VOL. XXXIX.

LONDON:

PRINTED FOR LONGMAN, HURST, REES, ORME, & BROWN, PATERNOSTER-ROW.

1819.
X, A double consonant, and the twenty-fourth letter in the English alphabet; which, however, begins no English word.

The x of the Latins, and χ of the Greeks, are compounded of c, and σ; whence, to this day, the letter x in the English and French has the same sound with c r or k r. Thus we pronounce Alexander exactly as if written Alexsander or Aleksander.

The Italians have no x at all in their language, but both speak and write Alessandro. The Spaniards pronounce the x like our c before s; viz. Alessandro, as if it were Alessandro. The Portuguese pronounce it like h.

In foreign words, used in English, we sometimes soften the x into a double r; as Bruxelles, for Brusselles, &c.

The letter is not known in the Hebrew, or other oriental languages; but in lieu of it, they write the two simple letters of which it is compounded. And the like do the modern Germans.

Peter Dacconus relates, that the letter X was introduced into the Roman alphabet in the time of Augustus; and that, before his reign, the Romans supplied the want of it by the letters C and S. But Mr. Astley observes, that this is a mistake; the letter X being found in the Ducoan pillar, inscribed in the year of Rome 494, and 259 before Christ. Origin and Progress of Writing, p. 78.

X is also a numeral letter, and signifies ten; as representing two V's placed one at top of the other. See V.

X Supra deno numero tibi dat ritenendam.

When laid flat, thus $\chi$, it signifies a thousand; and when a dafh is added over it, $\bar{X}$, it signifies ten thousand. If before X denotes the subtration, and after X the addition of unit; thus, IX = 9, and XI = 11. X before L or C

\[ \text{denotes the subtraction of 10 from 50, or 100: thus, XL = 40, and XC = 90.} \]

X on the French coins denotes those flruck at Amiens. We often meet with the Greek letters X and P joined in this manner, $\chi\pi\rho\alpha\nu\theta\gamma\nu\mu\alpha\iota\nu$ on ancient medals. The first we find are on some large brass coins of the Ptolemies, kings of Egypt, where it was placed on a civil account.

Some writers have taken it for a date, and others for the initial letters of a proper name; but as no reasons are given for either of those conjectures, Mr. Ward rather supposes it an abbreviation of the word xphma, money, impressed on those pieces, to denote their currency as money; which might be thought proper, as they have not the heads of kings stamped upon them, like their silver and gold coins; but always that of a Jupiter on the front, and an eagle perched on a thunderbolt on the reverse.

This character was afterwards applied to a very different purpose by Constantine the Great, who made use of it to denote xeproto, both in his coins and military ensigns; in which he was followed not only by some succeeding emperors, but also by private persons, who out of devotion put it on their lamps and other utensils.

It afterwards came to be used merely as a critical note, to point out remarkable passages in manuscripts; and then it stood for the initials of xepicomon, useful; as we learn from Isidore, Orig. lib. i. cap. 20. See Phil. Trans. No. 474, sect. 1.

X, with a P, or Greek R, in the middle of it, is also the monogram of the name of CHR1ST, which constantly occurs in the catacombs or burial-places of the ancient Christians, and which was the chief ornament of the Labarum or military standard of Constantine, and the succeeding emperors. See Labarum.

B XABEA,
XABEA, in Geography, a fea-port of Spain, in the province of Valencia, near the coast of the Mediterranean; 36 miles N.N.E. of Alicante.

XABORECTORA, in Ancient Geography, a name given by P. Mela to Abarros, a river of Meopotamia.

XACA, in Geography; see XACA.

XACUA BAY, a large bay on the south coast of the island of Candia; 18 miles S.E. of Settia.

XAGUA BAY, a large bay on the south coast of the island of Cuba. This is one of the belt ports in the West Indies, and is 15 miles in circumference, surrounded with mountains, which break off the force of the winds. N. lat. 22° 10'. W. long. 81° 20'.

XANTES, SANTOS, or All-Saints' Islands, as having been discovered on that holiday by the Spaniards; three small islands in the West Indies, situated to the south-east of Guadaloupe. The most westerly of them is called Terra de Bas, or the Low island, and the most easterly, Terra de Haut, or the High island. The third, which lies exactly in the middle between the other two, seems to be nothing more than a large barren rock, but is of use in affording to form a very good harbour. The island of Terra de Bas is about nine miles in circumference, but the other is larger. These islands have constantly a fresh breeze, let the wind blow from what quarter it may; and on the Terra de Bas is a neat wooden church, with two very convenient creeks both for anchorage and landing. They are about six miles distant from Guadaloupe, and 15 from Mariegalante. N. lat. 15° 56'. W. long. 61° 32'.

XALAPA, a considerable town of Mexico, or New Spain, in the fertile province of Tlascala, formerly famous for the fair held on the arrival of the fleet of vessels from Europe; and since the declared freedom of commerce, a considerable mart for European commodities. It is situated on the southern skirts of a mountain, in a beautiful climate, the soil being partly clay and partly flaky, while pure waters issue from a white land, and fertilize the country. The population consists of 243 Spanish families, 182 Melizones, and 361 Indians. When north winds prevail at Vera Cruz, it always rains at Xalapa; but the climate is effeemed very healthy. The purging powder of the country is made of the root of a plant, to which the town gives the name of Jalap; 30 miles E. of Puebla de los Angeles. N. lat. 19° 50'. W. long. 98° 26'.

XALISCO, a province of Mexico, in the audience of Guadalajara. It is washed by the South Pacific ocean on the south and west; bounded on the east by Guadalajara Proper and Mexico; and separated from Chiapen on the north, by a narrow strip of land belonging to Guadalajara, and running out into the sea. It is not above fifty leagues in extent either way. It abounds with Indian wheat and silver mines, but has very few cattle of any sort. From this province is brought the oil of the infernal fig-tree, as the Spaniards call it, much used in medicine.

XALISCO, a town of Mexico, which gives name to a province; 9 miles N.W. of Compostella Nueva. N. lat. 21° 25'. W. long. 106° 26'.

XALON, a river of Spain, which rises in a mountain near Medina Celi, and runs into the Ebro, about six miles above Saragozza.

XAMACA, a river of America, which runs into the gulf of Mexico, 16 miles from Vera Cruz.

XAMBRINA, a town of Spain, in the province of Leon; 2 miles S.E. of Tordefilla.

XAMELLalah, an Arabic term, used as a grace or thanksgiving after meat.

The greatest men of that nation will often call in the meanest, even the beggars, to eat with them; who, as soon as they have done, always rise and pronounce this word, which signifies, God be praised. Pococke's Egypt, F. 20.

XAMI, a name given by some of the old writers to the ecreation of the Greeks, or carrot-tree. See CHAPEX.

XAN, in Geography, a river of the principality of Georgia, which runs into the Kur, 6 miles E. of Gory.

XANGA, a river of Africa, in the kingdom of Mongallo, which runs into the Indian sea, opposite to the island of the same name.—Also, one of the Querima islands in the Indian sea, near the coast of Africa. S. lat. 10° 45'.

XANILA, a town of Fezzan, in the road to Egypt; 140 miles E.N.E. of Mourzouk.

XANQUE, or GUIAPA, a river of Mexico, which runs into the Spanish Main, 30 miles W. of Cape Camaron.

XANTEN, or SANTEN, a town of France, in the department of the Roer, near the Rhine; 7 miles N.E. of Gueldres.

Gen. Cbl. Male, Cal. Perianth of one leaf, in five or fix small, deep, imbricated, roundifh, concave, acute figments, with a pair of minute opposite feales at the bafe. Cor. Petals five, roundifh, fpreading, larger than the calyx. Stam. Filament one, columnar, erect; anthers five, two-lobed, forming a peltate concave disk, full of gluten, their under fide burifling, and difcharging the pollen.

Female, Cal. like that of the male, permanent, inferior. Cor. as in the male. Stam. Filament none; anthers five, prifmatic, erect, imperfect. Pij. Germen superior, roundifh, with five furrows; fyle none; £igmas five, roundifh, thick, emarginate, feated on the germin. Peric. Capsule small, globofe or oval, with five furrows, five cells, and five valves, burifling at the furrows, their membranous partitions adhering to the central column. Seeds numerous, oblong, imbedded in the pulp, inferted in a double row upon the five-angled columnar receptacle.

Obf. It appears that one-fifth is frequently added to the parts of fructification, in the male as well as female flowers.

Female, Calyx and Corolla like the male. Stigmas five, fefible. Capsule of five cells, with many pulpuy feeds.

1. X. scandens. Twining Xanthé. Wildl. n. 1. (Quaopya scandens; Aubl. Guian. 898. t. 343.)—Leaves obvate, feelfy. Capsule globofe.—Native of the forefts of Guiana, flowering in November. The fperm is shrubby, with knotty branches, twining round neighbourifing trees. Leaves oppofite, on fhort flalks, fimple, entire, thick, and smooth, three or four inches long, with a thick mid-rib, and a fhort blunt point, but no branching veins. Panicles at the ends of the drooping branches, compound, three-forked, smooth. Flowers small, yellow; their partial flaks longer than the calyx. Petals feelfy. Capsule about the fize of a black currant, feelfy, crowned with the black feedmar all meeting in a point. Seeds red. Every part of the plant, when wounded, discharges a transparent, white, vifcid, refinous juice. The Indians call this species Quapyoa. See Quaopya.

2. X. par-
   —Native of the same country. Differs from the preceding in having thinner leaves; smaller flowers, with shorter petals and an oblong, thicker, yellowish fruit. The bark and leaves, if cut or broken, discharge a yellow glutinous juice, which, when dried, resembles Gamboge, and is, like that substance, soluble in water. Aublet.

XANTHICA, xantè, in Antiquity, a Macedonian festival, so called because it was observed in the month Xanthus, at which time the whole royal family with the army was purified. See Illustration.

Gen. Ch. Male flowers compound. Common Calyx of many imbricated, slender, equal scales, as long as the numerous florets. Cor. compound, uniform, equal, hemispherical, confiding of numerous, tubular, funnel-shaped, monopetalous, upright, five-cleft florets. Stam. Filaments in each floret five, united into a cylinder; anthers erect, parallel, diaphanous. Common Receptacle small, with chaffy scales between the florets.

Female flowers below the male, on the same plant, doubled. Cal. Involucrum two-flowered, of two opposite, acutely three-lobed leaves, (their middle lobe longest,) befit with hooked prickles, and closely enfolding, as well as united to. the germen, except the lobes, which are free. Cor. none. Pfl. Gemen oval, bipid; styles two pair, capillary; stigmas simplex. Peric. Drupa dry, ovate-oblong, cloven at the point, clothed all over with hooked prickles. Seed. Nut of two cells.

Obs. Linnaeus Remarks, that the fruit of Xanthium could scarcely have been well understood, without a previous knowledge of that of Ambrosia. Thefe genera in fact belong to that ambiguous tribe, whose habit, qualities, and in part the structure of their male flowers, all associate them with the compound or syncarionous order; while the dispersion of their flowers, and the general nature of their female flowers, and fruit, necessarily refer them to the Diclini, or in the artificial system of Linnaeus, the clafs Monocotyledon.

1. X. Strumarium. Common Burweed, or Small Burdock. Linn. Sp. Pl. 1400. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Eng. Bot. t. 2544. Fl. Dan. t. 970. Bigelow Bot. 221. (Xanthium ; Fuchs's Hist. 579. Camer. Epit. 626. X. feu Lappa minor; Math. Valgr. v. 2. 545. Bardana minor; Ger. Em. 829.)—Stem without thorns. Leaves heart-shaped; three-ribbed at the base. —Native of dung-hills, and rich moor ground, in various countries of Europe, as well as North America, flowering towards autumn. In this island it is of very rare occurrence, though occasionally met with about London, and in the west. Dr. Sibthorp noticed the plant in many parts of Greece, where the soil is rich and rather wet, and found it called, by the modern Greeks, σαμνήχια a name alluding to its bur-like property, rather than to the quality on which its ancient appellation is founded. The root is annual. Herb branched, rough, dark green, rather fettid, of a coarse rank habit, with furrowed, rather hairy, branchies. Leaves alternate, falked, heart-shaped, acutely lobed, and toothed or serrated; their two lateral ribs marginal, for a small space, at the base, as in the great Burdock, Arctium Lappa, and a few other plants. Male flowers globular, green, few together, in axillary or terminal clusters, about the upper part of the branchies; female in axillary sessile tufts. Fruit elliptical, double-pointed, hard, near an inch long, befit with firm, prominent, awl-shaped, hooked prickles, which attach themselves to the coats of animals, and thus serve to disperse the feed.

2. X. orientale. Oriental Burweed. Linn. Sp. Pl. 1400. Willd. n. 2. Ait. n. 2? Linn. Fil. Dec. 33. t. 17. “Schkuhr Handb. v. 3. 239. t. 291.” — Stem without thorns. Leaves ovate, slightly three-lobed, somewhat triple-ribbed; wedge-shaped at the base. —Native of Ceylon, Japan, and China, from which last country it was imported, according to the younger Linnaeus, with other seeds for the Upal garden, in 1761. Sir Hans Sloane is recorded by Ray as having introduced this Xanthium into England in 1685; but their plant seems to have been a flight variety of the firit, figured by Moreion, fect. 15. t. 2. f. 2, found in America, and not answering to the distinctive characters of the present species, though Morifon, and others who speak of this variety, are cited by Linnaeus and Willdenow. The true X. orientale is an annual herb, of a more slender habit than the Strumarium, and more hardy, though less hairy. Their effential differences are indicated in our specific characters. The most remarkable feems to be the taper base of the leaves, in the present species, and the union of their three ribs, at a greater or less distance, above the inference of the footstalk. The fruit is twice as large as the foregoing, with peculiarly strongly hooked thorns.

3. X. echinatum. Compound-thorned Burweed. "Murray in Comm. Goett. for 1784, with a figure." Wildl. n. 3.—"Stem without thorns. Fruit oval; its prickles hooked, crowded, compound at the base." Annual.—Its native country unknown. Willdenow. We have not seen either a specimen or figure.

4. X. spinifum. Spinos Burweed. Linn. Sp. Pl. 1400. Willd. n. 4. Ait. n. 3. (X. spinifum, atriplicis folio; Moril. fect. 15. t. 2. f. 3. X. luftanticum spinifum; Herm. Parad. 246, with a figure. Volkm. Norib. 404, with a figure. X. luftanticum, laciniatum, validissimis aculeis mainum ; Magnol. Hort. 208. t. 20.)—Stipulas thorny, three-cleft. Leaves lanceolate, three-lobed; hoary beneath.—Native of the south of France, as well as of Italy, Spain, and Portugal. It might be raised here as a tender annual, and planted out in a border, were there sufficient beauty in its copious, long, flame-coloured thorns, to entitle it to a place in the flower-garden. The leaves are not inelegant. Their upper surface is of a fine green, nearly smooth; the lower downy and white. The thorns are in fact fipulas, an inch long, very sharp, standing in pairs at the base of each footstalk, separating just above their origin into three spreading needle-like points. Flowers small and inconsiderable. Fruit oval, covered with copious.
copious, small, hooked prickles. The wild plant makes a
conspicuous appearance in winter, on banks about
Montpellier.

For *X. fruticosum*, Linn. Suppl. 418, see *Franseria*.

**XANTHIUM**, in *Agriculture*, a term under which the leifer
burdock is sometimes known by writers, and which is
found to be a very troublesome weed. See Weeds.

**XANTHOCYXUS**, in *Botany*, received that name, either
from Dr. Roxburgh or Mr. Dryander, in allusion to the
remarkable yellow juice of its fruit; the word being
composed of *xanthos*, yellow, and *χοξος*, juice. — Roxb.

Cor. Petals five, orbicular, nearly sessile, opposite
to the calyx-leaves, and twice as long. Nectaries
of five broad, short, abrupt, porous glands, opposite to
the petals, alternate with the filaments, inserted into the receptacle
under the germen. *Stam.* Filaments twenty, united into five
oblong, linear, flat bodies, alternate with the nectaries, and
above twice as long: anthers flat, roundish, of two lobes
and two cells. *Pyl.* Germen superior, globose; style
scarce any; stigmas five, spreading horizontally, obtuse,
deciduous. *Peric.* Berry globose, succulent, with five ovate
seeds, immersed in the pulp, some of which are generally
abortive.

*Eff.* Calyx of five leaves. Petals five. Nectaries
five, abrupt. Stamens united into five sets, alternate with
the nectaries. Berry with from one to five seeds.

Cor. Petals five, orbicular, nearly sessile, opposite
to the calyx-leaves, and twice as long. Nectaries
of five broad, short, abrupt, porous glands, opposite to
the petals, alternate with the filaments, inserted into the receptacle
under the germen. *Stam.* Filaments twenty, united into five
oblong, linear, flat bodies, alternate with the nectaries, and
above twice as long: anthers flat, roundish, of two lobes
and two cells. *Pyl.* Germen superior, globose; style
scarce any; stigmas five, spreading horizontally, obtuse,
deciduous. *Peric.* Berry globose, succulent, with five ovate
seeds, immersed in the pulp, some of which are generally
abortive.

*Eff.* Calyx of five leaves. Petals five. Nectaries
five, abrupt. Stamens united into five sets, alternate with
the nectaries. Berry with from one to five seeds.

Cor. Petals five, orbicular, nearly sessile, opposite
to the calyx-leaves, and twice as long. Nectaries
of five broad, short, abrupt, porous glands, opposite to
the petals, alternate with the filaments, inserted into the receptacle
under the germen. *Stam.* Filaments twenty, united into five
oblong, linear, flat bodies, alternate with the nectaries, and
above twice as long: anthers flat, roundish, of two lobes
and two cells. *Pyl.* Germen superior, globose; style
scarce any; stigmas five, spreading horizontally, obtuse,
deciduous. *Peric.* Berry globose, succulent, with five ovate
seeds, immersed in the pulp, some of which are generally
abortive.

*Eff.* Calyx of five leaves. Petals five. Nectaries
five, abrupt. Stamens united into five sets, alternate with
the nectaries. Berry with from one to five seeds.

Cor. Petals five, orbicular, nearly sessile, opposite
to the calyx-leaves, and twice as long. Nectaries
of five broad, short, abrupt, porous glands, opposite to
the petals, alternate with the filaments, inserted into the receptacle
under the germen. *Stam.* Filaments twenty, united into five
oblong, linear, flat bodies, alternate with the nectaries, and
above twice as long: anthers flat, roundish, of two lobes
and two cells. *Pyl.* Germen superior, globose; style
scarce any; stigmas five, spreading horizontally, obtuse,
deciduous. *Peric.* Berry globose, succulent, with five ovate
seeds, immersed in the pulp, some of which are generally
abortive.

*Eff.* Calyx of five leaves. Petals five. Nectaries
five, abrupt. Stamens united into five sets, alternate with
the nectaries. Berry with from one to five seeds.

Cor. Petals five, orbicular, nearly sessile, opposite
to the calyx-leaves, and twice as long. Nectaries
of five broad, short, abrupt, porous glands, opposite to
the petals, alternate with the filaments, inserted into the receptacle

abortive.

