticulated; that variegated with black spots; the red and white fuscated; the lightly inflated green; and the undulated nerita.

Of the umbilicated shells we have nine species; viz. the long umbilicated; that with an exserted apex; that with a depressed apex; testiculated; the hermit; the umbonated; the small nipple; the heavy white; and the orange-coloured coeccae. Hilt. Natural. Eclaire. part ii. p. 256.

SEMILUNARI S Linea, in the abdomen, is the line following the outer edge of the rectus abdominis muscle. See Osti.läuft.

SEMIMEMBRANOSUS, (ischio-fous-tibien; demi-aponérotique); a muscle of the thigh, situated on the posterior part of the limb, elongated, and extending from the tuberosity of the ischium to the upper and back edge of the tibia. It commences from the tuberosity of the ischium, in front of the biceps and feminitisofhus, and blends the quadratus femoris, by a broad flat tendon, which soon expands into a broad aponeurosis, thicker at its external than at its inner edge, and giving origin successively by the latter to the mucular fibres. The latter are all parallel, short, and placed obliquely, and form a thick
an inch, which is larger at its middle, and thinnest at the top and roots. They extend gradually towards, and terminate in feathers, which, by being appressed to the end of the fronds, enclose the fronds towards, and cords below in a slanting way, which parallel behind the fronds, and divide into the feathers. The external is a narrow and arrow-sharp; the internal is outwards behind the vein, and also inwards above it, and has a slanting line of the thall, connected with the external head of the gallar coroll, the middle, which is broad and continues with the preceding, is fixed to the back of the inner tubercle of the thall, and lends an elevation over the poplons. The internal, more round and rounded, seems to be the continuation of the thall; it turns round the tuber, and is attached in front of it, contained in a fibrous sheath, lined by a decided membrane, which must be opened to gain a clear view of it.

It is covered by the feminal axis, the beaks, and the talus; it lies on the quadrants, the adductor muscle, the peripheral artery, the knee-cort, and the inner head of the gallar coroll, between which and its tender there is a decided membrane.

It binds the egg of the thall, or the thall on the edge; and it extends the thall on the pelves, or carries the pelves backwards on the thall.

SEMINAL, a term formerly applied in Chemistry, to that part not possessing ductility or malleability; these properties being then considered as the principal characters of a metal. In a more modern point of view this is doubled the case, but the chemical properties of this numerous class of bodies are so striking, as to render the above distinction obsolete. See Metals.

SEMINA, in Ancient Geography, a town of Asia, in Partha Phrygia.

SEMINAGUR, in Geography, a town of Hindustan, in Oude; 76 miles N. of Katubad.

SEMINAL, the term formerly applied in Chemistry, to that part not possessing ductility or malleability; these properties being then considered as the principal characters of a metal. In a more modern point of view this is doubled the case, but the chemical properties of this numerous class of bodies are so striking, as to render the above distinction obsolete. See Metals.

SEMINAL, in Ancient Geography, a town of Asia, in Partha Phrygia.

SEMINAL, a term formerly applied in Chemistry, to that part not possessing ductility or malleability; these properties being then considered as the principal characters of a metal. In a more modern point of view this is doubled the case, but the chemical properties of this numerous class of bodies are so striking, as to render the above distinction obsolete. See Metals.

SEMINALIS, in Anatomy, a name by which some authors have called the femoral.

SEMINARA, in Geography, a town of Naples, in Campania Ultra; destroyed by an earthquake in 1783; though the habitants escaped; 17 miles N.E. of Reggio.

SEMINARY, a place appointed for the instruction of young persons destined for the ministry, in its duties, ceremonies, and offices; first instituted, as Thomassin tells us, by St. Augustine.

Of these seminaries there are many abroad, furnished with halls for the assemblies of the exercentutes, and little cham-
apartments are taken off for the nursery, the ground should be double dug, and lie fallow the following summer, mowing it with rotten dung, and double-digging it about Midsummer, as before. In autumn it will be ready to be fown yet, which should be done with seeds of a different nature from those by which it was before occupied. The fernary should be well fenced and guarded. The fernary which is most in use is for the supply of the flower-garden, and this is the place where flowers are to be raised from their seeds, to procure varieties, or, as the florists express it, new flowers; as also for the sowing of all the biennial plants, to succeed those which decay in the flower-garden.

The fernary should always be situated at some distance from the house, and be walled or paled round, and kept ununder lock and key, to keep out dogs, &c. and to prevent a great deal of damage that is frequently done by those who are not acquainted with gardening before they are aware of it. The several directions for the management of the fernary are to be seen under the names of the several plants intended to be raised in it.

SEMINATION, in Agriculture, the act of sowing grain or other sorts of seed. It is of much consequence to have this performed in as equal and regular a manner as possible; the crops being thereby much better, and more productive. See Sowing.

SEMINERVOSUS, in Anatomy. See SEMINTENOSUS.

SEMINIFEROUS Tubes or Ducts, the innumerable fine canals composing the body of the testis, into which the seminal fluid is secreted. See Generation.

SEMINIUM, a term used by the writers on fossils to express a sort of drift principle, from which the several figured horns, or, as they are more usually called, the extraneous fossils, are supposed to have their origin.

The generality of the learned world, at this time, supposed these to be the remains of real shells, &c. brought from the sea to the places where they are now found, at the time of the universal deluge. See Formed Stones, and Adventitious Fossils.

But those who differ from this system pretend, that these fossil bodies, though they exactly represent shells, &c. yet never were in the sea at all, but that their minute first principles, or, to use their own term, their feminia, have been carried from the sea, through subterranean passages, to the places where we now find the complete shells, &c. into which they have grown. Langius, who has written expressly on this subject, though he has candidly collected all that has been said in favour of the diluvian system, by the abettors of it, yet is not convinced by those arguments, but rather inclines to the other side of the question, or the rite of such fossils from feminia.

These fossil shells are usually found throughout one and the same subfulation, and that the most different imaginable from the subfutation of the living creatures which they represent; and often, though found in pairs, and perfectly closed on all sides, yet when broken, they are found full of the subfutation of the bone in which they lie; and the armature of several kinds of them, particularly of many of the cornea ammonis, is supposed to plead greatly in favour of this hypothesis; as it is not of the nature of or at all owing to the subfutation of the matrix in which they lie, or of the matter of which they are formed, and is therefore to arise solely from the nature of the feminia from which they are formed.

The immense number of the seas-shells, as they are called, thus found fossil, is also thought to argue much on this side of the question; as the followers of this hypothesis suppose that the sea could not, at any one time, have given up such numbers as the earth is stocked with, though there are no limits to the numbers supposed to be raised from feminia; and the immense columns of black marble found in Ireland, and found of such regular joints, are brought as a proof of the possibility of such a formation of fossils as this from feminia, which they suppose must have given origin to those pillars.

SEMINOLES, in Geography, a division of the Creek nation of Indians, who inhabit the flat level country on the rivers Apalachicola and Flint.

SEMIORDINATES, in Geometry, the halves of the ordinates or applicates. See Ordinate and Conic Sections.

SEMI-PARABOLA, a curve defined by the equation, 
\[ a x^{n-1} = y^n \] as a \( x^2 = y^3 \), a \( x^3 = y^6 \).

In semi-parabolas \( y^n \); \( y^n \left( a y^n - 1 \right) \); \( a y^{n-1} \); \( z^{n-1} \), or the powers of the semi-ordinates are as the powers of the abscissae, one degree lower; \( e.g. \) in cubical semi-parabolas, the cubes of the ordinates \( y^3 \) and \( x^3 \) are as the squares of the abscissae \( x^2 \) and \( y^2 \). See PARABOLA.

SEMI-PELAGIANS, in Ecclesiastical History, a name anciently, and even to this day, given to such as retain some tincture of Pelagianism.

St. Prosper, in a letter to St. Augustine, calls them re-ligias Pelagii.

Many learned men, principally among the Gauls, who could not come into St. Augustine's doctrine of grace, &c. were accused of Semi-pelagianism; they were also called Maffilians, or Criers of Marseille, in regard their opinions had their first rise in that city.

Cassian, who had been a deacon of Constatinople, and was afterwards a priest at Marseille, was the chief of these Semi-pelagians. And about the year 430, several other persons embarked in the undertaking of fixing upon a kind of mean between the opinions of Pelagius and those of Augustine, and formed this new sect.

The leading principles of the Semi-pelagians were the five following. 1. That God did not dispence his grace to one more than another in consequence of predetermination, \( e.g. \) an eternal and absolute decree, but was willing to save all men, if they complied with the terms of his gospel. 2. That Christ died for all men. 3. That the grace purchas'd by Christ, and necessary to salvation, was offered to all men. 4. That man, before he received grace, was capable of faith and holy desires. 5. That man was born free, and was consequently capable of refilling the influences of grace, or of complying with its fuggitation. The Semi-pelagians were very numerous; and the doctrine of Cassian, though variously explained, was received in the greatest part of the monastic schools in Gaul, from whence it spread itself far and wide through the European provinces. As to the Greeks, and other eastern Christians, they had embraced the Semi-pelagian doctrine before Cassian, and still adhere firmly to it. In the sixth century, the controversy between the Semi-pelagians and the disciples of Augustine, prevailed much, and continued to divide the Western churches. Mofheim's Eccl. Hist. vol. i.

SEMI-PERIOD, in Grammar, a mark of division recommended by Dr. Ward, but not admitted by other grammarians. It is greater than the colon, and supposed to anwer the same purpose between the colon and period as the semicolon does between the comma and colon. It is used to terminate a perfect sentence, when a new sentence arising out of
of the preceding is annexed to it, and he distinguishes it by
beginning the new sentence with a small letter. But the colons
and full stops, differently applied, supercede the necessity of
his new division.

SEMPOLATNOI, or SEMPOLAT, in Geography, a
fortress of Russia, in the government of Kolvan, on the
Irtysh, first built in the year 1714, on the bank of the
Irtysh; but afterwards taken down and erected in several
different situations. It now stands in its fourth situation,
and is easily commanded from the mountains that lie to the
left of it; and the adjacent country is very pleasant and
fruitful, but remains uncultivated. The gardens at Sempola
treat a very fine species of corn. The fort derives its
name from Sempolat, a runaway slave, from about 1½
dvls on the river Irtysh, where are seen some remains
of old stone buildings. The Russian settlers found here
seven houses, as the name of the place imports. Some
learned men are of opinion, that certain inscriptions found
among the ruins, relate to the mytholgy of the Kalmucks;
and that this place was deserted by these people, in
conformity to a maxim of their religion, that when any
consecrated place is profaned by war, it should be for ever
reliquished; 148 miles S. of Kolvan. N. lat. 50° 25'.
E. long. 80° 14'.
SEMI-PORCELAM, in the History of Shells. See
STILLS.
SEMI-PREBEND. See PREBEND.
SEMI-PROOF, an imperfect proof.
In the French law, the deposition of a single evidence
only makes a semiproof.
The testament of a person deceased is deemed a femi-
proof.
In enormous cases, the semiproof frequently determined
them to try the torture.
SEMIQUARTILE, or SEMIQUADRATE, is an aspect
of the planets, when distant from each other 45 degrees, or
one sign and a half.
SEMIQUAVER, in Music. See QUAVER.
SEMIQUINTILE is an aspect of the planets, when at
the distance of 15 degrees from one another.
SEMIRA, in Geography. See SAMIRA.
SEMIRAMIS, in Biography, queen of Assyrity, a very
distinguished personage, in ancient history, lived at a period
so remote, that little can be known with certainty of her
actions. It appears, however, that Semiramis was a female
of obscure origin, but of great beauty and a superior under-
standing, and that she became the wife of Menon, an officer
of high rank under king Ninus; that following her hus-
band to the army, she engaged in the invasion of Bactria,
and attracted the king's notice, whom she afterwards married,
her former husband, through jealousy or defair, having put
an end to his life. After the death of Ninus, who left her
regent and guardian of their infant son, she assumed the
reins of empire, and governed with great glory. She
founded the famous city of Babylon; then purifying her
husband's plan of conquest, and marching through Media
and Persia, every where, it is said, leaving traces of her
splendour, in works of magnificence and utility, penetrated
to the banks of the Indus. She there encountered the king
of the country, at the head of a vast army, and underwent
a total defeat, which obliged her to return to Bactria with
carefully a third part of her forces. A conspiracy being
then entered to assassinate her, at the instigation of her own
son, she either fell under it, or was obliged to reign her
crown after wearing it upwards of 40 years.
SEMI FORCE, in Chemistry, a term
used to express such a reverberatory fire, as which
the gases the heat back up the better of the void.
SEMISHOMEUS, a name given to a
SEMIRACAS, in Geography. See SAMIRA.
SEMISEXTILE, or SEMIQUARTER, on S. S. an effect
of two planets, when they are distant from each other
one-twelfth part of a circle, or 30 degrees.
The semitendineus was added to the ancienir aspects by
Kepler; and, as he lays, from meteorological observa-
tions.
SEMISICHICUS, a word used by some pharmacists
writers to express a draught.
SEMISIDERATUS, a word used by some for a person
trucked with a hemiplegia.
SEMISOSPIRO, in the Italian Music, a little pause,
or the eight part of a bar in common time.
SEMISPINALIS DORSI, in Anatomy, a portion of
the muscular mafas, which fills the hollow of the spine
between the transverse and the spinous processes. It
arises from the transverse processses of four, five, six, or seven
of the inferior dorsal vertebrae, beginning with the second from
the loins, and is inerected in the spinous proccssses of the two
lower cervical, and of the two, three, or four first dorsal
vertebrae. It lies on the multifidus spine, with which it is
much connected; and it is covered by the long lumbar dorso
and complexus. It is described as a distinct muscle by Al-
nius and Soemmerring: Boyer and Bichat include it with
the multifidus spine under the name of transversari euxepus.
See MULTIDUS, under which article its action is de
scribed.
SEMITA LUMINOSA, a name given to a kind of lucid
stret in the heavens, which a little before the vernal equino
or after the autumnal, may be seen about six o'clock at
night, extending from the western edge of the horizon up
wards the Pleiades.
The phenomenon has been taken notice of by Caffimi and
Fatio, who both evince, that this light comes diffusd from
both sides of the sun, its brightnness is much the same with
that of the vites lucis, or the tail of a comet: it is seen
plainest with us about the beginning of October, or the
latter end of February.
Fatio conjectures, that the bodies, or rather the conge-
rates or aggregate of bodies, which occasions this light,
conforms to the sun like a lens, and takes it to have ever
been the same; but Caflini thinks it arises from a vain
number of small planets, which encircles the sun, and
give this light by reflection; others think it not to have
existed long before he observed it. See ZODIACAL LIGHT.
SEMITALES, among the Romans, a name given
to the gods who were the protectors of roads.
SEMITENTS. See TEINTS.
SEMITENDINOSUS, semimervorus, [schio-pre-tibias],
in Anatomy, a long muscle at the back of the thigh, thicker
above and very slender below, extending from the tuberity
of the ischium to the tibia. It arises from the ischium by
a tendon, which, for the space of three inches, is common
it with the long head of the biceps flexor cruris. The muscle
fibres arising from this tendon form a fascieus, which is first
thicker, then larger, and then again diminished, and inter-
sected in its middle by an aponeurosis very obliquely directed.
The semitendinosus passes along the inner and posterior edge
of the thigh, and terminates below in a tendon, which first
constitutes...
SEMITE. See Fever, Semitertian.

SEMITONE, in Music, one of the degrees, or consecutive intervals, of concords.

There are three degrees, or less intervals, by which a sound can move upwards and downwards successively from one extreme of any concord to the other, and yet produce true melody; and by means of which, several voices and instruments are capable of the necessary variety in passing from concord to concord. These degrees are the greater and less tone, and the semitone. The ratio of the first is 8:9; that of the second 9:10.

The ratio of the semitone is 15:16; its compass is five commas; which interval is called a semitone, not that it is geometrically the half of either of the tones, for it is more; but because it comes somewhat near it. It is also called the natural semitone, and the greater semitone, because greater than the part it leaves behind, or its complement to a tone, which is four commas. The Italians also call it seconda minore, or a lesser ledge.

There are several species of semitones; but those that usually occur in practice are of two kinds, distinguished by the addition of greater and less. The first is expressed by the ratio of 16 to 15, or $\frac{16}{15}$; and the second by 25 to 24, or $\frac{25}{24}$. The octave contains ten semitones major, and two dies, nearly; for the measure of the octave being expressed by the logarithm 1.000000, the semitone major will be measured by $0.0293109$; and the octave contains seventeen semitones minor, nearly; for the measure of the semitone minor will be $0.059464$. The two differ by a whole enharmonic dies, which is an interval practicable by the voice, and was much in use among the ancients, and not known even among the modern practitioners. Euler, Tent. Nov. Theor. Mus. p. 107. See INTERVAL.

These semitones are called fictitious notes; and with respect to the natural tones, are expressed by characters called flats and sharps.

Their use is to remedy the defects of instruments, which, having their sounds fixed, cannot always be made to answer to the diatonic scale.

By means of these we have a new kind of scale, called the SEMITONIC SCALE; which see.

In practical music, on keyed and fretted instruments, it is a nominal half-tone; though mathematicians, in theory, find it impossible to divide a tone into halves. Rouleau, after explaining the scientific and nominal difference between the major and minor semitone; the major changing its place, as to $f$; and $b$ to $e$; and the minor remaining on the same line, or on the same space of the staff; as $F_E$ $F_A$, $B_B$ $B_A$; observes, that though the imaginary change of tone is expressed by the accident of a sharp or a flat, yet there is no difference in the sound of $E_k$ and $F_A$, or in $A_A$ and $B_C$, on the organ or harpsichord, the same tones being sometimes major and sometimes minor, sometimes diatonic and sometimes chromatic, according to the key we are in.

For the importance of the semitone in music, see Mattson's Organista profci, or Treatise on Thorough-bafe, where he has bestowed many pages on this interval. Zarlino calls it il fale, the flat, or meaning of music.

The use of semitones has been much abused of late, by the now too common trick of running up and down the piano forte in half-notes. Our flow chromatic is fundamental, and productive of modulation; but the quick chiefly consists of appoggiatures, and mere notes of taste, unmoored in the base and the accompaniments. See Modern CHROMATIC.

For the further use of succeeeive semitones with good taste and effect, see Mozart's Theme, No. 5, Var. 4. second strain.

SEMITONIC SCALE, or the Scale of Semitones; a scale or system of music, consisting of 12 degrees, or 13 notes, in the octave, being an improvement on the natural or diatonic scale, by inferring between each two notes of it another note, which divides the interval or tone into two unequal parts, called semitone.

The use of this scale is for instruments that have fixed sounds, as the organ, harpsichord, &c. which are exceedingly defective on the foot of the natural or diatonic scale. For the degrees of the scale being unequal, from every note to its octave, there is a different order of degrees; so that from any note we cannot find any interval in a series of fixed sounds; which yet is necessary, that all the notes of a piece of music, carried through several keys, may be found in their just tone, or that the same fong may be begun in a different note, as may be necessary for accommodating some instrument to others, or to the human voice, when they are to accompany each other in unison.

The diatonic scale, beginning at the lowest note, being first settled on an instrument, and the notes thereof distinguished by their names, a, b, c, d, e, f, g; the inserted notes, or semitones, are called fictitious notes, and take the name or letter below with it, as $e$, called $c$ sharps, signifying that it is a semitone higher than the sound of $e$ in the natural series; or this mark $f$, called a flat, with the name of the note above, signifying it to be a semitone lower.

Now $\frac{16}{15}$ and $\frac{25}{24}$ being the two semitones the greater tone is divided into; and $\frac{24}{23}$ and $\frac{16}{15}$, the semitones the lesser tone is divided into; the whole octave will stand in the following scheme, where the ratios of each term to the next are written fraction-wise between them below.

Scale of Semitones.

For the names of the intervals in this scale, I may be considered, that as the notes added to the natural scale are not designed to alter the species of melody, but leave it still diatonic, and only correct some defects arising from something foreign to the office of the scale of music, viz. the fixing and limiting the sounds; we see the reason why the names of the natural scale are continued, only making a diminution of each into a greater and less. Thus an interval of one semitone is called a left second; of two semitones, a greater second; of three semitones, a left third; of four, a greater third, &c.

A second kind of semitonic scale we have from another division of the octave into semitones; which is performed by taking an harmonical mean between the extremes of the greater
SEM

This is the 83rd of Jullien's orders, the 5th of his 14th class, whose characters may be found at length under the article Sempervivum. The Sempervivae are defined as follows.

Calyx inferior, divided deeply into a definite number of segments. Petals inserted into the bottom of the calyx, alternate with its segments, and agreeing with them in number, or more rarely the calyx is monopetalous, either tubular, or deeply divided. Stamens either as many as the petals, and alternate therewith; or twice as numerous, inserted alternately into the claws of the petals, and the bottom of the segments of the calyx; anthers roundish. Germanos several, equal in number to the petals, joined together by the internal angle of their base, glandular at the opposite part, their glands, in some instances, affuming the form of scales; filaments and filaments as many as the germinos. Capsules as many, of one cell, with many seeds, separating at the inner margin into two valves, whose edges bear the seeds. Curculin incurved, surrounding a farinaceous mass. Stem herbaceous, or somewhat thorny. Leaves opposite or alternate, succulent.

The genera are Tilliae, Caryophylla, Costoloba, Rhodiol, Sedum, Sempervivum, and Semp. to which Penicillium is subjoined, as akin to the red, but differing in habit, (as being not succulent,) and in the mode in which the capsule bursts; see Penicillium, in which Jullien's mistake is rectified, and this genus referred to the order in question, without any exception or doubt.

Eff. Ch. Calyx inferior, cleft into twelve deep segments. Petals twelve. Capsules twelve, with many seeds.

Ohl. Linneus in a remark under the natural character in his Gen. Pl. makes the greater number of petals the essential distinction between this genus and Sempervivum, but in the Syb. Veg. the nectariferous scales are properly made characteristic of the latter. According to this principle, Sempervivum seditiforme, of Jacquin, has been referred by sir J. E. Smith, in Tr. of Linn. Soc. v. 10. 6, to Sedum, with which it accords also in habit, differing altogether from Sempervivum, except in number of petals, &c. a circumstance known, in this cafe, to be uncertain. Nevertheless, there being in Sempervivum birtum, according to Schmelde's figure at heel, a minute indication of a scale, or tooth, at the base of each germinos, the learned editor of Hort. Kew, was induced, on that ground alone, to prefer the character deduced from number, in the above plant of Jacquin. Both Willdenow and Martyn enumerate fourteen species of this handsome genus, including Sediforme; many of these are beautifully figured by Jacquin and Curtis. The following, beginning with the only British species, may serve as an epitome of the whole.

Vol. XXXII.
S. tectorum. Common Houfeleek. Linn. Sp. Pl. 664. Engl. Bot. t. 1320. Curt. Loud. fac. 3. t. 29. Fl. Dan. t. 601.—Leaves fringed. Offsets spreading. Common on old tiles and decayed thatched roofs, where it forms large, dense tufts, flowering, though sparingly, in July. — Roots perennial, fibrous, throwing out numerous, roaceous, leafy runners. Stems erect, nearly a foot high, round, flothy, downy, leafy, corymbose at the top, many-flowered. Leaves extremely succulent, carinated, acute; the radical ones obovate; those of the stem alternate, lanceolate, more flender, reddish. Flowers pale pink, or flesh-coloured, downy.— "The bruised leaves are by ruffle furgeous used as a cooling external application, but their virtues are inconsiderable."

S. globiferum. Globular Houfeleek. Linn. Sp. Pl. 665. Curt. Mag. t. 507. Jacq. Avr. t. 5. t. 40. App.—Leaves fringed. Offsets resembling little globes.—Native of Russia and Germany, flowering in June and July.—Roots perennial, resembling those of the leaf species in habit, as indeed do all the other parts. Stems not so high, more leafy. Leaves narrower, closely fringed, tipped with red; those of the globular offsets compactly imbricated. Flowers large and handsome, in a terminal cluster; their petals yellow, and lilac coloured at the base.

S. arachnoidium. Cobweb Houfeleek. Linn. Sp. Pl. 665. Curt. Mag. t. 68. Jacq. Avr. t. 5. t. 42. App.—Leaves interwoven with hairs. Offsets globular.—Native of the Alpes of Italy and Switzerland, flowering in the summer.—This very elegant species, commonly known by the name of Cobweb Sedum, resembles all the other species in habit, but is exceedingly remarkable for its woolly substance on the top of its globular offsets, which, as the leaf expands, is extended with them, and affummes the appearance of a cobweb, whence the specific name. Flower-flakes about six inches high, of a bright pink colour, like the flem-leaves. Flowers terminal, corymbose, pink or reddish.

S. montanum. Mountain Houfeleek. Linn. Sp. Pl. 665. Curt. Mag. t. 41. App.—Leaves not fringed. Offsets spreading.—Native of Switzerland, flowering in June and July.—This elegant species differs chiefly from S. tectorum in having smaller leaves without any fringe or indenture at their edges, and more expanded offsets. Flowers beautifully variegated with lilac and a brownish-red colour.

S. monanthes. Cluttered or Dwarf Houfeleek. Ait. Hort. Kew. v. 3. 174. Wildl. n. 14. Curt. Mag. t. 93.—Leaves roundish, club-shaped, clustered together. Stalks solitary, generally single-flowered. Nectaries obcordate.—Native of the Canary Islands, flowering in July.—Remarkable as being by far the smallest species of Sempervivum, but more so on account of its nectaries, which are usually feven in number, and form a principal part of the fructification.

The remaining species are S. arboresum, canariense, glutinosum, glandulosum, villifolium, sellaturn, and biturn. Sempervivum, in Gardening, contains plants of the succulent, hardy, herbaceous, evergreen, and shrubby perennial kinds, of which the species cultivated are; the common houseleek (S. tectorum); the globular houseleek (S. globiferum); the cobweb houseleek (S. arachnoidium); the mountain houseleek (S. montanum); the tree houseleek (S. arboresum); and the Canary houseleek (S. canariense).

In the sixth fort a variety with variegated leaves was obtained from a branch accidentally broken from a plant of the plain fort, at Badmington, the seat of the duke of Beaufort.

Method of Culture.—The different herbaceous sorts are all capable of being increased without difficulty, by planting their off-set heads, which should be flipp'd with a few root-fibres to them, and planted in the spring season on rubbish, rock-works, or other places, or in pots for variety; and the tender greenhouse sorts may be raised from cuttings of the branches and from seeds; but the first is the better method. The cuttings should be made from the smaller branches in the early summer months, and be planted out in pots, or a bed of fine earth, in a warm shaded situation: when the cuttings are succulent, they should be laid in a dry place for a few days to heal over the cut part; they should be shaded from the sun; and those in pots lightly watered in dry weather: when they are become well rooted, they should be carefully removed into separate pots of a middle size, being placed in the greenhouse. Some forward these plants by means of bark hot-beds.

The feeds of the Canary kind should be found in the autumn or early spring in pots of light mould, placing them in a garden-frame to protect them from frost, having the air freely admitted in mild weather, when the plants are come up, and have a little stxrength, they should be removed into small pots and placed in the greenhouse.

The drift sorts are ornamental on walls, buildings, and rock-works, as well as in pots; and the last two kinds among other potted greenhouse plants.

SEMPHROPOL, in Geography, a town of Russia, in the province of Tauris; 60 miles S. of Perekop. N. lat. 45° 8'. E. long. 34° 10'.

SEMPHORIS, in Ancient Geography, a town situated in the environs of Galilee, according to Josephus.

SEMPRONIUS, in Geography, a port-town of New York, nearly in the centre of the county of Onondago, within the jurisdiction of the township of Scipio, 20 miles S.E. from the ferry on Cayuga lake, and 457 miles from Washington.

SEMP, a river of Bavaria, which runs into the Ifer, 5 miles above Landshut.

SEMR, a town of Hindooflan, in Bahar; 38 miles N. of Chuprah. N. lat. 26° 45'. E. long. 84° 51'.

SEMSAT. See SAMSAAT.

SEMSHIN, or SEMPTCHIN, a town of Little Bucharia; 18 miles E.S.E. of Tourfan. N. lat. 44° 30'. E. long. 89° 49'.

SEMTCHIARSKO1, a fortress of Russia, on the Irich. N. lat. 51°. E. long. 78° 10'.

SEUMUR, or SEMUR en Auxois, a town of France, and principal place of a district, in the department of the Côte d'Or, seated on a rock, near the river Armançon; 10 miles N.W. of Dijon. The place contains 4295; and the canton 14,782 inhabitants, on a territory of 2772 quadratkilometres, in 28 communes. Its principal commerce consists in woolen cloth of its own manufacture. N. lat. 47° 29'. E. long. 4° 23'.

SEUMUR en Brionois, a town of France, in the department of the Saône and Loire, and chief place of a canton, in the district of Charolles; 12 miles S. of Charolles. The place contains 598, and the canton 11,166 inhabitants, on a territory of 1824 quadratkilometres, in 16 communes. N. lat. 46° 16'. E. long. 4° 16'.

SEMUSSYR, one of the Kurilsky islands, 30 versts from Keti, another of the same islands. Its length is 130 versts, and its breadth not more than 10. This island has four mountains, one of which exhibits evident traces of
its having been formerly burnt: in other respects it has the same properties with those of Ketis; which fece. The paffage from this island to Thirspo Ot is 300 versts.

SEMYDA, in Botany, the name of a tree, mentioned by Theophrastus, and by some suppos'd to be the fame with the kedia, or birch-tree, but very erroneously.

SEMYSTA, in Ancient Geography, an island of the British ocean, near the coast of the Ofinmi, in which the Gauls had a celebrated oracle, according to Pomponius Mela.

SEMA, in Geography, a town of Ruffia, in the government of Archangel; 16 miles N.E. of Mezen.

Sena, or Marse, a town of Africa, in the country of Moeranga, on the river Zambesi, where the Portuguese have a factory. S. lat. 17° 35'. E. long. 35° 20'.

Sena, Senna, or Egyptian Caffia, in the Materia Medica, a purgative leaf much used in draughts and compositions of that intention.

The thrue which bears it is a species of cafia; which fece.

There is also a kind of fena growing about Florence; but it is inferior to that of the Levant, as it is owned by the Italians themselves. Father Plummer mentions also a third kind growing in the Antilles islands.

M. Lemery distinguishes three sorts of fena of the Levant: the first brought from Seyda, called fena apolo, that is, cydon fena, by reason of the cutium paid the grand signor, for the privilege of exporting it; the second comes from Tripoli; the third is called fena of Mocha.

Sena is a native of Egypt, the best of which is said to grow in the valley of Bafabras, or of Nubia: it also grows in some parts of Arabia, especially about Mocha; but as Alexandria has ever been the great mart from which it has been exported into Europe, it has long been distinguished by the name of Alexandrian fena or fena.

The best fena, named in Nubia "guebally," grows wild, and yields two crops of leaves, the abundance of which depends on the periodical rains. The first crop is collected after the first rains, about the middle of September; the second in the following March. The plants are cut down, and exposed on the rocks to dry in the sun. The leaves are then picked, packed up in bales, and sent down to Alexandria, where they are mixed with two other species of cafia: the one the C. fena of Phulich, with obtuse leaves; the other probably the C. angustifolia of Willdenow, the leaves of which are longer, narrower, and sharper pointed than those of the proper fena, and come from Mocha. There is reason also for thinking that it is further adulterated with the leaves of coluster, bladder-sena, and of box. The fena, after being thus mixed, is repacked in bales at Alexandria, whence it is exported to Europe.

M. Blondel, who was French consul at several seas-ports of the Levant, informs us, that the true fena grows only in the woods of Ethiopia, and in Arabia; and that the fena, which was brought from Saide and Tripoli, was carried there by the caravans; and this opinion is strengthened by the negative testimony of Alpinus, who, in his book "De Plantis Aegypti," does not notice fena. But as Haef-quist found this plant growing spontaneously in Upper Egypt, Blondel's assertion is not to be implicitly received.

Sena appears to have been cultivated in England in the time of Parkinson, A.D. 1640.

The colour of fena leaves is faint, rather disagreeable, and feckly; the taffe slightly bitter, sweetish, and nauseous. Boiling water extracts about one-third of the weight of the leaves employed: the infusion has a deep reddish-brown colour, with the odour and taffe of the leaves. This infusion, when exposed to the atmosphere, deposits a lemon-yellow-coloured insoluble matter; and a similar precipitate is produced by oxymuriatic acid, and several other substances. Alcohol and sulphuric ether, dejected on the powdered leaves, acquire a deep olive-green colour. When the liquid is poured on the surface of pure water, a dark blue precipitate remains after the evaporation of the ether, which is readily insoluble, and has all the properties of chloroform; this colour is transmitted to the water. This colour may be produced by some extractive being taken up by the ether, closely united to the fena. The precipitate in these cases is rendered only of a dirty colour by the addition of water, and scarcely any precipitate is produced; but a brown or blackish precipitate is thrown down by water or the acid. The active principle of fena appears to be a very volatile extractive, not a peculiar volatile matter; and it contains also no arsenic, and some saline ingredients. According to Bell's Lexicon, the residue of the water is much evaporated to dryness, and burnt, yields potash, sulphate of potash, oxide of lime, magnesia, and sulphiure.

It is in common use as a purgative, generally operating after four hours after it is taken; and it is adapted for all cases, in which the bowels require certain, but meteoric evacuation (see Cassia Sena); and it is much esteemed for its bitter taste and its operation. To this purpose Dr. Cullen remarks, that when fena was infused in the infinium agram, a less quantity of the fena was necessary for the dose than the simple infusion of it. Sena, however, when infused in a large proportion of water, as a drachm of the leaves to four ounces of water, rarely occasions much pain of the bowels; and to those who do not object to the bulkiness of the dose, may be found to answer all the purposes of a common cathartic, its operation being aided by plentiful draughts of weak broths or gruel. The dose, in infusion, is from a scruple to a drachm; in infusion, from one drachm to three or four. It gives out its virtue both to watery and phlegmatic menfhra; communicating to water and proof spirit a brownish colour, and to rectified spirit, a fine green. The two inconveniences attending the use of this medicine, are its being liable, in most compositions, to occasion gases, and its being accompanied with an ill flavour, which is apt to nauseate the stomach and palate. The griping seems to be occasioned by the resiny matter, as the infusion made with cold water does not grip, although it purges. The first may be greatly obviated by dilution; the latter by aromatic and other additions; e. gr. cinnamon, or a drachm or two of its distilled water, or carraway, or cardamom seeds. The decoction is a bad form in which to administer this drug, as its activity is much impaired by boiling; owing, according to Cresp, to the total dissipation of the resinous and volatile principles; but, as Thomson conceives, to the oxidation of the extractive, which also accounts for the severe gripings occasioned by the decoction.

Several compositions of this kind are prepared in the hops, sufficiently palatable, and which operate for the most part like cold and mild infever. Such are the following: the confection of fena, the electuary of fena of the Lond. Ph. of 1787, and the lenitive electuary of P. L. 1745 and 1780. (See Electuary of Sena.) The Dublin pharmacopoea directs the electuary of fena to be prepared by taking of fena leaves, in very fine powder, 8 ounces; pulv. of prunes, 1 pound; pulv. of taraxamis, 2 ounces; molasses, 1/2 pint; and essential oil of carraway, 2 drachms. Boil the pulps with the syrup, to the thickness of honey; then add the powder; and when the mixture is nearly cold, the oil: finally, mix the whole thoroughly together.

These electories furnish a mild and pleasant purgative, and well adapted for those who are afflicted with habitual collovenes, and also for pregnant women. The dose is from 3 to 51, or more, taken at bed-time.
**Extract of Sena. See Cassia.**

As the activity of sena is impaired by the preparation of it in the form of a decoction, it must necessarily suffer much more in this preparation. The extract is black, shining, and tenacious, and has an odour similar to that of wort, and a bitterish taste. It is almost inert as a purgative, and might properly be altogether rejected.

However, some have highly extolled M. Geoffroy's dry extract, which is made of a very strong infusion, evaporated to a dry and pulverizable substance. This, they say, is easily taken, of no ill taste, and operates in a very small quantity, one-third part containing the virtue of the whole, or nearly so; the nicest calculations show, that 24 grains of the extract, some part of which may be supposed to be earth, or other accidental or useless matter, poifles the virtues of a drachm in substance. Mem. de l'Acad. des Sciences, Paris, 1738.

**Inffusion of Sena. See Cassia.**

The Dublin pharmacopoeia directs this infusion to be prepared by taking 3 drachms of sena leaves, half a drachm of teller cardamom seeds, freed from the capsules and bruised, and boiling water, as much as will yield, when strained, 6 ounces by measure. Digest for an hour, and when the liquor is cold, strain it. These infusions will spoil in warm weather in 48 hours; and by simple exposure to the air, attract oxygen, which occasions a yellowish precipitate of oxydized extractive, that gripes violently, but is not purgative; on which account they should be preferred in a well-closed vessel, and made only when wanted. They are also precipitated by the strong acids, the alkaline carbonates, lime-water, solutions of nitrate of silver, oxymurate of mercury, superacetate of lead, tartarized antimony, and infusion of yellow eichonon bark, which are consequently incompatible in formulæ with those infusions. The infusions now mentioned contain all the purgative principles of the plant, and the aromatics correct its griping properties. They are given alone, or more generally combined with neutral salts and manna. The dose of the simple infusions may be from $\frac{1}{3}$ to $\frac{1}{3}$; but with the addition of $\frac{3}{5}$ of the tartrate of potas, or $\frac{1}{3}$ of the sulphate of magnesia, which are the usual auxiliaries, $\frac{1}{3}$ are sufficient.

**Infusion of Tamarinds and Sena is prepared, according to the Edim. Ph., by taking of preferred tamarinds, 1 ounce; sena leaves, 1 drachm; coriander seeds, bruised, half a drachm; raw sugar, half an ounce; and boiling water, 8 ounces. Macerate in a covered earthen vessel, which is not glazed with lead, shaking frequently, and after 4 hours strain it. It may be made with double or triple the proportion of sena. This infusion is made, according to the directions of the Dubl. Ph., in the same manner as the infusion of sena, except that $\frac{3}{4}$ of tamarinds is added, before straining the liquor.**

In these infusions, the nauseous taste is covered by the sugar and the acid of the tamarinds; but in other respects they agree both in their properties, and in the effects of the incompatible substances; to which, however, must be added all the salts having potas for their base.

**Compound Powder of Sena. See Cassia, and Powder of Sena.**

**Tincture of Sena is prepared, according to the Lond. Ph. of 1809, by taking of sena leaves, 3 oz., caraway seeds bruised, 1 oz., cardamom seeds bruised, 1 dr., raisins toned, 4 oz., and proof spirit, 2 pints. Macerate for 14 days and filter. The Dubl. Ph. directs to take of sena leaves 1 lb., caraway seeds bruised, 1 oz., dexter cardamom seeds bruised and bruised, $\frac{1}{4}$ oz., and proof spirit, a gallon. Digest for 14 days, then filter.**

**Compound Tincture of Sena, formerly called Elixir salutis, or Elixir of health, is prepared by taking of the leaves of sena, 2 oz., jalap root bruised, 1 oz., coriander seeds bruised, $\frac{1}{2}$ oz., proof spirit, $\frac{3}{4}$ lb. Digest for 7 days, and to the filtered tincture add of refined sugar, 4 oz.** These tinctures are homœopathic and purgative: they are very efficacious in flatulent colic, atonic gout, and as an opening medicine for those whose bowels have been weakened by intemperance. The dose is from $\frac{1}{2}$ to $\frac{1}{3}$ in any appropriate vehicle.

**Syrup of Sena, according to the Lond. Ph., is prepared by taking of sena leaves, 1 oz., fenel seeds bruised, 1 dr., manna, refined sugar, of each 1 lb., and boiling water, a pint. Macerate the sena leaves and the fenel seeds in the water for 12 hours; strain the liquor and mix it with the manna and the sugar. The Dubl. Ph. directs to take of manna, refined sugar, of each 1 lb., fenel leaves, $\frac{1}{2}$ oz., and boiling water, a pint. Let the sena leaves be macerated in the water in a covered vessel for 12 hours; then dilute the manna and the sugar in the strained liquor. This syrup contains the purgative properties of the sena, and is chiefly intended for children; but the simple infusion of sena, sweetened with sugar, and with the addition of a little milk, given in the form of tea, is more willingly taken by children, and operates with greater certainty. Lewis Woodville, Thomson.**

**Sena, Baldaria, in Botany. See Cassia.**

**Sena, Badder. See Colutea.**

**Sena, Paddled. See Cornylla.**

**Sena, Scorpion, Emerus, a species of corolla; which see. The leaves of this plant are used, but Boerhave is unacquainted with any medicinal virtue in them. Ruppius writes, that the common people substitute the leaves instead of those of sena; and Buxbaum tells us, that old women who pretend to medicine, call it fenès blatter, and use it instead of sena leaves.**

**Sena, in Ancient Geography, a river of Italy, in Umbria, between the Metaurus and the Mius, according to Silius Italicus.**

**Sena Gallica, Senagaglia, a town of Italy, in Umbria, of Gaulish origin, as its name indicates. When the Romans had put the Gauls to flight, they established a colony in this city, towards the year 359. Pompey vanquished Marcus in this place and destroyed it. Ptolemy assigns it to the Senones, from whom it derived its name.**

**Sena Infusa, an island, according to Mela, in the British ocean, on the coast of the Obiandriis. It is now the Isle of Sein or of Saints, on the coast of Bretagne.**

**Sena Julia, Sienna, a town of Italy, in Eturria, E. of Volatere, from which it is separated by mountains. Different accounts have been given of its origin, from which we may infer, that it is not one of the ancient towns of Eturia. The Romans established a colony in this place in the year of Rome 476. as others say, 471. A new colony was established in this place in the time of Julius Cæsar, who gave it the name of Julia. In 1370 it was subject to Charles IV.: it suffered much in the wars of the Guelphe and Ghibelines. Charles V. gave the investiture of it to Philip II. his son, who sold it to Cofno, duke of Florence, in 1558.**

**SENABA, in Geography, a town of Egypt, on the left bank of the Nile; 13 miles S. of Meda.**

**SENAC, John, in Biography, a distinguished French physician, was born in Galony, about the close of the 17th century. Little is recorded respecting the progres of his education and life; but he is said to have been a doctor of the faculty of phyfic of Rheims, and a bachelor of that of Paris; which latt degree he obtained in the year 1724 or 1725. He was a man of profound erudition, united
SEN

united with great modesty, and became posses'd, by his industry in the practice of his profession, of much solid medical knowledge. His merits obtained for him the favour of the court, and he was appointed consulting physician to Louis XIV., and subsequently succeeded Chavotin in the office of first physician to that monarch. He was also a member of the Royal Academy of Sciences at Paris, and of the Royal Society of Nancy. He died in December, 1770, at the age of about 77 years, and the king appointed no physician as his successor, as long as he lived.

This able physician left some works, which will probably maintain a reputation as long as medicine is studied. We allude more especially to his treatise on the heart and its diseases, "Traite de la Structure du Cœur, du fon Action, et de ses Maladies," Paris, 1749, in two volumes, 4to, which is still a standard work upon this interesting subject.

An essay "De recondita febrifum intermittentium et remittentium natura," Ann. 1759, is generally ascribed to Senac. He also published, when young, an edition of Heister's Anatomy, with some interesting comments and observations of his own, entitled "Anatomie d'Heister, avec des Eilais de Physique sur l'Usage des Parties du Corps Humain," Paris 1724, and afterwards "Dificours sur la Methode de Françoise, ou sur celle de M. Rau touchant l'Operation de l'Eaiile," 1727. "Traité des Caufes, des Accidents, et de la Cure de la Pelle," 1744. A work under the assumed name of Julien Morison, entitled "Lettres sur la Chois des Sangsues," 1730, was from his pen; as well as a paper in the Memoirs of the Academy of Sciences for 1725, under the title of "Reflexions sur les Noyes," in which he commanded some erroneous opinions respecting the cause of death by drowning, and the treatment founded upon them. A work, entitled "Nouveau Cours de Chymie suivant les Principes de Newton et de Stahl," Paris, 1722 and 1737, has been attributed by mistake to Senac; it was in fact a compilation of notes taken at the lectures of Geoffroy by some students, and is unworthy of his pen. See Eloy, Dict. Hift. de la Médecine.

SENACIA, in Botany, a genus of Commeron's, apparently intended by him in honour of the French physician Senac, (see the preceding article,) whom perhaps have patronized the expedition of Commeron, but of whose botanical merits we find nothing recorded. Jussieu, Gen. Pl. 378, merely mentions this genus under Celagia, as differing from that in having a longer style, oblong anthers, and a fruit with generally two cells, two valves, and fix seeds. Our predecessor, the Rev. Mr. Wood, seems to have intended to adopt Sensaeis; see Celagia, at the end. We do not however find that any other writer has done so, nor do we know of what species the genus in question ought to confine, except those mentioned in the place just cited. The precise structure of the cypae, and the number of the seeds, are so little ascertained in some reputed species of Celagia, and the variables of these characters, in others, is so well known, that while Gartner himself has even doubted the distinction between Ecosmus, (see that article,) and Celagia itself, we feel little inclination to subdivide the latter. The comparative length of the styles in these plants, variable in different states of the flowers, can afford no certain mark of generic distinction.

SENAILLE'S, JOHN BAPTISTE, in Biography, a French musician, born about 1688. He was a great performer on the violin for his time. Having travelled into Italy, the manager of the Opera at Modena engaged him to perform in his orchestra, and did him the honour to prepare for his reception a fest more elevated than was allowed to the rest of the band. The duke desired him to play some successions between the acts of the opera, and he obeyed his serenc helpers, to the great joy of the work audience. He has left five books of fancies, which had great reputation, till those of Le Claire appeared; which are now as little known as those of Senaille, though infinitely superior to them. What a fluctuating age is music, and how transient the fame of its professors! since we may be certain, that the works of him who now enjoys the highest reputation, will be for ever plunged into oblivion, at the latest, in a period of 25 years; or appear as ridiculous to our children, as our ancient music now does to us!

SENAMARIIO, in Geography, a river of Guiana, which runs into the Atlantic, N. lat. 5° 30'. W. long. 54° 6'.

SE-NAN, a city of China, of the first rank, in the province of Koei-techen, surrounded on all sides by mountains; 845 miles S.S.W. of Peking. N. lat. 27° 50'. E. long. 107°.

SE-NAN, a town of Algiers; 20 miles S. of Oran.

SE-NANLU, a town of Affric Turkey, in Caramania; 30 miles N.W. of Seleucia.

SE-NAPSE, a town of Egypt, on the left bank of the Nile; 17 miles W. of Dendera.

SE-NARPONT, a town of France, in the department of the Somme; 22 miles W. of Amiens.

SENATE, SENATES, an assembly or council of senators, is, of the principal inhabitants of a state, who have a thare in the government.

Such were the senates of Rome, of Carthage, &c. among the ancients; and such are the senates of Venice, of Genoa, &c. among the moderns.

The senate of ancient Rome was, of all senates, the most celebrated, during the splendour of the republic. Cicero in his oration for Milo, defines it, tempalum sanctius, amplitudinis, libertatis, concilii publici Romani, raput orbis, ara factorum, portuque omnium gentium. The Roman senate exercised no contentious jurisdiction; it appointed judges either out of the senate, or among the knights; but it never flopped to judge any proceffes in a body. The senate concerted matters of war, appointed who should command the armies, lent governors into the provinces, took order, and dispossessed of the revenues of the commonwealth. Yet did not the whole sovereign power reside in the senate; it could not alone elect magistrates, make laws, nor decide of war and peace; but in all these cases, the senate was to consult the people. Under the emperors, when the senate became deposed of most of its other offices, they began to hear causes. For those of less consequence they appointed particular judges; the rest, principally criminal causes, they referred for their own cognizance, to be judged by them in a body, and that frequently in the emperor's presence. This was put in their way to keep their heads from state affairs. Nero farther committed to the senate the judgment of all appeals; but this did not hold long; nor do we find any footsteps of it anywhere but in the fifty-second Novel.

With regard to the jurisdiction of the senate, Dr. Middleton observes, that the supreme power at Rome was in the collective body of the people; yet where haste, perhaps, or secrecy was required, and where the determinations of the senate were so just and equitable, that the consent of the people might be presumed, and taken for granted, the senate would naturally omit the trouble of calling them from their private affairs to an unnecessary attendance on the public; till by repeated ommissions of this kind, begun at first in trivial matters, and proceeding ineflably to more serious,
fensive, they acquired a special jurisdiction and cognizance in many points of great importance, to the exclusion even of the people; who yet, by the laws and constitution of the government, had the absolute dominion over all. For example:

1. They assumed to themselves the guardianship and superintendence of the public religion; so that no new god could be introduced, nor altar erected, nor the Sibyllic books consulted, without their express order.

2. They held it as their prerogative, to settle the number and condition of the foreign provinces, that were annually assigned to the magistrates, and to declare which of them should be consul, and which praetor province.

3. They had the distribution of the public treasury, and all the expences of the government; the appointment of tribunes to their generals, with the number of their lieutenants and their troops, and the provisions and clothing of their armies.

4. They nominated all ambassadors sent from Rome, out of their own body, and received and dismissed all who came from foreign states, with such answers as they thought proper.

5. They had the right of decreeing all supplications, or public thanksgivings, for victories obtained, and of conferring the honour of an ovation, or triumph, with the title of emperor, on their victorious generals.

6. It was their province to inquire into public crimes or treasons, either in Rome, or the other parts of Italy; and to hear and determine all disputes among the allied and dependent cities.

7. They exercised a power, not only of interpreting the laws, but abolishing men from the obligation of them, and even of abrogating them.

8. In the case of civil divisions, or dangerous tumults within the city, they could arm the confuls by a vote with absolute power, to destroy and put to death, without the formality of trial, all such citizens as were concerned in exciting them.

9. They had a power to prorogue, or postpone the assemblies of the people; to decree the title of king to any prince whom they pleased; thanks and praise to those who had deferred them; pardon and reward to enemies, or the discoverers of any treason; to declare any one an enemy by a vote; and to prescribe a general change of habit to the city, in cases of any imminent danger or calamity.

The tribunes soon matched from them that original right, which they had enjoyed from the very foundation of the city, of being the authors, or first movers of every thing, which was to be enacted by the people, and excluded them from any share or influence in the assemblies of their tribes; and though in the other assemblies of the curia and the centuries, they seemed to have referred to them their ancient right, yet it was reduced to a mere form, without any real force; for instead of being what they had always been, the authors of each particular act that was to be proposed to the people's deliberation, they were obliged, by a special law, to authorize every assembly of the people, and whatever should be determined in it, even before they had proceeded to any vote. And C. Gracchus afterwards, in his famous tribunate, used to boast that he had demolished the senate at once, by transferring to the equestrian order the right of judicature in all criminal causes, which the senate had professed from the time of the kings.

It has been a question among the learned, how senators were created, and how the vacancies of the senate in old Rome were supplied.

Dr. Middleton is of opinion, that the constant and regular supply of the senate was from the annual magistrates; who, by virtue of their several offices, acquired an immediate right to sit and vote in that assembly. The usual gradation of these offices was that of quæstor, tribune of the people, ædile, praetor, and conful; which every candidate, in the ordinary forms of the constitution, was obliged to take in their order, with this exception only, that he might forego either the tribunate, or the ædileship, at his own choice, without a necessity of passing through them both. See Qæstor, Tribune, &c.

But though those offices gave both an immediate right, and actual entrance into the senate, yet the senatorial character was not esteemed complete, till the new senators had been enrolled by the consuls at the first lufrum, or general review of all the orders of the city, which was generally held every five years. Yet this enrolment was but a matter of form, which could not be denied to any of them, except for some legal incapacity, or the notoriousity of some crime, or infamy upon their characters; for which the same consuls could expel, or deprive any other senator, of what rank or standing ever. See Censor.

It has been the opinion of some, that under the kings of Rome the choice and nomination of all the senators depended wholly on the will of the prince, without any right in the people, either direct or indirect; and that the consuls, who succeeded to the kingly power, enjoyed the same prerogative, till the creation of the consuls, who ever after professed the sole and absolute right of making and unmaking senators. But Dr. Middleton is of opinion, that the kings, the consuls, and the senators, acted in this affair but ministerially and subordinately to the supreme will of the people, in whom the proper and absolute power of creating senators always reposed. And the doctor affirms us, upon the strictest search into the state of the present question, as it stood under the kingly government, he cannot but conclude, from the express testimony of the chief historians, the concurrence of similar facts, and the probability of the thing itself, that the right of choosing senators was originally and constitutionally vested in the people. Middleton of Rom. Sen. p. 36.

But lord Hervey, who seems to have studied the Roman history with care and attention, is of a different opinion. The senate, at its first establishment (notwithstanding the judicial and legislative power it afterwards acquired) was nothing more than the king's council. In this light not only Feftsus, Eutropius, and Livy, represent the senate, but even Dionysius himself. It is therefore highly probable, his lordship says, that each member of this council was merely, as Livy and Plutarch relate, the choice of the king, and not, as Dionysius reports, elected by the people. Nor is there the least ground to imagine, he tells us, from any authority whatever, except Dionysius, that during the whole regal government, the people had, directly or indirectly, actually or virtually, any share or concern at all in the choice of the senators. The first institution, in a word, every augmentation, and every supply on vacancies, he supposes to have depended entirely on the will and authority of the kings. Nor does he, like Monfieur Vertot, imagine the reason why Dionysius had reported otherwise, proceeded from his republican spirit, but from what every body who reads him must find in his manner of describing every institution, law, or custom, among the Romans, viz. an affection of tracing its origin from some similar practice in the Grecian states, in order, from his partiality to that country, to give Greece the honour of having furnished the model of every plan, on which the Roman government was framed, and the Roman greats raised.

Soon after the expulsion of Tarquin, and the establishment of
of the consul government, the senate, which, by many condemnations to death, or exile, the last king had reduced to less than half its complement, was filled up to its former number of three hundred; this supply, according to every historian, was made out of the plebeians; and in all probability, his lordship says, by the sole power of the consuls, since no author relates otherwise, and all authors agree that the consular power at first differed from the regal powers in no particular but that of being annual, instead of perpetual, and divided between two persons, instead of being vested in a single one.

Till the time of the censors then, lord Hervey tells us, there is not the least reason to imagine, that the people had any hand in promoting any man to the senatorial rank. From the time that the people were allowed to choose the annual magistrates out of their own body, till the time the commonwealth fell into confusion, which ended, as confusion generally does, with a total loss of liberty, the only difficulty in accounting for the filling up of the senate, his lordship says, is to reconcile the right of the annual magistrates to enter the senate, with the power of the censors. And this, he thinks, may be done by distinguishing between a right to vote in the senate, and being a senator, which were two different privileges, and quite distinct honours. The right was obtained by virtue of exercising any public office, from the quaestorship to the consulship; and was consequently conveyed by the people; whereas the last was a dignity conferable only by the censors. Felts says, that those who held any public office in the state, and by virtue of that office voted in the senate, were nevertheless no senators till made so by the censors. And Aulus Gellius, in his chapter upon the "Pedari Senatus," says the same thing.

These two classes were always distinguished even in the edict that convoked the senate; the form of the edict, as may be seen in many writers, being to convene the senators, and all those who had a right to vote in the senate.

Nor was the difference, according to Aulus Gellius, between the voters in the senate, and the confirmed senators, so insensible, as it may at first appear; for those, who had only a right to vote in the senate, and were not enrolled senators, had no right to speak there, and could only pass in silence to one side or the other, when a division was made on the point in debate. Whereas an enrolled senator had a right, when he gave his vote, to speak as long as he pleased, and on what he thought fit; a privilege, which amounted to a power of stopping all proceedings for that day, and was often so used.

From the story of Fabius Maximus and Caius, related by Valerius Maximus, book ii. chap. 2, there appears to have been another very essential difference between a senator, and a voter in the senate; for by that story one must imagine that those who were enrolled senators, had not only the sole right of debating any question that came into the senate, but were like a secret committee, or cabinet council, who previously weighed every proposal that was to be made in a general senate, and determined whether it should be brought in or not.

The power of taking cognizance of the manners of every Roman citizen, was first annexed to the censorship, when the office itself was disjoined from that of the consuls, in the three hundred and eleventh year of Rome, as may be seen in Livy, book iv. chap. 8. But the power of choosing the new senators was not transferred from the consuls to the censors till a hundred years afterwards, in the tribune-ship of Ovinus: and it was then given to the censors by the people, to revenge the breach of the Licinian law (which law ordained that one of the consuls should always be chosen out of the plebeians) for both the consuls being that year patricians, and one of the censors that year, for the first time, being a plebeian, the tribune Ovinus put the people upon this expedient to do themselves justice, and mortify the nobility.

When the annual magistrates were not sufficient to supply the vacancies in the senate, the censors chose whom they pleased. And that the annual magistrates were seldom enough to supply the vacancies, may easily be concluded, when one considers how few they were, and how many vacancies must be made in a large body as three hundred men, by natural deaths, the change of perpetual war, and the purgations made by the reforming authority of the censors.

The filling up of the senate then from the Olivran tribune-ship till the time of the Gracchi, lord Hervey thinks, depended entirely on the censors; for though he allows that the annual magistrates, at the expiration of their office, had a right of claim and pretension to be put on the roll of senators, by the censors; yet as the censors, under the pretence of reformation, had an uncontrovertible power to remove senators already enrolled, so on the same pretence they could, if they pleased, refuse to enrol, and even without giving any reason; since their manner both of expelling or admitting senators was merely by omitting or inferring a name in the ceremony of calling over the roll.

Though the censorship, therefore, at its original institution by Servius Tullius, was nothing more than the office of numbering the people, and taking the valuation of their estates, and an office annexed first to the royal authority, and afterwards to the consul power; yet when it was detached from the consul power, and erected into a separate office, with the power of filling up the senate annexed; from that time, as the cognizance of the manners of every citizen of Rome was also in their department, his lordship looks upon the censors to have been full as absolute in the city and the civil government, with regard to all promotions and degradations, from the senate down to the lowest tribe, curia, or society, as the consuls were in the camp and the military government.

Ever after the time of the Gracchi, the state was either in such confusion, or such absolute slavery, that his lordship thinks there was no regular method at all observed in filling up the senate, or any justice in purging it. Whoever had the sovereign power in his hand, under what title ever he was, or conferred on him, modelled the senate by the introduction of new members, or the expulsion of old ones, just as he thought fit.

Dr. Middleton politely acknowledges, that the hypothesis of lord Hervey has the advantage of his own, and will be thought the more solid or plausible by the generality of readers. See Letters between Lord Hervey and Dr. Middleton, concerning the Roman Senate; published by Dr. Knowles, quarto, 1758.

The magistrates who had the power of assembling the senate were the dictator, the consuls, the praetors, the tribunes of the commons, and the interrex. Yet upon extraordinary occasions the same privilege was allowed to the tribuni militum, invested with consular power, and to the decemvirs, created for regulating the laws; and to other magistrates chosen upon some unusual occasion.

In the early ages of the republic, when the prejudices of the city were small, the senators were personally summoned by an appurten; and sometimes by a public crier, when their affairs required immediate dispatch; but the usual way of calling them, in later days, was by an edict appointing the time and place, and published several days before,
SENATE.

before, that the notice might be more public. These edicts were commonly understood to reach no farther than to those who were resident in Rome, or near it; yet when any extraordinary affair was in agitation, they seem to have been published also in the other cities of Italy. If any senator refused, or neglected to obey this summons, the conful could oblige him to give security for the payment of a certain fine, if the reasons of his absence should not be allowed. But from sixty years of age they were not liable to that penalty, nor obliged to any attendance but what was voluntary.

The senate could not regularly be assembled in a private or profane place, but always in one fet apart, and solemnly conformed to that use by the rites of augury.

The senate frequently met in certain curiae. See CURIÆ.

But their meetings were more commonly held in certain temples, dedicated to particular deities; as in that of Jupiter, Apollo, Mars, Vulcan, Castor, Bellona; of Concord, Faith, Virtue, the Earth, &c.

These temples, on account of the use which the senate made of them, were called likewise curiae; as well as the proper curia, or senate-houses, on account of their solemn dedication, are frequently called temples.

On two special occasions the senate was always held without the gates of Rome, either in the temple of Bellona, or of Apollo. first. For the reception of foreign ambassadors, and especially of those who came from enemies, who were not permitted to enter the city. secondly. To give audience, and transact business with their own generals, who were never allowed to come within the walls as long as their commission subsisted, and they had the actual command of an army.

The senate met always, of course, on the 1st of January, for the inauguration of the new consuls, who entered into their office on that day.

The month of February, generally speaking, was referred entirely by old custom to the senate, for the particular purposes of giving audience to foreign ambassadors.

In all months, universally, there were three days, which seem to have been more especially defined to the senate, the kalends, nones, and ides, from the frequent examples found in history, of its being convened on those days. But Augustus enacted afterwards, that the senate should not meet regularly, or of course, except on two days only of each month, the kalends, and ides.

On their days of meeting, they could not enter upon any business before the sun was risen, nor finish any after it was set; every thing transacted by them, before or after that time, was null and void, and the author of it liable to cenure. Whence it became a standing rule, that nothing new should be moved after four o'clock in the afternoon. The senate, as has been shewn above, was composed of all the principal magistrates of the city, and of all who had borne the same offices before them: and confided therefore of several degrees and orders of men, who had each a different rank in it, according to the dignity of the character which he sustained in the republic. At the head of the senate was the dictator and consuls, in chairs of state. Manutius thinks that the other magistrates sat next to the consular chair, each according to his rank; the praetors, censors, aediles, tribunes, quaestors. But Dr. Middleton rather thinks that the consular magistrates, who, in all ages of the republic, were the leaders and first speakers in the senate, used to sit next in order to the consuls; and after them the praetors; and all who were of praetorian dignity, or had been praetors; then the aediles, the tribunes, and the quaestors, on distinct benches; and on the same bench with each, all who had borne the same offices; but the curule magistrates, as the praetors and aediles, were perhaps distinguished, at the head of their several benches, by seats somewhat raised, or separated at least from the rest, in the form of our fettes, or of that longa cathedra, which Juvenal mentions, to denote the curule dignity.

All the private senators sat on different benches, and in a different order of precedence, according to the dignity of the magistrates which they had severally borne. First the consular, then the praetorian, aedilic, tribunitian, and quaestor; in which order, and by which titles, they are all enumerated by Cicero. And as this was their order in sitting, so it was the same also in delivering their opinions when it came to their turn. Cic. Phil. i. 13, 14.

The senate being assembled, the consuls, or the magistrate, by whose authority they were summoned, having first taken the auspices, and performed the usual office of religion, by sacrifice and prayer, used to open to them the reasons of their being called together, and propose the subject of that day's deliberation; in which all things divine, or relating to the worship of the gods, were disfpatched preferentially to any other business. When the consul had moved any point, with intent to have it debated and carried into a decree, and had spoken upon it himself as long as he thought proper, he proceeded to ask the opinions of the other senators, severally in their name, and in their proper order, beginning always with the consuls, and going on to the praetorians, &c. It was the practice originally to ask the prince of the senate the first; but that was soon laid aside, and the compliment transferred to any other ancient consular, distinguished by his integrity and superior abilities; till, in the later ages of the republic, it became an established custom to pay that respect to relations, or particular friends, or to those who were likely to give an opinion the most favourable to their own views and sentiments on the question proposed. But whatever order the consuls observed in asking opinions on the 1st of January, when they entered into their office, they generally purloined the same through the rest of the year. Julius Caesar, indeed, broke through this rule; for though he had asked Crassus the first, from the beginning of his consulship; yet, upon the marriage of his daughter with Pompey, he gave that priority to his son-in-law, for which, however, he made an apology to the senate.

This honour of being asked in an extraordinary manner, and preferably to all others of the same rank, though of superior age or nobility, seems to have been feldom carried farther than to four or five distinguished persons of consular dignity; and the rest were afterwards asked according to their seniority. And this method, as has been said, was observed generally throughout the year, till the election of the future consuls, which was commonly held about the month of August; from which time, it was the constant custom to ask the opinions of the consuls elected, preferably to all others, till they entered into their office, on the 1st day of January following.

As the consuls elected had this preference given in speaking before all the consuls, so the praetors, and tribunes elected, seem to have had the same, before the rest of their particular orders.

None were allowed to speak till it came to their turn, excepting the magistrates, who seem to have had a right of speaking on all occasions, whenever they thought fit; and for that reason, perhaps, were not particularly asked, or called upon by the consuls.

If in the debate several different opinions had been offered, and each supported by a number of senators, the
The decree of the senate were usually published, and
openly read to the people, or if they were passed, and
an authentic copy of them was always deposited in the public
treasury of the city, yet even these were not considered
as legal or valid.

As to the force of these decrees, it is difficult to define
precisely what it was. It is certain that they were not con-
trolled by law, but were to have been acted upon as
acts grounded in the report of the people; for in all ages of the
republic, no law was ever made, but by the general suffrage of the
people.

By even under the kings, the collective body of the people
was the real sovereign of Rome, and the denier resorted in
all cases. But their power, though supreme and final, was
yet qualified by this check, that they could not regularly
execute any thing, which had not been previously considered
and approved of by the senate. This needed to continue to be
the general way of proceeding in all quiet and regular times,
from the beginning of the republic to the end of it; and the
constant style of the old writers, in their accounts of the
public transactions, is, that the senate voted or decreed, and
the people commanded such and such an act. Middleton,
ubi supra, and the authorities cited by him.

Before the accession of Augustus the senate had lost
its power, and also its dignity. Many of the most noble families
were extinct; the republicans of spirit and ability had per-
rished in the field of battle, or in the profligacy. The
door of the assembly had been defilyed left open for a
mixed multitude of more than a thousand persons, who
reflected disgrace upon their rank, instead of deriving honour
from it. Julius Cæsar introduced soldiers, intruders, and half-
barbarians into the senate; and this abuse, recorded by Suet-
onius, became still more scandalous after his death. Au-
gustus, soon after his accesion, set about the reformation of
this. He was elected censor: and in concurrence with his
faithful Agrippa, he examined the list of the senate, expelled
a few members whose vices or whose obliquity required a
punishment example; persuaded near two hundred to
prevent the shame of an expulsion by a voluntary retreat; placed
the qualification of a senator to above ten thousand pounds;
created a sufficient number of patrician families; and accepted
for himself the honourable title of prince of the senate, which
had almost been belittled, by the censors, on the citizen most
eminent for his honours and services. But in thus restoring
the dignity, he destroyed the independence of the senate,
the principles of a free constitution being irrecoverably lost,
when the legislative power is nominated by the executive.

How he was afterwards recompeded by the flattery of the
Senate is well known. (See Augustus, Proconsul, and
Imperator.) It was, however, on the dignity of the
senate, that Augustus and his successors founded their new
empire; and in the administration of their own powers, they
frequently consulted the great national council, and seemed
to refer to its decision the most important concerns of peace
and war. Rome, Italy, and the inland provinces, are
subject to the immediate jurisdiction of the senate. With
regard to civil objects, it was the supreme court of appeal;
with regard to criminal matters, a tribunal, constitu-
ted for the trial of all offences that were committed by
men in any public station, or that affected the peace and
majesty of the Roman people. The exercise of the judicial
power became the most frequent and iterated in operation of
the senate; and the important causes that were pleaded before
them afforded a last refuge to the spirit of ancient eloquence.

As a council of state, and as a court of justice, the senate pro-
selled
feffed very considerable prerogatives; but in its legislative capacity, in which it was supposed virtually to represent the people, the rights of sovereignty were acknowledged to reside in that assembly. Every power was derived from their authority; every law was ratified by their sanction. Their regular meetings were held, as we have already said, on three flatted days in every month; their debates were conducted with decent freedom; and the emperors themselves, who gloated in the name of senators, fat, voted, and divided with their equals.

Augustus found by experience, what he had previously expected, that the senate and people would submit to slavery, provided they were respectfully affurred, that they still enjoyed their ancient freedom; a feeble senate and an encraved people cheerfully acquiesced in the pleasing illusion, as long as it was supported by the virtue, or even by the prudence of the successors of Augustus. It was a motive of self-preservation, not a principle of liberty, that animated the conspirators against Caligula, Nero, and Domitian. After seventy years of patience, the senate made an ineffectual attempt to realign its long-forgotten rights. When the throne was vacated by the murder of Caligula, the confuls convoked the assembly in the Capitol, and during forty-eight hours acted as the independent chiefs of the commonwealth. But while they deliberated, the praeatorian guards had resolved: the dream of liberty was at an end; and the senate awoke to all the horrors of inevitable servitude. Deforted by the people, and threatened by a military force, that feeble assembly was compelled to ratify the choice of the praeatorians, and to embrace the benefit of an amnesty, which Claudius had the prudence to offer, and the generosity to oblige.