*Eff.* Calyx of five leaves. Petals five. Nectaries
five, abrupt. Stamens united into five sets, alternate with
the nectaries. Berry with from one to five seeds.
fame bud as the leaves, of a dark copper-coloured purple, like *Veratum nigrum*, and though not gay or brilliant, not inegalent, when contrasted with the foliage. The root and stem are internally of a bright lemon-colour. The affinity of this plant to *Cimicifuga*, *Aloe*, *Helichorus*, &c. would lead us to suspect, though there is no remarkable fetor, that its properties might be active, and accordingly it seems that the American physicians have employed it successfully in practice, as a tonic or stimulant. Probably its qualities may not be dissimilar from those of *Helichorus triangularis* of Linnaeus; *Coptis triangularis*, Sabl. Tr. of Linn. Soc. v. 8. 305. Pursh 390. Bigelow Am. Med. Bot. v. 1. 60. t. 5; the root of which the late-mentioned writer informs us is purely and intensly bitter, strengthening the stomach and other visceras, and promoting digestion. It makes a yellow tincture, like that of Geranium in flavour and medical virtues.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* inferior, of one petal, in fix deep, nearly equal, oblong, permanent segments; the three inner ones concave, converging at the base. *Stam.* Filaments fix, inserted into the lower part of the corolla, linear, flat, smooth, and naked, longer than the segments; anthers veritable. *Pist.* German superior, ovate, with the rudiments of many seeds in each cell; style cylindrical, with three furrows; stigma simple. *Peric.* Capsule projecting beyond the closed permanent corolla, ovate, with three blunt angles, woody, almost horny, polished, acute, of three cells, and three valves, the partitions from the middle of each valve. *Seeds* one or two in each cell, bordered, compressed, with a hard black shell; the scar at the base, naked; embryo transverse; albumen soft and fleshy.

Mr. Brown, from whose examination, of the living plants, we have improved our generic description above, remarks, that the species of this genus have a peculiar habit, so striking, that where they abound, they give a singular character to the face of the country. The body of the root is sometimes elevated into a thick, scarred, black stem, often divided or branched, and several feet in height, exuding a fragrant yellow resin; in other instances it is very short, scarcely rising above the surface of the ground. Leaves very numeros, crowded, narrow, graceful, of great length, linear, somewhat triangular, or two-edged, spreading every way; recurved at the extremity; dilated, and half-sheathing, at the base; rigid and elastic when dry. *Flower-floak terminal*, quite simple, round, often many feet in length, smooth, firm, hard, and durable. *Spéé* terminal, solitary, cylindrical, dense, many-flowered, resembling a catkin, sometimes equal in length to the floak itself. *Flowers* fleshy, closely crowded, small, white, each accompanied by numerous, imbricated *bractées*, tapering at the base into a claw, the innermost gradually smallaff. *Capsules* of a shining chestnut, partly black.

The structure of the seeds agrees with Bory's, Labill. Nov. Holl. t. 107. Brown Prodr. v. 1. 286; nor are these two genera very dissimilar in foliage or inflorescence. They are placed at the end of the *Aphelandeae*, because of their fleshy albumens, and the black crustaceous skin of their seeds; *Brown*.

1. *X. arbores*. Arboreous Yellow-gum. *Br.* n. 1.—"Stem arborecent. Leaves two-edged; triangular beyond the middle; flattened in front. Stalk scarcely the length of the very long spike. *Bractées* and corolla bead-lefs." —Native of the country near Port Jackson, New South Wales. Each division of the thick stem is crowned with a large tuft of innumerable long, slender, drooping leaves, in the centre of which the flower-floaks stand solitary.

See n. 3.

2. *X. australi*. Southern Yellow-gum. *Br.* n. 2.—"Stem arborecent. Leaves compressed longitudinally. Stalk shorter than the elongated spike. *Bractées* and outer segments of the corolla, down to the point. —Native of New South Wales, from whence we received specimens in 1790, by favour of Dr. John White. It is said to have been sent, in 1803, to Kew garden, by Philip Gidley King, Esq. A green-house plant, flowering in April and May. In the description given by Dr. White, at the place above quoted, he evidently confounds this species and the *X. arborea*; for he says "it is about the size of an English Walnut-tree. The trunk grows pretty straight for about fourteen or sixteen feet, after which it branches out into long spiral leaves, which hang down on all sides, and resemble those of the larger kinds of goats, or edge. From the centre of the head of leaves arises a single footflok, eighteen or twenty feet in height, perfectly straight and erect, terminating in a spike of a spiral form. This large flok is used by the natives for making spears and fish-gigs, being pointed with the teeth of fish, or other animals." The first part of this description appears to belong to the *arborea*; the latter, regarding the inflorescence, to the *Hafliele*; which might easily, perhaps, except by a scrutinizing botanist, be supposed different stages of growth, or varieties, of the same plant. Such a mistake may be more easily accounted for than that of the great Linnaeus, in combining nearly the whole genus of *Aloe* into one species. The Yellow Reif is produced by the present, and some other, species of this genus, by spontaneous exudation from the trunk; promoted sometimes, as we judge from the appearance of certain specimens, by fires kindled by thebage natives of the country. The juice, fluid at first, soon hardens in the sun, into a concrete brittle form, of a dull orange colour. Burnt on hot coals, it emits a fragrant smoke, smelling like a mixture of balm of Tolu and Benzoin, approaching in some degree to Storax. This reif is perfectly soluble in spirit of wine, but not in water, nor even in effential oil of turpentine, unless digested in a strong heat. The varnash which it makes with either is weak, and of little use. Dr. White found this Yellow Gum a good pectoral medicine, in many cases. If burnt in a room, the scent, though pleasant to some people, soon proves oppressive, and the smoke irritating to the lungs. Olive gum, used by the Italians, is preferable for fumigation.

Native of New South Wales, from whence we received specimens in 1790, by favour of Dr. John White. It is said to have been sent, in 1803, to Kew garden, by Philip Gidley King, Esq. A green-house plant, flowering in April and May. In the description given by Dr. White, at the place above quoted, he evidently confounds this species and the *X. arboere;* for he says "it is about the size of an English Walnut-tree. The trunk grows pretty straight for about fourteen or sixteen feet, after which it branches out into long spiral leaves, which hang down on all sides, and resemble those of the larger kinds of goats, or edge. From the centre of the head of leaves arises a single footflok, eighteen or twenty feet in height, perfectly straight and erect, terminating in a spike of a spiral form. This large flok is used by the natives for making spears and fish-gigs, being pointed with the teeth of fish, or other animals." The first part of this description appears to belong to the *arborea*; the latter, regarding the inflorescence, to the *Hafliele*; which might easily, perhaps, except by a scrutinizing botanist, be supposed different stages of growth, or varieties, of the same plant. Such a mistake may be more easily accounted for than that of the great Linnaeus, in combining nearly the whole genus of *Aloe* into one species. The Yellow Reif is produced by the present, and some other, species of this genus, by spontaneous exudation from the trunk; promoted sometimes, as we judge from the appearance of certain specimens, by fires kindled by thebage natives of the country. The juice, fluid at first, soon hardens in the sun, into a concrete brittle form, of a dull orange colour. Burnt on hot coals, it emits a fragrant smoke, smelling like a mixture of balm of Tolu and Benzoin, approaching in some degree to Storax. This reif is perfectly soluble in spirit of wine, but not in water, nor even in effential oil of turpentine, unless digested in a strong heat. The varnash which it makes with either is weak, and of little use. Dr. White found this Yellow Gum a good pectoral medicine, in many cases. If burnt in a room, the scent, though pleasant to some people, soon proves oppressive, and the smoke irritating to the lungs. Olive gum, used by the Italians, is preferable for fumigation.

Mr. Brown near Port Jackson. He is not quite confident of its being a distinct species from the last.

5. X. minor. Lesser Yellow-gum. Br. n. 5. — "Stem none. Leaves triangular; flat in front; rather concave beyond the middle. Stalk many times longer than the spike. Bracteas scarcely longer than the tufts of flowers, all, like the corolla, beardless."—Gathered by Mr. Brown, in New South Wales. The spike of this species measures from five to eight inches. Brown.

6. X. braechata. Long-bracteate Yellow-gum. Br. n. 6. — "Stem none. Leaves triangular; below the middle somewhat elevated in front; beyond it rather concave. Stalk many times longer than the spike. Bracteas subtending the tufts twice or thrice the length of the flowers, lanceolate and diverinated, all, like the corolla, beardless."—From the same country. The spike is only from three to six inches in length. Brown.

7. X. bomilis. Dwarf Yellow-gum. Br. n. 7. — "Stem none. Leaves below the middle flatish, with a slightly elevated ridge on both sides; beyond it triangular and channelled. Stalk many times longer than the ovate spike. Bracteas nearly equal, bearded as well as the corolla."—Gathered by Mr. Brown, in the tropical part of New Holland. The flower-flalk itself is, in this species, only a foot high. Brown.

XANTHONYXULYM, received its name from governor Cadwallader Colden, because of the yellow hue of the wood, to which ſtate, yellow, and ſtate, wood, alludes. We make no figure to follow the example of professor Martyn, in rectoring the proper orthography; nor is it requisite to burthen our readers with a perpetual indication of the original blunder, under every species, though that blunder has the sanction of Linnaeus, and perhaps of all the authors, except Martyn, that we may have to quote. They generally write the word Xanthonyxulym, or Xanthonyxylon.—Linna. Gen. 519. Schreb. 634. Willd. Sp. Pl. v. 4. 753. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 352. Pursh 209. Swartz Ind. Occ. 570. Jull. 374. Lamarch Dict. v. 2. 38. Illinit. t. 811. Garttn. t. 68. (Fagara; Duham. Arb. v. 1. 229. t. 97. Swartz Prodr. 33.)—Clafs and order, Dioces Pentandria. Nat. Ord. "Hederaceae," Linna. rather his Dumou. Terribinatceae affine, Jull.

Gen. Ch. corrected. Male, Cal. Perianth very small, in three or five deep, concave, rather acute segments. Cor. Petals three or five, oval, erect, concave, thrice the length of the calyx. Stam. Filaments three or five, awl-shaped, erect, longer than the petals; anthers roundish, two-lobed, furrowed.

Femal, Cal. like the male, inferior, permanent. Cor. like the male, deciduous. Fil. Germs from two to five, roundish, each terminating in an awl-shaped style, longer than the petals; stigmas obtuse. Peric. Capsules from one to five, flatked, each of one cell, and two coriaceous valves, burking at the inner margin. Seeds solitary, roundish, polished, pendulous from an upright brittle-flaked flalk.

Eff. Ch. Male. Calyx in three or five small deep segments. Petals three or five.

Female. Calyx like the male, inferior, permanent. Petals three or five. Capsules from one to five, of two valves, and on each, seeds solitary, pendulous.

Obs. This genus is distinguished from Fagara, (see that article,) by having separated flowers, either three-cleft, or five-cleft, and pendulous seeds. Botanists appear to have mistaken its real character, taking the calorys for a calyx. To this error Linnaeus and Dubamel led the way, and Jussieu, Willdenow, and others, have followed them. Yet Linnaeus in his Gen. Pl. subjoins to his generic description a more correct statement, altogether superceding the former; and Willdenow admits species from Swartz, whose petals by their presence contradicts his essential character. We have not seen living specimens of Xanthonyxulym, but the descriptions of Browne and Swartz leave little doubt of the correctness of the above characters. We are much tempted to unite the two genera in question, but as they really have not been sufficiently investigated, and Gartner seems to have discovered a distinctive mark of Xanthonyxulym, in the flatked pendulous seeds, we leave them for future inquiry. The whole genus is shrubby or arborescent, with alternate, pinnate, sometimes only ternate, entire, or somewhat crenate leaves, and clustered, or panicled, flowers. The stem is, in most infances, armed with prickles, that are sometimes very formidable. The wood is hard, and serviceable for many purposes.

Sec. i. Stem without prickles.

1. X. ternatum. Three-leaved Yellow-gum. Swartz Ind. Occ. 570. Willd. n. 1. (Fagara trifoliata; Swartz Prodr. 33.)—Prickles none. Leaves ternate, obovate, slightly emarginate, shining; dotted beneath.—Received by Sir Joseph Banks from the island of Dominica. A shrub, six feet high, with roundish, subdivided branches, angular when young. Leaves on smooth, spreading, channelled footflaks. Leaves on partial small flalks, entire, rigid, veiny; contracted at the base; paler beneath, and minutely dotted with black. Clusters axillary, compound. Flowers small, whitish. Germs three, contiguous, like one three-lobed germs. Stigmas three, fertile. Capsules three, each of two hemispherical valves, with two internal, membranous, whitish valves. Seeds solitary, roundish, polished. Swartz.

2. X. emarginatum. Emarginate Yellow-gum. Swartz Ind. Occ. 572. Willd. n. 2. Ait. n. 1. (Fagara emarginata; Swartz Prodr. 33).—Brown, affinis, terebinthi folio alato, ligno odorato candito, flore albo; Sloane Jam. v. 2. 24. t. 168. f. 4.—Prickles none. Leaves pinnate, ovate, emarginate, veiny. Flowers triandrous.—Native of mountains in the interior parts of Jamaica, where it is vulgarly called Ligannum rorum, a corruption of Lignum Rhodium, the smell of every part of the shrub resembling the latter when rubbed, or held near the fire. The stem is woody, branched, round. Leaves about three pair, rarely with a odd one, above an inch long, veiny, rather coriaceous, and shining. Clusters terminal, somewhat compound, erect. Flowers minute, whitish. Calyx in five deep, ovate, acute, permanent segments. Petals only three, ovate, concave, spreading, twice the size of the calyx. Stamens three, very short. Germs three-lobed, with three fertile stigmas. Capsule fleshy more than one perfect, with two internal, as well as external, valves, and one orbicular, black, shining seed. Swartz.

3. X. acuminatum. Pointed-leaved Yellow-gum. Swartz Ind. Occ. 575. Willd. n. 3. (Fagara acuminata; Swartz Prodr. 33.)—Prickles none. Leaves pinnate, elliptical, pointed, coriaceous. Flowers triandrous.—Native of mountainous parts of Jamaica. A shrub, with round spreading branches. Leaves three or four pair, laurel-like, shining. Gymnos terminal, subdivided in a forked manner. Flowers crowded, small, white. Calyx of three minute oval leaves. Petals three, obtuse, concave, one line and a half long. Stamens three, shorter than the corolla. Fruit globose, the size of a pepper-corn, only one capsule, out of three, coming to perfection.

Sec. 2. Stem prickly.

4. X. punctatum. Dotted Yellow-gum. Willd. n. 4. "Weit
"Welt St. Croix 236."—Stem prickly. Leaves ternate, or pinnate, oblong, finely crenate; dotted beneath.—Native of the island of Santa Cruz. Willdenow.

5. X. spinosum. Prickly Triandrous Yellow-wood. Swartz Ind. Occ. 574. Willd. n. 5. (Fagara spinosa; Swartz Prodr. 33.)—Stem prickly. Leaves pinnate, with many pairs of fiddle, ovate, pointed leaflets; prickly beneath, as well as the branches. Flowers triandrous. Native of dry mountainous situations in Jamaica. A frutic, about 6 feet high, with a round, branching, upright stem. Spines (rather we presume prickles) scattered, prominent, needle-like, as long as the finger-nail; base of the main stem stronger, and thicker at the base. Leaves a foot long, with a compressed footstalk, round and prickly at its base, and, if we understand right, furnished with a pair of prickles before each pair of leaflets, which are nearly fiddle, eight or ten pairs in all, ovate, with a short emarginate point, veiny, rigid, smooth, and shining, very minutely crenate at the edges, their mid-rib occasionally prickly. Cyms terminal, with minute, white, crowded flowers. Calyx with three ovate acute segments. Petals three, ovate, larger than the calyx. Filaments scarcely any. Anthers ovate, converging. Germin in three distinct lobes. Stigma three, fiddle, obtuse. Fruit not observed. Swartz.

We have been more full in our descriptions of Dr. Swartz's four species, that the reader may compare their characters with Fagara. Nothing is said of their flowers being sepaled, or dioecious.

6. X. Clava Herculis. Great Prickly Yellow-wood. Linna. Sp. Pl. 1455, excluding the synonymy of Duhamel. Amev. Acad. v. 3. 16. Willd. n. 6. Ait. n. 2. Swartz Obs. 375. (X. spinosum, lentisci longioribus folis, euonymi fructu capsulari; Catebe Carolin. v. 1. t. 26, according to Linnaeus. X. aculeatum, fraxini filifolii et puneatique folis; Pluk. Phyt. 239. f. 4.)—Stem prickly, with broad angular prickles. Leaflets ovate, pointed, crenate; nearly equal at the base; common footstalk prickly. Flowers terminal, panicked. Native of woods in the West Indies and Carolina, flowering in March and April. It is marked by Mr. Aiton as a green-house plant, cultivated ever since Miller's time, flowering in April and May. The trunk is woody, often, according to Swartz, 30 or 40 feet high, armed with very powerful prickles, which are thick at their base, angular and sharp at the point. Leaves a foot long, pinnate, as in all the following species; their common footstalks armed with scattered straight prickles, one-third of an inch long; leaflets about seven pair, on short partial stalks, unequally divided by their smooth mid-rib, and somewhat falcate, an inch and a half or two inches long, bordered with shallow unequal notches, smooth and rather shining. Clysters terminal, compound. Flowers polygamous, there being some united ones, though not perfecting seed, on one tree, and others entirely female, on another. The former have a minute five-toothed calyx. Petals five, thrice as long, ovate, crenate, or a little incurved. Filaments five, twice the length of the petals, and inserted between them. Anthers oblong, crenate at the base. Germs roundish, abortive, with five awl-shaped erect styles, and simple stigmas. The female flowers have a five-toothed calyx; five concave petals; no stamens. Germens five, united into a roundish body. Styles none. Stigma peltate, slightly convex, a little elevated, with five furrows. Capsules five, combined, or one of five lobes, each lobe having two valves, and containing a roundish, black, shining seed. Our description of the fructification is taken from Dr. Swartz. The leaves bear but a flight resemblance to the Gillick-tree, or any other species of Phylacia, being decidedly crenate.

7. X. aromaticum. Aromatic Yellow-wood. Willd. n. 7. (Euonymo affinis aromatica, f. Xanthoxylon spinosum, fraxini folium cheumif scrim; Pluk. Amath. 78. t. 393. f. 2.)—Stem with opposite prickles. Leaflets ovato-lanceolate, ferrated; unequal at the base: common footstalk prickly. Panicles terminal.—Native of Chufan. "A frutic with straight prickles. Leaflets two, three, or four pair, pointed, one inch and a half long, marked with pellucid dots; rounded near the base, at the upper edge; contracted at the lower. Common footstalk betit with strong, nearly opposite, prickles." Willdenow, from a dried specimen, without flowers. Pluket's says, "the fruit is a single, round, rough, or warty capillum, tautly turgid of campshair, lined with a white, smooth, inflipid membrane, containing a black polished seed, with a hollow whitish scar, in which lies the thread connecting the seed with its capsule." This very accurate description determines the genus. He adds, that the Chinese use this fruit instead of pepper.

8. X. sesquifolium. Shooter-leaved Yellow-wood. Lamarck n. 2. Willd. n. 8. (Euonymo affinis aromatica, five Xanthoxylum spinifolium, fraxini angulitse folio punctatum; Pluk. Amath. 76. t. 392. f. 1.)—Stem prickly. Leaflets lanceolate, finely ferrated; nearly equal at the base: common footstalk downy and prickly. Panicles axillary.—Brought from the islands of Chufan, like the preceding. The leaves are a foot long. Leaflets ten to eleven pair, with an odd one, each three inches in length, pointed, dotted; slightly downy beneath. Footstalk sometimes without prickles. Willdenow. Pluket's figure represents the panicle much like the preceding, but lateral. The capsula seem to be one, two, or three from each flower.

9. X. juglandifolium. Walnut-leaved Yellow-wood. Willd. n. 9. (X. americanum, five Hercules arbor aculeata major, juglandis folia alternis parum filifosis; Pluk. Phyt. t. 239. f. 63.)—Stem prickly. Leaflets oblong, pointed, obscurely ferrated; unequal at the base: common footstalk more or less prickly. Panicles terminal.—Native of Hispaniola and Nevis. Leaves pinnate, with an odd one; leaflets alternate, coriaceous, two or three inches long, marked with dintant, scarcely visible, pellucid dots; their edges entire to the naked eye, but under a magnifier appearing furnished with close dintant ferratures; contracted near the base, at the upper edge; rounded at the lower, rather downy beneath. Common footstalk betit with a few short scattered prickles. Panicles terminal, much branched, dense, downy. Capsules four or five, rather downy, pointed. Seeds black.

10. X. rigidum. Rigid Yellow-wood. Willd. n. 10.—"Stem prickly. Leaflets elliptical, entire, emarginate, painted; their veins hairy beneath; mid-ribs and footstalks prickly."—Native of South America. Humboldt and Bonpland. Leaflets four pair, coriaceous, on very short stalks; the upper ones largest, two inches long; lower but half an inch; their base rather unequal; sometimes having a short, obtuse, crenate point; their upper side polished, reticulated with veins; under paler, with one long, reddish, awl-shaped prickles on the mid-rib of each, of which there are several on the common stalk. Flowers not seen. Willdenow.

united.—Gathered by Aublet, in the forests of Cayenne, flowering in May, and bearing fruit in August. A tree, whose trunk is 40 or 50 feet high, and two feet and a half in diameter, with a prickly bark. The wood is white, hard, and compact. *Leaves* about five pair, nearly sessile, smooth; the largest six inches long, and an inch and a half broad. *Panicles* large and much branched, composed of numerous, small, white flowers, having flaments and pistils in the same individual. *Panicles* three, four, or five from each flower, redish, each containing a black, shining, oily seed. These *panicles* have a pungent aromatic flavour, and the Creoles call them negro's pepper.

12. *X. fraxinum*. Ash-leaved Yellow-wood, or Common Tooth-ache Tree. Willd. n. 12. Arb. 413. Ait. n. 2. Pursh n. 1. (X. Clava Hercules, Linn. Sp. Pl. 1455. X. ramiformor; Michaux Boreal.-Amer. v. 2. 235. Fagara fraxini folio; Duham. Arb. v. 1. 239. t. 97.)—Stem prickly. *Leaves* ovate, very minutely serrated; equal at the base. Umbels axillary.—Native of shady woods, near rivers, from Canada to Virginia and Kentucky, flowering in April and May. A tincture of the bark and *capsules* is recommended in rheumatism and the tooth-ache, whence its English name. *Purp.* A large deciduous shrub, whose branches are armed with sharp, conical, compressed, brown prickles, very broad at the base. *Leaves* four or five pair, with an odd one, an inch and a half long, on short partial flanks; contracted at each end; more or less distinctly crenate, or bluntly serrated; smooth above; soft and downy beneath. Their common footstalk is described without prickles; but in our specimens it is always furnished with nine, and occasionally with very numerous ones. The flowers are small, yellow-green, in little dense umbels, just above the scars of last year's footstalks, accompanied by a tuft of downy young leaves. The mode of inflorescence abundantly distinguishes this species from all the rest. It is hardy in our gardens, flowering in March and April, before the leaves appear. The bark is used in America, as a powerful sudorific and diuretic, whence its use, as above-mentioned, in rheumatic disorders. This is the species most popularly taken for *X. Clava Hercules*, as appears by the herbarium of Jacquin, purchased formerly by Sir Joseph Banks, and even by that of Linnaeus. The two species, nevertheless, are widely different.

14. *X. hierophyllovum*. Various-leaved Yellow-wood. (Macqueria Commeronii; Juss. 374, under Xanthoxylum.)—Young branches prickly; their leaves with very numerous serrated leaflets, on prickly common flanks; old ones unarmed, their leaves of seven entire leaflets, on unarmed common flanks. *Panicles* axillary. *Capsules* solitary.—Gathered in the Isle of Bourbon, by Commeron, some of whose specimens are in our possession. Nothing can be more paradoxical than the appearance of this shrub. We must rely on its discoverer for the accuracy of his specimens, as the two branches, so very different in appearance, are not connected together; though we cannot doubt their general identity. The young branch is slender, covered with innumerable, sharp, ascending prickles, of various sizes, a line long at most. *Leaves* alternate; common footstalk of each five or six inches long, round, straight, channelled, bevel with numerous prickles, like those of the branch, but smaller; *leaflets* from 4 to 6, more or less opposite or alternate, oval, bluntish, smooth, crenate or bluntly serrated, one quarter or one-third of an inch in length, of a fine green, paler beneath, marked with pellucid dots; their mid-ribs bearing one or two prickles at the back. The older or flowering *branches* are stout, rugged, unarmed, leafy at their extremities only. *Leaves* alternate, rather crowded, altogether defolute of prickles, each consisting of three pair of obovate, bluntly pointed, entire, coriaceous, veiny, smooth *leaflets*, with an odd one; the lowestmost *leaflet*; *common footstalk* channelled, smooth. *Panicles* compound, rather shorter than the leaves; their stalks unarmed, compressed, and angular. *Panicles* only one, perfect in each flower, brown, the size of a pepper-corn, rugged, full of pellucid dots lodging a pungent aromatic camphorated oil, and very bitter. *Seed* black, polished, with a bivalve elatic tunic, or lining of the capsule.

For *X. trifoliatum*, Linn., see *Panax Ateculatum*.

*XANTHURUS INDICUS*, in *Ichthyology*, the name of a fish called by the Dutch *geel-sard*.

It is of the size and shape of the bream; its jaws are armed with straight and very sharp teeth, which fland almost straight out; its back is yellow, and its tail very strongly tinged with that colour; its belly is of a bluish-white; its head brown, and its fins of a fine red. It is caught with hooks among the rocks on the shores of the Earl Indies, and is a very wholesome and well-fatted fish.

*XANTHUS*, in the *Natural History of the Ancients*, the name of an iron-ore of the hematrites or blood-flone kind, and usually accounted a species of it, and called by others *Elatinus*.

It was of a pale yellowish-white, or the colour of the French pale yellow ochre, used by our painters; but like all other ferruginous bodies it became red by burning.

Therophrastus gives us expressly the etymology of the name, observing that it was called so from its colour; the Dorians calling a yellowish-white *ξανθον*; *xanthus*.

*XANTHUS*, in *Ancient Geography*, a famous river of Aisia Minor, in the Troade. According to Pliny, it had its source in mount Ida, and discharged itself at the port of the Achaeans into the Hellespont, after having joined the Sinois.—Allo, a river of Aisia Minor, in Lycia, which had its source in mount Taurus, and watered the towns of Xanthus and Patara, and ran into the Mediterranean, near the laft of these places. This river was anciently called Sirbes, according to Strabo, and he says that the temple of Latona was situated ten stadia above its mouth, and sixty stadia farther was the town of Xanthus.

*XANTHUS*, or *Xanthopolis*, a town of Aisia Minor, and the largest in Lycia. It was situated seventy stadia from the mouth of the river on its bank. Pliny reckons fifteen miles from this town to the mouth of the river. Under Appian, the inhabitants of Xanthus were such enthusiastic for liberty, that when it was taken by Brutus they burnt it, and preferred death to submission to the conqueror. He adds, that the same circumstance occurred with regard to Harpalus, general of Cyrus the Great, and Alexander the Great. It fulfilled in the time of Strabo.—Allo, a town of the Isle of Lesbos.

*XANTIPPE*, a Biography. See *Socrates*.

*XANTON*, in *Geography*, a town of France, in the department of the Vendee; 5 miles E. of Fontenay-le-Comte.
XANXUS, in Natural History, a name given by some authors to a large species of sea-shell, somewhat like that with which the Tritons of old were painted. It is found in great abundance near Ceylon, and is used there in medicine as an alkali and absorbent in the same cafes in which we give the terebaceous powders.

XAPARACO, in Geography, a town of Mexico, in the province of Mechoaca; 85 miles W.N.W. of Mechoaca.

XARAMA, a river of Spain, which runs into the Tagus, a little below Aranjuez.

XATIVA, now St. Felipe, in Geography. See St. Felipe.

XAVIER, a town of Spain, in Navarre, the native place of the celebrated missionary of that name; 3 miles E. of Sanguefa.

XAVIER. See SABI.

XAVIER Gogo, a town of Africa, in the country of Whidah; 12 miles N.N.E. of SABI.

XAVIER, Saint. See Saint Xavier.

XAVIER Zante, a town of Africa, in the country of Whidah; 14 miles N.W. of SABI.

XAUXA, a town of Peru, in the bishopric of Guamanga, containing two churches; 90 miles E. of Lima. S. lat. 12°. W. long. 75° 50'. See XAUJA.

XAXA, a river of South America, which rises in the Andes, about 75 miles N. from Atun Xauxa, and uniting with the Apurimac, forms the Ucayale.

XAUXA, a town of Morocco, on a river, and at the foot of a mountain, both of the same name; 15 miles N. of Morocco.

XEBEC, in Sea Language, a small three-masted vessel, navigated in the Mediterranean sea, and on the coasts of Spain, Portugal, and Barbary. The fore and main masts are called block-masts, being short, and formed square at the head, to receive sails, to receive the jibs, &c. The mizen-mast is fitted with a top-mast, &c. similar to a small English ship, and which has been lately added, to keep them better to the wind. The xebecs have no bowsprit, but a small boomkin, wounded and confined to the prow, nearly horizontal (see Galley), to the outer end of which lead the bow-lines. The fore-mast rakes much forward, has no flap, and the hounds set up, similar to the runners in English cutters or sloops, to toggle fixed in the foils. These foils are easily shifted when the vessels go about. The main-mast is nearly upright, and rigs as the fore-mast. Each mast carries a latteen-fail, the largest side of which is bent to a yard that hoists by a purrel round the mast, at about one-third its length; the yards are worked at the lower end by bow-lines, and the fail extended by a fleet at the clue. The upper lee-yard-arm is worked by a brace, and the sail supported by vangs near the mast. The mizen-mast carries a latteen-fail, similar to the main and fore masts. Vessels with latteen-fails will lie one point nearer the wind than a square-rigged vessel. Xebecs, particularly in France, have been rigged similar to polarcars; but they never fail so well as they did in their primitive situation.

The xebec, generally equipped as a corsair, is constructed with a narrow floor, to be more swift in pursuit of the enemy; and of a great breadth, to enable her to carry a great force of fail for this purpose, without danger of overturning. As these vessels are ideally very low built, their decks are formed with a great convexity from the middle of their breadth toward the sides, in order to carry off the water, which falls aboard, more readily by their foppers. But as this extreme convexity would render it difficult to walk thereon at sea, particularly when the vessel rocks by the agitation of the waves, there is a platform of grating along the deck from the sides of the vessel toward the middle, on which the crew may walk dry-footed, whilst the water is conveyed through the grating to the foppers.

When a xebec is equipped for war, she is occasionally navigated in three different methods, according to the force or direction of the wind. Thus, when the wind is fair, and nearly astern, it is usual to extend square furls upon the main-mast, and frequently upon the fore-mast; and as the failure are rarely used in a heavy wind, they are of an extraordinary breadth. When the wind is unfavourable to the course, and yet continues moderate, the square yard falls are removed from the masts, and laid by, in order to make way for the large latteen yards and failure, which soon after assume their place; but if the foul wind increases to a gale, these failure are also lowered down and displaced, and small latteen yards, with proportional furls, are extended on all the masts. The xebecs, which are generally armed as vessels of war by the Algerines, mount from sixteen to twenty-four cannon, and carry from three hundred to four hundred and fifty men, two-thirds of whom are generally fiders. Falconer.

XEBEROS, in Geography, a town of South America, in the audience of Quito; 40 miles S.W. of La Laguna.

XEIUI, a river of Paraguay, which runs into the Paraguay.

XEKIAS, in Biography, a name given by the Chinefe and Japanece to an Eastern philosopher of mythological origin and character, called also Buddha among the Indians, Sonomoadom in Siam, and after his death Foe or Fotoki, who pacificated the whole northern and eastern region of Asia, as well as part of the southern, with his pantheistic doctrine. It is probable, as some have said, that he lived about 600 years before Christ; and having first appeared in the southern part of India, on the borders of the Indian ocean, differentiated his philosophy by means of his disciples to all India. It is said that he spent twelve years in solitude, when he was instructed by the Tolpoine, called by the ancients 'hylobii," i.e. "fylvan hermits; and that in his 50th year he devoted himself to contemplation, and attained to the intuitive knowledge of the first principles of all things, from which he took the name of Foe, which signifies, "something more than human." His mystical philosophy was delivered to his innumerable disciples under the veil of allegory. The Japanece add, that in his contemplations, during which his body remained unmoved, and his senses unaffected by any external object, he received divine revelations, which he communicated to his disciples.

Budda, or Xekias, in his esoteric doctrine, taught the difference between good and evil; the immortality of the souls of men and brutes; different degrees of rewards and punishments in a future world; and the final advancement of the wicked, after various migrations, to the habitations of the blest. Amidus, who, according to the Chinefe, is Xekias himself, prefigures in these habitations, and is the mediator, through whose intercession bad men obtain a mitigation of their punishment. These dogmas are contained in an ancient book, called Kio, which all the Indians beyond the Ganges, who follow the doctrine of Xekias,
receive as sacred, and which is illustrated by innumerable commentaries.

The doctrine which Xekias delivered towards the close of his life to his ecstatic disciples was very different. Vacuum, or void, was, according to his instruction, the principle and end of all things, simple, infinite, eternal, but devoid of power, intelligence, or any other similar attribute; and that to be like this principle, by extinguishing all passion and affection, and remaining absorbed in the most profound contemplation, without any exercise of the reasoning faculty, is the perfection of happiness. The first principle in this system cannot be pure nothingness, which admits of no properties; probably, it is First Matter, without variable qualities, whence all things are supposed to arise, which is not to be perceived by the senses, but contemplated as the latent divinity, infinitely distant from the nature of visible things, yet the origin of all substances. The emanations from this fountain became, in the popular theology, objects of the grosser superstition and idolatry.

The doctrine of Xekias was embraced by innumerable disciples. Among these, one of his most eminent successors was Tamo, a Chinefes, who was so entirely devoted to contemplative enthusiasm, that he spent nine whole years in profound meditation, and was on this account defied.

According to the Brahmins, Xekias had neither father nor mother; and as no Indian city claims the honour of his birth, he was probably a foreigner, who migrated to the southern part of India from some neighbouring maritime country, perhaps from Lydia; whither he came with some Egyptian colony, and who had been instructed in the Egyptian mysteries. It is not improbable, that at the time when Cambyses conquered Egypt, and dispersed almost the whole nation, this imployer might have passed over into India, and propagating his doctrine among an ignorant and superstitious people, became an object of universal veneration. Brucker's Philol. by Enfield, vol. ii.

Appendix. See Boodh, Brachmans, China, Japan, &c.

XEL, in the Materia Medica of the Ancients, a name given to the fruit fel.

XELSA, in Geography, a town of Spain, anciently a Roman colony, called Julia Celsa.

XELVA. See CHELV.

XENDAY, a town of Japan, in the island of Niphon; 115 miles N. E. of Jedo. N. lat. 39°. E. long. 141° 52'.

XENEXTON, a word used by Paracelsus, to express a fort of amulet to be worn about the neck, to preserve people from infection in the plague.

XENIA, δακτυλιον, q. d. gifts, in some Ancient Customs, were gifts, or presents, made to the governors of provinces, by the inhabitants thereof.

The word occurs pretty frequently in charters of privileges; where quietus et xenit denotes an exemption from making such presents to kings and queens, upon their travelling through such precincts.

XENIA, in Geography, a township of Ohio, in the county of Greene, with 1429 inhabitants.

XENIL, a river of Spain, which rises in Grenada, and runs into the Guadalquivir, about three miles below Écija.

XENINHPHIDEI, a word used to express a fort of invocatory spirit, mentioned by the adepts, as delighting to discover the occult qualities of bodies to men.

XENISMI, ενοικως, in Antiquity, sacrifices offered at the Athenian festival Anaea.

XENOCRATES, in Biography, a famous Grecian philo-

osopher, was born at Chalcidon, in the first year of the 96th Olympiad (B.C. 396), and attached himself at first to Elechines, but afterwards became a follower of Plato, and suc-

ceeded Speusippus in the chair of the old academy (B.C. 339). His temper was gloomy, his aspect severe, and his manners were little tinctured with urbanity. Plato took pains to correct these obliquities of his disposition and character; and as he highly respected his master, he probably improved by his instruction, so that he was reckoned as one of his most esteemed disciples.

Xenocrates was held in such estimation among the Athenians for his virtues, and especially his integrity, as well as his wisdom, that in a public trial his simple alliteration was accepted instead of an oath, which was usually required; and that even Philip of Macedon found it impossible to corrupt him. Dreading his influence, and the temptation of a bribe, he declined all private intercourse with the Macedonian sovereign, and was honoured by him with this testimony; that of all persons who had come to him on embassies from foreign states, Xenocrates was the only one whose friendship he was not able to purchase. On occa-

sion of being employed as an ambassador to the court of Antipater, for the redemption of several Athenian captives, he waved the honour of accepting the invitation of this prince to sit down with him at supper, in the words of Ulysses to Circe, cited from Homer's Odyssey. (I. x. v. 383;)

thus translated,—

"What man, whose bosom burns with generous worth,
His friends enthrall'd, and banish'd from his fight,
Would take a selfish, solitary joy?"

The patriotic spirit expressed in this appropriate passage gratified Antipater so much, that he immediately released the prisoners. As another example of his moderation, it is alleged, that when Alexander, wishing to mortify Aristot-

e, on account of some accidental pique, sent Xenocrates a magnificent present of 50 talents; he accepted only 30 mines, returning the residue to the donor with this message; that the whole sum was more than he should have been able to spend during his whole life. In this instance, he also mani-

fested a superiority to that kind of jealousy and revenge which might have actuated more timid minds, when it is considered that Aristo
tle had instituted a school in the Lyceum, in opposition to the academy over which Xenocrates presided.

In the use of food he was singularly abstemious; his habil-

ia was invincible by the seducing arts of Phryne, a cele-

brated Athenian courtesan; and his humanity was testified by the shelter which he afforded to a sparrow that was pur-

sued by a hawk, and fled into his bosom, where he allowed it to remain till its enemy was out of sight, alleging that he would never betray a suppliant. In the employment of his time, he allotted a certain portion of each day to its proper be

nife, one of which he devoted to silent meditation. His high sense of the importance and utility of mathematical studies was sufficiently evinced by his refusing to admit into his academy a young man who was ignorant of geometry and astronomy, because he was deftitute of the habits of philosophy. Upon the whole, Xenocrates was eminent, both for his purity of morals, and his acquaintance with science; and he supported the reputation of the Platonic school by his lectures, his writings, and his conduct. His life was prolonged to the third year of the 116th Olympiad (B.C. 314), or the 82d year of his age, when he acciden-

tally fell in the dark into a retainer of water; and the

sagacious tenets were Platonic; but in his lectures he adopted the language of the Pythagoreans. In his sys-
tem, unity and diversity were principles in nature, or gods; the former being the father, and the latter the mother of the

universe.
universe. The heavens he represented as divine, and the stars as celestial gods; and besides these divinities, he taught that there are terrestrial demons, of a middle order between the gods and men, partaking of the nature both of mind and body, and, like human beings, capable of passions, and liable to diversity of character. He probably conceived with Plato, that the superior divinities were ideas, or intel-
ligible forms, proceeding immediately from the Supreme Deity, and the inferior gods, or demons, to be derived from the soul of the world, and, like that principle, compounded of a simple and a divisible substance, or of that which always remains the same, and which is liable to change. Diogen. Laert. Plut. de Virt. Mor. De Is. et Osir. De Anim. Gent. Cicero de Nat. Deor. Brucker's Hist. Phil. by Enfield, vol. i.

XENODOCHUS, formed of ξένος, stranger, and ὁδοιπορός, I receive, an ecclesiastical officer of the Greek church, the same with the hospitaler, or a person who takes care of the reception and entertainment of strangers. St. Isidore, a priest and solitary, surnamed Xenodochus, lived in the fourth century. He was thus called, because entrusted with that office in the church of Alexandria.