To cenure, to depose, or to punish with death the first magistrate of the republic, who had abused his delegated trust, was the eminent and undoubted prerogative of the Roman Senate; accordingly they condemned Nero to be put to death, as Suetonius oberves, more majorum; but on the death of Commodus, that feeble assembly was obliged to content itself with inflicting on a fallen tyrant that public justice from which, during his life and reign, he had been shielded by the strong arm of military despotism. Till the reign of Severus, the virtue and even the good fene of the empire, had been distinguished by their real or affected reverence for the Senate, and by a tender regard to the nice frame of civil policy instituted by Augustus. But Severus, trained from his youth to the deputation of military command, disdainful to profess himself the servant of an assembly that detainted his perfon, and trembled at his power: he assumed the conduct and style of a sovereign and a conqueror, and exercised, without diffiguie, the whole legislative as well as executive power. Hence the senate, neither elected by the people, nor guarded by military force, nor animated by public spirit, rested its declining authority on the frail and crumbling basis of ancient opinion. The fine theory of a republic infamibly vanished, and made way for the more natural and substantial feelings of monarchy. The polished and eloquent flaves from the Eastern provinces, by whom the Senate was filled, justified personal flattery by speculative principles of service. The lawyers and the historianst concurred in teaching that the imperial authority was held, not by the delegated commission, but by the irrevocable reafignation of the Senate; that the emperor was freed from the restraint of civil laws, could command by his arbitrary will the lives and fortunes of his subjects, and might difpoie of the empire as of his private patrimony. Pollicy, who experienced the fatal effects of the maxims and example of Severus, judilily considered him as the principal author of the decline of the Roman empire. Such was the timid ingratitude of Gallienus, that, unmindful of his obligations to the Senate and people for repelling the Alemanm from Rome, he published an edict, prohibiting the senators from exercising any military employ; and even from approaching the camps of the legions. Tacitus was chosen emperor by the Senate, and the judgment of this assembly was confirmed by the consent of the Roman people, and of the praeatorian guards. By this election the Senate regained several important prerogatives, the principal of which were the following: 1. To invest one of their body, under the title of emperor, with the general command of the armies and the government of the frontier provinces. 2. To determine the lift, or as it was then styled, the college of consuls. 3. To appoint the proconsuls and praecons of the provinces, and to confer on all the magistrates their civil jurisdiction. 4. To receive appeals through the immediate office of the prefect of the city from all the tribunals of the emperor. 5. To give force and validity by their decrees to such as they should approve of the emperor's edicts. 6. To those several branches of authority, we may add some inspection of the finances, since even in the flern reign of Aurelian, it was in their power to divert a part of the revenue from the public service. Diodorean expressed his dislike of Rome and Roman freedom, by framing a new system of imperial government, which was afterwards completed by the family of Conflantine; and as the image of the old constitution was religiously preferred in the Senate, he resolved to deprive that order of its small remains of power and consideration. The name of the Senate was mentioned with honour till the last period of the empire; the vanity of its members was still flattered with honorary dilations; and the assembly which had been so long the source, and so long the instrument of power, was respectuflly suffered to fall into oblivion. The Senate of Rome losing all connection with the imperial court and the actual constitution, was left a venerable but useless monument of antiquity on the Capitoline hill. During the Gothic war, and in consequence of the conquest of Rome by Narses, the institution of Romulus, after a period of thirteen centuries, expired; and if the nobles of Rome still assumed the title of senators, few sublernent traces can be discovered of a public council, or constitutional order. A few hundred years, and contemplate the kings of the earth soliciting an audience, as the flaves or freedmen of the Roman Senate. From the year 144 the Senate was restored and its establishment is dated as a glorious era in the acts of the city. After its revival, the confept fathers, if the expression may be ufed, were invested with the legislative and executive power; but their views seldom reached beyond the prefent day, and that day was most frequently disturbed by violence and tumult. In its utmost plentitude, the order or assembly consisted of fifty-five senators, the most eminent of whom were distinguished by the title of counfellers; they were nominated, perhaps anualy, by the people; and a previous choice of their electors, ten perons in each region or pariis, might afford a basis for a free and permanent constitution. The pope confirmed by treaty the establishment and privileges of the Senate, and expected from time, peace, and religion, the reformation of their government. The motives of public and private interest might sometimes draw from the Romans an occasional and temporary facrifice of their claims; and they renewed their oaths of allegiance to the succesors of St. Peter and Conflantine, the lawful head of the church and republic. At length the union and vigour of a public council were diffolved in a lawless city; and the Roman fee adopted a more strong and simple mode of administration. They conformed the name and authority of the Senate to a single magistrate, or two colleagues; and as they were changed at the end of a year.
SENATOR or a member of a senate.

There were two orders, or degrees, among the Roman nobility: that of the senators, and that of the knights; after these two came the people. The first hundred senators were appointed by Romulus, and called patres, fathers. Upon the union with the Sabines, Romulus, or as others say, Tullus, added a second hundred, called patres majorum gentium; this distinguished them from a third hundred, added by the elder Tarquin, and called patres minorum gentium, fathers of the lower rank.

In ancient Rome, the number of senators is commonly supposed to have been limited to three hundred, from the time of the kings to that of the Gracchi. But this must not be taken too strictly. The Senate generally had that number, or thereabouts, and upon any remarkable deficiency, was filled up again to that complement by an extraordinary creation. But as the number of the public magistrates increased with the increase of their conquests and dominions, so the number of the Senate, which was supped of course by those magistrates, must be liable also to some variation. To what number Sylla increased them is not absolutely certain; but in Cicero's time they were not less than four hundred and fifteen, as appears by his letter to Atticus, lib. i. ep. 14.

In the time of Gracchus they were fix hundred; during the civil wars they were reduced to three hundred. Julius Cæsar augmented that number to nine hundred; the triumvirs to above a thousand; and Augustus reduced them to fix hundred, according to Dion Cassius; and to three hundred, according to Suetonius. For the choice of senators belonged at first to the kings, then to the consuls, then to the centors, who in their census or survey every fifth year, appointed new senators in lieu of those dead or degraded; but at length it fell to the emperors. See Senator.

Though, for a long time, none were raised to the dignity of senators, but those most conspicuous for their prudence, &c.; yet some regard was afterwards had to their estate, lest their dignity should become debased by poverty. To hold the senatorial dignity, a yearly revenue of eight hundred thousand fities was required, which amount was to be even six and seven thousand pounds of our money. Half as much was required for the qualification of the knights. The senators who fink below this revenue, were debarred, and expunged out of the list of the centors; and this was increased by Augustus to twelve hundred thoudand.

This qualification must not be taken, as it is by some, for an annual income, but the whole estate of a senator, real and personal, as estimated by the survey and valution of the cenors.

This proportion of wealth may seem perhaps too low, and unequal to the high rank and dignity of a Roman senator, but it must be considered only as the limit to which they could be reduced; for whenever they had once, they forfeited their seats in the Senate.

In ancient Rome, a certain age was required for a senator, as is often intimated by the old writers, and by the state itself; but rarely we can discover what it was. The most usual age for entering into the number of senators was settled, by the laws of Tullus, at eighteen years; and they were obliged, by Publius, to serve ten years in the wars, before they could pretend to a civil magistracy. The State the proper age of fund for the quinarian, or the first step of honour, to the twenty-eighth year; and as this office gave an admission into the Senate, so the Genius of the learned seem to have given the same date to the senatorial age. Some writers, indeed, on the authority of Dion Cassius, have imagined it to be twenty-five years, not reflecting that Dion mentions it here as a regulation only proposed to Augustus by his favourite Maeceus. Dr. Middelton takes the quinarian age, which was the same with the senatoria, to have been thirty years complete.

The laws concerning the age of magistrates were in very ancient times; and were made to check the forward ambition of the nobles, and to put all the citizens upon a level in the pursuit of honours. And Livy tells us, that L. Villius, a tribune of the people, was the first who introduced them, A. U. 573, and acquired by it the surname of Anahil. Middlet. of Rom. Sen. p. 99.

The senators were ordinarily chosen from among the knights, or from among such as had borne the principal offices. At first the magistrates were taken wholly from among the senators; whence Tacitus calls the Senate the senary of all dignities; but after the people had been admitted to magistracies, senators were taken from among such as had discharged those offices, though before plebeians.

There was some law subsisting from the earliest times, concerning the extraction and descent of senators, enjoining that it should always be ingenous; and as their morals were to be clear from all vice, so their birth likewise from any stain of base blood. In consequence of which, when Appius Claudius, in his censorship, attempted to introduce the grandsons of freed slaves into the Senate, they were all immediately turned out again.

There are some of the laws by which the cenors were obliged to act, in the enrolment of the new, or the omission of old cenors; and when we read of any left out, without any intimation of their crime, it might probably be for the want of one or other of these legal or customary qualifications.

It was from the senatorial order alone, that all ambassadors were chosen and sent to foreign states; and when they had occasion to travel abroad, even on their private affairs, they usually obtained from the Senate the privilege of a free legation, as it was called; which gave them a right to be treated every where with the honours of an ambassador, and to be furnished on the road with a certain proportion of provisions and necessaries, for themselves and their attendants; and as long as they resided in the Roman provinces, the governors used to attorn them a number of litterers, or mace-bearers, to march before them in state, as before the magistrates in Rome. And if they had any law Suit, or cause of property depending in those provinces, they seem to have had a right to require it to be remitted to Rome.

At home, likewise, they were distinguished by peculiar honours and privileges; for at the public shows and plays they had particular seats set apart, and appropriated to them.
in the most commodious part of the theatre; and on all solemn festivals, when sacrifices were offered to Jupiter by the magistrates, they had the sole right of seating publicly in the Capitol, in habits of ceremony, or such as were proper to the offices which they had borne in the city.

The peculiar ornament of the senatorian tunic was the *latus clavus* (see Laticlavium), as it was called, being a broad stripe of purple sewed upon the fore part of it, and running down the middle of the breast, which was the proper distinction between them and the knights, who wore a much narrower stripe of the same colour, and in the same manner. The fashion also of their shoes was peculiar, and different from that of the rest of the city; this difference appeared in the colour, shape, and ornament of the shoes. The colour of them was black, while others wore them of any colour perhaps, agreeable to their several fortunes; the form of them was somewhat like to a short boot, reaching up to the middle of the leg, as they are sometimes seen in ancient statues and bas-reliefs; and the proper ornament of them was a half moon sewed, or fastened upon the fore-part of them, near the ankle.

Confuls, praetors, exiles, tribunes, &c. during the year of their magistracy, always wore the praetexta, or a gown bordered round with a stripe of purple. In which habit also, as has been signified above, all the rest of the senate, who had already borne those offices, used to affect at the public festivities and solemnities.

The senators carried their children with them to the senate, to inform them betimes of affairs of state; though these children had not admittance till seventeen years of age. Some make a distinction among the senators, and say, that besides the senators who were allowed to speak, and were asked their opinions, there were others, who, without speaking, or being ever asked their judgment; were only to follow the opinion of those they thought the most reasonable, and were hence called *pedarii*. A. Gelius gives us another notion of the pedarii, and says, those were thus called, who, having never borne the office of curule magistrate, were obliged to go to the senate on foot.

They had the name senators, q. d. old men, given them in imitation of the Greeks, who called their senate *agnusena*. So when the Athenians assembled the people to consult about the affairs of the public, the officers summoned none but such as were at least fifty years old.

The Egyptians and Persians followed the same example, after the Hebrews; and the Lacedaemonians and Carthaginians received none but such as were sixty years of age. See Conscript.

As to other matters relating to Roman senators, see the article Senate, supra.

**SENEATUS** Auctoritas. See Senate.

**SENEATUS-CONSULTUM**, a vote, or resolution, of the Roman Senate, pronounced on some question, or point of law, proposed to it. See Senate.

The senatus-consulata made a part of the Roman law: when passed, they were deposited in the temple of Ceres, under the custody of the *aediles*; and at last they were carried, by the censores, to the temple of Liberty, and put up in an armory called tabularia.

Julius Capitolinus speaks of a sort of *senatus-consulata ta- bularia*, which he says were made in reference to affairs of great moment and secrecy by the senators themselves, without the privity of the public officers, under an oath of secrecy, till their designs should be effected.

The narrative of the famous senatus-consulatum, or rather decrees, against the musician Timotheus, at Sparta, for augmenting the number of strings on his lyre, is confirmed by Paulyanis and Suibus.

This curious piece of antiquity is preferved at full length by Boethius (De Mufica, cap. 1.) Mr. Stillings Sleat (Prin. and Power of Harm. § 185,) has given an extract from it, in proof of the simplicity of the ancient Spartan music. The fact is mentioned in Athenaeus; and Calauberus, in his notes on that author (Animad. in Athen. p. 386), has inferred the whole original text from Boethius, with corrections, to which we refer the learned reader. We shall here, however, give a faithful translation of this extraordinary Spartan Act of Parliament.

"Whereas Timotheus the Miletian, coming to our city, has dishonoured our ancient music, and, defiling the lyre of seven strings, has, by the introduction of a greater variety of notes, corrupted the ears of youth; and by the number of his strings, and the novelty of his melody, has given to our music an effeminate and artificial dref, instead of the plain and orderly one in which it has hitherto appeared; rendering melody infamous, by composing in the chromatic, instead of the enharmonic; — The kings and the ephori have, therefore, reolved to pass a sentence upon Timotheus for these things: and, farther, to oblige him to cut all the superfluous strings of his eleven, leaving only the seven tones; and to banish him from our city, that men may be warned for the future, not to introduce into Sparta any unbecoming customs."

The same story, as related in Athenaeus, has this additional circumstance, that when the public executioner was on the point of fulfilling the sentence, by cutting off the new strings, Timotheus, perceiving a little flutus in the same place, with a lyre in his hand, of as many strings as that which had given the offence, and throwing it to the judges, was acquitted.

Indeed the decree only informs us, that the use of a lyre, with more than seven strings, was not allowed at this time by the Lacedaemonians; but does not prove that the rest of Greece had confined their music within the compas of seven notes; nor, consequently, acertain how many of the eleven strings were additions peculiar to Timotheus. That the outcry against the novelties of this musician was, however, not confined to Sparta, appears from a passage in Plutarch's Dialogue, where he has a lift of the innovators who had corrupted and enervated the good old melody, by additional notes both upon the flute and lyre.

"Laus of Hermione," says he, "by changing musical rhythms to the dithyrambic irregularity of ancient move, and, at the same time, emulating the compas and variety of the flute, occasioned a great revolution in the ancient music. Melanippides, who succeeded him, in like manner, would not confine himself to the old music; any more than his scholar Philoxenus, or Timotheus."

The same thing also appears from the bitter invectives to which the comic poets at Athens, especially Pherecrates and Arilopanes, gave a loose: not, perhaps, from understanding music, or being at all sensible of its effects, but from that envy which the great reputation of the musician had excited. An exalted character is a shooting butt, at which fatirists, and wicked wits, contently point their arrows; and the rage at all times wages war against whatever calls off the public attention from itself.

The abuse, therefore, of this musician, which abounds in ancient authors, is, perhaps, as great a proof of his superiority as the praise. A Greek epigram, preferred in Macrobius, informs us, that the Ephesians gave him a thousand pieces of gold for composing a poem in honour of Diana, at the dedication of the temple of that goddess; and
Sendia, in Geography, a town of New Mexico, on the Bravo; see also S. of Santa Fe.

Sendivig, a town of Hindoostan, in Behar; 45 miles S.S.W. of Patna.

Sendibera, in Botany, a genus of Delphinium, dedicated to Mr. John Sibthorp, a German naturalist, who published a work upon Vegetable Physiology, in 1751.

Sendic, in Aminta, Geography, a people of Scythia, in the country called Sendica, in the vicinity of the country of the Tauro-Scythians.

Phny.

**SENNA**, in Geography, a town of Hindoostan, in the cazar of Bickaner; 5 miles E. of Jelfemere.

**Sence**, a river of England, which rises in Leicestershire, and runs into the Anker, near Atherstone, in Warwickshire.

Send, is used by seamen, when a ship, either at an anchor, or under sail, falls with her head, or stern, deep into the trough of the sea, i.e., into a hollow made between two waves, or billows. They say the *send* much that way, whether it be a head or a stern.

Sendal, in our Old Writers, a kind of thin fine silk, mentioned in the flat, 2 Rich. II. cap. 1.

**Sendebas**, in Geography, a town of Egypt, on the east branch of the Nile; 13 miles S. of Sememud.

**Sendese**, a town of Egypt, on the Kalilis Menhri; 3 miles N. of Behnefe.

**Sendegea**, a town of Asia Minor. In Notoria; 13 miles S.E. of Bilkediri.

**Sendgeshow**, a town of Poland, in the palatinate of Sambir; 36 miles S.S.W. of Sandomirz.

**Senlir, or Sine**, in Aminta, Geography, a people of Scythia, in the country called Sendea, in the vicinity of the country of the Tauro-Scythians.
tious, and kept himself out of sight as much as possible. Notwithstanding his prudence, it is said that the tyrant engaged one of his freedmen to poison him, and that Seneca by good fortune escaped the snare. It was not long, however, before an occasion was given to the emperor to gratify his hatred against one, whom he felt as a secret censor of his vices. Under the pretence of Seneca's connection with a conspiracy, a military tribune was sent with a band of soldiers to Seneca's house, where he was at supper with his wife Paulina, and two friends. He was, without much ceremony, commanded to put an end to himself. The philosopher heard the sentence with equanimity, and only asked for time sufficient to make his will. This was refused, and turning to his friends, he said, that since he was not allowed to flow his gratitude to them in any other way, he would leave them the image of his life, as the best memorial of their friendship. He then exhorted them to moderate their grief. He embraced Paulina, and endeavoured to comfort her; but she refused any other consolation than that of dying with him. The death which he chose was that by opening his veins, and he expired in the year 65, and in the 12th year of Nero's reign. The emperor would not suffer Paulina to die with her husband; but he never recovered the loss of blood which she had experienced, before the imperial decree arrived.

The character of Nero has been greatly extolled by some writers, and not less deprecated by others; but Tacitus, without pretending to conceal his faults, inclines to a favourable opinion of him; and it is completely ascertained, that while Nero followed the precepts of his master, he appeared a good prince; and that all virtue was banished from the court, when Seneca left it.

"If," says one of the philosopher's biographers, "a writer could be estimated by his works, a purer moralit could not easily be found; for their constant tenor is that of solid virtue, tempered with humanity, and exalted by the noblest principles of theism. They are indeed marked with the timid pride inculcated by the Stoic fect, to which he chiefly adhered, though he freely adopted what he found good in others." Of his writings which have come down to us, the greater part are moral, confuting of epistles, 124 in number, and of distinct treatises on Anger, Consolation, Providence, &c. There are, moreover, seven books on physical topics, entitled "Natural Questions," in which are to be found the rudiments of some notions regarded as fundamental in modern physics.

A number of tragedies are extant, under the name of Seneca, but they are probably not his; nor is it at all known to whom they ought to be ascribed. The editions of Seneca's works are very numerous. Of the works, not including the tragedies, the most esteemed are those of Lipsius; the Variorum, 3 vols. 8vo.; the Leipzic, 2 vols. 8vo.; and the Bipontine. Of the tragedies, are the Variorum; that by Heinlin, with notes by Scaliger; and the quarto Delphin.

Seneca, in Geography, a town of America, in the county of Onondago, in New York, laid out in irlscts and squares, on the north side of Seneca Falls. The inhabitants have erected, at a great expence, flour and saw-mills, of the best kind in this place, and also a bridge across Seneca river; and as the place is central, and accessible from the eastern and western countries, it promises a rapid increase.

Seneca Creek, a creek in Maryland, which has two branches; one called Little Seneca. It empties into Potomac river, about 19 miles N.W. of the mouth of Rock creek, which separates George-town from Washington city.

Seneca Lake, a lake in Ontario county, New York, which is a handsome piece of water, from 35 to 40 miles in length, and about 2 miles wide. At the N.W. corner of the lake stands the town of Geneva; and on the E. side, between it and Cayuga, are the towns of Romulus, Ovid, Hector, and Ulysses, in Onondago county, New York. Its outlet is Scayac river, which also receives the waters of Cayuga lake, 9 miles N.E. from the mouth of Canada Saga, 18 miles below Geneva.

Seneca River, a river in the state of New York, which has an easterly course, and receives the waters of Seneca and Cayuga lakes, which lie north and south, 10 or 12 miles apart, and empties into the Onondago river, 14 miles below the Falls, at a place called the Three Rivers. The river is navigable from the lakes downwards. Within half a mile of the river is the famous salt lake.

Seneca, or Seneca, Antoine Bauderon de, in Biography, a French poet, was born at Macon in 1543. He was brought up to the bar, and pleaded for a time, rather in compliance with his father's wishes, than from his own inclination. A duel, in which he was engaged, obliged him to retire to the court of Savoy, where he had another quarrel with the brothers of a lady, who attacked herself to him; and the consequences of which caused him to withdraw to Madrid. After this he returned to France, married, and purchased the place of first valet-de-chambre to Therese, the wife of Lewis XIV. Lofing that office, on the death of the queen, he, with his family, was received into the house of the duchess of Angouleme, where for 30 years he enjoyed an honourable retreat. At her death, he fixed his residence at his native town, where he died in 1737, having attained to his 94th year. Seneca devoted himself to literature, and many of his compositions were infant in the "Mercuries," and other periodical works of the time. By his poems he has obtained a rank among the Successful votaries of the French muses. Voltaire denominated him "a poet of a singular imagination," and says, that his tale of "Kaimae" is a distinguished performance. He also speaks in praise of his "Travaux d'Apollon." His tale, entitled "La Maniere de Filer le parfait Amour," is much esteemed. He was also the author of "Remarques Historiques," with observations on the Memoirs of Cardinal de Retz.

Senecas, or Senekas, in Geography, a tribe of Indians, being one of the Six Nations. They inhabit the territory on Genesee river, at the Genesee castle. This tribe consists of about 1700 persons. They have two towns of 60 or 70 inhabitants each, on French creek, in Pennsylvania; and another town on Buffalo creek, which falls into the eastern extremity of lake Erie, on the New York shore; and two small towns on Allegany river. The Seneca Indians are wonderfully expert in the use of bows and blow-guns, with which they shoot squirrels in the woods. The blow-gun is a narrow tube, about six feet long, made of a cane-reed, or some pithy wood, through which they drive slender arrows by the force of the breath. The arrows are not much thicker than the lower string of a violin: they are generally headed with small triangular bits of tin; and round the opposite ends, for the length of two inches, they have three inches, a quantity of the down of thistles, or something like it, is bound, so as to leave the arrows at this part of such a thickness that they may but barely pass into the tube. The arrows are put in at the end of the tube that is held next to the mouth; the down catches the breath, and with a smart puff they will fly to the distance of 50 yards.

Senecay, or Grand Senecay, a town of France, in the department of the Saone and Loire, and chief place of
of a rampion, in the district of Chaloun for Salve; 3 male.
S. of Chaloun for Salve. The place contains 2,154, and
the rampion 14,612 inhabitants, on a territory of 352
kilometres, in 18 communes.

SENECIO, in Eng., an ancient name, occurring in
Pliny, derived from sene, an old man; or seneaceae, to
grow old; which is said to have been borrowed from the
fancied resemblance of its capitulei feed down to the grey or
Lamarck Histo. t. 676. Gaertn. t. 170. (Jacobsen; Gaertn. t. 170.—Clas and order,

Senecea Podagrica Superfusia, Nat. Ord. Composita Dif.

Gen. Ch. Common calyx calyculate, conical, truncated;
septae awl-shaped, numerous, parallel and converging into
cylinders at the upper part, contiguous, equal; not so nu-
merous at the base, but imbricated, withering at the tip.
Cor. compound, higher than the calyx; flowers of the disk
perfect, tubular, numerous, funnell-shaped, with a five-leafed
lobe or throat, the disk radially symmetrical, if any; many,
hairy, pubescent hairs on the flower-heads. Filaments five,
capillary, very small; authors cylindrical, tubular.
P. (in all the flowers) Germain ovate; flye
thread-threaded, the length of the flament; ligments two,
long, reversion. Peric, none, except the conical, converging
calyx. Seeds in both kinds of flowers alike, solitary, ovate,
crowned with capillary, long down. Recept, naked, flat.
Obs. Senecea of Tournesort and others, is definite of a
common radius to the corolla, whereas their Jacobea
are furnished with one. This, however, is by no means a sufficient
generic distinction. Most authors have accordingly united
them into one genus.

Efl. Ch. Receptacle naked. Down simple. Calyx cy-
lindrical, many-leaved, equal, fearly at the base; scales
dead at the tip.

In the Species Plantarum of Linnaeus we meet with only
forty species of Senecea, (to which however many others are added
in his Supplement Plantarum,) whereas Willdenow enumerates
one hundred and twenty-two. These are divided into
the four following sections, from each of which we shall
select a few species in order to give as clear and concise an
account of this extensive genus as we are able.

Sec. 1. Floribus filifloribus. Flowers without a radius.
Willd. n. 1. (S. granifolius; Jacq. 1c. Rar. v. 1.
t. 174.)—Corolla naked. Calyx ventricose, somewhat im-
bricated. Leaves thread-shaped, linear, quite entire, smooth.
—Native of the Cape of Good Hope, flowering from June to
October. Stem herbaceous, about three feet high, tawny,
reclined and branched at the top, yellowish-green, round.
Leaves sessile, flat-topped, partly spreading, revolute at the
eight, rough. Flowers terminal, white, golden-brown, with
a glaucous calyx.
Willd. n. 6. (Calacca villosa; Jacq. 1c. Rar. v. 3.
t. 580.)—Corolla naked. Leaves lyrate, hairy; the upper ones
laceolate, toothed.—Native of the Cape, and flowering from
June to September. Stem even, thick. Stems
numerous, erect, a foot high, fruited. Leaves alternate,
lyrate, obtuse, thickish; the lower ones on long flanks; all
beautifully veined. Flowers terminal, corymbose, purple,
rather small.

embace the stem, and the taper-pointed scales at the base of the calyx, which are not blackened and abrupt at the tip, as in perhaps every other Senecio.” This species varies much in the depth of the segments of its leaves. The florets of the radius are not at first revolute, but gradually become so.

S. fuscifolius. Mountain Groundsel. Linn. Sp. Pl. 1217. Eng. Bot. t. 748. “Fl. Dan. t. 869.”—Radius revolute. Leaves pinnatifid, lobed, toothed. Scales of the calyx short. Stem erect, strait, corymbose.—Common in bulky spots upon gravelly or sandy heaths, flowering in July. Root perennial. Stem three feet high, leafy, forked, rather hairy, many-flowered. Leaves numerous, cleft, with an unpleasant smell, and finely villose. Flowers yellow, but paler and smaller than in S. fuscifolius, of which some authors have confidered this as a variety, but from which it is perfectly distinct.

The remaining species of Willdenow in this section are, S. triflorus, egypius, aureus, latus, craphia, lenticis, leucanthemifolius, auritus, giganteus, telephifolius, trilobus, cicenfis, juncus, coronopifolius, multifolius, nebrodenis, glaucus, and varicosus.

Sect. 3. Floribus radiatis, radio patens; folis pinnatifidis. Flowers with a spreading radius and pinnatifid leaves.

S. hyalatus. Spleen-wool-leaved Groundsel. Wild. n. 45. (Jacobba afr periennis viscose lutea, apfieni folis; Dill. Elth. 183. t. 152. f. 184.)—Radius spreading. Leaf-flalks embracing the stem. Flower-flalk thrice as long as the leaf. Leaves halftate, finnutate.—Native of the Cape of Good Hope, flowering mostly part of the summer. Stem herbaceous, perennif, about two feet high, branched at the bottom. Leaves flalked, narrow, seven or eight inches long, very glutinous. Flowers terminal, yellow, two or three on each flalk.

S. elegans. Elegant Groundsel, or Purple Jacobba. Linn. Sp. Pl. 1218. Wild. n. 58. Curt. Mag. t. 238.—Radius spreading. Leaves hairy, vilif, pinnatifid, equal, much-spreading. Common flalk narrowed below. Calyx hairy.—Native of the Cape, flowering from June to autumn. Linnaeus gave to this annual the name of elegans, because of the beauty of its flowers, their radius being of a most brilliant purple, and their disk bright yellow; colours peculiar to this and S. sylvestris, Wild. n. 57.—The stem is about eighteen inches high, erect, branched, furrowed. Leaves at the stem-points, bright green. The figure of Curtis exhibits a beautiful variety of this species, with double flowers, whose colours are equally brilliant as when single. It occasionally produces white flowers.

S. fuscifolius. Inelegant Ragwort. Linn. Sp. Pl. 1218. Eng. Bot. t. 600.—Radius spreading, longer than the calyx; its florets elliptical and entire. Leaves pinnatifid; their segments different, somewhat linear. Plentiful on almost every wall in and about Oxford, flowering from June to October. Root annual or biennial. Stem erect, branched, much spreading, sometimes a little hairy. Leaves fefible, deeply pinnatifid, narrow, smooth, flat, rather felifly, often purplif beneath. Flowers solitary, of a bright golden yellow, on terminal, solitary, branched, corymbose flalks. The whole herb has a peculiar fmmell, somewhat like Tansy or Mugwort.

S. abrodisanifolius. Southern-wood leaved Groundsel. Linn. Sp. Pl. 1219. Jacq. Anf. t. 79.—Radius spreading. Leaves pinnatifid, jagged; leaflets linear, naked, acute. Stalks mofily two-flowered.—Native of the Auflrian Alps, flowering from July to October. Root perennial, composed of many, long, fender fibres, fhirking deep, and spreading on all sides. Stem from one to two feet high, fhirited upwards. Lower leaves biffpinatifid, flaked; upper pinatifid, fefible; all dark green above, glaucous beneath. Flowers large and fample, lemon-coloured, in terminal bunches.

S. tenuifolius. Hoary Ragwort. Wild. n. 75. Eng. Bot. t. 574. Jacq. Anf. t. 278.—Radius spreading. Leaves pinatiftad, somewhat revolute; paler and faggty beneath. Stem erect, cottony.—Found occasionally in woods, on hedges, and by roads fides, chiefly in a calcareous soil, flowering in July and August. Root perennial, rather creeping. Stem erect, wand-like, forked, leafly, corymbose at the top. Leaves numerous, alternate, embracing the stem, more or less cottony beneath, and often white with down. Flowers corymbose, bright yellow. This is certainly distinct from S. crucifolius of Linnaeus, fays the author of Englifh Botany, who is inclined to think it may rather be a variety of S. crucifolius which it more nearly resembles.

S. aquatitus. Marjor Ragwort. Wild. n. 77. Sm. Fl. Brit. 835. Eng. Bot. t. 1131. Fl. Dan. t. 784.—Radius spreading; florets elliptical. Leaves lyrate, ferrated; the lowermost obvate and undivided. Seeds smooth.—Very common in moif woods and ditches, where it flowers from July to the end of autumn. The herbage of this pe-rennial is fhirited smooth, except when it grows in dry situations, and then it is sometimes a little woolly. Stem erect, branched, purplif at the bafe, like the last species. Leaves variable in shape, from ovate to deeply pinatifid, of a much lighter green than in Jacobea. The flowers are larger, fewer in number, and of a brighter colour; but the entire sampooths of its fefels confitute the moft fhirking mark of fpecific distinction between this and the last, of which Linnaeus confidered it only as a variety. “In having the fefels both of the disk and radius quite fhirited, it differs (fays for J. E. Smith) from every other Senecio we have been able to examine.”

The remaining species of Willdenow in this section are, S. symphosius, inflatus, carnofus, acpulsus, lycites, fyrifolius, pulferus, earvaef, montanus, eypiftris, dentatus, venifius, cru-folius, specifius, cefius, uniflorus, incaenus, carnioles, parvi-florus, muricatus, leovigatus, grandiflorus, myrifolius, difi-fius, canadenfis, delphiniolus, auriculatus, auris, Bal-fmites, obovatus, and umbellatus.

Sect. 4. Floribus radiatis; folis indivisibus. Flowers with a radius. Leaves undivided.

the base, smooth above, paler and downy beneath. *Flowers*
above an inch in diameter, bright yellow; in a kind of ter-
nial corymb, the lowestest *flats* arising from the blos-
oms of the upper leaves.

Jacq. *Auct. t. 185. — Radius nearly revolute. Leaves
ovalo-lanceolate, serrated, fringed at the margin, 
very slightly downy beneath, subelliptic, unequal at the base.
— Native of *Austria* and Switzerland; flowering in July and
August. *Root* perennial, fibrous, not creeping. *Stems*
usually single, two or three feet high, erect, slightly an-
gular or grooved towards the top, pale green, purplish here
and there. *Leaves* alternate or scattered, five or six inches
long, pointed, smooth above, hairy beneath. *Flowers* very
numerous, yellow, in terminal compound corymbs.

spreading. *Flowers* corymbose. Leaves lanceolate,
serrate, nearly smooth. — Native of the south of Europe,
and occasionally though very rarely found in Britain.
It flowers in July and August. *Root* perennial, creeping.
*Stems* erect, from three to five feet high, angular, leafy,
smooth, corymbose at the top. *Leaves* alternate, serrate, sub-
lanceolate, slightly downy. *Flowers* bright yellow, in a
large, terminal corymb, with narrow, lanceolate, pointed
*flats*, and rather downy *flats*. — This is one of our rarest
British plants. The specific name alludes to its being used
by the Saracens as a vulnerary. Its qualities are astrigent,
with considerable astringency.

Outer scales of the calyx spreading. Leaves somewhat
decurrent, oblong-lanceolate, glaucous, smooth, serrate.
— Native of *Austria*, flowering from July to September.
*Root* perennial, brownish, bitter, with long white fibres.
*Stems* from two to five feet in height, much branched
upwards, serrated. *Leaves* alternate, lower ones *flats*; upper
serrate; all of them extremely glaucous and ribbed. *Flowers*
rather small, numerous, palish yellow, in terminal, com-
ound corymbs.

*Stem* simple, softly single-flowered. Leaves undi-
vided, serrate; radical ones ovate, hairy beneath. — Native of
the south of Europe, flowering from July to September.
*Root* perennial, fibrous. *Stems* perfectly simple, hairy.
*Radical leaves* thick, thickish, plain or slightly serrate on
either side of the mid-rib; *stem-leaves* small, lanceolate, nearly
wedge-shaped. *Flowers* large, terminal, mostly solitary, of
a deep yellow or orange-colour, on longish, thick, hairy
*flats*.

Jacq. Hort. Schoenbr. t. 304. — Radius spreading. *Leaves*
lanceolate, heart-shaped, and embracing the stem at the
base, smooth, densely serrate. *Stem* shrubbery. — Native of
the Cape of Good Hope, flowering from July to October.
*Root* perennial, fibrous. *Stems* numerous, annual, round,
smooth; from four to six feet high, streaked with purple.
*Leaves* alternate, somewhat hispidly, smooth, glaucous,
pointed, veined with purple. *Flowers* in terminal, thick,
compound corymbs, bright yellow; the *dyke* turning
brown.

The remaining species of this last and fourth section
described by Willdenow are the following. — *S. limi-
folius, juniperinus, rosmarinifolius, afer, friatus, cruciatus, rigescens,
pinna tus, haincianus, ovatus, coriaceus, orientalis, Barrellii, arenarius,
glabref us, aperinus, longifolius, undulatus, lysan-

S. senega. *Gardening*, contains plants of the herb-
aceous, annual, and perennial kinds, of which the species
cultivated are; the four-seamed groundsel (*S. inaurulhus*); the
Chenelle groundsel (*S. pseudo-chama*); the five-wool-
leaved groundsel (*S. haitatus*); and the elegant groundsel,
or purple Jacobea (*S. elegans*).

In the fourth species there are varieties with very double
purple, and with equally double white flowers. The former
is now chiefly cultivated.

And there are other species that may be cultivated for
variety.

Method of Culture. — The last and two last sorts are
readily increased by planting cuttings of the branches in
 pots filled with fine mould in the summer season, shading
them till they have taken root; and, as the winter ap-
proaches, removing them under the protection of the green
house, where they should remain till May, when they may
be placed out in the borders or clumps. They may like-
wise be raised from seed, which should be sown in the spring
in pots, and placed in a gentle hot-bed.

The second sort should be more carefully attended to,
being raised from offsets, which should be planted in pots in
the spring season, and be plunged in the hot-bed of the
flour, where the plants should be constantly kept.

The first and two last sorts afford variety in the borders,
and among potted plants; and the second in flower col-
lections.

**SENECA.** *Angustis, the-exuvia, or floughs of ser-
-pents. The snakes cast their whole skin, and with it were
lupposed to call off their age, and be born anew; whence
the name of these cast skins. A decoction, or infusion of
these, is recommended by medical writers against pains of
the ears and eyes, and some superstitious people recom-
ended it to women to tie about their waists, to prevent
miscarriages, and about their thighs, in time of labour to
harden delivery.

**SENEFFE, in Geography,** a town of France, in the
department of Jemappe, and chief place of a canton, in the
district of Charleroy; 13 miles N.W. of Charleroy. The
place contains 5253, and the canton 12,663 inhabitants,
on a territory of 167¼ kilometres, in 13 communes.

**SENEGA.** See *Gum Senega.*

**SENEGAL, or SENEGAMBIA,** in Geography, a country of
Africa, situated between the rivers Senegal and Gambia,
and including many kingdoms and states. It derives the
former name from the river Senegal, and the latter from
that of Gambia. According to Bruns, all the coast ex-
tending from Cape Blanco to the mountains to the N. of
Senegal, has been called Upper Senegambia. It is fre-
quently by the Moors, wandering shepherds in the desert of
Zaara or Sahara. They acknowledge the supremacy of
the emperor of Morocco; but only obey him as they find
it to be their interest. The Egyptians trade with these
people in gum; and the establishment of Portedeeck,
formed by the Dutch, and that of Arguin, have been dis-
pensed by several European nations, with inconceivable
emergence. The dreadful portrait which Mango Park has
given us of the foolish pride, perfidy, and barbarity of
the Moors of the environs of Tombeutoo, perfectly agrees
with that given by Bruns of those who inhabit the coasts.
The whole country watered by the rivers of Senegal and
Gambia has been called Senegambia, and extends, accord-
ing to Bruns, from the northern shores of Senegal to the
northern shores of Sierra Leone.
SENEGAL.

Senegal, a river of Africa, which winds in the interior of the country, and runs, after a winding course, into the Atlantic. It takes its rise by various streams in a chain of mountains, situated, according to Mr. Park's discoveries, between the 5th and 9th degrees of west longitude, and directs its course towards the N.W. Within the same space are the sources of the Gambia, which runs to the W.-N.W., and those of the Joliba or Niger flowing towards the E.-N.E. A large portion of the tract bounding on the northern foot of the mountains, whence the branches of the Senegal river issue, is covered with thick forests. One part of this tract is denominated the Jallonka wildernesses, in which no inhabitants are to be seen during nine days of forced marching. The head of the principal branch of the Senegal is about 50 geographical miles W. of that of the Joliba; and the head of the Gambia is about 100 miles W. of the Senegal. The branches of the latter are very numerous, and intersect the country for about 200 miles from E. to W., in the line of the caravan route. In Mr. Park's judgment, the Senegal river, below the falls of F'low, or Foleo, as Labat calls it, was about the bulk of the Tweed at Melro's in summer; but this was in the dry season, or Christimas; and as the river does not swell periodically, till many months after that, Mr. Park did not see it at its lowest point. And yet this was the affluentage of all the rivers, the Falemé excepted, which was itself about three feet deep at the same feason. But the Senegal is even fordable in some places before the conflux of the Falemé, according to Labat; for the Moors cross it in the dry season, and commit depredations on some of the lands to the south. However, almost all the towns and villages are placed on the south side, with a view of being in security for the longest possible term. The Senegal river is then by no means a very capital stream, except in the rainy season; when, like all other tropical rivers, its bed is filled, and it very commonly overflows. Mr. Park observed, by the mark of the highest point of swelling of the river Kokoro, or easterm branch of the Senegal, that it had been twenty feet higher than when he crossed it, in the line of the southern route. The main branch of this river, the Ba-ring, or Black river, was not fordable, and was crossed over a temporary bridge of a very singular construction. Alligators and crocodiles are found in all these rivers, at the height at which Mr. Park passed them. The Falemá river has a remote source, and drains a great extent of country. The great body of the river Senegal is precipitated from the upper level, containing the political divisions of Manding, Jallonkadu, Foolsadu, Kaffon, Gadon, and some other smaller streams, to the intermediate one; thus forming the falls of Govinea. The intermediet level contains Bambouk, Konkaddoo, Satadoo, Dentila, and some others, and is bounded on the S.W. by the great slope of country at Kirwanney, when the waters first begin to flow towards the W. On the N.W. it is bounded by the great dehient which forms the second or lower fall of the Senegal river, named F'low. This fall is about 50 miles below Govinea, 48 above fort St. Joseph; and here the river, being arrived at the lowest level of the country, continues navigable, with little interruption, to the sea. The Falemá river, of course, must run on a far lower level than the other heads of the Senegal river. The distance between Koonia-karry in Kaffon, lat. 14° 34', and the Senegal river, 13 miles points to a W.N.W. course, or therabouts, of the river between the falls; not much different from its general course, lower down. But as the Ba-fing, or principal arm of the river, must run almost directly to the N. from the place where Mr. Park crossed it, in Jallonkadu, it is highly probable that the two great branches unite at no great distance above the upper fall; the fame ridge of mountains that occasion the fall, may, perhaps, occasion a junction of the different streams above it. These falls are faid by Labat to be from 30 to 40 toifes perpendicular, or 180 to 240 French feet. The Senegal, in its course, separates the two countries of Kajaga and Kaffon.

Within six miles of the fea, the river in its course takes a sudden turn to the south, and for the remainder of its passage is divided from the fea only by a natural ridge of land, sometimes not 100 toifes over. By this curve it prolongs itself for 35 miles farther, from north to fouth, till at length it discharges itself into the ocean, in N. lat. 15° 50'. This great river separates the country of the Negroes from the Moors of Sahara, or the D. Sert, stretching by a number of windings to a prodigious length, from east to west. The extreme rapidity of this river is attributed to the space passed through by fo large a body of water, confined within fo narrow a channel; the mouth of it being no more than a mile and a half over, and that choked up with fand, called a bar, which renders the passage exceedingly difficult and dangerous. This bar is doubly dangerous, on account not only of the shallowness of the water at all times, but the shifting of the bar, and the change of its situation after floods and heavy rains, by which the channels are loft, and new foundings requisite to discover them; indeed the Senegal would be quite shut up, but for one channel of 200 toifes in breadth, and two fathoms depth, which has long kept its situation immoveable, amidst the floods and overflowing of the river. This bar prevents ships of 500 tons from entering the river, and mooring under the fort; an inconvenience that obliged the French company to keep a veifeil constantly at anchor in the channel, for no other purpose than to keep an account of the foundings. The most commodious time of the year for crossing the bar, is from the month of January till August, the winds being then variable, the river smooth, and the bar fixed till the ensuing rainy season, when the prodigious swell of the river, and south-west winds, opposed to its rapid course, raise waves of fo prodigious height at the bar, that their breaking resembles the fhook of mountains, and fo furious, as to dash in pieces the stoutest ship. After crossing the bar, it becomes a beautiful smooth, and gently gliding river, at four fathoms depth. In advancing three miles higher, the country on the south side is clothed with a beautiful verdure, the trees in perpetual bloom, than which nothing can form a more agreeable contrast to the dry, sandy, and barren points of land, that fift pr felon themselves to the shipping. All around it lie a great number of islands, pleafantly fcocked with trees, fruits, herbage, and birds, but appropriated to no ufe, except the ifland of Senegal.

Fort St. Louis, at the mouth of the Senegal river, according to the observations and refults of M. D'Anville and M. Feureiue, is placed in lat. 16° 5' (by D'Anville), long. 16° 8' by Feureiue: and Cape Verdi in lat. 14° 38', long. 17° 34' W. of Greenwich. By the treaty of 1765, the river of Senegal and its dependencies were left in the poftification of the French, who had extended their territories above 500 miles from the shore. In 1784 was founded the company of the gun of Senegal, which obtained an exclusive privilege of trading in gums, ivory, wax, and other products of the river Senegal, and dependencies, from Cape Blanco to Cape Verdi. Goree was chofen as the residence of the administrators. In 1791 this company was suppressed by the national assembly, and the trade with Senegal was declared free.

The Moors chiefly gather the gum in the three forests of 10 Sokel,
Sakel, Eliazar, and Alfectak, situated on the north of the island St. Louis. The season is the month of March, and the consumption in Europe is estimated at a thousand tons, each of 2000 pounds. In 1788, different ports in France employed in this trade 105 ships, the tonnage exceeding 35,000. The French settlement on the coast of Africa, according to Herbin, is Arguin, a little settle granted to the company of Senegal in 1727. A considerable trade in gum was maintained with the river St. Juan, which is not far distant; and by the treaty of 1783 the English obtained the right of trading with this river. On the river Senegal there were some French settlements, particularly in the Isle of St. Louis at the mouth of that river, which is a great seat of the gum trade. The white population may be about 400; but in 1801 the whole, including captives, was computed at 10,000.

SENEGAL, an island of Africa, in the river so called, about one mile and a quarter in length, from north to south, and almost half a mile in breadth, from cast to west. It is composed of a bed of loose sand, productive of nothing but what is forced by art and the richelieu manner, notwith standing which it contains 3000 inhabitants, whose principal food is fish and maize. This sort of corn grows in great plenty almost all over the whole country. It may seem surprizing, that a part of the world so very unhealthy as this, should yet be so populous, but the wonder will cease when we come to understand, that the greatest pride among the men consists in the number of their wives; so that every one takes as many as he is able to maintain; some five, others eight, and others twelve at a time. In the year 1758, this island was taken from the French by the British troops, and by the peace of 1763 it was ceded to Great Britain. N. lat. 16° 5'.

SENEGALIA, or Senegalus, in Ornithology, the Loxia afrill. See Loxia. See also Fringilla Senegala.

SENEKA, Rattlesnake-root. This is a root lately brought into use among us, and which seems to deserve very great regard. It is the root of a species of polygala, or milk-wort, (see Polygala Senega,) distinguished by Gronovius, in his Flora Virginica, under the name of the erect polygala, with a simple stalk, with oval leaves, pointed at the end, and with an erect cluster of flowers. We generally call it the rattlesnake-root, and the French, from the place whence it comes, Seneka. The plant is a native of Virginia, Pennsylvania, and Maryland, and is cultivated in some of our gardens.

The root is perennial; the thickness of it is generally about that of a man's little finger. It is four or five inches, or more, in length, and is variously contorted and twisted, and divides into many branches, furnished with small fibres, and with a membrane of it running all along it. It is yellowish on the outside, and white within, very acid, and somewhat bitter to the taste, and has somewhat of an aromatic flavour. From this root arise numerous stalks, all simple, and without branches; some lie on the ground, others stand erect. These are ten or twelve inches high, when full grown. The leaves stand alternately on the stalks, and the flowers are white, and perfectly like those of our own kinds of polygala. This root, which is brought from Virginia in bales, each containing from two to four hundred weight, is of no remarkable smell, but has a peculiar kind of frutile, pungent, penetrating taste. Its virtue is extracted both by water and spirit.

Dr. Tennent, who brought over a large quantity of this root from America some years ago, and took great pains to introduce it into practice, praises it very largely as a diuretic, a diaphoretic, and an alexipharmic, and a very powerful attendant and resolvent. He says it will sometimes vomit and purge.

The Senegaw Indians first taught the use of it to the Europeans; they esteem it a sovereign remedy against the bite of the rattlesnake; and Dr. Tennent assures us, that he saw two persons, who had been bitten by this creature, in the month of July, when their poison was most fatal, perfectly restored to health by it. The powder, or a decoction of the root, is taken internally; and either the powder or cataplasm made with it applied to the wound.

He afterwards gave it as a pleurisy and peripneumata with great success, and in all other cases where the blood is impurified. The effect of this medicine was found to be, that it made the first blood fluid, (which is contradicted by a strong fact added by Dr. Haen,) procured a plentiful perspiration, increased perforation and urine, and sometimes purged or vomited. If the first doses of it provoke a vomiting, it is not at all the worse, except in cases in which the patient is very weak; and in such this effect is easily prevented, by giving some of the telling powders with it.

In pleurisy it is best to take away ten ounces of blood, before the entering on the use of the medicine; in other cases no precaution is required, but it is to be given in powder, or tincture, in white wine, particularly Madeira wine; and the ordinary drink, during the use of it, should be marshmallow tea. Its good effects in pleurisy have been attested by several of the French academicians and others. But repeated bleeding is not to be neglected.

This medicine may be given either in powder or decoction, and combined with aromatics, opium, or camphor, which check its nauseating qualities; but Dr. Tennent prefers the decoction, having observed it to give relief sooner than the powder does. The dose of the powder is thirty-five grains, and he gives at once three spoonfuls of the decoction, prepared by boiling three ounces of the root bruised in a quart of water to nearly the half. The dose is repeated every six hours. He is also fond of this root in the rhematism, dropsy, and gout, in which last disease, he says, he has given it with successes. See his Letter concerning the Seneka, or Rattlesnake-root. The extract of it in combination with carbonate of ammonia has been found by Dr. Brandreth, of Liverpool, to be efficacious in some cases of lethergy; and in America the decoction given in divided doses, at short intervals, till it vomits, has been employed with seeming success in croup; it has also been lately used as a stimulating gargle in the same disease.

The usual dose, says Woodville, is from one scruple to two of the powder, or two or three spoonfuls of a decoction prepared by boiling an ounce of the root in a pint and a half of water till it is reduced to a pint.

SENEMBI, in Zoology, a name given by Marcgrave to the Lacerta iguana. See Lizard.

SENESCHAL, Senegalus, a name recently used for a herald or major-domo; formed from the German, hauze, house, or family, and frit, servant.

Thus the seneschal of a lord, or a baron, is his herald or bailiff, who holds his courts, and manages his demesne lands; and the sub-seneschal, his under-bailiff.

High seneschal of England is the high-bailiff of England; high seneschal del hotel de roi, is the herald of the king's household.

The office of seneschal was at all times a great office; but the jurisdiction of it increased much, when the grand
judiciary's was diminished; which did not happen till after the decease of king Henry II. Indeed these offices could not possibly have fulfilled together, in the height of their power; the functions and dignity appertaining to each of them having been nearly the same. But in the reign of Henry II. that of benevol was much inferior to the other; and the authority of it seems to have been not very different from that of the lord steward of the household at present.

The ancients used the term fenestralis indifferently with that of daphis; whence we are sure it signifies steward.

SENECHELALO et marblesal quod non teneaut placia de libero tenimento, in Lavo, a writ directed to the steward and marshall of England, inhibiting them to take cognizance of an action in that court that concerns freehold.

SENECINO, Francesco Bernardo, Detto, in Biography, called Senefino, from being a native of Siena, one of the greatest singers and the best actor who performed in Handel's operas during the Royal Academy of Music, established in the year 1720, and dissolved in 1729. He continued singing in England till the year 1735; but in an opera established by the nobility and gentry in opposition to Handel.

We have conversed with several good judges of music, who had been confidant in their attendance at the operas of those times, who always spoke of Senefino's voice, style of singing, figure, and action, in the highest terms of admiration. In early youth his voice had been a sopranino, but it had defended into the full, most melihouse, and most flexible contralto, that was ever heard in this country. He had not more than six or seven notes in his compass; but these were so mellow and powerful, and his execution of divisions fo granito, or difficil, that, without the rapidity of a bravura finger, he seemed possessed of every solid and lasting charm of a great performer. Quantz, who heard him at Dresden in 1719, gives him the following character. "Francesco Bernardo, called Senefino, had a powerful, clear, equal, and sweet contralto voice, with a perfect intonation, and an excellent shake; his manner of singing was masterly, and his elocution unrivalled; though he never loaded adagios with too many ornaments, yet he delivered the original and essential notes with the utmost refinement. He sung allegros with great fire, and marked rapid divisions, from the chiet, in an articulate and pleasing manner; his countenance was well calculated for the stage, and his action was natural and noble: to these he joined a figure that was truly majestic, but more suited to the part of a hero than a lover."

When he returned to his own country, he sung no more on a stage; but retired to Siena, the place of his nativity, where he built himself a magnificent mansion, called there a palazzo, and ended his days in splendid tranquillity.

SENESOTO, in Geography, a cape on the S.W. coast of the island of Corfica; 20 miles W. of Sarcenca.

SENEZ, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Castellane, before the revolution the see of a bishop, suffragan of Embrun; 6 miles N.W. of Castellane. The place contains 768, and the canton 2081 inhabitants, on a territory of 180 kilometres, in 4 communes.

SENTENBERG, a town of Austria; 3 miles N. of Stain.—Alto, a town of Bohemia, in the circle of Kingigratz; 3 miles N. of Geyerberg.—Alto, a town of Saxony, in the margravate of Meißen, containing about 300 houses, surrounded with ramparts and ditches; 32 miles N.E. of Meißen; M. lat. 51° 31'. E. long. 14° 1'.

SENGARA, a town of Hindoostan, in the Mewat country; 95 miles S.W. of Delhi.

SENGEN, or SENG, a town of Peru, in the province of Khorasan; 25 miles S.E. of Mesghid.

SENGEN, or SENS, a river of Switzerland, which joins the Saan river, near Laupen, in the canton of Berne.

SENGEN, or SEN-GUEN, a city of China, of the first rank, in Quang-hi. N. lat. 23° 24'. E. long. 109° 34'.

SENGERHASARA, a town of Peru, in the province of Ghilan; 69 miles N.W. of Rehfd.

SENGIN, or SEN-GUEN, a town of China, of the third rank, in Quang-hi; 25 miles N.W. of King-yuen.

SENGLEA, a town of the island of Malta, divided by a canal from Vittoriafola; and containing about 4000 inhabitants.

SENGMA, a town of Africa, in the country of Calbari; 5 miles N. of Cape Formosa.

SENOA, a town of Peru, in the province of Adirbeita or Azerbajin; 48 miles S.E. of Tauris or Taibreez.

SENGRAIN, in Botany. See Saxifrages.

SENGWARDEN, in Geography, a town of Germany, in the lordship of Kniphafen; 6 miles E. of Jever.

SENJEN, a small island in the North sea, close to the coast of Norway. N. lat. 69° 14'.

SENGAGLIA. See SINGAGLIA.

SENINGHEM, a town of France, in the department of the Straits of Calais; 9 miles W. of St. Omer.

SENIONTZ, a town of Bohemia, in the circle of Königigratz; 6 miles N. of Königigratz.

SENORE, a town of Algiers; 22 miles W. of Tiffeth.

SENI TO, a river of Naples, which runs into the Sibari.

SENITZ, a town of Hungary; 25 miles W. of Tapoloz.

SENKE, a town of Hungary; 24 miles E. of Toudfong.

SENLIS, a town of France, and principal place of a duchy, in the department of the Oise, before the revolution the see of a bishop, suffragan of Rheims; 5½ miles N.E. of Paris. The place contains 4312, and the canton 11690 inhabitants, on a territory of 2231 kilometres, in 18 communes. N. lat. 49° 12'. E. long. 2° 40'.

SENN, a town of Asiatic Turkey, in the government of Moful, on the Tigres; 80 miles S.S.E. of Moful.

SENN, or SENNAH, a most romantic and flourishing little town of Peru, in the province of Ardelan, included in the bofom of a deep valley, well cultivated and interpered with orchards of peach, apricot, pear, apple, and cherry trees. Its population amounts to about 8000 persons, of which number 2000 are Jews, Armenians, and Neitarians, who trade to Moful, Bagdad, and Ihalan. The Whalea, who seldom quits this place, resides in a fumptuous palace, built on the top of a small hill in the centre of the town, where he maintains a degree of flate and splendid superior to any thing in Peru, except at court. His house is ever open for the entertainment of strangers, and he always retains about his person a body of horse. The mountains to the W. of Senna are covered with forests of oak, which produce fine timber and abundance of gall-nuts. The former is made into rafts and floated down the Tab into the Tigres; the latter is an article of trade, and exported to India. A small river of the fame name flows about one mile and a half or two miles from it. The route from Tabrez by way of Mirago to Senna is 223 miles; that from Senna by Kermanshaw to Bagdad is 303 miles; and that from Senna to Hamadan is 89 miles.

SENN,
though these people are Mahometans, they are so brutal with regard to their women, that they sell their slaves after having lived with them, and even after having had children by them. The king himself, it is said, is often guilty of this unnatural practice, utterly unknown in any other Mahometan country. Once in his reign the king is obliged, with his own hand, to plow and sow a piece of land. From this operation he is called Bada, the countryman or peasant; and this name is common to the whole race of kings, as Cesar was among the Romans.

No horse, mule, ox, or any beast of burden, will breed or even live at Sennar, or many miles about it. Poultry does not live there. Neither dog nor cat, sheep nor bullock, can be preferred there for a season. All of them must be removed every half year to the lands. Though all possible care be taken of them, they die in every place where the fat earth is about the town during the first season of the rains. Hence, it appears that the soil of Sennar is very unfavourable both to man and beast, and particularly adverse to their propagation. This circumstance is ascribed by Bruce to the noxious quality of the fat earth; for this noxious quality is not known in the lands. Aira, between three and four miles from Sennar, which has no water near it but the Nile, surrounded with white barren sand, agrees perfectly with all animals. Nevertheless this soil contributes very abundantly to the nourishment of man and beast. It is said to render 300 for 1; though this must be an exaggeration; as is shown with dura or mellet, which is the principal food of the natives. The salt used at Sennar is wholly extracted from the earth about it, especially at Halsaia, in lat. 15° 45' 54". E. long. 32° 49' 15", is strongly is the soil impregnated with this useful fulfil. Halsaia is a large, handsome, and pleasant town, though built with clay. The houses are terraced at the tops. This town is the limit of the rains, and is situated upon a large circular peninsula, surrounded by the Nile from S.W. to N.W. about half a mile from the river. It consists of about 500 houses, and derives its principal gain from a manufacture of very coarse cotton cloth, called Densour, which serves for small money through all the lower parts of Atbara. The people here eat cats, and also the river-horse and the crocodile, which are very plentiful.

About twelve miles from Sennar, nearly to the N.W. is a collection of villages called Shadly, from a great fault, who in his time directed large pits to be dug, and platted closely with clay, into which a quantity of grain was put when it was at the cheapest, and these were covered up, and platted again at the top, which they call fealings, and the hole itself matamore, These matamores are in great number all over the plain, and, on any prospect of corn growing dearer, they are opened, and corn sold at a low price both to the town and country.

To the north of Shadly, about twenty-four miles, is another foundation of this sort, called Wed-Aboud, still greater than Shadly. Upon these two characters the chief subsistence of the Arabs depends; for as there is continual war among these people, and their violence being always directed against the crops rather than the persons of their enemies, the destruction of each tribe would follow the loss of its harvest, was it not for the extraordinary supplies furnished at such times by their granaries.

The small villages of Teldires are scattered up and down through this immense plain to watch the grain that is sown, which is dora only, and it is said that here the ground will produce no other grain. Prodigious excavations are made at proper distances, which fill with water in the rainy season, and are a great relief to the Arabs in their pal-
tween the cultivated country and the sands. The fly, that
incororable persecutor of the Arabs, never pursues them
to the north of Shaddly. The knowledge of this circumstance
was what, perhaps, determined the first builders of Sennaar
to place their capital here; this too, probably, induced the
two saints, Shaddly and Wed Aboud, to make here these
vast excavations for corn and water. This is the first rift-
ing-place the Arabs find, where, having all things necessary
for subsistence, they can at leisure tranfact their affairs with
government.

To the westward of Shaddly and Aboud, as far as the
river Abiad, or El-ace, the country is full of trees, which
make it a favourite itation for camels. As Shaddly is not
above three hours ride on horfecake from Sennaar, there
could not be chozen a situation more convenient for leying
the tribute; for though Gerri, from the favourable situa-
tion of the ground, being mountainsous and rocky, and jut
on the extremity of the rains, was a place properly chozen
for this purpole by the Arab prince before the conquest of
the Funge, (for his troops there cut them off, either from
the sands, or the fertile country, as he pleased), yet many of
them might have remained behind at Shaddly, and to the
westward, free from the terror of the fly, and confequently
without any neceffity of advancing for far north as Gerri,
and there subjeeting themselves to contribution.

In this extensive plain, near Shaddly, arife two moun-
tainsous driftrits, the one called Jibbel Moia, or the Moun-
tain of Water, which is a ridge of confiderable hills nearly
of the fame height, clothly united; and the other Jibbel
Segud, or the Gold Mountain, a broken ridge compofed
of parts, some high and some low, without any regular form.
Both these enjoy a fine climate, and are full of inhabitants,
but of no confiderable extent. They ferve for a protection
to the Dahera, or farms of Shaddly and Wed Aboud.
They are alfo fortrefles in the way of the Arabs, to detain
and force them to payment in their flight from the cultivated
country and rains to the dry lands of Atbara. Each of
these driftrits is governed by the defendant of their ancient
and native princes, who long refitted all the power of the
Arabs, having both horfe and foot. They continued to be
Pagans till the conquest of the Funge. Bloody and un-
natural sacrifices were faid to have been in use in thefe
mountainous flates, with horrid circumftances of cruelty,
till Abdeleader, fon of Amru, the third of the kings of
Sennaar, about the year 1554, befieged firft the one and
then the other of these princes in their mountain, and forced
them to surrender; and, having fattened a chain of gold to
each of their ears, he expoed them in the public market-
place at Sennaar in that situation, and fold them to the
highelt bidder, at the vile price of something like a farthing
each. After this degradation, being circumcifed, and con-
verted to the Mahometan religion, they were refored each
to their government, as slaves of Sennaar, upon very easy
conditions of tribute, and have been faithful ever since.
Nothing is more pleafant than the country around Sennaar,
in the end of Auguft and beginning of September, I
mean (fays Bruce) fo far as the eye is concerned; instead of
that barren, bare waste, which it appeared on our arrival in
May, the corn now sprung up, and covering the ground, made
the whole of this immense plain appear a level, green land,
interperfed with great lakes of water, and ornamented at
certain intervals with groups of villages, the conical tops of
the houfes preffing, at a distance, the appearance of small
campaments. Through this immense, extenfive plain, winds
the Nile, a delightfull river there, above a mile broad, full
to the very brim, but never overflowing. Every where on
these banks are feen numerous herds of the moft beautiful
cattle of various kinds, the tribute recently extorted from
the Arabs, who, freed from all their vexations, return home
with the remainder of their flocks in peace, at as great a
distance from the town, country, and their oppressors, as
they possibly can.

The banks of the Nile about Sennaar refeemble the ple-
fant parts of Holland in the summer fefon; but foon after,
when the rains caele, and the fun exerts his utmoft
influence, the dora begins to ripen, the leaves to turn yel-
low and to rot, the lakes to putrefy, Smell, and be full of
vermin, all this beauty suddenlly disappears; bare, focheched
Nubia returns, and all its terrors of poifonous winds and
moving sands, glewng and ventilated with fultry blasts,
which are followed by a troop of terrible attendants,
epilepsies, apoplexies, violent fevres, obfinate agnes, and
lingering, painful dyenteries, still more obfinate and
mortal.

War and treafon feem to be the only employment of this
horrid people, whom heaven has seperated, by almost im-
pallable deferts, from the reft of mankind, confining them
to an accurfed spot, seemingly to give them earneft time
(as Mr. Bruce forebodes) of the only other worfe which he
has referved to them for an eternal hereafter.

The drefs of Sennaar is very fimple. It confifts of a long
fhirle of brown Satrat cloth called Morowty, which covers
them from the lower part of the neck down to their feet,
but does not conceal the neck itself; and this is the only
difference between the men's and the women's dreffes; that
of the women covers their neck altogether, being buttoned
like ours. The men have fometimes a fath tied about their
middle; and both men and women go bare-footed in the
houfe, even thofe of the better fort of people. Their floors
are covered with Perifian carpets, efpecially the women's
apartments. In fair weather, they wear tandals; and with-
out doors they ufe a kind of wooden patten, very neatly
ornamented with fehels. In the greatest heat at noon, they
order buckets of water to be thrown upon them instead of
bathing. Both men and women anoint themfelves, at leaft
once a day, with camels' grease mixed with civek, which
they imagine softens their skin, and prefserves them from
cutaneous eruptions, of which they are fo fcarcd that the
ftallcs pimple in any viil part of their body keeps them in
the house till it disappears: for the fame reafon, though
they have a clean ftirt every day, they ufe one dipt in
grege to lie in all night, as they have no covering but this,
and lie upon a bull's hide, tanned, and very much ftofened
by this contant greating, and at the fame time very cool,
though it occafions a fmal that no walking can free them
from.

The principal diet of the poorer fort is millet, made into
bread or flour. The rich make a pudding of this, toaffing
the flour before the fire, and pouring milk and butter into
it; befides which, they eat beef, partly roasted and partly
raw. Their horned cattle are the largest and fattelf in the
world, and are exceedingly fine; but the common meat
fold in the market is camel's flefh. The liver of the animal,
and the spare rib, are always eaten raw through the whole
country. Bruce never faw one infance where it was drefed
with fire; it is not then true that eating raw flefh is peculiar
to Abyssinia; it is practifed in this infance of camels' flefh
in all the black countries to the westward.

Hogs' flefh is not fold in the market; but all the people
of Sennaar eat it publicly: men in office, who pretend to
be Mahometans, eat theirs in secret.

There are three principal governments in the kingdom
of Sennaar. The firft is at El-ace, the capital of that coun-
try, from which the Shillook came. The Babar el Abiad
spreads
frees itself all over the territory, and, divided into a quantity of small channels, (whether by art or nature we know not,) surrounds a number of little islands, upon each of which is a village, and this collection of villages is called the town of El-aice. The inhabitants are all fishermen, and have a number of boats, like canoes, in which they fish up and down to the cataracts. With incredible fleets of these their invasion was made when they undertook the conquest of the Arabs, who had not the smallest warning of the attempt. They had, at that time, no weapons of iron; their swords and lances were of a hard wood called Dengui-Sibber. It must be a relation of the Mek of Sennaar that commands at El-aice; and he is never suffered to leave that pool, or come to Sennaar.

The second government, next to this in importance, is Kordofan. The revenue consists chiefly in slaves procured from Dyre and Tegla. It seems this situation is the most convenient for invading those mountains, either from its having water in the way, or from some other circumstance that is not known. Mahomet Abu Kalec had this government, and with him about 1000 black horse, armed with coats of mail, with whom he maintained himself at this time independent of the king. It is a frontier near to Dar-Fows, a black state still more barbarous, if possible, than Sennaar, and by them it often has been taken from Sennaar, and again retaken.

The third government is Fazuelo, bounded by the river El-aice on the west, and the Nile on the east, and the mountains of Fazuelo, where are the great cataracts, on the south. These are part of the large chain of mountains of Dyre and Tegla, which reach so far westward into the continent, from whence comes the chief supply both of gold and slaves which constitute the riches of this country; for the greatest part of the revenue of Fazuelo is gold; and the person that commands it is not a Funge, but the same native prince from whom the army of Sennaar conquered it. This seems to be a very remarkable piece of policy in this barbarous nation, which must have succeeded, as they constantly adhere to it, of making the prince of the state they have conquered their lieutenant in the government of his own country afterwards. Such was the cafe with Dongola, whose Mek they continue; also with Wed Ageeb, prince of the Arabs, whom they subdued; and such was the cafe with Fazuelo, Wed Aboud, Jibbel Mois, and other petty states, all of which they conquered, but did not change their prince.

The forces at Sennaar, immediately around the capital, consist of about 14,000 Nuba, who fight naked, having no other armour but a short javelin and a round shield, very bad troops, as Bruce supposes; about 1600 horse, all black, mounted by black slaves, armed with coats of mail, and without any other weapon but a broad Scelavonian sword. These, he supposes, by the weight and power of man and horse, would bear down, or break through double the number of any other troops in the world; nobody, that has not seen this cavalry, can have any idea to what perfection the horse rides here. The Mek has not one musket in his whole army. Besides these horse, there is a great, but uncertain number of Arabs, who pay their tribute immediately to the Mek and to the great men in government, and live under their protection close by the town, and thereby have the advantage of trading with it, of supplying it with provisions, and, no doubt, must contribute in part to its strength and defence in time of need.

The diseases of Sennaar are the dysentery, or bloody flux, fatal in proportion as it begins with the first of the rains, or the end of them, and return of the fair weather. Intermittening fevers accompany this complaint very frequently, which often ends in them. Bark is a sovereign remedy in this country, and seems to be by so much the furer, that it purges on taking the first dose, and thus it does almost without exception. Epileptics and leprous have are likewise very frequent, owing, as is supposed, to their debasing or diminishing perispiration, or stopping the pores by constant usection, as also by the quantity of water they deluge themselves with at the time they are hottest.

The elephantiasis, so common in Abyssinia, is not known here. The small-pox is a disease not endemic in the country of Sennaar. It is sometimes twelve or fifteen years without its being known, notwithstanding the constant intercourse they have with, and merchandizes they bring from Arabia. It is hkwise said this disease never broke out in Sennaar, unles in the rainy season. However, when it comes, it sweeps away a vast proportion of those that are infected; the women, both blacks and Arabs, those of the former that live in plains, like the Shillook, or inhabitants of El-aice, those of the Nuba and Guba, that live in mountains, all the various species of slaves that come from Dyre and Tegla, from time immemorial have known a species of inoculation which they call Tihettee el Juddeere, or, "the buying of the small-pox." The women are the conductors of this operation in the fairest and driest season of the year, but never at other times. Upon the first hearing of the small-pox any where, these people go to the infected place, and, wrapping a fillet of cotton cloth about the arm of the person infected, they let it remain there till they bargain with the mother how much she is to sell them. It is necessary that the terms be discussed judicially, and that the bargain be not made collusively or gratuitously, but that one piece of silver, or more, be paid for the number. This being concluded, they go home, and tie the fillet about their own child's arm; certain, as they say, from long experience, that the child infected is to do well, and not to have one more than the number of pultules that were agreed and paid for. There is no example, as far as Bruce could learn, either here or in Abyssinia, of this disease returning, that is, attacking any one person more than once.

The trade of Sennaar is not great; they have no manufactories, but the principal article of consumption is blue cotton cloth from Surat. Formerly, when the ways were open, and merchants went in caravans with safety, Indian goods were brought in quantities to Sennaar from Jidda, and then dispersed over the black country. The return was made in gold, in powder called Tibbar, civet, rhinoceros's horns, ivory, offish feathers, and, above all, in slaves or ghas, more of which was exported from Sennaar than all the east of Africa together. But this trade is almost destroyed, for it is that of the gold and ivory. However, the gold still keeps up its reputation of being the pured and best in Africa, and therefore bought at Mocha to be carried to India, where it all at last centers. If the weight of Abyssinian gold falls at 16 patakas, the Sennaar gold falls at the same price for 22 patakas. The ivory falls at 15 oz. per rotol at Cairo, which is about 25 per cent. lighter than the rotol of Mocha. Men-foaves, at a medium, may be about a wakea per head at Sennaar. There are women, however, who fell for 14 or 14 wakeas. What their peculiar excellencies may be, which so far alters the price, Bruce could not tell, only they are preferred by rich people, both Turks and Moors, to the Arab, Circassian, and Georgian women, during the warm months in summer.

The Daveina Arabs, who are great hunters, carry the ivory to Abyssinia, where they are not in fear. But no
Sennaar comes now from Sudan (Nigritia) to Sennaar, nor from Abyffinia or Cairo. The violence of the Arabs, and the faithfulness of the government of Sennaar, have hutt them up on every side but that of Jidda, whither they go once a-year by Suakem.

The wakea of Sennaar, by which they fell gold, civet, scented oils, &c. confisits of 10 drachms; 10 of these wakeas make a rotol. This wakea at Sennaar is accounted the fame as that of Maluah and Cairo. It is equal to 7 drachms 57 grains troy weight.