XENOPHAROCHUS, formed of ξένω, stranger, and παροχός, of ἀμφίπορος, I furnis, among the Romans, an officer who provided ambassadors with all kinds of necessaries, at the public expense.

XENOPHANES, in Biography, the founder of the Eleatic sect, was born at Colophon, about the 56th Olympiad (B.C. 556) and having left his country, took refuge in Sicily, where he gained a sobriquet by reciting, in the court of Hiero, elegiac and iambic verses, which he had written against the theogonies of Hekod and Homer. From Sicily he removed to Magna Graecia, where he became a celebrated preceptor in the Pythagorean school, without ad-
hering fealty to the doctrines of Epimenides, Thales, and Pythagoras. His life was prolonged to the advanced age of 100 years, that is, till the 81st Olympiad (B.C. 456), during 70 years of which he occupied the Pythagorean chair of philosophy. In Enfield's Philosophy of Brucker we have the following summary of the doctrine of Xenophanes:—In metaphysics, he taught, that if ever there had been a time when nothing existed, nothing could ever have existed. That whatever is, always has been from eternity, without deriving its existence from any prior principle; that nature is one and uniform; that what is one is similar in all its parts, in which it would be many; that the one infinite, eternal, and homogeneus universe, is immutable and incapable of change; that God is one incorporeal eternal being, and, like the universe, spherical in form; that he is of the same nature with the universe, comprehending all things within himself; is intel-
ligent, and pervades all things; but bears no resemblance to human nature either in body or mind.

In physics, he taught, that there are innumerable worlds; that there is in nature no real production, decay, or change; that there are four elements, and that the earth is the basis of all things; that the stars arise from vapours, which are extinguished by day, and ignited by night; that the fun conflits of fiery particles collected by humid exhalations, and daily renewed; that the course of the sun is rectilinear, and only appears curvilinear from its great distance; that there are as many suns as there are different climates of the earth; that the moon is an inhabited world; that the earth, as appears from marine shells, which are found at the tops of mountains, and in caverns far from the sea, was once a gener-
al mass of waters; and that it will at length return into the same state, and pass through an endless series of similar revolutions.

The doctrine of Xenophanes concerning nature is so obscurely expressed by those who have transmitted an imperfect account of it, that it has been misunderstood and misrepre-

sented. Some have confounded it with the atheistical sys-
tem of Spinoza; by others it has been accommodated to the ancient doctrine of emanation; and others have main-
tained its similarity to the Pythagorean and Stoical notions of the soul of the world. The truth seems to have been, accordi

The doctrine of Xenophanes concerning nature is so obscurely expressed by those who have transmitted an imperfect account of it, that it has been misunderstood and misrepresented. Some have confounded it with the atheistical system of Spinoza; by others it has been accommodated to the ancient doctrine of emanation; and others have maintained its similarity to the Pythagorean and Stoical notions of the soul of the world. The truth seems to have been, according to Brucker's statement, that he held the universe to be one in nature and subsistence; distinguishing in his con-
ception between the matter of which all things consist, and that latent divine force, which he considered not as a distinct subsistence, but an attribute, and yet necessarily inherent in the universe, and the cause of all its perfection. This view of his notion is consistent with the language he used, and with the account of his doctrine, preferred by Sextus Empiricus, that God is of the same nature with the universe; τὸν Θεὸν ἐν ὑπὸ τοῦ ἀκατηγόρητον. When he asserted that there is no motion in nature, it is probable that he understood the term motion metaphorically, meaning merely that there is no such thing in nature as passing from nonentity to entity, or the reverse. Accordingly, the ancients more generally applied the term motion to a change of nature than to change of place. Brucker is of opinion that the notion ascribed to Xenophanes concerning the nature and origin of the celestial bodies, as meteors daily re-
newed, must have been founded on a misconception and mis-
representation of his opinion on the subject. See Eleatic Philosophy.

XENOPHILES, an able Greek musician, who pro-

fessed the philosophy of Pythagoras, and who lived at Athens, where he arrived at the great age of 105. It is Lucian who gives this account of his extraordinary longevity from Aristotheus.

XENOPHON, the son of Gryllus, an Athenian, was distinguis-

hished as a philosopher, commander, and histori-

an. His engaging appearance whilst he was a youth in-
duced Socrates to admit him into the number of his disci-

ples. Under his tuition he made rapid progress in that kind of wisdom for which his master was so eminent, and which qualified him for all the offices of public and private life. Having accompanied Socrates in the Peloponnesian war, and mani-

fested his valour in defence of his country, he after-

wards entered into the army of Cyrus as a volunteer; but his enterprise against his brother proving unfortunate, Xen-

ophon, after the death of Cyrus, advised his fellow-fielders to attempt a retreat into their own country under the auspices of the victor. His advice was regarded, and he was chosen as their commander. In the exerci-

cise of this duty he acquired by his prudence and firmness a high degree of honour; and the memorable adventure is re-

lated by himself in his "Retreat of the Ten Thousand." Having joined Agesilaus, king of Sparta, after his return into Greece, and fought with him against the Thebans in the celebrated battle of Chaeronea, he displeased the Athenians by this alliance; and he was publicly accused for his former engagement in the service of Cyrus, and con-
demned to exile. Thus ignominiously treated, the Spartans took him under their protection, and provided for him a com-
fortable retreat at Scillus, in Elis. In this asylum he enjoyed the pleasures of domestic life with his wife and two children for several years, and avoided himself of the leis,
ure that was thus afforded him by writing those historical works which have rendered his name immortal. On occasion of a war between the Spartans and Eleans, he was obliged to abandon this agreeable retreat, and to join his son, who was settled at Lepreus. From hence he afterwards removed with his whole family to Corinth, where, in the second year of the 105th

His

"Cyropædia," or "Institution of Cyrus," is generally regarded as a work of fiction rather than of real history, exhibiting, under the name of the elder Cyrus, the picture of a perfect prince, according to his own conception of the character. His "Anabasis" (or Ascent) is an account of that memorable expedition of the younger Cyrus, in which he himself appears so conspicuously. This work appeared under the name of Themistogones of Syracuse, to whom Xenophon himself ascribes it; nevertheless it has been universally ascribed to Xenophon: but if this be the case, it must have been written from memory, long after the events, which are differently related by Diodorus. Among his political works we may enumerate his accounts of "The Republic and Laws of Sparta;" "Of the Republic of Athens and its Revenues;" his "Præfate of Agesilus;" and his "Hiero, or Dialogue on Tyranny." Of a miscellaneous class, he wrote a treatise on "Oeconomics;" "On Hunting;" and "On the Office of Master of the Horse." The character of Xenophon, portrayed in his writings, seems to have exemplified virtue and humanity, kind and generous feelings, and a considerable degree of piety blended with superstition. In his Anabasis he exhibits a singular degree of credulity and regard to celestial warnings, which, in his view of them, governed his conduct, and were miraculously verified by the event. For his preference of the Spartan to the Athenian government and manners, derogating from his patriotism, the only apology is his beneficence. His style has been always admired for its purity, simplicity, and correctness; and his works are reckoned amongst the most perfect of the Greek classics, and have palled, collectively and separately, through several editions. Laertiæ. Ælian. Hist. Var. Fabr. Bib. Græc. vol. ii. Brucker’s Philof. by Enfield, vol. i.

XENOXUA, in Geography, a town of European Turkey, in Macedonia; 36 miles S.E. of Akrida.

XÉQUETEPEQUE, a town of Peru, in the government of Truxillo, on the Pasco Mayo; 55 miles N. of Truxillo.

Gen. Ch. Common Calyx imbricated; scales numerous, elliptic-lanceolate, saccate, permanent, the inner ones much longer than the disk, coloured, forming a radiant crown to the whole compound flower. Cor. compound, somewhat unequal; florets of the disk very numerous, all perfect, tubular, funnel-shaped, much shorter than the calyx, in five equal spreading segments; theohe of the circumference fewer, female, tubular, somewhat two-lipped, with five unequal segments. Stam. (in the perfect florets) Filaments five, capillary, very short; anthers forming a cylinder rather longer than the corolla. Pifl. (in the same florets) German short; style thread-shaped, longer than the flaments; stigma clowen; in the female florets, Stam. none. Pifl. German and style as in the perfect florets; stigma simple, club-shaped. Peric. none, except the calyx scarcely at all altered, except being closed. Seed in both kinds of florets alike, oblong; down a row of taper-pointed narrow scales. Recept. flatish, clothed with linear acute scales, rather longer than the florets.

Obf. Gaertner has long ago observed, what indeed no one could overlook, that the essential character of this genus, as given by Linnæus, answers to his first species only, X. annuum. This stands in the Syll. Peg. making a distinction by itself, characterized by a chaffy receptacle; whereas the other fections, "with a naked receptacle," receive all the numerous species besides, and directly contrast the generic character, "receptaculum polareum." Gaertner, Juffieu, and Willdenow, have properly corrected this oversight, as we have shown under Eichhornium. The true Xeranthemum, therefore, would be left with a solitary species, sufficiently well marked indeed to be so distinguished, as far as the Linnæan species go. But our great master is proved to have confounded several together, under his X. annuum. Willdenow distinguishes three species, two of which we cannot separate, but we shall subjoin a fourth. They were all known to Tournefort, who indeed divides them still further, mistaking double or white flowered varieties as species. The root of the whole genus is annual. Herb erect, rigid, alternately branched, clothed with fine, white, close, cottony down, easily rubbed off. Leaves alternate, feflle, lanceolate, acute, undivided, entire; tapering at the base. Flowers solitary, on long, terminal, slightly scaly, flanks. Outer scales of the calyx roundish, membranous and shining, at least at the edges; inner oblong, spreading while in flower, purple or brownish, occasionally white, very brilliant and ornamental.

2. Linn. Sp. Pl. 1201. X. imperatum; Willd. n. 2. Ait. n. 21; excluding the fyn of Morifon. X. capitulus imperatis; Hall. Enum. 700. t. 23. X. no. 122; Hall. Hist. v. 1. 52. Ptarmica Imperati; Ger. Em. 606, no figure. Jaccæ olear folio, minore flore; Bauh. Pin. 274.)

Outer calyx-scales roundish-elliptical, awned, smooth at
the keel; inner lanceolate, spreading. Crown of the seed lanceolate, shorter than the calyx. — Native of dry hilly ground in Austria, Hungary, France, Italy, and Greece; it is found in Switzerland, Spain, and Germany. This species is a hardy annual, common in our gardens, ever since the time of Gerarde and Lobel, flowering in July and August. The first variety, and especially the fimbifoliate kind, figured by Philip Miller in his *Icones*, is preferred for cultivation. The flowers with their stalks, dried quickly, prefer their shining purple colour very long, and make part of the winter decorations of a chimney-piece; but for this purpose, the back of every coloured scale of the calyx should be drawn, while fresh, over the edge of a blunt knife, to keep the flower open after it is dried. The stem is erect, branching, bearing linear-lanceolate, white, cottony leaves, and numerous flowers, an inch or more in diameter. The outer calyx-scales are membranous and shining, pale, quite smooth, each with a bright orange midrib, most conspicuous upwards, and terminating in a smallawn-like point.

In the variety B the flowers are of a smaller diameter, and the calyx spreads less; but we do not find that its outer scales are more acute, though somewhat variable in that respect; the inner are less strikingly purple, and turn browner as they fade. This variety we have from the Valais, as the undoubted plant of Haller, from the late Mr. Davall. Both kinds have a pleasant aromatic scent, different from the strong colour of the following.

1. Xeranthemum, Cylindrical Xeranthemum, Sm. Prodr. Fl. Græc. n. 2046. (X. orientale, flore minimo, calyce cylindraceo; Tourn. Cor. 38. X. oleæ folio capitulis simplexibus, incaucam, fescenta, flore purpuraceo minore; Morif. v. 3. 43. feet. 6. t. 12. f. 1.)—Outer calyx-scales elliptical, pointless, woolly at the keel; inner lanceolate, erect.—Native of Germany and Asia Minor. Gathered by Dr. Sibthorp in the Bithynian Olympus, or in its neighbourhood. Seeds of this species were given to Mr. Davall by Professor Lachenal at Bâle, for the common X. annuum, as figured by Haller; but on seeing the real plant of that author, above described, from the country of the Valais, he allowed them to be distinct. Mr. Davall first detected the true specific difference, in the woolly scales of the calyx, which, moreover, want the red mid-rib of the preceding species. Morifon indeed describes this mid-rib, which proves that he confounded X. annuum B, as many other people have done, with our *cylindricalum*; for Mr. Davall observed the strong difegniable fmmel in his fpecimens, by which Morifon characterizes the plant before us.

2. X. orientale. Oriental Xeranthemum. Willd. n. 3. Ait. n. 3. (X. annuum; Linn. Sp. Pl. 1221. X. orientale, fructu maximo; Tourn. Cor. 38. X. oleæ folio, capitulis compacitis; Morif. v. 3. 44. feet. 6. t. 12. f. 4. Jacea oleæ folio, capitulis compacitis; Bafl. Phil. 272.) J. incana, flore oleæ; Dalech. Hiift. 1193. Lob. lec. 545. f. 1.)—Outer calyx-scales roundish, membranous; inner ovate, pointed, erect. Crown of the seed ovate, awned, longer than the calyx.—Native of Armenia and Syria. The leaves of this species appear to be broader and more elliptical than either of the foregoing. But its most striking difference is visible in the ovate scales, forming the crown of the seed, each of them ending in a long point, far overlapping the upright radiating scales of the calyx. We have never seen a specimen, but the figures above cited render the plant sufficiently intelligible. Wildenow describes the flowers the size of X. annuum, or larger. Surely Lamarck's t. 692. f. 2. cannot be intended for this plant! We know nothing answerable to that figure.

**Xeranthemum**, in *Gardening*, contains plants of the herbaceous, flowering, annual kinds, in which the species cultivated are, the annual xeranthemum, or common eternal flower (X. annuum); the reflexed-leaved eternal flower (X. retortum); the golden eternal flower (X. speciosissimum); the vilifery eternal flower (X. sambroides); the proliferous eternal flower (X. proliferum); the leafy-flowered eternal flower (X. vellitum); and the imbricated eternal flower (X. imbricatum).

As to the species of Xeranthemum, see the preceding article. The first is an herbaceous flowering plant, of which there are varieties with large white flowers, with double white flowers, with double purple flowers, and with double violet-coloured flowers.

**Method of Culture.**—In the first fort and varieties, the culture is readily effected by blotting the seeds in pots of light fresh mould, in the autumn or spring, or at other seasons for a seccus, plunging them in a moderate hot-bed, to bring forward the plants. In the spring they may also be trown in patches where they are to remain, or in beds to be afterwards removed. When the plants have a few inches growth, they should be pricked out in rows a foot apart on beds, or into the borders, clumps, or other places where they are to grow. They should afterwards be kept clean from weeds, and have occasional waterings immediately after pricking out, and afterwards in dry weather.

The other forts are raised by planting cuttings of the young shoots in the summer, in pots filled with light mould, giving them a little water and shade; or, which is better, plunging them into a hot-bed, and covering them with hand-glasses. When they are become firmly established in the autumn, they should be carefully removed into separate pots, being replaced in the hot-bed till re-rooted, after which they should have the management of other thorny green-home plants.

The first fort produces a fine effect in the borders, clumps, &c. while growing, as well as in pots when the flowers are taken off; and the other forts afford variety in green-house collections, among other potted plants of the same kind.

**Xerasia**, in *Medicine*, the name of a disease, a species of alocpecia, in which the hair falls off through a dryness of the part, and want of due nourishment.

**Xerasia**, in *Animals*, denotes a certain kind of diseased state, which conflits in a dryness of the hairs, caused by the want of due and sufficient nourishment and support, from which they decay and fall off. It is met with in such animals as have been starved, and kept and fed in a stinted manner only on poor forts of food. It is to be removed by a better and more full kind of fodder, and other forts of keep, and by being turned into a good falt-marsh pature. See *Surfeit*.

**Xerequaro**, in *Geography*, a town of Mexico, in the province of Mechoacan; 45 miles N.E. of Mechoacan.

**Xeres**, a town of South America, in Paraguay, now in ruins. S. lat. 20° 5'.

**Xeres de Badajos**, or Xeres de las Caballeros, a town of Spain, in Estremadura; 72 miles N.N.W. of Seville. N. lat. 38° 17'. W. long. 6° 52'.

**Xeres de la Frontera**, a town of Spain, in the province of Seville, on the Guadalete; near which a battle was fought between the Moors and Goths, in the year 713, in which Roderick, the last king of the Goths, lost his life. The environs are celebrated for that excellent wine corruptly called sherry. The bold and richell fort of sherry is called "pagarette," from the Spanish word *pago*, a diörique, and particularly applied to this vintage. In one aranzado (an acre of vineyard) they plant 1800 vines at regular distances.
XER

rances. It is reckoned a good year if it gives three butts per acre, middling if two, and bad if but one: some years, however, it yields four or five. The number of inhabitants is estimated at 40,000, of whom one-twentieth, Mr. Swinburne says, are religious; 15 miles N.N.E. of Cadiz. N. lat. 36° 41'. W. long. 6° 15'.

XERES de la Frontera, a town of Mexico, in the province of Zacatecas, with a garrison of Spaniards to protect the mines; 25 miles S. of Zacatecas.

XERES de Guadalma, a town of Spain, in the province of Seville, near the frontiers of Portugal; 74 miles W. of Seville.

XERES NUEVA, a town of South America, in the province of Venezuela.

XERES. See Chulutaeca.

XERICA, a town of Spain, in the province of Valencia; 7 miles N.W. of Segorbe.

XERIFF, in Commerce, a money of account in Morocco, which is divided into eight paeis.

XERITO, in Geography, a small river of Spain, which runs into the Alagon.

Eff. Ch. Calyx two-flowered, of two unequal valves, parallel to the hollow of the receptacle, and half sunk therein; the outer valve smaller. Corolla of both flowers longer than the calyx, of two valves, awl-shaped, membranous, awnless. Stamens in the outermost flower. Styles in the inner one, combined at the base. Nectary none. Seed enclosed in the inner, paper-like, valve of the corolla.

This genus consists of perennial, rushy, dry, smooth grasses. Leaves awl-shaped, straight and finely, with a very short filiform. Stem terminated by alternate sheaths, each containing from two to four short spikelets, of few flowers. Xerocloa is akin to Aptlado, whose character requires correction. Brown.

XERODES, in Animals, a term which is applied, and which serves to express any fort of humour that is attended with the property of excitation or dryness. See TUMOUR.

XEROMYRON, formed of ἕρως, dry, and μούση, ointment, a word used by the ancients to express what they do at other times call in express words a dry ointment. It was a composition of warm aromatic drugs, or of other things fit for external use, but without the fatty ingredients, by which they were usually reduced into the form of ointments.

XEROPHAGY, ἕρωςφαγος, formed of ἕρως, dry, and φαγεῖν, to eat; among the Ancients, the feeding only on dry victuals, which was the practice of the athletes. In the first ages of the church, some, not contented with simple fasting, added the xerophagy thereto; abstaining not only from flesh and wine, but also from all fresh, succulent, and vinous fruits. And some even brought themselves to bare bread and water.

Tertullian, in his book De Abstinencia, cap. 9. speaks of the xerophagia as a thing commendable in time of persecution.

XEROPHTHALMIA, ἕρωςφαγος ἐπικύρως, compounded of ἕρως, dry, and ἐπικύρως, eye, a kind of ophthalmia, in which the eyes itch, and are red, but without swelling or watering.

XEROPHYLLUM, in Botany, from ἕρως, dry, and φυλλος, a leaf, a genus founded by Michaux upon Helonia apsbdolodes of Linnaeus. —Michaux Boreal.-Amer. v. 1. 210. Wild. Enum. 492. —We confest ourselves unable to make out any sufficient reason for this measure, either in the author's description, or in the plant itself. Mr. Pursh probably was equally puzzled; for he has not even cited the Xerophyllum of Michaux, as a synonym under the above Helonia. It seems the bafes of the ferns are dilated in the apsbdolodes, more than in other species of Helonias. See that article.

Gen. Ch. Col. none. Cor. of one petal, superior; limb in fix deep ovate-oblong, acute, permanent segments; the three outer ones narrowest, spinous-pointed, flouette, externally glandular. Stam. Filaments fix, inserted into the lower part of each segment, thread-shaped, very short, equal; anthers erect, linear, half as long as the corolla. Fil. Germ. inferior, turbinate; style one, short; stigma tumid, oblong, undivided. Peric. Capule ovate, rough, crowned with the faded corolla, with three cells, and many seeds.

Eff. Ch. Corolla in fix deep segments, permanent; three outermost narrowest, spinous-pointed. Stamens inserted into the base of each segment. Stigma club-shaped. Capule inferior, of three cells, with many seeds.

1. X. pinifolia. Fir-leaved Xerophyta. Wildl. n. 1. —Gathered by Commerson, in Madagascar. A hard rigid shrub, whose stem is round, alternately branched; the wood formed of parallel tubes, as in the generality of the monocotyledonous tribe: bracteae quarter of an inch in diameter, thickly clothed with the imbricated, deeply furrowed, permanent bracts of the last year's foliage, each crowned with the reflexed base of a leaf, by which the whole branch assumes a singular feasty appearance. Leaves alternate, two inches, or more, in length, linear, rigid, channelled, falcate, with thick entire edges, and a pungent spinous point; their base theathing, fibrous, and somewhat woolly. Flowers terminal, one or two at the end of each branch, on simple stalks, an inch long, rough, like the deren, with minute prominent glands, of which some traces are also found on the backs of the three outward segments of the corolla. The colour, of the inner segments at least, appears reddish. Each flower is about half the size of a flowerdrop. Nothing is known of the ripe fruit, in which perhaps some better marks, than have hitherto been given, may be found, to distinguish the essential characters of this genus from those of Hypoxis. See that article.

XEROPKIN, in Commerce, a silver coin of Goa, in the East Indies, which is worth 2s. 11d. sterling, nearly.

XEROTES, in Botany, ἕρως, dry, ἐν ψείμα, a name chosen by Mr. Brown to express the arid dry habit of this genus, in preference to Lomandra, by which it is designated in the work of M. Labillardiere. This latter appellation, formed of ψείμα, a border, or rather fringe, and ἐν, a male, is designed to indicate the ocassionally bordered anthers. It might perhaps have been allowed to remain, as well as many other names which are liable to some exception, though the anthers are not properly fringed. —Brown Prodr. Nov. Holl. v. 1. 159. (Lomandra; Labill. Nov. Holl. v. 1. 92.) —Cliffs and order, Dioscorea Hexandria. Nat.
XEROTES.

Gen. Ch. Male, Cal. Perianth of fix regular, ovate, coloured leaves; the three innermost, or perhaps all the six, connected at the base. Cor. none, unless the calyx be so called. Stam. Filaments six, very short, inserted into the base of each leaf of the calyx; anthers orbicular, peltate. Some rudiments of a pistil.

Female, Cal. Perianth of six separate, permanent leaves. Cor. none. Stam. imperfect. Pij. German superior, ovate, with three furrows; styles three, short, combined at the base; stigmas obtuse. Peric. Capsule cartilaginous, the centre of three cells and three valves, with partitions from each valve. Seeds solitary, peltate.

Female, Calyx of six separate, permanent leaves. Styles three. Capsule superior, coated, of three cells; valves with central partitions. Seeds peltate, solitary.

This New Holland genus consists of perennial herbs, of a dry rigid texture, and a peculiar aspect, resembling the Junci and Calamari. Root fibrous. Stem none, or generally very short; sometimes divided, and clothed with sheathing foliage. Leaves granny, linear, either flat or channelled, rarely thread-shaped; their base dilated, membranous, half sheathing; their extremity sometimes toothed. Flowers terminating the stem, or radical stalk, either panicked, racemose, spiked, or capitate. Inner leaves of the calyx often different from the outer in texture or size. When the flowers are female, they are inviolate with imbricated membranous bracteas; the male ones are sometimes flaked, without bracteas. Bark of the capsule at length separating, and occasionally a little pulpy. In some species, the stem of the seed adheres so loosely, as to resemble a distinct tunic. The embryo is longitudinal, straight, in the bottom of a cartilaginous albumen. Xerotes is allied in many points to the Palmæ. See that article. Brocas.

Sec. 1. Female flowers in solitary heads. Leaves entire at the extremity.

1. X. flexilis. Spiral-leaved Xerotes. Br. n. 1. (Draçena obliqua; Thunb. Draçen. 6. t. 1. f. 2.)—Stem somewhat branched. Leaves shorter than the branches, two-ranked, twisted; their edges rough with minute teeth; their points withering, acute. Male spikes interrupted, somewhat branched longer than the leaves. —Native of New South Wales, from whence specimens were sent us by Dr. White. The stem is about a foot high; woody at the base; more or less branched above, clothed with numerous, narrow, smooth, filariated leaves, an inch or an inch and a half long, spreading in two directions; their sheathing bafes imbricated, and bordered with a long, thin, torn, flipulaceous membrane at each side. Male flowers small, whitish, in long, mostly branched, rigid, filariated spikes or clusters, separated into little small-like tufts, accompanied by brown scaly bracteas. Female flowers rather larger, in round solitary heads, terminating short leafy branches in the forks of the stem.

2. X. mucronata. Pointed Xerotes. Br. n. 2.—Stem somewhat branched. Leaves shorter than the branches, but longer than the male spikes, two-ranked, straight, or slightly twisted; their points withering, acute; their margins roughish, with very minute teeth; dilated and entire at the base.—Gathered by Mr. Brown, near Port Jackson, New South Wales, as well as the foregoing.

3. X. collina. Hill Xerotes. Br. n. 3.—Leaves taller than the stem, narrow and straight; rough with marginal teeth; withering and very acute at the point; dilated and jagged at the base. Head of female flowers testile.—Found by Mr. Brown, on the southern coast of New Holland.

4. X. glauca. Glaucous Xerotes. Br. n. 4.—Leaves taller than the stem, narrow and straight; withering and blunter at the point; rough with marginal teeth; dilated and jagged at the base. Tufts of flowers in the male spikes testile.—Gathered on the south coast of New Holland by Mr. Brown.

5. X. leucopetala. White-headed Xerotes. Br. n. 5.—Male, as well as female, flowers capititate. Receptacle woolly. Leaves narrow, smooth-edged, longer than the perfectly simple stalk, bearing one or two heads of flowers. Stem short.—Gathered by Mr. Brown, in the tropical part of New Holland.

Sec. 2. Female flowers racemose or spiked; male ones racemose or panical; partial stalks featterd; flowers drooping.

6. X. paniculata. Few-flowered Xerotes. Br. n. 6.—Flowers few in the male cluster, in diffus whorls. Leaves very narrow, acute and smooth; dilated and entire at the base; shorter than the divided stem.—Found by Mr. Brown, near Port Jackson, New South Wales.

7. X. filiformis. Thread-shaped Xerotes. Br. n. 7. (Draçena filiformis; Thunb. Draçen. 6. t. 1. f. 1.)—Leaves thread-shaped, femicylindrical, elongated; flattened in front; rough-edged; finely fricated at the back; round at the point. Male cluster feecrly branched. Stem short.—Gathered near Port Jackson, New South Wales, by Dr. White, and Mr. Brown. The root is woody. Stem feecrly any. Leaves several, a span or more in length, erect, rigid, very fnder; flattened and whitish in front, with a green, fricated, central farrrow; convex at the back. We do not find that the point is always, as Mr. Brown says, round or cylindrical. Clusters much shorter than the leaves, branched in our specimens, as in Thunberg’s figure, erect, lax, with rough stalks. Flowers featterd, in pairs, drooping, whitish, small; the outer fegments of the calyx smaller, and more membranous than the inner. Bracteas awl-shaped, acute, at the base of the partial stalks. Mr. Brown notices three varieties: a, male perianth nearly globular, twice the length of the partial stalk; b, male perianth nearly globular; partial stalk longer than that part, or the bracteas: c, male perianth turbinate; partial stalk shorter than it, or the bracteas. The leaves feem variable in breadth and flatness.

8. X. tenisliformis. Fine-leaved Xerotes. Br. n. 8.—Leaves thread-shaped, elongated; channelled in front; deeply fricated at the back. Male clusters somewhat divided, their branches alternate. Stem short.—Observed by Mr. Brown, on the southern coast of New Holland.

9. X. gracilis. Slender Xerotes. Br. n. 9.—Leaves very long and narrow, channelled; fricated beneath; flat and entire at the point. Male panicles lax, alternately branched; partial stalks fultary. Stem short.—Found by Mr. Brown at Port Jackson.

10. X. dentilata. Small-toothed Xerotes. Br. n. 10.—Leaves elongated, thread-shaped, comprefled, channelled, with two or three terminal teeth. Male clusters fimple or divided. Stem short.—Gathered by Mr. Brown at Port Jackson. We have some fpecimens which answer to this defcription, in the teeth of their leaves, but they seem nearly akin to X. filiformis to be feparated from that fpecies, and they exactly accord with Thunberg’s fig. 1, drawn from a dried fpecimen. We are not, however, certain of their being Mr. Brown’s dentilata.

11. X. laxa. Loose-flowered Xerotes. Br. n. 11.—Leaves elongated, linear, flat, entire at the point. Male panicles
XEROTES.

paiciles loose, with whorled branches, and distant clusters; partial stalks solitary, shorter than the nearly globular perianth, but longer than their minute bracteas."—Gathered by Mr. Brown, in the same country with the two last.

Sec. 3. Flowers either foaked or paniced, their branches and tufts opposite or whorled. Male perianthia fife, imbricated with bracteas. Capsule smooth. Leaves toothed at the end.

12. X. rigida. Rigid Xerotes. Br. n. 12. Ait. Epit. 376. (Lomandra rigida; Labill. Nov. Holl. v. 1. 93. t. 120.)—Stem very short. Stalks and spikes much shorter than the foliage. Leaves two-ranked, carilaginous; convex beneath; abrupt, with two marginal teeth, at the end; smooth at the edges; dilated and entire at the base.—Gathered by Mr. Brown in the southern part of New Holland. M. Labillardiere found it in Van Lewin's land. Root woody. Leaves a span in length, full a quarter of an inch in breadth, spreading in two directions, thick, rigid, smooth; greatly dilated, and bordered with a membrane, at the base; finely divided, and three-pointed, at the end. Common flower-flats terminal, thick, sharply two-edged, sometimes triangular, smooth. Tufts of flowers one above another, not numerous, forming an interrupted, branched, upright spike; each tuft accompanied by several unequal, lanceolate, acute bracteas. Three alternate flaves, according to Labillardiere, are longer than the rest, and bear clowes, not bordered, anthers.

13. X. montana. Mountain Xerotes. Br. n. 13.—"Stem none. Leaves elongated, linear, flat, membranous, smooth-edged; their sharp point with two very short lateral teeth. Female spike undivided, many times shorter than its flat."—Found by Mr. Brown, near Port Jackson.

14. X. fluvioctis. River Xerotes. Br. n. 14.—"Stem none. Leaves elongated, narrow, channelled, smooth-edged, two or three toothed, with an acute sinus, at the extremity. Female spikes simple or divided. Bracteas rather rigid, twice as long as the tufts of flowers."—Gathered by Mr. Brown in the same country, but, as appears by the name, in the vicinity of rivers.

15. X. longifolia. Long-leaved Xerotes. Br. n. 15. Ait. Epit. 376.—Stem none. Leaves elongated, linear, coriaceous, erect; irregularly toothed at the point; rough-edged. Paiciles lanceolate, rather denfe, with opposite bracts. Flower-flats flat. Anthers uniform.—Gathered near Port Jackson, by Mr. Brown; at the Cape of Van Diemen, by M. Labillardiere. The leaves are a foot and a half long, somewhat fribated; dilated at the base, and bordered in that part with a membrane, which at length separates, and becomes torn. Stalk from nine to twelve inches high, two-edged. Flowers more numerous and crowded than in X. rigida, n. 12, with long taper-pointed bracteas. Capsule ovate, acute, twice as long as the calyx, chestnut-coloured; pale yellow at the base; its coat separating in irregular fragments.

16. X. hybriis. Porcupine Xerotes. Br. n. 16.—Stem none. Leaves elongated, linear, lax, smooth-edged; somewhat toothed at the extremity. Stalk rather convex on both sides. Male panicizes repeatedly compound, with whorled branches. Bracteas leafy, rigid, spinous pointed. —Sent from the neighbourhood of Port Jackson, among the first botanical communications from thence, by Dr. White. It has also been gathered there by Mr. Brown. We have seen the living plant in some garden near London, possibly at Kew, and were much struck with the delightful fragrance of its copious panicles of male flowers, reminding the scent of Crocosmia coccinea, Meijikeyrahymum montiflorum, or a Bergamot Pear. Yet it does not occur in

Hort. Kew. The leaves are a foot and a half or two feet long, spreading. Flower-flats of the male plant numerous, erect, two-edged, though convex at each side, from one to one and a half feet high, somewhat zigzag occasionally, each bearing a flattish panicle, from six to fourteen inches long, composed of numerous triangular branches, from four to eight in a whorl, beset with numerous tufts, or whorls, of feathery flowers, accompanied by several scaly, inner bracteas, and subtended by about three long, spreading, external ones, with needle-like points. The flowers, and whole paniciles, are of a delicate straw-colour, with a tinge of brown about the calyx or anthers. We have not seen the female plant. This species well deserves a place in the green-house, for the singularity of its appearance, as well as for its fine smell.

18. X. dillani. Distant-flowered Xerotes. Br. n. 18.—"Stem none. Leaves very long, channelled, very rough at the edges. Male panicile with undivided branches, and distant tufts of flowers. Partial flats shorter than the calyx."—Native of the tropical coast of New Holland. The male paniciles are a foot long; calyx about a line and a half. Brown.

19. X. media. Intermediate Xerotes. Br. n. 19.—"Stem none. Leaves very long, channelled, smooth-edged. Branches of the male panicile undivided. Flowers five or six in each tuft; their partial flats scarcely so long as the very short calyx. Female spike divided in the lower part, each branch bearing one head of flowers."—From the same country as the last. Calyx only one-third of a line in length; male panicile six inches. Brown.

21. X. multiflora. Many-flowered Xerotes. Br. n. 21.—"Stem none. Leaves very long, channelled, smooth at the back and edges. Male panicile with undivided branches, each bearing from one to three many-flowered tufts. Partial flats longer than the calyx."—Found by Mr. Brown in the same country as the four preceding species.

22. X. amula. Rough-long-leaved Xerotes. Br. n. 22.—"Stem none. Leaves very long, channelled, erect; rough at the back and edges. Male panicile with undivided branches, each bearing from one to three many-flowered tufts. Partial flats longer than the calyx."—Found by Mr. Brown, in the country near Port Jackson, New South Wales. The roughness of the leaves seems chiefly to distinguish this species from the last. We have seen no specimens of either.

23. X. Banksii. Bankian Xerotes. Br. n. 23.—"Cauliflora. Leaves two-ranked, flat, rough-edged. Female panicile denfe, about the length of its two-edged flate; branches quadrangular, very short."—Gathered by Sir Joseph Banks, in the tropical part of New Holland, where it was not found by Mr. Brown.

Sec. 5. Flowers of each sex in a cylindrical cask-like spike.

24. X.
XERES, in Geography, a river of Spain, which passes by Placentia, and runs into the Alagon.

XERTIGNY, a town of France, in the department of the Vosges; 7 miles E. of Epinal.

XERUMENHA, or Jerumenha, or Gurumenha, a town of Portugal, in Alentejo; 10 miles S. of Elvas. N. lat. 38° 35'. W. long. 6° 58'.

XERKENA, in Ancient Geography, a country of Asia, on the confines of Lesser Armenia, of which it makes a part.

XEROS, in Biography, was the son of Darius I. by Atossa, the daughter of Cyrus; and on the death of his father, succeeded to the crown of Persia, in the year 485 B.C. Having in the second year of his reign subdued the revolted Egyptians, and committed them to the government of his brother Achemenes, he determined to renew the invasion of Greece, in which Darius had been disappointed; and for the success of his expedition, he formed an alliance with the Carthaginians, on condition of their making an attack on the Greek colonies in Italy and Sicily, so that they might not have it in their power to afflict the mother-country. His preparations were immense, and occupied several of the first years of his reign. Having provided a large navy, he formed a project of cutting a canal through mount Athos, of sufficient breadth to admit two galleys abreast; and to this undertaking, which some have regarded as a fiction, he devoted three years. He also constructed a bridge of boats across the Hellepont, in order to convey his army from Asia to Europe; and as the first bridge which had been laid was demolished by a storm, he not only manifested his childish rage by ordering 300 lashes to be inflicted on the sea, and a pair of fetters to be thrown into it, but his tyrannical and cruel disposition by beheading those to whom the conduct of the work had been committed. The number of sea and land forces which he employed in this expedition is said to have amounted to two millions and a half, to which we may add as many more attendants. When he ascended a high tower at Abydos, and took a view of the immense number that covered the sea and surrounding plain, his pride and triumph are said to have given way to tears, when the reflection occurred, that the brevity of human life was such as not to allow one of this countless host to survive the lapse of 100 years. Without detailing the events of this disastrous expedition, which are the proper subjects of history, we shall merely mention that it terminated in the defeat of Xerxes's navy at Salamis, and the subsequent overthrow and dispersion of Mardonius's army of 400,000 men; and specify some traits of the disposition and character of this ambitious despot. For his ignominious treatment of Leonidas, we refer to his article. Upon his taking possession of Athens, he wreaked his vengeance on the buildings and the temples, and dispatched a special messenger to his uncle Artabatus, to inform him of this inglorious triumph. Having erected a throne on a lofty mountain, in order to view the expected victory at Salamis, the event produced such consternation, that he suddenly left Mardonius and the army, and hastened to the Hellepont, where finding his bridge shattered by storms, but still haunted with terror, he intrusted himself in a fishing-boat, and hastened to Sardes; but when Mardonius was defeated, and all his hopes of conquering Greece were frustrated, he quitted Sardes, after having given orders for the demolition of all the temples in the Greek cities of Asia, and proceeded with all possible expedition to the Persian frontier. The other traces of his disgraceful expedition were the records of the cruelties and debaucheries exercised by himself and his family. So much at length did Xerxes become the object of contempt and hatred, that a conspiracy was formed among his own guards, which terminated in his murder during sleep, in the 21st year after his accession, B.C. 465. Herodotus. Diodorus. Anc. Un. Hist.

XISTA, or Xystis, an Attic measure of capacity, answering to the Roman sextary.

XESTES; an ancient Greek liquid measure, which is = 2 cotylis. See Measure.

XIMETLA, in Geography, a town of Mexico, in the province of Xalisco; 30 miles S.E. of Purificacion.

XISSI, a town of the duchy of Warwick; 20 miles S.E. of Poen.

XIBACA, a town of Japan, in the island of Nippon; 20 miles S.W. of Mexico.

XICOCO, called also Sikoka, and Sikoji, an island of Japan, about 90 miles in length, and about half as many in breadth, divided into several provinces, situated near the south-west extremity of Nippon, from which it is separated by a strait, full of small islands, and to the north-east of Ximo. It has several convenient harbours, and many towns within the country. N. lat. 33° 30'. E. long. 132°.