1 Rotol = 10 Wakeas.
1 Wakea = 10 Drachms.

But there is another wakea used by the merchants called the Atareys.

1 Rotol = 12 Wakeas.
1 Wakea = 12 Drachms.

But this is only used for coarce goods. There is but one long measure in Sennaar, called the Drai, which is the peck, or cubit, and is measured from the centre of the elbow-joint to the point of the middle finger. This is probably the ancient cubit of Egypt, and of the holy scripture.

Bruce’s Travels, vol. iv.

Sennaar, a city of Africa, and capital of the kingdom of the fame name, situated on the W. side of the Nile, and close upon its banks. The ground on which it stands rises just enough to prevent the river from entering the town, even in the height of the inundation, when it comes to be even with the street. Poncet says, that when he was at this city, his companion, father Brevedent, a Jesuit, an able mathematician, on the 21st of March 1699, determined the latitude of Sennaar to be 13° 4' N. The difference therefore will be about half a degree. The reader however may implicitly rely on the situation given by Poncet, being the mean result of above fifty observations, made both night and day, on the most favourable occasions, by a quadrant of three feet radius, and telescopes of two, and sometimes of three feet focal length, both reflectors and refractors made by the best makers.

The town of Sennaar is very populous, there being in it many good houses after the fashion of the country. Poncet says, in his time they were all of one story high; but now the great officers have all houses of two. They have parapet roofs, which is a singular construction; for in other places, within the rains, the roofs are all conical. The houses are all built of clay, with very little straw mixed with it, which sufficiently shews the rains here must be less violent than to the southward, probably from the distance of the mountains. However, when Poncet was there, a week of constant rain happened, and on the 30th of July the Nile increased violently, after loud thunder, and a great darknes to the south. The whole fiream was covered with wrecks of houses, cases, wooden bowls, and platters, living camels and cattle, and several dead ones passed Sennaar, hurried along by the current with great velocity. A hyena, endeavouring to cross before the town, was surrounded and killed by the inhabitants. The water got into the houses that stand upon its banks, and, by rising several feet high, the walls melted, being clay, which occasioned several of them to fall. It seemd, by the floating wreck of houses that appeared in the fiream, to have destroyed a great many villages to the southward towards Fazuo.

It will not be thought surprizing, considering the latitude of Sennaar, that the heats should be excessive. The thermometer rises in the shade to 110°. Nevertheless, from 70° to 78° Fahrenheit’s thermometer, the air is cool; from 79° to 92° temperate; at 92° it begins to be warm. N. lat. 13° 34' 36". E. long. 33° 30' 30". For further particulars relating to this city see the preceding article.

SENNE, a river of France, which enters the Demer, a little below Malines.

Sennecy, Grand. See Senecy.

Senneterat, an island near the W. coast of West Greenland. N. lat. 61° 28'. W. long. 47° 35'.

Sennertus, Daniel, in Biography, an able and learned physician, was born at Bredlaup, in Silefia, on the 25th of November, 1572, where his father was a shoemaker, and died in his childhood. He received his early education in his native city; under the direction of his mother, and was then sent to the university of Wittemberg, in the year 1593, where he exhibited such proofs of acuteness of mind and solidity of judgment, that every opportunity was afforded him, by visiting the other celebrated universities of Germany, especially those of Leipfice, Jenf, Francfort on the Oder, and Berlin, of cultivating his talents. He returned to Wittemberg in 1601, and received the degree of doctor in September of that year, and in the same month of the following year was appointed to a professorship of medicine. In this office his eloquence and knowledge were calculated to raise him to a high reputation, and his luminous method of teaching brought crowds of pupils to his lectures. He also endeavoured, by means of various publications with which he enriched the profession among his contemporaries, to affit him in cultivating the science of medicine. By these means his reputation became so extensive, that patients came to him from all parts of the world, and he refused his affliance to nobody. He took what was offered for his trouble, but demanded nothing, and even returned to the poor what they gave him. The plague prevailed seven times at Wittemberg, while he was professor there; but he never retired, nor was ever known to refuse to visit the poorest sick. George I., elector of Saxony, whom he had cured of a dangerous illness in 1629, appointed him one of his physicians in ordinary; but with the permission to remain at Wittemberg, that the world might continue to derive the benefit of his public instructions. He was three times married, and had seven children by his first wife, three of whom survived him. He was at length carried off by an attack of the plague, which was raging in Wittemberg, in the month of July 1637, in the sixty-fifth year of his age.

Sennertus was a voluminous writer, and has been characterized, by some critics, as a mere compiler from the works of the ancients. It is true that his writings contain an epitome, but, it must be added, a most comprehensive, clear, and judicious epitome, of the learning of the Greeks and Arabs, which renders them, even at this day, of considerable value as books of reference, and which are highly creditable, considering the age in which they were composed, to his learning and discrimination. The freedom, indeed, with which he impugned many of the doctrines of the ancients, called up many opponents, and led him into much controversy. He was the first to introduce the study of chemistry into the university of Wittemberg, and demonstrated his freedom from the shackles of ancient opinion, by combining much of the chemical with the Galenicai doctrines; an union which the mere advocates of antiquity strongly deprecated, as well as the introduction of chemical medicines. His treatise “De Confusio et Difflae Galenicorum et Peripateticorum cum Chymicis,” 1619, may be said to have introduced a new fire into Germany by this union. His various works have been collected together, and published at different times and places, under the title of “Opera omnia;”
but they were principally promulgated by limidure under the following titles: "Quarto Institutionum Medica trium controversiarum Libri:" 1609. "Institutiones Medicae, de Originie am-
serum in Brux.; 1611. "Epitome Scientiarum Natu-
"De Sertorius Prætutus;" 1624. "Practica Medicæ,
Liber prius;" 1628. Five other books of the same work
were successively published. "Practica Medicæ &
Tractatus de Arthritis;" 1641. "Epitome Institutionum
Medicæam disputatuum 18 componib.;" 1651. "Epitome
Init. Med. et Librorum de Fabrius;" 1654. "Hyppomnesta phytica;" 1655; and
at or two small works of his note. Almost all thes
works have passed through many editions and tran-
lations.

Senni, (of sennin and Binit,) a sort of flat, braided
cordage, formed by plaiting five or seven ropes to-
togtl. This is beaten smooth and flat with a hammer,
and forced to keep the ropes to which it is applied
from

Sennor, in Geography, a small island in the Medi-
terranean, near the coast of Naples. N. lat. 41° 3'. E. 110'.

Sena, a river which rises in the N. part of Etruria,
crosses the department of the Amone, in Italy, and runs
into the S. branch of the Po, between Ferrara and the
Adriatic.

Senogu, a town of New Navarre; 270 miles S.E. of
Cata Grande.

Senomaly, a town of Bohemia, in the circle of
Rakotz; 5 miles W.S.W. of Rakonitz.

Senonca, a town of Naples, in Lavora; 43 miles
W. of Cuma.

Senones, a town of France, in the department of
the Eure and Loire, and chief place of a canton, in the
district of Dreux; 9 miles W. of Chateaueneuf. The place
contains 1,856, and the canton 7,541 inhabitants, on a terri-
tory of 205 kilometres, in 12 communes.

Senone, a river of France, which runs into the Meurte,
5 miles S.E. of Nancy.

Senones, a town of France, in the department of
the Vosges, and chief place of a canton, in the district of
St. Die; 9 miles S. W. of Salem. The place contains
1,809, and the canton 10,979 inhabitants, on a territory
of 215 kilometres, in 19 communes.

Senones, in Ancient Geography, a people of Gallia Cel-
tica, who occupied nearly the whole extent of the dioce-
e of Sens and that of Auxerre, according to the ancient divisions
of France. According to Caesar, they were confined to
Begica. This author says of them: "off civitas in primis
firma, et magne apud Gallos authentatia."—Alfo, a people
of Italy, in Gallia Cispadana, upon the borders of the
Adriatic sea. Their arrival in Italy may be fixed in the year
before the vulgar era 397. Having joined a leader named
Aruns, who wished to avenge himself of one of the Leu-
cens in Etruria, they passed the Alps in a numerous body,
and traversed the plains watered by the Po, where other
Galla were already established, and arrived on the other side
of the river, in Umbria, fully occupied by its ancient inha-
britants. They established themselves from the Utis as far
as the Ceis, having the Adriatic sea to the N.E. and the
Apennines to the S.W. After having spent about six years in
forming their establishments, Aruns conducted them to
Clufium, to besiege that place, where his wife and her
relations were. The Romans, whole nation was reduced,
took part with the inhabitants of Clufium, and joined the
troupes of that city. The Senones were indignant, and de-
termend to do themselves justice. Accordingly they marched
towards Rome, and penetrated into the city, in defense of
the army that was opposed to them. The Capitol made
a vigorous resistance; till at length Camillus arrived,
defeated the Senones, and rescued Rome. About 262 years
after this expedition they engaged in a war, and were over-
powered in the year of Rome 465, by M. Cursus Cestinum
and P. Cornelius Rufinus. They were afterward driven
from the whole country which they occupied, from the Alps
to the Rubicon. A colony was sent into their country,
which assumed the name of "Sena Gallia." Seven years
afterwards they were almost entirely exterminated by Della-
becia.

Senople, See Senople.

Senora, in Geography. See Senora.

Sernonca, in Botany, a name by which some authors
have called the banana-tree, or mapp fritti brewer. 

Senosad, in Geography, a town of Bohemia, in the
circle of Cratia; 20 miles S.S.W. of Cratia.

Senosecz, or Senoseich, a town of Carniola; 8
miles S.W. of Cirkinitz.

Senra, Senara, or Serra, in Botany, a genus of
Cavausses, upon which different authors have bestowed
the above appellations. None of these, however, been satis-
factory, for it has been suggested, that Senra would be a
preferable name to any of the foregoing. We are ignorant
Nat. Ord. Malvaceae, Jull.

Gen. Ch. Cal. Perianth double, permanent; outer of
three, heart-shaped, roundish leaves; inner very small,
of one leaf, cloven half way down into five segments. Car.
of five petals, malvaceous, tubular. St. Filaments com-
monly ten, united, placed on the upper superficies of the
tube; anthers kidney-shaped. Pith. Germen ovulate, con-
celed in the tube, surrounded by four membranes, or rather
by a single four-toothed membrane; style simple, five-cleft.
Stigma globose. Peric. Fruit ovulate, downy. Seeds ten,
oblong, kidney-shaped.

Ell. Ch. Calyx double; outer of three leaves; inner
five-toothed. Petals five. Style five-cleft. "Capule
five-celled?" 1. S. angulata. Cavan. Diff. 2. 1. 35. f. 3. Willd.—Na-
tive of Arabia, opposite the Island Socotra. The whole
plant is white with down, whence its specific name. Stem
scarce three inches high, flat, heart-shaped, solitary. Leaves alternate,
filated, heart-shaped, ovate, truncated, terminating with three notchs. Flowers axillary, solitary, nearly fel-
le, probably yellowish.

Described by Cavamines from a dried specimen, which
was communicated to him by Sir Joseph Banks. It appears
to be allied both to Malvaceae and Malvaceae.

Sens, in Geography, a town of France, and principal
place of a district, in the department of the Yonne, situate
on the Yonne. Before the revolution it was the seat of
an abbey, and contained 16 parish churches, and 14 abbeys
and convents. In the reign of Edward III. and Henry V.
Sens was taken by the English; 24 p. As N.N.W. of Dijon.
The place contains 16,500, and the canton 21,847 inhabi-
tants, on a territory of 2574 kilometres, in 23 communes.
N. lat. 45° 12'. E. long. 3° 27'.—Allo, a town of
France, in the department of the Ille et Vilaine; 14
miles N.N.E. of Rennes.—Allo, a town of France, in the
department of the Saône et Loire; 7 miles N.N.E. of
Louvain.

Sensabary, a town of Bengal; 70 miles N. of
Nulbin.
Sensation, a town of Africa, in the kingdom of Fez, near a mountain of the same name; 25 miles S. of Tetuan.

Sensation, in Physiology, a general term denoting the effect produced in the mind by the impressions of external bodies on our organs of sense, by various changes in the internal organs, and by affections of any parts of the body which poises nerves. The appropriate external objects, being presented to the eyes, ears, nose, tongue, or skin, give us the sensations of those parts respectively the organs: hunger and thirst, nausea and sicknese, griping, fainting, agitation, &c. are the results of particular states of internal organs: fatigue is caused by exertion of the muscular system; mechanical or chemical applications to any parts poising nerves cause pains of all kinds and degrees. Thus feeling, hearing, smelling, tasting, and touching; hunger and thirst, sicknese, fainting, &c.; and all the agreeable or disagreeable effects produced by external objects acting on our frame, are so many modes of sensation, so many states of existence, accompanied each with a peculiar feeling or act of consciousness.

In the first place, sensation requires a healthy condition of the external organs of the brain, and of the nerves which pass between the organs and the brain. The absence of either of these conditions destroys sensations: if the optic nerve be divided there is no seeing, although the eye and brain be healthy; if the brain be compressed, the nerve and the eye remaining unaffected; or if the eye be diseased, the nerve and the brain being found, vision is destroyed. The same is the case with the general feeling of the frame; if the nerves of a limb be divided, or the brain be compressed, there is no sensation; a pin might be thrust into the part without being felt. The dependence of the internal feelings on the brain is not so clearly made out in every instance. On the whole, however, physiologists consider it as established, that sensation is the function of the nervous system. On this subject, as well as on the phenomena of sensation exhibited by the brain and nerves, we refer to Brain, Physiology of the, to Life, and Nervous System.

As there are so many different phenomena included under the common term of sensation, what is the point in which they agree? What is the character by which they are all recognized as sensations? It is the feeling excited, the ceaseless analysis of a new mode of existence, the modification which the sentient being experiences. Sensation in short is feeling.

This is the only point in which the various sensations agree; independently of this there is little resemblance, or even analogy between them. Hearing is no more like seeing, and either of these is no more like hunger or thirst, than a muscle is to a nerve or the skin.

Sensations may be reproduced without any external objects, by an active state of the brain; thus in dreams we pass through scenes, and experience feelings, which are not distinguishable from real occurrences.

Sensation, according to Dr. Reid, is a name given by philosophers to an act of mind, which may be distinguishable from all others by this, that it hath no object distinct from the act itself. Pain of every kind is an uneasy sensation. The pain and the feeling, he says, are one and the same thing, and cannot be disjoined even in imagination. Pain, when it is not felt, has no existence. The same observation may be applied to every other sensation. This author adds, that when we have acquired a distinct notion of that simple act of the mind called sensation, we shall be able the more easily to distinguish it from every external object that accompanies it, and from every other act of the mind that may be conjoined with it. Hence it is of importance, that the name of sensation should, in philosophical writings, be appropriated to signify this simple act of the mind, without including any thing more in its significance, or being applied to other purposes. The word feeling, which signifies the perceptions we have of external objects by the sense of touch, is also used to denote the same thing as sensation; in which sense it has no object, the feeling and the thing felt being one and the same. He acknowledges, however, that between, being taken in this last sense, and sensation, there may be this small difference; that sensation is more commonly used to signify those feelings which result from our external senses and bodily appetites, and all our bodily pains and pleasures. But there are feelings of a nobler nature, accompanying our sensations, our moral judgments, and our determinations in matters of taste, to which the word sensation is less properly applied.

Dr. Reid, in another place, observes, that almost all our sensations have corresponding sensations, which constantly accompany them, and, on that account, are very apt to be confounded with them. Hence the names of most of our sensations become ambiguous, and this ambiguity hath very much perplexed philosophers. He alleges several facts that serve to illustrate and evince this ambiguity, in reference to the names we have for smells, tastes, sounds, and for the various degrees of heat and cold, which names denote both a sensation, and a quality perceived by means of that sensation. The caufe is the fame with respect to many operations of mind to which we give one name, and which we always consider as one thing; and yet they are complex in their nature, and made up of several more simple ingredients; of which ingredients sensation very often reckons one. Indeed, the number of our sensations and feelings is prodigious; and the most general and important division of them is into the agreeable, the disagreeable, and the indifferent.

The preceding remarks serve to evince the importance of distinguishing carefully between our sensations and that perception of external objects which is constantly conjured with them. Sensation, says this author, taken by itself, implies neither the conception nor belief of any external object. It supposes a sentient being, and a certain manner in which that being is affected, but it supposes no more. But perception, in his view of it, implies an immediate conviction and belief of something external; something different both from the mind that perceives and from the act of perception. Things so different in their nature ought to be distinguished; but by our constitution they are always united. Every different perception is conjured with a sensation, that is proper to it. The one is the sign, the other the thing signified. They coalesce in our imagination; they are united by one name, and are considered as one simple operation. To the philosopher it belongs to distinguish between them.

Our author elsewhere observes, that when certain impressions are made upon our organs, nerves, and brain, certain corresponding sensations are felt, and certain objects are both conceived and believed to exist. But we can neither discover the cause of any one of these operations, nor any necessary connection of one with another.

On the subject of this article, in its connection with metaphysics, or the philosophy of the human mind, we refer to Idea, Perception, Mental Philosophy, Vibration, and other terms of a similar import, or in any degree connected with them, occurring in various parts of the Cyclopaedia.

SENSBURG, in Geography, a town of Prussia, in the province of Bartenland; 14 miles S. of Ratenburg. N. lat. 53° 44'. E. long. 21° 23'.

SENSE. Senses, in Physiology and Anatomy, the organs
by which we become acquainted with surrounding objects, by which external bodies impress our frame, so as to communicate to us a knowledge of their properties. They are in number, viz. the eyes, ears, nose, tongue, and fingers, for the natural and physiological account of what we refer to those articles. There are often called the external sense; while the internal organs, the parts of the brain which are concerned in knowing and reflecting, have sometimes been called the internal sense. See Mental Philosophy.

Dr. Hutcheson gives us a more extensive and philosophical notion of sense. On his principle, sense is defined, a power of perception, or a power of perceiving ideas; at least if what is absolutely passive may be properly called a power.

On some occasions, instead of power, he chooses to call it a determination of the mind to receive ideas; and the ideas thus perceived, or received in the mind, he calls sensations.

Sense, he considers, either as natural or moral; and the natural, either as external or internal; though the distribution is chiefly founded on the common ways of conceiving; for, in reality, they appear to be all natural and necessary. Some restrict, however, for the distinction, will be shewn under the several articles of it.

External senses, then, are powers of perceiving ideas, upon the presence of external objects. On such occasions, we find the mind is merely passive, and has not power directly to prevent the perception, or idea, or to vary it at its reception; so long as the body is continued in a state fit to be acted upon by the external object.

When two perceptions are entirely different from each other, or agree in nothing but the general idea of sensation, the powers of receiving those different perceptions are called different senses. Thus, seeing and hearing denote the different powers of receiving: as ideas of colours and sounds. And though colours, as well as sounds, have vast differences among themselves; yet is there a greater agreement among the most opposite colours, than between any colour and a sound; and hence all colours are deemed perceptions of the same sense.

All the several senses seem to have their distinct organs, except feeling, which is, in some degree, diffused over the whole body. Inquiry into the Original of our Ideas of Beauty and Virtue, p. 2. Svo. 1726.

In another place, the same writer defines the external senses to be those determinations of nature, by which certain perceptions constantly arise in the mind, when certain impressions are made upon the organs of the body, or motions raised in them. Some of these perceptions are received solely by one sense; others may be received by two or more. Of the former class are these five sorts: viz. colours, sounds, tastes, smells, cold, or heat. Some ingenious authors reckon more: these we may call the proper ideas of sensation. System of Moral Philosophy, vol. i. p. 4.

Internal senses are powers or determinations of the mind to be pleased with certain forms and ideas, which occur to our observation, in objects perceived by the external senses. Of these there are two different species, distinguished by the different objects of pleasure, viz. pleasurable or beautiful forms of natural things, and pleasurable or beautiful actions, or characters of rational agents: whence the internal senses become divisible into natural and moral; though what others call the internal natural sense, our author calls simply, and by way of eminence, the internal sense.

In reflecting on our external senses, we plainly see, that our perceptions of pleasure and pain do not depend directly on our will. Objects do not please us, according as we incline this should the pleasure of some objects necessarily please us; nor can we by will will our own pleasure, or avoid pain, thereby growing another kind of pain, and avoiding the latter. But in every state of nature, the mind is made the occasion of delight, and the other of discomfort. In effect, our internal perceptions are pleasant, and painful, immediately, without any knowledge of the cause of this pleasure and pain, or of the cause of how they excite it, or are occasions of it, or without any bias to what further advantage, or detriment, the act of these objects might tend. Nor would the mind accurately know the cause of these things, if not the pleasure or pain of the perception: hence the mind, in understanding what is pleasant, plain, or painful, in the common prospect of anticipated advantage or satisfaction, the natural objects, or the natural laws, by which the mind is made the cause of its own pleasure and pain. Thus we shall find our senses pleased with a regular form, a piece of architecture, or painting, a composition of names, a theorem, an action, an affection, a character; and we are conscious, that this pleasure naturally arises from the contemplation of the idea then present to the mind, with all its circumstances, though some of those ideas have nothing of what we call sensible perception in them; and in those which have, the pleasure arises from some uniformity, order, arrangement, and imitation; and not from the simple ideas of colour, or sound, or mode of extension, separately considered.

It seems hence to follow, that when instruction, education, or prejudice of any kind, raise any desire or aversion towards an object; this desire, or aversion, is founded on an opinion of some perfection, or deficiency, in those qualities, for perception of which we have the proper senses. Thus, if beauty be defined by one who has not the sense of sight; the desire must be raised by some apprehended regularity of figure, sweetness of voice, smoothness, softness, or some other quality, perceptible by the other senses, without relation to the idea of colour.

The only pleasure of sense, which our philosophers seem to consider, is that which accompanies the simple ideas of sensation; but there are vastly greater pleasures in those complex ideas of objects, which obtain the names of beautiful and harmonious. The power, then, by which we receive ideas of beauty and harmony, has all the characters of a sense. It is no matter, whether we call these ideas of beauty and harmony, perceptions of the external senses of seeing and hearing, or not: we should rather choose to call these ideas an internal sense, were it only for the convenience of distinguishing them from other sensations of seeing and hearing, which men may have without perception of beauty and harmony. Hutcheson's Inquiry, &c. Preface, and p. 3. &c.

For the general manner in which our senses act, or more properly, the manner in which we become sensible, that is, perceive external objects, see Sensation.

For the particular senses, or, more properly, the particular manner in which we become sensible, by the particular organs of sense, see Hearing, Seeing, Smelling, &c.

For the several organs of sense, ministering to the several manners of sensation, see Eye, Ear, Nose, &c.

Pliny observes, that of all the senses, seeing and tasting are those which men enjoy in the greatest perfection. As to seeing, he says, he is excited by the eagle, &c.; as to smelling, by the vulture, &c.; and as to hearing, by the mole, even when hid under ground.
The fenfes have been sometimes found greatly sharpened and improved by dileances. Mr. Boyle mentions a gentleman, who, during a diſtemper he had in his eyes, had his organs of flight brought to be fo fenſible, that when he walked in the night, he could, for a while, plainly fee and diftinguifh colours, and other objects; and the fame author gives an inſtance of another perfon, who, after getting halffuddled with claret, if he walked in the night, could fee for fome time to read a moderate print.

Grimaldi tells us, that fome women of Megara were able by their eyes alone to diftinguiffh between eggs laid by black hens, and thofe by white ones. Grimaldi de Lum. & Col.

In the Philofophical Transaflions, No. 312, we have an account of Dan. Fräifor, who continued deaf and dumb from his birth to the feventeenth year of his age: when, upon recovering from a fever, he perceived an uneasy motion in his brain, after which he began to hear, and by degrees to fpeak.

Dr. Reid, in his second Effay, fuggels a variety of methods, by which our fenfes may be improved, as they give us information of things that concern us. Our original powers of perceiving objects by our fenfes admit of great improvement by ufe and habit; but, befides, there are various ways in which our fenfes may be improved, or their defects remedied by art; as by a due care of the organs of fenfe, that they be in a found and natural state; by accurate attention to the objects of fenfe; by additional organs or instruments contrived by art; and by discovering the connection which nature has efablifhed between the fenſible qualities of objects, and their more latent qualities.

Dr. Reid fuggels, that the fallacy of the fenfes has been a common complaint among philofophers, both ancient and modern; and this, he thinks, is founded on a common error, to which another has been added, that our ufe of reafon is to detect the fallacies of fenfe. In his opinion, there is no more reafon to account our fenfes fallacious, than our reafon, our memory, or any other faculty of judging which nature hath given us. They are all limited and imperfect, but widely suited to the prefent condition of man. We are liable to error and wrong judgment in the ufe of them all, but as little in the information of fenfe as in the deductions of reafoning; and the errors we fall into, with regard to objects of fenfe, are not corrected by reafon, but by more accurate attention to the information we may receive by our fenfes themselves.

Sence, Moral, is a determination of the mind to be pleaded with the contemplation of thofe affections, actions, or characters, of rational agents, which we call good or virtuous.

This moral fenfe of beauty in actions and affections, may appear ftrange at first view; fome of our moralifts themfelves are offended at it in Lord Shaftesbury, as being accufomed to deduce every approbation, or averfion, from rational views of interefl. Our gentlemen of good tale can tell us of a great many fenfes, tastes, and relifts for beauty, harmony, imitation in painting and poetry; and may we not find, too, in mankind a relift for a beauty in characters, in manners? The truth is, human nature does not feem to have been left quite indifferent in the affair of virtue, to form to itself observations concerning the advantage or disadvantage of actions, and accordingly to regulate its conduct. The weaknefs of our reafon, and the avocations arifing from the infirmities and necneffities of our nature, are fo great, that very few of mankind could have framed thofe long deductions of reafon, which may have fome actions to be, in the whole, advantageous, and their contrary pernicious.

The Author of nature has much better furnifhed us for a virtuous conduct than our moralifts feem to imagine; by almoft as quick and powerful instructions, as we have for the prefervation of our bodies; he has made virtue a lovely form, to excite our purfuit of it; and has given us frong affections, to be the fprings of each virtuous action. Hutcheon's Inquiry, &c. ubi fupra. Eflay on the Nature and Conduct of the Passions, p. 5. &c. See Mental and Moral Philosophy, and after Virtue.

Sence, Common, is a term that has been variously ufed both by ancient and modern writers. With fome it has been fynonymous with public fenfe; with others it has denoted prudence; in certain infirmities it has been confuned with fome of the powers of falt; and, accordingly, thofe who commit egregious blunders with regard to decorum, faying and doing what is offensive to their company, and inconfident with their own character, have been charged with a defect in common fenfe. Some men are diftinguifhed by an uncommon acutenefs in difcovering the characters of others; and this talent has been fometimes called common fenfe: fimilar to that which is ufe of the term, which makes it to fignify that experience and knowledge of life which is ac- quired by living in fociety. Hor. lib. i. fat. 5. lin. 66. To this meaning Quintilian refers, fpeaking of the advantages of a public education: "Senfund ipsum qui communis dictur, ubi defcit, cum fe a congregi, qui non hominibus femus, fed mutis quoque anamibus eali, regarum?" Lib. i. cap. 1.

Dr. Reid observes, in his 6th Effay, "of Common Senfe," that, in common language, fenfe always implies judgment, nor is the popular meaning of the word fenfe peculiar to the English language: the correffponding words in Greek, Latin, and probably in all the European languages, have the fame latitude. The Latin words fenfe, fenfatus, fenfas, fenfas, from the last of which the English word fenfe is borrowed, exprès judgment or opinion, and are applied in diftinctly to objects of external fenfe, of taste, of morals, and of underftanding.

This is the meaning which Mr. Pope has given to it; and in his epiftle to the earl of Burlington he has thus defcribed upon it:

"Off have you hinted to your brother peer, 
A certain truth, which many buy too dear;
Something there is more needful than expence,
And something previous even to taste — 'tis Senfe.

Good fenfe, which only is the gift of Heaven;
And though no science, fairly worth the feven:
A light, which in yourself you must perceive,
Jones and Le Notre have it not to give."

Having fhewn that fenfe, in its moft common, and therefore moft proper meaning, signifies judgment, our author infers that common fenfe should mean common judgment; as it really does.

Lord Shaftesbury has given to one of his treatifes the title of "Senfas Communis," and he has introduced fome criticism upon this word in Juvenal, Horace, and Seneca: after fhowing in his faceitious manner, that the fundamental principles of morals, of politics, of criticism, and of every branch of knowledge, are the dictares of common fenfe, he fums up the whole in these words: "that fome moral and philosophical truths are fo evident in themselves, that it would
SxKE.

would be eafe to imagine half mankind run mad, and joined
precisely in the fame species of folly, than to admit any
thing as truth, which should be advanced against fuch natural
knowledge, ufual notions, and common fense; and on taking
leave he adds; "and now, my friend, should you
find I had moralized in any tolerable manner, according to
common fense, and without coolnefs, I fhall be fatisfied with
my performance." After citing other numerous testimonies
in vindication of common fense, as a principle of knowledge,
our author concludes with obferving, that it is abfurd to
conceive that there can be any opposition between reason
and common fense. To reason we affign two officers, or
two degrees. The firft is to judge of things fendent; evident;
the second to draw conclufions that are not fendent from
thofe that are: the firft of thefe is the province, and the
fcale province, of common fense; and therefore it comedies
with reason in its whole extent, and is only another name for
one branch or degree of reason. The firft is purely the gift
of heaven; the leccond is learned by practice and rules, when
the fird is not wanting.

Our author further obferves, that the province of com-
mom fensc is more extensive in refutation than in confirmation.
A conclufion drawn by a train of fendent reafoning from true
principles, cannot poffibly contradict any dellion of common
fense, becaufe truth will always be confident with itfelf.
Neither can fuch a conclufion receive any confirmation from
common fense, becaufe it is not within its jurifdiction.
But it is poffible that, by fetting out from fende fentences, or by
an error in reafoning, a man may be led to a conclufion that
contradicts thedecisions of common fense. In this cafe, the
conclusion is within the jurifdiction of common fense, though
the reafoning on which it was grounded be not; and a man
of common fense may fairly reject the conclufion, without
being able to fhew the error of the reafoning that led to it.

After these preliminary remarks, we obferve that the term
common fense hath in modern times been used to dignify
that power of the mind which receives truth, or com-
mmd notions, not by progreflive argumentation, but by
an infiantaneous, infinite, or infolvable impulfes; derived
rather from education nor from habit, but from nature;
acting independently of our will, whenever its object is pre-
ferred, according to an efablifhed law, and, therefore,
called fende; and acting in a fimilar manner upon all, or at
leaff upon a great majority of mankind, and, therefore,
called common fense. The firft among the moderns who took
notice of this principle as one of the fprings of our knowl-
ledge, was Buffier, a French philofopher of the laft cen-
tury, in a book entitled "Traité des Premières Vertus;" and
this doctrine hath lately, in our own country, been illu-
minated and maintained by Drs. Reid, Beattie, Osvald, and
Campbell.

In order to evince that there is a real and effential dif-
ference between this faculty and that of reafon, it is ob-
ferved, that we are conscious, from internal feeling, that the
energy of understanding, which perceives intuitive truth,
is different from that other energy which unites a conclufion
with a fendent principle, by a gradual chain of intermediate
relations; that we cannot difcern any necefsary connectionetwcen reafon and common fense; that the one is more in
our power than the other; the faculty of reafoning being
improveable by cultute, whereas common fense, like other
infincts, arrifes at maturity with almighty and care of ours,
and it is impossible to teach common fense to one who wants
it; though this, like other infincts, may lengthen for want of
exercise; and that a distinction, fimilar to that which is
here maintained, is acknowledged by the vulgar, who speak
of mother-wit as something different from the deductions of
reason, and the refinements of fcienee. All things taken
into account, it is laid, all ultimately rest on the principles of
common fense, that is, on principles intuitively evident, or
ftoutly probable; and, consequently, common fense is the true
judge of truth, to which reason must continually be
in subordination. This is the doctrine for this faculty, an
original and infiuent power of the human mind, alien
to every extenfive enquirer, and authority that adapts itself
and absolute. And they have proceeded to far as to hiftc the
in the room of Mr. Locke's abstraction, this facility as
characterized as infallibility. To them they refer all the
axioms of mathematical truth, of external and internal fense,
memory, of reafoning from the effect to the cause, or probable
or experinental reafoning, of analogical reafoning, of
faith infalibility, and, indeed, of all primary truths. To
common fense, therefore, all truth must be conformable:
this, they fay, is its fixed and invariable standard. And
whatever contradicts common fense, or is inconsistent with
this standard, though supported by arguments that are
deemed unanswerable, and by names that are celebrated by
all the critics, academicians, and philosophers on earth, is not
true, but falfehood. In a word, the dictates of common
fense arc, in respect to human knowledge in general, what
the axioms of geometry are in respect to mathematics:
on the fupposition that these axioms are falfe or dubious, all
mathematical reafoning falls to the ground; and on the
fupposition that the dictates of common fense are erroneous
or deceitful, all truth, virtue, and science, are vain.

And hence it appears, that, according to this fystem, common
fense is not only the tell of truth, but the standard of moral
obligation.

Dr. Priefley, in his attack upon this fystem, has charged
the abettors of it with an unceafing innovation in the re-
ceived ufe of a term; as no perfon ever denied that there are
fendent truths, and that these must be allowed as the
foundation of all reafoning. But they also recommend par-
ticular poflitions as axioms, not as being founded on the
perception of the agreement or disagreement of any ideas,
which is the great doctrine of Mr. Locke, and which makes
truth to depend upon the neceffary nature of things, to be
absolute, unchangeable, and everlasting; but merely fome
unaccountable infidtive perceptions, depending upon the
arbitrary constitution of our nature, which makes all truth
to be a thing that is relative to ourselves only, and confe-
quently to be infinitely vague and precarious. This fystem,
he fays, admits of no appeal to reafon, properly confidered,
which any perfon might be at liberty to examine and difcufl;
but, on the contrary, every man is taught to think himfelf
authorized to pronounce decisively upon every question,
according to his prefent felling and perfonation; under the
notion of its being something original, infidtive, ultimate,
and incontrovertible, though, if strictly afcalified, it might
appear to be a mere prejudice, the offspring of infalce.
Some of the axioms which they have adopted as fendent
truths, and which they have multiplied without neceflity,
are fo far from being fendent, that, in the judgment of
many fober and candid enquirers after truth, they are not
tru, but capable of a ficaticy refutation.

At the fame time, fince no man can pretend to any natural
right to fix the principles of truth and another, they teach un-
believers, and by their example authorize them, to reject the
principles of religion by the fame human and infidtive
powers, as what appear to them to be, at first fight,
too absurd, and ridiculous to be admitted as true and divine.

Dr. Priefley apprehends, that the inconfistencies above-
mentioned, may attend even the calling of that faculty by
which we difcern truth by the name of fense. By this term,
philofophers
philosophers in general have denominated those faculties, in consequence of which we are liable to feelings relatively to ourselves only, and from which they have not pretended to draw any conclusions concerning the nature of things; whereas truth is a thing not relative, but absolute and real, independent of any relation to this or that particular being, or this or that order of beings. Besides, if the determinations of this new principle of common sense be so instantaneous, irresistible, and infallible, as Dr. Reid, Dr. Beattie, and Dr. Oswald represent, how can we account for all the error there is in the world? Not to add, that this system, in its practical influence, tends to prevent the exercise of free and unrestricted enquiry, with regard to truth or duty, and to confine it, in many cases, the extravagancies of credulity, enthusiasm, and mysticism. Dr. Priestley also observes, that Dr. Price (in his Review of the Principal Questions and Difficulties in Morals, 8vo.) though unnoticed by the writers above cited, by maintaining that the understanding is the source of many of our most important simple ideas (see Idea), has secured all the flattering advantages of the new doctrine of common sense, without the capital inconveniences attending it. Like this system, his scheme cuts off, if it be admitted, all objections to primary moral truths, refting them on a simple appeal to the faculty of intuition; and refusing to reason upon a subject, which is maintained to be as evident as the truth of the geometrical axiom, that if equal things be taken from equal things, the remainders will be equal.

If the ideas of moral right and wrong, &c. be perceived by a sense, it depends upon our arbitrary constitution, that we conceive of them as we do, or whether we perceive them at all; and we have no method whatever of investigating, whether they have any foundation in the absolute nature of things; whereas by making moral ideas the object of the understanding as such, the principles of morality become part of this system of necessity, eternal, and unalterable truth, perceived by the divine Being as by ourselves, but altogether independent of his will, as well as of all other beings and things whatsoever; as much so as the truth of the axiom above-mentioned, or of the proposition, that two and two make four.

It is added, that these writers seem even to have borrowed their language, as well as their ideas, from Dr. Price, who also uses the term common sense, though applied in a different manner. Reid's Enquiry into the Human Mind on the Principles of Common Sense, 8vo. ed. 2. 1765, Reid's Essays, above cited. Beattie's Essay on the Nature and Immutability of Truth, 8vo. ed. 2. 1771. Oswald's Appeal to Common Sense in behalf of Religion, 8vo. ed. 2. 1768. Campbell's Philosophy of Rhetoric, 8vo. 1776, vol. i. p. 169, &c. Priestley's Examination of Reid, Beattie, and Oswald, 8vo. 1774. For a farther account of this system, see ABSTRACTION and IDEA.

SENSE, in Geography. See SENSE.

SENSIBILITY, in Physiology, the power of receiving an impression, and transmitting it to the brain, so as to cause sensation or feeling. The question whether any part be sensible is, therefore, whether by acting on it in any way, feeling can be excited. Sensibility in this, its common acceptation, obviously refers to the internal feeling or act of consciousness resulting from its exercise. Some physiologists have used the word in a more extensive sense, to denote all impressions produced on our organs, even those which are not felt; as that of the blood on the heart, the food on the alimentary canal, &c. They call the former animal sensibility, because it is peculiar to living beings; and they distinguish the latter by the name organic, as it belongs to those parts where motions are involuntary, and which constitute the automatic or organic life. See Life.

Rousseau has given the word sensibility a place among French medical terms. The soul of the composer should furnish ideas, the performer should be gifted with feeling in its expression, and the audience should be capable of being impressed with the beauties and defects of the music which is executed for their amusement.

SENSIBLE Horizon, Point, and Qualities. See the sublunaries.

SENSIBLE Note. See NOTE, Sensible.

SENSIBLE Fluid. Some have imagined a sensible fluid to be the principle that preserves animals from corruption, and to which we owe our sensation and motion. This animal fluid pales in the proper nervous tubes to the organs of motion; but is contained in the fibrous coats of the nerves to become an organ of sensation. This sensible fluid is, according to M. Le Cat, capable of thinking, and is so modified by the ganglions, that what is lodged in each part, is capable of being impressed by the object proper to each organ. And from the doctrine concerning this animal fluid, he endeavours to account for most operations, which are generally said to depend on the soul. (Med. Eth. Edinb. Abbr. vol. ii. p. 481.) But all these attempts to account for sensation and thought, from the properties of matter, seem to be very desperate undertakings, not to say absurd.

SENSIBLE Plant, in Botany. See Mimosa.

The sensible plant is sufficiently known to the world for its remarkable property of reeding from the touch, and giving signs, as it were, of animal life. Philosophers in general have, however, contented themselves with admiring the fact, without giving themselves any trouble about the cause. See Leaf.

Mr. Hook, indeed, has made some conjectures about it; but the greatest light that has been given into the thing, is from the inquiries which Mellers. Du Fay and Du Hamel, gentlemen of the Academy of Sciences at Paris, concerted together, and afterwards made separately on different flinches, or at different times, that each might be able to correct the errors of the other.

Botanic writers mention many kinds of sensible plants, some of which contract at a touch, others with heat, others with cold. The truth is, many, if not most, vegetables expand their flowers, down, &c. in warm fine-dry weather, and again close them towards evening, or in rain, &c. especially at the beginning of flowering, or after the flowers are fallen, whilst the seed is yet young and tender; as is very evident in the down of dandelion, &c. and in the flower of the pimpernel, the opening and shutting of which are the countryman's weather-wiser; by which, Gerard says, he foretells what weather shall follow the next day; for if the flowers be close shut up, it betokens rain and foul weather; if they be spread abroad, fair weather.

The structure of the sensible plant is this; from the large flents, or main branches of the whole, there part off several other lesser ones, and from these there go off others still lesser, which, by way of distinction, may be called the ribs of the leaves, as they serve to support a number of leaves arranged on each side, and standing on short pedicles in pairs, over against one another. Several other plants have this fort of compound leaves, as the coffee, culottes, and the like; and all these shut their leaves together at night, and open them again in the morning, in the same manner as the sensible plant does. This periodical opening and shutting of the leaves are therefore common to many plants, not peculiar to the sensible plant; but the wonder in this is, that before having this motion periodical and regular, it is to be brought on.
at other times, and by accidents, some requiring no more
time than such. If the plant is cut, it forms, as usual, the
inner surface of a tube which is made smooth or bright.
A close observation of the motions in which this is per-
formed, will give many hints towards the making of its cause.

It was a very difficult thing to touch the leaf of a vigorous
tentative plant to lightly, as not to make it drip: its foliage
is extremely delicate, and its larger or smaller, which arise
along its middle, is as a worm's tongue, on which the two
halves of the leaf move when they turn upon being touched,
till they flatten erect, and by that means meet one another.

The slightest touch imaginable gives this motion to the
side of the leaf which is touched, which is communicated
immediately to the other side, or half, and they move to-gether; and if the touch has been a very little rougher, the
opposite leaf on the same rib receives the impression, and
exhibits in the same manner with that which was actually

Nur in all this, for when the two sides of each of their
leaves move upwards, the pedicle of each half moves up-
wards at the same time, and by this means they, in some
manner, approach towards each other, and make the angle
of their pedicles with the main rib, or flaky, of the composite
leaf, less than before; and the total motion of each leaf is
compos'd of these two motions.

If the touch be still rougher, the whole arrangement of
leaves on the same rib feels its influence on each side, and all
close in the same manner with the single pair in the preceding
example; and if the touch be yet stronger than this, the rib
itself feels it, and attempts to close in its way; moving itself
upwards towards the branch from which it is produced, just
as the single pedicles of the leaves did towards it; and if the
touch be yet more hard and rough, the very branches have
the sensation propagated to them, and apply themselves to
the main branch, or trunk of the shrub, as the simple leaves
did before to their rib, and that rib to the branch; so that
the whole plant in this state forms itself from a very compexly
branched figure, into a sort of straight cylindrical one. That
motion which has, of all others, the greatest effect upon this
plant, is a shaking one.

These motions of the plant are performed by means
of three distinct and sensible articulations; the first that of
the single leaf to its pedicle, the second that of the pedicle
to its branch, the third that of the branch to the trunk. The
primary motion of all which, is the closing of the two halves
of the leaf upon their rib, which ought also to be performed
in a similar manner, and by a similar articulation; thus,
however, is much less visible than the other.

These motions are wholly independent of one another, as
may be proved by experiment. It should appear, that if the
stalks are moved, and collapse towards the branches, or
towards the trunk, the leaves whole motion is usually primary to these, should be affected also; yet expe-
iment proves, that it is possible to touch the branches in
such a manner, as to affect them only, and make them apply
themselves to the trunk, while the leaves feel nothing of the
touch; but this cannot be, unless the branches are so dis-
persed, that as they can fall to the trunk without suffering
their leaves to touch any other part of the plant in their
path, because, if they do, they immediately become affected.

Winds and heavy rains cause the sensitive plants to shut
up their leaves, while each flower doth not at all affect them;
it is plain, hence, that the agitation of the plant by the wind,
and the strokes given by the large and heavy drops of rain,
are what cause the contraction.

By whatever means the leaf is made to close its
leaves, it always, in the same manner. For, however,
cut or leafed the plant is, its movements are, as I have
noticed, the same, and in all cases, the leaf is shut up half
an hour; and the manner in which it is shut up, at the
same time, fer hours over the same period. This, and
then several other instances, which I don't think worth
mentioning, proves, that the motion of the plant, the
proposition above stated, have occurred, that these are
performed by means of a sort of very small, and long
filaments, which communicate one with another by means of
minute and slender cords, which are sufficiently strong to
be seen when the plants are sufficiently detached, and the cord
broken; and what gives this theory probability to this
conjecture is, that the delayed and dilly leaves of the plant
perform this motion in a very regular and vigorous manner,
which is true and full of juice.

It seems plain, that while the juice is evaporating, and
the parenchymatous infusion of the leaves drying up, there
are more solid parts, the bones and organs, retain their figure;
and, consequently, if it be by means of these that the motion
is always performed, it will be as well performed in these
as in the fresher leaves, which could not be the case were it
owing to the juices.

The natural opening and shutting of the leaves of the
plant at night and morning, are not so fixed but that they are
variable also, according to circumstances of place, temper-

ture, &c.

In the month of August, a sensitive plant was carried in
a pot out of its usual place into a dark cave, the motion that
it received in the carriage shut up its leaves, and they did not
open till twenty-four hours afterwards; at this time they
became moderately open, but were afterwards subject to no
changes at night or morning, but remained three days and
nights with their leaves in the same moderately open state.

At the end of this time they were brought out again in the
air, and then recovered their natural periodical motions, shut-
ting every night and opening every morning, as naturally
and as strongly, as if it had not been in this forced state;
and while in the cave, it was observed to be very little left
affected with the touch than when abroad in the open air.

Repeated experiments have proved, by these philosophers,
that it is not the light of the day that opens the leaves of
this plant, nor the darknesse of the night that closes them; neither
is it the alternate warmth of the day and cold of the night,
that have this effect, since it fluxes in nights which are much
warmer than the days often are in which it opens; and the
increasing the heat of the place in which it is kept, and mark-
ing the increase or decrease on the thermometer, have been
found to have not the leaf effect, as to its sooner or later
opening or shutting its leaves.

The most probable conjecture seems, that it is not great
heat, or great cold, such as it can bear, that bring on
this effect, but the sudden change from one to the other, and
this is confirmed by this experiment, that if one of these
plants be raised under a glass bell, or cage, in a bottle or
covering be taken off, it immediately closes, even though it
be in the middle of the day; and this is also observed, that
the more open or exposed the plant stands, the more strong
and lively are its shutting and opening; and that they are
most observable in summer, and much less so when it is kept
in a close house in winter.

The great heats of summer, when there is open sunshine
at noon, affect the plant in some degree like cold, causing it to
flint up its leaves a little, but never in any very great degree.

The plant, however, is leaf of all affected about nine o'clock in the morning, and that is consequent upon the proper time to make experiments on it. A branch of the sensitive plant cut off, and laid by, retains yet its property of fluting up and opening in the morning for some days; and it holds it longer if kept with one end in water than if left to dry more suddenly.

The leaves only of the sensitive plant shut up in the night, not the branches; and if it be touched at this time, the branches are affected in the same manner as in the day, shutting up, or approaching to the stalk or trunk, in the same manner, and often with more force. It is of no consequence what the substance is with which the plant is touched, it answers alike to all; but there may be observed a little spot, distinguishable by its paler colour in the articulations of its leaves, where the greatest and nicest sensibility is evidently placed.

The sensitive plant plunged into water immediately cloths its leaves, which is partly owing to the touch, partly to the coldness of the water; afterwards the leaves expand again, and if they are then touched, close again as before, as if in the open air, only that they do it with less force.

If the end of one of the leaves be burning with the flame of a candle, or by a burning glass, or touching it with hot iron, it closes up in a moment, and the opposite leaf does the same, and after that the whole series of leaves on each of the ribs, then the rib itself, the branch, all do the same, if the burning has been in a sufficient degree. This proves that there is a very nice communication between all the parts of the plant, by means of which the burning, which only is applied to the extremity of one leaf, diffuses its influence through every part of the shrub.

If a drop of aqua fortis be carefully laid upon a leaf of the sensitive plant, so as not to shake it in the leaf, the leaf does not begin to move till the acid liquor corrodes the substance of it; but at that time, not only that particular leaf, but all the leaves placed on the same rib, close themselves up. The vapour of burning sulphur has also this effect upon many leaves at once, according as they are more or less exposed to it; but a bottle of very acrid and sulphureous spirit of vitriol, placed under the branches untopped, produces no such effect.

The wetting of the leaves with spirit of wine has been observed also to have no effect, nor the rubbing oil of almonds over them; though this latter application destroys many plants.

A branch of the plant was cut away longitudinally, till only a third part of the substance remained, yet it communicated the effects of the touch, in the same manner as before, to those branches which arose lower on the shrub. The transpiration of the plant being retarded, is of no effect as to its periodical opening and closing; for one kept under a close glass bell fluts and opens as regularly night and morning, as when it stands in an open green-houle. A branch of it put into the exhausted receiver of an air-pump, is found to have its force of opening and closing up much impared, but not wholly taken off. Mém. de l’Acad. des Scienc. Par. 1756.

Dr. Hill, notwithstanding the experiments and observations above recited, confiders the phenomenon of the sensitive plant as the effect of light, and in an express dissertation on this subject, endeavors to account for it from this principle; ascribing that other phenomenon, which is called the sleep of plants, to the absence of light. Hill’s Sleep of Plants, and the Caufe of Motion in the Sensitive Plant explained, 12mo.

Mr. Ellis has described a sensitive plant, which is a nature of the swamps in North Carolina, called Iiona muhipura, or Pept’s fly-trap, (see DIONEA,) and which, from his account of it, appears to be the most animated of the whole sensitive tribe of vegetables. Its sensibility exists in its leaves, each of which exhibits, in miniature, the figure of a rat-trap with teeth cloven on every fly or other insect that is tempted to take the sweet liquor which is supposed to be secreted in certain minute red glands that cover its inner surface; but before it has had time to take it, the lobes of the leaves rise up, and incline and grasp the invader, and he is then deprived of his life by the action of three small erect spines, fixed near the middle of each lobe; nor do the leaves open again, while the dead animal continues there. The same effect is produced by a straw or pin.

Mr. Ellis conjectures, that in the construction and motive powers of this plant, nature may have had some view to its nourishment, by forming the upper joint of each leaf like a machine to catch food, and by having laid a bait upon the middle of it, to entice the unhappy insect that becomes its prey. But, perhaps, it may be equally probable, that nature has armed and animated this plant for the preservation of its juices against the depredation of insects. Ellis’s Directions for bringing over Seeds and Plants, &c. 1779.

Sensitive Plant, Bellard. See ESCHYNOME. Sensitive Power. See Mental Philosophy.

Sensitive or Sensitive foul, the soul of brutes, or that which man is supposed to have in common with brutes. See BRUTE.

It is thus called, either as intimating its utmost faculty to be that of sensation; or, perhaps, because it is supposed to be material, and to come under our senses.

Lord Bacon afferts, that the sensitive or brute soul is plainly no more than a corporeal substance, attenuated by heat, and thus rendered indivisible; or a kind of aura or vapour, partly of an aerial, and partly of a fiery nature, endowed with the softness of air, to be fit to receive impressions, and with the vigour of fire to communicate its action; fed partly with oily matters, and partly with aqueous ones included in the body, and, in the more perfect animals, principally in the head, moving along the nerves, and restored and repaired by the spirituous blood of the arteries. Bac. de Augment. Scient. lib. v. See Life.

SENSKOWA, in Geography, a town of Pruffia, in the palatinate of Cuilm; 15 miles N.E. of Thorn.

SENSORIUM, in Physiology, the part which feels and perceives, the common centre, to which sensations are conveyed, and from which volition emanates; in other words, the brain. In medical and physiological writings, this expression is used as synonymous with brain; thus we read of affections of the fenforium; of senforial power and influence, &c. Senforium commune, is the imaginary point of the brain, the residence of the metaphysical soul, to which every sensation is brought, and from which all determinations of the will proceed. The speculations on this subject have been founded in the afoined unity of the soul. Physiologically speaking, there is not the slightest ground for supposing such a part to exist in the brain. Our remarks on the functions of the brain and parts connected with it, will be found under the articles Brain, Life, and Nervous System. See also Mental Philosophy.

Sir Isaac Newton confiders the universe as the fenforium of the godhead.

SENTELIUS, LODOWICUS, in Biography, a disciple of Henry Izaac, and in 1530 appointed chapel-master to the duke of Bavaria. Many of his compositions are in the Dodecachordon of Glareanus, with great encomiums.
He was in high favour with Martin Luther, a good judge of music: and Saladin Haydon, in 1540, calls him the prince of German musick.

SENTENCE, in Lexis. A: a judgment passed in court by the judge upon 1. prouestos either civil or criminal.

Sentences are either defective, which put an end to the lult and controversy, and regard the principal matter in question; or interrogatory, which determine only some incidental matter. The latter. &c.

There are sentences of absolute, exclamation, &c. Superior judges may either confirm or annul the sentences of inferior ones.

Every sentence must be in writing, on a stamp, and it must be pronounced in the presence of both parties; otherwise sentence given in absence of one of the parties is void.

Sentences. Three are conformable, one is conformable, and the Roman Civil Law, it is allowed to appeal three times; so that there must be three conformable sentences before the decisions of the judges can take effect. The first degree of jurisdiction is in the bishop's official; from him an appeal lies to the metropolitan, from the metropolitan to the pope, or immediately to the pope. If the appeal come from the metropolitan to the pope, the pope is obliged to delegate judges in partes; and then if the three sentences passed in these three stages be conformable, there is no further appeal; but if one of them annuls another, new judges are to be required of the pope for a fourth sentence; and thus they sometimes proceed to a sixth or seventh sentence.

This number of jurisdictions is found infinitely prejudicial to the public, and vexations to private persons.

Sentence, in Grammar, denotes a period, or a set of words comprehending some perfect sense or sentiment of mind.

Every sentence comprehends at least two words.

Mr. Harris, in his Hermes, p. 17, &c. confidering that the leading powers of the soul are those of perception and volition, observes, that every sentence, in reference to these powers, will be either a sentence of affection, or a sentence of volition: and he describes it as a compound quantity of found significant, of which certain parts are themselves also significant. Thus he distinguishes a sentence from a word, which is a found significant, of which no part is of itself significant.

The business of pointing is, to distinguish the several parts and members of sentences, so as to render the sense of it the clear, apt, and full, possible. See Punctuation.

Every sentence there are two parts necessarily required; a noun for the subject, and a definite verb; whatever is found more than these two, affects one of them, either immediately, or by the intervention of some other, by which the principal is affected.

Again, every sentence is either simple or conjunct: a simple sentence is that consisting of one single subject, and one finite verb. A conjunct, or compounded sentence, consists of several subjects, and finite verbs, either expressly or implicitly; or it consists of two or more simple sentences connected together.

A simple sentence needs no point or distinction, only a period to close it; as, A good man loves virtue for itself. In such a sentence, the several adjuncts affect either the subject, or the verb, in a different manner. Thus the word good expresses the quality of the subject, virtue the object of the action, and, for itself, the end of it. Now none of these adjuncts can be separated from the rest of the sentence; for if one be, why should not all be? And if at all, the sentence will be made in almost a many parts as there are words.

But if several adjuncts be introduced in the same sentence, either to the subject, or to the verb, the sentence becomes conjunct, and is to be divided into parts.

In every conjunct sentence, as many subjects, or as many finite verbs as there are, either expressed or implied, so many distinctions may there be. Thus, My hopes, fears, joys, pains, all centre in you; and thus Cicero, Catiline, abus, exceptus, eos qui excepti. The reason of which parting is obvious; for as many subjects or finite verbs as there are in a sentence, so many members does it really contain; whenever, therefore, there occur more nouns than verbs, or contrariwise, they are to be conceived as equal; thus, as every subject requires its verb, so every verb requires its subject, with which it may agree; excepting, perhaps, in some figurative expressions.

Indeed there are some other kind of sentences which may be ranked amongst the conjunct kind, particularly the absolute prepositions, as it is called. Thus, Physicians, the bye laws; once discovered, think the cure half effected; where the words, by our once discovered, are equivalent to, when the cause of the disease is discovered. So also in nouns added by apposition, as, The Scott, an handy people, endured it all, so also in vocative cases and interjections, as, This, my friend, you shall allow me: and, What, for heaven's sake! would be at?

The case is much the same when several adjuncts affect either the subject of the sentence or the verb in the same manner, or at least something by which one of them is affected, as, A good, wise, learned man is an ornament to the commonwealth; where the several adjectives, denoting so many qualities of the subject, are to be separated from one another. Again, when I say, Tell voice, countenance, gesture, terrified him, the several nominative cases denote so many modes of the verb, which are likewise to be distinguished from each other. The case is the same in adverbs, as, He behaved himself modestly, prudently, virtuously. In the first example, the adjuncts immediately affect the subject; in the third, the verb; in the following one, another adjunct, as, I saw a man laden with age, ficknels, wounds.

Now, as many such adjuncts as there are, so many several members does the sentence contain; which are to be distinguished from each other, as much as several subjects or finite verbs; and that this is the case in all conjunct sentences, appears hence, that all these adjuncts, whether they be verbs or nouns, &c. will admit of a conjunction copulative, by which they may be joined together. And wherever there is a copulative, or room for it, there a new member of a sentence begins. For the other partitions, &c. of sentences, see Colon, Semicolon, and Period.

Sentence is also used, in Rhetoric and Poetry, for a short pithy remark, or reflection, containing some sentiment of use in the conduct of life.

Such as Difcent juftitiam monit, & non tenacem divos; or, A temeris auxilium multum est, &c.

Sentences, father Boile observes, render poems useful; and, besides, add I know not what further, and spirit, which pleases. But there is no virtue which is not accompanied with some dangerous vice. Too many sentences give a poem too philosophical an air, and sink it into a kind of gravity; this is left fit for the majesty of a poem than the fluidity of a learned man, and the quantities of a dogmatist. Such thoughts not only contain, but inspire a certain calm wisdom, which is directly opposite to the passions, and cools them. 
them both in the harpers and in the speaker. Lastly, the affection of speaking sentences leads a person to trilling and impertinent ones, instances of which we have an abundance in Seneca’s tragedies. Petronius recommends it to authors to disguise their sentences, that they may not stand glaring above the thread or ground of the discourse.

**SENTER HABOUR, in Geography, a cove in the N.W. part of Lake Winnipigooe.**

**SENTENHEIM, a town of France, in the department of the Upper Rhine; 10 miles N.E. of Besf.**

**SENTICA, in Ancient Geography, a town of Spain, in the Tarragonenis, alligned by Ptolemy to the Vaccans.**

**SENTICE, a country of Macedonia, according to Livy.**

**SENTITI, a people of the Maritime Alps, S.E. of the Bodanici, mentioned by Ptolemy, who alligns to them the town of Dina.**

**SENTIMENTS, in Poetry, and particularly dramatic, are the thoughts which the severer persons express, whether they relate to matters of opinion, passion, boudelies, or the like.**

The manners form the tragic action, and the sentiments explain it, discovering its causes, motives, &c. The sentiments are to the manners, what these are to the fable. In the sentiments, regard is to be had to nature and probability; as man, for instance, mult speak as a man; a lover, as a lover; a hero, as a hero. The sentiments, in great measure, are to sustain the character. The word sentiment, in its true and old English sense, signifies a formed opinion, notion, or principle; but of late years it has been much used by some writers to denote an internal impulse of passion, affection, fancy, or intellect, which is to be considered rather as the cause or occasion of our forming an opinion, than as the real opinion itself.

**SENTINEL, GREAT, in Geography, an island in the East Indian sea, about 10 miles in circumference; 20 miles S.W. from the Greater Andaman. N. lat. 11° 30'. E. long. 92° 40'.**

**SENTINEL, LITTLE, a small island in the East Indian sea, about 8 miles from the Little Andaman. N. lat. 10° 59'. E. long. 92° 23'.**

**SENTINEL, CENTRY, or Sentry, in War, a private soldier placed in some post to watch any approach of the enemy, to prevent forpriles, and to stop fuch as would pass without orders, or without discovering who they are. They are placed before the arms of all guards, at the tents and doors of general officers, colonels of regiments, &c.** The word is modern; it is not long since they said, To be on the scout, in the same fense as we now say, To stand sentry, &c. Menage derives the word a sentiando, from perceiving.

**Sentinel perdus, is a sentinel placed at fome very advanced and dangerous point, whence it is odds that he never returns. See Perdue.**

The sentinel’s word, when he challenges, is, Who is there? Qui vive, or Qui va là! Stand! Demure la!

**SENTINUM, in Ancient Geography, a town of Italy, in Umbria, according to Strabo and Ptolemy.---Allo, a town of Italy, belonging to the Senones, S.W. of Suafa.**

**SENTINUS, a river of Italy, in Picenum.**

**SENTO, in Geography, a river of Naples, which runs into the Adriatic; 3 miles S.E. of Lanciano.**

**SENTOU, a town of China, of the third rank, in Se-tchuen, on the river Kincha; 22 miles N.E. of Pei.**

**SENTUR, a town of Egypt; 9 miles N.W. of Fayoum.**

**SENEUS, in Ancient Geography, a river of Hibernia, according to Ptolemy, who places its mouth on the western coast, between the mouths of the Alcon and of the Dar,—Allo, a river of India, in the country of the Sines, according to Ptolemy, who says, that it was connected with the Coniaris, at a great distance from its mouth.**

**SENZA, an Italian preposition, implying, in Myfes, without; as in Handel’s organ concertos, when passages are to be wholly left to the violins, fenza organo implies, without the organ; fenza violo, without the tenor; fenza batta, without the base, &c.**

**SENZARSKAIA, in Geography, a fortress of Russia, in the government of Toboli; 80 miles S. of Yalutorof.**

**SEODA, a sea-port of Japan, on the S. coast of the island of Nippon; 105 miles E. of Mexico. N. lat. 37° 30'. E. long. 159° 10'.**

**SEON, in Ancient Geography, a town of Palestine, in the tribe of Issachar, according to Joshua. Eusebius says, that in his time there was a place of this name at the foot of mount Tabor.**

**SEON St. Henry, in Geography, a town of France, in the department of the Mouths of the Rhone; 4 miles N. of Marseille.**

**SEOUJI Kiamen, a port of Chinefe Tartary, in the country of the Mongulis; 23 miles S.W. of Kara Hotun.**

**SEPARABLE MODES. See Mode.**

**SEPARATE Affect. See Affect.**

**SEPARATE, Penuminate of the. See Penuminate.**

**SEPARATE Island, in Geography, a small island in the Chinefe sea. N. lat. 3° 6'. E. long. 107° 45'.**

**SEPARATED Flowers, in Botany, are fo called when the flaments and pifilis are fo situated in different flowers of the fame species. Hence it appears that separated flowers are confined to fuch plants as are either monceous, dioceous, or polygamous. They are termed by Linneus, Diclines.**

**SEPARATION, among Horses, the teeth usually called incisors, by which the animal separates or bites off a portion of his food for chewing. See Teeth.**

**SEPARATION, in Navigation, the fame with what we more usually call departures.**

**SEPARATION of Men and Wife. See Divorce.**

**SEPARATION, Waters of. See Water.**

**SEPARATION Day, in Geography, a day in the Straits of Magellan, on the coast of Terra del Fuego; 10 miles S.E. of Cape Pillar.**

**SEPARATISTS, in Ecclesialfical History, a religious sect in England, so denounced from their setting up a separate church, different from that established by law. See Dissenters, &c.**

At prefer, Separatists is rather the name of a collection of sects than of any particular one; but nearer their original, there was that agreement among them, that one name ferved them all. Their division into Presbyterian, Anabaptists, Independents, &c. is a more modern thing.

The Separatists, Hornius tells us, Hift. Eccl. are such as under Edward VI. Elizabeth, and James I. refuced to conform to the church of England, and who were firft called Puritans, then Separatists, and laftly, Nonconformits.

The firft leader of the Separatists is Bolton, who, upon quitting the party he had formed, was succeeded by Robert Brown, from whom the Separatists were called Brownits.**

**SEPARATORIUM, the name of a surgical instrument used for separating the pericranium from the skull.**

**SEPARATRIX, in Arithmetic, denotes the point, or comma, which separates and diftinguishes decimals from integers; thus, 465:32 or 465:32.**

**SEPARI,
SEPH, a mountain of the Eaul, probably about Armenia. (See Gen. x. 30.) This mountain seems to have been the habitation of the Sepharvaim and of the Supleus, mentioned by geographers.

SEPHARVAIM, a people who were brought by Shalmanezer into Palebne, to supply the place of the Israelites, whom he carried away from Samaria to a country beyond the Euphrates (2 Kings, xviii. 24. 31.) A.M. 3253, B. C. 752. Their former habitations seem to have been on the mountains of Sephar, and the Sopires or Supleus, who, according to Herodotus (lib. i. iii. vii.) were the only people that inhabited between the Colchian and the Medes, who were probably the Sepharvaim. The Scripture speaks (Izaias, xxxvi. 13; 2 Kings, xix. 13.) of the city of Sepharvaim, which was probably the capital of these people, and the king of Sepharvaim was the god of these people. See 2 Kings, xviii. 34. 16. xxxvii. 13; 2 Kings, xix. 13.

SEPHIROS, a word used by Paracellus and his followers, to express a sort of dry and hard impomthum, or kind of spurious firrhus.

SEPHIROTH, a Hebrew word signifying brightnesses; and the cabalists give the name of Sephiroth to the motl secret parts of their science.

SEPHORIS, in Ancient Geography, a famous city of Zebulun, and the capital of Galilee; afterwards named Doclea; 18 according to some, and according to others 19 miles from Tiberias. It was not far from Tabor and the great plain. Josephus represents it as the largest and best city in Judea, and lates, that it became the capital of it, after Nero had given Galilee to the younger Agrippa. The first city of Galilee in going from Ptolemais was Sephoris. Joseph. de Bello, l. i. c. 23. l. iii. c. 1.

SEPHOURY, or Saphene, in Geography, a town or village of Palestine, anciently Sephor or Sephoris, which was once the strongest town of the country, and capital of Galilee, before Tiberias; called also Doclea. Here was held one of the five judicatures of Palestine. It was fortified by Herod, and destroyed in the time of Constantius, on an insurrection of the Jews. It was once much venerated as the habitation of Joachim and Anna, parents of the blefled Virgin; 12 miles N.W. of Tiberias.

SEPPIA, in Ancient Geography, a mountain of the Peloponnesus, in Arcadia, to the left of mount Geronte, near a place called Tricene, upon which Egyptus, the son of Elatus, died from the king of a serpent, and where he was buried, according to Paulus. Sepia, in Natural History, the Cuttle-fish, a genus of the Vermes-Mollusca clafs and order, of which the generic character is as follows; the body is fleshy, receiving the breath in a sheath, with a tubular aperture at its base; it has eight arms, beset with numerous warts or suckers, and in molt species two pedunculated tentacles; the head is short; the eyes large; the mouth resembling a parrot's beak. Their annual inhabit various seas, and in hot climates some of them grow to an enormous size; they are armed with a dreadful apparatus of holders furnished with suckers, by which they fasten upon and convey their prey to the mouth; they have the power of squirting out a black fluid resembling ink, and which is said to be an ingredient in the composition of Indian ink; the hole in the back is converted into a panicle: the eggs are deposited upon sea-wood, and exactly resemble a bunch of grapes; at the moment the female deposits them they are white, but the male pafs over them to impregnate them, and they then become black; they are round, with a little point at the end, and in each of them is enclosed a living cuttle-fish, surrounded by a gelatinous fluid. There are eight species, of which five are natives of this country.

* Octopus. The specific character of this species is, that the body has no tail or appendage; it has no pedunculated tentacles, or longer arms. It is found in the Mediterranean and Indian seas, in the latter of which it sometimes grows to a vast size; the arms are said to be eight or nine fathoms long. In these seas the Indians never venture out without latches in their boats, to cut off the arms, should it attempt to fall upon them under water. This species is characterized by the shortness of the body, which is rounded behind; the arms taper to a point, joined at the base by a membrane or web, and covered within with two rows of alternate suckers. When opened this animal is said to exhibit so brilliant a light as to illumine a large room.

* Squilla. Body without tail or appendage, and surrounded by a margin; it has two tentacles, or longer arms. This is found on our own coasts, and also in other oceans, and is frequently the prey of the whole tribe, and of plajfe; its arms are frequently eaten by the conger-eel, and are reproduced; the bony scale on the back is that which is fold in the heaps; and the black matter which it fquirs out to daeken the waters round it, and elude the purfuit of its enemies, is sometimes used as ink. The body was eaten by the ancients, and it is even now used as food by the Italians. The body of this species is ovate, the margin crenate, and interrupted at the bottom; eight of the arms are short, and pointed; the two tentacles are four times as long as the others; they are rounded, and the tips are very broad, and furnished within with numerous suckers.

* Unguiculata. The body of this is without a tail or appendage; the arms are furnished with hooks, and is found in the Pacific ocean. The body is rounded behind; the arms are furnished with hooks, which are retracable within their proper sheaths instead of suckers.

* Hexapus. The body of this is tailed, four or five-jointed; arms only fix in number. This also is found in the Pacific ocean. The body is about half a foot long, and the thickness of a finger; arms furnished with very minute suckers, which fick fall to whatever it fixes on.

* Media. Body long, slender, cylindrical; the tail is finned, pointed, and carinate on each side; it has two long arms. It inhabits the ocean, and in some respects it resembles the S. officinalis. The body ends in a point, and is furnished with a membrane on each side, commencing about the middle of the body.

* Loligo; the Calamary. The body of this is subcyindrical, tubulate, and furnished with a flattened sharp-edged rhombic membrane at the tail on each side. This is found in divers parts of the ocean, and is from nine to twelve inches.
inches long. The body is of a reddish-brown, with two longer arms or tentacula; the eyes are of a fine blue; the cartilaginous plate or bone in the back is long, lance-shaped, and transparent; it has sometimes been placed as a species of the pennatula.

* SEPILA. The body of this species has two rounded wings or processae behind. It is found in the Mediterranean and European seas, and is very small. The body is short, rounded behind, with a round membrane or fin at the lower extremity; it has two long arms.

Tunicata. The body of this species is entirely enclosed in a black pellicular membrane, with two femicircular wings or processae behind. This is an inhabitant of the Pacific ocean. The body is very large, and is said sometimes to weigh one hundred and fifty pounds, and is convertible into palatable and pleasant food.

SEPAICE, in Italian Myfic, signifies that the part it is joined to may be repeated or not, at pleasure.

SEPIAS, in Ancient Geography, a promontory of Thebais, in Magnesia, at the entrance of the Pelagic gulf, according to Ptolemy. Cape Sepias is now the promontory of St. George's.