XICONA. See XICONA.

XILCA. See CHILCA.

XILOA. See quiloa.

XILoca, a river of Spain, which rises in the south part of Aragon, about 7 miles N.E. of Albarracin, and at Calataud changes its name to Xalon.

XILOTEPEC, a town of Mexico, in the province of Guadaluca; 90 miles S.S.W. of Panuco.

XILVAN, a town of the principality of Georgia; 20 miles N. of Gory.

XIMABARA, a town of Japan, on the south coast of the island of Ximo, on a gulf to which it gives name; 33 miles E. of Nangafaki. N. lat. 32° 45'. E. long. 132° 47'.

XIMAGUINO, a town of Japan, in the island of Xico; 10 miles S. of Awa. N. lat. 35° 50'. E. long. 130° 30'.

XIMENA, a town of Spain, in the province of Seville. Near this town Carihus is said to have concealed himself in a cave, till Marius and Cinna were overthrown by Sylla; 24 miles E. of Medina Sidonia.

XIMENES, Francis, Cardinal, in Biography, was born in 1437 in Old Castile, and educated at Alcala and Salamanca. Renouncing prelatures which he obtained in his youth, he assumed the habit of St. Francis, in a monastery of the Observantines, one of the most rigid orders of monks in the Romish church. Distinguished by his humble life and devotion, he became confessor to Queen Isabella; and still retaining his customary mode of living, he was far engaged in his death by his attachment to the archbishopric of Toledo, the richest benefice in Europe next to the papal see; but his real affection was to accept this high prelacy could be overcome only by the authority of the pope. In this elevated station he maintained his strict adherence to the rigours of the order to which he belonged, and far from relaxing in it...
in his fervities, he indulged them to the extreme of selfmortification and penance. Having thus acquired a complete mastery over his own passions, and poising political talents in a very high degree, he was thought peculiarly fitted to exercise dominion over others; and accordingly Ferdinand and Isabella entrusted him with a principal share in the administration. When a strong party was formed among the Cathilians to deprive Ferdinand of the authority as regent, devoted upon him by the will of the queen, he was defeated by every peril of distinction except Ximenes and two nobles; and after he had resigned it to the archduke Philip, he again acquired it upon Philip's death in 1506, by the influence of Ximenes. In 1507 Ximenes was created a cardinal by pope Julius II.; and in the following year he undertook the conquest of Oran, and of other places on the coast of Barbary, with an armament, the expense of which he offered to defray out of his own revenues, and he succeeded in this enterprise. Such was Ferdinand's confidence in the abilities and integrity of the cardinal, that when he was dying in 1516, he appointed him regent of Castile until the arrival of his grandson Charles. Although he was then in his 75th year, he took an active part in securing the throne to Charles, though in his own judgment he disapproved the king's conduct, who in his assumption of power contended the declared opinion of the Cortes. With no less firmness and inflexibility, he prosecuted a plan for extending the royal authority, which the nobility had very much circumscribed. The measures which he adopted for this purpose excited violent opposition, but he perfidiously, and ultimately succeeded. During his administration he was also engaged in two foreign wars; one for the preservation of the kingdom of Navarre, in which he was successful, and another against Horace Barbarossa, who advanced himself from the condition of a corsair to the sovereignty of Algiers and Tunis, in which the Spaniards were totally defeated. When Charles was prevailed upon by Ximenes to visit Spain, the cardinal took a journey towards the coast to meet his majesty; but being disabled to proceed by the attack of a disorder, supposed to be the effect of poison, he requested an interview with the king; but Charles having conceived prejudices against him, returned a cold answer, with permission for his retirement to his diocese, that he might finish his days in tranquillity. In a few hours after the receipt of this letter, he expired November 1517, at the age of 80 years.

Ximenes was held in high estimation by his superlitiad countrymen, under a delusive idea that he possessed the gift of prophecy, and a power of working miracles. But his more unequivocal claims to their respect were founded on his extraordinary talents and learning, his liberal patronage of literature, and the munificence of his public charities, to which he devoted the immense revenues of his archbishopric. At Alcalá he built the magnificent college of St. Ildefonso, endowed with forty-six professorships, and conducted under excellent regulations. Here he printed the Complutian Polyglott, (see Polyglott,) the Mozarabic liturgy, and the theological works of Tolstaus. Here he also established a splendid monastery for the education of indigent females of quality, which served as a model for that of St. Cecily, under Lewis IV. The granaries which he constructed remained without decay for centuries; and upon the whole he was justified in declaring on his death-bed, that to the belt of his knowledge he had not misappropriated a crown of his revenue. Robinson's Charles V. vol. ii. p. 158.

XIMENES, in Geography, a town of Spain, in the province of Leon; 10 miles S. of Alorga.

XIMENESIA, in Botany, Cavan. Ic. v. 2. 60. Ait. Hort. Kew. v. 5. 85, a genus which can by no means be separated from Palusia. See that article. Nothing can be more trifling as a generic, or even specific distinction, than the difference between the fynogenous orders of Polygonum-superba, and P. fruticulosa, of the Linnean sytem, provided the form of the flories be alike. The ptil, of which rudiments are found in several genera of the latter, may occasionally become perfect, as it does now and then in Helianthus, and this overles the distinction.

XIMENIA, owes its name to Plummer, who consecrates this genus to the memory of the Rev. Father Francis Ximenes, a Spanish monk, one of the twelve Franciscan friars who first preached Christianity to the Mexicans. Being well skilled in the language of the country, he collected a great store of information concerning the properties and medical uses of the plants and animals of New Spain, and especially of Mexico; whom he composed a work, printed in four books, at Mexico, in 1615, which is quoted with approbation by De Laet, in many parts of his own publication. It is some consolation to find any of the apostles turning their minds to the study of their Maker's works; as we cannot suppose such to have been contaminated with that infernal spirit, which renders the whole history of the Spaniards in America a foul reproach to humanity, and to Christianity itself, so prostituted or so mifunderstood!—Plum. Stalks many-flowered.—Native of the neighbourhood of Carthagena, as well as of Hifpaniola, flowering in September and October, and ripening fruit in December. Jacquin. Of the rocky shores of Hisfpaniola, flowering in July. Swartz. We believe Linnaeus never saw any specimen of this, except in Cliffort's herbarium. That before us was given to the younger Linnaeus by Jaff. Joseph Banks. Though Miller might have the plant at Chelsea in 1759, it would now probably be vainly sought for in any collection. The stem is either shrubby or arboreous. Young branches spinous, round, flattened. Leaves two or three together, in alternate tufts, from buds of many years' duration, fleshed, elliptic-oblong-obtuse with a minut point, rarely emarginate, entire, single-ribbed, smooth on both sides, about two inches long. Footstalks quarter of an inch
inch long, smooth. Thorns lateral, erect, longer than the foot-talks, awl-shaped, stout, but sparingly produced. Flower-talks axillary, or rather from the same bud as the leaves, not half their length, deflexed, round, divided into from three to five smooth, single-flowered partial tals. Calyx spreading quadrangular. Petals four, white, fraggy, from the base almto to the apex, on the infide; smooth exter-

... Filaments (Amyris and XIPHIAS, clufive fecond this Species Ifnard, leaves, very on towards Leaves foliariis Willd. Aublet. X. of compars long, to Lyclum, which defines it under the title of "Makaira." This fish was cafl on the ifle of Rhé, near Rochelle in France. Its length was 330 feet or 98 centimetres, and its weight 265 kilograms; its colour was blackish. It was eaten by many of the inhabitants of Rochelle, and found to be tolerable food, though somewhat dry; the flesh was white. The "round-tailed sword-fish" is also described by Cepede, from the sword or finot preferred, with the fore-part of the head, in the Paris Musewm. Shaw's Zoology, vol. iv. part i.

XIPHIAS, also ued to express a fiery meteor, in form of a sword. See Acontias.

XIPHIAS, in Afronomy. See Dorado.

Gen. Ch. Cal. none. Cor. inferior, of six petals, regular, permanent; the three outer ones largest. Stam.
Filaments three, linear, opposite to the three inner petals; anthers ovate. 
\textit{Pijf.} German superior, globosae; 
\textit{fylle} thread-shaped; stigma simple. 
\textit{Peric.} Capsule at first fleshy, then dry, roundish, with three furrows, and three cells. 
\textit{Seeds} numerous, roundish, pointed, inferted into a fleshy, central, nearly globular, receptacle.

El. Ch. Corolla regular, of six petals. Capsule superior, of three cells, with many seeds.

Obf. The regularity of the flower readily distinguishes this genus from \textit{Wachendorfia}. See that article.

\textit{Xiphion adscendens.} Many-flowered Xiphidium. Swartz Prod., 17. Ind. Occ. 80. Vahl n. 1. (X. albidum; Lamareck Illhtr. v. 1. 131. X. album; Willd. n. 1. Ixia; Linn. in Lefl. L. 175.)

\textit{X. xerocolum;} Aubl. Guian. 33. t. 11. Willd. n. 2.

Ait. n. 1.—Native of South America, as well as of Tobago and St. Kitt's. Mr. Maffon is recorded by Dr. Swartz as having gathered the white-flowered kind, \( a \), at the foot of some hills, near Sandy Point, in the latitude-mentioned island; \( b \) was found in Guiana, by Aublet. We have a specimen of the latter from Miller's herbarium, gathered in some part of South America. The root is perennial, somewhat creeping, jointed. 

\textit{Stem} a foot or more in height, round, simple, as thick as the little finger, leafy in the lower part; more or less minutely hairy. 

\textit{Leaves} numerous, alternate, sessile, somewhat laciniate, leaf-shaped, pointed, entire, or minutely serrate, furnished with numerous longitudinal ribs.

\textit{Clavate} compound, terminal, erec, of many spreading, simply racemose, branches, more or less hairy, with a very minute bracteae under each partial flower-flake. 

\textit{Flowers} not half an inch in diameter. Three outer petals green, and downy at the back; white or blue in front, as the three inner ones are on both sides.

Swartz and Vahl have united the two supposed species of other authors. The latter affords the blue-flowered variety to be sometimes entirely smooth in its leaves as well as flowers.

\textbf{Xiphilitus, John,} in \textit{Biography}, was born at Trebizond, in the 11th century, and having passed the earlier period of his life in a monastery on mount Olympus, was advanced to the patriarchate of Constantinople, which office he held till his death in 1075. 

Before a sermon printed in the Bibliotheca Patrum, he is reputed by some to be the author of an "Abridgment of the History of Dion Cassius," in Greek, written faithfully, which was printed at Paris in 1592, fol.

\textbf{Xiphion,} or \textit{Xiphium}, in \textit{Botany}, \( \xi = \omega = \) Dioecoides, so called from the sword-shaped leaves, appears evidently, by the account of that ancient writer, to be \textit{Gladiolus communis}, Linn. Sp. Pl. 52. Our Common Cornflag, \textit{Xiphium} nevertheles is retained by Linnaeus as the specific name of a common, but very elegant and fragrant bulbous \textit{Iris}, with blue and yellow flowers. To this it seems he was led by Tournefort, who applies the name of \textit{Xiphion} to the whole tribe of bulbous-rooted species of \textit{Iris}, of which he makes a separate genus, characterised by the root. This is rather unfortunate, as the Linnaean \textit{Iris} \textit{Xiphium} has rather awl-shaped than sword-like leaves.

\textbf{Xiphoides,} \( \xi = \omega = \), in \textit{Anatomy}, a cartilage placed at the bottom of the sternum, called also \textit{enosiformis}.

It is about an inch long, and shaped like the point of a sword. Whence its appellation, from \( \xi = \omega = \), sword, and \( \omega = \omega = \), figure.

\textbf{Xiphonoe Promontorium,} in \textit{Ancient Geography}, a promontory of Sicily, near port Xiphonius.

\textbf{Xiphos,} \( \xi = \omega = \), among the Athenians, a capital punishment, by beheading with the sword.

\textbf{Xipixapa,} in \textit{Geography}, a town of South America, in the audience of Quito; 80 miles N.W. of Guayaquil.

\textbf{Xiquacon,} a town of Mexico, in the province of Mechoacan; 50 miles S.E. of Zacatula. N. lat. 18° 4'. W. long. 102° 34'.

\textbf{Xiquena,} a town of Spain, in the province of Málaga; 15 miles W.N.W. of Lecia.

\textbf{Xiquito,} a town of Japan, in the island of Xino; 16 miles S. of Naka. N. lat. 33° 26'. E. long. 133° 15'.

\textbf{Xir}, a word used by the chemists to express mercury.

\textbf{Xisimum,} a word used by some of the chemical writers to express vinegar.

\textbf{Xivert,} in \textit{Geography}, a town of Spain, in Valencia; 7 miles N.W. of Segorbe.

\textbf{Xivry le Frang,} a town of France, in the department of the Mofelle; 9 miles S. of Longwy.

\textbf{Xixona,} a town of Spain, in Valencia. In the neighbourhood of this town a great number of perfoms are employed annually to collect the drug called Kerme, and a small district, called \textit{de la Grana}, produces some years to the value of 20,000 dollars; 15 miles N. of Alicante. N. lat. 38° 32'. W. long. 40° 42'.

\textbf{Xizaboras,} mountains of South America, in the province of Venezuela.

\textbf{Xoana,} in \textit{Ancient Geography}, a town of India, on this side of the Ganges.

\textbf{Xochicocito,} in \textit{Botany}, a name used by some authors for the tree which produces the liquid amber, and is called the sweet gum by the inhabitants of the Weil Indies.

\textbf{Xochitenacatl,} in \textit{Ornithology}, a name given by some to the toucan, or American great-beaked magpie.

\textbf{Xochitenacatl, Allia,} the name of a bird described by Nieremberg, of the nature of the toucan, or Brazilian magpie.

It is of the size of a pigeon; its beak is large and thick, and is black and pointed; its wings and tail are variegated with black and white; it has a large black mark reaching from its back to the breast; the anterior part of the wings is yellow, the ruf of its body of a pale colour, and the legs and feet brown. It always is found among the sweet-flowering trees, and is not uncommon in many parts of South America.

\textbf{Xocotlan,} or \textit{Xocuttan,} in \textit{Geography}, a town of Mexico, in the province of Xalisco; 15 miles S.W. of Purification.

\textbf{Xocochohitl,} the Indian name of the clove-berry-tree, or the \textit{caya carpefolvina}, the bark of which is used in medicine.

\textbf{Xodracel,} in \textit{Ancient Geography}, a town of India, on this side of the Ganges. Potelamy.

\textbf{Xoles,} an island of the Mediterranean, on the coast of Egypt, near the mouth of the Nile, called "Xebenniticum:;" and also a town of the same name. Steph. Byz.

\textbf{Xois,} a town of Egypt, in the Nome, denominated Xoites Nomos. Potelamy.

\textbf{Xola,} in \textit{Geography}. See \textit{Sooloo}.

\textbf{Xolo.} See \textit{Glolo}.

\textbf{Xomtoll,} in \textit{Ornithology}, the name of an American bird, of which the Indians are very fond, making a part of their garments of its feathers.

Nieremberg has given a short account of it. It is a web-footed fowl; its back and the upper part of its wings are black, and its breast is brown. When it is angry, it raises up the feathers of its head in form of a crest. Ray.

\textbf{Xorullo,}
XORULLO, or Jorullo, *Volcano of*, in Geography, a balsatic cone of New Spain, which appeared above ground on the 15th of September 1759, and which is at this day 249 fathoms or 1494 feet above the surrounding plain. It is situated in the province of Mechoacan, at the distance of eight leagues from Pafquaro the capital, towards the S.W.; the volcano of Colima being in the same direction, but at a greater distance. A delicious and fertile vale, eight leagues in length from N. to S., and three in breadth, was called Xorullo by the Indians, a word in their language signifying paradise; but upon the eruption of the volcano, this valley assumed an infernal aspect, blackened with perpetual smoke, covered with deformed rocks and ashes, the trees consumed, the earth full of deep breaks and openings, and now forming a hill of considerable height, crowned with a volcano. A rivulet which fertilized the valley is now so hot as to burn men and animals who attempt to pass it, which is peculiarly inconvenient, as it is in the direct road to the copper-mines in this quarter. Before this catastrophe, there were constantly heard horrible subterraneous noises, and earthquakes were felt, which excited conflagration in the inhabitants.

XOOUHQUITICPATLI, an American name of a stone of the jasper kind, and of a beautiful green, but usually pale, and sometimes with a mixture of grey, and variegated in several places with spots of a deeper green.

It is found among the several kinds of *lapis nephriticus*, with which that country abounds, and most of which the Indians celebrate for their virtues against diseases; they are not, however, acquainted with any medicinal virtues of this species.

XV. VIR, *Quindecinvir*. See *Quindecinvir*.

Authors, and especially antiquaries, make use of such abbreviations, which they borrow from medals, and other monuments of antiquity, where those names are prefixed.

XUAREZIA, in Botany, according to De Theis, is a genus dedicated, in the *Flora Peruviana*, p. 20, to Gaspar Xuarez, a Spanish botanist, who has devoted himself to the study of the plants of Italy.

XUCAHA, or *Xucaaa*, the name of a plant much famed for its virtues among the ancient Arabsians, but unknown at this time.

XUCAR, in Geography, a river of Spain, which rives in New Caftile, and runs into the Mediterranean, 20 miles S. of Valencia.

XUCHEIS, or *Zecheis*, in Ancient Geography, a town of Africa, in Libya. Steph. Byz.

XULI, in Geography, a town of Peru, in the diocese of La Paz, near the west coast of lake Titicaca, chiefly inhabited by Indians, and governed by Indian magistrates; 100 miles N.N.W. of La Paz. S. lat. 16° 25'. W. long. 70° 6'.

Xuli, a small island in the Pacific ocean, near the coast of Peru. S. lat. 16° 50'.

XULLA, or XULLOE, an island in the East Indian sea, about 42 miles long, and from 10 to 15 broad. The English some years since formed a settlement in this island, but from the badness of the soil, and some other circumstances, they were induced to abandon it, and remove to Balambangan, on the coast of Borneo. S. lat. 1° 53'. E. long. 115°.

XULLABELLA, an island in the East Indian sea, about 25 miles long, and 6 broad. S. lat. 2° 15'. E. long. 120° 12'.

XULLAMANCOLA, an island in the East Indian sea, about 30 miles long, and 10 broad. S. lat. 1° 54'. E. long. 125° 42'.

XUN, a city of China, of the second rank, in Set-chen; 150 miles S.W. of Pao-king. N. lat. 30° 18'. E. long. 103° 20'.

XUNDALE, a town of South America, in the province of Popayan; 8 miles S.W. of Santo Fe de Antioquia.

XUQUI. See Jegui.

XUTHIA, in Ancient Geography, a country of Sicily. Diod. Sic. It is represented as a town by Steph. Byz.

XUXUY, in Geography, a town of La Plata, which chiefly trades in cattle, E. to the miners of Potoí, and brought in considerable number to the great fair of Salta; but now in a declining state. See Jujuy.

XYLAGIUM, a name given from authors to the lignum fumftum or guaiacum.

XYLANDER, William, in Biography, whose family name was Holtsmann, was born in indigent circumstances at Augsburg, in 1532, and enabled by public liberality to study at Tubingen and Basil, in the latter of which places he took the degree of M.A. in 1556. In 1558 he was invited to undertake the Greek professorship at Heidelberg; where, with all the disadvantages of penury, he pursued his literary labours, and acquired an amplitude of erudition, which comprehended the learned languages, history, poetry, music, philosophy, and physics. The works by which he is chiefly known are Latin translations, (with notes,) of Dion Cassius, Pintarch, Strabo, and Credrenus. His life was prematurely terminated in consequence of hard study, in 1576, at the age of 44 years. Moreri.