SEPUSSA, an island situated on the coast of Asia Minor, in the Ceramic gulf, according to Pliny.

SEPOORY, in Geography, a fortress of Hindooftan, in the cirearc of Ghoub; 18 miles S.W. of Narwa.

SEPOU, a town of Hindooftan; 12 miles S.W. of Agra.

SEPRA, or SIPRA, a river of Hindooftan, which rises near Indore, joins the Callifind in the cirearc of Kitchwara, and, united with other streams, forms the Chumbul.

SEPIO, a town of Italy, in the department of the Onona; 20 miles N.W. of Milan.

SEPS, in Zoology, the name of a very peculiar animal of the lizard or lacerta kind, but seeming as if of a middle nature between that genus and the snakes, and appearing rather a serpent with feet than a lizard.

It is a small species; its body is rounded, and its back variegated with longitudinal lines of black; its eyes are black; it has ears, and a small and very slender tail. What appears molten sanguine in it is, that it has four legs, with feet divided into toes; the first pair are placed very near the head, the other by the anus; the scales are laid in a reticulated manner, they are of an oblong figure, approaching to a rhomboides, and laid longitudinally; its belly is white, with a flight call of blue, and it has no tails near the end of the finot. Columba took five living young ones out of the body of one of this species, some of which were included in membranes, and others loose, as is the case in the fetus found in the viper.

The bite of the sepas is said to occasion an instant putrefaction of the flesh of the whole body.

SEPT MONCEL, in Geography, a town of France, in the department of the Jura; 2 miles E. of St. Claude.

SEPTA, in Antiquity, were inclosures, or rails made of boards, through which perfous went in to give their votes in the assemblies of the Romans.

The word also signifies divisions, and, in that sense, is used to express the plates of spar, which separate or divide the tail of the lusus Helmontii, thence called by Dr. Hill, sectoria; which see.

SEPTALIUS, or SEPTALUA, LOUIS, in Biography, an Italian phisician of celebrity, was born at Milan, in February, 1527. He evinced from his early childhood, a strong inclination to the pursuits of literature, and at the age of sixteen defended some theses on the subject of natural philosophy with an acuteness of reasoning far above his years, and which excited the surprize of the audience, among whom was the archbishop of Milan. It was now suppos'd that he would follow the steps of his ancestors, both mat'rinal and paternal, who had been much distinguished at the bar; but his inclination led him to the medical profefion, and he accordingly repaired to Pavia, for the purpose of commencing the study of it. Here he proceeded with the fame success, and obtained the degree of doctor in his 21st year, and was even appointed to a chair in this celebrated university in his 23d year. In his professorial capacity, through fo young, he gave fo many demonstrations of his talents and acquisitions, that he soon became known to the most distinguished men of his time. Nevertheless, at the end of four years from the time of his appointment, he determined to relinquish the professorial dignity, for the purpose of exercising his medical skill in his native city. While he was engaged in the practice of his art at Milan, Philip III, king of Spain, selected him for his historiographer. But though fully sensible of the value of this compliment, yet neither this, nor many other more congenial honours, that were offered to him, could induce him to quit his native city, to which he was ardently attached. He was invited by the elector of Bavaria to a professorship in the university of Ingoldstadt; by the grand duke of Pisga, to a chair at that place; and by the city of Bologna to a similar appointment in their schools; and the senate of Venice, by fill more considerable offers both of honour and reward, laboured affiduously to bring him to the university of Padua. But he declined all these opportunities of elevation, content with the esteem and affection of his fellow-citizens, which he amply obtained; and with the domestic felicity, which the society and education of his family, conferring of seven sons and six daughters, contently afforded him. The only honour which he accepted was the appointment of chief phisician to the slate of Milan, which Philip IV. conferred upon him in 1627, as a reward for his virtues and talents. In the year 1628, the plague visited Milan. Septaluis gave all the aid in his power to his fellow-citizens, and in the midst of his labours to alleviate the difficulties occasioned by this fatal calamity, he was himself seized with the disease. He had scarcely recovered from this attack, when he was suddenly surpris'd by a fit of apoplexy, which left him speechless, and paralytic on one side. From this, however, he recovered in a great measure, and lived several years afterwards, but in a state of feebleness and imperfect health. He died in September 1633, in consequence of an attack of dysentery, at the age of 81. Septaluis was a man of acute powers, and solid judgment, and was reputed extremely successful in his practice. He was warmly attached to the doctrines of Hippocrates, whose works he never ceased to study. He was author of the following works: "In Librum Hippocratis Coi, de Acribus, Aquis, et Locis, Commentari quinque," 1590; "In Aristotelis Problematum Commentaria Latina," tom. i, 1602, ii, 1607; "De Nevis Liber," 1606. In this work Septaluis has not displayed his usual judgment; for he attributes the nevis, or mother-spots, to the imagination of the pregnant mother, and deduces from their appearances many practical inferences, which are as unfounded as the notion of their origin. "Animadversionum et Cautionum Medicarum Libri duo, septem aliss additis," 1629. This is a valuable work, the result of 40 years of practice, and equal to any of its contemporaries of the 17th century. "De Margaritis Judicium," 1618; "De Peste et Pestiferis Affeditis Libri V." 1622; "Analyticarum et Animaliarum Differtationum Libri II." 1626; "De Morbis ex mueronata
SEPTA, in Natural History, the name of a large class of fossils, called by some ludus Holmantis, and by others the nester tiris. They are defined to be fiddle-shaped, not inflamable, nor soluble in water, naturally found in broken detached mafles of a moderately firm texture and dainty hue, divided by several septa, or thin partitions, and composed of a spongy matter greatly debased by earth, not giving fire with steel, fermenting with acids, and in great part dissolved by them, and calcining in a moderate fire.

Of this class there are two distinct orders of bodies, and under these six genera. The septa of the first order are those which are usually found in large masses of fiddle-shaped uniform construction, but divided by large septa, either into larger or more irregular portions, or into smaller and more equal ones, called rudi.

Those of the second order are such as are usually found in smaller masses of a cancellated structure, formed by various incrustations round a central nucleus, and divided by very thin septa.

The peculiarity of character in Septas, with regard to the prevalence of the number seven, in the parts of construction, is not so constant as Linnæus seems to have imagined; hence Thunberg was induced to refer this genus to Crafula.

L. urocoho has given the name of Septas to a plant in Didyma Mirus Angiosperma, which, according to Professor Martin, is allied to Thunbergia.

SEPTA, in Ancient Geography, a town of Asia Minor, in Phrygia, according to the tolemy.

SEPTEM AGUA, a town of the Sabines, situated on an eminence, and commanding the Ruma river, or the fine Neapolitan valley. It is impounded by the abbe Chiapui to be the present Pont Grispoli.
That likely to find any such quality; these were chalk, common salt, and tactual powders. He mixed twenty grains of crab's eyes, prepared with six drachms of ox's gall, and an equal quantity of water. Into another phial he put an equal quantity of gall and water, but no crab's eyes. Both these mixtures being placed in the furnace, the putrefaction began much sooner where the powder was, than in the other phial. On making a like experiment with chalk, its septic virtue was found to be much greater than that of the crab's eyes; nay, what the doctor had never met with before, in a mixture of two drachms of flesh, with two ounces of water and thirty grains of prepared chalk, the flesh was reduced into a perfect mucus in a few days.

To try whether the tactual powders would also dissolve vegetable substances, the doctor mixed them with barley and water, and compared this mixture with another of barley and water alone. After a long maceration by a fire, the plain water was found to swell the barley, and turn mucilaginous and foul; but that with the powder kept the grain to its natural size, and though it softened it, yet made no mucilage, and remained sweet.

Nothing could be more unexpected, than to find sea-salt a hastener of putrefaction; but the fact is this: one drachm of salt preserves two drachms of fresh beef in two ounces of water, above thirty hours uncorrupted, in a heat equal to that of the human body; or, which is the same thing, this quantity of salt keeps flesh sweet twenty hours longer than pure water; but then half a drachm of salt does not preserve it above two hours longer. Twenty-five grains have little or no antifeptic virtue, and ten, fifteen, or even twenty grains, manifestly both hasten and heighten the corruption. The quantity which had the most putrefying quality, was found to be about ten grains to the above proportion of flesh and water.

Many inferences might be drawn from this experiment: one is, that since salt is never taken in aliments beyond the proportion of the corrupting qualities, it would appear that it is sublervient to digestion, chiefly by its septic virtue, that is, by softening and resolving meats; an action very different from what is commonly believed.

It is to be observed, that the above experiments were made with the salt kept for domestic uses. See Pringle's Observ. on the Difefes of the Army, p. 348, seq. See Salt and Scoury.

From some experiments of Mr. Canton, it appears likewise, that the quantity of salt contained in sea-water hastens putrefaction; but since that precise quantity of salt which promotes putrefaction the most, is less than that which is found in sea-water, he concludes it probable, that if the sea were less salt, it would be more luminous. See Luminousness of the Sea.

SEPTEMIÉ, Fr. Septima. Lat. Setima. Ital. the seventh. Broffard has been the guide of all subsequent musical lexicographers. He has been very awkwardly translated by Gräffino; Gräffino has been followed in the last folio edition of Chambers; and Roufleau, who writes clearly and elegantly, has retained the mixture of theory, ratios, and the useful jargon of major and minor tones and semi-tones, with practice, to much, as to render the useful knowledge of this important interval totally unintelligible to young students in harmony; to whom we shall address all we have to offer on the subject of the present article, referring scientific enquirers to Harmonics, Ratios, and the definitions of major and minor tones and semi-tones.

The 7th in music, is one of the principal discords; some say the only original discord, as all the rest are derived from it. The 2d and the 9th are only inventions of the 7th. The 4th in itself is a concord, and only made a discord by another discord being struck upon it; but the 2d and the 9th, however derived from inversion, are discords to the ear at all times and in all places.

There are three kinds of 7ths used in practical harmony: the minor, or flat 7th, ten semi-tones, or half notes, above the base; the major, or sharp 7th, eleven semitonic intervals above the base; and the extreme flat 7th, only nine half notes above the base or lowest note, as B♭ B♭ , and F♭ F♭ .

In counterpoint and thorough-bass, the 7th is accompanied by the 9th, or common chord, from which its harmony only differs by the addition of that single found from the triad. And as a base, in practice, is called fundamental, by being accompanied only with the common chord, the addition of the 7th to this common chord does not rob the base figured with a 9th of its title of fundamental.

The 7th in bounding notes is prepared in the 3d, 5th, 6th, and 8th, and resolved on the 6th, 3d, and 5th. Dr. Pepusch has given an excellent chapter on 7ths prepared and resolved in the treble; and to his instructions for 7ths prepared and resolved in the base, p. 37 of the text, we cannot subscribe. See Pepusch, and Analysis of his Treatise on Harmony.

The 7th is the only discord which need not be always prepared. The sharp 7th, which the French call la note faiblest, till about the middle of the last century, was only used in re-creative; but since that time it has been rapidly increasing in favour; first in German symphonies, and afterwards in songs, and every species of elegant music. Its chord is generally indicated by a 37, a sharp 7th; but different matters frequently use the following numerical expressions of this chord: 37, 57, 77, and 79. Its origin is an appoggiatura organized.

The extreme flat 7th gives what has been termed by Roufleau the enharmonic chord, containing entirely of flat 3ds, whence twelve modulations may be acquired, by making each note of the chord the sharp 7th, or leading note to a new key; by which means these three chords G♭ 7 7 7 7 G♭ 7 7 A♭ 7 give 36 modulations. See Music, Plates, and Intervals, Chords, Modulation, and Counterpoint.

SEPTIER, or SETIER, a French measure, differing according to the species of the things measured.

For dry measure, the septier is very different in different places and different commodities; as not being any vessel of measure, but only an estimation of several other measures.

At Paris, the septier of wheat consists of two mines, the mine of two minots, and the minot of three bushels or boiffaux, and 12 septiers are a maid. The boiffau contains 16 litrons. A maid of wheat weighs about 2880lbs. poids de marc; and a septier, 240lbs. But a maid of oats contains 24 septiers. The boiffau is a cylinder 8 inches 2½ lines in height, and 10 inches in diameter; its contents are, therefore, 664 French cubic inches, or 780 English ditto; hence 11 septiers of Paris are = 6 English quarters, and 11 boiffaux = 4 English bushels. A maid of salt contains also 12 septiers, and a septier, 4 minots, 16 boiffaux, 256 litrons, or 4006 meforceus, weighing about 400lbs. poids de marc, or 432lbs. avoirdupois. At Abbeville 18.87 septiers are equal to 10 English quarters, and each septier is 9364 cubic inches.
SEP

inches. At Amiens, 85 79 lepers = 10 English quarters, and each leper = 2005 cubic inches. At Arles, 47 40 lepers = 10 English quarters, and each leper = 5928 cubic inches. At Boulanger, 16 32 lepers = 10 English quarters, and each leper = 10 554 cubic inches. At Calais, 16 95 lepers = 10 English quarters, and each leper = 10 144 cubic inches. At Cetté, 420 lepers = 10 English quarters, and each leper = 3 272 cubic inches. At Lige, 94 14 lepers = 10 English quarters, and each leper = 1837 cubic inches. At M. St.Epplier, 53 21 lepers = 10 English quarters, and each leper = 3 337 cubic inches. At Nantes, 19 68 lepers = 10 English quarters, and each leper = 8 599 cubic inches. At Paris, 18 38 lepers = 10 English quarters, and each leper = 9 260 cubic inches. At St. Valery, 18 38 lepers = 10 English quarters, and each leper = 9 260 cubic inches.

The leper is also a liquid measure at Paris and in other parts of France, and in Geneva. A muid of wine at Paris and in some other parts of France, contains 30 lepers, 144 quarts, or 288 pints, and 280 pints without the keg. The pale contains 23 chapters, 4 dem-lepers, or 8 pottins, in all 474 French cubic inches, or 574 English dittos; so that a French pale is nearly equal to an English quart; and a muid of wine contains 71 English gallons.

At Geneva, the char, wine measure, contains 2 lepers; the leper, 24 quarters, or 48 pots, and the leper is about 12 English gallons; 8 37 lepers are = 100 English gallons wine measure, and each leper = 2760 cubic inches.

SEPTIMANCA, SIMANCAS, in Ancient Geography, a town in the interior of Hispafia Citerior, belonging to the Vacceans. In the itinerary of Anthony it is marked on the route from Emerita to Saragossa, between Amallubrica and Nivaria. It was situated on the Duris, S. of Pallentia.

SEPTIEMIN. See SEPTIMAN.

SEPTIMINICIA, a town of Africa Propria, upon the route from Thysdrus to Acre, between Madalama and Tabata, according to the itinerary of Antonine.

SEPTIMONTIUM, among the Romans, a festival celebrated in December, on all the seven hills of Rome; whence also it had this name, being otherwise called Agonalia.

SEPTIZON, SEPTIZONIUM, in the Ancient Architecture, a term almost appropriated to a famous mausoleum of the family of the Antonines, which, Aur. Victor tells us, was built in the tenth region of the city of Rome, being a large insalated building, with seven flages or stories of columns.

The plan was square, and the upper stories of columns falling back much, rendered the pile of a pyramidal form, terminated at top with the statue of the emperor Septimius Severus, who built it.

It had its same septizon, septizonium, from septem and zona, q. d. seven zones or girdles, by reason of its being girt with seven rows of columns.

Historians make mention of another septizon, more ancient than that of Severus, built near the Thermae of Antonine.

SEPTUAGESIMA, in the Calendar, denotes the third Sunday before Lent, or before quadragesima; and quinquagesima is the next before quadragesima, then sevagesima and septimegasiia: these were all days appropriated by the church to acts of penance and mortification, by way of preparing for the devotion of the lent enfuing.

It is suppos'd by force to take its name from its being about seventy days before Easter; pope Telephorus first made it a feast day, and appointed Lent to commence from it.

The laws of king Camillus ordained a vast ban from literature, from septagesima to quinquagesima. (See Quinquagesima.) From septagesima to the octaves after Easter, marriage is forbidden by the canon law.

SEPTUAGINT, LXX, or the Seventy, a term滥用 among divines and critics, for a version of the Old Testament out of Hebrew into Greek, and to have been performed by seventy-two Jewish interpreters, in obedience to an order of Ptolemy Philadelphus.

The ancient, till Jerome's time, universally believed, that the Seventy were united persons, not more translators, grounding their belief on a fabulous history of this version given by Arintheus; who tells us, that the high-priest Eleazar chose six doctors out of each tribe for this office, which made the number of seventy-two; and that these being shut up each in his several cell, each translated the whole; and without seeing what any of the rest had done, they were found to agree to a letter.

The learned Dr. Holy, " De Bibliorum Textibus Originarios," &c. who seems to have studied the origin of the Greek version more accurately than any critic before him, has laboured very successfully in detecting the false story of Arintheus; and he has likewise proved, that this version was made by the Jews living at Alexandria, for the use of themselves, and many thousands of their brethren, who were then settled in Egypt, and who, living among the Greeks, generally used the Greek language. And he has also proved, that the whole Hebrew bible was not translated into Greek at once, but that different parts were translated at different times; that the Pentateuch was translated first, about 285 years before Christ; that only the Pentateuch was read in the synagogues till about 170 years before Christ, when Antiochus Epiphanes, their cruel persecutor, forbade them to recite any part of the law; that soon after this prohibition, the Jews translated into Greek Isahah, and the following prophets, for the use of the temple at Heliopolis and the Alexandrian synagogues; and that the other books were translated afterwards, with different degrees of skill and care, at various times, and by various persons. See also on this subject Prideaux's Connect, vol. iii. p. 38. &c. Brett's Difertation on the ancient Version of the Bible, published in Bishop Watson's Collection of Tracts; Domp's Canon, Walton's Prolegomena, &c. &c. See ALEXANDRIAN Copy, and GREEK BIBLE.

SEPTUAGINT, Chronology of the, or Seventy, is an account of the years of the world, very different from what is found in the Hebrew text, and the Vulgate; making the world 1466 years older than it is found in these latter.

The critics are much divided as to the point of preference. Baranius prefers the account of the Seventy; and H. Vossius makes an apology for it. The two last and most fire

uous advocates in this dispute, are father Pezzan, a Bernardine, and father Le Quien, a Dominican; the former of whom defends the chronology of the Septuagint, and the latter that of the Hebrew text. See SACRED CHRONOLOGY.

SEPTUM, in Anatomy, a name applied to various parts of the body; generally such as separate contiguous cavities.

The SEPUM Auricularum in the heart is placed between the two auricles. See HEART.

SEPTUM Cerebri and Cerebelli, the falicform processes of the dura mater. See BRAIN.
SEP

SEPULCHRUM, the partition between the ventricles of the heart. See Heart.

SEPULCHRUM Breviarii, the partition between the two lateral ventricles of the brain. See Brain.

SEPULCHRUM Narium, the partition between the nostrils. See Nose.

SEPULCHRUM Pelvisferum Penis. See the description of the penis under Generation.

SEPULCHRUM Serrit. See Generation.

SEPULCHRUM Thoracis, the mediafimum, which forms the partition between the two sides of the chest. See Lung.

SEPULCHRUM Transectum, or Musculares, the diaphragm. See Diaphragm.

SEPULCHRUM Septum, in Ancient Geography, a people of Gallia Narbonenfis, who inhabited the town of Bittere, according to Phily. In procfs of time a province of their territory was denominated Septimania.

SEPU, in Geography, a town of Aftatic Turkey, in the government of Sivas; 40 miles S.E. of Sivas.

SEPULCHRAL, SEPULCHRALS, something belonging to sepulchres or tombs.

SEPULCHRAL Column. See Column.

SEPULCHRAL Inscriptions, are the fureft monuments we have of antiquity.

SEPULCHRAL Lamps. See Lamp.

SEPULCHRAL, or SEPULCHRALS, is also the appellation of a fcet; thus called from their supposed principal error, which was, that by the word hell, whither the Scripture tells us Jesus Christ descended after his death, they understood no more than his grave or sepulchre. See Hell.

SEPULCHRALS Pecunia. See Pecunia.

SEPULCHRE, SEPULCHRUM, a tomb, or place, dedicated for the interment of the dead.

The term is chiefly used in speaking of the burying-places of the ancients; those of the moderns we usually call tombs.

Besides the usual sepulchres for the interment, either of the whole body, or of the ashes of the burnt, the ancients had a peculiar kind, called cenotaphia, being empty sepulchres made in honour of some persons, who, perhaps, had no burial at all; from a superfluous opinion, that the soule of those who wanted burial wandered a hundred years before they were admitted to pass into the Elysian fields. See Burial and Cenotaph.

The pyramids are supposed to have been built as sepulchres for the kings of Egypt. And the oblikts had generally the same intent.

Sepulchres were held facred and inviolable, and the care taken of them was deemed a religious duty, grounded on the fear of God, and the belief of the soul's immortality. Thofe who searched or violated them, have been odious to all nations, and always severely punished.

The Egyptians call their sepulchres _eternal house_, in contradiiction to their houses and palaces, which they called _inni_; by reaon of the short fojourn we have in the one, in comparison of our long _lay_ in the other. The efternal pilgrimages are all made with defign to visit the holy sepulchre, that is, the tomb of Jesus Christ. Nobody enters here but bare-footed, and with abundance of ceremonies. The Turks exact twenty-four crowns of each pilgrim, whom devotion carries to the holy sepulchre.

SEPULCHRE, St., or the Holy Sepulchre, gives the deno-
mation to an order of regular canons, anciently inlfituted in Jerusalem, in honour of the holy sepulchre.

They ascribe their institution to Godfrey of Boulogne, who, they fay, upon his taking Jerusalem in the year 1099, placed canons in the patriarchal church of the Holy Sepul-

chre, which indeed is true, but then they were not regulars.

In effeot, it was Arnoul, who, of archdeacon of the church of Jerusalem, got himfelf elected patriarch of it, that, in 1114, firft obliged his canons to live in community, and to follow the rule of St. Augustine.

From the Holy Land numbers of these canons were brought into Europe, particularly into France by Louis the Younger; into England by king Henry; into Poland by Jaxa, a Polish gentleman; and into Flanders by its counts.

But the order was afterwards suppressed by Innocent VIII., and its effeots given to that of Our Lady of Bethlehem, which ifelf cealing, they were bellowed, in 1484, on that of the knights of St. John of Jerusalem, and the infitution did not take place in Poland, nor in several provinces of Germany, where they flill subsift: their general is in Poland: their habit, father Heliot observes, has been different in different places.

SEPULCHRE, St., or the Holy Sepulchre, is also the name of a military order, established in Palentine, as some fay, by Godfrey of Boulogne, but according to others by his facceflor, Baldwin.

However, it is certain there were none but canons in the church of St. Sepulchre till the ear 1114; and it is no more than probable, the knights were only inlfituted upon the ruins of the canons, four hundred years after, and that by pope Alexander VI. in order to excite rich and noble perfons to visit the holy places, by giving them the title of _knights of the Holy Sepulchre_, and to this end, inlfituting an order under that name, of which he referred the quality of mater to himself and his faucceflors.

Leo X. and Clement VII. granted to the guardian of the religious of St. Francis, in the Holy Land, the power of making thefe knights; which power, firft granted _vis a vis_, was afterwards confirmed by a bull of Pius IV. In 1558, the knights of this order in Flanders, chose Philip II. king of Spain, their mater, and afterwards his fon; but the grand master of the order of Malta prevailed on him to reign; and when afterwards the duke Nevers alomed the fame quality in France, the fame grand mater, by his interest and credit, procured a like renunciation of him, and a confirmation of the union of this order to that of Malta.

SEPULCHRI Prestitum. See Prestitum.

SEPULVEDA, John Genesius, in Biography, an eminent Spanish divine, born in the diocefe of Cordova in 1491. He became distinguished for his knowledge of law, philofoophy, and divinity, and was, on account of his great learning, nominated by the emperor Charles V. hiftoriographer and theologian. His fame was chiefly owing to his version of Aristotle into the Latin language. When in the height of his reputation, he was engaged in a controversy from which he derived no honour. It is thus related :

At the time that the celebrated Las Cafas, bishop of Chiapa, was pleading the caufe of the oppressed Indians before the court of Spain, Sepulveda, induced by some Spaniards who had tyrannized over that people, wrote a book in the Latin language, by way of dialogue, in which he undertook to prove, that the wars of the Spaniards in the Indies were just, and founded on their right to subdue the people of that new world; that it was the duty of the Indians to submit to be governed by the Spaniards, on account of their own inferiority in knowledge and wisdom; and that if they would not voluntarily acquiesce in the Spanish dominion, they might and ought to be compelled by force of arms. Sepulveda, to add weight to his argument, declared that his whole object was to establish the right of the kings of Castile and Leon to take possession of their domain in the

As
his real, and to detain them, subject to the order of the court. It ill suits on the return of the forfeit at arms, in which it was certified that the defendant had secreted himself.

Sequestrations were first introduced by Sir Nicholas Bacon, lord keeper, in the reign of queen Elizabeth; before which the court found some difficulty in enforcing its processes and decrees: and they do not seem to be in the nature of processes to bring in the defendant, but only intended to enforce the performance of the court's decree.

Sequestration, in London, is made upon an action of debt: in which case, the action being entered, the officer goes to the shop or warehouse of the defendant, when there is nobody within, and puts a padlock upon the door, &c. using these words, "I do sequestrate this warehouse, and the goods and merchandizes therein of the defendant in the action, to the use of the plaintiff," &c. and having put on his seal, makes return of it to the compter; and after four court days, the plaintiff may have judgment to open the doors, and appraise the goods by a serjeant, who takes a bill of appraisement, having two freemen to appraise them, for which they are to be sworn at the next court holden for that compter; and then the officer puts his hand to the bill of appraisement, and the court giveth judgment.

However, the defendant in the action may put in bail before satisfaction, and so dissolve the sequestration; and after satisfaction may put in bail ad diem prorogandum debita, &c.

Sequestration, Sequestration, in Chemistry, a term used by some writers to express separation.

SEQUESTRO HABENDO, in Law, a writ judicial for the disbursing a sequestration of the profits of a church-benefice, granted by the bishop at the king's commandment, in order to compel the parson to appear at the suit of another. The parson, upon his appearance, may have this writ for the release of the sequestration.

SEQUIN, ZECAIN, Zecchio, a gold coin struck at Venice, Genoa, Rome, Milan, Piedmont, and Tuscany, and in several parts of the grand signior's states.

Ablancourt derives the word from Cicizium, or Cicixeni-um; as supposing the sequin first struck at Cuzium: Menage, from the Italian zecchino, of zecca, the name of the mint at Venice. At Florence, pieces of 3 sequins are called Ruffoni (see Ruspono); zecchini or sequins, called Gigliati, weigh 2 denari 23 grains, and are worth 131 lire or 20 palii. The Roman and Genoa sequins circulated here are valued at 13 lire; Venetian sequins at 132 lire. The sequin Gigliato weighs 532 English grains, and the gold is 232 carats fine; it is therefore worth 91.6d. sterling. At Rome 100 francoloni, or 50 zecchini, are exchanged for 100 fendi Roman, more or less. At Genoa, the sequins are valued at 13 lire 10 foldi. In 1607 the Roman sequins were valued here at 14l., and the Venetian at 14l. 17s. The weight of the sequin at Genoa is 70 grains of gold 232 carats fine, and its value is 91.5d. At Leghorn the sequin is current for 13 lire 6 foldi 8 denari, of moneta buona, and for 13 lire 18 foldi 3 denari of moneta langua. At Lucca in Italy the sequin pales for 141 lire; Venetian sequins are taken at the same as other Italian sequins, and German ducats at 14 lire 6 foldi. In the island of Malta, Venetian sequins pass for 6 fendi; the scudo current money being worth 20. d. sterling. At Marseille, Italian sequins pass for 11 livres 2 sous, more or less. At Milan, sequins, weighing 2 denari 204 grains, are valued at 15 lire 4 foldi. At Parma the sequin is valued at 45 lire, the lira being worth 23d. nearly.

At Rome, the zecchini or sequins are current at 21½ paoli, with their doubles and halves in proportion. The sequin is to weigh 2 denari 21½ grains, or 52½ English grains, and the gold is 232 carats fine; so that it contains little more than 52 grains of pure gold, and is therefore worth 91. 3d. sterling. At Tunis, a Venetian sequin pallies for 2 piastres, 32 apfers, more or less. At Venice, the gold coins of the old republic are zecchini or sequins, with halves and quarters. The sequin is commonly reckoned at 22 lire, but it bears a fluctuating agio, which in the year 1805 was 37 per cent.: 68½ zecchini or sequins are to contain a Venetian mark of fine gold; and are said to have no alloy; the quantity of alloy, however, is small and uncertain. The Venetian sequin weighs 54 English grains nearly, and it is therefore worth 91. 6d. sterling.

The aßay of the Genoa sequin is better than the English standard of 22 carats, and its value, &c. according to the mint price of gold in England, viz. 3/. 17½. 10½d. per oz is as follows: viz. the aßay 1 carat 32½ grains, weight 2 dwt. 53 grains, contents in pure gold 53.4 grains, and value in sterling 91. 53d. The sequin of Milan is better than the English standard; its aßay is 1 car. 3 grs., its weight 2 dwt. 53 grains, its contents in pure gold 53.2 grains, and its in sterling value is 91. 52d. The sequin or two-ducat piece of Naples, of 1762, is worse than Eng. aßay.; its aßay is 1 car. 22 grs., weight 1 dwt. 203 grains, contents in pure gold 53.4 grains, and its in sterling value 73d. The sequin of Piedmont (and half sequin in proportion) is better than Eng. aßay.; its aßay is 1 car. 23½ grs., weight 2 dwt. 53½ grains, contents in pure gold 52.9 grains, and value 91. 45d. The sequin of Rome, coined before 1760, is better than Eng. aßay.; its aßay is 1 car. 2 grs., weight 2 dwt. 43½ grains, contents in pure gold 51.4 grains, and value 91. 14d. The aßay of the sequin coined since 1760 is 1 car. 32½ grs., its weight 2 dwt. 43½ grs., its contents in pure gold 53.6 grains, and its value 91. 53d. The zecchino or sequin (the half and quarter in proportion) of Venice is better than the English standard; its aßay is 1 car. 33½ grs., its weight 2 dwt. 52½ grs., its contents in pure gold 53.6 grains, and its value 91. 53d.

The impressions on the Italian sequins are as follow: on that of Genoa, St. John the Baptist holding a croos; legend, NON SURREXIT MAJOR, i.e. a greater has not arisen, and the date; reversé, the arms of Genoa with a crown; legend, DUXX ET GUB. RÉPUBL. GENU. I. D. doxe and governor of the republic of Genoa. On that of Milan, the head of the reigning emperor of Germany, with name and title this; JOSEP. H. D. G. R. IMP. S. AUG. G. H. ET P. REGES. A. A. i.e. Joseph the second, by the grace of God, emperor of Rome, emperor of Austria, king of Germany, Hungary, and Bohemia, archduke of Austria; reversé, arms of Milan; legend, MEDIO LANI ET MANTUAE: duke of Milan and Mantua. On that of Venice, a man holding a croos, and another kneeling before him with the doge's name, as ALOY. MOC. (Alvayus Mocenigo), and the letters s. m. v. e. n. e. one above the other near the edge of the piece, i.e. Sanctus Marcus Venetus; also the letters d. v. x. DUXX, duke or doge, placed in the same manner above the knobbing figure: reversé, a whole length figure of St. Mark, holding a book, and surrounded with flares; legend, ST. T. X. P. D. Q. T. REGIS ISTE DUCA, supposéd by Muratori in his "Antiquitates Italicae Medii Aevi," to denote, SIT TIBI CHRIJE DATUM, quod (vel quia) tu regis Iste ducatum, i.e. To thee, O Christ,
O Christ, be it (this coin) given, because thou governest (universally). He, St. Mark, governs the duck. Muratori doubts this interpretation and supposes that it might have been originally ". The legend, however, is curious, as being both an hexameter verse and a monikith rhyme.

The half and quarter sequins bear the same muntteniations, but the legend on the reverse is, Egg sum, i.e. I am the light of the world.

At Cochin, on the Malabar coast, Venetian sequins are worth 72panams, of which 20 are reckoned for a rupee. At Goa, Venetian sequins are worth 16good tings, each of which is worth about 7½d. feeling. At Surat, the weight of a Venetian sequin is reckoned at 24 valls, of which 8½ make 1 oz. troy.

The gold coins of Turkey are the sequin or chequen, called the sequin funduch, coined in the year 1764; 100 of these weigh 110 Turkish drahms, or 5415 English grains, and are about 23 carats fine. The sequin funduch at Constantinople passed at first for 3½ piastres, or 4½ apers; but its price was gradually raised to 4 piastres.

In 1769 most of them were called in for a new coinage. There is another sequin, called mahbub, or zermahbub, and ingerly; the nisef, or half mahbub; and the roubbie, or one-third dito: 100 mahubs, 200 nisies, or 300 roubbies, were to weigh 8¼ Turkish drahms, or 4061 English grains: they were at first 22 carats fine; but in 1781 were reduced to 19½ carats; and in subsequent coinages they have been still more debased. Venetian sequins pass at present for 94 piastres. At Alexandria in Egypt the sequin, called funduncle, is worth 146 medini; that called zumabob is valued at 120 medini, 40 medini being a piastre. At Grand Cairo in Egypt, contracts are made in funduncle and mahbub sequins; the former are reckoned at 146 medini, and 3 mahubs are equal to 4 pataejas, so that the mahbub is worth 120 medini. The only coins allowed by the Turkish government to be struck at Cairo are the mahbub (or zermahbub) sequins, and medini: 40 medini are valued at 19½d. feeling, so that the mahbub is worth 41. 9¼d. feeling. Mahubs, however, of inferior value, are coined by the Beys in Egypt, and generally pass for 110 medini. The Turkish coins are current at Patras in the Morea. Some European gold ducats and sequins circulate in Persia. The sequin funduch of Constantinople of 1773 is worse than the English standard: its assay is 2 car. 26 gr.; its weight 2 dwt. 52 ½ gr.; its contents in pure gold 43.4 gr., and its feeling value 71. 83d. The sequin funduch of 1789 is worse than the English standard: its assay is 2 car. 33 ½ gr.; its weight 2 dwt. 52 ½ gr.; its contents in pure gold 42.0 gr., and its value 71. 73d.

The double sequin mahbub of Constantinople of 1773 is better than the English standard: its assay is 1 car. 33 ½ gr.; its weight 3 dwt. 44 gr.; its contents in pure gold 73.1 gr., and its value 125. 11½d. The sequin mahbub of 1789 is worse than the English standard: its assay is 2 car. 22 ½ gr.; its weight 2 dwt. 13 gr.; its contents in pure gold 28.9 gr., and its value 51. 10d. The sequin of Cairo of 1773 is also worse than the English standard: its assay is 3 car. 04 gr.; its weight 1 dwt. 15 ½ gr.; its contents in pure gold 31 gr., and its value 51. 54d. The sequin of Cairo of 1789 is also worse than the English standard: its assay is 5 car. 24 gr.; its weight 1 dwt. 15 ½ gr.; its contents in pure gold 26.9 gr., and its value 46. 04d.

As the representation of men and animals is forbidden by the Mahometan law, the Turkish coins have no other imitations but inscriptions stating the names, titles, deficient, &c. of their sultans, with the date of the hegra, or Mahometan era. They are in the Arabic language, and the following translations from the principal cases of sultan Selim (1566) may serve as a specimen, all the rest being in the form of style of these compositions.

The sequin mahbub has on one side, " Sultan Selim, son of Mulufa Khan, may he be victorious, and his value be blest, struck at Slanbul (Constantinople) in the year 1203;" and on the reverse, " Sultan of the two lands, and sovereign of the two less, sultan by inheritance, son of a sultan."

The words, " May he be victorious, and his value be blest," are occasionally used by the Turks at the end of their prayers. By the "two lands," are meant Europe and Asia; and by the "two less," the Black Sea and the Archipelago. The latter is also called here the White Sea.

The sequin funduch has on one side, " Sultan Selim, son of Mulufa Khan;" and on the other, " Struck at Slanbul, in the year 1203;"

The imitations of sequins of different periods mostly answer to either of the foregoing descriptions; but the sequins coined at Cairo, under sultan Abdulhamid in 1773, have their inscriptions as follows: " Sultan Abdulhamid, son of Ahmed Khan, may his value be blest, struck in Egypt in the year 1787;" and on the reverse, the titles as on the sequin mahbub of Selim.

The pieces of two, three, four, and five sequins bear the same inscriptions as the single sequin, and are sometimes also encircled with ornaments.

The sequins of the Barbary States are coined in the name of the grand seigneur, and are only distinguished by the words, "Struck at Tunis, Tripoli," &c. They bear on the reverse the titles as on the sequin mahbub of Selim.

Kelly's Un. Cambill.

SERA, in Ancient Geography, a town of Senaca, which had the title of metropolis, according to Ptolemy.

SERA, in Geography, a town of Hindoostan, and capital of a district, once a considerable subah, conquered by Hyder Ali; taken from the dominions of his son Tippoo, and given to the Nizam in the year 1800; 58 miles N.W. of Bangalore. N. lat. 13° 28'. E. long. 75° 54'.—Also, a town of Hindoostan, in Guzerat; 24 miles S. of Dungarpour.

SEERA CAPRIOIA, a town of Naples, in the province of Capitanata; 14 miles S.S.E. of Termoli.

SERAB, a district of Adiribiztan, or Azerbaijan, and a town, 15 miles E. of Tabris.

SERABIS, in Ancient Geography, a river of Hispania, in the Tarragonensis. Ptolemy.

SERACH, in the Turkish Military Orders, an officer who holds the stiring of the caza of the janizaries in charge, attends him when he goes out on horseback, and serves him as a mel linger on all occasions. After this office he has the title of shous; and after he has passed through this, he has the same office under the age of the janizaries. Pococke's Egypt, p. 165.

SERACONYA, in Geography, a town of Bengal; 38 miles E.S.E. of Ismailbad.

SERACORRO, a town of Africa, in Bamburra; 80 miles W.N.W. of Segu.

SERAES, or SERIKAS, a town of Persia, in the province of Khorsan; 180 miles N.W. of Herat. The Bedouin has its source near this place.

SERAFFINI, in Biography, an Italian singer, with a feeble soprano voice, but so good an actor, that in 1754, when Metalasfo's "Attilio Regolo," let by Halle, was performed in London, in the last scene of this opera, which ends with an accompanied recitative, without an air, he was constantly encored; but perhaps it was the poet who

1.2

was
SER AGANORE, in Geography, a town of Hindoothan, in the Carnatic; 5 miles S.S.W. of Ootacoor.

SERAGE, in Ornithology, an English name for a bird of the larus, or gull-kind, more usually called the sea-swallow, and by authors larus.

SERAGIO, in Geography, a town of the island of Corfica; 6 miles S. of Corve.

SERAGLIO, a district of Italy, south of Mantua, in which Augustus had some palaces; called also "Virgian Fields."

SERAGLIO, formed of the Turkish word serai, which is borrowed from the Persian seraw, signifying a boyce, among the Levantines denotes the palace of a prince or lord.

At Constantinople they say, the seraglio of the ambassador of England, or France, &c. of Honour.

The seraglio is used, by way of eminence, for the palace of the grand feignior at Constantinople, where he keeps his court, and where his concubines are lodged, and where the youth are trained up for the chief pets of the empire.

It is a triangle about three Italian miles round, wholly within the city, at the end of the promontory Chrysoceras, now called the Seraglio Point. The buildings run back to the top of the hill, and from thence are gardens that reach to the edge of the sea. It is inclosed with a very high and strong wall, upon which there are several watch towers: and it has many gates, some of which open towards the sea-side, and the rest into the city: but the chief gate is one of the latter, which is constantly guarded by a company of cafooeches, or porters; and in the night it is well guarded towards the sea.

The outward appearance, du Loir tells us, is not beautiful, in regard the architecture is irregular, being cantoned out into separate edifices and apartments, in manner of pavilions and domes. No stranger, it is said, has ever yet been admitted to the inmost parts of the seraglio. See SULTANA.

The old seraglio is the place where the emperor's old mistresses, who have died or who have been deposited, and the fultanas that have belonged to the deceased grand feignior, are kept.

They are here fed and maintained with some luxury, and served with much attention, but they can no longer go out of this place of retirement; for it would not be decent, in the estimation of the Mussulmans, that a slave, suppos'd to have enjoyed the favours of a sultan, should pass into the arms of another man.

The harem is a quarter of the seraglio in which the females are kept. This is soon replenished, becaufe traders come from all parts to offer young slaves, and the pachas and great men are eager to present beauties capable of fixing the attention of the sovereign; thus hoping to obtain instantly his good graces, and place about his person the women who at some future time may be useful to them.

It is very difficult, and perhaps impossible, to learn exactly the manner in which the female slaves are treated in the harem of the grand feignior: never has the eye of the observer penetrated into this abode of hatred, jealousy, and pride; into this abode where pleasure and love have so feldom rekindled. But, according to the account of the women, whose profession calls them thither, the reader may reprefent to himself three or four hundred black eunuchs, malicious, peevifh, tormented by their impotence, cursing their nullity, endeavouring to counteract the female flaves intrusted to their charge; then a confiderable number of young women, whose hearts would willingly expand, whose fonfees are moved at the idea of the pleasures which they wish in vain to know, jealous of the happy flaves which they are perfuaded that their rivals enjoy, cursing the overfeers who perplex them, solely taken up with their toilet, with their fads, and with all the nonfence which idlenes and ignorance can fuggelt to them; feking, rather from vanity than from love, every means of pleasing a master, too frequently difpainful. We may reprefent to ourselves, in short, a fultan young or old, malfiered by ridiculous prejudices, without delicacy, often whimifical or capricious, alone in the midst of five or fix hundred women, all equally beautiful, in whom he gives birth to defires which he is unable to gratify, who enjoys with them no pleasures but fuch as are too eafy and without prudence, in which the heart has no fhare, and we may have a f true idea of what paffes in the harem of the grand feignior.

The charge of the women is intrusted only to black eunuchs, whose mutilation is fuch, that there remains no trace of their sex. Oriental jealoufy has very rightly judged, that fuch creatures were rather capable of infliring sentiments of hatred and contempt, than of affection and friendship, which would not have failed to take birth, if the charge of the harem had been intrusted to women. It was not enough to condemn thefe unfortunate females to long privations, never to let them know of love only what was to excite in them defires, it was even neceffary to deprive them of the conflation of opening their heart in the bosom of friendship.

The chief of the black eunuchs, called kiflar-agaj, is one of the greatest perfonages of the empire; he is who carries to the female flaves the will of his master; he it is who announces to them the happyflses which they have to pleaf him. Independently of the authority which he exercises in the harem, he has the superintendence of all the imperial moqifes; he is charged with the general administration of all the pious foundations which relate to them; he has the pre-eminence over the chief of the white eunuchs, and, what is more flattering to a slave, he more frequently approaches his master, and more commonly enjoys his confidence. His income is very considerable.

The kllifin-rekili is the second eunuch of the seraglio; he replaces the kiflar-agaj, when he dies, or is turned out of office. He has the general administration of the inferior imperial treasure, which must be distinguished from the private treasure of the grand feignior, administered by the khanadar-agaj, one of the pages of confidence. There are some other eunuchs raised in dignity, fuch as he who belongs to the queen-mother, he to whom the care of the princes is intrusted, those who serve the royal moqif of the fultana Valida, whiter the flaves of the grand feignior go to fay their prayers; he who has the particular superintendence of the apartment of the hajfeke; and a few others whose functions are less important.

The white eunuchs do not approach the women; they are employed out of the harem, and in the particular service of the fultana. They have the charge of the gates of the seraglio; they superintend and intruct the pages. Their chief is called capou-agaj. (See CAPO-AGAJ.) For an account of other officers of the seraglio, see BOSTANGI-BASCHI, ICHOGLAN, and CAPO-AGAJ.

Balzac observes, that the seraglio at Constantinople is only a copy of that which Solomon anciently built at Jerusalem, for his wives and concubines. For a particular description
SERAPIS, in Geography, a town of Bengal; 28 miles N. of Mauludah.

SERAPH, or SERAPHIM, in the Hierarchy of Angels, a spirit supposed to be of the first or highest rank. The seraphs, or rather sefaraph, make that chas of angels, supposed to be the most inflamed with divine love, by their nearer and more immediate attendance on the throne, and to communicate their heat to the inferior and remoter orders: hence their name, which is formed from the Hebrew root 5517, to burn, inflame.

Seraph is also said to be the name of a Turkish gold coin, worth about 57. florins.

Seraph's head, in Heraldry, is used to denote a child's head, with three pair of wings, two in chief, two in fess, and two in base.

Seraphic, something belonging to the seraphan.

Mr. Boyle has a treatise of seraphic love, i.e. of divine love, or the love of God.

In the schools, St. Bonaventure is called the Seraphic Doctor, from his abundant zeal and fervour.

St. Francis, founder of the Cordeliers and Franciscais, is called the Seraphic Father, in memory of a vision he saw on mount Alverna.

Seraphim. See Seraph.
Rudb. Elyt. v. 2. 204. Orchidæ Etruria; Petiv. Gazoph. t. 128. f. 1—3? Telficti species tertia; Matth. Valgr. v. 2. 233. f. 1. Dalech. Hist. 1551.)—Lateral segments of the lip erect; middle one ovate, smooth.—Native of open mountainous situations in the south of Europe. Dr. Sibthorp gathered it in Zante, as well as in Greece, and we readily ascribe to the opinion of a learned German writer, in the Allgemeine Literatur-zeitung, for June 1807, n. 133. 1066, that this plant, and not Iris tuberosa, is probably the true nobilis of Dioecorides. The root conflicts of two stalked, roundish knobs, like others of this tribe, but rather smaller. Stem a foot high, clothed in the lower part with lanceolate, sheathing, smooth leaves. Spike of from two to eight flowers, with a large, concave, purplish-grey bractea to each. Calyx ribbed, of the same colour as the bracteas, and pointed like them, three quarters of an inch long. Lip twice that length; its disk whitish, with a dark red, oblong, undivided elevation at the base, and two rounded, erect, lateral lobes of the same colour; the central lobe dependent, ovate, pointed, undulated, purplish, veiny, smooth. Haller justly refers both to the above synonyms of Rudbeck to this species.

2. S. cordigera. Heart-handed Serapis. Linn. Sp. Pl. 1342. Willd. n. 2. Att. n. 2. Sm. Fl. Græc. Sicibh. t. 932, unpublished. Andr. Repof. t. 475. (Orchis montana italicæ, flore ferrugineo, linguæ oblongæ; Rudb. Elyt. v. 2. 203 f. 18. O. Etruria, linguæ ferruginea piolaris; Petiv. Gazoph. t. 128. f. 4.)—Lateral segments of the lip erect; middle one heart-shaped, hairy.—More frequent than the foregoing in the south of Europe, and north of Africa, in the same kind of situations. We gathered it in July 1787, in pastures at St. Orfeke, near Genoa. The whole plant, especially the bulb and flowers, are larger than in S. Lingua, and the whole spike is of a more dingy hue. The colour, however, of the different parts is variable in both. The broad hairy lip of cordigera, with a divided glandular elevation at its base, is sufficiently characteristic. We trust we are right in the citation of Rudbeck, and that he misquotes Matthiolus.

Willdenow's S. oxyglossis, founded solely on Petiver's t. 128. f. 5 & 6, appears to us too uncertain to be adopted, though we doubt not that some distinct species of this order, and perhaps of this genus, are still latent in Italy.

Serapias, in the Materia Medica, the official name of the dried root, called falan.

SERAPION, of Alexandria, in Biography, lived about the year 260 before Christ, or in the 125th Olympiad, and is ascribed to Celsus to have been the founder of the empirical sect of physicians, and accused by Galen of vaunting himself, and of mal treating the character of Hippocrates. (See Empiric.) He was probably a contemporary of Philinus, to whom also the origin of the fame-fect has been attributed. See Celsus, Praef.

SERAPION, JOHN, or JOHN, the Son of Serapion, an Arabian physician, lived between the time of Mene and Rhazes, and was probably the first writer on physic in the Arabic language; for it appears that Mene, like his predecessor Aaron, or Ahrun, wrote in the Syriac tongue. Haly Abbas, when giving an account of the works of his countrymen, describes the writings of Serapion, as containing only an account of the cure of disease, without any precepts concerning the preservation of health, or relating to surgery; and he makes many critical observations, which, Dr. Freind observes, are sufficient proofs of the genuine existence of the works ascribed to Serapion, from their truth and correctness. Rhazes also quotes them frequently in his "Continent." Serapion must have lived towards the middle of the ninth century, and not in the reign of Leo Haurus, about the year 720, as some have stated. One circumstance remarkable in Serapion, Dr. Freind observes, is, that he often transcribes the writings of Alexander Trallian, an author with whom few of the other Arabians appear to be much acquainted. This work of Serapion has been published, in translations, by Gerard of Cremona, under the title of "Practica, Dieta Breviaria," and by Torinus, under that of "Therapeutica Methodus." See Freind's History of Physic, and Sprengel Geschichte der Arzneikunde, ii. 365.

Some confusion appears to exist respecting another Serapion, whom Sprengel calls the younger, and places 180 years later than the former, and who was probably the author of a work on the materia medica, entitled "De Medicamentis tam simplicibus, quam compositis." This work bears intrinsic evidence of being produced at a much later period, since authors are quoted who lived much posterior to Rhazes. It is probable that this work, which might obviously have been composed in the latter part of the eleventh century, (for Aventzor, who wrote in that century, is quoted in it,) is the same with that which is often cited by Constance, the African, under the name of Joannes Damascenus, a name which some authors have erroneously given to the elder Serapion, instead of the subject of the present article; and some to Mefue; to the latter of whom Freind has shewn that it could not belong. See Freind and Sprengel, as above quoted.

SERAPIONIS Portus et Præmonstrariorum, in Ancient Geography, a port and promontory of Ethiopia, between Efinna emporium and Tonice emporium, according to Ptolemy.

SERAPIS, in Mythology, an Egyptian deity, who was worshipped under various names and attributes, as the tutelary god of Egypt in general, and as the patron of several of their principal cities.

Tacitus informs us, that he was worshipped as a kind of universal deity that represented Ecclepius, Oforis, Jupiter, and Pluto; and he was sometimes taken for Jupiter Ammon, the Sun, and Neptune; and the honours that were rendered to him at Alexandria were more solemn and extraordinary than those of any other place.

Learned writers have differed in opinion as to the time of the introduction of this deity into Egypt: some have supposed that he was known and worshipped in this country long before the time of the First Ptolemy, and that he was the same with their Aphis; Serapis being no other than Aphis or Esous, i.e. Aphis in his coffin. Accordingly, they say, that while the sacred bull, which the Egyptians worshipped for their great god, was alive, he was called Aphis; and that when he was dead and buried in his coffin, he was called Serapis, that is, Aphis in foro, and thus they derive his name by corruption from sarapis: and some have even imagined that the patriarch Joseph was worshipped under this title; but to this etymology it has been objected, that as the Ptolemies first brought the Greek language into Egypt, if Serapis had been an ancient god worshipped in that country before the Ptolemies reigned there, his name could not have had a Greek etymology.

According to the learned Mr. Bryant, sar signifies any thing noble; and Oforis, the great husbandman, who had been exiled in an ark, was styled sar-apis, which signifies illithrus genitor, the great father of mankind. But, he observes, that there was likewise the term sar, from whence came the sarapis of the Greeks, which signified a beur or coffin, and also a place of internment. Hence the temple where the dead Aphis was deposited, had the name of Sar-apis, rendered inaccurately sarapis.

Plutarch,
Phæareth, who did not know this, then fancied that some people in Egypt would not allow Serapis to have been a god: the difpute was about the found of a word: no Egyptian could deny the divinity of the god Serapis; but Serapis had another meaning; and this was the term in debate. Upon the whole he concludes, that the demon, or deified man, was Serapis, and that Serapis was the tomb of Apis. Analysis of Ancient Mythology, vol. ii. p. 428.

Others have maintained, that Serapis was not originally an Egyptian deity, and was worshipped in that country, but an adventitious god brought thither from abroad. The ancient place of its mention, according to Ptolemy, was on the coast of the Propontis, on the Thracian side, over against Hieras; and there Jason, when he went on the Argonautic expedition, sacrificed to him. Thence its image was brought to Sinope in Pontus; and from Sinope, Ptolemy, the first of that name, in obedience, as it is said, to a supernatural direction, brought it to Alexandria, and set it up in one of the suburbs of that city, called Rhakasis, where it was worshipped by the name of Serapis; and this new god had in that place, soon after, a very famous temple erected to him, called the Serapeum. This temple, says Annius Marcellinus, did, in the magnificence and ornaments of its buildings, exceed all other edifices in the world, next to that of the Capitol at Rome. Hence Serapis became the god of the court, and led the Egyptians almost to forget their ancient gods. The provinces vied with each other in building temples to him, and burning incense on his altars. The most ancient temple, according to Pausanias, was that at Memphis.

And this, say the advocates of this opinion, was the first time that this deity was either worshipped or known in Egypt.

Ptolemy found great difficulty in obtaining this image; but the inhabitants of Sinope, being oppressed with a grievous famine, were relieved by Ptolemy with a fleet of corn, and in return they consented to part with the image of their god.

The statue of Serapis, according to Macrobius, was of a human form, with a basket or buflfet on his head, resembling plenty, and referring, as some say, to the history of Joseph's supplying the Egyptians with corn; or, according to others, to the relief of Sinope by Ptolemy: his right hand leaned on the head of a serpent, whose body was wound round a figure with three heads, of a dog, a bull, and a wolf; in his left he held a measure of a cubit length, as a wolf to take the height of the waters of the Nile.

Those who maintain that Serapis was a foreign god, unknown to the Egyptians before the time of the Ptolemies, argue, that Herodotus, who dilates in his account of the Egyptian gods, makes no mention of Serapis; which he probably would have done, if he had been one of the great gods of that people. Moreover, the Iliac tableau, upon which so many Egyptian deities appear, presents us with nothing that resembles Serapis. Besides, Tacitus relates, that Serapis appeared in a dream to Ptolemy, under the figure of an exquisitely beautiful young man, and ordered him to feed two of his most faithful friends to Sinope, a city of Pontus, where he was worshipped, and to bring his statue from thence. Ptolemy, having communicated this vision, deputed a select embassy to Sinope, and from thence the statue of that god was brought. Hence it is concluded that he was unknown in Egypt before this event.

On the other hand, those who contend that Serapis was one of the great gods of Egypt, where he was worshipped before the time of the Ptolemies, allege, that before the testimony of Tacitus can be admitted, it must be proved that Serapis was the deity actually worshipped at Sinope, whereas, they say, that the god to whom that city paid adoration was Pluto; and that the same Serapis was not given to him till his statue was brought unto Egypt. Ptolemy tells us, that he had not that name when he came into Egypt; but upon his arrival at Alexandria, he took the name which the Egyptians gave to Pluto, which was Serapis. When Pausanias relates, that the Alexandria was received from Ptolemy the worship of Serapis, he says, at the same time, that there was already at Alexandria a very magnificent temple of that god; and another, not to grand, but of great antiquity, in the city of Memphis. Tacitus himself, when he says that Ptolemy, after Serapis was brought into Egypt, built a flatly temple to him in the place named Rahasis, affirms also, that there was another smaller one, consecrated to the same god, and to Isis; which proves, that not Serapis was not worshipped in Egypt till the time of the embassy to Sinope, but only that the worship of that god, perhaps neglected for a long time, was re-established there with solemnity. The silence of Herodotus, and the omission in the Iliac table, may be accounted for by the following considerations. Though it is true that Herodotus set apart his second book for the history of the Egyptian religion, yet we cannot be sure that he has omitted none of their gods. Besides, having spoken fully of Osiris, who was perhaps the same with Serapis, he might think it needless to say any thing particularly of the latter. The same observance is applicable to the Iliac table. Although a great number of the Egyptian gods may be found there, yet it cannot be affirmed that they are all there, and much less that they can all be distinguished by their particular symbols. The proof drawn from the diversity of representations is yet less conclusive. The Egyptians varied exceedingly with respect to the figures of their gods, and the symbols annexed to them. The figures frequently bore a vast number of attributes, which could not agree to a single divinity. These are what have been called the Pantheon figures, which represented several deities; as any one may be convinced by viewing some of those of Isis, of Harpocrates, and others. From these, and from other considerations, many learned men have inferred that Serapis was an Egyptian god, known and worshipped by that people long before the time of the Ptolemies; and that he was the same with Pluto; and though the testimonies of Tacitus and Plutarch, above cited, were less conclusive than they are, yet one of the finest statues of that god, at whose feet we see the three-headed Cerberus, would leave no room to doubt. See a print of this figure in Montfaucon's Antiquity, tom. ii. p. 185. Antiquarians have furnished us with several other figures, always known to be those of Serapis by the calathus, or a kind of bonnet which he wore upon his head. Sometimes he is joined with Isis, and represented like a young man, and then he is taken for Osiris or the Sun; frequently like a bearded old man, very much resembling Jupiter, whose name he also bore; at least, from the time that the Greeks became masters of Egypt. Varro says, that there was a law which forbade saying, under pain of death, that Serapis had been a mortal man.

We shall here add, that Osiris was variously represented, sometimes by a sceptre and eye, to express his power and providence; at other times, by the image of a hawk, because of its sharp flight, swiftness, and other qualities; and in later times, in a human form, in a posture not very decent, signifying his generative and nutritive faculty; but the greatest adoration was paid to his living image, the bull.

The image of Isis was usually in the form of a woman, with cow's horns on her head, representing the appearance
of the moon in her incease and decrease, and holding the sistrum (a kind of cymbal) in her right hand, and a pitcher in her left; the former signifying the perpetual motion there is in nature, and the other the fecundity of the Nile. But sometimes she was represented as Cybele, having her body full of breaths, to express her nourishing of all things.

It is observed, that when Serapis was introduced into Egypt, at the period above-mentioned, as writers have inferred from the silence of Herodotus, and of other authors who wrote before the times of the Ptolemies, he brought in with him among the Egyptians, a new way of worship: for till the time of the Ptolemies, the Egyptians never offered any bloody sacrifices to their gods, but worshipped them merely with their prayers and frankincense; but the tyranny of these princes having forced upon them the worship of two foreign gods, viz. Saturn and Serapis, they in this worship first introduced the use of bloody sacrifices among that people. And so averse were the Egyptians to this mode of worship, that they would never suffer any temple to be built to either of these gods within any of the walls of their cities, but they were always erected in their suburbs: and they seem to be only Egyptians of the Greek original who conformed to this practice, and not those of the old race. See Exod. viii. 26, 27. Prid. Conn. vol. iii. p. 15, &c.

The famous temple of Serapis at Alexandria was destroyed by order of Theodosius; and the celebrated statue of this deity was broken in pieces, and its limbs carried first in triumph by the Christians through the city, and then thrown into a fierce fire, kindled for that purpose in the amphitheatre. As the Egyptians ascribed the overflowing of the Nile, to which was owing the fertility of that country, to the benign influence of their god Serapis, they concluded, that, now he was destroyed, the river would no longer overflow, and that a general famine would ensue; but when they observed, on the contrary, that the Nile swelled to a greater height than had been known in the memory of man, and thereby produced an immense plenty of all kinds of provisions, many of the pagans, renouncing the worship of idols, adored the God of the Christians. Ancient Univ. Hist. vol. vi. p. 417.

The figure of Serapis is found on many ancient medals.

SERAPIU, in Ancient Geography, a place of Egypt, beyond the Nile, between Hero and Clidmo, according to the Itinerary of Antonine.

SERAQUINO, in Geography, an island in the Grecian Archipelago; 8 miles N.E. of Scopelo.

SERARIUS, NICHOLAS, in Biography, a learned Jew, was born at Ramherrillers, in Lorraine, in 1555. He studied at Cologne, where he entered into the society of the Jews, and afterwards was for twenty-four years a professor of the languages of philosophy and theology at Wurtzburg. He died at Mentz in 1609, having, besides his employment in teaching, occupied himself in the composition of a vast number of works, which were printed collectively at Mentz, in 3 vols. folio. Of these, the most esteemed were "Commentaries on several Books of Scripture," "Prolegomena on the Holy Scriptures," "Trihexedrum, seu de celeribus tribus, apud Judaeos, Pharisæorum, Sadduceorum, et Elenorum Seificus." This last work was afterwards printed at Delft, with the addition of the treatises of Driusius and Scaliger on the same subject. Serarius was a strenuous defender of the church of Rome against the reformers, and wrote several works against Luther and his followers. Cardinal Baronius gives him the title "of the luminary of the Germanic church." Dupin says, that the Prolegomena of Serarius have a great deal of erudition, but that he handles his questions in too scholastic a manner, and mixes up too much controversy in them: he thus furns up the literary character of this author; "Serarius," says he, "was very learned, and well versed in the languages, and in topics relating to the Holy Scriptures: he is not equally exact in ecclesiastical history, nor equally powerful in controversy. He wrote with ease, but without politenes. In treating on a subject, he often defends to impertinent and tedious trilling, and sometimes wanders from the point to attack the Protetants, and diffuses controversial questions."

SERASAPOUR, in Geography, a town of Hindooftan, in Bahar; 18 miles W. of Bahar.

SEASKER, a Turkish word, composed of fer, which in Perzian signifies head, and after, i.e. soldiers. This is a military degree, that admits of no superior, somewhat like generalissimo, and is a title given to those who command on the frontiers, or are detached with a considerable body of troops.

SERASPARE, in Ancient Geography, a town of Asia, in the Leffer Armenia, and in the prefecture of Rhanena, according to Ptolemy.

SERASS, in Ornithology, a bird of the same genus with the colum, which comes yearly to Surat in the Eait Indies, from mount Caucafus, and distinguished by a plication of the alperia arteria; which is designed to anwer similar purposes with that of the colum.

SERAT, SERED, or Sredo, in Geography, a town of Hungary, on the river Waag; 27 miles E. of Prefburg.

SERATZ, a town of Scelavonia; 28 miles N.W. of Polzega.

SERAVEN, in Ornithology, the name given by Buffon to the Loxia Aarhus, which lee.

SERACOURT, in Geography, a town of France, in the department of the Aine; 6 miles S. of St. Quinten.

SERAVI, a town of Egypt, on the E. branch of the Nile; 21 miles N. of Cairo.

SERAUSTH, a town of Candahar; 30 miles S.W. of Cabul.

SERAY, a town of Hindooftan, in Bahar; 12 miles N. of Chuoprah. N. lat. 25° 18'. E. long. 84° 53'.—Also, a town of Hindooftan, in Boggicund; 20 miles W. of Rewah.

SERAYA, a town of Hindooftan, on the right bank of the Jumnah; 42 miles S.E. of Agra.—Also, a town of Hindooftan, in Bahar; 10 miles S. of Bertiah. N. lat. 26° 28'. E. long. 86° 53'.

SERBADJE, a town of Egypt, on the E. bank of the Nile; 20 miles N. of Cairo.

SERBAJEE, in the Eastern Military Orders, is a captain in the horse in the service of the grand siegior.

SERBAR, in Geography, a town of Peria, in the province of Mekran; 50 miles N.N.W. of Kidge.

SERBATIS, Yisser, in Ancient Geography, a river of Africa, in the eastern part of Mauritania Cenaraeis, which discharged itself into the Mediterranean, to the E. of Rufugine colonia. Ptolemy places its mouth between Modunga and Ciffa.

SERBI, a people of Asiatic Sarmatia, who dwelled with the Orinix and Vali, between the Ceraunius mountains and the river Rha, according to Ptolemy.—Also, a people called likewiev Seythians, who inhabited a territory towards Dalmatia.

SERBINUM, a town of Lower Pannonia, along the Danube.

SERBONIS, LAUS, or Serbonis lake, a lake which was situated between Egypt and Palestine, near mount Cafius;
fun; and miles by different authors has been assigned to Egypt, Syria, Palestine, or Judea. Strabo says that it was 150 miles long. Strabo assigns to it 150 miles of length, and 200 of breadth. It had communicated with the Mediterranean by an opening which was filled up in the time of Strabo. The fable says that Typhon lay at the bottom of this lake, and the Egyptians called it the breathing-hole of Typhon.

SERBOKA. See Schwarzkopf.

SERBOKI LAKE. See Dead Sea.

SERBURA, the name of a dog, assigned by the mythological legends of the Hindoos, as an attendant on Yama, the regret of their infernal regions. The name means varied, or spotted, and reminds us of the three-headed Cerberus of western fable. It might as well be written Cercura; and when we add that another of his names is Trifora, or three-headed, and that he is to be represented, we can no longer doubt of their identity, and of the fable of one nation being borrowed from the other, or both from a common source. See Triedram, and Yama.

SERCELLI, in Geography. See Sherwood.

SERCHIO, a river which rises in the duchy of Modena, and after traversing the flat of Lucca, runs into the Mediterranean, 4 miles N.N.W. of Pisa.

SERD, a town of Persia, in the province of Adrbeitza; 15 miles N. of Tabris.

SERDAN, a town of Persia, on the Kerman; 83 miles S.S.W. of Kerm.

SERDAR, O, town of Portugal, in the province of Alentejo; 30 miles W.N.W. of Ouirique.

SERDAPO, a town of Hungary; 2 miles S. of Sarat.

SERDOB, a town of Russia, in the government of Saratov, on the Donetz, near its source; 72 miles N.W. of Saratov. N. lat. 52° 50'. E. long. 45° 36'.

SERDOBOL, a town of Russia, in the government of Viborg, on the lake Ladoga; 60 miles N.N.E. of Viborg. N. lat. 61° 12'. E. long. 30° 14'.

SERDEZ KANEN, a cape on the N.E. coast of Russia, in the Frozen sea, so called from its fputed resemblance to a heart. N. lat. 64° 30'. E. long. 170° 25'.

SERE, in Falconry, the yellow between the beak and eyes of a hawk.

SERE, in Geography, a river of Spain, which runs into the sea, 6 miles S. of Penafiel.

SEREA, a town of Abyaffia, near lake Dombra; 90 miles E.N.E. of Mitre.

SEREBRANKA, a gulf of Russia, on the W. coast of N. W. Zembla. N. lat. 75° 35'. E. long. 52° 14'.

SERECH, a town of Persia, in the province of Segelsson, or Sedlan; 84 miles S.S.W. of Kerm.

SERED, SERET, or Sabor, a town of Cordillan, on the Tigris, S. of Zok, supposed to be the ancient Tigranocerta, a city built by Tigranes, and intended by him for the capital of Armenia, and peopled with inhabitants collected from all parts of Asia. It was taken and plundered by the Romans under Lucullus in the year 69 B.C. It is now peopled by 5000 Curius, Syrians, and Chaldeans, and governed by a prince subject to that of Zok; 75 miles S.E. of Dezarbek.

SERED. See Sarat.

SEREEK, a town of Persia, in the province of Mekran, and the residence of the chief of Jajk; it contains a large mud fort, and 600 huts, situated four miles from the sea, and six from the hills. The country between Jajk and this place contains numerous plantations of palms, and abundance of wheat. Jajk is tributary to the Imam of Mufcat, and pays 2,500 rupees a-year. It lies two miles from the sea.

and eight from the hills, and the town consists of 2,500 huts, defended by a mud fort.

SEREGIPPE. See Servia.

SERELIANN, a town of Tyrol; 38 miles N.E. of Trent.

SERENNO, a town of Italy, in the duchy of Milan; 10 miles N. of Milan.

SERELI, Feather of a Hawk, the name which answers to pinions in any other fowls.

SERELON, in Geography, a town of Spain, in the province of Eltrimadura; 20 miles S. of Placentia.

SERA, a river of Chili, which runs into the South Pacific ocean, near Coquimbo; which fee.

SERENA, Curta, in Medicine, the name as a marosus. See Guitta Serena.

SERAINE, an evening concert, given by a lover under the window of his mistress. It generally consists of instrumnental music; sometimes, however, vocal is added.

These pieces in Italy are also called sonate. The mode of sonatas, says Rouleau, has been long discontinued, unless by the common people; and its discontinuance is to be lamented. The silence of the night, which banishes all distraction, gives music additional charms, and renders it more delicious. In the summer of 1720, this was not the case at Venice, six years after Rouleau's Dictionary was written; as we find in our journal, during the month of August of that year, the following memorandum. "The people here (at Venice) during summer, seem to begin to live only at midnight. Then the canals are crowded with gondolas, and St. Mark's square with company; the banks too of the canals are all peopled, and harmony prevails in every part. If two of the common people walk together arm in arm, they seem to converse in song; if there is company on the water, in a gondola, it is the same; a mere melody, unaccompanied with a second part, is not to be heard in the city: all the ballads in the streets are sung in do. Luckily for us, this night, August 7th, a bargain, in which there was an excellent band of music, consisting of viols, flutes, horns, bagpipes, and a kettle-drum, with a pretty good tenor voice, was on the great canal, and floated very near the house ware we lodged; it was a piece of gallantry, at the expense of an innumerator in order to serenade his mistress. Shakespeare says of nocturnal music, "Methinks it sounds much sweeter than by day.

Silence befo PST the virtue on it—I think

The midnightal, if the should sing by day,

When every goose is cackling, would be thought

No better a musician than the wren."

Whether the time, place, and manner of performing this music, gave it adventitious and collateral charms, we will not pretend to say; but all we know is, that the symphonies formed to us are admirable, full of fancy, full of fire; the passages well contrived; sometimes the graceful, sometimes the pathetic preserved; and sometimes, however strange it may be thought, even noisy and harry had their effect.

SERAINE, SERENITY, a quality or title of honour given to certain princes, and chief magistrates of republics. The king of England is styled, the most serene; the same term is also applied to the doges of Venice. The pope and the sacred college, writing to the emperor, to kings, or the doges, give them no other title but that of most serene. Indeed the Venetians let the title of serenity above that of highness.

In 1646, Wicquart observed, there was a clashing between the courts of France and Vienna, because the emperor Mm refused...
refused the king of France any other title than that of ferene. Bishops also were anciently addressed under the title of ferene.

The kings of France, of the first and second race, speaking of themselves, use no other quality but notre ferenité.

The emperor gives no other title to the king of England, nor even to any other king, excepting the king of France. The king of Poland, and other kings, give it to the electors. The emperor, writing to the electors, or other princes of the empire, only uses the term délection; but in treating with them he uses électoral ferenité to the electors, and ducale ferenité to other princes.