XYLARIA, in Botany, from *xylos*, wood, a name given by some cryptogamic botanists to the first section of the genus *Sphéria* in Perforo. (See that article.) The idea appears to have been suggested by the old name of *Hypoxylon*, belonging to one of the species. But it may also apply to the woody and durable texture of that and some others of the same section.

XYLENOPOLIS, the Town of the Woods, in Ancient Geography, a town of India, at one of the mouths of the river Indus, according to Pliny, who reports that it was built by Alexander. M. D'Anville thinks that this town is the fame with Hyala. It subsisted in the time of Pliny.

XYLINA, IXIL, a town of Aia, in the Colchide, and country of the Lazi. It was situated on the right bank of the Arcamis, near its mouth in the Euxine sea, north of Chorôdia.

XYLINE, a town of Cappadocia, in Cappadocian Pontus. Ptol.

XYLINES, a people of Africa, in Libya interior, E. of the Agangines, from the foot of mount Arvalle, as far as mount Arangas. Ptol.

XYLÁLOE, compounded of *xylon*, wood, *aloë*, aloes, in Medicines, the lignum aloes; called also agarholcum. See *Aloe*, and *Calambar*.

XYLÁLO-BALSAM, *Xylálo-balsam*, compounded of *xylon*, wood, and *balsam*, balm, a name which naturalists, &c. give to the wood of the tree, which yields that precious gum known to the Latins by the name of *opobalsamum*, and, among us, by the name of *balsamum* or *balmum* of Gilded.

We have branches of this tree brought from Cairo. They are very straight, brittle, unequal, and full of knots; their bark is reddish without, and greenish within. The wood is whitish, and full of pitch; and, when broken,
broken, yields an agreeable smell, resembling that of the
ballam.

The *xylo-balsamum* is reputed good to strengthen the
brain and stomach, and to expel poison.

**XYLOCARACTA,** or *XYLOCARACTE,* in the *Materia
Medica,* a name by which some authors have called the
carap; or *Cilicia dulcis,* the sweet pipe-tree.

This was called by some of the Greek writers *xylocaratan,*
the tree bearing pods, and from a corruption of this name
the other has been formed.

**XYLOCARAPUS,** in *Natural History,* a name given by
some authors to a poisonous kind of wood.

It was the wood of that tree whose gum was called
*carapus* and *opocarpamus.*

**XYLOCARUS,** in *Botany,* from ἕνδον, wood, and
ἐκαρπός, fruit, alluding to the woody texture of the feed-
in Lamarck Dict. v. 8. 806.—Clafs and order, *Orandria
Ch. Car. Perianth inferior, of one leaf, club-shaped,
continuous, somewhat coloured, with four roundish teeth.
Cor. Petals four, ovate-oblong, rather coriaceous, widely
spreading, twice the length of the calyx. Nectary erect,
ovate, inflated, somewhat fleshy, with eight marginal
segments. Stam. Filaments no other than the eight seg-
ments of the nectary, linear, obtuse, marginate, shorter
than the petals; anthers eight, attached to the inner side
of the filaments, and of the same length, linear-oblong, abrupt.

*Pyl.* Gern man superior, ovate, smooth, slightly rugged at the
base; style very short and thick; stigma abrupt, broad;
bordered, its margin furrowed, its silk furrowed croft-
wife, and perforated. *Peric.* Drupa large, globous, dry,
with a thick coat; externally smooth, marked with four or
five furrows; internally woody and fibrous. *Seeds.* Nuts
eight, ten, or more, angular, unequal, irregular; their
outer skin soft, and rather fiky; inner woody and fibrous;
kern in some degree woody, brittle, with a prominent
embryo.

Eff. Ch. Calyx oblong, with four teeth. Petals four.
Nectary inflated, with eight teeth bearing the anthers.
Drupa superior, dry, woody, with four or five furrows.
Nuts numerous, angular, irregular.

as above. Willd. n. 1. (Granatium littoreum; Rumph.
Amboyn. v. 3. 92. t. 61. Cadal gaba of the natives of
Ceylon. *Candilanguy* in the Tami language.)—Native of
muddy thickets on the sea-shores of Amboyna, Ceylon,
and other parts of the East Indies, among *Rhizophora*
branches, flowering in November, and bearing fruit in January and
February. A tree varying greatly in size, sometimes little
more than a shrub; its wood elegantly veined, but so
twisted and knotty, that no large handseme pieces can be
procured. The trunk is erect, with a hard, deeply cracked
bark; the bead dense, roundish, or oblong. Larger branches
scattered; smaller generally opposite, numerous, clothed
with a greyish bark. *Leaves* opposite, falkled, spreading,
oblong, obovate, or elliptical, acute, entire, rather larger
than those of an apple-tree; dark-green, smooth and shining
on the upper side; veiny beneath, with a prominent mid-
rib. *Pooiflakes* short, roundish, spreading, a little curved,
rugged, of a chestnut-brown. *Chlifers* scatcered or axillary,
flakked, rather spreading, shorter than the leaves; their sub-
divisions opposite, or three-forked, with round, smooth, red,
tough, naked *filcs;* the ultimate ones shorter than the
flowers, which are small, yellowish, or dirty white. Their
nectary somewhat resembles a Lily of the Valley, but these
flowers have no smell. The *fruit* is larger than a pome-
granate, sometimes the size of a child's head of three years old,
and contains from eight or ten to two hundred angular unequal
or bigger, which do not appear to be used as food. There is a very remarkable disproportion between
the magnitude of the *flowers* and *fruit.* Rumphius, from
whom, as well as from Koenig, we take our description, hints
that the *flowers* are perhaps dioecious. It is certain that
most of these, so numerous in each cluster, must be abortive,
or there would not be room to perfect the *fruit.*

**XYLOCASIA.** See *Cassia.*

**XYLOCCUCUM,* in the *Materia Medica,* a name given
by some of the later Greek writers to the carob-tree, or
filica dulcis.

**XYLOCOLLA,** a word used by some of the ancient
writers to express what was more usually called *naurecola,*
glot made of the ears and genitals of a bull.

**XYLOCOPIA,** *Robur* *Cassii,* among the Greeks, a punish-
ment with a cudgel. See *Fustigation.*

**XYLODON,** in *Botany,* from ἕνδον, wood, and ἐκαρπός,
a *tooth,* an appellation given by Perlooon to the third fiction of
his genus *Sistotrema,* *Syn. Fung.* 550. (See that article.)
The lamelle of that genus, (which is intermediate, as he justly
says, between *Boletus* and *Hydnum,* though, in our opinion,
most akin to the latter,) are of a firm, woody, and durable
nature, and divided into many compressed irregular teeth.

**XYLOGLYCON,** a name given to the carob, or *filica
dulcis,* by some of the old Greek writers.

The word expresses a sweet orweet-fruited tree.

**XYLOIDES,** or *Hyloides,* a term used by many of
the ancient writers to distinguish those plants which had
woody flakcs, though they never grew up to any con-
iderable size; such as the garden-thyme, marjoram, and
the like.

**XYLOMA,** so called from the firm or woody fululence
of the whole fungus, and the jagged or radiating margin
of one of the most common species, *X. acerinum,* the *flower*
being apparently composed of ἕνδον, wood, and ἐκαρπός,
—Clafs and order, *Cryptogamia Fungi.* Nat. Ord. *Fungi
Angiocarpi.*

Eff. Ch. Flat, nearly orbicular. Receptacle various,
hard, somewhat fleshy internally; either remaining clofed, or
bursting unequally.

Seet. 1. Compound. Several receptacles combined. Rather
large.

Meth.* 5. t. 2. f. 4.—Thick, tuberulated; internally carti-
laginous, and white at the base.—Frequent on the leaves
of *Salix caprea.* This, according to Perlooon, is generally
clofed, but he has found it in the spring, as delineated in
the work quoted, breaking, in the upper part, into several por-
tions, like the shell of a tortoise, from whose interstices the
fine powdery *feeds* flew off like *fimoke.* The breadth of the
whole fungus is about half an inch; its colour black.

—*Oblong, thickish, with rib-like elevations, polished.*—
Found in summer on the leaves of *Andromeda polifolia,* which
hence appear as if pitch had been dropped upon them.
Sometimes each fungus is as long as the whole leaf; some-
times only half as long. Its thickcens is coniderable with
regard to the size. The lower *frutum* is white and firm, as
in the foregoing.

3. *X. acerinum.* Maple Xyloma. Perf. n. 3. (Spharia
macrocarpa; Ehrh. Carm. Beitr. v. 7. 171.)—Dilated, somewhat orbicular, thin, flat, black, slightly cor-
rugated towards the centre.—Frequent on the leaves of

Acer
Acer platanoides, and A. campestre, in the autumn. It consists of numerous, black, opaque, inseparable patches, scattered over the upper side of the leaf, each about a quarter or one-third of an inch in diameter; the margin sometimes variably and elegantly notched, or fringed, and always circumcised by a very striking yellow, or tawny, discoloration of the leaf. Perfoon says he has observed the surface of this species, though usually almost even and uniform, cracking into waved bordered figures. We can see something of this in a specimen from professor Schrader.

4. X. punctatum. Sycamore Xyloma. Perf. n. 4. Obl. Mycol. v. 2. 100.—Diluted, thin, imperfectly orbicular, somewhat convex, black. Receptacles unequal, aggregate, parallel, oblong, blunt, superficial. —Often on the fading or fallen leaves of Acer Pseudoplatanus, which are rarely without this parasite in autumn and winter. The patches are from half an inch to an inch wide, closely united with the leaf, slightly convex above, and rather concave at the under side, which is somewhat blackened by them, especially at the circumference of each. The wrinkles, or receptacles, are frayed like the clefts of an OPOGRAPHIA (see that article); but much more shallow, as well as more uniform in colour.

5. X. fellare. Starry Xyloma. Perf. n. 5. Obl. Mycol. v. 2. 100.—“Thin, pitchy; the margin fringed with radiating fibres.” —Found by Perfoon, on the leaves of Phyto- lemma spicatum, though rarely. About half an inch broad, more or less, of a handom appearance, with an uniform smooth disc, very black; the marginal fringe either black, or greyish. No distinct receptacles have yet been noticed.

6. X. rubrum. Red Xyloma. Perf. n. 6. Obl. Mycol. v. 2. 101.—“Aggregate, orbicular, somewhat confluent, red.” —Generally found in autumn on the leaves of Plana Injum varia, rarely on P. spinosa. At first fight the red colour of this species, all the others being black, causes it to be taken for an A. Platanus, or Urnus; but on examination the internal substance proves to be solid, uniform, scarcely containing distinct receptacles, or feel-reefs; its genus, however, is reckoned by Mr. Perfoon as very doubtful. The patches are each from two to four lines broad, rather thick, with darker-coloured superficial dots, visible only with a microscope. Perfoon.

Sec. 2. Simple. Receptacles solitary, scattered; generally rounded, like a Peziza; or dot-like. Smaller.

7. X. penisoides. Cup-like Xyloma. Perf. n. 7. (Peziza conica; Sovern. Fung. t. 118. P. viridis; Bolt. Fung. t. 109. f. 1.)—Rather crowded, orbicular, black; opening at length, with an upright, somewhat crenate, border, and a pale olive or greenish disc.—Found on fallen leaves of oak in December; more rarely, and in lefs perfection, on those of beech. The specimens are pretty uniform in size, larger than mustard-feeds, closely attached to the surface of the leaf; the border of each sometimes pale, sometimes black, unless Sowerby and Bolton describe two different species.

8. X. spheroidees. Dot-like Xyloma. Perf. n. 8.—“Scattered, dot-like, softish, with an open disc, and a collapsed inflexed border.” —On the leaves of Salix caprea. This at a distance resembles Sphero phloris; but under a magnifier it looks like some Peziza, with a crispel margin. The outside is black; the disc, rarely all displayed, is paler.

9. X. hylteroides. Oblong Xyloma. Perf. n. 9. “Ic. et Defer. Fung. t. 10. f. 3. 4.”—“Elliptical, shining, ranged nearly parallel.” —On the fallen leaves of Hawthorn, in the spring. Each plant is one-third of a line long, ovate, or elliptical, of a shining black; solid within. A longitudinal line feeds to mark the place where it finally bursts.

10. X. farctrum. Willow Xyloma. Perf. n. 10. (“Spre- ria fuliginosa; Ebrh. Crypt. v. 290.”) —“Aggregand and rather crowded, orbicular, thin, with a somewhat convex disc.” —On the leaves of Salix caprea, occupying nearly their whole surface. Each individual is from one-third to one-half a line broad.

11. X. populina. Aspen Xyloma. Perf. n. 11.—“Ag- gregate, flattened, variably shaped, smooth, opaque, black.” —Found on the old leaves of Populus tremula, in the spring. About a line broad; the disc here and there greyish.

14. X. alnca. Alder Xyloma. Perf. n. 14.—“Mi- nute, scattered, roundish, plaited.” —This species is met with in summer, upon Alder-leaves, while they are still green. It consists of a few black different dots.

These minute productions are necessarily very obscure in their characters and economy. The present genus is marked by its internal solidity, of a corky or woody substance, having nothing of a gelatinous nature, nor are there any distinct round capsular receptacles, as in SPHERIA. See that article.

Gen. Ch. Cut. none. Cor. Petals four, regular, equal, linear; externally hairy; a little dilated and concave at the tip; revolute soon after expansion. Nectary four glands at the base of the germin. Stem. Filaments four, very short, inserted rather above the middle of each petal, and becoming prominent by its recurvation; authors linear, inflexed, of two lateral parallel lobes, with a membranous edge; imperfect in some of the flowers. Pyll. Germin superior, roundish; style crect, rigid, the length of the petals, deciduous; Stigma vertical, club-shaped, obtuse, often small and abortive. Pyt. Follicles woody, very thick, ovate, of one eccentric small cell, and bursting into two diovicated half valves, at the point. Seeds two, roundish, compressed, each with a terminal, oblong, rather oblique, membranous wing, as long as the follicle.

Eff. Ch. Petals four, bearing the petals above the middle, regular, revolute. Nectariferous glands four. Stigma club-shaped. Style deciduous. Follicle woody, of one eccentric cell, with two winged seeds.

1. X. pyriformis. Wooden-pear. Brown n. 1. (Bankia pyriformis; Gaertn. v. 1. 280. t. 47. f. 1. Lamarck Illuir. v. 1. 242. f. 54. f. 4. White’s Voyage 224. t. 21. Hakea pyriformis; Cavan. Ic. v. 6. 25. t. 336.) —Gathered on the eastern coast of New Holland, near Port Jackson, by the firr settlers in that colony. We received specimens from Dr. White,
Dr. White, in 1780 and 1793. Mr. Brown says it grows
on stony hilly ground. This, the only known species, is a
tree, with opposite branches; downy and roughy when young.
Leaves opposite, flaked, five inches long, lanceolate, acute
at each end, entire, rather coriaceous, smooth, with one rib,
and many prominent reticulate veins; pale and yellowish
beneath; clothed, when they first come out, with downy, de-
ciduous, roughy down: those of young plants, according to
Mr. Brown, are toothed. Feowflats flatish, an inch long,
smooth. Stipulas none. Spikes axillary, opposite, catkin-
like, cylindrical, dense, much shorter than the leaves, many-
flowered, shaggy with roughy down. Flowers simple, hardly
an inch long, in pairs, each pair accompanied with one small
downy bractia; all of them abortive, except the lowermost,
so that from specimens seen in fruit only, the flowers were
judged to be fertile. The fruit is ovate, or inervertly
pear-shaped, very hard, even, downy, two or three inches in
length. Seeds and their wings brown. Mr. Brown remarks,
that the greater part of the flowers, having a small stig-
ma, and no germen, are necessarily abortive. Many of the authors
too have, as above-mentioned, an imperfect appearance;
but having never seen living flowers, we cannot tell whether
this be an error, or defect, or merely owing to their having long
ago performed their office. It is possible that the roughy
hue of the flowers and young leaves, so rich and beautiful in
our specimens, may partly, or if not altogether, be owing to
drying. This plant, though procured for Kew garden, by
Sir Joseph Banks, in 1789, appears never yet to have
blossomed there.

XYLON, is so well described by Pliny, book 19.
chap. 1, as to leave no doubt of its being our Cotton. (See
Gossypium.) He says it served to make the choice
garments of the Egyptian priests. Dr. J. R. Forster,
the famous botanist and circumnavigator, published in 1776 a
most learned little volume, to prove Cotton the true Bybus
of the ancients. See also Math. Valgr. v. 1. 376.

XYLON, Xylon, among the Athenians, a punishment
inculcated, by putting the offender into the trucks.

XYLOPHYLLA, in Botany, very expressively named
by Linnaeus, after Rumphius, from xylon, wood, and
xylon, a leaf, in allusion to the hardiness and rigidity of its foliage,
which indeed serves the purpose of both leaves and flowers.
(Phyllanthus; Browne Jam. 188.)—Clafs and order.
Monocia Monadelphia. (Pentandria Trigynia; Browne,
Juff.

Gen. Ch. Male, Cal. Perianth in fix regular
segments; the three innermost largelst. Cor. Petals none,
unless the calyx, or its inner segments, be taken for such.
Nectary of six globular glands. Stam. Filaments united
into a very short column; anthers three or fix, roundish;
two-lobed.

Female, on the same plant, and in the same situation, as
the male. Cal. and Nectary as in the male. Fil. Germin
superior, sessile, roundish; styles three, short, spreading;
stigmas three-cleft. Peric. Capsule roundish, with three
furrows, three cells, and six elastic valves. Seeds two in
each cell, roundish.

Eff. Ch. Male, Calyx in fix deep segments; three
of them inferior. Petals none. Nectary of six globose
 glands.

Female, Calyx and Nectary like the male. Styles three.

Stigmas three-cleft. Capsule of three cells, with fix elastic
valves. Seeds two in each cell. 1816. Dr. Sim's, in Curt. Mag. 1021, has justly
indicated this genus as too near Phyllanthus (fee that
article); where the seeds are erroneously said to be fertile.
Whether the difference between their neftarias be permanent,
we have not seen enough to determine. At any rate,
these two genera must stand next to each other, in the Lin-
nuce artificial fytem, as well as in every natural one.

Mant. 221. Wildl. n. 1. Swartz Obf. 112. (Xylo-
phyllus ceramicas ; Rumph. Amboyn. v. 7. 19. t. 12.)—
Leaves linear, alternately toothed. Flowers solitary at
each tooth.—Found only on the lofty, flaty, cold mountains of
the island of Ceram. The trunk is shrubby, scarcely so
thick as a man's arm, dividing above it into many round
branches, as thick as the finger. These end in numerous
alternate, drooping, long, linear, acute leaves, or perhaps
winged branches, with blunt alternate teeth, usually an inch
distant from each other. The flowers are solitary, nearly
feellite, at each notch. Of their structure nothing is known;
nor of the fruit, except what Rumphius relates, and this,
that Dr. Swartz observes, does not agree with the genus
before us, Linneas having merely adopted this remarkable
plant as a Xylophylla, on account of its habit, which is
striking enough. Rumphius says, "the calyx resembles a
small close, and is red, bearing a roundish-oblong fruit,
resembling a Bay-berry, or the Abris of Alpinus, (and
Linneas,) green, hard, with a small point. When opened,
a small nucleus is found, resembling a grain of rice, fixed
on the flalk, and tainting sweet, like a Fliberd, being enclosed
in a white skin." It is very unlikely that the kernel of
any species of this genus should be edible.