SERENÉ, in Geography, a small island in the Red sea. N. lat. 22°. E. long. 39° 30′.

SERENT, a town of France, in the department of the Morbihan; 13 miles N.E. of Vannes.

SERENUS, Sammonicus, Quintus, in Biography, a Roman physician in the reigns of Severus and Caracalla, who was afflicted at a banquet by the order of the late mentioned emperor. He left an immense library, said to contain twenty thousand volumes, to his son, who was preceptor to the younger Gordian, to whom he presented this valuable bequest. Serenus was the author of several works on history and the products of nature; and also of a medical work in verse, which has passed through a multitude of editions, under the title of "Carmen de Medicina." He was superstitious in the choice of his remedies, and especially in that which he proposed for the Semterian fever, which consisted in wearing about the neck, suspended by a linen thread, a piece of paper, on which was written the word Abracadabra in the form of a triangle. Eloy Dict. Hist. de la Méd.

SERENZ, in Geography, a town of Hungary; 9 miles W. of Tokay.

SERERES, a people of Africa, in the vicinity of Cape Verd, differed into several small republics, which unite into one body against a common enemy. Their laws are merely those of nature. They wear no clothing, and they have little or no idea of a Supreme Being or future life: nevertheless they seem to be inoffensive, unacquainted with strong liquors, indolent, and hospitable to strangers.

SERES, in Ancient Geography, a name given to those people who were situated to the east of India, and who, by the investigations and discoveries of the moderns, are supposed to have inhabited Serica. They were renowned for their justice, according to Mela, and for their longevity of 200 years, according to Strabo. They had an insect which produced filks, says Paulaneris. (See Serica.) People of the same name were also established in the northern part of Taprobana.

SERET, in Geography. See Serit.

SERETIUM, in Ancient Geography, a town of Dalmatia. Dion Cassius reports, that Tibérius was obliged to raise the siege of this town, but that it was afterwards taken by the Romans.

SERETINA, in Geography, a town of Russia, in the government of Irkutsk, on the Angara; 24 miles E.S.E. of Balaganskoi.

SERGA, a town of Russia, on the Volga; 40 miles S. of Astrakan.

SERGAG, a town of Russia, in the government of Nizni Novgorod; 48 miles S. of Nizni Novgorod. N. lat. 56° 30′. E. long. 45° 42′.

SERGE, in Commerce, a woollen quilted stuff, manufactured on a loom with four treddles, after the manner of ra-7 ions, and other fluffs that have the whale. The goodness of serge is known by the quilting, as that of cloth by the spinning.

Of serges there are various kinds, denominated either from the different qualities of them, or from the places where they are wrought. The most considerable is the London serge, now highly valued abroad, particularly in France, where a manufacture has been carried on with good success, under the title of serge façon de Londres.

Serge, Manufacture of London. For wool, the longest is chosen for the warp, and the shortest for the woof. Before either kind is used, it is first scoured, by putting it in a copper of liquor, somewhat more than lukewarm, composed of three parts of water, and one of urine. After having flaked long enough therein for the liquor to disolve, and take off the grease, &c. it is stirred briskly about with a wooden paddle; then taken out of the liquor, drained, and washed in a running water; dried in the shade, beaten with flisks on a wooden rack, to drive out the coarser dirt and filth, and then picked clean with the hands. Thus far prepared, it is greased with oil of olives, and the longest part, defined for the warp, is combed with large combs, heated in a little furnace for the purpose. To clear off the oil again, the wool is put in a liquor composed of hot water, with soap melted in it: whence being taken out, wrung, and dried, it is spun on the wheel.

As to the shorter woof, intended for the woof, it is only carded on the knee with small cards, and then spun on the wheel, without being scoured of its oil. Note, the thread for the warp is always to be spun much finer, and better twisted than that of the woof.

The wool both for the warp and the woof being spun, and the thread divided into skains, that of the woof is put on spools (unless it have been spun upon them) fit for the cavity or eye of the shuttle; and that for the warp is wound on a kind of wooden bobbins to fit it for warping. When warped it is stiffened with a kind of size, of which that made of the shreds of parchment is held the best; and when dry is put on the loom.

When mounted on the loom, the workman raising and falling the threads (which are passed through a reed), by means of four treddles placed underneath the loom, which he makes to act transversely, equally and alternately, one after another, with his feet, in proportion as the threads are raised and lowered, throws the shuttle across from one side to the other; and each time that the shuttle is thrown, and the thread of the woof is crossed between those of the warp, strikes it with the frame to which the reed is fastened, through whose teeth the threads of the warp pass; and this stroke he repeats twice or thrice, or even more, till he judges the crossing of the serge sufficiently close: thus he proceeds till the warp is all filled with woof.

The serge now taken off the loom is carried to the fuller, who fulls, or scourcs it in the trough of his mill, with a kind of fat earth, called fullers-earth, first purged of all stones and filth. After three or four hours scouring, the fullers-earth is washed out in fair water, brought by little and little into the trough, out of which it is taken when all the earth is cleared; then, with a kind of iron pincers, or ployers, they pull off all the knots, ends, flaws, &c. from the surface on either side; and then returning it to the fulling trough, where it is worked with water somewhat more than lukewarm, with soap dissolved therein for near two hours: it is then washed out till such time as the water becomes quite clear, and there be no signs of soap left; then it is taken out of the trough, the knots, &c. again pulled off, and then put on the tenter to dry, taking care as fast as it dries to stretch it out both in length and breadth till it be brought to its just dimensions. When well dried, it is taken off the tenter, and dyed, thorn, and pricked.
SERGENTIUM, in Ancus Geography, a town situated in the interior of Sicily. Ptolemy.

SERCIEV, in Geography, a town of Russia, in the government of Tobolsk, on the Ledy; 72 miles N. of Enelmak.

SERGIEVSK, a town of Russia, in the government of Upha; 180 miles W. of Upha. N. lat. 54. E. long. 54 44'.

SERGIEVSKAIA NOVA, a fortress of Russia, in the government of Upha, on the Samara; 56 miles N.W. of Orenburg.

SERGIESK, a town of Russia, in the province of Uf hug, on the Vma; 52 miles N.E. of Yarenf.—Ato, a town of Russia, in the province of Ekaterinburg; 48 miles S.W. of Ekaterinburg.

SERGILUS, in Botany, a genus formed by Gartnert, t. 2. 429. t. 174. F. 6. of the Linnaean Caled flopura, Chrysocoma, n. 2, Browne Jan. 316. t. 34. f. 4, by the following character.

Calyx somewhat turbinate, imbricated with chief-prefixed, unequal, slightly membranaceous scales. Flowers all perfect and fertile, five-crest. Receptacle naked. Down capillary, tufted at the summit.

The above author remarks that this plant "differs in its receptacle, as well as seed-down, from Caled, but from Chrysmum in the seed-down only, so that it is near akin to the latter. The leaves seem to be sometimes opposite, but are generally very remote, as well as extremely minute." The only species known is

1. S. flopura. Native of the coldest mountains of Jamaica. Browne says it has the habit of our European broom, being the only tree of the same appearance, observed by him in that country. Swartz has not noticed this plant.

See Caleda and Chrysocoma.

SERGINES, in Geography, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Sens; 9 miles N. of Sens. The place contains 14,843, and the canton 10,994 inhabitants, on a territory of 260 kilometres, in 18 communes.

SERGNALE del Conda, a river of Brazil, which runs into the bay of All Saints.

Sereino, or Servino, a capancity or province of Brazil, which chiefly produces cattle, grain, and tobacco, for which last Brazil is particularly celebrated.—Alfo, a capital of the district, situated near the coast of the Atlantic, on a river of the same name, which runs into the Atlantic, S. lat. 12°. The town is distant 140 miles from St. Salvador. S. lat. 11° 42'. W. long. 38° 36'.

SERGIUS I., pope, in Biography, was descended from a family at Antioch, but was himself born, and brought up at Palermo. He came to Rome in the time of pope Adeodatus, and entering among the clergy of that capital, was ordained priest by Leo III. On the death of Conuin, in the year 687, there was a great schism respecting his successor, one party espousing the cause of Theodore the archpriest, and the other that of Pafulchad the archdeacon. The principal persons of Rome, not being able to bring them to an agreement, concerted in the choice of Sergius, and put him in possession by force. Theodore instantly resigned his claim, but Pafulchad did not give up his pretensions for a considerable time. He at length, however, submitted. The second year of the pontificate of Sergius was rendered memorable by the arrival at Rome of Cendalad, king of the West Saxons, who came to receive baptism from his hands, and who died soon after he had submitted to that rite. In 690 the emperor Julian III. assembled a council at Constantinople, in which a number of canons were passed. Five of these were opposed by the pope, among which was one condemning a former canon of the church, that forbade ecclesiastical persons to have any connection with their wives after ordina-

tion. Sergius not only resisted these persons, but the account invalidates all the pretensions of the pope, and so much exasperated the emperor, that he sent him as a bearer with an order to appear at his court, and to offer his hands to Constantiniople. The latter, finding it so much to his disadvantage, he dared not execute his commission, and was glad to quit Rome in safety. In 699, Sergius consecrated Willibald bishop of the Franks, recommended to him by Pepin the elder, as a person every way adapted to deprecate the conversion of that heathen people. Sergius died in the year 701, in the 14th year of his pontificate. He had the reputation of much learning and virtue, and is said to have repaired and enriched several churches, which added, in those times, very much to his celebrity.

SERGIUS II., pope, a Roman, was elected in 844, on the death of Gregory IV. He had a competitor in John, deacon of the Roman church, who took possession of the Lateran, but was expelled by the nobility. Sergius was consecrated immediately after his election, without waiting for the imperial confirmation. Lothaire, the emperor, so much reftent this seeming humility, that he sent into Italy his son Lewis, whom he had declared king of Lombardy, with a powerful army, attended by his uncle Drogo, archbishop of Metz. This prince, after cruelly ravaging the ecclesiastical state, marched to Rome, and entered the city amidst the acclamations of the people. He proceeded to the Vatican church, in great solemnity, with the pope, and was afterwards crowned by the latter as king of Italy. Sergius now gladly took the accursed oath of allegiance to the emperor, and received a confirmation of his election. This pontificate, short as it was, is marked by the predatory incursions of the Saracens, who fall upon the Tiber, burnt the suburbs of Rome, and pillaged the churches of St. Peter and St. Paul without the walls. Sergius died in 847. The famous festa-famula, or holy fair-cate at Rome, was erected during the pontificate of Sergius II.

SERGIUS III., pope, a prebendary of the church, though elected by a party, in 897, after the death of Theodred I., was not able to enter upon the duties of his office. A more powerful party supported John IX., and Sergius was glad to seek his safety by flight from the city. He lay in concealment for seven years, during which he contrived to engage in his interest his relation Adelbert, marquis of Tuscany, by whose affidavit he was enabled to expel Chrifopher, who had forcibly intruded into the pontifical seat, and placed himself there in the year 924. Sergius, who is termed by Baronius, and apparently with good reason, "one of the most wicked of men," had a scandalous connection with the infamous Marozia, who with her mother Theodora, and her sister of the same name, at that time almost entirely governed Rome, and dispossessed of the holy see. Marozia, who had already been a disciple of the marquis Adelbert, bore a son to the pope, who was afterwards raised to the papal throne under the name of John XI., such is the purity of the holy bishops of the Roman church. Sergius received a solemn embassy from Leo, emperor of the East, on account of the refult of the patriarch Nicholas to confirm the fourth marriage of Leo, as forbidden by the Greek church. Sergius, as there was no hindrance to the number of successive marriages in the Roman church, not only approved the marriage of Leo, but sent legates to Constantinople to confirm it. The patriarch, however, could not be prevailed upon to admit its legality. Sergius died in 911. He rebuilt the Lateran church.

SERGIUS IV., pope, a native of Rome, whose family name is said to have been Peter Buccspore, or in English, M M 2. H.
Hog's-snout, was bishop of Albano at the time of his election to the papal see in 1089, after the death of John XVIII. Little is recorded of the transactions of this pontiff: he sent a legate into France to consecrate a monastery in the diocese of Tours, which the archbishop of that see regarded as an encroachment upon his jurisdiction; he also determined a dispute between the abbots of Hamburgh and the bishop of Verden. He was greatly respected for the mildness of his disposition, and his liberality to the poor. He died in 1012.

Sergius I., patriarch of Constantinople, is well known in ecclesiastical history for the support which he gave to the doctrine of the Monothelites. He was a Syrian by birth, and born of parents who adhered to the heresy, as it was denominated, of the Monophysites. He was raised to the patriarchal dignity in the year 610. The emperor Heraclius, being devious of re-uniting the perfecuted Nertorians to the Greek church, and having held conferences with persons of influence in that sect, was affurred by them, that there would be no difficulty in terminating the controversy, provided the Greeks would assent to the following proposition, "that in Jesus Christ there was, after the union of the two natures, but one will, and one operation." Sergius thought this proposition might be adopted without the smallest injury to the truth; and without derogating from the authority of the council of Chalcedon, which had condemned the doctrine of a single nature: in consequence of this decision, the emperor illused an edict in the year 630 in favour of the doctrine of the fuge-avit. This hope of concord was soon frustrated, by the violent opposition of Sophronius, a monk, and patriarch of the see of Jerusalem, who also endeavoured to gain pope Honorius to his party, but Sergius was beforehand with him, and had perused his homilies to approve the doctrine in question. In order to quiet the commotions in the church, Heraclius, in 633 illused an edict conformed by Sergius, which was entitled "Euthysis," or an exposition of the faith in which all controversies on the question "whether in Christ there were one or two operations," were prohibited, though the edict plainly inculcated the doctrine of one will. Sergius died in the same year, and his memory was afterwards anathematized in several councils.

Sergode, in Geography, a town of Hindoostan, in Bednore; 8 miles S.W. of Saccaratam.

Sergom, a town of Hindoostan, in Baglana; 25 miles N. of Baffien.

Sergour, a town of Hindoostan, in Bednore; 25 miles W. of Saccaratam.

Sergian. See Sergian and Keriman.

Seriana, in Botany, could hardly be supposed to have been designed to commemorate a person of the name of Sergian; yet such was the intention of Plummer. The Rev. father Philip Sergeant, a native of Calais, of the order of Minims, in Provence, an able botanist, but more able physician, practised medicine at Rome for 25 years, with so much success, as to gain the high esteem of all ranks of people. His departure from that city caused the deepest regret, but he was welcomed at Paris with no less exultation." Plummer, from whom we take this account, named the genus Sergiana but Linneux, who united it to Paulinia, by accident, as it seems, altered the word, as he adopted it for a specific name, to Seriana. So it now remains, the genus having been restored by recent authors; nor do the botanical claims of the reverend father appear sufficiently great, to make us licentious about the precise mode of spelling the name of his plant.—Plum. Gen. t. 34. t. 35. —"Schumacher in Act. Hill. Nat. Hist. v. 3. p. 2." Wildl. Sp. Pl. v. 2. 464. (Paulinia; Lamarck Illust. t. 318. f. 1, 2, 3.) —Clays and order, Odandria Trigyna. Nat. Ord. Tribulata, Linn. Sapindi, Jull. Gen. Ch. Call. Peranthis inferior, of five ovate, concave, spreading, permanent, unequal leaves. Cor. Petals four, obovate-oblong, twice the length of the calyx, furnished with claws; 10 of the petals more distant than the rest. Nectariferous tube; one of four oblong scales, inserted into the claws of the petals; the other of four glands at the base of the petals. Stam. Filaments eight, filiform, short; anthers oval, ovate, two-lobed. Pist. Gemen superior, filiformed, obovate, with three furrows; styles three, combined at the base, recurved; stigmas filiform, obure. Peric. Capulis three, globose, combined longitudinally, each of one cell, not burbling, dilated at the base into a half-ovate membranic wing. Seeds solitary, ovate.

Of the fruit sufficiently distinguishes this genus from Paulinia, see that article, however familiar the flowers, and habits of the plants.

1. S. funata. Wildl. n. 1. "Schumacher, as above, t. 12. f. 1." (S. scandens, triphylla et racemosa; Plum. Gen. 34. Lc. t. 119. f. 2. Paulinia Seriana; Linn. Sp. Pl. 524. Jacq. Obst. fale. 11. t. 61. f. 2.) —Wings of the capules dilated below their infection. Leaves ternate; leaflets ovate-lanceolate, finnated and toothed.—Native of South America. Neither this, nor any other of the genus, is known in our gardens. The stam is angular, furrowed and downy, climbing by means of tendrils. Leaves alternate, filiformed; leaflets about two inches long, veiny, tapering at the base; roughish to the touch, though somewhat shining, above; paler beneath. Flowers small, in compound downy clusters. Wing of each capule near an inch long.

2. S. diversicata. Wildl. n. 2. "Schumach. t. 12. f. 2." (Paulinia diversicata; Swartz Ind. Occ. v. 2. 606.)—Leaves twice ternate; leaflets ovate, acute, entire, filiformed, shining. Common footstalks without wings.—Native of the woods of Jamaica. Stem climbing to a great height, zigzag, with a few distant flat prickles, angular, smooth. Footstalks two inches long, furrowed, smooth. Leaflets filiformed, the leaf of the middle one winged. Tendrils axillary, divided at the extremity. Panicles from the same point, on long footstalks, their branches racemose, alternate, spreading. Flowers white.

3. S. caracafana. Wildl. n. 3. (Paulinia caracafana; Jacq. Hort. Schorb. v. 1. 52. t. 99.)—Wings of the capules not dilated below their infection. Leaves twice ternate, leaflets oblong, acute at each end, dimly toothed. Common footstalks without wings.—Native of the Caracas, from whence we presume it was sent by Dr. Martier to the flowers at Vienna, where it flowers in the summer. The numerous flowers climb by tendrils to a great height. Leaves smooth; leaflets elliptic-oblong, two or three inches in length. Flowers white, in compound cylindrical elefters, each cluster on a long footstalk, accompanied by two strongly revolute tendrils at the top of the footstalk.

5. S. spectabilis. Wildl. n. 5. "Schumach. t. 12. f. 4." —Wings of the capules dilated below their base. Leaves twice ternate; leaflets ovate; the terminal one abrupt. Foot-
Footballs winged.—Native of the Wt Indies. Communicated by Mr. J. Banks, from Muller's herbarium. This has much of the habit of B. serrulata, but the winged footballs, and obtuse leaves, differ from it essentially. We do not find any tendrils under the flowers, as Schumacher notes, nor are the leaves, as Wildenow says, quite entire.

6. S. mexicana. Wildl. n. 6. (Paulonia mexicana; Linn. Sp. Pl. 535; excluding Plukenets and Hender son synon.) — Schumach, t. 11. f. 3.;—Leaves twice ternate; leaflets obovate, entire, all coriaceous. Footballs winged. Clusters aggregate.—Native of Mexico. Axin to the leaf, but the entire leaves, and compound inflorescence dilligent it. The clusters, each of which is simple, are ranged alternately, in one large panicle. Wildenow says Schumacher's figure is taken from the specimen of the Linnean herbarium. With this Linneus at one time confused the true Paulonia mexicana, to which the figure of Hender son better answers. The Linnean specimen wants fruit, and yet its habit, colour, and leading characters, are so near the Serrana we have just been describing, that it can scarcely be doubted of its belonging to this genus.

7. S. angehysiceps. Wildl. n. 7. (S. caudatus, eme phylla et racemosa; Plum. Gen. 34. t. 1. t. 113. f. 1.);—Leaves twice ternate; leaflets linear-lanceolate, acute, entire. —Native of South America. Nothing can be less like the leaf, with which Linneus confounded this narrow-leaved species, whose clusters moreover are pubescent. We know it only from Plummer's figure.

8. S. lupulina. Wildl. n. 8. "Schumach. t. 12. f. 5. ":—Wings of the capsules half-oval. Leaves twice ternate; crenate, rarely rounded; the terminal leaflets nearly rhomboid; the lateral ones ovate. Footballs lightly winged. —Native of South America. Clusters almost simple, the length of the leaves, and accompanied by two tendrils. Schumacher.

9. S. lucida. Soland. MSS. Wildl. n. 9. Schumach. as above, p. 188. ":—Wings of the capsules half-oval. Leaves twice ternate; leaflets ovate, acute, serrated. Footballs feebly winged.—Native of Santa Cruz. The upper surface of the leaves is highly polished, and strongly reined. Clusters in some meadow compound, accompanied by two spiral tendrils. Communicated by Sir J. Banks, to the younger Linneus.

10. S. truxumata. Wildl. n. 10. (S. scandens, polyphylla et racemosa; Plum. Gen. 34. t. 1. t. 112. Paulinia truxumata; Linn. Mant. 256. Jacq. Off. f. 11. f. 62. f. 11; Amer. t. 160. f. 32? S. polyphylla; Jacq. Off. f. 61. f. 10.) —Leaves thrice ternate; leaflets ovate, obtuse, wavy. Footballs winged. Clusters aggregate.—Native of South America, or the West Indies. The clusters are not accompanied by tendrils, but form a sort of panicule, as in S. mexicana. See Pauliniana, n. 8.

There seem to be more species, of which incomplete specimens or descriptions exist, but with which we are not sufficiently acquainted to reduce them to order. Nor is the genus, in every case, to be ascertained, for want of the fruit, so essential in differentiating Serrana and Paulinia.

SERIANE, Smer, or Etrich, in Ancient Geography, a town of Asia, in Syria, situated in the mountains S.E. of Chalea, at the 35th degree of latitude. It appears by its ruins to have been formerly a large town.

SERIATE, in Geography, a town of Italy, in the department of the Serio: 3 miles E.S.E. of Bergamo.

SERICA, in Ancient Geography, an oriental country, the position of which was indicated very vaguely by the writers of antiquity, but which has been, it must be acknowledged, more precisely ascertained by Ptolemy. Its situation and history, however, have been more accurately delineated by M. d'Anville, in an interesting memoir entitled "Recherches Geographiques et Historiques pour la Sublime Asie." M. d'Anville refutes the opinion of those who supposed that the Seres described by Ptolemy corresponded to the western part of China; and he adopts the opinion of M. de Gennes, in his History of the Huns, that it belonged to the country of the Chinese towards the west. M. d'Anville adds, that with the exception of a small angular territory at the extremity of the province of Shen, towards the N.W., China formed no part of Seres. In speaking of Sarytha, on the other side of the Imaus, Ptolemy mentions a passage in this mountain, which was the habitat of merchants that traded with the Seres. Continuous to this station, according to Ptolemy, is a country called Cala, which M. d'Anville supposes to be the name of Caligar, called by the Chinese Nam. In proof of their identity it may be alleged, that the tables of Nafir-Uddin and Ulaph-Beigh allude to Caligarr 44° of latitude, and that Ptolemy makes the latitude of Cala 43°, differing only by one degree. Ptolemy mentions the river Orchards, which M. d'Anville supposes to be the Prophe. Another river near the limits of Seres, mentioned by Ptolemy, is that called Baius, which, in its course towards the Neb, is joined by the lateral branch of another river purling the same direction, and those circumstances correspond with that of the present Etzine. The Bautes, as M. d'Anville apprehends, reside itself in certain lagunes, at the entrance of the deted called by the Tartars Cabi, and by the Chinese Shao-on. Only informed concerning the Bautes of Ptolemy, M. d'Anville was able to settle the position of Seres, the metropolis of Serica. For according to the ancient geographers, this town is very near the point where the left branch of the Bautes separates from it, and a town is actually found at the eastern branch of the Etzine, towards its source. This town must therefore correspond to the Seres of Ptolemy, and bear the name of Can-tcheou. It is the first considerable town that occurs at the entrance of the Chinese province of Shen. This town belongs to a particular country known to the Orientals under the name of Tangut. Tangut may therefore probably be the country anciently inhabited by the Seres, of which Serica was the capital. Another decisive proof that Can-tcheou is the Seres metropolis of Ptolemy, is deduced from the circumstance that this town, according to the Greek geographer, is 38° 39' of latitude, and that the latitude of Can-tcheou, according to the Jesuit astronomers, is 3° 1', the difference being only 25'; Ptolemy places the Etzine about Serica. But Elledon or Eldeko signifies a charis, and some of the Sichians, called by the Greeks Hamaxobis, or persons living in charis, it has been inferred, that the people bore the name of Elledone, in the Seres of Ptolemy, were merely those whose habituation was in charis, and it is also added, that a part of the country of the Seres had borne the name of Eygur, and that the nation who occupied a part of this country is called by the Chinese Kao-tche, a word which signifies high charis.

Sera, according to Ptolemy, is bounded to the W. by Scythia, on the other side of the Imaus; to the S. by unknown territories, and by a part of India beyond the Ganges and the Sines; the other boundaries are unknown. Its principal mountains are the Asibi, which compass the Seres to the N.; the A Kasich, which extend to the Seres by their eastern parts; the Asimac in the country; the eastern part of the Casian mountains; mount Thargus, called also Ithagurus; the mountains Emozi and Serica. The chief rivers are the Ochardes or Ochardes, which rise in the A Kasichan mountains; and the Bautes, which springs from Mount Caullaus. The north of Seria was inhabited by Anthro-
throphopagi; below these were the Annibi, bearing the name of "these mountains; the Axacii and the Sizyeses, below whom were the Damnæ; the Piadax extended themselves to the river Oedhars. The Garinaz and the Nabbanæ lay more to the east than the Annibi. To the S. was the country called Almiræa, where were the mountains of the same name; the Ildones, or Effides, were situated to the S., and extended themselves to mount Callius; and these formed a powerful nation; the Thraoni lay to the E., and below them the Vishurangi; the Afpacare lay to the S. of the Ildones, and below them the Bataz; the Otororochææ were situated to the S. The principal towns were the Damnæ, Piada, Albireæ or Almiræa, Tharrana or Thraoni, Ildœon, Serice, Afpacara, Drofache, Pabiana, Affagana, Thogara, Daxata, Orotana, Otororochra or Otororoccan, Solana, and Serà Metropolis. It appears from the article Little Bucharía, to which we refer the reader, that no region but this can correspond to Ptolemæy's Serica.

SERICH, the name of a feed used in the food of the Egyptian Coptics. It is produced by an herb called amim, and is pounded and put into oil. In this they dip their bread, which is always new, being baked as often as they eat, in small flat cakes; these they dip in this oil with raw onions, or else they break the cakes to pieces, and put them into a syrup of sugar, made when the canes are green. See Egypt, p. 183.

SERICORA, in Geography, a town of Persia, in the province of Mazanderan; 15 miles N.E. of Afterabat.

SERICUM, Silk. See Silk.

Sericum is also a name given by several chemical writers to the flowers of zinc raised by sublimation in an inclined open crucible. These flowers are not reducible into zinc again, and are of a fibrous texture, and a beautiful bright white colour. This has made them be called also the philosophic cotton, and others have named them the aqua fixa philosophorum.

SERIDIA, in Botany, a generic name given by Juffieu to those species of Centaurea which are included under the sixth section (Stech) of that genus. Jull. 173. See Centaurea.

SERJEANT, or SERJEANT, a term in our Law, applied to fundry offices. Serjeant at law, or of the coif, is the highest degree taken in the common law, as that of doctor is in the civil law.

The first mention which judge Blackstone has met with of serjeants, or countors, is in the latt. of Welt. 1. 3 Edw. 1. c. 29. But M. Paris, in his life of John II. abbot of St. Alban's, which he wrote in 1255, 59 Hen. III. speaks of advocates at the common law, or countors (quos bani narratores vulgari appellamus) as of an order of men well known; and the antiquity of the coif appears from the same author's Hist. of England, A.D. 1259. Serjeants were anciently called servientes ad legem, and servientes narratores; Mr. Selden adds, that they were also called doctores legis; though others are of opinion that the judges are more properly the doctores legis, and serjeants, the bachelors of law.

Spelman observes, that however a serjeant may be richer than all the doctors of the Commons, yet a doctor is superior in degree to a serjeant, for the very name of a doctor is magisterial, but that of a serjeant ministerial. Hence, the doctors are seated and covered when they plead, but the serjeants stand uncovered at the bar, excepting for their coif.

As these are fuppos'd the most learned and experienced, there is one court appropriated for them to plead in by themselves, which is the Common Pleas, where the common law of England is most strictly observed; but they are not prohibited pleading in other courts; and all judges, who, by custom, must first be serjeants, call them brothers.

Serjeants at law are bound by a solemn oath to do their duty to their clients; and by custom the judges of the courts of Westminster are always admitted into this venerable order, before they are advanced to the bench; the original of which was probably to qualify the puifné barons of the exchequer to become justices of assize, according to the exigency of the statute of 14 Edw. III. c. 16.

They are called by the king's mandate, or writ, directed to them, commanding them to take upon them that degree, by a day assigned. See Barrister.

Out of these, some are made the king's serjeants to plead for him in all causes, especially in cases of treason; and one is usually appointed, called premier serjeant. See Counsel and Precedence.

Serjeants at Arms, are officers appointed to attend the perfon of the king, to arrest traitors, and perfons of quality offending, and to attend the lord higheward when he fits in judgment on any traitor, &c.

These officers were first instituted by king Richard I. in imitation of a corps of the same name, formed by Philip Augustus, king of France, when on a crusade, to guard him against the subjects of the old man of the mountain, famous for their daring affronts. Of these by statute (13 Ric. II. c. 2) there are not to be above 20 in the realm.

The duty of these serjeants originally was to watch round the king's tent in complete armour, with a mace, a bow, arrows, and a sword, and occasionally to arrest traitors, and other offenders, about the court, for which the mace was deemed a sufficient authority. They were called the valourous force of the king's errand, in the execution of justice; they held their places for life; their number was originally twenty-four, all persons of approved worth, and not under the degree of the son of a knight; but afterwards the sons of gentlemen were admitted into the body. In the reign of Edward I. the serjeants at arms were allowed two marks for winter, and the fame for summer robes; their pay in that of Edward II. was 12 d. per diem, when they attended on horfeback, and 8d. when they attended without a horfe. Their allowance, when absent from court, on the king's affairs, was 12d. each by the day; and under, another head they appear charged at 26s. 8d. each for winter, and 20s. for summer. They were besides entitled to certain fees from persons arrested, in proportion to their rank and degree. According to the orders given by Thomas of Lancaster, confable at the siege of Caen, Sept. 3d. 1417, a serjeant at arms was to appear in the king's presence, with his head bare, his body armed to the feet with the arms of a knight riding, wearing a gold chain with a medal, bearing all the king's coats, with a pemon royal, or mace of silver, in his right hand, and in his left hand a truncheon. In the 7th of Hen. VII. they were ordered to attend the army. The number of this corps has varied exceedingly. In the reign of Edw. IV. they were reduced to four; in that of Edw. VI. they were increas'd to twenty-two, and in the succeeding reign to twenty-three; but by king James I. retrenched to sixteen, and afterwards to eight.

Such is the number now at court, at 100l. per annum salary each; they are called the king's serjeants at arms, to distinguish them from others; they are created with great ceremony, the perfon kneeling before the king, his majesty lays the mace on his right shoulder, and says, Rise up serjeant at arms, and esquire for ever. They have, besides, a patent for the office, which they hold for life.

They have their attendance in the preference-chamber, where the band of gentlemen-pensioners wait; and receiving the king at the door, they carry the maces before him to the chapel door, whilst the band of pensioners (and foremoft, and make a lane for the king, as they also do when the king goes to the house of lords.

They

SE
Thus, of the former kind, we have

\[ \frac{1}{a + b} = (a + b)^{-1} = \frac{1}{a} - \frac{b}{a^2} + \frac{b^2}{a^3} - \frac{b^3}{a^4} + \&c. \]

\[ \frac{1}{a - b} = (a - b)^{-1} = \frac{1}{a} + \frac{b}{a^2} + \frac{b^2}{a^3} + \frac{b^3}{a^4} + \&c. \]

and a variety of others. And of the latter,

\[ \frac{1}{a^2} + \frac{2}{a^3} + \frac{3}{a^4} + \frac{4}{a^5} + \frac{5}{a^6} + \&c. \]

\[ \frac{1}{a^2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \&c. \]

Many of which are still irreducible to any equivalent finite function.

Series also receive several different denominations according to certain circumstances attending their formation, the law which they follow, the form of the function to which they are reducible, \&c. \&c. as arithmetical, geometrical, converging, diverging, reciprocal, \&c. series.

Series, Convergent, are those in which the terms decrease, or become successively less and less; as

\[ 1 + \frac{1}{2} + \frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \&c. \]

Series, Divergent, are those in which the terms continually increase; as

\[ 1 - 2 + 2^2 - 2^3 + 2^4 - 2^5 + \&c. \]

Series, Neutral, are those in which all the terms are equal to each other; as

\[ 1 - 1 + 1 - 1 + 1 - 1 + \&c. \]

This arises from the division of 1 by 1 + 1, and is therefore equal to \( \frac{1}{2} \).

Series, Indeterminate, is sometimes used to denote a series, whose terms proceed according to the powers of some indeterminate letter or quantity; as

\[ \pi + \frac{1}{2} \pi^2 + \frac{1}{3} \pi^3 + \frac{1}{4} \pi^4 + \&c. \]

Other writers, however, mean by this denomination those series whose sums are indeterminate in any finite form.

Series are again either ascending or descending.

Series, Ascending, are those in which the powers of the indeterminate quantity continually increase; as

\[ 1 + a x + b x^2 + c x^3 + d x^4 + \&c. \]

Series, Descending, are those in which the powers decrease in the numerator, or increase in the denominator; as

\[ 1 + a x^{-1} + b x^{-2} + c x^{-3} + d x^{-4} + \&c. \]

or

\[ 1 + \frac{a}{x} + \frac{b}{x^2} + \frac{c}{x^3} + \frac{d}{x^4} + \&c. \]

Series, Circular, are those whose sums depend upon the quadrature of the circle; thus,

\[ 1 = \frac{1}{3} + \frac{1}{5} + \frac{1}{7} \]

\[ 1 = \frac{1}{3} + \frac{1}{5} + \frac{1}{7} - \&c. \]

and

\[ 1 = \frac{1}{3} + \frac{1}{5} + \frac{1}{7} \]

are circular series; the former being equal to one-twelfth of the circumference of a circle whose radius is 1; and the latter equal to one-sixth of the square of the semi-circumference to the same radius.

Series, Logarithmic, are those which express, or whose sums depend upon the logarithms of numbers; as

\( (a - 1) - \frac{1}{3} (a - 1)^{3} + \frac{1}{5} (a - 1)^{5} - \frac{1}{7} (a - 1)^{7} + \&c. \)

which is equal to the hyperbolic logarithm of \( a \).

Series, Arithmetical, are those whose successive terms differ from each other by a certain and determinate quantity; as

\[ a + (a + d) + (a + 2d) + (a + 3d) + \&c. \]

\[ a + (a - d) + (a - 2d) + (a - 3d) + \&c. \]

Series, Geometrical, are those whose successive terms are some multiple or submultiple of those immediately preceding them; as

\[ a + r a + r^2 a + r^3 a + r^4 a + \&c. \]

\[ a + \frac{r}{a} + \frac{r^2}{a} + \frac{r^3}{a} + \&c. \]

Series, Fractional, are those whose terms are all fractional; as

\[ \frac{a}{b} + \frac{a}{b + c} + \frac{a}{b + 2c} + \frac{a}{b + 3c} + \&c. \]

Series, Trigonometrical, are those which relate to trigonometrical lines or quantities; as

\[ \sin a + \frac{1}{2} \sin a + \frac{1}{3} \sin a + \frac{1}{4} \sin a + \&c. \]

\[ \tan a - \frac{1}{3} \tan a + \frac{1}{5} \tan a - \frac{1}{7} \tan a + \&c. \]

which are each expressions for the length of a circular arc, the former in terms of the sine, and the latter in terms of the tangent.

Series, Exponential, are those which arise from the expansion of, or whose sum depends upon exponential quantities; as

\[ 1 + \frac{x}{1} + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \&c. \]

which is equal to \( e^x \), \( e \) being the number whose hyperbolic logarithm is 1.

Series, Recurring, are those in which each term has a constant relation to a certain number of the preceding terms.

See Recurring Series.

Series, Law of \( a \), is used to denote that relation which subsists between the successive terms of a series, and by which their general term may be denoted; thus the series

\[ 1 + \frac{2}{3} x + \frac{8}{15} x^2 + \frac{16}{35} x^3 + \frac{128}{315} x^4 + \&c. \]

may be put under the form

\[ 1 + \frac{1}{3} x + \frac{1}{3} x^2 + \frac{1}{3} x^3 + \frac{1}{3} x^4 + \&c. \]

where the law by which it may be indefinitely continued is manifest; and from which we draw the general term, viz.

\[ 2 \cdot 4 \cdot 6 \cdots 2(n - 1) x^{n-1}. \]

Series, Interpolation of, See Interpolation.

Series, Reversion of, See Reversion.

Series, Summation of, is the finding the sum of a series, whether the number of its terms be finite or infinite; the various methods of performing which is treated of in the subsequent part of this article.
Method of series is used in a general sense to denote the principle upon which different authors have treated this subject, as well with reference to the reversion and interpolation of series, as to the finite and approximate summation of them.

The doctrine of series is certainly one of the most important subjects of mathematical investigation, and has been very appropriately denominated by James Bernoulli the sect. undaer of analysis; being our only hope and last resort, in a variety of difficult problems, which had defied to every other method of computation.

The summation of series, and the quadrature of a curvilinear space, are intimately connected with each other, as well in their origin as in their subsequent progress. We have flitted under the article Quantities, that Archimedes was the first who found the area of a curvilinear space, which he effected by means of the summation of an infinite series upon geometrical principles, and which is the first instance on record of such an operation; from which time, for nearly two thousand years, little or nothing was attempted relative to this subject; but about the middle and the latter end of the 17th century, it began to attract the general attention of mathematicians, and has since that time been pursued with a degree of perseverance and success commensurate with its great importance, and the general progress of analysis during the same period.

Wallis, in his Arithmetic of Infinites, seems to have been the first amongst the moderns who drew the attention of mathematicians to the doctrine of series. Lord Brouncker, sir Christopher Wren, Mercator, and James Gregory, also pursued the subject with considerable success, exhibiting the quadrature and rectification of different curves under the form of infinite series.

In 1668, Leibnitz published in the Leipzic Acads a memoir entitled "De proportiones circulii ad quadratum circumscripturn, in numeros rationalibus," in which he gave several numerical series of a very novel kind, whose terms were expressible in finite terms, without, however, accompanying them with their demonstrations; amongst the moit curious of which we may reckon the following: \[ \frac{1}{3} + \frac{1}{8} + \frac{1}{15} + \frac{1}{24} + \frac{1}{35} + \frac{1}{48} + \&c. \]

\[ \frac{1}{2^2 - 1} + \frac{1}{3^2 - 1} + \frac{1}{4^2 - 1} + \frac{1}{5^2 - 1} + \&c. \]

The form of an infinite number of terms of which is equal to \( \frac{1}{3} \); the sum of its odd terms being equal to \( \frac{1}{2} \), and the sum of its even terms equal to \( \frac{1}{2} \): that is

\[ \frac{1}{1} + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \frac{1}{9} + \&c. = \frac{1}{2} + \frac{1}{1 + 3} + \frac{1}{5 + 3} + \frac{1}{7 + 3} + \frac{1}{9 + 3} + \&c. = \frac{1}{2} \]

\[ \frac{1}{1} + \frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \frac{1}{8} + \frac{1}{10} + \frac{1}{12} + \&c. = \frac{1}{2} \]

The sum of an infinite number of terms of the same series, omitting every three terms after the 1st, the 5th, the 9th, &c. as

\[ \frac{1}{1} + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \frac{1}{9} + \frac{1}{13} + \frac{1}{15} + \frac{1}{17} + \frac{1}{19} + \&c. \]

is equal to the area of a circle of which the inscribed square is \( \frac{1}{4} \).

But if we begin at the second term, and thence omit every three terms, as above, we shall have

\[ \frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \frac{1}{8} + \frac{1}{10} + \frac{1}{12} + \frac{1}{14} + \frac{1}{16} + \&c. \]

Vol. XXXII.
SERIES.

This is obviously equal to
\[
\frac{a}{b} + \frac{a}{b^2} + \frac{a}{b^3} + \frac{a}{b^4} + \text{&c.} = \frac{ad}{b^d - b}
\]
\[
= \frac{ad}{b^d - b} + \frac{c}{b^d} + \frac{c}{b^{d+1}} + \frac{c}{b^{d+2}} + \frac{c}{b^{d+3}} + \text{&c.} = \frac{cd}{b^d - b}
\]
\[
+ \frac{c}{b^{d+1}} + \frac{c}{b^{d+2}} + \frac{c}{b^{d+3}} + \text{&c.} = -\frac{cd}{b^d - b}
\]
\[
+ \frac{c}{b^{d+2}} + \frac{c}{b^{d+3}} + \text{&c.} = \frac{cd}{b^d - b^2}
\]
\[
+ \frac{c}{b^{d+3}} + \text{&c.} = \frac{cd}{b^d - b^2} + \text{&c.} = \frac{cd}{b^d - b^2} + \text{&c.}
\]

Each of which series being geometrical, are found by the known rules for such progressions; and it is obvious that all these sums, except the first, are also in geometrical progression; the sum of which, viz. of
\[
\frac{cd}{b^d - b} + \frac{cd}{b^d - b^2} + \frac{cd}{b^d - b^3} + \frac{cd}{b^d - b^4} + \text{&c.}
\]
\[
+ \text{&c.} = \frac{cd}{b(d - 1)^2}
\]
to which therefore adding\[
\frac{ad}{b(d - 1)} + \frac{b(d - 1)}{b(d - 1)^2}
\]
to the sum of the proposed series,

C. of 2.—When the numerators of the fractions proceed according to the triangular numbers. Let
\[
\frac{c}{b} + \frac{3c}{b^2} + \frac{6c}{b^3} + \frac{10c}{b^4} + \text{&c.} = \frac{cd}{b(d - 1)^2}
\]
be the proposed series. This may be resolved as follows: \(\text{viz.}\)
\[
\frac{c}{b} + \frac{c}{b^2} + \frac{c}{b^3} + \text{&c.} = \frac{ed}{b - b^d}
\]
\[
+ \frac{c}{b^2} + \frac{c}{b^3} + \text{&c.} = \frac{2c}{b - b^d}
\]
\[
+ \frac{c}{b^3} + \frac{c}{b^4} + \text{&c.} = \frac{3c}{b^d - b^2}
\]
\[
+ \frac{c}{b^4} + \text{&c.} = \frac{4c}{b^d - b^3}
\]
\[
+ \text{&c.} = \frac{cd}{b^d - b^2} + \text{&c.}
\]
which sums, with the exception of the first, constitute a series agreeing in form with that solved above, and from which we derive \(\frac{cd}{b(d - 1)^2}\) for the sum required.

Cor.—If we make \(a\) in the first series \(= 0\), the sum of that series will be to the sum of the latter, as \(d - 1 : d\); that is,
\[
\begin{align*}
&\frac{a}{b} + \frac{a}{b^2} + \frac{a}{b^3} + \frac{a}{b^4} + \text{&c.} = \frac{ad}{b^d - b} \\
&\text{as } d - 1 : d : \frac{cd}{b(d - 1)^2} + \frac{cd}{b(d - 1)^3}.
\end{align*}
\]
And when the numerators proceed according to the figurate numbers of the first order, \(\text{viz. } 1, 4, 20, 35\); then the sum of this series will be to that of the latter, as \(d : d - 1\); that is,
\[
\begin{align*}
&\frac{4c}{b} + \frac{10c}{b^2} + \frac{20c}{b^3} + \frac{35c}{b^4} + \text{&c.} = \text{the sum of the series}
\end{align*}
\]
In a similar manner is found the sum of the series, when the numerators are squares, cubes, &c. from which the author draws the following results; \(\text{viz.}\)

Nat. Num.
\[
\frac{1}{2} + \frac{2}{2^2} + \frac{3}{2^3} + \frac{4}{2^4} + \text{&c.} = \frac{2}{1}
\]

Trian. Num.
\[
\frac{1}{2} + \frac{3}{2^2} + \frac{6}{2^3} + \frac{10}{2^4} + \text{&c.} = \frac{4}{1}
\]

Fig. 1st order
\[
\frac{1}{2} + \frac{4}{2^2} + \frac{10}{2^3} + \frac{20}{2^4} + \text{&c.} = \frac{8}{1}
\]

Squares
\[
\frac{1}{2} + \frac{4}{2^2} + \frac{9}{2^3} + \frac{16}{2^4} + \text{&c.} = \frac{6}{1}
\]

Cubes
\[
\frac{1}{2} + \frac{8}{2^2} + \frac{27}{2^3} + \frac{64}{2^4} + \text{&c.} = \frac{26}{1}
\]

As an illustration of the second method, that is, of summation by subtraction, we shall give an abstract of James Bernoulli's sixteenth proposition, which is as follows.

Prop.—To find the sum of an infinite series of fractions, whose numerators constitute a series of equal numbers, and denominators, a series of triangular numbers, or of their multiples.

From the series\[
\frac{a}{c} + \frac{a}{2c} + \frac{a}{3c} + \frac{a}{4c} + \frac{a}{5c} = \frac{S}{c}
\]
we subtract\[
\frac{a}{2c} + \frac{a}{3c} + \frac{a}{4c} + \frac{a}{5c} + \frac{a}{6c} + \frac{a}{c} = \frac{S - a}{c}
\]
and we have\[
\frac{a}{2c} + \frac{a}{6c} + \frac{a}{12c} + \frac{a}{20c} + \frac{a}{30c} = \frac{a}{c}
\]
the double of which\[
\frac{a}{c} + \frac{a}{3c} + \frac{a}{6c} + \frac{a}{10c} + \frac{a}{15c} = \frac{2a}{c}
\]
which left is a series of fractions of the form proposed, their denominators forming the series of triangular numbers, multiplied by the constant quantity \(a\). Thus in numbers; if from the series\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \text{&c.} = S
\]
(without regarding what may be the value of \(S\)), we take\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \text{&c.} = \frac{S}{1} + \text{&c.} = S - 1
\]
we shall have\[
\frac{1}{4} + \frac{1}{4} + \frac{1}{4} + \frac{1}{4} + \text{&c.} = \frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \text{&c.} = 1.
\]

In the same way we find\[
\frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \text{&c.} = \frac{3}{4}
\]
On the same principle, John Bernoulli demonstrated, that the sum of the reciprocals of the natural numbers is infinite. Let
\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \text{&c.}
\]
be changed into the equivalent form
\[
\frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \text{&c.}
\]
and
SERIES.

...and let this be resolved into the infinite series
\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \cdots + \frac{1}{n} + \cdots = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \cdots + \frac{1}{n} + \cdots
\]

Whence it follows, that the sum of
\[
1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \cdots + \frac{1}{n} + \cdots = \text{and ad infinitum} = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \cdots + \frac{1}{n} + \cdots
\]

which equality can only have place when the first sum is infinite.

John Bernoulli afterwards found the sum of the series of the reciprocals of the natural squares, a problem mentioned by his brother, in his illoquium on proposition 17, in which he declared that the solution of it had evaded his industry; and that whoever solved it should receive his warmest thanks.

It should be observed, however, that though James had failed in finding the true sum, he had discovered several curious properties of this series; viz. that the sum of the odd terms, \(1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots\), is the sum of the even terms, \(\frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \cdots\), as 3 to 1. And generally, if we have a series of the reciprocals of any powers whatever, as \(1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots\), the sum of the terms in the odd places beginning at unity, is to the sum of the terms in the even places, as \(n - 1\) is to 1. Hence,
\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots + \frac{1}{2n - 1} + \frac{1}{2n - 1 + \frac{1}{2n - 1} + \cdots + \frac{1}{n - 1} + \cdots = \frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \cdots + \frac{1}{2n - 1} + \cdots
\]

John Bernoulli's solution of the above problem depends upon the expression for the finite arc in terms of the square, the same as that of Landen, of which we shall speak in the subsequent part of this article, and shall, therefore, only give here the results that Bernoulli drew from his solution; viz. he proved that
\[
1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots + \frac{1}{n} + \cdots = \frac{\pi^2}{6}
\]

and
\[
1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots + \frac{1}{n} + \cdots = \frac{\pi^2}{6} \cdot \frac{\pi^2}{6}
\]

\[\text{etc.} \quad \text{etc.} \quad \text{etc.}\]

where \(\pi\) denotes the semi-circumference of a circle whose radius is 1. Montucla has, by mistake, attributed the first summation of this series to Euler, see page 241, \textit{Histoire des Mathemathiques.}

We shall further notice with regard to the numbers, that we here find the four first terms of the expansion of the binomial
\[
(a + b + c + d + e + f + \cdots)^{n+1}
\]

with the method of finding them by means of quadratrix, cubic, and biquadratic equations, in our articles \textit{Quadratrix, and Surfaces.}

3. \textit{Montmort: Method of Series.} The two methods above illustrated, by means of which the Bernoulli arrived at the summation of various series, are both direct, and are better suited to finding summable series, than to the summation of any series proposed; they are moreover only applicable to such series as continually decrease \textit{ad infinitum.}

In 1712 another interesting correspondence took place on series of a different kind, between M. Montmort, John Bernoulli, and his nephew Nikolaus Bernoulli. They were led to these considerations, in consequence of certain problems relating to the doctrine of probabilities, which at that time began to excite great interest among both the English and French mathematicians. The object here was not the determination of the sum of an infinite number of decreasing terms, but the summation of any finite number of terms, either increasing or decreasing; and the formula of M. Montmort, given at page 65 of his \textit{``Essai d'Analyse fur les Jeux de Hazard,''} second edition, for this purpose, is as follows.

Let \(a + b + c + d + e + f + \cdots\) be the presented series, and \(n\) the number of terms whose sum is required; also, let \(D', D'', D''', D''''\), &c. be the first terms of the first, second, third, fourth, &c. differences; then the sum of the \(n\) terms will be expressed by
\[
n + \frac{n(n-1)}{1 \cdot 2} D' + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} D'' + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} + \cdots + \frac{n(n-1)(n-2)(n-3) \cdots (n-k)}{1 \cdot 2 \cdot 3 \cdots k} + \cdots
\]

which series will terminate in all cases, no matter of any of the order of differences become zero; but in others it will only give an approximation.

Let it be required, for example, to find the sum of \(n\) terms of the natural series of the squares
\[
1^2 + 2^2 + 3^2 + 4^2 + 5^2 \cdots + n^2
\]

Here \(n = 1, D' = 3, D'' = 2, D''' = 0\); therefore
\[
n + \frac{n(n-1)}{1 \cdot 2} D' = 3 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} D'' = 2
\]

is the sum required.

If it were the series of triangular numbers,
\[
1 + 3 + 6 + 10 + \cdots + \frac{n(n+1)}{2}
\]

then we should have
\[
n = 1, D' = 2, D'' = 1, D''' = 0; \text{ therefore the sum of } n \text{ terms will be expressed by}
\]

\[
n + \frac{n(n-1)}{1 \cdot 2} D' = 1 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}
\]

\(n \in 0\) From
SERIES.

From this general formula are readily drawn the following particular expressions for the sums of the different orders of polygonal and figurate numbers; as also for the squares, cubes, and higher powers.

**Figurate Numbers.**

&c. &c.

A variety of other series fall under the above general formula of M. Montmort; viz. series of which the sum may be exhibited in a finite form: and in all cases where the successive differences decrease, an approximation may be obtained by it, and that with a considerable degree of facility, when the terms are alternately + and - 1, but when they are all plus, or all minus, except the first, little, if any, advantage is gained by it.

The above method of summation is commonly called the differential method, and was first used for interpolation by Briggs, in the construction of his table of logarithms. Newton also applied it to a variety of interesting problems in his "Methodus Differentialis," but Montmort, as far as we have been able to trace, was the first who employed it in the summation of series.

The following formulae, all relating to the differential method, will not be unacceptable to the reader.

Let \( a + b + c + d + e + f + \&c. \) be any series; make

\[
D' = b - a
\]

\[
D'' = a - 2b + c
\]

\[
D''' = a - 3b + 3c - d
\]

\[
D^{iv} = a - 4b + 6c - 4d + e
\]

\[
D^{v} = a - nb + \frac{n(n-1)}{1 \cdot 2} c - \frac{(n-1)(n-2)}{1 \cdot 2 \cdot 3} d + \&c.
\]

From which last general formula the first term of any order of differences may be found independent of all those which precede it.

Again,
Again, let $N$ represent the $n$th term, and $S$ the sum of $n$ terms; then will

$$N = a + \frac{(n-1)}{1} \frac{D^n}{1} \left( \frac{n-1}{1} \right) \left( \frac{n-2}{1} \right) \left( \frac{n-3}{1} \right)$$

$$S = a + \frac{n}{1} \frac{D^n}{1} \left( \frac{n}{1} \right) \left( \frac{n-1}{1} \right) \left( \frac{n-2}{1} \right) \left( \frac{n-3}{1} \right)$$

which latter expression for the $S$ is, as we have above observed, due to M. Montuça. The same author also published in the Philosophical Transactions for 1718, some other formulae for the summation of series; but as these are nothing more than particular cases of the method of increments, we shall not notice them in this place; but refer the reader to the article INCREMENTS, for an illustration of the method of summation as depending upon these principles, first published by Dr. Brooke Taylor, in his "Methodus Incrementorum," 1715.

4. De Moivre's Method of Series. The next author who made any considerable improvement in this theory was De Moivre, to whom we owe the doctrine of RECURRING SERIES, in the principles of which we have spoken at some length under that article of the present work; we shall not therefore enter again upon the subject in this place, but confine ourselves to an illustration of his method for finding summable series, which is not referred to in the article above mentioned; it was first given by him in his "Miscellanea Analytica," 1730.

Let there be allowed any series, and let this be multiplied by any binomial or trinomial factor, thus that the resulting series will have its powers of $x$ recurring again in the same order; then, by equating the resulting series to $0$, and transposing the negative terms, a new numerical series will arise, the sum of which will be given.

Thus, let there be taken the series

$$1 + \frac{3}{1} \cdot x + \frac{3}{2} \cdot x^2 + \frac{3}{3} \cdot x^3 + \frac{3}{4} \cdot x^4 + \&c. = S.$$  

Multiplying this by $x - 1$, we have

$$-1 + \frac{1}{1} \cdot x + \frac{1}{2} \cdot x^2 + \frac{1}{3} \cdot x^3 + \frac{1}{4} \cdot x^4 + \&c. = (x - 1) S.$$  

Whence, making $x - 1 = 0$, or $x = 1$, we have

$$\frac{1}{1} + \frac{1}{2} \cdot 3 + \frac{1}{3} \cdot 4 + \frac{1}{4} \cdot 5 + \&c. = 1.$$  

Again, assume

$$1 + \frac{1}{1} \cdot x + \frac{1}{2} \cdot x^2 + \frac{1}{3} \cdot x^3 + \frac{1}{4} \cdot x^4 + \&c. = S.$$  

Multiplying by $x^2 - 1$, we have

$$-1 + \frac{1}{1} \cdot x + \frac{2}{1} \cdot \frac{1}{3} \cdot x^2 + \frac{2}{1} \cdot \frac{2}{3} \cdot x^3 + \frac{2}{1} \cdot \frac{3}{3} \cdot x^4 + \&c. = (x^2 - 1) S.$$  

where making again $x = 1$, we have

$$\frac{1}{1} + \frac{1}{2} \cdot 3 + \frac{1}{3} \cdot 4 + \frac{1}{4} \cdot 5 + \&c. = \frac{3}{2},$$  

or

$$\frac{1}{1} + \frac{1}{2} \cdot 3 + \frac{1}{3} \cdot 4 + \frac{1}{4} \cdot 5 + \&c. = \frac{3}{2}.$$  

As another example, let the same series

$$1 + \frac{1}{1} \cdot x + \frac{1}{2} \cdot x^2 + \frac{1}{3} \cdot x^3 + \frac{1}{4} \cdot x^4 + \&c. = S$$  

be multiplied by

$$\frac{1}{(2x - 1)} \left( \frac{3x - 1}{1} \right) = 6x^3 - 5x + 1,$$

and we have

$$1 - \frac{3}{2} \cdot x + \frac{3}{3} \cdot x^2 + \frac{3}{4} \cdot x^3 + \&c. = \frac{3}{2}.$$  

The law of both which series is obvious, the numerators being in arithmetical progression. This method is not much different in principle from the second method of Bernoulli above explained.

5. Stirling's Method of Series. In the recurring series of De Moivre, each term is connected with a certain number of the preceding terms, by a constant and invariable law, but in the series considered by Stirling, in his "Methodus Diferentialium," 1730, each term is a certain function of the number of terms from the beginning, or from some determined term of the series; which function may therefore be considered as the general term, and the method of summation depends on the following principles.

Having first determined the general term of the series in some function of $x$, its distance from the beginning, or some determined term of the series; it follows, that the sum of all the terms to that place will also be some function of $x$. Therefore, if $x$ is made to denote the distance of any other term from the same point, the sum of that term will be the same function of $x$, as the other sum is of $x$; and each term of the series may be considered to represent the difference between two consecutive sums, or the difference between two similar functions, &c. of $x - 1$ and $x$; and the object of the author is to determine what those sums or functions are from the difference between them being given.

To be a little more explicit, if there be any series of quantities

$$a, b, c, d, \ldots \ldots, t^2, t, t', t'',$$

proceeding from the first $a$, by any uniform law, either increasing or decreasing; and if $x$ be taken to represent the distance of any term, as $t$, from the beginning of the series, or from any term in the same, then will $x$ be expressible by some function of $x$; $t$ by the same function of $x + 1$; $t''$ by the same function of $x + 2$, &c. : denoting therefore this function by $f(x)$, we shall have

$$t = f(x - 1), t = f(x), t' = f(x + 1), \&c.$$  

Also if $f^3, f^4, f^5, f^6, \&c.$ denote the sums of all the terms from the beginning to the terms $t^3, t^4, t^5, \&c.$, respectively, these several sums will also be some function of $x + 1, x + 2, x + 2, \&c.$ which we may denote by

$$f^3 = \varphi(x - 1), f^4 = \varphi(x) ; f^5 = \varphi(x + 1) ;$$

whence we draw immediately

$$f - f^0 = t, \&c. -(x - 1) = f(x).$$
SERIES.

Now the function \( f(x) \) is given, being the general term of the series, and the object of enquir} is, from this given function to determine the two functions \( \phi(x) \) and \( \phi(x-1) \), of which it is the difference; for the former of these, \( \phi(x) \), will then be the sum of the terms of the series to the term \( x \) inclusive.

To illustrate this by a familiar example; let the proposed series be

\[ 1 + 3 + 5 + 7 + 9 \]

the general term of which is \( 2x - 1 \); therefore,

\[ \phi(x) - \phi(x-1) = 2x - 1; \]

whence we have obviously \( \phi(x) = x^2 \), for

\[ x^2 - (x - 1)^2 = 2x - 1; \]

therefore \( x^2 \) is the sum of \( x \) terms of the above series.

Again, let it be required to find the sum of \( x \) terms of the series

\[ 1, 7, 19, 37, \ldots \]

of which the general term

\[ f(x) = 3x^2 - 3x + 1, \]

therefore,

\[ \phi(x) - \phi(x-1) = 3x^2 - 3x + 1; \]

conssequently \( \phi(x) = x^3 \), the sum of \( x \) terms of the series.

In these two examples, the finding the sum \( \phi(x) \) from the difference is extremely simple; but in the generality of cases it is far from being so obvious, and even in some, it is impossible to exhibit the sum of the terms in any other manner than by another series; but as in the latter case the transformed series may be made to posses almost no degree of convergency we praise, this method of summation is still attended with important advantages, and even more perhaps in the latter case, than in any other; because moll, if not all, summable series, may be summed on some other principles; viz. either by the method of recurring series, or by the differential method, or by increments; while the transformation of a slowly converging series, into another of rapid convergency, is frequently extremely difficult to effect on any other principle than that of Stirling's, or some other tantamount to it.

From what is stated above it appears, that the principal object of enquir} is, in what manner we are to determine a function from the difference between two states of it being given. In the examples we have chosen for illustration, the function whence the difference is derived is extremely obvious; but this in many cases is, as we have before observed, attended with some difficulty. In this respect the summation of series resembles in a great degree the inverse method of fluxions. There is little or no difficulty in any case in finding the fluxions of any proposed quantity; but the finding of a fluent of any given fluxion is far from possessing the same facility. So also in the present case, if the question was to find the difference between two different states of a given function, we should find the operation direct and simple; but the converse, or the finding the function from the difference being known, is indirect, and frequently difficult to be determined.

It is obvious also, that two different functions, which differ from each other only by some constant quantity, will give the same difference, and, consequently, a given difference may give rise to different functions, the same as happen in finding fluxions, and it will therefore be necessary in this case, as in that, to have recourse to a correction, which will be found in the same manner, as is practised in that calculus, viz. by finding the value of the series, when the variable quantity is made equal to zero, or some determined magnitude.

Of the general Term of a Series.—With regard to the general term of a series, it is difficult, particularly within our limits, to lay down any fixed or constant rule for its determination; it is besides seldom necessary, as the law of the series is commonly presented in the terms of the series itself; we shall leave this determination, therefore, as in fact it must be in most cases, to the ingenuity of the analyst, and shall proceed immediately to the other subjects of investigation.

It may not, however, be amiss to state, that in such cases as have an order of their differences vanish, the general term is always of the form

\[ A^n + B n^{n-1} + C n^{n-2} + D m^{-3} + \&c. \]

where \( m \) denotes the order of the differences that vanish, and \( n \) the number of terms from the beginning. The values of \( A, B, C, D, \&c. \), being found by making \( n \) successively equal to 1, 2, 3, \&c., and equating the results with the \( 1, 2d, 3d, \&c. \) terms of the series.

Of the Transformation of a given Function to an equivalent one of a different Form.—Since we shall confine our investigation only to those series whose terms are either integers or rational fractions, it is obvious that the general term must also be some rational function either of the form,

\[ a + b x + c x^2 + d x^3 + \&c. \]

or

\[ a + b x + c x^2 + d x^3 + \&c. \]

and our object is to transform either of those general forms into others, whence the general function from which they have been derived may be the more readily determined. Different transformations may be employed for this purpose; but the most general, and that, in fact, to which Stirling principally confines himself, is to transform the above general terms into other equivalent ones of the form

\[ A + B x + C x (x - 1) + D x (x - 1) (x - 2) + \&c. \]

or

\[ \frac{A}{x(x + 1)} + \frac{B}{x(x + 1)(x + 2)} + \frac{C}{x(x + 1)(x + 2)(x + 3)} \]

from either of which the general function whence they have been derived may be readily determined. For it is obvious that the first is equal to the difference between the two following functions

\[ A x + \frac{1}{2} B (x + 1) x + \frac{1}{2} C (x + 1) x (x - 1) + \frac{1}{2} D (x + 1) x (x - 1) (x - 2) + \&c. \]

and

\[ A (x - 1) + \frac{1}{2} B x (x - 1) + \frac{1}{2} C x (x - 1) (x - 2) + \frac{1}{2} D x (x - 1) (x - 2) (x - 3) + \&c. \]

For by subtracting these from one another, we have

\[ A + B x + C x (x - 1) + D x (x - 1) (x - 2) + \&c. \]

And therefore, from what has been stated, the first of the above formulæ will be the general sum of that series of which the general term is

\[ A + B x + C x (x - 1) + D x (x - 1) (x - 2) + \&c. \]

And in a similar manner it may be shewn, that the second general form is equal to the difference between the two following functions
SERIES.

\[
\begin{align*}
A + & \frac{B}{x + 2 (x + 1)^2} + \frac{C}{x (x + 1)} + \frac{D}{x (x + 1) (x + 2)} + \text{&c.} \\
\text{and} & \frac{A}{x + 2} + \frac{B}{(x + 1) (x + 2)} + \frac{C}{(x + 1) (x + 2)(x + 3)} + \frac{D}{x (x + 1) \ldots (x + 4)} + \text{&c.}
\end{align*}
\]

For by subtracting these one from the other, we have

\[
\frac{A}{x (x + 1)} + \frac{B}{x (x + 1) (x + 2)} + \frac{C}{x (x + 1) (x + 2)(x + 3)} + \frac{D}{x (x + 1) \ldots (x + 4)} + \text{&c.}
\]

and consequently the former is the sum of that series whole general term is

\[
\frac{A}{x (x + 1)} + \frac{B}{x (x + 1) (x + 2)} + \frac{C}{x (x + 1) (x + 2)(x + 3)} + \frac{D}{x (x + 1) \ldots (x + 4)} + \text{&c.}
\]

So that the whole difficulty is now reduced to that of transforming any proposed function, expressing the general term of a series into an equivalent function of one or other of the above forms.

To transform a quantity of the form

\[a + bx + cx^2 + dx^3 + &c.
\]

into another of the form

\[A + B x + C x(x - 1) + D x(x - 1)(x - 2) + &c.
\]

By the actual multiplication of the latter formula, we have

\[
\begin{align*}
A &= A \\
B x &= B x \\
C x(x - 1) &= -C x + C x^2 \\
D x(x - 1)(x - 2) &= D x - 3 D x^2 + D x^3
\end{align*}
\]

And equating the coefficients of the like powers of \(x\) in this and the original series, we obtain

\[
\begin{align*}
d &= D \\
e &= C - 3 D \\
b &= B - C + D \\
a &= A
\end{align*}
\]

Whence the values of \(A, B, C, D, &c.\) are determined by means of the known coefficients \(a, b, c, d, &c.\) And the same method may obviously be employed in any other similar case. The following tablet, however, will facilitate the operation; viz.

\[
x = x \\
x^2 = x + x(x - 1)
\]

Now

\[
\begin{align*}
\frac{1}{x} &= \frac{1}{x(x + 1)} + \frac{1}{x(x + 1)(x + 2)} + \frac{2}{x(x + 1) (x + 2)(x + 3)} + \frac{6}{x(x + 1) \ldots (x + 4)} + \text{&c.} \\
\frac{1}{x^2} &= \frac{1}{x(x + 1)(x + 2)} + \frac{3}{x(x + 1)(x + 2)(x + 3)} + \frac{11}{x(x + 1) \ldots (x + 4)} + \text{&c.} \\
\frac{1}{x^3} &= \frac{1}{x(x + 1)(x + 2)(x + 3)} + \text{&c.}
\end{align*}
\]

Or by making

\[
\begin{align*}
A &= a \\
B &= a + b & & C = 2 a + 3 b + 4x & & D = 6 a + 11 b + 6 x + 3 \eta + \lambda \\
E &= 24 a + 50 b + 35 x + 10 \eta + \lambda & & F = 120 a + 274 b + 225 x + 85 \eta + 15 \lambda + \nu
\end{align*}
\]

which

\[+ \text{&c.}
\]

The most general method of performing this transformation is, by actual division to reduce it first to the form

\[
\frac{+ a}{x^2} + \frac{+ b}{x^1} + \frac{+ c}{x^0} + \text{&c.}
\]

see, by actual division to reduce it first to the form

\[
\frac{+ a}{x^2} + \frac{+ b}{x^1} + \frac{+ c}{x^0} + \text{&c.}
\]

To transform any general term of the form

\[
a + b x + c x^2 + d x^3 + &c.
\]

into another of the form

\[
\frac{A}{x(x + 1)} + \frac{B}{x(x + 1)(x + 2)} + \frac{C}{x(x + 1)(x + 2)(x + 3)} + \text{&c.}
\]

\[
\frac{A}{x(x + 1)} + \frac{B}{x(x + 1)(x + 2)} + \frac{C}{x(x + 1)(x + 2)(x + 3)} + \text{&c.}
\]
which values substituted for A, B, C, &c. will give the transformation sought, and which will terminate by one of those expressions becoming zero, when the series is summable, but when it is not the expression itself will become an infinite series, but such that we may give it almost any degree of convergency at pleasure.

Let us now illustrate what has been said by a few examples, remembering that the sum of a series, whose general term is

\[ A + B x + C x (x - 1) + D x (x - 1) (x - 2) = A x + \frac{B}{2} (x + 1) x + \frac{C}{3} (x + 1) x (x - 1) + &c. \]

Let it be propos'd to sum the series of odd numbers,

\[ x + 3 + 5 + 7 + &c. \]

Here the general term is \( 2 x - 1 \), or \( x + 2 \); so that \( a = -1 \) and \( b = 2 \); whence \( A = -1 \), and \( B = 2 \), and \( C = 0 \); whence \( A x + \frac{B}{2} (x + 1) x = x - x + x^2 - x = x^2 \), which is the known expression for the sum of \( x \) terms of the above series.

Again, require the sum of the series,

\[ 1 \cdot 2 + 2 \cdot 3 + 3 \cdot 4 + 4 \cdot 5 + &c. \]

Here the general term is \( x(x + 1) \), or \( x^2 + x \); by the preceding table,

\[ x = x \]

\[ x^2 = x + x (x - 1) \]

Therefore \( A = 0 \), \( B = 2 \), and \( C = 1 \); whence we have

\[ \frac{\frac{B}{2}}{x + 1} x + \frac{C}{3} (x + 1) x (x - 1) = \frac{1}{2} (x^2 + 3 x^2 + 2 x), \]

the sum of \( x \) terms, as required.

But as there is no advantage gained by the application of this method to series of the above kind, nor indeed to any summable series, as there are commonly more readily resolved by some one of the preceding methods than by this, we shall pass immediately to series of the second kind, in which it possesses a facility of application, which is perhaps unattainable by any other principle at present known.

Here we must observe, that after the general term of any series is reduced to the form,

\[ \frac{A}{x(x + 1)} + \frac{B}{x(x + 1)(x + 2)} + \frac{C}{x(x + 1)(x + 2)(x + 3)} + &c. \]

the sum of that series is expressed by

\[ \frac{A}{x} + \frac{B}{2 x(x + 1)} + \frac{C}{3 x(x + 1)(x + 2)} + &c. \]

and the series of the series is expressed by

\[ \frac{1}{4 x(x + 1)} + \frac{1}{8 x(x + 1)(x + 2)} + \frac{1}{16 x(x + 1)(x + 2)(x + 3)} + \frac{1}{32 x(x + 1)(x + 2)(x + 3)(x + 4)} + &c. \]

1. Let it be proposed to find the sum of the infinite series,

\[ \frac{1}{1 \cdot 4 \cdot 7} + \frac{1}{4 \cdot 7 \cdot 10} + \frac{1}{7 \cdot 10 \cdot 13} + &c. \]

where the general term is

\[ \frac{1}{3 x (3 x + 3) (3 x + 6)} = \frac{7}{27} x (x + 1) (x + 2) \]

\( x \) being successively \( 1 \), \( 1 \), \( 2 \), \( 3 \), &c.

Now this is of the required form, \( A = 0 \), and \( B = \frac{1}{27} \); therefore the required sum is

\[ \frac{1}{54} x (x + 1) = \frac{1}{27} \]

by taking \( x = \frac{1}{2} \), its first value. If we took \( x = \frac{1}{2} \),

\[ \frac{1}{2 \cdot 4 \cdot 6} + \frac{1}{4 \cdot 6 \cdot 8} + &c. \]

we should have the sum of all the terms of the series, except the first; if \( x = \frac{1}{2} \), we should have the sum of all but the first two terms, and so on; and it is by this means that we are enabled to give so great a degree of convergency in those series that are not summable; for we may assume any one of the values of \( x \), and by that means give almost any magnitude to the denominators of our converging fractions; and it is only that of the leading terms of the series as are not included must be summed by themselves, and added to the approximation found as above. As this is the great characteristic of Stirling's method, we shall confine our future remarks to one or two examples, which are not summable, in order to illustrate the nature of his approximations.

Let there be proposed the series,

\[ \frac{1}{1 \cdot 2} + \frac{1}{3 \cdot 4} + \frac{1}{5 \cdot 6} + \frac{1}{7 \cdot 8} + &c. ; \]

which is that found by Lord Brounker, for the quadrature of the hyperbola.

Here the general term is

\[ \frac{1}{2 x (2 x + 1)} \]

or

\[ \frac{4 x (x + \frac{1}{2})}{4 x^2 + 2 x} \]

taking \( x = \frac{1}{2} \), \( 1 \), \( 2 \), &c. Now

\[ \frac{1}{4 x^2 + 2 x} = \frac{1}{4 x^2} - \frac{1}{8 x^3} + \frac{1}{16 x^4} - \frac{1}{32 x^5} + &c. ; \]

which is

\[ \frac{1}{4 x^2 + 2 x} \]

when converted into the required form, is,

\[ \frac{1}{4 x^2} \]

where the law of continuation is obvious, and the sum will be expressed by

\[ \frac{1}{4 x} + \frac{1}{16 x (x + 1)} + \frac{1}{48 x (x + 1) (x + 2)} + &c. ; \]

in which the law is also obvious, the co-efficients in the denominator being \( 4 = 2^2 \), \( 16 = 2^3 \times 2 \), \( 48 = 2^4 \times 3 \), \( 128 = 2^7 \times 4 \), &c.; but the series will not terminate, because the original general term \( \frac{1}{4 x (x + \frac{1}{2})} \) includes the fraction \( \frac{1}{2} \).

The original series has, therefore, been converted into another infinite series, but with this advantage attending the latter, that we may give it almost any degree of convergency at pleasure, according to the value we give to \( x \). If we assume \( x = 13 \), which is its value in the 14th term, then the preceding series will exhibit the sum of the original series.
SERIES.

fured from that term, to which adding the sum of the first
13 terms, we have, for the whole sum,

\[ \text{13 first terms } = \frac{654295656}{18581259} \]

\[ \text{9 first terms of the new series } = \frac{10034719}{18581259} \]

\[ \text{Whole sum } = \frac{-83474178}{18581259} \]

This is true to nine places of decimals, which, if we had
used the original series, would have required the summation of
at least one hundred million of its terms.

Hence the advantage of the transformation, which con-

Now, from what has been said, it appears that

\[ x = a \left(1 + \frac{1}{x}\right) + \frac{1}{x} (x + 1) (x + 2) + \frac{1}{x} (x + 1) (x + 2) (x + 3) + \&c. \]

and consequently the sum will be

\[ \frac{1}{x} + \frac{1}{2 x} + \frac{1}{3 x} + \frac{1}{4 x} + \&c. \]

in which substituting 15 for \( x \), etc. its 15th value, we find,
by summing 15 terms of the new series, and adding that sum =
\(-70957427\), to the sum of the 15 terms of the original series,
we have \( 1.554957659\), we have \( 1.044093065\)
for the whole approximate sum, true to nine places of decimals.

Our limits will not allow of our entering farther upon
this method, and we shall therefore conclude our illustration of
it, by merely giving the author's formula for the sum-

of those series, in which the successive powers of an

\[ x^\sum \times \left(\frac{a}{(1-x)x} + \frac{b}{(1-x)x} + \frac{c}{(1-x)x}(z+1)(z+2) + \&c.\right) \]

where \( A, B, C, \&c. \) represent the terms immediately
preceding those in which they are found.

This latter expression, like those in the preceding pro-

positions, will terminate when the series is summable: in
other cases, it will be itself an infinite series, but such
that we may give it any degree of convergency required.

Simpson's Method of Series. — In 1743 Simpson published
his "Mathematical Dissertations on a variety of Physical
and Analytical Subjects," and amongst other interesting re-
searches in that work, there is one relating to the summation of
series, which is perhaps as general and complete as any
we have yet noticed; at least, if we except (with regard to
approximations) that of Stirling's, above explained. This
method consists in deriving the sum of one series from
that of another being given or known; which former sum is ex-
pressed by a finite or infinite formula, according as the suc-
cessive differences of certain parts of its terms are of definite
or indefinite extent; thus,

\[ a^n + b a^{n+1} x + c a^{n+2} x^2 + d a^{n+3} x^3 + \&c. \]

be any power \( n \) of the binomial \( a + x \), \( n \) being either in-
tegral, fractional, positive, or negative; and the terms of
it be respectively multiplied by any series of quantities,
\( p, q, r, s, \&c. \); and we make \( q - p = D, r - q = D', D'' = D''', \&c. \) being
the first terms of the successive orders of differences, then the sum of

\[ a^n + b a^{n+1} x + c a^{n+2} x^2 + d a^{n+3} x^3 + \&c. \]

be expressed by

\[ f(a + x)^n + D' b x (a + x)^{n-1} + D'' c x^2 (a + x)^{n-2} + D''' d x^3 (a + x)^{n-3} + \&c. \]

which formula will obviously be finite, if any order of the

Vol. XXXII.
be expressed by the fluxional formula

\[(r - p) A + \frac{x A}{x} = B;\]

where, because it is given in finite terms, \(A\) will always likewise be had in finite terms, and consequently, also, the value of \(B\). And in the same manner as we have

\[a x^r + b x^{r+n} + c x^{r+2n} + \&c. = A;\]

we have

\[r a x^r + (r + n) b x^{r+n} + (r + 2n) c x^{r+2n} + \&c. = (r - p) A + \frac{x A}{x} = B;\]

so also

\[\frac{(i - p) B + \frac{x B}{x}}{x} = C \&c. &c.\]

The three preceding cases are the first, second, and third propositions in the author's chapter on series, which contains four other propositions equally general and important; but for these we must refer the reader to the treatise itself.

Since the publication of Simpson's work above referred to, a variety of other treatises have appeared either wholly or in part devoted to this subject, besides numerous memoirs in all the principal academies and learned societies in Europe. It will be impossible to enter upon these at any considerable length within the limits of this article, and we shall therefore merely select two or three of the principal authors whose methods are the most eligible for the purposes of general discussion.

Euler, in this, as in every other branch of analysis, has distinguished himself by the many new lights he has thrown upon this theory, and the general and elegant investigations that he has given of many very interesting problems relating to this doctrine. These investigations are found in various memoirs in the Acta Petrop., and in his "Institutiones calculi differentialis," also in the first volume of his "Introductio in Analysis Infinitarum," many of these, however, may be referred to the Method of Increments and Recurring Series, which have been already treated of under these articles; the theory of circular series is also handled in his usually masterly manner, but for our purpose we shall prefer adopting the method employed by Landen in his "Mathematical Calculations," and shall therefore, in this place, limit our observations to Euler's differential method.

**Euler's Differential Method of Series.**—Let there be posposed the general series

\[S = a x + b x^2 + c x^3 + d x^4 + \&c.\]

in which \(a, b, c, d, \&c.\) are constant and positive quantities, \(x\) being indeterminate. This series Euler transforms into the following equivalent series, *viz.*

\[S = \frac{x}{1-x} a + \frac{x^2}{(1-x)^2} \Delta a + \frac{x^3}{(1-x)^3} \Delta^2 a + \&c.\]

in which \(\Delta a, \Delta^2 a, \Delta^3 a, \&c.\) denote the first terms of the first, second, third, &c. differences of \(a, b, c, \&c.\) observing that the leading term is always supposed to be taken from the following, so that when the terms diminish, this difference will be negative. It is obvious here, as in the other differential series, we have had occasion to notice, that when any order of differences vanish, the transformed series will be finite, but in other cases infinite, the same as that whence it is derived.

Let, for example, the series

\[S = x + 2 x^2 + 3 x^3 + 4 x^4 + \&c.\]

be the one posposed. Here the first differences are \(1, 1, 1, \&c.\) and, consequently, the second differences are zero; that is, we have \(a = 1\), and \(\Delta a = 1\); so that we have

\[S = \frac{x}{1-x} a + \frac{x^3}{(1-x)^2} \Delta a = \frac{x}{1-x}\]

Hence, by substituting \(x = 1, \frac{1}{2}, \frac{1}{3}, \&c.\) we obtain

\[x = 1; S = 1 + 2 + 3 + 4 + \&c. = \frac{1}{1-1} = \infty\]

\[x = \frac{1}{2}; S = \frac{1}{2} + \frac{2}{4} + \frac{3}{8} + \frac{4}{16} + \&c. = \frac{\frac{1}{2}}{1-\frac{1}{2}}^2 = 2\]

\[x = \frac{1}{3}; S = \frac{1}{3} + \frac{2}{9} + \frac{3}{27} + \frac{4}{81} + \&c. = \frac{\frac{1}{3}}{1-\frac{1}{3}}^2 = \frac{8}{5}\]

Again, let the posposed series be

\[S = x + 3 x^2 + 5 x^3 + 7 x^4 + \&c.\]

Here \(a = 1, \Delta a = 2, \Delta^2 a = 0;\) therefore

\[S = \frac{x}{1-x} a + \frac{x^2}{(1-x)^2} \Delta a + \frac{x^3}{(1-x)^3} \Delta^2 a + \&c.\]

Making therefore, as before, \(x = 1, \frac{1}{2}, \frac{1}{3}, \&c.\) we have

\[x = 1; S = 1 + 3 + 5 + 7 + \&c. = \frac{\frac{1}{1}}{1-1}^2 = \infty\]

\[x = \frac{1}{2}; S = \frac{1}{2} + \frac{3}{4} + \frac{5}{8} + \frac{7}{16} + \&c. = \frac{\frac{1}{2} + \frac{1}{2}}{1-\frac{1}{2}}^2 = 3\]

\[x = \frac{1}{3}; S = \frac{1}{3} + \frac{3}{9} + \frac{5}{27} + \frac{7}{81} + \&c. = \frac{\frac{1}{3} + \frac{1}{3}}{1-\frac{1}{3}}^2 = 1\]

Without farther examples, it is obvious, that a most extensive class of summable series may be drawn from this one simple principle, by merely changing the values of \(x\); and those of \(a, b, c, d, \&c.\) being so assumed, that a certain order of their difference may vanish, which will always happen, if they be made to represent any order of polygonal or figurate numbers, or any order of powers whatever. This method, however, is not limited to finding summable series, it may frequently be employed to great advantage in approximating towards the real value of slowly converging series that are not summable in any finite form, as for example, the series

\[1 - \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c. = \text{hyp. log. 2;}\]

putting this under the form

\[S = x + \frac{1}{2} x^2 + \frac{1}{3} x^3 + \frac{1}{4} x^4 + \&c.\]

we have \(a = 1, \Delta a = -\frac{1}{2}, \Delta^2 a = \frac{1}{2}, \Delta^3 a = -\frac{1}{2} \&c.\) whence

\[S = \frac{x}{1-x} a + \frac{x^3}{(1-x)^3} \Delta a + \frac{x^3}{(1-x)^3} \Delta^3 a + \&c.\]
will become, by making \( s = -1 \),
\[
S = -\frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} = \frac{1}{7} = \text{etc.}
\]
whence, by changing signs, we have
\[
1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} = \text{hyp. log. 2}
\]
which latter series, though indefinite like the first, is so much more converging, that 25 terms of it will give a result as true as 10,000 terms of the original series.

The same formula is also applicable to certain diverging series, but we can only give some of the more remarkable results, as
\[
1 - 1 + 1 - 1 + 1 + \text{etc.} = \frac{1}{2} \\
1 - 2 + 3 - 4 + 5 - 6 + \text{etc.} = \frac{1}{4} \\
1 - 4 + 9 - 16 + 25 - \text{etc.} = 0 \\
1 - 3 + 9 - 27 + 81 - \text{etc.} = \frac{1}{4} \\
1 - 1.2 + 1.3 - 1.4 + 1.5 + \text{etc.} = 0.5965473601237
\]
Euler also employed other methods for summable series which we have not referred to either in the above article, or in the articles INCREMENTS or INFINITELY RECURRING SERIES, one of the most general of which is by means of certain fluxional operations; but as this has been carried to a greater extent by Lorgna, in his tract "De Seriesbus convergentibus," we shall defer any further mention of it till we come to an explanation of Lorgna's method.

We ought to give here some account of the differential method of Maferes and Hutton, but our article has already been carried to a greater extent than is usual for mathematical subjects, we must limit ourselves to giving merely the theorems, and leave the application of them to the ingenuity of the reader.

8. **Maferes differential Formula for slowly converging Series.**

Let
\[
a + bx + cx^2 + dx^3 + \text{etc.}
\]
represent any series, and \( D, D', D'', \text{etc.} \) the first terms of the successive order of differences of the-co-efficients \( a, b, c, d, \text{etc.} \) which are supposed continually to diminish, then will the sum of the above series be expreessed by the differential series
\[
a - \frac{b}{1 + x} - \frac{D' x^3}{(1 + x)^2} - \frac{D'' x^3}{(1 + x)^3} - \text{etc.}
\]
which is necessarily converging, provided \( x \) be equal to, or greater than unity. By means of this series, the author finds the circumference of the circle from the series
\[
1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \text{etc.}
\]
true to seven places of decimals, by the summation of ten terms, whereas, in its original form, 10,000 of its terms will only give two decimals correct. For a further illustration of this method, the reader is referred to the Phil. Trans. for 1775, or to the author's Treatise on Converging Series.

9. *Hutton's Method for slowly converging Series.*—This method applies only to those whose terms are alternately plus and minus, as \( a - b + c - d + \text{etc.} \) the total sum of which series is given alternately in excess and defect, by the successive quantities
\[
\frac{a}{2} - \frac{b}{4} + \frac{c}{8} - \frac{d}{16} + \text{etc.}
\]
and each of these quantities, as we have stated above, is an approximation towards the whole sum; the first is in excess, the second in defect, the third in excess, and so on; but each is a nearer approximation than the preceding. The general formula for \( n \) terms is
\[
\left(2^n - 1\right) a - \left(A - n\right) b - \left(B - n^2\right) + \text{etc.}
\]

The method of applying this formula to computation, however, is such, that we must refer the reader for an explanation of it to the author's Miscellaneous Tracts, published in 1801, in 1778, or to the new edition of the same in 3 vols. 8vo, published in 1812.

10. **Lorgna's Method of Series.**—This consists in multiplying the terms of the proposed series by such powers of an inutendeterminate quantity, that the fluxion of the whole series being taken, and then divided by \( x \), there shall result a known series, from which the sum of the original one may be readily derived. Thus, let there be proposed the series,
\[
\frac{1}{\rho + q} + \frac{1}{\rho + 2q} + \frac{1}{\rho + 3q} + \text{etc.}
\]
Multiply each term successively by
\[
x^{\rho + q} + x^{\rho + 2q} + x^{\rho + 3q} + \text{etc.}
\]
and there results
\[
\frac{x^{\rho + q}}{\rho + q} + \frac{x^{\rho + 2q}}{\rho + 2q} + \frac{x^{\rho + 3q}}{\rho + 3q} + \text{etc.}
\]
Make the sum of this series \( S \), and then taking the fluxion on both sides, we have
\[
\frac{q S}{x} = x^{\rho + q} + x^{\rho + 2q} + x^{\rho + 3q} + \text{etc.}
\]
or
\[
\frac{q S}{x} = 1 + x + x^2 + x^3 + \text{etc.} = \frac{1}{1 - x}
\]
whence \( S = \frac{x}{1 - x} \); and consequently,
\[
\frac{q S}{x} = \frac{x^{\rho + q}}{\rho + q} + \frac{x^{\rho + 2q}}{\rho + 2q} + \frac{x^{\rho + 3q}}{\rho + 3q} + \text{etc.}
\]
which, by making \( x = 1 \), becomes the same as the series originally proposed, viz.
\[
\frac{1}{\rho + q} + \frac{1}{\rho + 2q} + \frac{1}{\rho + 3q} + \text{etc.}
\]
It must be observed, however, that in all such expressions, the fluxion must be so taken, as to vanish when \( x = 0 \), and to be perfectly integrable where \( x = 1 \).

By a similar process, the author finds the sum of the series,
\[
\frac{1}{\rho + q} - \frac{1}{\rho + 2q} + \frac{1}{\rho + 3q} - \frac{1}{\rho + 4q} + \text{etc.}
\]
On x

10
to be equal to $\frac{1}{q} \int \frac{x^l}{1 + x^m}$; the fluent being taken under
the same restriction as before. And in nearly the same way
he finds the sum of $n$ terms of the former to be
$$\Sigma = \frac{1}{q} \left\{ \int \frac{x^l}{1 + x^m} - \int \frac{x^{l+n}}{1 + x} \right\}$$
and the latter,
$$\Sigma = \frac{1}{q} \left\{ \int \frac{x^l}{1 + x} - \int \frac{x^{l+n}}{1 + x^m} \right\}$$

In a similar manner, M. Lorgna finds for the infinite sum of
$$\frac{1}{(p + q)^m} \frac{1}{(p + q)^{m+1}} + \frac{1}{(p + q)^{m+2}} + \cdots$$

$$S = \frac{1}{q} \int \frac{x^l}{x^m} \frac{x^l}{x^m+1} \frac{x^l}{x^m+2} \cdots$$
and the sum of $n$ terms,
$$\Sigma = \frac{1}{q} \int \frac{m^n - x^n}{m^n - x^n} \frac{x^l}{x^m} \frac{x^l}{x^m+1} \cdots$$

And $\Sigma = \frac{1}{q} \int \frac{2^n - x^n}{2^n - x^n} \frac{x^l}{x^m}$, when alternately plus
and minus.

For a further illustration of this method, we refer the reader to Clarke's translation of Lorgna's treatise, “De Seriesibus Convergentibus,” 4to. 1779.

11. Circular Series.—We have hitherto, when illustrating
the methods of summation employed by the Bernoullis,
that James, although he had discovered several curious pro-
erties of the series,
$$\frac{1}{1^1} + \frac{1}{2^2} + \frac{1}{3^3} + \frac{1}{4^4} + \cdots$$
had not been able to find its sum; but this his brother
John afterwards effected, and the solution of it is published
in the 4th volume of his “Opera Omnia.” Bernoulli
found this sum to depend upon the rectification
of the circle, shewing that it is equal to one-sixth of the square of
the semi-circumference of a circle, whose radius = 1. This
refult he drew from the known series, which expresses
the sine of an arc in terms of the arc, viz.,
$$\sin x = \frac{x}{2} + \frac{x^3}{2 \cdot 3 \cdot 4} - \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} \cdots$$
which, when $\sin x = \varphi$, becomes, after dividing by $x$,
$$\varphi = 1 \frac{1}{3 \cdot 4} \frac{x^3}{2 \cdot 3 \cdot 4 \cdot 5} \cdots$$

Or writing $x = \frac{\varphi}{\varphi}$,
$$\varphi = 1 \frac{1}{3 \cdot 4} \frac{x^3}{2 \cdot 3 \cdot 4 \cdot 5} \cdots$$
Again, multiplying by $z^m$,
$$\varphi = z^m \frac{1}{2 \cdot 3} z^{2m} + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} z^{3m-4} \cdots$$

Now the sum of the roots of every equation of this form
being equal to the co-efficient of the second term with its sign changed, we have
$$a'' + a''' + a'''' + \cdots$$
or
$$\frac{1}{\varphi^2} + \frac{1}{\varphi^3} + \frac{1}{\varphi^4} + \cdots$$
denoting by $z^l$, $z^m$, $z^n$, &c., or $z^l$, $z^m$, $z^n$, &c., the
successive roots of the above equation.
But we know that the values of $x$, answering to the case
of $\sin x = \varphi$, are $\varphi$, $2 \varphi$, $3 \varphi$, $4 \varphi$, &c.; $\pi$ denoting
the semi-circumference; substituting, therefore, these successive
values of $x$, we have
$$\frac{1}{\varphi} + \frac{1}{\varphi^2} + \frac{1}{\varphi^3} + \frac{1}{\varphi^4} + \cdots$$
$$\frac{1}{\varphi^2} + \frac{1}{\varphi^3} + \frac{1}{\varphi^4} + \cdots$$

Landen's method depends upon exactly the same prin-
ciples; but he has rendered it more general, and exhibits
several very remarkable series of this kind. He first
deduces the formula for expressing the sums of the several
powers of the roots, $a$, $b$, $c$, &c. of any equation
$$x^n + Ax^{n-1} + Bx^{n-2} + Cx^{n-3} + \cdots$$
viz. if $S' = a + b + c + \cdots$
$$S'' = a^2 + b^2 + c^2 + \cdots$$
$$S''' = a^3 + b^3 + c^3 + \cdots$$
then $S' = - A$
$$S'' = - 2 B - A S'$$
$$S''' = - 3 C - B S' - A S''$$
$$S'' = - 4 D - C S' - B S'' - A S'''$$

Then from the series for the sine and cosine of any
arc $x$, viz.,
$$\sin x = x - \frac{x^3}{2 \cdot 3 \cdot 4} - \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} \cdots$$
$$\cos x = 1 - \frac{x^2}{2 \cdot 3 \cdot 4} - \frac{x^4}{2 \cdot 3 \cdot 4 \cdot 5} \cdots$$
he derives the sum of their roots, when $\sin x = \varphi$, or
when $\cos x = \varphi$; and then, from the preceding formula for the
sums of the squares, cubes, &c. of the roots of an equation,
draws the values of the several powers of those quantities.
Thus in the series for the cosine, when $\cos x = \varphi$, we
have for the several roots, (denoting the quadrant or $\frac{\pi}{2}$
by $\varphi$,)
$$\frac{1}{\varphi} + \frac{1}{3 \varphi} + \frac{1}{5 \varphi} + \frac{1}{7 \varphi} \cdots$$
there being no second term, but the sum of these squared,
viz.,
$$\frac{1}{\varphi^2} + \frac{1}{3 \varphi^2} + \frac{1}{5 \varphi^2} + \frac{1}{7 \varphi^2} \cdots$$
SERIES.

\[
\frac{2}{3} + \frac{3}{5} + \frac{2}{7} + \cdots = S_n = \frac{1}{6}
\]

In a similar manner we have

\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots = \frac{\pi}{6}
\]

and on the same principle, the sum of the series,

\[
1 + \frac{3}{5} + \frac{1}{7} + \cdots = \pi
\]

may be found, \( n \) being any positive number whatever.

Euler's method is still more general than Landen's, but it depends upon principles of very nearly the same origin; we must, however, limit ourselves to giving a few of the principal results. Representing by \( \pi \) the semi-circumference to radius 1, he shews that

\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots = \frac{\pi}{2}
\]

and

\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots = \frac{\pi}{2}
\]

where the law of the first multiplier is obvious, but the coefficients of \( \pi \), \( \pi \), \&c. are not so easily seen: those for the following powers are \( \frac{3}{5} \pi \), \( \frac{5}{7} \pi \), \( \frac{6}{9} \pi \), \&c.

If each of these series be multiplied by their first fraction, they give

\[
\frac{1}{2^1} + \frac{1}{4^1} + \frac{1}{6^1} + \cdots = \frac{1}{2^1} \cdot \frac{2^1}{1.2.3} \cdot \pi \]

\[
\frac{1}{2^1} + \frac{1}{4^1} + \frac{1}{6^1} + \cdots = \frac{1}{2^1} \cdot \frac{2^1}{1.2.3} \cdot \pi \]

\&c. \&c. \&c. \&c. \&c.

and subtracting these from the first, we have

\[
1 + \frac{1}{3^1} + \frac{1}{5^1} + \cdots = \frac{2^1 - 1}{2^1} \cdot \frac{2^1}{1.2.3} \cdot \pi \]

\&c. \&c. \&c. \&c. \&c.

Again, subtracting the first from these last, we find the sum of the powers under the alternate signs plus and minus, and so on, almost in endless variety.

Other series, whose sums are found in nearly the same manner, are as follows, viz.

\[
1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots = \frac{\pi}{4}
\]

\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots = \frac{\pi}{8}
\]

\[
1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots = \frac{\pi}{16}
\]

\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots = \frac{\pi}{96}
\]

\&c. \&c. \&c. \&c. \&c.

For a great variety of other series of this kind, see Euler's "Introduction to Analysis of Infinites," and his "Institutiones Calculi Difficile," and also Legendre's "Elliptic Functions of the Various Orders of the Transcendentals," 4th ed., where the reader will find series very similar to the above, but which were not found by Euler's method, are treated of, and investigated by him in a very able manner.

We ought perhaps to apologize to such of our readers, who are not interested in mathematical inquiries, for the length to which we have extended this article; but those who are, will not, we presume, be displeased to find a condensed form a general view of the first introduction, and successive improvements, which have been made in this important branch of analysis. We have, of course, been obliged to pass over in silence many authors who have written on this subject; but we have endeavoured to include all those who have introduced into the doctrine any methods distinctly different from those who preceded them, at least, if we except Mr. Spence's method, published in his "Logarithmic Transcendentals," and that of M. Arbogast, given in his "Calcule des Derivations." We had indeed, in the first instance, intended to give a full illustration of the principles of these two authors; but the length to which the article has already extended, and the nature of their notation, which render necessary a considerable degree of previous explanation, put it out of our power to execute this part of our plan, and we can therefore do nothing more than refer the reader for information to the works themselves; we refer him also to the "Calcul des Differences Fines," by La Croix, and to an ingenious memoir by professor Vince, in the 72d volume of the Philosophical Transactions.

As the preceding article is arranged wholly with reference to the historical order of the subject, we intend, in conclusion, to furnish the reader with a general synopsis of the doctrine of series for the advantages of practical operations.

12. General Synopsis for the Summation of Series.—In the following table, \( S \) denotes the sum of a finite number of terms \( (n) \), and \( \Sigma \) the sum of an infinite number.

1. To find whether the sum of any proposed series be finite or infinite; let \( p, q, r \), be any three equidistant terms; then, if \( p (q - r) > r (p - q) \), the sum is finite; but if \( p (q - r) < r (p - q) \), it is infinite.

2. The general term of a series, when any order \( m \) of its differences vanish, is of the form

\[
T = A n^m + B n^{m-1} + C n^{m-2} + \cdots + E
\]

and its sum of the form

\[
\Sigma = A' n^{m+1} + B' n^m + C' n^{m-1} + \cdots + E'
\]

the values \( A, B, C, \&c. \) being found as stated in art. 5, and those of \( A', B', C', \&c. \) in a similar manner.

3. Simple arithmetical Series.

\[
a + (a + d) + (a + 2d) + \cdots + a + (n - 1) d
\]

(1) Infinite \( S = \frac{n}{2} (2a + (n - 1) d) \).

If the series decrease, then \( d \) is negative, and

\[
(S) = \frac{n}{2} (2a - (a - (n - 1) d).
\]

4. Simple geometrical Series.

\[
a + ra + r^2a + \cdots + r^{n-1} a
\]

(2) \( \therefore \frac{a}{1 - r} \).

\[
(S) = \frac{r^n - 1}{r - 1} a
\]

5. Powers
5. Powers of Arithmeticals.

\[ (m + p)^r + (m + 2p)^r + (m + 3p)^r + \ldots + (m + np)^r \]

\[ (S) = \frac{n^{r+1}}{(r+1)p} + \frac{n^r}{2} + \frac{prn^{r-1}}{3 \cdot 4} - \frac{r(r-1)(r-2)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} p^{n-1} \]

\[ + \frac{1}{6} \frac{r(r-1)(r-2)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} \ldots \frac{(r-8)}{2} \]

\[ + \frac{1}{42} \frac{r(r-1)(r-2)}{2 \cdot 3 \cdot 4 \ldots 9} p^{n-9} - \text{&c.} \]

continued till they terminate. The co-efficients are the same as \( \frac{1}{A}, \frac{1}{B}, \text{&c.} \).

This form includes all the powers of the natural series, of which we have given the particular forms to the fifth power, under art. 3.

\[ 1 + m + \frac{m(m+1)}{1 \cdot 2} + \frac{m(m+1)(m+2)}{1 \cdot 2 \cdot 3} + \frac{m(m+1)(m+2)(m+3)}{1 \cdot 2 \cdot 3 \cdot 4} + \text{&c.} \]

\[ (S) = \frac{n(n+1)(n+2)(n+3)}{1 \cdot 2 \cdot 3 \cdot 4} \text{to m terms,} \]

See particular results, art. 3.

7. Series of compound Arithmeticals.

\[ (m + p) (p + e) + (m + 2p) (p + 2e) + \ldots + (m + np) (p + ne) \]

\[ (S) = nmp + \frac{n+1}{2} (m + p)e + \frac{(n+1)(2n+1)}{6} e^3 \]

8. Series of compound geometrical Numbers.

\[ (b - m) (c - p) e^i + (b - 2m) (c - 2p) e^{i+1} + (b - 3m) (c - 3p) e^{i+2} + \text{&c.} \]

\[ (S) = \frac{e^i}{1-e} \left\{ b \frac{c}{1-e} - \frac{b - p + cm}{1-e} \right\} \]

\[ \left\{ (b - mn)(c - pn) \frac{(b - mn)n + (c - pn)m}{1-e} + \frac{mp(1+e)}{1-e^2} \right\} \]

\[ 1 + m \times + \frac{m(m+1)}{1 \cdot 2} x^1 + \frac{m(m+1)(m+2)}{1 \cdot 2 \cdot 3} x^1 + \frac{m(m+1)(m+2)(m+3)}{1 \cdot 2 \cdot 3 \cdot 4} + \text{&c.} \]

\[ (S) = \frac{1}{(1-x)^n} \]

10. Series of the Reciprocals of figurate Numbers.

\[ 1 + \frac{1}{m} + \frac{1}{m(m+1)} + \frac{1 \cdot 2}{m(m+1)(m+2)} + \frac{1 \cdot 2 \cdot 3}{m(m+1)(m+2)(m+3)} + \text{&c.} \]

\[ (S) = \frac{m-1}{m-2} \]

\[ \frac{1}{a^m} + \frac{1}{(a+d)^m} + \frac{1}{(a+2d)^m} + \frac{1}{(a+3d)^m} + \ldots + \frac{1}{(a+(n-1)d)^m} \]

\[ (S) = \frac{p^{m-1}}{(m-1)a^{m-1}} + \frac{p^m}{2a^m} + \frac{p^{m+1}}{2 \cdot A \cdot a^{m+1}} - \frac{p^{m+1}}{2 \cdot 3 \cdot 4 \ldots B \cdot a^{m+2}} \]

\[ + \frac{p^{m+1}}{2 \cdot 3 \cdot 4 \ldots C \cdot a^{m+3}} - \text{&c.} \]
where the law of continuation is obvious, \( \rho \) being \( \frac{a}{a + nd} \), and the values of \( \frac{1}{A}, \frac{1}{B}, \frac{1}{C}, \) &c. being derived as follows, we denoting these respectively by \( \frac{1}{\alpha}, \frac{1}{\beta}, \frac{1}{\gamma}, \frac{1}{\delta}, \) &c.

\[
\frac{i}{\rho} = \frac{1}{\delta}
\]

\[
\frac{i}{\gamma} = \frac{3}{\nu} - 2, \nu
\]

\[
\frac{i}{\delta} = \frac{5}{\nu} - 3, \nu - 5, \nu
\]

\[
\psi = \&c. \&c. \&c. \&c.
\]

\[
\varphi = \frac{n}{2m + 4} - \frac{n + 1}{2} \psi - \frac{(n + 1) n(n - 1)}{2 \cdot 3 \cdot 4}, \varphi - \frac{(n + 1) n(n - 1)(n - 2)(n - 3)}{2 \cdot 3 \cdot 5 \cdot 6}, \varphi \&c.
\]

12. Fractional Series of the following Form.

\[
\frac{m}{\beta} + \frac{m(m + \rho)}{\beta(\beta + \rho)} + \frac{m(m + \rho)(m + 2 \rho)}{\beta(\beta + \rho)(\beta + 2 \rho)} + \cdots \frac{m(m + \rho) \cdots (m + (n - 1) \rho)}{\beta(\beta + \rho) \cdots (\beta + (n - 1) \rho)}
\]

\[
(\varphi) = \frac{m}{\beta - \rho - m}
\]

\[
\frac{1}{(\rho + q)(m + r)} \pm \frac{1}{(\rho + 2q)(m + 2r)} + \frac{1}{(\rho + 3q)(m + 3r)} \pm \&c. \frac{1}{(\rho + qn)(m + nr)}
\]

\[
(\omega) = \frac{1}{\beta q n} \int \frac{x^n - x'}{x^2} \frac{dx}{1 + x}
\]

\[
(\beta) = \frac{1}{q} \int \frac{(x^n - x')}{x^n(\beta + x)} \frac{dx}{\beta + x}
\]

where \( \beta \) must be affirmative, and not less than unity.

\[
\frac{a}{b(b + c)} + \frac{a}{(b + c)(b + 2c)} + \frac{a}{(b + 2c)(b + 3c)} + \&c. \cdots \frac{a}{(b + (n + 1)c)(b + nc)}
\]

\[
(S) = \frac{n a}{b(b + nc)} \quad (\Sigma) = \frac{a}{bc}
\]

\[
\frac{a}{b(b + c)} + \frac{a}{(b + c)(b + 2c)} + \frac{a}{(b + 2c)(b + 3c)} + \frac{a}{(b + 3c)(b + 4c)} + \&c. \cdots \frac{a + 2c}{b + (n + 1)c}
\]

\[
(S) = \frac{2ab + ac - bc}{2b(b + c)(b + nc)} n + \frac{(ac + bc)n}{b + (n + 1)c}
\]

\[
\frac{a}{a + 1} + \frac{a + b}{(a + 1)(a + 1 + b)} + \frac{a + 2b}{(a + 1)(a + 1 + b)(a + 1 + 2b)}
\]

\[
(S) = 1 - \frac{1}{(a + 1)(a + 1 + b) \cdots (a + 1 + (n - 1)b)}
\]

\[
\frac{a + c}{(a + b)(a + b + c)}
\]

\[
(S) = \frac{ac(q^n - 1) + abcq^n - bceq(q^n - 1)}{q - 1}
\]
\[
(8) \quad \frac{a}{c} + \frac{a + b}{c q} + \frac{a + 2b}{c q^2} + \frac{a + 3b}{c q^3} + \&c.
\]
\[
(8) \quad \frac{a(q - 1) + b}{c q^{r-1}} (q - 1)^{\frac{1}{r}}
\]

For a great variety of other fractional series, see Clarke's translation of Largna's Series; for the several differential formulae, our articles 3, 6, 7, 8, and 9, which are about this article; for the summation of Recurring Series, see our first article; for the most useful logarithmic series, see LOGARITHMS; and for various trigonometrical series, see the articles SINES, and TRIGONOMETRY.

SERIGNAC, in Geography, a town of France, in the department of the Finiferre; 10 miles N. of Carhaix.

SERIGNAN, a town of France, in the department of the Herault; 6 miles S. of Beziers.

SERIGNI, a sea-port town of the island of Java, in the straits of Sunda, belonging to the king of Bantam.

SERIGO. See Cerigo.

SEMINOA, a town of Italy, on the lake Como; 27 miles N. of Como.

SERJHARYODOU, a town of Chinefe Tartary, in the country of the Mongols. N. lat. 42° 15'. E. long. 105° 34'.

SERIKOTCHE, a town of Persia, in the province of Chorasan or Khorasan; 195 miles N. of Herat.

SERIMSAH, a town of Egypt; 16 miles S. of Damietta.

SERIN, or Serain, a river of France, which runs into the Yonne, between Auxerre and Joigny.

SERIN, or Serinus, in Ornithology, the name of a small bird; a species of the Fringilla in the Linnean System, common in Germany and Italy, and called by the Auritians BERGRIFF, or BIRGREIL. Its back is of a reddish-brown, and its head yellow; the colour being deeper in the male, and paler in the female; the rump is of a beautiful yellowish-green, as is also the breast; the belly is white, and the sides have some oblong blackish spots; the tail, and long feathers of the wings, are black, and a little greenish at their extremities; the beak is very thick, strong, and short, and is very sharp at the point. It is kept in cages, and feeds very sweetly.

SERIN of Surinam. See Pipra Crijata.

SERIN of the Canaries. See Fringilla Canaria.

SERIN of Jamaica. See Fringilla Cana.

SERINDA, in Ancient Geography, a town of India, on this fide of the Ganges, the inhabitants of which paid great respect to the emperor Julian.

SERINE, in Geography, a town of European Turkey, in the province of Macedonia; 44 miles S.E. of Saloniki.

SERINEAH, a town of Bengal, 18 miles S. of Purunah.

SERINETTE, a bird organ, said in the Encyclopédie to be an invention of Barby. The pitch is very high, being in unison with the largest Æolus in French organs, and with our 15th. It is used to teach birds little tunes, by those unable to play on the flageolet. Its compass is only an octave, or 13 pipes, as no scale is ever wanted.

SERINGAPATAM, in Geography, a city in Hindoostan, and capital of Mylore, situated on an island in the Cañary, which is here about five repetitions; it runs over a rocky channel, about 200 or 300 miles from Madras. The length of this island is about 4 miles, and its breadth about four and a half miles; the western side being allotted to the forts, which occupied 2000 yards, distinguished by regular outworks, magnificent palaces, and lofty moleks; for Tippoo and his father were both Mahometans, nor were they averse from the perdition of the Hindoos and Christians. The environs were decorated with noble gardens; and among other means of defence was the "bound hedge," as it was called, consisting of every thorny tree and caustic plant of the climate, planted to the breadth of from 30 to 50 feet. Covered on the north and south by the river, this fortres was defended till the peace of 1792 by a single rampart; the earl and west faces being much weaker, were strengthened by double walls and ditches, by outworks before the gates, by circular work upon the four-cant angle, and by several formidable cavaliers within and upon the southern rampart. The rampart, which is thick and strong, varies in height from 20 to 35 feet and upwards; the whole of the revetment, except the north-west bastion, is composed of granite cut in large oblong pieces, laid in cement, transversely in the walls. The ditches are cut out of the solid rock. A stone glacia extends along the north face. But the interior of the fort has few good buildings, and the town in general is mean. The old Myfor palace being in a ruined state, has been converted into a military flounder. The sultan's palace is a magnificent edifice, in the Asiatic style, but much disfigured by a high wall, and a number of unfinished buildings round it. The great mosque is covered with the finest chunam (or polished cement), and ornamented with lofty minarets. In the year 1792, lord Cornwallis laid siege to this city, and compelled Tippoo, king of Mylore, to a peace, by which he made a cession of great part of his dominions, and agreed to pay three crores and thirty lakhs of rupees towards the expenses of the war. In the year 1799, the British troops, after a short siege of a few days, took it by assault. The loss of the besiegers amounted to 32 officers, and 45 wounded, 181 Europeans rank and file killed, 622 wounded, and 22 missing; 119 natives killed, 420 wounded, and 100 missing. There were in the fort 13,739 regular infantry; and without the fort and in the intrenchments of the island 8100. The loss must have been very great, as in the assault only, 24 principal officers were killed, and seven wounded, besides Tippoo himself, who received a shot in his head. There were found in the forts 373 brass guns, 60 mortars, 11 howitzers, 466 iron guns, and 12 mortars, 444,400 round shot, 520,000 lbs. of gunpowder, and 99,000 muskets, carbines, &c. Within the fort there were 11 large powder magazines, 72 exxence magazines, 11 armories, two cannon foundries, three buildings with magazines for boring guns and muskets, four large arsenals, and 17 other flouehouses, containing accoutrements, swords, and other articles, besides many granaries abundantly floured with provisions of all kinds. Of treasure and jewels the total value was 2,553,804 florin pagodas, or 1,132,216l. sterling. The fall of this city put the whole kingdom of Mylore, with all its resources, into the power of the British government. Tippoo's sons surrendered on the fall of Seringapatam. When the strength of the fortifications of all kinds of this place, and the number of Tippoo's troops and artillery are considered, our repeated successes afford a convincing proof that no climate or fortres can overcome British courage, conduct, and perseverance. N. lat. 12° 31'.

SERINGHAM, an island of Hindoostan, in the river Cauvery, on which are two pagodas, much venerated by the Hindoos, and especially the object of devotion. In 1751 the French took possession of this pagoda, and in the following year it was taken by the English under major Lawrence; 4 miles N.E. of Tritchinopoli.

SERINHAEM,
SERINHAEM, a river of Brazil, which runs into the Atlantic, S. lat. 11° 59'.

SERINO, a town of Naples, in Principato Ultra; 19 miles S. of Florence.

SERINPALLE, a town of Africa, in the country of Cayor, on the left bank of the Senegal. N. lat. 16° 59'. W. long. 15° 5'.

SERINPETA, a town in the river Senegal, where the caños of the country are constructed.

SERIO, a river of Italy, which runs into the Adria at Ponthecce—Also, a department of Italy, composed of the Bergamasco; it contains 1057 inhabitants, who elect 15 deputies. Its capital is Bergamo.

Gen. Ch. Symagynus calyx simplex, composed of linear, nearly equal, erect leaves. Cor. compound, imbricated, uniform, composed of numerous, equal, perfect flowers; proper of one perigon, linear, truncate, five-toothed petals. Stam. Filaments five, capillary, very short; anthers cylindrical, tubular. Pest. German ovate; ille thread-shaped, the length of the flower; stigma two, reflexed. Peric. none, except the unchanging calyx. Synth. oblong, the length of the calyx. Down capillary, feathered, with ten rays hairy at the sides. Recept. chaffy, decussate, as long as the calyx.

3. S. cretifi. Cretan Seriola. Linn. Sp. Pl. 1139. ("Acheiroporus hritusus, dentis leonis folio lentere dete- rate; Vaill. Act. 745.") —Herb rough with hairs. Leaves lanceate,—Native of the island of Candia or Crete. We know not of any figure or description of this species. It reeds on the above quoted authorities.

Vol. xxIi.

Obf. Wilderow and the editor of Hortus Kewensis have not adopted this genus. They refer the several species of it to Artemisia and Stebs.

Gen. Ch. Cal. Peranthus double; outer of five, rosy, imbricated, downy leaves; inner of five, erect, acuminate, awl-shaped, smooth, fleshy leaves, which are twice so long as the outer ones, single-flowered. Cor. of one petal, funnel-shaped, shorter than the inner calyx; limb five-toothed. Stam. Filaments five, capillary; anthers cylindrical. Pest. German between the calyx and the flower; style thread-shaped; stigma rather cleft. Peric. none, except the unchanging, closed calyx. Seed solitary, oblong.

Eff. Ch. Calyx double, imbricated. Corolla of one petal, regular. Seed solitary, oblong, below the calyx.

1. S. cincceum. Heart-shaped Seriphium. Linn. Sp. Pl. 1316. (Starb. cinerea; Willd. Sp. Pl. v. 3. 2450. Tamarictus cincticusus, Cordia folio glabra; Pluk. Mant. 178. t. 297. f. 1.)—Flowers in whorled spikes, spreading.—Native of the Cape of Good Hope, as indeed are all the remaining species. They flower from July to September. Stem upright, branched. Leaves spreading, small, lanceolate, crowded, recurved, glabrous at the base, hoary. Flowers in lengthened spikes, like a fox's tail, pale red, interrupted. Scales of the calyx almost bracty.

The seed-sown of this species being feathered at the tip, induced Linn. to make it a Seriphium.

SERIPHUS, or Seriphos, in Ancient Geography, an island in the Archipelago, and one of the Cyclades, Pp
SERIPPO, a town of Hifpania, in Bética. Pliny.

SERI SOMTOU, in Geography, a district of Thibet, situated between E. long. 95° and 96°, and between N. lat. 30° and 31°.

Gen. Ch. Cal. Perianth superior, divided into five, awl-shaped, erect segments. Cor. of one petal, funnel-shaped; tube short; limb broad, reflexed, five-creft; segments trid, acute. Stam. Filaments five, very short, below the mouth of the tube; anthers oblong, incumbent. Pif. Germin inferior, roundish; style thread-shaped, the length of the corolla; stigma oblong, villous, cloven, reflexed. Peric. Berry roundifh, small, of one cell. Seeds numerous, (according to L'Heritier and Brown only two,) ovate, small.

Eff. Ch. Corolla funnel-shaped, fringed at the mouth. Segments of the limb mostly three-lobej. Berry inferior, with two seeds.

This elegant little shrub produces numerous white flowers, which have the appearance of those of Jasminne, but are without scent, as indeed is the whole plant, until it be squeezed or bruised, when it emits a highly disgusting smell. A variety with double flowers is not uncommon in the gardens about London.

SERIUM, in Ancient Geography, a town of European Sarmatia, in the vicinity of the Borythennes. Ptolemy.

SERKA, in Geography, a town of Nubia; 200 miles S. of Sennar.

SERKESI, a town of Ruffia, in the government of Kaluga; 44 miles W.S.W. of Kaluga. N. lat. 54° 16'. E. long. 34° 34'.

SERKES. See Tserkesh.

SERKIS, a town of Asiatic Turkey, in Caramania; 50 miles W. of Cogni.

SERLIO, Sébastiano, in Biography, an eminent architect, was a native of Bologna, who flourished in the early part of the sixteenth century at Venice, in the character of an architect. He afterwards travelled through Italy, and resided a considerable time at Rome, where he studied the fine arts, and made many drawings of edifices, ancient and modern, and he is said to have been the first who examined, with the eye of a man of science, the remains of ancient architecture. The knowledge which he acquired was given to the public in a complete treatise of architecture, of which he planned several books, and the first that appeared was the fourth in order, comprehending the general rules of architecture, which he printed at Venice in 1537; dedicated to Hercules II. duke of Ferrara. The other six books appeared successively at different intervals, and the different editions made of them prove their popularity. Serlio, in 1541, was invited to France by Francis I. and was by that sovereign employed in the erections at Fontainebleau, where he thenceforth resided, and where he died, at an advanced age, in 1578. Though as an author he was much attached to the principles of Vitruvius in his designs as an artist, he very much neglected them. His school of St. Roch, and palace Grimani at Venice, are built in a grand and magnificent style. Gen. Biog.

SERMAISE, in Geography, a town of France, in the department of the Marne; 19 miles S. of Meurch.ill.

SERMAISES, a town of France, in the department of the Loiret; 7 miles N. of Pithiver. u.

SERMAKI, a town of Sweden, in the province of Tavalland; 170 miles N. of Tavallhus.

SERNANICOMAGUS, in Ancient Geography, a town of Gaul, which, according to the tables of Peutinger, was situated in Aquitanica secunda. It was on the right of the Charente, at some distance N. of Iulcria, according to M. d'Anville; it is the present Cerems.

SERNMATIA, in Geography, a town of Hindooftan, in the fuboh of Agra; 25 miles N.E. of Kerowly.

SERNMATTA, an ifland in the East Indian fea, about 22 miles long, and six broad. S. lat. 8° 6' E. long. 129° 11'.

SERNESOK, an ifland near the W. coast of Greenland. N. lat. 61° 50'. W. long. 47° 43'.

SERRIA, a river which rife near Montegio, in the flate of Genoa, and after pafling by Serravalle, Tortona, &c. runs into the Tanaro.

SERRIN, a town of Italy; 2 miles N.E. of Capo d'Itria.

SERNIONE, a town and castle of Italy, in the Veron, on a neck of land running into lake Gorda, the harbour of which may be shut by means of chaus, defended by a castle. This was the native place of the poet Catullus; 16 miles W. of Verona.

SEMPIONE, in Geography, a town and castle of Italy, in the Veron, on a neck of land running into lake Gorda, the harbour of which may be shut by means of chaus, defended by a castle. This was the native place of the poet Catullus; 16 miles W. of Verona.

SERNOMINATION, Sernocinatio, in Rhetoric, denotes discourse in general, whether held by a person alone, or in company, and is the fame with what is otherwise called discollin.

SERNOMOSUS, Sernologus, an ecclesiastical book composed of sermons, or homilies of pope, and other persons of eminence and sanctity, formerly read at the feafts of the Confellers, the Purification, All Saints, and on every day from Christmas to the octave of the Epiphany. See Homil.

SERNOM, a discourse delivered in public, for the pur- pose of religious instruction and improvement: or a per- spective oration.

As to the choice of subjects for a sermon, they should be such as in the judgment of the preacher seem to be the most useful, and the best accommodated to the circumstances of his audience. The unmeaning applause which the ignorant give to what is above their capacity, common lefeé and common probity must teach every man to despife. Usefulness and true eloquence are inseparable, nor can an any man be justly deemed a good preacher, who is not an useful one. In a sermon, considered as a peculiar species of composition, the first object of attention is its unity; by which we mean, that there should be some one main point, to which the whole strain of a sermon should refer. This unity, however, does not require that there should be no separate heads or divisions in the discourse, or that one thought should again and again be presented to the hearer in different lights. Separate divi- sions or distinct heads, provided that they are numerous
SERMON.

numeros and too minute, serve to aid the composer and the
hearer of a sermon. In order to render them more
striking, and consequently more useful, the subject of them
should be precise and particular. General subjects, though
often chosen by young preachers, because they offer a more
ample supply of matter, without much labour of thought,
and a wider scope for the display of showy talents, are by no
means the most favourable for producing the high effect of
preaching. These subjects, often recurred to, admit of
little diversity and variety. The attention of the hearer is
more certainly engaged and fixed, by forming some particular
view of a great subject, some single interesting topic, and
directing to that point the whole force of argument and
elocution. Here indeed the execution is more difficult, but
the merit and the effect are higher. Moreover, the com-
poser of a sermon should never fludly to say all that can be
said upon a subject; no effect can be greater than this. On the other
hand, the preacher should select the most useful, striking, and
persuasive topics which the text suggests; and with this view
he should consider, that discourses for the pulpit are intended
for information than persuasion, and that nothing is more
opposed to persuasion than an unmeaning and tedious fulness.
Again, in studying a sermon, the preacher ought to place
himself in the situation of a serious hearer; and derive his
principal materials from those views of a subject, and those
arguments and reflections which would operate most favour-
ably and most effectually on his own mind. Above all things,
the preacher should fludly to render his instructions interesting
to the hearers. In this respect, much depends on the delivery
of a discourse, but much will also depend on the composition of
it. Correct language and elegant description are but
the secondary ingredients of preaching in an interesting
manner. The great secret lies, in bringing home all that is
said to the hearts of the hearers, so that every man may be
led to think that the preacher is addressing him in particular.
It is hardly necessary to subjoin a caution here, that perno-
ality should be avoided. For the attainment of the end now
flated, the preacher should avoid all intricate reasonings,
and expressing himself in general speculative propositions, or
laying down practical truths in an abstract metaphysical
manner. As much as possible, the discourse ought to be
carried on in the strain of direct address to the audience;
in the strain of one writing an essay, but of one speaking
to a multitude, and fludying to mix what is called applica-
tion, or what has an immediate reference to practice, with
the doctrinal and discursive parts of the subject. In this con-
nection we may add, that the preacher should adapt his discourses,
with a view of making them interesting, to the different ages, characters, and conditions of
men, and that he should avail himself of any personal or do-

castic occurrence, for imparting either instruction or con-

Some of the most impressive discourses are those that
delineate and exhibit examples founded on historical
facts, and drawn from real life. Many of these may be
found in scripture, which, when they are well chosen, command a
high degree of attention. Bishop Butler's sermon on the
"character of Balaam," affords a specimen of this kind of
preaching. It is of importance to observe, farther, that the
preacher should be cautious not to take his model from
particular fashions that chance to have the vogue. It is the
universal tale of mankind, which is subject to no changing
trends, that alone is entitled to please any authority; and
this will never give its function to any strain of preaching
that is not founded in human nature, connected with use-
ful facts, adapted to the proper idea of a sermon, as a fervent
persuasive oration, delivered to a multitude, in order to make
them better men. Let the preacher form himself upon this

As to the style of sermon, it should be clear, plain, very
peremptory. Pleasure and all things beside, and of course all
external, trivial, or high-sounding words should be avoided; and especially that which is too
metaphorical, or merely philosophical. Dryness of expres-
ding indifferent, but that clearness of expression, adapted
with simplicity, and that weighty and persuasive
which is imparted by the orator, is that which a preacher
ought to attempt to feel, and not merely to affect, and published by the praise and
importance of the pulpit. He need not only employ
metaphors and comparisons, but, on proper occasions, may
poetize the faith of the faithful, may personify moral
things, break out into bold exhortations, and, in general,
command the most passionate figures of speech.

The language of scripture, properly employed, is a great
ornament to sermons; and it may be employed either in the
way of quotation or allusion. But the allusions which the
preacher uses should be natural and easy, and if they be forced, they approach to the nature of 
itra
ds. In a sermon, no points or conceits should appear, no affected
figures and quatrains of expression, which do not spring from the
dignity of the pulpit. It is a strong expulsive style, rather
than a sparkling one, that ought to be studied. Epithets
have often great beauty and force, but it is a great error to
imagine, that we render style flowing and expressive, by
a constancy and multiplied use of epithets.

As to the question, whether it be most proper to write
sermons fully, and commit them accurately to memory, or to
study only the matter and thoughts, and trust the ex-
pression, in part at least, to the delivery, Dr. Blair is of
opinion that no universal rule can be given. Preachers must
adopt either of these methods, according to their different
genus, and we may add according to the situation where they are
settled, and the rank or character of the audience which they
address. It is proper, however, to begin, at least, the practice
of preaching, with writing accurately as possible. He thinks
it also proper to continue, as long as the habits of industry
last, in the practice both of writing and committing to
memory. The practice of preaching is, as our author
says, one of the greatest obstacles to the eloquence of the
orator in Great Britain, where alone this practice prevails.
No discourse which is designed to be persuasive can have
the same force when read as when spoken. We are of opinion,
however, that sermons from memory have little advantage,
in point of effect, above those that are read. An
extemporaneous sermon has this advantage in an eminent degree; but
few excel, and many discourses of this kind are such as
would disgust a judicious, though candid, hearer.

The French and English writers of sermons proceed upon
very different ideas of the eloquence of the pulpit. A
French sermon is, for the most part, a warm animated ex-
oration; an English one, a piece of cool instructive
reasoning. The French preachers address themselves chiefly to
the imagination and the passions: the English, almost solely
to the understanding. The union of these two kinds of
composition, of the French ornamental and warmth with the
English accuracy and reasoning, would form, in Dr. Blair's judgment, the model of a perfect
sermon. The censure which, in fact, the French critics pass on the English preachers is, that they are philosophers and logicians, but not orators. Among the French
Protestant divines, Saurin is the most distinguished; and the late Mr. Robinson of Cambridge
has done a public service by translating many of his discourses into the English language.

pp 2

Saurin
SER

Saunin is copious, eloquent, and devout, though, in his manner, too effecituous. Among the Roman Catholics, the two most eminent are Bourdolus and Maffillon. The French critics differ in their opinion to which of these preachers the preference is due. To Bourdolus they attribute more fidelity and close reasoning: to Maffillon, a more pleasing and engaging manner. The former is a great reasoner, and inculcates his doctrines with much zeal, piety, andearnestnes; but his style is verbose, and abounding with quotations from the fathers, and he wants imagination. Maffillon has more grace, more sentiment, and, as Dr. Blair thinks, may have more genius. He discovers much knowledge, both of the world and of the human heart; he is pathetic and perspicius, and is perhaps the most eloquent writer of sermons which modern times have produced. During the period that preceded the restoration of Charles II., the sermons of the English divines abounded with scholastic catusitical theology, but in their application they adopted more pathetic address to the conceptions of the hearers. Upon the restoration, preaching assumed a more correct and polished form. What ever was earnest and passionate, either in the composition or delivery of sermons, was reckoned enthusiastic and fanatical; and hence that argumentative manner, bordering on the dry and unperspicuous, which is too generally the character of English sermons. Dr. Clark, who excels in a variety of respects, may be esteemed an elegant and instructive composer of sermons, but he is deficient in the power of interesting and feizing the heart. Tillotson’s manner is more free and warm, and he approaches nearer than most of the English divines to the character of popular speaking; and he, even now, one of the best models for preaching. Dr. Barrow is admirable for the prodigious fecundity of his invention, and the concurrence, strength, and force of his conceptions; but less happy in execution, or composition. Atterbury deserves to be particularly mentioned as a model of correct and beautiful style, besides having the merit of a warmer and more eloquent strain of writing in some of his sermons, than is commonly met with. If Buller had given us more sermons in the strain of those upon self-deceit and the character of Balasam, in the room of abstrac philosophical essays, he might have been distinguished for that species of critical sermons above recommended.

The parts of a sermon, discourse, or regular formed oration, are the following fix; viz.: the exordium or introduction, the state and division of the subject, narration, and explication, reasoning, or arguments, the pathetic part, and the conclusion. (See each under its proper head.) The introduction of an English sermon is too often stiff and formal, whereas those of the French preachers are very splendid and lively. Common-place topics should be avoided; variety should be studied; and in some cases the discourse may commence without an introduction. Explanatory introductions from the context are not uncommon, they are appropriate and instructive; but they should not be too long. An historical introduction has, generally, a happy effect in cauing attention. To the proposition or enunciation of the subject generally succeeds the division; but it has been questioned, whether this method of laying down heads, as it is called, be the best method of preaching. Archbishop Cambray declares strongly against it; alleging, that it is a modern invention, that it was never practised by the fathers of the church, and that it took its rise from the schoolmen. But we are of opinion, with Dr. Blair, that it serves useful purposes, and ought not to be laid aside. (See the preceding part of this article.) But in any discourse or sermon, there are certain rules which should be observed, e.g. the several parts into which the subject is divided should be really distinct from one another: the order of nature should be followed, beginning with the simplest points, or those that are most eagerly apprehended and needful to be first diffus’d, and then proceeding to those which are built upon the former, and which suppose them to be known:—the several members of a division ought to exhaust the subject:—the terms in which the partitions are expressed should be as concise as possible:—and the number of heads should not be needfully multiplied. Another part of a discourse or sermon is narration. This part must be concise, clear, and distinct, and in a style correct and elegant, rather than highly adorned. The argumentative part is succeeded by the pathetic, in which, if any where, eloquence reigns, and exerts its power. (See Pathetic.) In sermons, inferences from what has been said make a common conclusion. With regard to these care should be taken, not only that they rise naturally, but that they should so much agree with the strain of sentiment throughout the discourse, as not to break the unity of the sermon. The precille time of concluding a discourse is an object of importance. It should be so adjutted that our discourse is brought to a point; neither ending abruptly and unexpectedly; nor disappointing the expectation of the hearers, when they look for the close; and continuing to hover round and round the conclusion, till they become heartily tired of us. We should endeavour to go off with a good grace; not to end with a languishing and drawing sentence; but to rise with dignity and spirit, that we may leave the minds of the hearers warm; and dismfs them with a favourable impression of the subject, and of the speaker. Blair’s Lectures, vol. ii. See Elocution of the Pulpit, and Preaching. SERMON, Funeral. See Funeral. SERMONES, the title which Horace gives his Satires. See SATIRE.

Critics are divided about the reason of the name; the opinion of father Bofti seems belted ground. A mere obscurance of feet and measure, such as we find in Terence, Plautus, and in Horace’s Satires, he thinks is not sufficient to constitute verse, to determine the work to be poetical, or to distinguish it from profe; unless it have some farther air, or character of poetry; somewhat of the fable or the sublime. Hence he judges it is, that Horace calls his Satires profi, or sermons: his Odes have quite another air, and are therefore called poems, carmina. SERMONETTA, in Geography, a town of Italy, in the Campania, situated on a mountain difficult of access. Some say that it occupies the feite of the ancient Sura; but others say that it occupies the spot on which Sulmo flood; 13 miles S. of Veletri. SERMONIUM, in Old Records, a kind of interlude or historical play, which the inferior orders of clergy, afflicted by boys, &c. used at times to act in the body of the church, suitable to the solemnity of some festal or high precession day.

This is supposed to have been the origin of the modern drama. SERMONTON, in Botany, a species of the lactor-wort in the Linnean syllym, and, according to others, of the fefeli, or wild spigiel, which grows wild in some of the southern parts of Europe, is raiied with us in gardens, and flowers in June.

The seeds of this plant are the part directed for use in our pharmacopoeias, and the roots appear to be useful aromatics, though not regarded in practice; of an agreeable smell, and a warm glowing sweetish taste; the roots have the greatest warmth and pungency; the seeds the greatest sweetness, and the molt pleafant flavour. A spiritual extract
trait of the seeds is a very elegant aromatic sweet. Lewis 53.
See 

SERMUR, in Gravina, a town of France, in the department of the Cevennes; 6 miles S.W. of Auzances.

SERNA, L., a town of Spain, in the province of Leon; 54 miles N. of Palencia.

SERNADELLE, a town of Portugal, in the province of Beira; 10 miles S.E. of Lamego.

SERNETTY, a town of Burgos; 31 miles E.S.E. of Coimbra.

SERNINICUM, in Ancient Geography, a town of Italy, on the route from Milan to Colombe, in passing through Piacenza, according to the Itinerary of Antoninus, where it was marked by the Achadum Certa, and Piacenum Certa.

SERNON, in Geography, a town of France, in the department of the Var; 7 miles N.W. of Grasse.

SERSANT, a town of Switzerland, in the canton of Glarins, near a river of the same name; 3 miles S. of Glarins. The river runs into the Svandach at this place.

SEROGLAZOWSKAIA, a fortress of Russia, in the government of Coacac, on the Volga; 24 miles N.W. of Astrachan.

SEROLZECK, a town of the duchy of Warsaw, at the union of the rivers Nabwe and Bug; 20 miles N. of Warsaw.

SEON, a town of Spain, in the province of Graeneda; 7 miles W. of Puebres.

SERONIUM, in Ancient Geography, the quantity of two hundred weight; of watered, it is from three to four hundred; of Calillic top, from two hundred and a half to three hundred and three quarters.

SEONGE, in Geography, a town of Hindostan, in the Malwa country, celebrated for its manufacture of printed cottons and chintzes; 13 miles N.E. of Ougrin. N. lat. 24° 50′; E. long. 78° 40′.

SEOROS, a town of Hindostan, in Dowlatabad; 24 miles S.S.W. of Amednagar.

SEROS, Los, a town of the island of Cuba; 38 miles N. of Trinidad.

SEROSITY, the watery part of the blood, or serum.

See Blood.

SEROTA, in Ancient Geography, a town of Pannonia, between Lentuli and Marconnae.

SEROUZE, in Geography, a town of Aesian Turkei, in the province of Diarbeik; 80 miles S.W. of Diarbeik.

SEROWRA, a town of Hindostan, in Oude; 4 miles N. of Lucknow.

SERPA, a town on the E. coast of the island of Corfu; 8 miles N. of Corfu.—Allo, a town of Portugal, in Atenjo, containing two churches, and about 4,000 inhabitants; 12 miles S.W. of Moura.

SERPA, in Ancient Geography, a town of Hispania, in Bertica, on the left of the river Ana, and nearly E. of Pax-Julia.

SERPEGER, in the Manager, was used to denote the riding a horse in the serpentine way, or in a trench with waved turnings like the pottle of a serpent's body; but is now become obsolete.

SERPENTARA, in Geography, a small island near the E. coast of Sardinia. N. lat. 35° 18′ E. long. 10° 21′.

SERPENTARIA, in Botany, a name applied by the older botanists and medical writers, to various plants, either on account of the serpent-like form of their roots, as in Polygonum Bifera, their spotted stems, as in Arum Dracunculus, or some other fanciful resemblance. The name has likewise been given to plants supposed to cure the bites of serpents, as Arum Serpentaria or Varia Serpentaria.

For a treatment of certain species of Plants, no seeds have been discovered of Serpentaria.

SERPENTARIA, in Botany, a name applied to the eastern half of Cape, called also Ophiocodon, and lately Alcyonaria.

The slugs in the constellation Serpentarii, in Poeten's catalogue, are 29; in Tycho's, 15; in Hevelius's, 43, in the Britannica catalogue, they are 74. See Conservation.

SERPENTES, Serpents, in Zoology, the last order in the Linnæan class Amphibia, which are thus generally characterized: they are toothless; their eyes are covered in a chain; the penultimate is double, and very small.

These animals are sufficiently distinguished from reptiles by their total want of feet, moving by the aid of their tails, and their general powers of contortion. The distinction of species in this numerous tribe is, according to Dr. Shaw, frequently very difficult. It was thought that an invariable criterion might be found in the number of plates on the abdomen, and beneath the tail; but, accordingly, attempted, in the Systema Naturae, to discriminate the species by this mark alone. This is now found to be, by much, too uncertain and variable for a specific test. The colour is indeed frequently variable, but the patters, or general distribution of markings in each species, appears to be more constant; the relative size of the head, the length of the body and tail, the size, smoothness, or roughness of the scales, as well as their shape in different parts of the animal, often afford tolerably certain specific marks.

The distinction of serpents into poisons and innocuous, can only be known by an accurate examination of their teeth; the fangs, or poison-teeth, being always of a tubular structure, and calculated for the conveyance or injection of the poisonous fluid from a peculiar reservoir, communicating with the fang on each side of the head: the fangs are always situated in the anterior and exterior part of the upper jaw, and are generally, but not always, of much larger size than the other teeth; they are also frequently accompanied by some smaller or subsidiary fangs, apparently divided to supply the principal ones, when lost either by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw, as to elevate or depress them at the pleasure of the animal. In a quiescent state, they are recumbent, with their points directed onwards or backwards; but when the animal is inclined to use them as weapons of offence, their position is altered by the peculiar mechanism of the above-mentioned bone, in which they are rooted, and they become almost perpendicular.

A general rule for the determination of the existence or non-existence of these organs, in any species of serpent, was proposed by Dr. Gray, in the Transactions of the Royal Society for the year 1788. According to this author, the fangs may be distinguished with great ease by the following simple method. When it is discovered that there is something like teeth in the anterior and exterior part of the upper jaw, which situation he considers as the only one in which venomous fangs are ever found, let a pin, or other hard body, be drawn from that part of the jaw to the angle of the mouth. If no more teeth be felt in that line, it may be fairly concluded that those first discovered are fangs, and that the tooth consequently is venomous; if, on the contrary, the teeth first discovered be observed not to stand alone, but to be only part of a complete row, it may as certainly be concluded that the serpent is not venomous. This rule, however, like most other general rules, may have its exceptions; and perhaps the most legitimate test of real
fangs in a serpents is their tubular structure, which may always be readily detected by the assistance of a proper magnifier. It is to be observed, that all serpents, whether poisonous or not, have, besides the teeth, whether fangs or simple teeth, in the sides of the upper jaw, two additional or interior rows, which are generally much smaller than the rest, and frequently scarcely visible. The general rule, therefore, is, that all venomous serpents have only two rows of true or proper teeth in the upper jaw, and that all others have four.

A head entirely covered with small scales is, in some degree, a character, but by no means an universal one, of poisonous serpents; as are also carinated scales on the head and body, or, such as are furnished with a prominent middle line. All serpents call their skins at certain periods: in the temperate regions, annually; in the warmer climates, perhaps more frequently. The serpents of the temperate and cold climate also conceal themselves, during winter, in cavities beneath the surface of the ground, or in some other convenient places of retreat, and pass the winter in a flate more or less approaching, in the different species, to complete torpidity. Some serpents are vipers, as the rattle-serpents, the vipers, and many other of the poisonous kind; while the common snake, and probably the greater part of the innoxious serpents, are oviparous, depofiting, as we have already observed, their eggs, in a kind of cavity or shell, in any warm and close situation, where they are afterwards hatched.

The broad divided laminae, or scaly plates, on the bellies of serpents, are termed scuta; and the smaller or divided plates, beneath the tail, are called subcaudal scales; and from these different kinds of laminae, the Linncean genera of serpents are chiefly instituted. In the edition of the Sytema Naturae by Gmelin, seven genera are enumerated and described, vis:

Acrochordus, Cecilia,
Amphisbaena, Coluber,
Anguis, Crotalus.
Boa.

Having, in our alphabetical arrangement, omitted a description of some of the above genera, and referred to the species of others which have not yet been given, we shall take the opportunity which the order itself gives us, of making up for the defects that have escaped our notice, beginning with

Acrochordus, of which the generic character is, that it has tubercles covering the whole body. Gmelin gives but a single species, vis. the javanicus; but Dr. Shaw has described three

Species.

Javanicus; or Warted Snake. Brown, beneath paler; the sides obscurely variegated with whitish.

This, as its specific name denotes, inhabits Java, chiefly among the pepper plantations; it grows sometimes to the length of seven or eight feet. The warts or prominences appear, by a magnifying glass, to be cowse carinate scales, and the smaller ones are furnished with two smaller prominences, one on each side the larger. The head is somewhat flattened, hardly wider than the neck; the body is gradually thicker toward the middle, and suddenly contracting near the tail, which is short and slightly acuminate.

This remarkable snake, which gave rise to the intitution of the genus, was first described by Mr. Hornsted, in the Swedish Transactions for the year 1787. It was found in a large pepper-ground near Sangafan, in the year 1784, and measured eight feet in length. Its neck was six inches thick, that of the largest part of the body ten inches, and that of the tail an inch and a half; the colour of the upper part of the animal was blackish, and of the under part whitish; the sides are marked with dusky spots; the head is truncated, depressed, and scaly; the jaws equal, the superior being emarginated beneath, the inferior curved; the eyes lateral, on the fore part of the head, the irides livid; the nostrils circular, small, approximated, and situated above the tip of the front; the body was entirely covered, as well as the tail, with rough tri-carinated warts; the vent is small, the body very suddenly tapering towards the tail. This animal was secured by a Chinefe, by means of a split bamboo passed over its neck, and thus carried to Batavia, where, on being skinned and opened, exclusive of a quantity of undigested fruit, were found completely formed five young, measuring nine inches each; the fhef of the animal was eaten by the Chinefe, who affirmed that it was excellent food, and the skin being preferred in spirits, was brought over to Europe by Mr. Hornsted, and deposited in the museum of the king of Sweden.

Dubius, or Brown Acrochordus, has a carinated abdomen, and its sides are spotted with black. In its general appearance and proportion, this very nearly resembles the javanicus just described; but the head of the dubius is covered with very minute rough or warted scales, differing in size alone from those on other parts of the animal. It is not more than about three feet in length; its colour is of an obscure brown, with some ill-defined clouds and patches of a darker colour, difperfed along the sides and abdomen. The specimen from which this description is taken, is in the British Museum; but its native place is not ascertained.

Fasciatus, or Fuliginous Acrochordus, called also the Hydrus granulatus, has a carinated abdomen, with whitish lateral bands. This is so much allied to the dubius, that it may be doubted whether it really differs in any other respect than age, age, and in the cast of colours, measuring about eighteen inches in length, and being of a dusky brown colour, with several paler fatches, which take their rise from the abdomen, and ascend on the sides; the abdomen is carinated as in the former. "This," says Dr. Shaw, "is certainly the Hydrus granulatus of Mr. Schneider, who, in his work on the Amphibia, describes it as a water-snake, though, seemingly, without any other foundation than its having a carinated abdomen; its other characters by no means agreeing with those of the genuine Hydry." Its native place is not known. A specimen is preferred in the British Museum.

Anguis, or Snake. This genus of serpents was noticed in its place, and the names of the species enumerated, with the intention of describing each species in the alphabetical order; after this time the plan of the work was somewhat altered, and the species will now be given with their appropriate description. The generic character is, scales on the belly and scales under the tail.

Species.

Striatus. The scales of the belly are 179 in number; those of the tail seven; the body is surmounted with transverse lines.

Melapogis. The scales on the belly of this are 165; those of the tail 32. It inhabits South America and some parts of India. It resembles the Lacerta ibipes (see Lizard); it is glaucous, with numerous longitudinal rows of black dots. There are two varieties, one dotted with brown, and one characterized by its long tail.

Colubrinus. Scales of the belly 180; of the tail 18. It inhabits Egypt; is varied with brown and pale ochre.

Miliaris. Scales of the belly 170; of the tail 52.

Found
SERPENTES.

Found near the Cape in Nov : it is 14 inches long, and about 2 1/2 inches in width; black, with numerous pale scales on the back, and dark ones on the sides; the head is green, sprinkled with black; the tail is 2 inches long, much thinner than the body, cylindrical, obtuse, variegated with brown, and covered in front with large scales, as in all other venemous serpents; the eyes are very small, the tail very thin, and the whole animal, and the young serpent, very small and slender, like other serpents. It lives in the interior of the country at different periods, and the young are commonly in deeper shade than the parents; it is, generally speaking, a timid animal rather than a very active one, and will stretch its body as far as it can, and the young are very likely to be seen as they are full of worms, but, on the contrary, aconsiderable degree of serenity, and is easily caught on the leaf, in order to cover itself from the sun, by stretching its body, and then emerging from its concealment on the approach of winter, and lying in a state of torpidity, and again emerging from their concealment on the approach of spring, when they call their skin and recover their former liveliness. It has been observed by some naturalists, that if the individuals of this species, and of some others likewise, be stuck with any degree of violence, the body will stretch abruptly on the spring part, and can frequently at different parts; the fles is remarkably strong and the animal, when handled or irritated, has a mode of inflating itself by stretching to its utmost length, in which state, if any part of the skin be injured, the separation soon takes place in consequence of this rigidity. The fragments will live a long time after their separation.

Venteral. Abdominal scales 127: subcaudal 22. This is an inhabitant of South Carolina. The body is of an ash-green, iridescent; lateral band black; belly short, and appearing as if appended by a hollow fixture; the tail is verticillate, three times as long as the body. A small blow will cause the animal to break into several pieces, the muscles being articulated quite through the vertebrae.

Platery. Tail compressed, obtuse. It is a native of the shores of Pine island, in the Pacific ocean. The body is a foot and a half long; above it is black, and beneath it is white; the scales are minute, sub-iridescent, not imbricate; head oblong; it is toothless, smooth; the back is subcarinate; the tail is variegated with black and white.

Lineatus. Blackish, but on the upper part it is white: a curved line runs down the whole body.

Cicluus. Greenish-brown; the plate of the front is larger and heart-shaped. It is found in some parts of Germany.

Annelatus. White, with straight brown bands meeting beneath, tail tapering, beneath with a double row of imbricate scales.

Cuculites. This is a very slender species; waved with white and black bands; plates of the head broad; tail sharpish. It is found at Surinam. The belly and tail beneath with transverse broad scales, like the boa. Cinelith thinks it does not belong to this species.

Corallinus. This is named by Shaw the pale-red flow-sworm, with blood-red variegations, and by Sclat called the red Brazilian serpent, so named probably from its colour, it being red with paler bands; the scales are tipped with black. This is a very elegant species; it is about a foot and a half long, the thickness of it is very considerable; the ground-colour is of a pale red, with very broad, alternating lines, and variegations of a deep coral red; the scales are moderately large, and of a rounded form, and the head and tail are remarkably obtuse. This highly beautiful animal is a native of the warmer parts of South America, where it is said to be found in woods, and to derive its colour from the

larger
larger insects, as escolopendras, &c.; in colour it sometimes varies, a mixture of black in different proportions being blended with the red on the sides, and the bands are also more numerous in some specimens than in others.

Atek. This, as its name denotes, is black with white bands; scales tinct with black. This is nearly allied in general appearance to the corallinus, but differing in colour; being white with black bands; the abdominal scales are dilated according to Seba’s figure, on the authority of which, a beautiful engraving of it is given by Shaw. It is a native of South America.

Rufus. Tawny, with transverse but interrupted white lines; beneath it is variegated. This is found at Surinam.

Hepaticus. Line on the top of the back, and a waved line on each side, of liver-colour, the spaces between paler, with roundish whitish spots. It inhabits Surinam.

Testellatus. This species is of a fawnish colour, with numerous bands, and three stripes: the head is white, and spotted with brown. It inhabits Paraguay.

Albus. The individuals of this species are entirely white; tapering towards each end.

Boa, another genus of the serpent race, has been generally described in the alphabetical arrangement, with references to the species, which having been neglected in their places, must be noticed now. (See Boa.) The genus, according to Gmelin, includes ten species, but Shaw mentions others; we shall first mention those given by Gmelin.

Species.

Contortrix; Hog-nosed Boa. The plates of the belly are 150 in number, and those on the tail 40. It inhabits Carolina; it is broad, and its back is convex; it is cincereous, with lateral round spots; it has a poisonous bag, but no fangs; the tail is about half the length of the body.

Canina. This species has 203 plates on the belly, and 77 on the tail. It inhabits America. By Shaw it is named the Green Boa, with transverse, undulated, white doral bands. It is a highly beautiful snake, measuring, when full-grown, about four feet in length, and of a proportionable thickness; the head is large, and shaped like that of a dog; the colour of the whole animal on the upper parts is a most beautiful Saxon green, with several short, undulating, transverse white bars down the back, the edges of which are of a deeper or stronger green than the ground-colour of the body; the under or abdominal part is white. There is a specimen of this species in the British Museum.

A variety of this species is described by Seba; the ground-colour is of a bright orange, the doral bands are of a pale yellow, edged with red, and the abdomen is of a pale yellow. It is a native of the East Indies, differing merely in colour from the former.

Hipsale. The plates on the belly are 179; those on the tail 120. It is found at Siam, and is of a yellowish colour, with white ocular spots on the back.

Constrictor. This, by some naturalists, is denominated the yellowish-grey boa, with a large chesnut-coloured chain-like pattern down the back, and subtrigonal spots on the sides. Dr. Shaw gives the generic character thus: leuta, or undivided plates, both on the abdomen and beneath the tail. But by Gmelin it is characterized simply by the 240 plates on the belly, and 60 on the tail.

Of all the boas, the most conspicuous is the B. constrictor, which is at once pre-eminent, from superiority of size, and beauty of colours; in this respect it appears to be subject to considerable variation from age, sex, and climate, but may be distinguished in every flake from the rest of its tribe by the peculiar pattern or disposition of its variegations. The ground-colour of the whole animal in the younger specimens is a yellowish-grey, and sometimes even a bright yellow; on which is diffused along the whole length of the back, a series of large, chain-like, reddish-brown, and sometimes perfectly red variegations, leaving large, open, oval spaces of the ground-colour, at regular intervals; the largest or principal marks composing the chain-like pattern above-mentioned are of a squaflriform, accompanied on their exterior sides by large triangular spots, with points directed downwards; between these larger marks are diffused many smaller ones of uncertain forms, and more or less numerous in different parts; the ground-colour itself is also scattered over by a great many small speckles of the same colour with the variegations; the exterior edges of all the larger spots and markings are commonly blackish, or of a much deeper cast than the middle part, and the ground-colour immediately accompanying the outward edges of the spots is, on the contrary, lighter than on other parts, or even whitish, thus constituting a general refinement of pattern, of which nothing but an actual view of a highly-coloured specimen of the animal itself can convey a complete idea.

In the larger specimens, the yellow tinge is often lost in an uniform grey cast, and the red tinge of the variegations sinks into a deep chesnut; and in some the general regularity of the pattern before described is disturbed by a kind of confluent appearance: the head is always marked above by a large longitudinal dark band, and by a narrower lateral band passing across the eye towards the neck.

The boa constrictor is a native of Africa, India, the larger Indian islands, and South America, where it chiefly reposes in the most retired situations in woody and marshy regions.

It was, in all probability, an enormous specimen of this very serpent that once diffused fear among the most valiant of mankind, and threw a whole Roman army into dismay. Histories relate this surprising event in terms of considerable luxuriance. Valerius Maximus mentions it from Livy, in one of the lost books of whole history. It was related more at length, and the learned Fenienhemus, in his Supplementa Liviana, has attempted a more ample and circumstantial narrative of the same event, of which the following is a quotation:

“In the mean time Regulus, where every victorious, led his army into a region watered by the river Bagrades, near which an unexpected misfortune awaited them, and at once affected the Roman camp with considerable loss, and with apprehensions still more terrible; for a serpent of prodigious size attacked the soldiers who were sent for water, and while they were overwhelmed with terror, and unequal to the conflict, engulphed several of them in its enormous mouth, and killed others by writhing round them with its fangs, and bruising them with the strokes of its tail; and some were even destroyed by the pellential effusion proceeding from its breath: it caused so much trouble to Regulus, that he found it necessary to contest the possession of the river with it, by employing the whole force of his army; during which a considerable number of soldiers were lost, while the serpent could neither be vanquished nor wounded; the strong arm of its fangs easily repelling the force of all the weapons that were directed against it; upon which recounture was had to battering engines, with which the animal was attacked in the manner of a fortified tower, and was thus at length overpowered. Several discharges were made against it without success, till its back being broken by an immense flone, the formidable monster began to lose its powers, and was yet with difficulty destroyed; after having diffused such a horror
SERPENTES.

hercules among the army, that they confessed they would rather attack Carthage itself than such another monster: nor could the camp continue long in the same situation, but was obliged to fly: the water and the whole adjacent region being tainted with the pestilential effluvia. A sort of invertebrate is humiliating to human pride! Here at last was an instance of a whole Roman army, under the command of Regulus, and universally victory as both by sea and land, opposed by a high lake, which confounded it when living, and even when dead obliged it to depart. The proconculum therefore, thought it a diminution to his dignity to spew the fumes of such an enemy to Rome, and to conceal at once the terrors of his victory and his terror, by this public memorial: for he caused the skin of the snake to be taken off and sent to the city; which is said to have measured 120 feet; it was fulfilled in a temple, and remained till the time of the Numantian war.

Certhini, the Rufescens Boa, with large dusky dorsal rings, and blackish kidney-shaped lateral spots with white centres; it has 265 plates on the belly, and 57 on the tail. It inhabits Surinam; it is greenish, with white ocellate spots; the irides are grey.

Ophiophagus, or Brown Boa, has on its belly 281 plates, on the tail 84; the body is brown, and in appearance it resembles the B. constrictor.

Enhydris; or Water Boa. This species is variegated with different shades of grey; the teeth in the lower jaw are longer than usual in this genus; the number of abdominal scales is 270, and of those on the tail 105. It is very like the hortulana, hereafter to be described.

Murnia; Grey Boa. This species has 254 plates on the belly, and about 65 on the tail. It inhabits America. It is glaucous, with round black spots.

Sevatale; Spotted Boa. Cinereous, with large orbicular black dorsal spots, and annulated lateral ones, with white centres; it has 250 plates on the belly, and 70 on the tail.

This is scarcely inferior in size to the B. constrictor, and is of similar manners, destroying, like that animal, goats, sheep, deer, &c.; it is generally of a grey or glaucous colour, marked with large orbicular black spots on the back, and with smaller ones of a similar form, but with centres; on the sides; while on the abdomen are scattered several oblong spots, and marks intermixed with smaller specks and variegations. It is a native of several parts of South America, and like other large snakes is occasionally eaten by the Indians.

Hortulana; Garden Boa. This is of a yellowish-grey, with brown variegations, those on the head resembling lace; the body sub-comprielled, and the sides marked by wedge-shaped spots; it has 290 plates of the belly, of the tail 128.

This very elegant serpent, which is of a moderate size, measuring only a few feet in length, and being of a slender form, has obtained its specific name from the singular variegations on the head, which represent the form of a parterre in an old-fashioned garden; the variegations on the body are, like those on the head, of a blackish-brown, on a pale ferruginous or yellowish ground; they are disposed into large circular, and sometimes angular patches on the sides, the centres of some being open, and of others marked by an oblong spot; besides these there are others intermixed of smaller size and of different forms; the abdomen is commonly yellowish, with dusky specks and patches; the ground-colour of the whole snake is sometimes of a pale violet, and the variegations of a dark purplish-brown; but in all its varieties this species may be easily distinguished by the rich, rounded appearance of the pattern, and some particular mark in the spot on the head; the body is also banded, with the neck more regular in proportion than in most of the other boa, the body evenly scaled, and the tail slender. It is a native of both America.

Such are the larger boas given by Gmelin, the following are alluded to, described by Dr. Shaw in his General Zoology.

Regia; Royal Boa. With a broad-edged neck, and body variegated either with brown and grey, or grey and black. This species is described by Seba, as, in its general shape, not at all to resemble the ophisaurus. It varies very much with respect to colour, the ground-work being white, but the variegations sometimes dusky or chestnut, and in several of an elegant variegated, accompanied by a tinge of blood. The head on the lighter parts of the pattern: the top of the head is filled by a large patch, from which run two large parallel stripes to a considerable distance on each side of the neck, leaving a wider stripe of the ground-colour along the upper part, and which afterwards ceasing, forms a part of the general variegation, which consists of a large chain-like dorsal band running down on each side, at moderately distant intervals, into oblong protuberances, some of which are bordered by the white ground-colour, the intervening lateral spaces being much lighter, and each is marked by a dusky patch on the upper part; the under parts of the body and tail are white, the head is covered in front with large scales, the tail is extremely short, and tapers rather suddenly.

Phrygia; Embroidered Boa. White, with a greyish call on the back; the body is most elegantly marked with black lace-like variegations. This is unquestionably one of the most elegant species of the whole serpent tribe; its variegations are so conducted, as to bear a striking resemblance to an embroidery in needlework. It is a native of the East Indies, where divine worship is paid to it.

Fasciata; Fasculated Boa. With subtriangular body annulated with blue; is a native of India, and most generally found in the country of Bengal. It is of a yellow colour, marked with numerous dusky-blue transverse bands, continued at equal distances throughout the whole length of the animal, each band completely covering the body; the body is of a trisonal form, the sides swelling very considerably; along the ridge of the back runs a continued series of hexagonal scales. This snake is among the number of poisonous species, and its bite is considered by the Indians as fatal. A specimen was brought to Dr. Raffles in the month of November 1788, in an apparently very weak and languid state. Being kept at liberty, it shewed no disposition to bite; it suffered a chicken to get on its back, without noticing it; but the thigh of the bird being put within its jaws, it shewed immediate symptoms of having been poisoned, and it expired in the course of half an hour. This was the only experiment which was made, the snake dying the next day; but from the languid state in which it appeared, and the effect of its bite on the chicken, it may be concluded that, when in full vigour, it must be an animal of a highly dangerous nature.

Viperina; Viperae Boa. Grey, with a black, undulating, dorsal band, edged with white; and the sides spotted with black. It is about a foot and a half in length, and of a moderately brown colour. It is said to produce by its bite a flow of walking of the fingers and toes, similar to what happens in some leprous cases. A living specimen, however, was obtained in 1778, and though in good health, yet its bite was not followed by any deleterious effects.

Lineata; Lineated Boa, called also Grédi Paragooedoo, 13 q

Vol. XXXII.
is of a slender form, with the general appearance of a coluber rather than a boa. It is of an extremely dark blue color, so as to appear almost black in certain lights, and is marked throughout the whole length of the upper part by several transverse curved and dotted white lines at unequal distances, and varying in number in different individuals, from about 40 to 50: they are so disposed as to almost represent so many large spotted circles. Dr. Shaw has given an account of some experiments on this animal, to whose work we refer our readers. See General Zoology, vol. iii. part ii.

Horatta. This is of a dark brown, with a waving yellow band on each side, and a row of dorsal spots. This is one of the smaller species, measuring only about fifteen inches in length. The fangs, or poisoning organs of this snake, shew that it is noxious, but in what degree has never been ascertained; it is, however, said to be one of the most fatal.

Palpebrosa. Whitish, obscurely faciated with grey; with prominent eyelids; this has 112 abdominal scuta, and 51 on the tail.

Annulata. Subferruginous, with black, orbicular, dorsal spots included in rings; reniform, ocellated, lateral spots, and abdomen undulated with dusky variegations. This is about two feet long, and in its general appearance it is allied to the B. hortularia and endriss. It is a native of South America.

Serpents, in Afromony, a constellation in the northern hemisphere, called more particularly Serpens Ophiuchi. The stars in the constellation Serpens, in Ptolemy's catalogue, are 18; in Tycho's, 13; in Hevelius's, 22; and in the Britannic catalogue, 64. See Constellation.

Serpent Cucumber, in Botany. See Trichosanthes.

Serpens Hypnoticus, See Hypnoticus.

Serpens Marinus, See Sea Snake.

Serpens Rubescens, the red serpent-jelly, in Ichthyology, the name of a fish, properly of the tetra kind. It resembles the common snake in figure, and is of a fine strong red in colour, and marked with oblique lines all down the sides, and long ones from the gills to the tail, one on each side; its mouth is but small, and its teeth sharp and serrated; and it has all over its back a number of fine capillaments, set at distances from one another, even to the tail, and the same on the belly; its tail ends in a fang or fin.

Serpens Terrens, the earth-serpent, a name given by some of the chemical writers to nitre. It was originally given to the nitre of the ancients, a fact very different from that which we call nitre, but it has since been applied also to that salt.

Serpent-Stones. See Snake-Stones.

Serpent's-Tongue, in Botany, a genus of the cryptogamia family; comprehending five species. See Adder's-tongue.

Serpents' Tongues. The island of Malta abounds with glossopetrae, or the petrified teeth of snakes, which, from their resemblance to a tongue, are by the vulgar supposed to be the tongues of serpents turned into stone by some miracle of St. Paul, when he was there. This island abounds not only with these, but with bufonites, and vulture teeth of other remains of sea productions.

Augustino Scilla, who has written at large on the fossils of this island, gives a very rational account of their being the real remains of animals, which, according to his fyltem, it is no way wonderful to find there.

In regard to the island of Malta, which so abounds with them at this time, he supposes that long since the time of the creation, and even without the assistance of the general deluge, it may have been formed out of the sea, and that it appears plainly to have been at first no other than a mass of soil, mud, with an immense number of sea-shells, teeth of fishes, and other remains of sea-animals mingled among it; and that this fusing as low as they could among that thickening matter, have made the island what we now find it, that is, a heap of earth with these things in vast quantities buried in it, and at different depths. Philos. Trans. No. 219, p. 182.

And though there are found among these teeth, &c. in the island of Malta, great quantities of shells, of such species as are not natives of those seas, this is no objection to the opinion; since it is well known, that the winds, when violent, as they probably were about the time of the formation of that island, will bring such light bodies as shells a vast way in water.

The mountains of Sicily afford some few glossopetrae, or snakes' tongues, but they are few in number, and worse prepared than those of the island of Malta; which is obviously to the high ground of those mountains being left to receive the refuse of the sea, and its foil, which is sandy, being less fitted to preserve them where there than the marble, of which the island of Malta consists.

The echini marini, or sea-eggs, and their species, which are very frequent among the serpent's tongues of Malta, all lie upon the surface of the ground, or near it; whereas the glossopetra is deeper, though at no great depth. This is a plain effect of all these things having been really animal bodies, and having floated in the mud, of which that island was formed; for in this it could not be otherwise, but that the glossopetra, or serpent's tongues, being heavy, would subside in the water, while the light shells of these other animals would float on or near the surface.

Whenever the glossopetra are taken carefully up out of the earth in Malta, the marble or earth, which served for their bed, is found to contain all their minutest traces and lineaments, like wax from a seal. This is a proof that the marble was as soft as melted wax when they were put into it, and that they were of the full size and growth when placed there, not having grown, or had any increase in that place.

The apophyses, or processes in the glossopetra, are also a strong proof of their being no other than real sharks' teeth, since they exactly answer to those in the teeth of recent sharks, by which every tooth is received or inserted into its neighbour in the jaw. Nay, whereas sharks' teeth are mortised into one another in such a manner, that a man may easily tell which belongs to each side, which lie near the throat, and which near the front of the mouth; and whereas, in a shark's mouth, the teeth on the left side will not fit on the right, nor those above serve below, but that on seeing a recent tooth, a peron of judgment will be able to say what part of the mouth it belonged to; so in the fossil sharks' teeth, or glossopetra, there is not any one which may not be referred to the particular part of the mouth of the living animal, and could have belonged to no other. Augustino Scilla, de Petrarca. See Glossopetra.

Serpent, in Music, a wind instrument of the brasson kind, blown by a mouth-piece. It has its name from its serpentine figure; and is composed of two pieces of walnut-tree-wood, and covered with thin leather or shagreen.

This instrument has fix holes, which give it a compass of twenty-seven notes. The mouth-piece is fixed in a socket of copper or silver. Its neck is curved, and its mouth-piece is of wood or ivory.

It is held in such a manner, that the fore-finger, the middle-finger, and the ring-finger of the left hand, can stop the
The Serpent, in Myth, was a very common symbol of the fun, and he is represented biting his tail, and with his body formed into a circle, in order to indicate the ordinary course of the luminary; and under this form it was an emblem of time and eternity.

The serpent was also the symbol of medicine, and of the gods which presided over it, as of Apollo and Asclepius: this animal was the object of very ancient and general worship, under various appellations and characters. In most of the ancient rites we find some allusion to the serpent, under the several titles of Ob, Ops, Python, &c.

The idolatry is alluded to by Mofes, Lev. xx. 27. The woman of Endor, who had a familiar spirit, is called Ob, or Ob, and it is interpreted Pythomilla: the place where the refided, says the learned Mr. Bryant, seems to have been named from the worship then instituted; for Endor is compounded of En-aror; and signifies fons pithonis, the fountain of light, the vespers of the god A dor; which oracle was probably founded by the Canaanites, and had never been totally suppressed. His pillar was also called Adabir, or Abadir, compounded of ab and adir, and meaning the serpent deity Adibir, the same as Adoros.

In the orgies of Bacchus, the persons who partook of the ceremony, used to carry serpents in their hands, and with horrid screams call upon Eva! Eva!

Eva being, according to the writer just mentioned, the name as opha, or opha, which the Greeks rendered ephes, and by it denoted a serpent.

These ceremonies, and this symbolic worship, began among the Magi, who were the sons of Chus; and by them they were propagated in various parts. Wherever the Ammonians founded any places of worship, and introduced their rites, there was generally some allusion to a serpent. There was a legend about a serpent at Cofelas, at Thebes, and at Delphi; and likewise in other places. The Greeks called Apollo himself Python, which is the same as Opis, Opis, or Oub.

In Egypt there was a serpent named Thermuthis, which was looked upon as very sacred; and the priests were said to have made use of it as a royal type, with which they adorned the statues of the gods. The kings of Egypt were phratries, terminating in a round, and adorned with folds of drapery; and the priests likewise had the representations of serpents upon their headdresses.

Ab, or , a monster, mentioned in the Revelation, was called by Mr. Bryant, to have been the same as . Ophite, with whose worship the world had been connected. This worship began among the people of thebes, who built the city of Opas upon the Three, and were greatly addicted to divination, and to the worship of the serpent. Thos. Chaldeus the worship passed into Egypt, where the Serpent was a deity called Conophis, and Osiris, and had the name of Ob or Oub, and was the same as the Ophite, or royal Serpent, the name of Thermuthis, and made use of by way of ornament to the statues of the gods. The chief of the Egyptians was to have been Vulcan, who was styled Ophus; he was the same as Osiris, the Sun, and hence was often called Ob-Phib, or Python felis; and there were pillars sacred to him, with curious hieroglyphical inscriptions, bearing the same name, whence the Egyptians, every thing gradually tapering to a point was styled or Ophites.

As the worship of the serpent began among the sons of Chus, Mr. Bryant conjectures, that from hence they were denominated Ethiopians and Athispians, from Athe-fes, or Ath-spes, the god whom they worshipped, and not from their complexion: the Ethiopians brought these rites into Greece, and called the island where they first established them, Ethipia, Solis Serpentis infusa, the name with Euboa, or Oucka, i.e. the Serpent-Island.

The fame learned writer discovers traces of the serpent worship among the Hyperboreans, at Rhodes, named Ophitua, in Pyrga, and upon the Hellepolis, in the island Cyprus, in Crete, among the Athenians, in the name of Crocyp, among the natives of Thebes in Bostra, among the Laconians, in Italy, in Syria, &c. and in the names of many places, as well as the people where the Ophites settled. One of the most early heresies introduced into the Christian church was that of the Ophies. Bryant's Analysis of Ancient Myth. Vol. i. p. 47, &c. p. 475, &c.

Serpent Islands, in Geography, small islands near the N. coast of lake Huron, N. Lat. 46° 2'. W. long. 82° 747'.

Serpents, Island of. See Zalge.

Serpentina, in Botany. See Serpentina.

Serpentines, in Chemistry, a worm, or pipe of copper or pewter, twilled into a spiral, and ascending from the bottom of the alembic to the capital, and serving in the distillation of rectified spirit of wine.

Serpentines, in Mineralogy, a stone, which derives its name from the variety of its colours, supposed to resemble those of the serpent. The ancient called this stone ophibs, from the Greek , serpent, as being speckled like a serpent's skin. The most prevailing colour is green of different shades, spotted with red, or with dark green, and also clouded and variegated. Some serpentines are red, varying from a peach-bloom to a blood-red or scarlet. In rich variety of colours, this stone far exceeds any other of the great rock-formations. It will receive a high polish, and is easily indelible by fire or acids, and is therefore eminently fitted for ornamental sculpture or architecture. The hard-ends of serpentines are variable: some kinds scarcely yield to the knife, others are easily worked. It is insubstantial by the blowpipe; the fracture is pimptery, passing into small con-}

Q q 2 chordal;
SERPENTINE.

choidal; the fragments are translucent at the edges; the lattic is somewhat wilful, and when powdered, it has an unctuous foamy feel. The specific gravity varies from about 2.0 to 2.7. Serpentine seems nearly allied to the mineral called hornblende, from which it differs in its constituent parts by containing more magnesia and fels iron. Chrome has been found in some serpentines. The analysis of different serpentines shows a considerable variation in the proportion of their constituent parts, from 45 to 29 Silex, 18 23 Alumine, 23 34 Magnesia, 3 4 Iron, 11 10 Water and lods.

Some serpentines contain 6 per cent. of lime.

The disciples of Werner divide serpentines into two species, the one called the noble serpentine, the other the common serpentine; the former they consider as older, and having a different geological position to the common serpentine; but for this distinction there does not appear sufficient reason, as the same beds will furnish specimens of both kinds. The noble serpentine has the richest variety of colours and the greatest degree of translucency. Serpentine, though not very rare in many alpine districts, is by no means so common as granite, flate, and limewhite. Serpentine occurs in beds of gneiss and primary limewhite, and in mica-late; it also covers many rocks in amorphous masses, and may be observed graduating into chlorite or talc-late. Serpentine has been remarked to exist generally at a low level in alpine districts; but there are some remarkable exceptions to this, particularly in the fumits which surround the central parts of mount Rofa, in Switzerland. These fumits have an elevation of more than 1700 fathoms, formed of beds of serpentine lying in a position generally horizontal.

Serpentine is more abundant in Europe, than any other part of the globe that has been yet explored. The whole front of the Alps facing Italy contains serpentine almost in every part, although there is very little in the side towards Switzerland. It extends through Italy, where it is called gabbio. One of the finest varieties is at the hills of Imperocetta, near Florence; it contains much of that green, fernisanprentand, and fatty substance, which Saunfile calls smaragdite, on account of its fine emerald-green colour. France has some mountains of serpentine, especially in Limoufain.

The finest serpentines of Spain are from Sierra Nevada; two leagues from Grenada, they have a green base filled with glintening plates of a yellow colour. Superb columns have been made of it, which decorate the churches and palaces of Madrid. According to Patrin, serpentine is almost entirely wanting in northern Asia, with the exception of the eastern part of the Ural mountains, which separate Europe from Asia. There are some hills of serpentine, which at great intervals accompany their base, following their direction from north to south; there are also some detached branches which appear near Tobolitk, which is not far from these mountains. But from hence to the river Amur, a space of about three thousand miles, scarcely any vestiges are found either in the great chains of Altai, Sayennes, or the mountains of Damria. The serpentines most known in Europe are those of Saldberg in Sweden, and Zeolitz in Saxony, from which vases of every kind are turned and exported to distant countries. The serpentine of Bayreuth is filled with garnets of the faxe of a pea, dispersed equally through the mass. When the fone is polished, they present a pleasing mixture of fine red spots in a green base. Trinkets and other ornaments are made of it.

The mountain called Roth Horn, or Red Horn, which faces mount Rofa towards Italy, is elevated 1526 fathoms; it is composed of immense masses of serpentine of an irregular shape. The surface of this serpentine becomes a mass by the action of the atmosphere, which oxygenates the iron it contains. It is this colour, and the elongated form, that have occasioned the mountain to be called Red Horn.

The serpentine of this mountain is covered by a flestite of a sea-green colour, mixed with carbonate of lime and grains of felspar. On this serpentine are laid beds of micaceous felschite, intermixed with limethone, composed of more than one half of mica. These are again covered by serpentine; all the beds are nearly horizontal, rising a little towards mount Rofa.

Mount Crevin, another mountain near mount Rofa, is an inaccessible obelisk of a triangular form, which is elevated 2309 fathoms above the sea. It is composed of three distinct masses; the uppermost, which forms the summit, is of a yellow fialbella colour. It is composed of serpentine mixed with micaceous felschite, containing limethone and quartz. The middle is of gneiss and micaceous felschite, and the lower one of base of the pyramid is serpentine; but the most remarkable hill of serpentine is in the chain of mountains that separates the margin of Bayreuth from the Upper Palatinate. Its elevation above the plain is about 300 feet; it extends in a direction from east to west. The rocks which crown the summit are of very pure serpentine, divided into beds, and repoling on gneiss and hornblende. M. Humboldt having brought his compass near these rocks of serpentine, four with ferschite, that the north pole of the peculiar fith to the south. He further observed, that the rocks on the northern and southern declivities have opposite poles. The eastern and western extremities of the hill do not exert any action on the magnetic needle, though the appearance of the fone is the same as on the north and south declivities. In the magnetic parts of the hill certain rocks are also observed, which are not magnetic in junction with similar rocks, that exert a strong action on the needle, some of them at the distance of 22 feet. The mountain not only exerts its action on the needle in its whole mass, like some other hills, it is manifest even in small fragments.

Humboldt observed, that minute fragments are briskly moved on presenting them to the point of a weak magnet; but they have not the least attraction for iron not magnetized. Humboldt convinced himself that this serpentine does not contain an atom of magnetic iron, all which it contains is in the state of oxity. Its specific gravity is much less than that of other serpentines, scarcely reaching to 2.70, that of common serpentine being upwards of 2.70. This mountain of serpentine, taken in the aggregate, may be regarded as one large natural magnet, having two poles, the part equidistant from each displaying no signs of magnetic power, as is the case with small natural and artificial magnets. Like them too, if a fragment be broken from the mass, each small piece has its north and south pole, and a central part, which is not magnetic. That particular kind of fleschite, which is capable of being turned into vials that reflect the action of the fire, is called pot-ffone, and has been already described. See Por-

Steatite and amianthus, a fibrous asbestos, are almost always associated with serpentine. (See Asbestos and Steatite.) The finest amianthus occurs in Corfinia form-
ing beautiful white silky threads of two or more feet in length, and is so abundant, that Dumas made use of it instead of flax to pack his minerals when he died.

Serpentine exists in various parts of Scotland and the Hebrides; it is found both pure and intermixed with calcareous and limestone.

No well-characterized rocks of serpentine are known in South Britain, except in Cornwall and the Isle of Anglesea. The serpentine of Cornwall is not particularly distinguished for the beauty of its colours. Rocks of this mineral extend to the Lizard Point.

The most beautiful variety of serpentine in Great Britain, or perhaps in Europe, is that on the western side of Anglesea. It occurs at a low elevation associated with rocks of tufaceous slate. The beds are of considerable size, and divided by veins of albitus. Some of the serpentine is intermixed with white crystalline limestone, like the verde antique from Italy; but the parties of white are generally smaller. Veins of quartz and hematite, with brilliant tufts of schiller spar, also occur in some of the beds. This is sufficiently hard to resist the point of a copper tool, and takes a high polish. The colours are various shades of light and dark green and red, varying from a pale-bloom to a blood-red sheen. The colours are intermixed and distributed in an infinite variety of spots and clouds, the effects of which are heightened by polishing.

Mells, Bullock, and Co. on Oxford-street, have established a manufacture of chimney-pieces, columns, and other ornamental articles of this stone, which has the advantage, being raised in vast blocks, 25 feet in height in one piece, from 12 to 20 feet in length, and of proportionate diameter and breadth. A column of 12 feet in one shaft, composed of red serpentine, which we measured at Mells. Bullock's manufactory, weighed two tons, and had no perceptible flaw or blemish in the whole piece. This is the most durable as well as the richest of British stones applied to ornamental sculpture, and is not exceeded in the variety or freshness of its colours by any of the costly marbles of Italy.

The Mona marble, as this serpentine is called by the proprietors, is not liable to have its colours injured by common fire, which is the case with many marbles, when made into chimney-pieces; neither are the colours affected by acids, air, or moisture.

With such a valuable material for ornamental sculpture in our own island, it is greatly to be regretted, that such large sums should be annually paid to foreign nations in the purchase of stone for similar purposes, which is less durable and less beautiful. It would surely be more patriotic to encourage the proper application of the mineral treasures of our own country.

The stone called verde antique is a mixture of green serpentine with white granitic limestone. See Verde Antique.

Serpentine, in the Muses. A horse is said to have a serpentine tongue, if it is always tripping and moving, and sometimes palling over the bit, instead of keeping in the void space, called the liberty of the tongue.

The Romans, in breaking and dressling their horses, used to work them in moving or serpentine lines, as the practice is, or ought to be, at present. The French call this riding a horse en serpentant. The Greeks and Romans know it by the term of riding in Meander, in allusion to the windings and doublings of the celebrated river which bore that name.

Serpentine Varia. See Varia.
half, long, resembling thole of *Veronica agrostis*. *Flowers* monoeocious, four-cleft, reddish, very minute.

4. *S. occidentalis*. American Serpulica. Pursh n. 1. (Elo-des camadensis; Michaux Boreal-Amer. v. i. 20.)—"*Flowers* united. Stigmata ligulate, cloven, reflexed. Leaves ternate, linear, acute."—Frequent in fragrant waters, from Canada to Virginia, flowering in July. Perennial. *Flowers* white, very small and delicate. Leaves when magnified very finely ferrulated. In the early part of the season they are, as Michaux describes, oblong and obtuse, but at the flowering time long, linear, and acute. *Pursh.*

SERPIGO. in *Medicinae, from serpere, to creep*, is nearly synonymous with *herpes*, and signifies, in the language of the older writers, any spreading tetter, or excoration of the skin. When the tetter is itationary, according to Forestius, it is called *impetigo*; but when it spreadeth and creeps from one place to another, it is called *serpigo*. (See *Forest. Obs. Chirurg. lib. ii. obf. 11.*). It is the property, however, of many eruptive diseasess to spread in this manner, though very different in their nature from each other; whence in the more accurate nomenclature of the present day, the term *serpigo* is not used. It would be applicable, in fact, to diseasess of every class, putrid, fealy, poplar, and vesicular; to the diseasess called *impetigo*, lepra, *Yolaris*, *lichen*, *herpes*, *eczema*, &c. It is, therefore, judiciously exploded.

SERPUCOV, in *Conchology*, a genus of the order Te-taceae, of which the generic character is, animal a terebell; shell univalve, tubular, and generally adhering to other sub-fissures; often separated internally by divisions at uncertain distances. There are about fifty species included in this genus, of which several are found in our own country.

Species.

NAUTIOIDES. Shell flattened, minute, confluent, verrucose, spiral, with very thin familiar internal divisions. It is found in the seas about Norway, adhering to the Madrepora *prolifera*, is very minute, brownish, or white; of an uncertain figure, sometimes rather oblong, sometimes more orbicular; the divisions are parallel, the aperture very narrow.

SEMILUNUM. The shell of this is regular, loofe, glabrous. It is found in the Adriatic and Red seas, and sometimes it is obtained off the coast of India. The shell is scarcely larger than a grain of sand, white and yellowish; the whorls are prossed close together; the aperture is narrow, and compressed.

PLANORBS. In this species the shell is orbicular, regular, flat, equal. It is found adhering to shells. The shell resembles a round scale, and when broken horizontally it exhibits the appearance of a spire in minute concentric circles.

SPHIRRUM. Shell regular, spiral, orbicular, pellucid, with round gradually decreasing whorls. It inhabits the ocean, on zoophytes, fumulative, and other marine sub-fissures; it resembles the next, which is a native of this country, but is much less in it.

*SPIRRORBS.* Shell regular, spiral, orbicular, the whorls slightly canaliculate above and inwardly, and growing gradually less towards the centre. It inhabits moist seas, adhering to flint and zoophytes. There is a variety; the shell is white, without polish, not complicated, but diffiged finely on the sub-fissure to which it is attached; the aperture is circular.

*TRIQUETRA.* The shell of this is creeping, flexuous, triangular. It inhabits the ocean, adhering to marine sub-fissures, itones, and the bottoms of ships; is from half an inch to an inch long. The shell is white, pellucid, irregularly twisted, carinate on the back, sometimes dentiliculate, with a narrow circular aperture.

*INTRICATA.* Shell filiform, rough, round, intricately twisted. It inhabits the European and Indian seas, and often on our own coasts, upon shells. The shell is of a greenish-white, a little rugged and coarse.

*FLEGORDIA.* Shell capillary, faciculate, in branched complications, and cancellate. It inhabits the Mediterranean; is four inches long, and forms a beautiful kind of network.

GRANULATA. The shell of this is round, spiral, glomerate, with elevated ribs on the upper side. It inhabits the North seas, in large masses, adhering to itones, shells, &c. The shell is white, and the size of a corridor fun.

*CONTORTIPICATA.* The shell is angular, rugged, and irregularly entwined. It is found in the European and American seas, and on our own coasts; is from three to four inches long; and sometimes it is as large as a goose-quill; the shell is white, cinereous, or yellowish-brown; within it is smooth, transversely striate.

GLOMERATA. The shell of this species is round, glomerate, with decussate wrinkles. It inhabits the European and Atlantic seas, in large masses. The shell is white, grey, or brownish; within it is smooth.

LUMBRICALIS. The shell of this is round, flexuous, with a spiral acute tip. There are three varieties of this species, which are found in the Atlantic and Indian seas, in large masses. The shell is from three to five inches long, transversely ribbed and longitudinally wrinkled.

POLYTHALAMIA. The shell of this is likewise round, diaphanous, smooth, straight-lined, with numerous internal divisions. It inhabits the Mediterranean and Indian seas, under the sand. The shell is outwardly white, transversely wrinkled, and annulate; the inside is separated by imperforated convex and concave divions, making it appear as if it consisted of numerous united tubes.

ARENARIA. Shell jointed, entire, different, flatish, beneath. It is found in India, and divers parts of the coast of Africa. It is probably a teredo, hereafter to be described. The shell is white, with pale brown undulate rays, or whitth; the outside cancellate, within it is smooth; spiralith twisted: there are about a hundred funs, which are sometimes nodulous.

ANGUINA. Shell roundish, sub-spiral, with a longitudi-dinal jointed cleft. It inhabits the Indian ocean; varies much in figure, being sometimes round and sometimes angular; it is more or less flexuous, glabrous or rough, with the joints of the cleft often obsolete. There is a variety of this species.

*VERMICULARIS.* Shell round, tapering, curved, wrinkled. It inhabits the European seas, and is from two to three inches long. The shell is whitish, ending in an obtuse point; the inhabitant is of a bright scarlet, with elegantly feathered tentacula, from the middle of which arises a trumpet-shaped tube, and a thicker fimple one.

PENSIS. The shell of this is round, straight, taper, with a dilated radius larger extremity; the disk is covered with cylindrical pores. This is denominated the *watering-pot*. It is found chiefly in the Indian ocean. The shell is white or cinereous, with a faint flade of red; smoothish, tapering, and open at the small end; the dilated margin at the larger end
end terminating in numerous small tubes; the disk is convex, and covered with round perforations, with a longitudinal canal in the middle.

**Laminae.** Shell round, 6 to 7 mm. in diameter, with numerous rows of prickles, clustering at the end. It is the size of a small quill, the form is sub-oval.

**Ostra.** The shell of this is smooth, irrate, brown. It resembles the Indian Gems, closely allied to Corbula.

**Protena.** Shell polished, unarmed, with decussate costa, light, with thin, white and green. The shell is round, with angle point, with white line, and the size of a quill. It is about the 12th size, the form is perfectly regular.

**Dilectata.** Shell round, with decussate line, finely wrinkled, flexible, red, with thin, white and white.

**Pepussiana.** The shell is smooth and white; the broader part is irrate, and transversely plated. The shell is from two to three inches long, white, or of a dusky brown.

**Akra.** Shell sub-irrate, yellowish-brown, round, twisted to three whorls, with a central tip. It is found about the coast of the island of Greece.

**Cerithia.** Shell round, smooth, yellowish, many times twisted. It inhabits America. The shell is long and narrow.

**Corne australis.** Shell conic, spirally twisted, yellowish, with brown bands; the middle is round and twisted; the aperture is obtusely orbicular. The shell, as to its form, is obtuse at the tip.

**Cerithia.** The shell is round, cancellate, yellow, with brown, hazy. It is found at Garee, fixed to telluric substances and wood; it is from eight to nine inches long, with elevated ribs; the longitudinal ones are crowded.

**Intestina.** Shell triangular, twisted, fragile, tuberculate, with hollow dots. This is found on the African coast. The shell is white, finely twirled, sub-umbilicate, within glabrous.

**Inundulosa.** The shell is round, white, transversely irrate, and three-twilled; the first bend appearing as it composed of five lines placed on each other.

**Pyramidalis.** Shell cuneus, above convex, beneath flat, pyramidal, hence its specific name, and it is many times twirled, the base decreasing inwardly. It is found in the Indian sea, adhering to telluric substances about as high long, open at the narrower end; sometimes it is straightish, or a little bent.

**Dentecta.** The shell of this is white, round, tuberculate, straight, toothed at the sides, with a longitudinal glabrous rib in the middle; the tip is little curved, and glabrous. It is found adhering to the Lepas, certain abalun. and is about three-quarters of an inch long.

**Melitensis.** Shell round, twisted, umbilicate, with decussate lines, and longitudinal recurved ribs within, smooth, with numerous divices. It is found off Sicily. The two first bends are placed on each other.

**Norwegica.** The shell of this is round, obtusely curved, with a nearly oblique oval base; the mouth is obliquely truncate. It is found, as its specific name denotes, in Norway.

**Porrecta.** Shell round, smooth, polished, ascending in a flexuous manner from the spiral base. It inhabits the North seas. The shell resembles the S. pyrum, but is white, pellucid, and not rugose; the inhabitant is short, with a red back and pueride sides.

**Viterba.** The shell is round, regular, spiral, orbicular, pellucid, shining, wrinkled, with a thickened aperture. This species is found in the Greenland seas, on terrae firma, transactions, and divers marine substances. It resembles the S. pyrum, but is white, pellucid, and not rugose; the inhabitant is short, with a red back and pueride sides.

**Serrula.** Shell round, spiral, orbicular, pellucid, shining, wrinkled, with a thickened aperture. This species is found in the Greenland seas, on terrae firma, transactions, and divers marine substances. It resembles the S. pyrum, but is white, pellucid, and not rugose; the inhabitant is short, with a red back and pueride sides.

**Syracusa.** Shell spiral, orbicular, with three spines, the branches are interrupted by transverse lines. It inhabits the Greenland seas, and resembles the S. pyrum. It is white, pellucid, with a thickened aperture. The species in two subspecies.

**Sylabiae.** Shell tuberculate, umbilicate, convex, radiate with wrinkles. This also inhabits the Greenland seas, on terrae firma, transactions. The shell is larger than a needle, violet, white, brown, or yellow, twisted with white; beneath it is flat, with a single wheel or bead; the aperture is very minute.

**Gigantea.** The shell of this is somewhat triangular, with a little bend, gradually tapering, violet, with smooth, pale yellow, the aperture is white, with undulate, and armed with a conical tooth. It inhabits Africa and America, attached to rocks and corals. The shell is small, thick, and with a little finger. It inhabited in white.

**Cineria.** The shell is flat, orbicular, conical, twisted, with a smooth, greyish-white, and flexuous.

**Sulcata.** Shell with two whorls, deeply and spirally grooved. It inhabits the coasts of Pembrokeshire, on the roots of the Fucus digitatus. It is a minute shell, of a greyish colour.

**Ovalis.** Shell sub-oval, imperforated. It is found at Terby. The shell has two bends, which form an oval; it is never perforated, and is minute.

**Replea.** The shell is regular, rounded, with a reflected margin at the aperture. This is found on the Pembrokeshire sands. It is minute; shell glossy, white, perforated; the aperture is above the plane of the lip. It inhabits Africa and America, attached to rocks and corals. The shell is regular, rounded, and pellucid with three whorls. This is often an inhabitant on the Pembrokeshire coast. It is brown above, and yellowish-white below.

**Bidorla.** Shell tuberculate, ventricose, white, opaque, glossy. It is found at Sandwich and Reculver, and is minute.

**Perforata.** Shell full, orbicular, perforated, white, opaque, glossy. It inhabits Sandwich, and do all those that will be hereafter described. This is, however, as well as the next, very rare and minute.

**Lacia.** The shell is ovate, thin, smooth, pellucid, with milky veins.

**Lagana.** Shell rounded, flat, grooved, with a narrow neck. This is described, as are all those which are found in this country, in Adams's work on the Microscope. The shell of this is exactly shaped like an oak-leaf, and is whitish.

**Kerura.** Shell rounded, margined, with a slender curved neck. The shell is white, opaque, shaped something like the retort used by chemists.

**Incurvata.** The shell is straight, with three close whorls at the smaller end. The shell is white and transparent, and resembles, in some respects, the Nautilus femur.

**Serpulina, in Botany, sometimes written Serpulum, derived from its humble creeping mode of growth. See Plumula.**

**Serqueux, in Geography, a town of France, in the department of the Upper Marne; 5 miles N. of Bourronne.**
SERRA, PAOLO, in Biography, author of an elaborate treatise on harmonization, published at Rome in 1768, small folio, entitled "Introduzione Armonica Sopra la nuova fere de Sion modulati oggidi, e modo di rettamente, e più facilmente intuonarla: or, "Harmonical Introduzione to a new series of modulated sounds, and a method for accurately, and with greater facility, learning to name and produce them with the voice."

The author begins, cap. 1, with the origin of music, its utility, and the different modes of naming the notes in fingering. After endeavouring to rob Guido of the invention of the hexachords and harmonization, and condemning his use, he proposes a new method of naming the notes in learning to finger; assigning a specific name to every found in the scale ending with the vowels A, E, I; as $ce$ for a flat note, $ce$ for a natural note, and $ci$ for a sharp note; beginning each found with the letters now in use in the Septenary, by which means the student is disembranched from all mutations, and every found in the scale has a specific and invariable name appropriated to it.

This method had the approbation of several of the best masters in Rome, who have signed a certificate of its effect upon the studies of a young finger of the name of Benedetti, who was rendered capable by it, in less than a year, of fingering at night any vocal music that was put before him, even without accompaniment. Benedetti has since fung the first man's part in the operas of several of the principal cities of Italy; and, perhaps, his genius may be such, as would have enabled him to have done the fame by any other method, with equal study and practice. Instrumental performers, at present, are not plagued with the ancient names of the notes and mutations, but learn them by the simple letters of the alphabet; and yet we have never heard of one that has been able to play at sight in a year's time.

Upon the whole, the alphabetic names of the notes seem the most simple and useful for every purpose but that of exercising the voice, which is best done by the vowels; and it may be said, that to syllabize in quick passages is little more than to speak; but to vocalize is to fing. However, we were told by a scholar of the famous Durante, that while he was in the conservatorio of St. Onofrio, at Naples, when the boys used to be tormenting themselves about the mutations, and the names of notes in transposed keys, with double flats and sharps, Durante cried out, "Quefle note intonatele, chiamatele poi anche diavole fe volete, ma intonate." Meaning, that if they did but hit the intervals right, and in tune, he did not care what they were called. And, perhaps, what Pope says of different forms of government, may be more justly applied to these several methods of fingering.

"What'er is best administer'd is best."

As, in the use of any of them, whoever has the best matter, and secounds his instructions with the greatest degree of intelligence and industry, will be the most likely to succeed. And when we recollect the great abilities and enchanting powers of many fingers of past times, who have been obliged to articulate every note of their *solfeggio* in the most rapid movements, we may apply to the new syllables what M. Rouleau said with respect to his own: "That the public has done very wisely to reject them, and to fend their authors to the land of vain speculations." For innovators will always find, that a bad method, already known, will be preferred to a good method that is to learn.

SERRA, in Botany, a genus of plants, so called in the *Flora Peruviana*, after a Spanish botanist of the fame name, who has studied the plants of Minorca. De'Their.

SERRA, in Geography, a town of France, in the department of the Jemappe, and chief place of a canton, in the district of Corté. The canton contains 2171 inhabitants.

SERRA, a town of Corfica; 11 miles S.S.W. of Cerione.

SERRA de Azenhao, mountains of Portugal, in Alentejo; 4 miles N. of Monfort.

SERRA d'Alcoa, mountains of Portugal, in the province of Beira, between Vifeu and Bragança Nova.

SERRA de Bouzno, mountains of Portugal, in Alentejo; 4 miles S. of Portalegre.

SERRA de Cudirivao, mountains of Portugal, between Algarva and Alentejo.

SERRA da Ebrica, mountains of Portugal, in the province of Entre Duro e Minho; 8 miles N. of Braganza.

SERRA Falperra, a town of Portugal, in Tras los Montes; 15 miles W. of Mirandela.

SERRA de Maram, a mountain of Portugal, in the province of Tras los Montes; 10 miles S. of Chaves.

SERRA de Monchique, mountains of Portugal, between Alentejo and Algarva.

SERRA de Monill, mountains of Portugal, between Mirandela and Torre de Moncorvo.

SERRA de Querra, a town of Africa, in Lower Guinea, on the river Camarones.

SERRA de Rebordannas, mountains of Portugal, south of Braganza, in Tras los Montes.

SERRA de St. Miguel, mountains of Portugal, in Alentejo, on the south side of the Tagus; 15 miles N.N.W. of Caffello de Vide.

SERRA de Salvador, mountains of Portugal, in Alentejo; 8 miles E. of Arronches.

SERRA Pisit, in Ichthyology, a name given by many authors to the *prifis*, or *faw-fish*.

SERRA is also a name given by Pliny to a species of the fishes, called by the generality of writers *scelopas*. It is distinguished by Artedi by the name of the balites, with two spines in the place of the belly-fins, and one behind the anus. See TRUMPET-fishes.

SERRAE, in Geography, a town of European Turkey, in Macedonia, the fee of a Greek archbishop; 36 miles E.N.E. of Saloniki.

SERRAIN, a town of Arabia, in the province of Hedsja; 40 miles S.W. of Mecca. N. lat. 21° 5'.

SERRANA, or PEARL ISLAND, a small island in the Caribbean sea, so called from Serrana, the commander of a Spanish vesel in the time of Charles V., who was shipwrecked on the coast. N. lat. 14° 5'; W. long. 78° 50'.

SERRANILLA ISLANDS, a cluster of small islands in the bay of Honduras. N. lat. 16° 10'; W. long. 80° 10'.

SERRAPETRON, a town of Italy; 7 miles S.W. of Ancona.
SERRATA, a name given by some of the Roman authors to the plant which the Gauls, according to Pliny, had named betelum, and which the Greeks called eumonimmon and praxeres. This was evidently the same plant with our serrata, or saw-wort; but besides this there was another plant called by the same, and which, according to Pliny, was the common firmer of the Greeks. Does it say nothing of the chamaedrys, but that its leaves were small? And it is much more probable, that the world should take the idea of a saw from the leaves of the serrata than from those of this plant, they being much more delicately than thou. So that those who have been influenced by Pliny, to suppose the germen and serrata of the ancient to be the same plant, are, in the wrong, though they have the countenance of this in generally reputed authentic author for it.

SERRATE FLEAS. In Natural History, a name given by authors to certain flies, distinguished from all the other kinds by their having a weapon resembling a double knife, placed at the hinder part of the body; this serves several species of them to make holes in the branches of trees, in which they deposit their eggs; but there are some of them which do not seem to make any use of this curious instrument, though they have it. See Rose-fly.

The fly of this kind that lays its eggs on the gooseberry-bush, deposits them only on the surface of the middle rib of the leaf, and the other-fly, which is one of this genus, produced from a hawfashion caterpillar of the other, lays its eggs on the intermediate surface of the leaves between the ribs.

There appears to be no use made of this curious instrument in the depositing of these eggs, since they are only laid in rows upon the leaves, and fixed to them by means of a viscous fluid which covers them. It is a very remarkable property in the eggs of this genus of flies, that they grow much larger after they are laid. This is observable in the eggs of the common rose-fly, which are at first buried in the wood, and by their growth force out the surface into tumours of an oval figure; but in those of the other-fly it is much more quickly, and the whole growth of the fetus in them is clearly seen, on examining them at different times of their growth, which may be easily done without disturbing them, as they lie naked on the surface of the leaf.

There seems a plain proof that the egg receives some sort of benefit, and that a very essential one to its preservation, from the juices of the plant on which it is deposited, since, if those leaves be pulled off from the plant, and left to dry, the eggs always dry up with them, and perish; whereas, if the ends of these leaves be put into water, and the leaf be by that means preferred fresh and juicy, the creature hatches from it as well as if it was left upon the tree. Recamier's Hist. Inf. vol. vi. p. 164.

SERRATED LEAF, in Botany. See LEAF.

SERRATITI, in the History of Coinage, a name anciently given to some Roman coins, and few eome other coins, which were ornamented by cutting out regular notches on the edges. Tacitus says, that the Germans preferred these to other Roman coins. But the old faggors made this kind of impression, which was intended to prevent forgery, by shewing the inside of the metal.

2. S. coronata. Siberian Saw-wort. Linn. Sp. Pl. 1144. Ait. n. 2. (Sp. prostrata centauroides montana italica; Bocce Muf. 45. t. 37; Card. n. 41; Gen. Sib. v. 2. 160. t. 23.)—Leaves sharply serrated, somewhat ciliated, more or less pinnatifid. Corolla level-topped. Florets of the circumference female, longer than the red.—Native of most parts of Siberia, flowering in the end of June. If Boccione's synonym be right, the plant grows also on mountains in Italy.
SERRATULA.

Italy. Gmelin says it is used in the former country for dying yellow, birch-leaves being superadded. This species is thrice as large as the *tintoria*; the leaves always deeply pinnatifid; the flowers much larger, furnished with radiating marginal florets, which, though dititute of stamina, produce seed.

3. *S. quinquifolia.* Five-leaved Saw-wort. Wildl. n. 3. Ait. n. 5.—Leaves ferrated, deeply pinnatifid, five or seven lobed. Flowers simply corymbose. Inner scales of the calyx elongated and coloured. Native of the north of Persia. Introduced into the gardens of England by Mr. Both, in 1843. A hardy perennial, flowering in July and August. Very like the last, but the leaves have only two or three pair of lobes; the calyx is rather smaller, and not downy, its long coloured inner scales resembling a radiant *corolla*. *Flowers* uniform. *Wildman*. The specific name is exceptional, for, by this author's own account, the leaves are only pinnatifid.

4. *S. humilis.* Humble Saw-wort. Desfont. Atlant. v. 24, t. 1720. Wildl. n. 4. (Jacea supina, carline capitato aculeata, tota inana; Bocc. Muf. 146.) J. inana chamaeleon's capitulum; ibid. t. 103.)—Leaves pinnatifid, with oblong entire segments; downy beneath. Flower solitary. Calyx hoary, with spreading-pointed scales. Native of Sicily and Barbary, flowering in summer. An elegant little perennial plant, with several spreading radical leaves, either simply or interrupted, but always very deeply, pinnatifid; smooth above. *Flower* rose-coloured. Its field appears to vary in length, being sometimes nearly wanting.

5. *S. mollis.* Soft-leaved Saw-wort. Cavan. f. v. 1. 62, t. 90. f. 1. Wildl. n. 5.—Leaves pinnatifid, with oblong, obtuse, entire segments; downy beneath. Flower solitary. Calyx downy, with erect scales. Native of hills in Spain, flowering in June. Cavanilles says the root is annual, but Wildmanow thought it seemed perennial. The latter, who had seen dried specimens of this and the last, was perplexed of their being distinct, and, besides the characters given above, he remarks that the seed-down of the present species is mossy feathery.

6. *S. pygmaea.* Dwarf Linear Saw-wort. Jacq. Auffr. v. 5. 20. t. 440. Wildl. n. 6. (Cnicus pygmaeus; Linn. Sp. Pl. 1156.)—Leaves nearly linear, revolute, loosely hairy. Stem leafy, hairy, single-flowered. Calyx-scales ovato-lanceolate, erect.—Found by Jacquin on the celebrated Auffrian mountain called *Schneberg* in 1761. Chlubn appears to have gathered the fame in Hungary, and Scopoli in Carniola. The perennial root, furnished with long black fibres, is crowned with a tuft of numerous spreading leaves, each two or three inches long, not half an inch wide, green on both sides, though clothed with loose feathered white hairs; their margin either entire, or dittantly toothed. Similar, though rather shorter, leaves clothe the simple stem, which is from two to five inches high, hollow, hairy, bearing one upright purplish flower, with prominent violet anthers. The scales of the calyx are broad, flat, purplish and downy. This is one of the rarest alpine plants, nearly related to the following, but certainly distinct.

8. *S. diffusa.* Wildl. n. 8. (Cirrim. n. 179; Hall. Hift. v. 1. t. 77. f. 6. C. n. 52; Gmel. Sib. v. 2. 67. t. 26. Herb. Linn. from the author. Carduus mollis, folidi lapathis; Ger. Em. 1184.)

Leaves cottony and white beneath, toothed, pointed, ovato-lanceolate, undivided; the radical ones somewhat ovate or heart-shaped. Flowers corymbose. Calyx clothed with soft hairs.—Native of the highest mountains of Europe, particularly Siberia, Wales, Scotland, and Switzerland, flowering in July and August. There can be no doubt that all the synonyms here cited belong to one species, nor is it easy to mark the limits of even its varieties. The *root* is perennial, tough, and woody. Stem from three to twelve inches, or more, in height, simple, leafy, *flattened, cottony, crowned with a level-topped tuft of elegant flowers*, on stalks of various lengths. *Calyces* of many soft, brown, hairy scales. *Florets* pink, with blue or violet anthers. The leaves are excessively variable in shape, from lanceolate to broadly heart-shaped; their margin toothed, sometimes wavy; their *footstalks* long and slender, short and thick, or altogether wanting. The upper surface of each leaf is green, smooth, and nearly or quite naked; the under covered with dense, white, cottony down. The narrow-leaved specimens grow in rich ground, amongst other plants.

8. *S. angustifolia.* Narrow-leaved Saw-wort. Wildl. n. 9. (S. alpina, angustifolia; Linn. Sp. Pl. 1145. Cirrum. n. 59; Gmel. Sib. v. 2. 78. t. 33. Herb. Linn. from the author.)—Leaves linear, revolute, entire; rather hairy beneath. Flowers somewhat racemose. Bracteas awl-shaped.—Gathered by Steller, on the banks of rivers in the eastern part of Siberia. A much more slender plant than any variety of the preceding. The *flower* is eighteen to twenty-four inches high, erect, slender, hollow, *flattened, purplish, nearly smooth*. *Leaves* cottony, hardly a line broad, quite entire, paler, and a little hairy, but not cottony, beneath. *Florets* few, on long, simple, dilatant, rather racemose than corymbose, *stalks*. Scales of the *calyx*; ovate, pointed, purplish or brown, hairy within.

9. *S. falicifolia.* Willow-leaved Saw-wort. Linn. Sp. Pl. 1145. Wildl. n. 10. Ait. n. 5. (Cirrum. n. 53; Gmel. Sib. v. 2. 69. t. 27.)—Leaves linear-lanceolate, entire; white and cottony beneath. Corymb compound, leafy. Scales of the calyx elliptical, ribbed, downy.—Native of Siberia, in dry open rocky places, where it flowers towards the end of July. Mr. Joseph Buhl is said to have brought this species into the English gardens in 1796. It is an elegant hardy perennial, distinguished by the snow-white whiteness of the backs of its leaves, whose edges are scarcely, if at all, revolute; their base tapering down into a bordered *footstalk*. The *flowers* rather more refulgent those of *S. tinctoria* than of *alpina*, but the *calyx* is slightly cottony.

11. *S. multiflora.* Many-flowered Saw-wort. Linn. Sp. Pl. 1145. Wildl. n. 12. (Cirrum. n. 54; Gmel. Sib. v. 2. 71. t. 28.)—Leaves lanceolate, rough, somewhat dentate, nearly entire; woolly beneath. Stem repeatedly corymbose, much *flowered. Scales* of the calyx lanceolate, keeled.—Gathered by Gmelin in mountaneous parts of Siberia. Dr. Forcher has sent us a less luxuriant specimen from Mount Caucatus. The *flowers* are said to be decumbent. The leaves vary in breadth, and are sometimes revolute; the radical ones coarsely toothed. Their green upper surface is rough like a file;
...the under clad with lâl white cottony wool. 

A. The leaves are oblanceolate, and have a dark, slender, purplish, finely downy, glaucous, Gmelin. I find fully that they differ in their plate to two large; yet Linnæus on this account doubts the certainty of its synonymy, for which there can be no reason.

Willd. n. 15. (Carduim n. 55; Gmel. Sib v. 2. 72. t. 29.) — Leaves lanceolate, rough-edged, naked, somewhat decurrent. Flowers corymbosum. Scales of the calyx dilated and rounded at the extremity. — Native of dry open fields in Siberia, on a faine foil, abundantly. Gmelin. Root as thick as the little finger, perennial, bitter, with a faintly flavour. Stem from a tap-root to one or two cubits high, simple or branched, leafy, angular, and furrowed. Leaves four or five inches long, and one broad, conic-shaped, tapering at each end, naked or nearly smooth on both sides, except the edges and middle; the lower ones stalked, toothed; the upper generally decurrent, and entire. Flowers several, purple, the size of Centaurea nigra or Jacea, but in the aspect and hue of their calyx most resembling the latter, except that the round apex of each scale, though jagged, is not fringed.

15. S. centroaoides. Centaury-like Seward-wort. Linn. Sp. P1. 1148. Willd. n. 16. Ait. n. 6. (Carduim n. 38; Gmel. Sib v. 2. 44. t. 17.) — Leaves deeply pinnatifid, acute, smooth, unarmed. Stem branched. Flowers solitary. Scales of the calyx partly point'd; the inner ones dilated and membranous. — Native of Siberia. Sent by Sir Joseph Banks to Kew, in 1804. A hardy perennial, flowering in July and August. This has the habit of several Centaurea, but wants the smaller marginal flares. The stem is foot to more in height, alternately branched, leafy, angular, smooth. Leaves rigid or coriaceous, with deep, entire, decurrent segments. Flowers solitary at the top of each branch, large, purple. Calyx ovate, of many ovate acute scales, several of the middle-mould of which bear a short spine, while the inner ones are much elongated into a linear, membranous-tipped appendage. The genus of this plant cannot but be considered as very doubtful, nor can we refer it without scruple to Strepatus, or Centaurea; perhaps we should, like Gmelin, remove it to Carduim or Cnicus, the calyx answering very nearly to that of the former.

...Serratula, in Garden, contains plants of the tall, hardy, herbaceous, perennial kind, of which the species cultivated are: the long-leaved faw-wort (S. noveboracensis); the tall faw-wort (S. praealta); the glaucous-leaved faw-wort (S. glauca); the rough-headed faw-wort (S. squarrosa); the ragged-cupped faw-wort (S. quadriata); and the spiky faw-wort (S. fucata).

Method of Culture. — These plants may all be increased by parting the roots, and planting them out in the autumn, when the stems decay, or in the spring; but the former is the better season. They may be planted in the middle or the back parts.

Serratula, in Anatomy, a name given to different muscles attached to the ribs, and arising by several distinct portions, so as to have a serrated edge. In French they are called dentelé.

Serratula Anticua, the name under which Albinus describes the pectoralis minor. It is also called ferratus minor anthicus.

Serratula Magnus, ferratus major anticus; le grand dentelé; scapula colton, a large muscle of the shoulder, broad and flat, lying between the scapula and the chest, and extending...
extending from the nine upper ribs to the bases of the scapula. It is irregularly four-sided, broader below and in front than above and behind. It arises from the eight or nine upper ribs by as many distinct pointed portions, which are first tendinous, then fibrous. The first, which is broad, very thick, short, and distinct from the rest, arises from the outer edge of the first rib, towards its back part, from the second, and from an intermediate aponeurosis. The second, third, and fourth, broad and thin, arise from the external surfaces of the second, third, and fourth ribs, in oblique lines directed from above and behind, downwards and forwards. The four or five left, narrower and increasing in length downwards, arise from the upper edge and external surface of the corresponding ribs, and are placed between the digitations of the oblique externus abdominis. From the origins just enumerated, the fibres of the muscle proceed, divided, particularly below, into fasciculi corresponding to each digitation, separated by cellular lines, and soon forming three distinct portions. The superior division is thick, narrow, and short, extends from the two first ribs to the superior angle of the scapula, ascends a little, and covering the upper edge of the second portion, to which it is united. The middle division, broad and thin, goes from the second, third, and fourth ribs to the upper three-fourths of the bases of the scapula; its fibres proceed horizontally from before backwards, except the inferior ones, which descend a little. The inferior portion of the muscle passes from the fifth, sixth, seventh, and eighth ribs to the inferior fourth of the bases of the scapula, and the inferior angle of the bone. This part is thick, radiated, broad in front, and narrow behind. The superior fibres of this portion go nearly horizontally from before backwards; the inferior ones are directed at the same time from below upwards, and are more oblique in proportion as they are lower: they are united towards the inferior angle of the bone.

The external surface of the serratus is covered, towards its lower and anterior part, by the skin, at the lower and posterior part by the latissimus dorsi. Above and towards the front it is covered by the pectoral muscles, by the axillary vessels, and the brachial plexus. In the rest of its extent it is in contact with the sub-scapularis. The external surface covers the seven or eight superior ribs, the external intercostal muscles, and behind a portion of the serratus superior politicus. The upper edge of the muscle is the shortest, extending from the margin of the first rib to the superior angle of the scapula: the inferior, much longer, reaches from the eighth or ninth rib, or about two inches from its cartilage, obliquely to the inferior angle of the scapula. The anterior edge is the longest, and fixed to the external surface of the eight or nine first ribs, by the distinct pointed fasciculi or digitated portions, from which the name of the muscle has been derived: the posterior is fixed to the front edge of the bases of the scapula, and of the superior and inferior angles of the bone.

The action of the serratus anticus produces two different effects, according as the scapula or the ribs are the fixed point. In the first case, the scapula being fixed by the trapezius, rhomboid and levator muscles, it draws the ribs outwards, elevating those to which it is fixed by its lower digitations: in this respect it is a powerful agent of inspiration, concurring with the pectoral muscles. In the second case, it carries the scapula forwards, antagonizing the rhomboid, trapezius, &c. But it moreover draws the inferior angle forwards, and consequently moves the upper and anterior angle of the bone, forming the shoulder, upwards. Thus the serratus anticus is an important muscle in supporting burdens carried on the shoulders. In this case the diaphragm and abdominal muscles are put in action to draw down the ribs, fix them, and prevent them from yielding to the efforts of the serratus.

**Serratus Major Anticus.** See **Serratus Anticus.**

**Serratus Politicus Inferior.** (denté polité antérieur; lombocostien,) is a broad, thin, and flat muscle, flattened at the lower part of the back, and extending from the spinous processes of the vertebrae to the ribs. It arises from the spinous processes of the two last dorsal vertebrae, of the three first lumbar, and the intervening intercostal ligaments, by a broad aponeurosis, completing one-half of the muscle, common to it and the latissimus dorsi, composed of parallel fibres, directed obliquely upwards and outwards. This aponeurosis is connected in front to that of the transversus abdominis, and by its lower edge to the obliquus internus. The muscular fibres, passing with the same obliquity as those of the aponeurosis, form four fasciculi or pointed ferrated portions, of which the first and breadth is fixed to the lower edge, and near the angle of the second false rib; and the three others, which are successively smaller, are also attached, by aponeurotic fibres, to the lower edge of the three succeeding ribs, farther from the angle. The posterior surface of this muscle is covered by the latissimus dorsi. The anterior surface covers the three last false ribs, the external intercostal muscles, the longissimus dorsi and facrolumbas, and the transversus abdominis. The upper edge is continuous with the thin aponeurosis, which immediately covers the longissimus dorsi and facrolumbas.

By drawing downwards the lower ribs, this muscle assists in expiration. It cannot produce any effect on the spine: it will confine the muscles lying at the side of the spine, and thus has the same effect as the serratus politicus superior and the fascia extended between them.

**Serratus Politicus Superior,** (denté polité antérieur; dorco-fasciel,) is a very small and thin muscle, flat and four-sided, placed at the upper part of the back. It arises from the ligamentum nuchae, the last cervical spinous processes, and the two or three upper dorsal ones, by a thin aponeurosis, composed of parallel fibres, directed obliquely downwards and outwards. The fibrous fibres follow the same direction, forming a thin fascia, which terminates in four small fasciculi or ferrated portions, ending in aponeurotic fibres, which are inserted in the upper edges of the forehead, third, fourth, and fifth ribs, near their angles. It is covered externally by the rhomboïdes: and it covers the splenius, transversarii coli, the vertebral muscles, the ribs, and the corresponding intercostal muscles.

It will have the effect of elevating the ribs, and thereby of enlarging the chest, or afflicting in inspiration.

**Serravalle,** in Geography, a town of France, in the department of Marne, on the Scina; 12 miles S. of Tontona.—Alfo, a town of France, in the department of the Seine; 18 miles N. of Versailles.—Alfo, a town of Italy, in the duchy of Mantua; 24 miles S.E. of Mantua.—Alfo, a town of Italy, in the Trevifan, 2 1/2 miles in circumference, partly on a plain between two mountains, and partly on the mountains near the river Mafehio, which runs through the middle of the town, and has its source in a small lake in the higher part of the town. At the extremity of the market-place is the public palace, and at the lower end the cathedral church, containing some good paintings. The town and its suburbs comprehend two parishes, and 30 churches, that of St. Augustla attracting notice by its noble architecture, and its long noble facrinas. Here are also two monasteries, and two nunneries. The inhabitants are industrious, and trade particularly
particularly in cloth, woollen and silk manufactures, and carried on a vast commerce in wool, hemp, and flax, in the adjacent provinces and with Germany: 2

SERRE, a L. in Barab, a maritime port of Geneva, which had been fortified and defended well by the Genoese, who had made it a centre of the Genoese colonies. He had defended the "Gros Armes," or Great Wall, the "Ballarat," or Ballarat, and the Towns of Tannaz, with his army of the "Terre Soudaine." The celebrated works of M. Serres were examined in two vues in says, both in 1599 and 1602, in which there are like many parts of the art disputable, in the practice and practice of artillery, which will both amuse and instruct musical minds.

Serres, or, chief intervals in music, such as the cardinal quarter in time of the ancient Greek music; and in the French, short and quick. See Serres.

Serres, L. in Gargny, a river which runs into the Oise, near La Fere, in the department of the Aisne.

Serris, a town of France, in the department of the Seine; 12 miles N. of Romani.

SERRIS, John, in Serpis, a Protestant minister, was born in the town of France, and studied at Lausanne. We find him in 1572, serving a country church in the neighbourhood of Geneva. Having made himself known by various works, he became rector of the college of Nimes, and a minister of that city, and was employed on several important occasions by Henry IV.; that prince having asked Serres if it were possible for a person to be favored in the communion of the church of Rome, he answered in the affirmative, with the confidence of promoting Henry's charge of religion. Notwithstanding this decision, he was a warm antagonist against the Catholics, and made a very severe attack upon the Jesuits, entitled "Tractatio Jezuista quaerenda est." As a learned author, he is chiefly known by an edition of Plato in three volumes folio, printed by Henry Stephens in 1578, with notes and a new Latin version, which is however not remarkable for correctness; and the style of these parts which Serres compos'd is very unequal to the majesty of the original. He was author of a number of works in history, and had the title of Historiographer of France; but his competences are laid by the Catholics to be partial and full of misrepresentations. The principal of them are as follow: "Commentarium de Ruth Religionis et Republicae in Regio Franciae," compiling the events from 1557 to 1576; "Memorie de la Fratricieu Guerre civile sous Charles IX."; "Recueil des Chose memorable avencees en France sous Henri II., Francois II., Charles IX., et Henri III."

SERRIS, and "histoire de l'Histoire de France." Serres, towards the end of his life, engaged in the hope of designing of uniting the Catholic and reformed churches, which brought upon him the contempt of one party and the enmity of the other. He died in 1578.

Serris, Olivier de, an eminent agriculturist, was born in 1539, at Villevieuve de Berg, in the Vivarais. During the civil tumults of his time, his property was plundered, and his house destroyed, and after it had been rebuilt, it was again destroyed by fire. He is said to have born these misfortunes with great equanimity, and to have forgotten them by engaging his mind in bodily and rural occupations. By his talents he became so advantageously known to Henry IV., that he sent for him to Paris, and employed himself in several improvements about his domains. Serres wrote works which rendered him the oracle of the cultivators in that age, and many of his ideas have been cons-

 practiced by later writers without and whole extent. The use of this, as he collected the medicinal plants, entitled "Tractatus de Plantis," in 1575, and has been translated in England. It has been translated by Hulst in 1620, and in 1650, in order that the name of this herb could be distinguished in the publication of the 17th, and the century of the 17th century. Dom Thibault died in 1619, at the age of 91, after having lived the natural fruit without the happy effects of the improve-

ment being performed by him.

Serris, in Geography, a town of France, in the department of the Hervar, and 10 miles of a canton, in the district of Gap; 24 miles W. N. W. of Gap. The place contains 319, and the area is 412.1 square miles, or a territory of 1755 square miles, in 10 communes. N. lat. 44° 26'. E. long. 5° 30'.

SERRIS, a town of Asia Minor, in Neapel; 30 miles S. of Catanzaro.

SERRISERES, a town of France, in the department of the Ardeche, and chief place of a canton, in the district of Tournon-sur-Rhône; 15 miles N. of Tournon. The place contains 1923, and the canton 9415 inhabitants, on a territory of 115 square miles, in 15 communes.

SERRIS, a town of Hindustan, in Bahar; 15 miles S. of Fatehpur Sikri. N. lat. 24° 51'. E. long. 84° 27'.

SERRO, a small island belonging to the cluster of Papuan isles. See Papa.

SERROPALPUS, in Entomology, a genus of insects, of the order Coleoptera, whose generic character is 28-12: antennae fematus; four unequal feakers; the anterior ones are the longer, and deeply serrated, composed of four joints, the last very large, truncate, compressed, parcelliform; the posterior ones are subelliptical, thorn-margined, concealing the head, with a prominent angle on each side; the head is reflected; and the feet formed for digging. There are two species.

SPIRATUS. The body of this insect is brown; the shells frattate. It inhabits the island Rumfale, and is described in the Stockholm Transactions for the year 1786; where it is said to be found chiefly on old wooden buildings, in the evening in autumn, and is about the size of the Euter aternum.

LAVIGATUS. This species is characterized by a black body, and smooth shells. It inhabits different parts of Europe, and is likewise described in the volume of the Stockholm Transactions already referred to.

SERRURIA, in Botany, a name rightly altered by Mr. Salibury and Mr. Brown, from the Serruria of prof. Dr. J.J. Barnard, who, in his Phaen. Africae, 266, establishes the latter appellation, in honour of Dr. Joseph Serrurier, Professor of Botany at Utrecht; but it is not easy to discover the above author's meaning in this perverting the word; or Serrurier is a name which, and has no reference to a law, or law. - Brown, Tr. of Linn. Soc. v. 1011. 112. Ait. Hort. Kew. v. 1. 168 - Class and order, Tamarindinae. Nat. Ord. Agugrate, Linn. Provence, Jull. Brown.

Eff. Ch. Cerollin in four deep segments. Stamens in the concave tups of the segments. Nectary four scales beneath the

A genus of rigid Cape shrubs, of which Mr. Brown describes thirty-nine species, eight of which find a place in the Hortus Kewensis. The leaves are thread-shaped, pinnatifid or three-leaf, rarely undivided. Heads of flowers either terminal, or, from the bases of the uppermost leaves, either simple and solitary, or composed of several fleshy partial heads, or corymbose. Bracteas imbricated, membranous, mostly commonly shorter than the flowers, in a few instances longer, in some wanting. Flowers always fertile. Petals purple. Phylica from the length of the corolla, with a club-shaped, rarely cylindrical, stigma. Nut ovate, finely downy, sometimes bearded, sometimes nearly smooth. We select the following examples, among which are included all the species known in the gardens of England.

Sec. 1. Heads simple; the flower-flakes undivided or wanting.

S. pinata. Wing-leaved Serruria. Brown n. 8. Ait. n. 1. (Protea pinata; Andr. Repof. t. 512.)—Heads stalked, somewhat aggregate. Bracteas lanceolate, villous, nearly as long as the flowers. Corolla bearded. Leaves pinnatifid or three-cleft, longer than the heads. Stem pro- cumbent, hairy.—Gathered by Mr. Niven, on dry hills at the Cape of Good Hope, particularly in ascending Paarlberg. It flowered in Mr. Hibbert's garden, in the summer of 1837. In a natural state the stem is said to be perfectly prostrate, dividing from the base into branches about a foot long, round, downy, leafy. Leaves above an inch long, turned upwards, confiding of three or five awl-shaped segments. Heads of flowers red, about as big as a walnut, either solitary and terminal, or partly axillary; the young buds enveloped in the white silky hairs, which clothe the tips of the corolla externally.

S. cyanoides. Trifid-leaved Serruria. Brown n. 12. Ait. n. 2. (Protea cyanoides; Linn. Mant. 188. Willd. Sp. Pl. v. 1. 507.)—Cyanus ethiopicus, rigidus capillaceus tenuifilis folis trifidis; Pluk. Mant. 61. Phyt. t. 345. f. 6.)—Heads terminal, longer than their stalks. Bracteas roundish, pointed, villous. One segment of the corolla nearly smooth. Leaves spreading; the lower ones three- cleft; upper subddivided. Stem nearly upright. —Native of hills about the Cape. Mr. Brown gathered it on the sides of mountains, near Simon's bay. A shrub of humble growth, flowering with us in June or July. The branches are scarcely pubescent. Leaves not an inch long, rather hairy while young. Flower-flakes solitary, downy, generally but half the length of the heads of flowers, which are the size of a large cherry, rising above the upper leaves, and accompanied by membranous silky bracteas.

S. pedunculata. Woolly-headed Serruria. Brown n. 13. Ait. n. 3. (Protea glomerata; Andr. Repof. t. 264.)—Heads terminal, stalked. Bracteas ovate, downy. Corolla curved, feathery; its inner segment silky. Leaves twice or thrice pinnatifid, hairy, as well as the upright stem. Found in various billy situations at the Cape of Good Hope, where the soil is rather fertile. Moffrs. Lee and Kennedy are recorded as having first raised this species, in 1789, from seeds obtained from Vienna. It flowers in summer, and makes a handsome appearance, with its copious many-cleft leaves, and large heads of light reddish-brown flowers, clothed with fine white plumy down. The anthers are yellow. Stigma blackish.

S. hirsuta. Hairy Serruria. Brown n. 15. (Protea phyllocloides; Thumb. Diff. n. 9. Prodr. 25. Willd. Sp. Pl. v. 1. 510, excluding the reference to Bergius.)—Heads terminal, longer than their stalks. Bracteas linear-lanceolate, hairy. Corolla feathery. Leaves doubly pinnate, about as long as the heads. Branches hairy. Stem crect.—Native of Rocky hills at the Cape. Mr. Brown observed it near Simon's bay. It seems unknown in our gardens. This flower is twice the feet high, with straight unbranched branches, rough with spreading permanent hairs. Leaves copious, moderately spreading, an inch, or sometimes an inch and a half, long, hairy when young only; their segments very sharp-pointed. Flower-flakes often more than one at the top of each branch, half the length of the heads, with lanceolate-awl-shaped, spreading bracteas. Heads as big as a walnut, rising above the upper leaves. Corolla slightly curved; the hairs on its inner segment shorter than those of the other three. Stigma cylindrical, somewhat club-shaped.

S. nervis. Niven's Serruria. Brown n. 17. Ait. n. 4. (Protea decumbens; Andr. Repof. t. 349.)—Heads terminal, feefile. Bracteas lanceolate, the inner ones silky. Corolla bearded. Leaves doubly pinnatifid; the uppermost longer than the head, and smooth like the branches. Stem decumbent.—Discovered by Mr. James Niven, on Swartberg, a rocky mountain at the Cape of Good Hope, and sent by him to Mr. G. Hibbert in 1800. It blooms in the summer, and is of a small stature, and decumbent habit. The flowers are of a dull red, clothed externally with white silky hairs; and each solitary head, smaller than a hazel-nut, is enwrapped with numerous, crowded, radiating leaves. Each leaf of the general foliage is about an inch long. Stigma hardly thicker than the hyve. Mr. Andrews's plate represents the branches as somewhat downy.

S. phyllocloides Physica-flowered Serruria. Brown n. 24. Ait. n. 5. (Leucadendron phyllocloides; Berg. Cap. 29. Protea phorophorica; Linn. Mant. 188. P. abortanofilia; Andr. Repof. t. 507.)—Heads terminal or axillary, on fealy flarks. Bracteas half as long again as the head, lanceolate, smooth; the outer ones narrower. Tips of the corolla bearded. Leaves twice compound, longer than the flower-flakes.—Native of the Cape, from whence it was sent to Kew, by Mr. Maflon, in 1788; flowering there in July and August. This is a smooth upright shrub, with reddish leafy branches. Leaves generally bipinnatifid, an inch or two long, moderately spreading. The flower-flakes, clothed with several lanceolate scales, and either solitary, or aggregated in a corymbose manner, are longer than the heads, but usually shorter than the foliage. Heads above half an inch in diameter, subtended by many longish, deflexed, green, red-pointed bracteas. Corolla whitish and smooth, except the ends of the segments, which are red, and densely bearded. Stigma red, cylindrical.

S. florida. Large-flowered Serruria. Brown n. 26. (Protea florids; Thumb. Diff. n. 2. t. 1. Prodr. 25. Willd. Sp. Pl. v. 1. 506.)—Bracteas longer than the flaked heads; the outer ones elliptic-oblong, pointed, smooth; inner concealed, linear-lanceolate, fringed. Leaves once or twice pinnatifid.—Thunberg and Maflon gathered this species on the mountains of Fransch Hock at the Cape. It has not as yet found its way into our green-houses, which is much to be regretted, no other Serruria being comparable to it in beauty. The leaves are three or four inches long, smooth, as well as the branches, which are of a purple hue. Flowers many together, on corymbose fealy flarks at the ends of the branches, large, remarkable for their beautiful red external bracteas, which are each an inch or inch and half long, attended by smaller ones, of the same kind, scattered down the stalk, while the innermost bracteas, coming into view by the spreading of the former, are linear, fringed with
with yellow hairs. This is a very rare plant, even in dried
collections.

Seft. 2. Heuxi. — Partially divided.

S. argentea. Training Serruria. Brown. n 27. (Protea
dormant, smooth, as well as the three leaflets, whose
segments are undivided. Each pachial head of about
four flowers. — Native of the thorny hills of mountains,
at the Cape of Good Hope; not as yet known as a garden
plant. It is smooth, dividing from the root into several
prostrate, leathery, wavy branches. Leaves ascending,
about two inches long, in two or three simple, thickish,
linear segments. Flowers flat, axillary and terminal, slender,
flaky, each bearing a small roundish head, enveloped in
ovate, pointed, richly flaky bracts, and composed of from four to six
smaller heads. Corolla flaky, very finely cut. Mr.
Brown remarks that the tips of the heads are, apparently
from iteration or abortion, simple.

Pl. v. 1. 592. Leucadendron glomeratum; Linn. Sp.
Pl. v. 17. 157.) — Serruria folis tenuisflimdivis, capitibus tenuioribus;
Burm. Afr. 264. t. 99. f. 2.) — Stem erect, smooth,
like the doubly pinnatid leaves. Parallel heads of many
flowers. Inner bracts somewhat flaky. Common
flowers flaky. Stigma club-shaped — Found in thorny hill
places at the Cape. Mr. Moffin is said to have first
seen it about the year 1789, to Kew, where it flowers in July
and August. A rather humble flower, with reddish branches.
Leaves from one to two inches long, slender, quite smooth.
Flowers flaky; the common ones often aggregate and
raceemose, clothed with broad, smooth, softly imbricated,
flaky bracts; partial ones shorter than their respective
heads. Corolla externally flaky.

Seft. 3. Flower-flaks divided. Heads simple, corysthbo
or raceemose.

Ait. n. 7. (Protea Serraria; Linn. Mant. 188. Wildl. Sp.
137. Serraria folis tenuisflimdivis, floribus rubris spalatais;
Burm. Afr. 264. t. 99. f. 1.) — Abrotanoides arboresum;
O; Pluck. Mant. 1. Phyt t. 329. f. 1.) — Heads corysthbo,
each of about ten flowers. Corollas level-topped,
more or less flaky, shorter than the partial flaks.
Leaves doubly pinnatifid, bristle-shaped, longer than the flower-
flaks. — Native of low barren flats, about the fides of falls
at the Cape, very frequent. Mr. Mctton at it in 1760
to Kew garden, where it blooms from May to July.
A humble corystthbo flower, with very slender acute leaves,
which are slightly hairy. The heads are small, reddish,
crowned with the long prominent styles. Mr. Burmann
mentions a variety, or possibly distinct species, whose leaves are
rather flaky, heads more obtuse at their base, and bracts
as well as flowers, altogether flaky.

Ait. n. 8. (Protea triernata; Thumb. Diff. n. 1. 1. Prodr.
Kepo. t. 447.) — Corysthbus compound. Heads globose,
many-flowered. Bracts and partial flower-flaks flaky.
Leaves thrice ternate, smooth as well as the stem.
— Gathered by Mr. Niven, near the river at Rooke Zant, Cape
of Good Hope. Moffins. Lee and Kennedy are said to
have first raised this elegant species, about the year 1802.
It blooms from June to August. The leaves are four or five
inches long, and as thick as a crown's quill, being larger,
well as more compound, than in most other species. Heads
of flowers of a silver white, flaky, numerous, each
rather above half as much diameter. Stem suberect, yellow.

SERALISIA, to named after a Near East
plant, much admired by James Garden, to which
what part of his writings we are not informed, is a species
separated by Mr. Brown, in his Prod. Nov. Hall. v. 1. 593.
from the Latin Siderum, as the character does not
seem to have any ea. One of this new genera in
ed. 2. v. 2. 133; another is called by Mr. Brown
Sideralagonabata. Both are native of the tropical parts of New
Holland. See Sideralina and Sideralions.

SERLY, in Geography, a town of Honduras, in
Oude; 25 miles E. of trinacht.

SERTA, GARLANDS, among the Ancients. See Gar-
lons.

SERTAM, in Geography, a town of Portugal, on the
river Peri, at Estremadura; 24 miles N.E. of Thomar.

SERTINO, a river of Sicily, which runs into the sea,
on the null sail.

SERTORIUS, Quintus, in Biography, a distinguished
Roman commander, was a native of Norba, in the Picentine
regions of Italy. His father died when he was a boy,
but by the care of his brother he received a most excellent
education; and even in his youth he gained a considerable
reputation as a pleader at Rome. He had, however,
a decided turn for the duties and glory attached to a military
life, and made his first campaign under Servilius Capito,
against the Cimbrians and Teutones in Gaul. In an early
campaign he was severely wounded, and would have lost
his life, if he had not possessed sufficient vigour to swim
across the Tiber, when encumbered with his armour.
He next served under Marius, and exhibited proofs of valour
and talents, which much gratified him with that general.
Spain was the next great theatre of his exertions,
where he served under Dibus, and acquired much reputation in
the campaign. On his return to Rome, he was made quellor
in Cilician Gaul; and when the civil war broke out, he
brought a well-timed reinforcement to the Roman army.
In a battle that ensued, he lost an eye, a mark of bravery
in which he always gloriéd, and which pointed him out to
the plaudits of the people, whenever he appeared in the
theatre, and other public places. He was candidate for
the tribuneship, but was disappointed in his hopes by the
overbearing interest of Sertorius; he accordingly joined
the cause of Marius in the ensuing civil war. He com-
manded one of the three armies which invaded Rome, and
honourably distinguished himself by abstaining from all
those acts of cruelty which disfigured the arms of Cinna
and Marius. When Sylla gained the ascendancy in Italy,
Sertorius withdrew to Spain, of which country he had
been appointed proetor. Here he hoped to be able to revive
his caue, and with this view he detached a body of troops
to seize the path of the Pyrenees; but the murder of their
commander induced them to abandon their post, and conse-
quentially laid Spain open to Sylla's officers. After some
various adventures, chiefly of the cutaneous kind, Sertorius
went into Africa, and assisted the Mauritanians to throw
off the yoke of a tyrannical king; defeating one of Sylla's
generals, by whom he was supported. His reputation now
courted him to be invited to Lepontia; and failing thereto
with a small body of Romans and Africans, he obtained
such an ascendency over the natives, that he soon had the
command of the whole Lepontian nation. He exercised
them in the arts of warfare, and introduced a rigid discipline
among them; but Roman taets being unsuitable to them,
he adopted a service better suited to the nature and circum-
crances
Aances of the country. He defeated, with his new-trained armies, several Roman generals, who were sent against him, and instituted a senate in competition with that of Rome, and imitated all the forms of the republic. He foiled the attempts of that eminent commander, Metellus, to reduce him; continually harrying his troops by sudden attacks and skirmishes, and intercepting his convoys. He adopted the liberal policy of civilizing the Latinians and neighbouring Spaniards, and familiarizing them with Roman letters and customs. For this purpose he established a great school in the city of Oca, at which the sons of men of distinction were gratuitously educated, and at the same time kept as hostages for the fidelity of their parents. Feeling that his power was not sufficiently firm, without the aid of superstition, which ever captivates the ignorant and uncivilized, he trained a white fawn, that had been presented to him, to such a degree of tameness, that it followed him whererever he went, and was his constant companion; and he encouraged the belief that the animal was the gift of Diana, and intended by that goddes to convey information of the deigis of his enemies. At length the famous Pompey was nominated to the command against him; and when he arrived, he found that all the Roman troops, which, after the death of Lepidus, had been carried to Spain by Per- fenna, with the design of setting up there for himself, had joined Sertorius, who was now at the head of a considerable army. Pompey proceeded against him with a superior force; but Sertorius took a town in his presence, and afterwards defeated him at the battle of Suero. He gave him a second defeat; but Metellus routed a separate division, and Sertorius was glad to take to the mountains. He then offered to lay down his arms, provided the proscription against him might be taken off, and he were permitted to return to Rome. Soon after he received an embassy from Mithridates, the formidable foe of the Romans, offering him an advantageous alliance, provided he were suffered to repossess the provinces from which he had been expelled by Sylla. But Sertorius would not agree to more than his recovery of Bithynia and Cappadocia, without touching upon the Roman province of Asia; and upon these terms the treaty was concluded. A conspiracy was formed against Sertorius by the Roman patriots in his army, and they succeded in exciting a revolt in several Lusitanian towns. Incensed at this defection, he caufed several of the children, whom he kept as hostages at Oca, to be flain, and others to be sold as slaves. This is said to have been the only act of cruelty by which his memory is tarnished. In revenge for the loss of their sons, the conspirators formed a plot against the life of Sertorius; in conference of which he was barely assassinated, when he was at a festival. This event took place in the year 73 B.C. “The great qualities and military talents of this eminent person would undoubtedly have raised him to the first rank among the chiefs of his country, had he not been a leader of a party, instead of a commander for the state. With nothing to support him but the resources of his own mind, he created a powerful kingdom among strangers, and defended it a long time against the arms of Rome, although wielded by the ablest generals of his time; and he displayed public and private virtues, which would have rendered a people happy under his rule at a leas turbulent period.” Univer. Hill.

SERTULA CAMPANA, in Botany, a name given by some authors to mellilot.

SERTULARIA, in Natural History, a genus of the clas Vermes, and order Zoophytes. The generic character is this: the animal grows in the form of a plant; the stem is branched, producing polypous from cup-shaped den-
ARGENTEA. Denticles nearly opposite, pointed; vehicles oval; branches alternate, pinnate. This is an inhabitant of the European and American seas; very much resembles the last, but the branches are thinner and looser, and the pinnate is more obtuse.

* Rhodospira. Denticles nearly opposite, obsolete; vehicles much wrinkled, and three toothed; the branches are flattened. This species inhabits the European seas, and is found growing on the Flustra foliacea, and other Sertulariae.

* Haliclona. Denticles alternate, tubular, and two-jointed; the vehicles oval, each united along the side to a small tubular stalk; the stem is alternately branched and pinnate. This is found in the European and Mediterranean seas. It is horn color, and of a yellowish-grey; the denticles are nearly obsolete.

* Tilia. The denticles in this species are arranged in two rows, closely adhesion to the stem; the vehicles oblong, margined; stem waved and thick, with a tuft of dichotomous branches near the tip. It is found on the northern coasts of England, and in the Mediterranean, and is about half a foot long.

* Myriophyllum. The denticles are truncate, all leaning one way on the stem; the stem itself is gibbous on the side opposite the branches; the branches lean one way. This is found in most European seas, and in the Mediterranean; it is about three inches long, pale and horn color; the stem is rather angular, with arching protuberances opposite the branches; the denticles are arranged in a sloop furnished with a short spine on the lower part.

HYPOSIDAE. Denticles pointing one way, campanulate, toothed, and beaked; vehicles with pinnate branches, and very crowded subdivisions. It inhabits the Indian ocean, is fixed inches high; in color it is brown, with yellowish imbricate radicles.

*Spectabilis. Denticles campanulate, effuse, toothed, and fleshy; the stem is pinnate, rigid, with incurved branches, mostly pointing one way. It is found in the Indian ocean, adhering to the tubular radicles of gorgonize; it is brown, horn color, and from three to four inches long.

* Falcata. The denticles of this species point all one way; they are imbricate and truncate; the vehicles are ovate; the branches are pinnate and alternate. There is a variety of this species described by Ellis, in his work on Corallines. It inhabits the European and Indian seas, and is from three to six inches long; the stem is a little flexuous; the denticles in a single row.

* Plumula. In this the denticles point one way, they are imbricate and campanulate; the vehicles are gibbous and crested; the branches are pinnate, alternate, and lanceolate. It is found on most European coasts, climbing up face; the branches are jointed; the denticles are ferrate at the margin, and supported in front by a small hollow spine; the vehicles have a denticulate margin, and generally live oblique crested ribs.

ECHINATA. Denticles opposite, pointing one way, campanulate; the vehicles are crested; the branches pinnate, alternate, and lanceolate. It inhabits chiefly the shores of Sweden, on fuel.

* Antennina. The denticles are verticillate, in fours, falcate; vehicles obliquely truncate, verticillate; the stems are generally simple. There is a variety which is branched. They are both found on the British coasts, often nearly a foot high; it is yellow, with very fine capillary yellowish radicles; the stem is surrounded with small incurved falcate branches, on the upper sides of which are rows of small cup-shaped denticles; the vehicles are placed on pedicles obliquely open towards the stem, and placed round it at the insertion of the branches.

* Verticillata. The denticles in this are obsolete; the vehicles campanulate, toothed round the rim, on long, twisted pedicles, and placed in rows near the stem; the branches are alternate. It is found on the British rocks; stem ribbed, very lofty branched; the denticles are not visible; the vehicles are nearly erect, and glabrous; the ovaries are oval, ending as a tubular mouth.

GELATINOSA. Vehicles campanulate; stem with numerous decotomous spreading branches. It is found on the coasts of the Netherlands; is half a foot long, and of a grey-brown color.

* Volubilis. The denticles in this are obsolete; the vehicles are alternate, campanulate, toothed round the rim, on long, twisted pedicles; the branches are alternate. It inhabits European seas, climbing up of a verticillata; it is whitish and minute; the stem is broadly branched; the ovaries are egg-shaped and smooth, or transversely wrinkled.

* Synhia. Denticles obsolete; vehicles cylindrical, mostly alternate, and placed on short twisted pedicles.

* Cuscata. Denticles obsolete; vehicles ovate, axillary; branches opposite and simple. It is found in the European seas, adhering to fuel.

* Pustulosa. Stem with alternate dichotomous branches, obliquely denticulate on the upper part. It inhabits the shores of the Isle of Wight, and is four inches long. The stem is long arising into alternate dichotomous joints, with small denticles, having a circular rim, with a point in the middle of each towards the upper part of each joint.

* Frutescens. Denticles cylindrical, campanulate, placed in a single row on the side of the branches; the branches are alternate, and pinnate. This is chiefly found on the British shores; rather hard, blackish with brown branches; the stem is composed of small united tubes.

PINASTER. In this species the denticles are opposite, effuse, with an incurved tubular tip; the vehicles are large, ovate, quadrangular; the angles terminating in a spine, and furnished with a tubular mouth in the centre, placed in a row along the branches; the branches are alternate.

* Pennatula. The denticles in this are in a single row, crenate on the rim, and supported by a slender, truncate, incurved horn; the branches are opposite. It is found in the Indian ocean; is five or six inches long; yellowish-brown; the denticles have two opposite spines on the rim.

* Filicula. Denticles opposite, ovate, with a single crest on the summit of the branches; vehicles obovate, with a tubular mouth in the centre; the stem is zizag-zizag, with alternate branches. It inhabits the British shores, is very tender, and the stem is much branched.

QUADRIDENTATA. Denticles in fours, opposite, at the joints of the stem; the stem is simple, with the joints tapering and twisted towards the base. It inhabits the African shores on the Fucus lenticigerus.

* Spicata. Denticles in three, cylindrical, terminal, and nearly closed at the mouth; vehicles ovate, axillary; stem tubular, pinnate, annulate, with trachydonous branches dished in whorls round the rings.

* Evansii. The denticles are short and opposite; the vehicles are lobed, arising from the branches which are opposite. It inhabits the British coasts, and is found on fuel; it is two inches high, very slender, and yellow, with fulvous vehicles.

* Muricata. The denticles of this species are pedicled, proceeding alternately from the joints of the branches; vehicles ovate, spiny; the stem is jointed. It is found on the shores of Scotland; the vehicles are nearly globular, S placed...
placed on pedicles, and full of pointed spines from crinkled ribs.

Secundaria. Denticles in a single row, campanulate; the vessels are axillary; the stem is minute, white, and incurved. This species is found in the Mediterranean; it is scarcely three lines high, and not thicker than a fine bristle.

Misenensis. The denticles are alternate, very thin, spreading; the vessels are oval, peduncles axillary; item much branched, dichotomous. It inhabits the Mediterranean, is very fleshy, pollicul towards the tip, and sometimes covered with the Cancer linearis.

Racemosa. Denticles scattered, pollicul; vessels clustered; item flat, round, opaque, horny, with slightly curved branches. It inhabits the Mediterranean.

Uva. Denticles obsolete; vessels ovate, clustered; item flat, branched, with alternate subdivisions. It inhabits the shores of this country and Holland, adhering to other zoophytes; vessels transparent, with a white nucleus.

* Lendigera. Denticles obsolete; vessels cylindrical, arranged in a single row along the branches, and growing gradually less towards the top; the item and branches are jointed. This is found on the European coasts, on other zoophytes. The branches are subdivided and irregularly interwoven; the vessels are placed in parallel ranks along the infide of the branches, and growing gradually shorter towards the top of the joints.

* Geniculata. Denticles alternate, twisted; vessels obovate, with a tubular mouth in the centre; the item is branched, jointed, flexuous. It inhabits the European coasts, adhering to felci.

* Dichotoma. Denticles obsolete; vessels obovate and axillary, on twisted pedicles; the item is dichotomous, with twisted joints. It inhabits the British and Dutch coasts, and is nearly a foot long; it is white, but becomes tawny with age.

* Spinosa. Denticles obsolete; vessels ovate, fusiform; the branches are dichotomous and spinous. It is found on most European coasts, as well as on those of this country, and is about eight inches long. The item is composed of interwoven tubular fibres; the branches are flexuous, loofe, forked, with pointed tips.

* Pinax. The denticles of this species are obsolete; the vessels are oblong, and surrounded with a corona of tubercles at the rim; item simple, pinnate, and lanceolate. It is found in Europe and in India, and is about three inches high. The item is simple, with alternate subdivisions; the vessels are placed in clusters round the item.

* Setacea. Denticles obsolete, remote, placed in a row on the upper side of the branches; vessels oblong, axillary; the item is simple, with alternate bent divisions. It inhabits the European coasts, and is about an inch and half high.

* Polyzona. Denticles alternate, slightly toothed; vessels obovate, transversely wrinkled; the item is loose, branched. It inhabits moist seas, adhering to marine substances.

* Pennaria. The denticles are placed in a row on one side the branches; the vessels are oval; the item is twisted, and doubly pinnate. It inhabits the Mediterranean sea, growing in tufts on rocks; the item is straight, ascending, flexible, horny, brown, with whitish branches.

* Lichenastrum. Denticles alternate, obtuse, in two imbricate rows along the item; the vessels are oval, in two parallel rows along the branches; the item is simple, alternately pinnate. It is found in the Irrib, Indian, Asiatic, and Armenian seas. The item is erect, jointed, compressed, and denticulate; the branches are alternate, denticulate, and straight.

Cedrina. Denticles subcylindrical, tubular, in four imbricate rows; the branches are irregular, quadrangular, and thicker upwards. Inhabits the seas of Kamchatka; the branches are dichotomous, obtuse, with four rows of vessels.

* Simbricata. The vessels of this species are subcylindrical, irregularly imbricate upwards; the item is slightly branched. This species is described and figured in the 5th vol. of the Linnaean Transactions. It inhabits the western coast of Britain, on the Fucus nodulosus; it very much resembles the last, but the vessels are not placed in any regular series; it is about three inches high; the smaller branches have the vessels placed bifurcately, but towards the tip they become imbricate.

Purneae. Denticles subovate, tubular, in four imbricate rows; the vessels are erect and campanulate; the branches are dichotomous and square. It inhabits the sea round Kamchatka, and is of a blackish-purple.

Articulata. Denticles pressed together; the vessels are ovate, rather large, covered with a bud, and placed in a single row; the item is jointed and pinnate. It is found in the Atlantic ocean, creeping on shells, and is about two inches long; pale yellow.

Ficilina. Denticles imbricate, placed on one side only; vessels jointed, item granulate, branched and pinnate; the subdivisions alternate. It inhabits the Indian ocean, is pale, and about three inches long.

Fruticans. The denticles of this species are in a single row on one side; semi-campanulate; the item is granulate, woody, with alternate tetradont subdivisions. It inhabits the American seas in tufts, on shells; it is fix inches long, and of a yellowish-grey.

B. The species of this division have a crustaceous item, inclining to flims, and composed of rows of cells; they have no vessels, but in the place of these there are small globules.

* Bursaria. Denticles opposite, compressed and truncate; the item is branched, and dichotomous. It is found on the British coasts, adhering to felci; it is minute, flexile, lyaline; the denticles are carinate, with a small clavate tube at the top.

* Lorictmata. Denticles opposite, obliquely truncate, and nearly obsolete; the branches are erect and dichotomous. It inhabits the British coasts, on old felteraria.

* Fastigiata. Denticles alternate, pointed; branches dichotomous, erect. This is found in the British seas; the denticles are marked with a black spot in the middle.

* Arctiliana. The denticles all point one way, nearly opposite, and furnished with two mucronate appendages; the globules appendaged; the item is branched and dichotomous. It is found in the European seas; is from one to two inches long; in colour it is of a dirty grey. It is very brittle.

* Neritina. The denticles are alternate, acute, and pointing one way; the branches are dichotomous, unequal, and straight. It is found in the European and American seas. It is soft; the globules have an opening surrounded by a dark-coloured margin.

* Scruposa. Denticles alternate, angular, spinous; the branches are dichotomous and creeping. It inhabits moist flats; is very brittle, linear, and pale, with a double row of cells.

Pilosia. The denticles are alternate, oblique, with a long mouth; the branches are dichotomous, fastigate, and strong.
Denticles.

E. The species is very much branched, dichotomous, erect, and with deformed ovate joints, armed with cells on one side. It inhabits the Rill, is large, flexible, and of a pale-grey colour.

FUCOSA. This is very much branched, dichotomous, erect, with wedge-shaped joints, having cells on one side. This is found only in the Indian ocean; is large, whith, and with greyish flexile joints.

* REPTANS. Denticles alternate, two-toothed; the branches are dichotomous and creeping. This found in the European seas, adhering to the Limita fusacea; it is not an inch long; white or pale-grey.

PARASITICA. The denticles of this species are verticillate, turbinate, elliptate, and parasitical. It is found in the Mediterranean and North seas, adhering to other fucitarias and corallines; in colour it is dull red, with terminal denticles.

* CILIATA. Denticles alternate, ciliate, funnel-form; branches dichotomous and erect. It inhabits the European seas, on marine tubulifera; not half an inch high; it is whitish; the cells have wide mouths.

* ERUSA. The denticles are alternate, truncate, a little prominent; the cells are gibbous, with a tubular beak on one side; the branches spreading. This inhabits the European and Mediterranean seas, and is found growing upon other fucitarias and fucus; is about an inch high, and white.

* CONSULTA. The denticles are alternate and truncate, with a single hair on the top of each; the cells are gibbous, with a tubular beak; the branches are alternate. This inhabits, like the last and following, the European and Mediterranean seas, on rock; it is fuscous, clear white, and not half an inch long. The denticles are curved, tapering towards the base, and placed on each other.

LORICATA. Denticles in a concatenate row, pointing one way, with a margined mouth, horned beneath; the branches are alternate. It is found on fucus. The denticles are like inverted horns placed on each other, with a short hair on the top.

* ANGENS. The item is very simple, without denticles, but bevel with very simple, obtuse, clavate arms, each with a lateral opening. This is found climbing on marine frustules; it is white, soft, flexible, varying in form, and appears to connect the fucitaria and hydras; the arms are tellacous.

CEREBORIDES. Denticles imbricate, with somewhat prominent mouths; the item is branched, jointed, and cylindrical. It inhabits the coast of Africa; is three inches high; whitish, fuscous, aggregated, with short joints.

TULIPHEM. Cells in threes on the upper part of the joints, and united together; item branched, with clavate joints. It inhabits the Well Indies, adhering to rock, about half an inch high, and clear white; the item is thin and subfuscous; the cells are terminal.

FELLELUM. This species is fuscous, branched, jointed, dichotomous; the joints are somewhat wedge-shaped, and have cells on one side. It inhabits the Bahama islands; is about two inches high, white, growing in tufts; the joints are convex and fuscous on one side; the others are flat, with a triple row of cells.

TENNATA. Branched, dichotomous, jointed, creeping; the joints are angular at their sides, with three cells in the front of each. It inhabits the thores of Scotland; it is fuscous, semitransparent.

CIRCADIA. Stony, jointed, flat, dichotomous, incurved, the joints are subfuscous, ovate, truncate, flat, and bearing cells on one side. It inhabits the lady, is about 1.2 inches high, and white, the thores are angular, and fructivate on one surface; the other is flattened, with a row of cells.

ORIENTALIS. Branches in threes, with sigmoid joints, covered with oblong prismatic cells. It inhabits the Euthen sea; is about half an inch high, erect, very much branched, white, fuscous, with the spores driped in a quincunx form.

SERVA, in Geography, a town of Perhia, in Sicyonia, 182 miles S.S.W. of Corinth.

SEVAGE. See Service.

SERVAIN, in Geography, a town of France, in the department of the L'Isle d'Avel, and chief place of a canton, in the district of St. Mabo. The place consists of 436, and the canton 10,617 inhabitants, in 4 communes.

SERVANDONI, John, in History, an eminent architect, was born at Brescia in 1607. He was employed by several of the sovereigns in Europe on occasions of magnificent public spectacles, in which he displayed a very fertile invention, with noble ideas, and a correct taste. At Paris he had the direction of the theatre during 18 years, and was architect, painter, and decorator to the king; and was admitted member of the several academies of arts. He gave a number of designs for the theatres of Dresden and London, and was sent by the latter capital on the rejoïgns for peace in 1749. He preceeded at the grand festivals exhibited at the court of Vienna, on the marriage of the archduke Joseph and the princes of Parma. The king of Portugal frequently employed him, and honoured him with the order of Car. He died at Paris in 1766, having acquired the reputation of being the first artist of the period in which he flourished. As an architect he has left a fine specimen of his taste in the portico and front of the church of St. Sulpius.

SERVANT, servus, a term of relation, signifying a person who owes and pays a limited obedience for a certain term to another, in quality of master; in contradistinction to one, over whose whole life and fortune the master claims an absolute and unlimited power. See Slave.

The first sort of servants, acknowledged by the laws of England, comprehends "menial servants; so called from being inters menos, or domestics. The contract between them and their masters arises upon the hiring: if the hiring be general, without any particular time limited, the law construes it to be hiring for a year (Co. Litt. 42. F. N. B. 168.); but the contract may be made for any larger or smaller term. All single men between twelve years of age and sixty, and married ones under thirty years of age, and all single women between twelve and forty, not having any visible livelihood, are compellable by two justices to go out to service in husbandry, or certain specific trades, for the promotion of honest industry; and no master can put away his servant, or servant leave his master after being so retained, either before or at the end of his term, without a quarter's warning, unless upon reasonable cause, to be allowed by a justice of the peace (ibid. 5 Eliz. c. 41.); but they may part by consent, or make a special bargain.

Another species of servants includes those called appren- tices (which see): a third sort belongs to that class denominated labourers. See Labour and Labouers.

And there is a fourth species, if they may be called servants, being rather in a superior capacity of service, such as factoris, factors, and bailiffs, whom, however, the law considers
A servant may maintain, i.e. abet or assist his servant in any action at law against a stranger; he may also bring an action against any man for beating or maiming his servant, assigning his damages by the loss of his services, and proving the loss upon the trial; he may likewise justify an assault in defence of his servant, and a servant in defence of his master (2 Roll. Abr. 546); and if any person hire or retain my servant, being in my service, I may have an action for damages against both the new master and the servant, or either of them; but if the master did not know that he is my servant, no action lies, unless he afterwards refuse to restore him upon information and demand. F. N. B. 167, 168.

As for those things which a servant may do in behalf of his master, they seem to be grounded on this principle, that the master is answerable for the act of his servant, if done by his command, either expressly given or implied; therefore, if the servant commit a trespass by the command or encouragement of his master, the master shall be guilty of it: if any inn-keeper’s servants rob his guests, the master is bound to restitution (Noy’s Max. c. 43); and if the drawer at a tavern sells a man bad wine, by which his health is injured, he may bring an action against the master. (1 Roll. Abr. 95.) In the same manner, whatever a servant is permitted to do in the usual course of his business, is equivalent to a general command; if I pay money to a banker’s servant, the banker is answerable for it; if a steward lets leaf of a farm without the owner’s knowledge, the owner must stand to the bargain: a wife, friend, or relation, that used to transport buffer for a man, are bound for his servants, and the principal must answer for their conduct.

Further, if a servant, by his negligence, does any damage to a stranger, the matter shall answer for his neglect: if a smith’s servant lames a horse while he is shoewing him, an action lies against the master and not against the servant. A master is chargeable if any of his family layeth or carrieth any thing out of his house into the street, or commonly

high way, to the damage of an individual, or the common nuisance of his majesty’s liege people. In case of fire the servant is accountable. Blackit. Comm. book i. See LARCENY.

Much depends upon the sobriety, integrity, and diligence of servants; and the case with which they obtain characters, or procure employment with such characters, real or fictitious, as they gain, is very injurious both to their employers and to themselves. Characters are given with so little reserve and veracity, “that I should as soon depend,” says the author of the Rambler, “upon an acquittal at the Old Bailey, by way of recommendation of a servant’s honesty, as upon one of these characters.” At the same time another extreme should be avoided, which is that of obstructing the advancement of a faithful and serving servant, either from remittance, caprice, or self-interest. In order to form good servants, attention should be paid to their domestic conduct, and that kind of discipline should be exercised at home which may contribute to prevent their corruption and misery.

What the Christian seriptures have delivered concerning the relation and reciprocal duties of masters and servants, breathes a spirit of liberalty, very little known in ages when servitude was slavery; and which flowed from a habit of contemplating mankind under the common relation in which they stand to their Creator, and with respect to their interest in another existence. (Ephef. vi. 5—9.) “Servants be obedient to them that are your masters, according to the flesh, with fear and trembling; in singlenefs of your heart, as unto Chrift; not with eye-service, as men-pleasers, but as the servants of Chrift, doing the will of God from the heart; with good will, doing service as to the Lord, and not to men: knowing that whatsoever good thing any man doth, the same shall he receive of the Lord, whether he be bond or free. And ye masters do the same thing unto them, bearing threatening; knowing that your master also is in heaven; neither is there respect of persons with him.” The idea of referring their service to God, of considering him as having appointed them their task, that they were doing his will, and were to look to him for their reward, was new; and affords a greater security to the master than any inferior principle, because it tends to produce a steady and cordial obedience in the place of that constrained service, which can never be trusted out of sight, and which is justly enough called eye-service. The exhortation to masters, to keep in view their own subjection and accountablenes, was no less reasonable.

The Romans, besides their slaves, whom they also called servii, had another kind of servants, whom they called nevi and addici, who were such as being in debt, were delivered up to their creditors by the praetor, to work out the debt, after which they were again at liberty.

The pope, out of his wonderful humility, calls himself in his bulls, the servant of the servants of God, servorum Dom. The first who used the appellation, as Dianconius tells, were pope Damasus, and Gregory the Great, which last is said to have used it to check, by his modesty, the arrogance of John, patriarch of Constantinople, who took the title of acumenical. Du-Cange adds, that the title servant has been assumed by some bishops, by some kings, and some monks.

SERVANT, in Agriculture, a person employed in the performing of some part of the busines of a farm, of whatever kind it may be. On this subject, the following judicious hints have been thrown out by the author of the “Landed Property of England,” for the direction of those servants who have the conducting of the management of farming
farming businesses. Nothing, he contends, contributes more to facility and satisfaction in this sort of businesses, than a forecast toward works to be done. A miscarriage is ever to be dreaded as a mischief; and when it is brought on by a want of forethought, it brings with it a degree of discredit, and a train of unpleasant reflections, which hour every enjoyment. This kind of servant should, he thinks, have a forecast towards crops for two or four years; toward team labour for as many months; and should look forward with a view to hard labour for some weeks, according to the season of the year. And bringing it to a deeper of certainty, it is necessary to produce a bill of the fields, or parcels of land, of which the farm consists; with the crops which each has horse for some years back; together with the manurings which they have severally received, in order that the future treatment of each may be decided upon with sufficient accuracy. And to prepare every autumn, by the assistance of such little, an arrangement of the crops that are intended for the ensuing year; classing the fields, or pieces, according to the purpses for which they shall be intended: thus ascertaining the quantity of each crop, whether arable or grass, as well as the quantity of ground intended for pasture; in order that the quantity of team-labour may be distinctly foreseen,—the required strength be estimated from time to time,—and the several crops be in due season; and in order that the flock of the ensuing summer may, in due time, be properly apportioned to the intended quantity of pasture ground; as well as that the works of summer and harvest may be constantly before the eye; and proper hand be engaged, in time, to perform them in season, and with the necessary dispatch and certainty. And he further advises a sort of memorandum list to be kept of businesses to be done,—immediately,—or in immediate succession; whether it relate to crops or to any other concerns of the farm; that nothing may escape the memory; and that the mode requisite may be brought forward hour; or another which is more suitable to the state of the weather, or other circumstances. In this, as well as other businesses, the great object to be aimed at is that of ensuring successes; which is not only profitable to an employer, but satisfactory to the person employed. Whereas a miscarriage injures at once the property of the one, and the character, as well as peace of mind, of the other. Hence a farm manager ought to engage in a work, whether of improvement or ordinary practice, with caution; and to proceed in it with attention and firmness. A standing rule, respecting this main object of management, is not to attempt too much, and never to begin a work without a moral certainty of being able to finish it in due season. Further; but besides the common work of a farm, as the culture and harveiting of crops, the rearing and fattening of live-stock, and the businesse of markets; there are various other objects of attention which ought to be constantly kept in the mind, or in the mind's way, of a manager; as on them the difference between good and bad, between correct and flaviouy management, very much depends; such as keeping the homelake in repair, and free from impediments; attending to private roads and driftways; keeping up fences, every where, in thorough repair; attending particularly to young hedges, and to the rearing of hedge-row timber; the seeding that gates lie clear, and catch with certainty; equally to preserve them from injury, and to prevent the flock from going astray; the attending to drains and water-courses; to see that superfluous waters have free passages to their proper outlets, and be readily discharged. And it is advised, that in summer strict attention be paid to drinking-pools and other watering places of stock, as well as to the state of pasturing, and the shifting of pasturing flock. Likewise to weeds, as well in grass grounds as in arable lands, to see that not a thistle blows, nor any other weed marries its bed, either in the areas, or on the borders of fields; as great injury is done by their shedding their seeds. Also in winter, much care is necessary to the cattle flock, not only to see that they are regularly supplied with proper fodder, but that sufficient shelter and comfortable rooms are assigned them, so that they may be kept in a proper thriving state. At this season also the watering of grass lands should be attended to as much as the nature of the situation will admit. And to the accumulation of manure an unremitting care should be bestowed the year round, as upon it much depends. And on the whole, to perform these and other objects with propriety, repeated examinations of every part and particular under his care; and committing to his memory whatever requires his more immediate attention; so that whether he is on the spot, or arranging his plan of operation, in the hour of leisure, it may be present to his mind, and take its proper course in the routine of work which is to be carried forward.

It may be noticed, that in the time of work the businesses of a managing servant lies in the field, in executing the plans he has formed, in passing from one set of workpeople to another: not more to see that the different operations are rightly executed, with proper dispatch, than to order any required assistance, (to the teams most especially,) in order that every part of the machine may be kept in profitable motion. And that in the ordinary operations of husbandry, and on common occasions, a steady even pace be recommended; equally for the good of working animals, and the work which they are performing. Nevertheless, there are times when quick dispatch is necessary; and then it is his duty to encourage good speed; by his example, and by promises of reward, if the occasion require it. That at all times, and on every occasion, idleness is a crime which ought not to be suffered to pass with impunity. It is a direct fraud; and a manager should guard against its harm the care and affluency as against pilfering. A day labourer who idles away an hour, robs his employer of an hour's wages; and thereby injures him as much as if he were to steal a farthing of equal value. This truth requires to be deeply imprinted on the minds of labourers. He has known the impression to have a good effect. But he properly remarks, that the right ordering of servants and workpeople is a difficult branch of moral duty; and forms an important part of that of the managing servant. They require to be treated according to their respective merits; encouraging bad ones by extra wages, or other rewards. Some men are worth double the wages of others, as day labourers. Yet custom makes no distinction between these in this respect! Hence the propriety of engaging the best workmen the country affords; and retaining them, by civil treatment, and suitable encouragement. The managing servant should keep his workpeople at a proper distance, without destroying that free communication of opinion respecting the work in hand, which, on ordinary occasions, every intelligent workman should be allowed. And a standing rule of conduct, in the ordering of workmen, is never to find fault without chiding with nor to commend, without reproof. Good fellows will not brook the former, nor will bad ones be mended by the latter. But it is right to habituate workmen in general to be told of their faults; first, in the mildest terms the occasion will admit of; referring the warmth of temper for extraordinary occasions.
occasions; and it is prudent to fit them with keen, rather than to load them with heavy, words: to endeavour to fit up their pride, rather than their malice or refinement. And much of the smoothness and uniform success of business depends on the manner of communicating orders to workmen. If orders are inaccurately or loosely given, it is unreasonable to expect that the execution of them should be faultless. It is difficult to explain business in words with sufficient accuracy to rustic workmen; and if a third person is suffered to intervene, errors are inevitable. The servant who has the management ought therefore to make a point of giving orders, in person, and if possible on the spot, to the men whom he means shall execute them. There he can explain himself to them intelligibly and fully; or affix them in marking out their work. There is always danger in merely verbal orders; and, in a message, certain mischief. It should be an invariable rule for him to let his men to a fresh work, in person; and if it is out of the common way of husbandry, to stay by them, or direct them with his own hands; and return to them, again and again, until he finds them completely in their work. In this view, this sort of servant, as well as for various other reasons, ought to be master of every implement, tool, and operation belonging to his profession; and if he find himself deficient in any particular, he should practice it day by day, until he make it familiar to him; or how is he to correct a bad workman; or to know when to be satisfied with a good one; who, knowing when he is right, will not bear the reproaches of ignorance? He has no other way of securing the clemency and attachment of good workmen, and of winning in a workman-like manner every thing he undertakes, than by making himself master of his business; without which little satisfaction will arise from it to himself, or profit to his employer. And in the general principles of conduct, in his dealings and intercourse with other men, punctuality is one of the most essential. Method is the best affluence of punctuality; and clear accounts are one of the best results of method. These should always be kept with exactness, and be sent, when required, to the proprietor, in weekly, monthly, and annual periods, so as to shew the daily rate of the work; the monthly rate of receipts and payments; and, lastly, the whole rate of accounts and balances.

Besides, it is extremely necessary for the farmer to be careful in providing his servants, not only to see that they are proper for the work, but that there be not more than are necessary for executing it, as the expense of them is now become extremely great. It has long since been recorded by the above writer, in his “Minutes of Agriculture,” that on the matured calculation he found the yearly expense of a man servant in the house to be 37l., and that of a boy 23l., supposing the man’s yearly wages to be 12l. and the boy’s 7l. Now the expense of a day-labouring man for a whole year (if he works every day) is but 27l. 10s., which is 7l. 10s. difference against keeping a man in the house by the year, and hiring one by the day. But that of a boy is still more in proportion, viz. the expense of a day-labouring boy for a whole year, if he works every day, is but 13l., which makes a difference of 12l., or more than three-fourths of a boy’s day-wages. In the above account, no deduction in the daily pay is made for rainy days. The impropriety, therefore, of keeping plough-boys in the house is very visible: and though it may be convenient to have the carters about the house, the convenience is not worth 7l. 10s. a-year. He therefore recommends putting a woman into a cottage, within about two hundred acres of the farm-yard, to take in lodgers; and to keep in the house no more farming servants than a butcher and a yardman. Indeed he says it is absolutely necessary to have somebody about a farm-yard in cases of emergency; but the above two are sufficient, as the carters in the adjoining cottage will be nearly as handy as if they were in the house. This measure, it is observed, like many others, is merely local, but the hint is universal.

But perhaps the farmer, who keeps no accounts, imagines he saves money by boarding his servants in the house; however, if he keeps them in the luxurious manner which farming-servants in general expect to be kept, he will be mistaken. A farmer, indeed, who sits at the head of his kitchen-table, may no doubt feed his men considerably cheaper, than a person who eats in a separate apartment. It is a jufit observation, that one fed by his master costs the community as much as two who provide for themselves; for discharge a grumbler, one who pretends to be dissatisfied, though in fact only satiated, and he will return to his bread and cheese with perhaps equal health and equal happiness. He sits down to his master’s table with a resolution to eat voraciously of the beef, to do himself justice; but at his own table eats sparingly of the meanest, to save his money. His motive in both cafes is the same; self-interest. The plan here inculcated is at this time still more necessary than it was at a former period.

And it is added, that in some counties, particularly in Surrey, it is an established custom for every man, in harvest, to work by the acre, or by the month, not by the day. If a labourer be constantly employed through the year, he expects during harvest to be constantly employed in mowing, reaping, &c. by the acre, or to have his harvest-month; that is, to have an advance of wages certain, wet or dry, during one month; which month commences when it belt suits his employer. This is very convenient; they are always at command in cases of emergency; and nothing but a continuance of rains while the barns are empty can make them burdensome. He strenuously recommends the employing of active young men; for one invalid or sluggish fellow will spoil the whole set; and this holds generally. Mix two or three old women, or two or three boys, with a company of men, and the effect will be very soon visible; for the men will soon conform to the ways of either the old women, or the playfellows of the boys. It is not prudent to employ many women with the men; and nothing but necessity can excuse it. Two women after the first or second day, will do as much work as half a dozen, alone. If it be necessary or convenient to employ a number of both men and women, it is but common good management to keep them separate; with this exception, which may be laid down as a maxim, viz. one man among women, and one woman among men. A cleanly conceited old fellow will check the goffipping of the women, and it has been remarked that raking after a young wench has animated more than a gallon of ale. Two are dangerous; they breed contention, and rather retard than accelerate. The most valuable servant in harvest is a good carter. It is necessary to common management that he should be able, willing, and careful. Every pitch of hay and corn, generally speaking, palates twice through his hands; he loads and unloads, which are the two most laborious tasks of harvest; he drives the team backwards and forwards; if he loiters by the way, the field-men or slack-men must stand idle; if he spill or overturn his load, or if he break his waggon, or set his horses, the arrangement of the day is broken; and, perhaps, the damage done by the loss of time rendered irreparable by the next day’s rain. A good carter will not suffer
fuffer his waggons to be overloaded. The field-men, too, that is, the pitchter and all-hands leader, should be young and active, and well matched with the carters.

But since the above was written, the prices of servants have considerably increased in every district of the kingdom, and the expenses of keeping them have been greatly augmented. This has led to fewer being kept, and especially in the house. It is said, that in Hertfordshire the annual wages of a carter or ploughman was formerly from six to nine guineas; boys from two to four guineas; and maidservants about five guineas; but they have since risen to nearly double these sums. And formerly in Norfolk farm-work was particularly distinguished by the cheapness as well as expedition with which it was performed; which, it is said, arose not merely from the cheapness of labour, but the greater exertions of servants and labourers than in most other districts; but this is considerably diminished at present. In some parts of that district the custom of allowing board-wage to farm-servants, instead of the old plan of feeding them in the house, is coming into use; and 8s. a-week are given. This is a bad, immoral regulation, which should be discontinued. In Yorkshire the wages of servants have also been greatly increased. In the West Riding the wages of a house servant (of which kind most of the ploughmen are) may be estimated from 25s. to 30s. yearly, including maintenance. There is a practice which prevails over a considerable part of this district, of giving them drink both forenoon and afternoon, to be the work it will; which is a ridiculous custom, and ought to be abolished without loss of time. What can be more absurd than to see a ploughman floating his horses half an hour, in a cold winter day, to drink ale? But the practice is so deep rooted, that it will not be easily removed without a compensation. It is suggested that the proper remedy is to let the value of the ale be paid to the servant in money, which probably would be as much for his interest, and certainly more advantageous to the farmer. In those places where long yokes are taken, say seven or eight hours, it may be necessary to feed both men and horses on the ground; but this practice cannot be recommended unless in urgent cases, it being very injurious to their health. In the belt regulated agricultural counties, five hours labour in the morning and four hours in the afternoon, when the feallon allows, and five hours, or four hours and a half, in short days, is considered to be as much as horses are capable of sustaining, and yokes of this duration require to refreshment on the ground. And it is added, that the hours of labour for men are generally in summer from six to fix, with the usual time for rest and refreshment, which gives between nine and ten hours labour each day, and in winter from light to dark. Much of the farm-labour, such as ditching, hedging, threshing, &c. is done by the piece, but the prices vary greatly in different places. And it may be added that when the farmer is a proper judge of his men's abilities, piece-work is not only most to his advantage, but the only way by which an active diligent servant can be properly rewarded for his labour.

In Berkshire, and many other counties, great care is taken to keep no more servants in the house, by the farmers, than are just sufficient for performing the ordinary business to be done. The pay of a carter is there from nine to twelve guineas the year; an under carter from four to seven guineas for the same length of time; a shepherd from eight to ten guineas, and the run of a few sheep; a boy from two to three guineas; and a dairy-maid from five to ten guineas, in proportion as she may be qualified.

In the manufacturing districts of Cheshire and Lancashire, the wages of house-farming servants run in this way.

They have lately been considerably on the increase in both of these districts.

In the county of Essex, and many other districts which are principally agricultural, the work of the farms is in great measure executed by hired daily or weekly labourers, very few yearly servants being kept by the farmers. This is supposed, in many instances, to be not only the cheapest, but the most convenient method of having such sorts of work performed; and the farmers are, at the same time, the most free from trouble in their houses and families. In the very southern agricultural districts of Devonshire and Cornwall, the wages of the farm servants, kept in the house, with washing and lodging, are, in the former, for a carter or head man, ten pounds a year; in the latter, and other parts of its extent, from eight to twelve guineas, with their board, for men, and from three to four pounds, with the same for maid servants during the year. These rates, however, vary a little, according to the qualifications of the servants, and the nature of the situations and farms.

In the county of Herefordshire, where the hours of labour are from light to dark in the winter, and from six in the morning to the same hour in the afternoon, in summer, the following are the average prices of wages now given to servants kept in the house by the farmers:

<table>

Likewise in East Lothian, in Scotland, the wages are mostly from ten to fourteen pounds per annum; but instances of servants is but small. The female servants have from four pounds to four pounds ten shillings, or five pounds. And in Clydesdale, the greater part of the agricultural labour is performed by servants hired by the half year, and living in the farm-houses. In many parts of the county the women servants work along with the men, at almost all kinds of out-work. But as more hands than ordinary are needed for cutting down the corn in harvest, and many haddowmen, to secure a fixed number for that purpose, when they can be got, contract with villagers to allow them during the time of reaping. All these labourers have no fixed hours, but continue their labour while light and weather admit, and circumstances require. The poor girls, when light is gone and the men fit down by the fire, refuse their household labours.
The labourers, both men and women, are sometimes hired by the day, particularly in the time of planting, sowing, and hoeing turnips and potatoes, hay-making, and harvest, when a fixed time is not provided. These work only ten hours in the day, beginning at five in the morning and stopping at six at night, and taking an hour to rest at breakfast, and another at dinner. Hired labourers, in winter, take breakfast before they go out in the morning, make a short pause to eat a little at mid-day, and quit when light fails in the evening. The following are the prices of wages.

But in Perthshire, for a man servant, who is master of all the operations in farming, only receives, in the corn country, between eight and twelve pounds, for twelve months. In the grazing districts, more remote from the seat of manufactures, their wages, and the price of all kinds of labour, are about one-fourth lower. But in many cases the servants are maintained in the farmer's family; but the practice of giving them land and a half galley of meal, together with a house, garden, and a cow's grass, free of rent, and some fuel, is daily becoming more general. Theses workers, who keep any married servants, have them all on this establishment of livery meal. The paid servants live all in their master's family, and are engaged for between three and four pounds, and in some cases five pounds of yearly wages, according to their expertness, and the nature of their work. But common labourers earn between one shilling and one shilling and three-pence a day; and if able-bodied and handy, they demand one shilling and sixpence, without viands. The various denominations of artisans charge according to the nicety of their art. The hours of labour from the field to the autumnal equinox, are from six to eight, allowing an hour for breakfast and another for dinner; and during the other half year, from the dawn of day till the light fails at night, with an allowance of one hour for breakfast. House servants are not so exact with respect to hours; in the long days, they continue to work after the time of night; and in short days they get out of bed before day light, where there is much grain to thrash. But in many of the large farms, threshing machines have been erected; and they are such a great saving, by the abridgment of labour, that more of them are let up every year, in different parts of the county.

And in Argyllshire, within these 30 years, the price of a day's work is somewhat more than doubled. It still varies in different parts of the country, but may be estimated in general at the following rates. A man servant's wages, per annum, with viands, from 6l. to 8l. A maid servant's, from 50s. to 4l. And that since 1795 the wages and the price of labour have been advanced more than one fourth, or from 2s. to 3s. per cent, and are still rising.

Further, in regard to the regulating the rate of wages, it has been figgled in the Agricultural Survey of the West Riding of Yorkshire, that the only mode of making them proportional to the rife or fall on the value of money and provisions, is to pay the labourer in kind, that is, with a certain quantity of corn, as parties shall agree, which incurs him, at all hazards, a comfortable subsistence, and prevents him from a daily or weekly visitation of the markets. When the labourer is paid in money, it exposes the thoughtless and inattentive to many temptations; whereas, when paid in kind, he cannot raise money to gratify the whim of the moment. In those counties where this mode of payment has been long established, we believe the ploughmen and labourers are, the whole, better fed, live more comfortably, and rear healthier children than in those parts where, from being paid in money, the deficiency of the article facilitates the expenditure, and prevents him from laying down a flock of provisions for his support, when laid off work by casualties or diftrefs.

In the part of the kingdom where the writer resides, nearly all farm-servants are paid in this manner. They have a certain quantity of grain, maintenance for a cow summer and winter, a piece of ground for planting potatoes and raising flax, and whatever fuel they require, given gratis. These, with the privilege of keeping a hog and a few hens, enables them to live, and bring up their families in a comfortable manner; and, while their income is considerably less than people of their station in other parts, they are, on the whole, better fed, better drest, and enabled to give a better education to their children. Placed under these circumstances, they are a respectable set of men; and, for frugality, faithfulness, and industry, they will bear a comparison with their brethren in any quarter. The introduction of a similar mode of paying farm-servants from the West Riding, is therefore recommended, which, although it might at first be attended with some difficulties, would contribute to the public good, and to the advantage of the farming patriarchy in many respects. And it is remarked in the Herefordshire Agricultural Survey, that if a certain proportion between the price of labour and the average price of wheat could be fixed by law, so as to render the applications for parochial aid necessary only in cases of very large families, of unusual illness, or fever, saisons, or any other emergency; the measure, it is presumed, will stimulate industry and fertility, would check dishonesty, and endeavor to a numerous class their native soil.

The advance in the rate of farm-servants' wages who live in the houes of the farmers, has, within the last twenty-five years, been probably not less than from a third to a fourth of the whole, according to the nature and situation of the diocese, over the whole country; but how far the agricultural and manufacturing state of the nation may thereby be affected, is difficult to determine. It is a matter of very great consequence to farmers, to have good, tractable, intelligent, able, and honest servants, as no fort of good farm-work, or improvements, can be properly carried on without them.

Servants' Rooms, in Rural Economy, the lodging places for farm-servants, which should always, if possible, be distant from the house upon farms of considerable size. And in cases of very extensive farms, and of course where many servants are required, especially if they be unmarried, proper and convenient accommodations for sleeping, and where they find their own provisions, for preparing and dressing them in, are not only requisite, but highly advantageous, both to the farmer and the men, as living much time, which would otherwise be lost in going to their meals, and keeping them togethe sober, steady, and ready for their different employments. And in this way the servants are much more comfortable, and live considerably cheaper than where it is the custom to go to public houses, or other such places for their meals, which is too much the case in many of the more southern districts of the kingdom, by which their manners often become depraved, and their constitutions enfeebled by the use of spirits, and other intoxicating liquors, which they are almost necessitated to take under
under such circumstances. But these inconveniences are perhaps the most effectually guarded against by such servants being provided for, where it can be done, from the tables of the farmers. But where this last method is followed, the eating rooms should be so situated, that they may be overlooked with facility. Their lodgings too, in all cases, are the most proper and the safest, when made in a building quite detached and distinct from the other houses and offices; as persons of this description are often extremely negligent of their fires, candles, &c., as well as irregular in other parts of their conduct. It has been advised, that whatever situation may be fixed upon for these conveniences, the ground floors should always be of stone or brick, and the upper ones made with plaster, as it is done in some of the midland counties, or brick, which is more easily laid. See Plaster Floors.

Most kinds of farm labour may, however, probably at present be performed more cheaply by other sorts of workmen, than servants provided for in any of these ways.

SERVE, in the Sea Language. To serve a rope, is to lay tpun-yarn, ropeyarn, lenum, a leather, a piece of canvas, or the like upon it, which is rolled fast round about the rope, to keep it from fretting or galling in any place.

SERVERETTE, in Geography, a town of France, in the department of the Lozere; 12 miles N.N.W. of Mende.

SERVETISTS, in Ecclesiastical History, a sect said to be the disciples or followers of Michael Servetus, the ring-leader of the Anti-Trinitarians of these last ages. See his article.

It is impossible (says the translator of Motheim's Eccl. Hist.) to justify the conduct of Calvin in the case of Servetus, whose death will be an indelible reproach upon the character of that great and eminent reformer. The only thing that can be alleged, not to efface, but to dim his crime is, that it was no easy matter for him to divest himself at once of that perfecting spirit, which had been so long nourished or strengthened by the popish religion in which he was educated.

Servetus, in reality, had not any disciples, as being burnt, together with his books, before his dogmas had time to take root. But the name Servetils has been given to some of the modern Anti-Trinitarians, because they follow the footsteps he had marked out.

However, those who were denounced Servetists, or Servetians, by the theological writers of the sixteenth century, not only differed from Servetus in many points of doctrine, but also varied widely from him in his doctrine of the Trinity, which was the peculiar and distinguishing point of his theological system.

Sixtus Senensis calls the Anabaptists Servetists, and seems to use the two terms indifferently. The truth is, in many things, the ancient Anabaptists of Switzerland, &c. coincide in opinion with Servetus.

As the books that he wrote against the Trinity are very rare, his real sentiments are but little known: M. Simon, who had a copy of the first edition, delivers them at large in his critical history.

Though Servetus uses many of the same arguments against the Trinity as therians, yet he professes himself very far from their sentiments. He also opposes the Socinians in some things; and declares his dissent from the opinions of Paulus Samofatenus; though Sandius hastily charges him with having the same sentiments.

In effect, he does not seem to have had any fixed regular

The year following he published his dialogues on the mystery of the Trinity. In the preface to which he adds himself satisfied with it. It was on this account he undertook another on the same subject, of much greater extent, which did not appear till the year 1554, a little before his death, under the title of "Christi

naus Rerumnotur." Those of Geneva, having seized the copies of this edition, had it burnt; nor were there above two or three that escaped; one of which was kept at Basil, where the book was printed, but is now in the college library at Dublin.

It was put to the press secretly in England, but being discovered, the impression was seized and destroyed.