Mant. 221, excluding the synonym. Wildl. n. 2. Ait.
28. Swartz Obf. 113. Curt. Mag. t. 1021. (Gennel-
phylla aspleniophila; L'Herit. Sert. Angl. t. 39. Phyllan-
thus n. 1. Browne Jam. 188. Heminontis affinis, ame-
ricana epiphyllanthos, &c.; Plunk. Phyt. t. 36. f. 7.)—
Leaves rhomboid, crenate; notches crowded, each bearing
one or more flatlke flowers.—Native of lime-floke rocks,
near the sea-foke, in the West Indies. Mr. Waller is re-
corded in Hort. Kew. as having first sent this elegant and
fingular shrub to his friends in England, in 1783. If we
mitake not, the marquis of Rockingham, who died in 1782,
received it from Mr. Waller some time before; the original
having been long one of the dowager marchioness's finest
plants. It flowers in a flow copiously in August and
September. The flum is four or five feet high, with a
round bushy head. Leaves a foot long, alternate, flatlke,
alternately pinnate; leaflets twelve or more, nearly fellite,
one or a half or two inches long, ovate-rhomboid, acute,
hard and rigid, ereet, flarised, smooth; entire towards the
base. Flowers copious, small, green, on simple crimson
flalks; thole of the female flowers much the longest.
Both floum and pinnate sometimes occur in the same flower,
according to Dr. Swartz.

Swartz Prodr. 28. Wildl. n. 3. (Phyllanthus speciafo;)
Jacc. Coll. v. 2. 36o. Ic. rar. t. 616. Swartz Ind.
Occ. 1107. Schneev. Ic. t. 30.)—Leaves pinnate, lan-
colate, pointed, crenate; notches crowded, each bearing
one or more flatlke flowers.—Native of the hloing rises
of lofty mountains, in the south part of Jamaica. Swartz.
We can discern no real specific difference between this and
the last. The leaves indeed are narrower, more elongated
and less falkate, but those characters vary. Dr. Swartz
153
lays a stress on the flowers being polygamous in *latifolia*, monoeocious in *Arbutfola*; but nothing is more variable than this circumstance. It is difficult to lay which of the two Schneevogel's figures represents.

4. *X. falcatu*. Sickle-leaved Sea-side Laurel. Swartz Prodr. 28. Willd. n. 4. Ait. n. 2. Andr. Repof. t. 331. (Phyllanthus Ephyllanthus; Linn. Sp. Pl. 1302. Ph. americana plants, flores e fingulis foliorum crebris proferens; Comm. Hort. v. 1. 199. t. 102.)—Leaves scattered, linear-lanceolate, somewhat falcate, dimly toothed. Flowers nearly felfile, many together at each tooth.—Native of the Bahama islands. Cultivated for above 120 years past in the flowers of England and Holland, flowering in July and August. The *fem* is five or six feet high, shrubby, with round branches. Leaves not pinnate, with a flat stalk, as in the two laft, but fattered irregularly over the branches, each proceeding from a fealy bud, simple, five or fix inches long, one-third of an inch wide, rigid, ftriated, tapering at each end; entire towards the base; alternately toothed in the upper part, the teeth an inch or more fufder. *Flowers* crimson, on short ftalks, fome male and fome female in each tuft; the latter fewest.

5. *X. anguifolia*. Narrow-leaved Sea-side Laurel. Swartz Prodr. 28. Willd. n. 5. Ait. n. 3. (X. elongata; Jacq. Hort. Schonbr. v. 3. 53. t. 348. Poirret n. 7. Phyllanthus n. 2; Browne Jam. 188. Ph. americana, anguli ci et longi folio, ramosa, caulecens; Plin. Phyto. t. 247. f. 4. Ph. anguifolia; Swartz Ind. Occ. 1111.)—Leaves pinnate, linear-lanceolate, rather dimly toothed, fcarceiy curved. Flowers on short ftalks, polygamous, one or more from each tuft.—Native of fkyony rocky situations, in the western part of Jamaica. *Swartz*. Cultivated in the English fflowers before 1789, flowering in July and August. Aiton. This agrees with our fecond and third fpecies, in having feveral alternate *tegfeis*, on a flat or channelled, bordered common *ftalk*; but fearceiy half as many on each *ftalk* as in thofe; and of a longer narrower form, not copiously crenate, but fparingly and rather dimly toothed, more in the manner of *X. falca*. The *fem* is only two feet high. The *flowers* are lefs copious than in the laft-mentioned fpecies, and, according to Dr. Swartz, there are fome perfect, intermixed with the male and female ones. Their colour is red; the male ones palel. (Jacquin's figure exprefles the contrary.) Plinnet's engraving, fuch as it is, manifestly agrees with this fpecies, but with no other. Linnaeus, no doubt, conftituted this, and, at one time, the *latifolia* also, with the *falcata*. Browne's synonymes are retitled by his own fpecies, though unmarked.

6. *X. linearis*. Linear Sea-side Laurel. (X. anguifolia *β*; Swartz Prodr. 28. Willd. n. 5. Phyllanthus linearis; Swartz Ind. Occ. 1113.)—"Leaves pinnate, linear, tapering, plant, crenate; their common *ftalk* bordered. Flowers feveral from each notc."—Native of fady fkyony banks of rivers, in the western part of Jamaica. *Swartz*. The *fem* is fcarceiy a foot high, erect, with round branches. Common *footftalks* four or five inches long, fattered, crenated, (rather defcribed,) bordered. *Leaves* linear, rather breadtht in the middle; tapering at the base; ending in a very long acute point, ftriated, paler beneath, two inches long, of a thinner fubftance than the foregoing fpecies, which circumstance, added to its humbler ftature, and different colour, has induced Dr. Swartz to conftider it as diftinct. The *flowers* are white, monoeocious, from three to fix at each notc of the leaves, on capillary *ftalks*, four lines in length.

8. *X. ramiflora*. Siberian Sea-side Laurel. Ait. Hort. Kew. ed. 1. v. 1. 376. ed. 2. n. 4. Willd. n. 7. (Pharylanthus? fuffructicum; Pallas It. v. 3. 716. t. E. f. 2.)—Leaves elliptical, flatkilled. *Flowers* axillary.—Native of the defarts of Siberia, from whence it was procured for the English gardens, in 1783, by the late Mr. Bell. It is a hardy shrub, flowering in July and August. Pallas, who never faw the plant alive, merely gefuled at its genus. By his figure, its habit is altogether that of a *Phyllanthus*. The *fem* is bfly, with many ftrait, wand-like, leafy branches, each a fpan long. *Leaves* scattered, thin, hardly an inch in length, blunt, crenate, or somewhat wavy. *Flowers* fix or eight together, making a little axillary tuft, accompanied by minute red *flipulas*, or *bracteas*. Segments of the *calyx* five, concave, white, with a coloured margin. *Anthers* five, thick, obtufe, furrowed at the outside. *Germen* in the fame flower, as we preffume from Pallas's defcription, very small. *Styles* three, thread-shaped, fimple, the length of the *flamen*. The genus of this fpecies is, at best, very doubtful, as Willdenow has already remarked.

*Phyllanthus* and *Xylophylla* are fo totally different in habit, and the latter is, in this refept, fo very peculiar, that a clear character between them is much to be defired. The true *Xylophylla* are all of Weft Indian origin. The tropical *Phyllanthi* are natives of the East Indies; a few hardy fpecies grow in North America.

*Xylophylla*, in *Gardening*, contains plants of the tender exotic kind for the flove, in which the fpecies cultivated are, the long-leaved love flower (*X. longifolia*), the broad-leaved love flove (*X. latifolia*), and the falcated love flove (*X. falcata*). The *frik* is a branching angular plant, but the fecond has round branches; and the *lait* is woody in the items and branches.

*Method of Culture.*—These plants are increased by fowing the seeds in pots in the early spring, and plunging them in a hot bed: when the plants are come up two or three inches in growth, they should be pricked out in separate pots, replacing them in the hot bed; they may afterwards be managed as other flove-plants of a fimilar growth.

They are also, fome of them, capable of being raised by off-sets, slips, and cuttings, affifted by a hot-bed in the fame manner.

They require the conftant protection of the flove in winter, but in the hot summer months may be set out in their pots in a feltered situation, being taken in on the approach of cold nights.

They afford variety, and are curious in fove collections among other plants of fimilar growths.

E. *XYLOPIA*,

*XYLOPIA,*
XYLOPIA.

XYLOPIA, in Botany, altered by Linnaeus from Xylopi- crum of Browne, a name which the latter took from Pluket, whose Xylopiocrum, formed from Xylo and piocrum, alludes to the bitternes of the wood. M. De Candolle, in following Linnaeus, observes that this abbreviation entirely destroys the sense. It certainly does to those who do not trace out the source of the word. If the original had been constructed in the most unexceptionable manner, we might have had its restoring it; but Xylopia is now too firmly established to be lightly disturbed, and is found nothing can be better.—Linn. Gen. 459. Schreb. 375. Willd. Sp. Pl. v. 2. 1750. Mart. Mill. Dict. v. 4. Aiit. Hort. Kew. v. 3. 350. Juff. 284. De Cand. Syll. v. 1. 499. Poiret in Lamarck Dict. v. 8. 816. Lamarck Illust. t. 495. Gaertn. t. 69. (Xylopliccrum; Pluk. Almagr. 395. Xy- lopicrum; Browne Jam. 250.)—Claus and order, Polyan- dria Polygynia. (Gynandria Polyanthera, Linn.) Nat. Ord. Coadunatae, Linn. Annea, Juff. Annonaceae, De Candolle.

Gen. Ch. Cal. Perianth inferior, of one leaf, in from three to five deep, broad, ovate, coriaceous, rather acute, permanent segments. Cor. Petals six, fleshy, linear-lanceo- late, coriaceous, much longer than the calyx; the three outermost large. Stam. Filaments none; anthers numerous, oblong, quadrangular, abrupt, parallel, crowded, seated on the mound, nearly globular, receptacular, in several rows. Pct. Germanic several, on short stalks, compressed; styles tapering, crowded together; stigma simple. Peric. Capsules several, stalked, coriaceous, compressed, bluntly angular, of one cell and two valves, bursting at the top. Seeds one or two, obovate, polished, tunicated at the base.

Eff. Ch. Calyx lobed, coriaceous. Petals six; the three outermost large. Capsules stalked, angular, compressed, of two valves. Seeds one or two, tunicated.

The plants composing this genus are trees or shrubs, with oblong or lanceolate (entire) leaves, and axillary, bracteate, simple or divided flower-stalks. The wood is bitter; bark and fruit aromatic. De Candolle, who describes eight species, of which the first is still the least understood.

Linnaeus, by a misapprehension of the true character of his own class of Xyloxiaceae, (see that article,) has placed this genus under the Annonaceae, from Annona, Univeria, &c., to which it is closely allied, both in natural and artificial distinctions.

Few genera have hitherto been less understood.

t. X. muricata. Rough-fruited Bitter-wood. Linn. Sp. Pl. 1567. Willd. n. 2. De Cand. n. 1. Aiit. n. 1. (X. frutescens; Gaertn. v. 3. 359. t. 69, excluding the synonym of Aubl.) Xyloplicium n. 1; Browne Jam. 253. t. 5. f. 2.)—Leaves ovate-lanceolate, pointed; clothed with close-preffed hairs beneath. Branches zigzag, nearly smooth. Stalks with several flowers. Fruit muricat. Found by Dr. Patrick Browne, at the foot of the moun- tains, in Sixteen-mile walk, Jamaica. His specimen, drawn in the plate above-cited, is in our hands, but deprived of the leaves. This deficiency is supplied by another very large and perfect one, gathered in Jamaica, by Mr. Maffen. The latter M. De Candolle unfortunately did not see, when the writer of this was favoured with too short a visit from this learned and amiable man. It is become necessary to correct some errors in the description, whose source is unknown to us. The leaves are certainly not "bearded at the point," nor do we perceive in what sense they are termed "arigone beneath." These are Wilkenow's expressions, adopted by De Candolle. Sir Joseph Banks sent a living plant of this species to Kew garden, in 1793; but if it survives, it has not yet flowered. This is a small tree, fifteen or twenty feet high, with alternate, round branches, zigzag when young, quite smooth, except towards the very extreme, which is slightly fleshy. Leaves alternate, on short thick stalks, spreading, rather ovate than lanceolate, with a blunt or emarginate, smooth point; their length two inches, or a little more; their margin entire, slightly revolute; their upper surface smooth and shining, reticulated with veins; under paler, more opaque, clothed with fine, scattered, close, fleshy hairs, after a while deciduous; mid-rib fleshy, rough with minute tubercles at the back. Flower-stalks cori- pious, axillary, solitary, short, knobby, bearing from two to five flowers. Calyx three-lobed, scarcely downy. Petal half an inch long, densely fleshy on both sides; the three innermost very narrow, triangular-awl-shaped. Capsules, by Gartner's account, which in the main agrees with that of Linnaeus, nearly ovate, but angular and compressed, sometimes as many as fifteen, coriaceous, covered with little points, of one cell and two valves, containing one or two oval seeds, each with a cup-like tunic at the bottom. Browne made no remarks on the bark or wood of this tree. We perceive little bitterness in either, though some aromatic flavour in the bark. This species being the type of its ge- nus, we have thought a full description requisite.

2. X. Juvata. Shrubby Silky Bitter-wood. Aubl. Guian. 215. 1742, excluding the synonyms of Linnaeus and Browne. Willd. n. 2. De Cand. n. 2. "Dunal Monogr. 120." Lamarck t. 495, copied from Aublet, excluding the fruit, which is Gartner's figure of the foregoing. Poiret n. 2. X. fetosa; Poiret n. 4, according to De Candolle. Embora feu Pindaiba; Pf. Bras. 71. Ibira; Marcgr. Bras. 99.)—Leaves lanceolate, pointed; glaucous and fleshy beneath. Branches fleshy. Stalks with few flowers. Capsules smooth.—Found by Marcgraf in Brazil, flowering in February; by Aublet in Cayenne and Guiana, bearing flowers and fruit in August. M. De Candolle has examined a specimen, and we, having seen none, are obliged to rely on him and the other authors here cited for the spe- cific distinctions between this and the first species. The smoothness of the fruit, the filkinness of the branches, and narrowness of the leaves, appear sufficient to ascertaining the present plant. Marcgraf lays the bark affords a tough kind of cordage. The fruit, equal in size to hazel-nuts, is aromatic and acid, serving, when powdered, instead of pepper.

3. X. Jalcifolia. Willow-Leaved Bitter-wood. "Humb. and Boupl. unpublished. Dunal Monogr. 121. t. 17, 2." De Cand. n. 3.—"Leaves oblong, with a blunter point; fleshy beneath. Stalks short, fingle-flowered, with small bractees."—Found by the celebrated travellers baron Humboldt and M. Bonpland, near Epsinal, in South America. A tree with blackish branches, marked with white dots. Leaves narrow, an inch and a half or two inches long, three or four lines broad, on short stalks, fingle-ribbed, without veins; smooth and green above; villous beneath, with close-pressed, fleshy hairs, of a rufous grey. Capsules from five to seven, gibbous, slightly pointed, not burring. Seeds one or two. De Cand.

4. X. hygrophyla. Privet-Leaved Bitter-wood. "Dunal Monogr. 121. t. 18." De Cand. n. 4.—"Leaves oblong, rather acute, smooth on both sides. Stalks short, with few flowers, and small bractees."—Gathered by Humboldt and Bonpland, at Buga, in South America. The branches are round, blackish, rugged, rough with whitish points. Leaves an inch and a half long, four lines broad, on very short stalks, fingle-ribbed, veinlets; somewhat shining above; paler beneath; the young ones silky at the under side. Stalks axillary, with three or four flowers, and roundish con- cave

Native of Cayenne. Branches wand-like, slightly rugged. Leaves on short stalks, smooth on both sides, three or four inches, (the author, by mistake as we presume, lays three or four lines,) in length, and from twelve to fifteen lines broad; shining above; rather glaucous beneath. Stalks single-flowered, axillary, very short, each bearing an extremely minute bracteas. Calyx deeply three-cleft. Petals ovate, acute, scarcely two lines long, being the smallest of this genus, or perhaps natural order. Capsules flaked, imperfectly bivalve. Seeds two, flat at the inner side, convex at the outer. De Candolle.

XYLORICRUM. See Xylopia supra.

XYLOPOLIS, in Ancient Geography, a town of Macedonia, in Mygdon. Ptolemy.

XYLOSMA, in Botany, from $\xi\lambda\sigma\mu\alpha$, wood, and $\epsilon\nu\rho\sigma\varsigma$, a fnell, a name given by Dr. George Forster to the Myroxylon of his father; the latter appellation having been appropriated by Linnaeus to a different genus. (See Myroxylon.)—Fort. Prod. t. 72. Schreb. Gen. 703. Willd. Sp. Pl. v. 3. 544. Mart. Mill. Dict. v. 4. Point in Lamarck Dict. v. 8. 817. Lamarck Illutr. t. 827. Myroxylon; Fort. Gen. t. 63. Juss. 444. Lamarck Dict. v. 193. Clavis and order, Dioscia Polyandra. Nat. Ord. uncertain. Juss.

Female, Calyx and Nectary as in the male. Style very short. Stigma slightly three-cleft. Berry dry, of two incomplete cells. Seeds two to each cell.

1. X. fulvoleuca. Serrated Sweet-wood. Fort. Prod. n. 380. Willd. n. 1. (Myroxylon fulvoleuca; Fort. Gen. 63. n. 1.)—Leaves ovate, ferrated.—Native of the Society islands of the South seas. The inhabitants employ this wood, to give a fragrant scent to cocoa-nut oil, for anointing their hair. We know not whether this be the precious Red Sanders Wood of the South sea islands, for a specimine of which we are indebted to sir Joseph Banks, whose scent resembles that of the East Indian wood of the same name. The tree which produced it, as long as possible, kept from the knowledge of our European voyagers.

2. X. orbiculatum. Entire-leaved Sweet-wood. Fort. Prod. n. 381. Willd. n. 2. (Myroxylon orbiculatum; Fort. Gen. 63. n. 2.)—Leaves roundish, entire.—Native of Savage island. We have never seen a specimen of either species.

XYLOSTEO, a name by which some authors have called the small red-berried double-fruited chamæceraeæus.

XYLOSTEO, Dod. Pempt. 411. Tourn. 609. t. 379. Juss. 212. Pursh 161. (Chamæceraeæus; Tourn. ibid.), a word formed of $\xi\omicron\alpha\omicron\nu$, wood, and $\omicron\nu\omicron\alpha$, bone, being synonymous with a Swis name for the same thubs, which allude...
alludes to the hardnct of their wood, and perhaps to its tubular form, filled with pith, as a bone is with marrow. The authors who retain this genus split the Lonicera of Linnaeus, (see that article,) into several, without necessity or utility, offering, in our opinion at least, great violence to nature.

**XYLOSTROMA,** so called from ξυλοστρόμα, wood, and στρομα, a ftratum, or layer, because this fungus forms indefinite expansions, like cloth or leather, in the inside of the trunks or branches of trees.—Tode Fung. Mecklenb. v. 1. 36.—Claris and order, Cryptogamia Fungi. Nat. Ord. Fungi angiocarpi?

Efl. Ch. Expanded, coriaceous, two-fided, shapelefs, concealed; surface smooth and even. Seminola globules very minute, attached to internal fibres.

1. **X. gigantum.** Oak Leather. Tode as above, t. 6. f. 51. Sowerb. Fung. t. 358. (Racodium Xylostroma; Perl. Syn. Fung. 702.) Fungus coriaceous quercinus hematicus; Rall Syn. 25. "F. amplifimus; Scop. Pl. Subterr. 116. t. 44." Byffus candida β; Lightf. Scot. 1004.—This singular production is found in the centre of the trunks of growing oaks, spreading in a form of a piece of a cloth or leather, with numerous ramifications, through some of the largest trees. But whether it is, like the Boletus labrymanis, or Dry Rot, in wrought timber, theca of their decay, or its confluence, we have not sufficient information to decide. Tode's observations countenance the former opinion. He says the wood of the trees, occupied by this fungus, becomes rotten and perfectly dry. Its smooth surfaces are owing to the smoothness of the ffurces, through which it spreads in a tender flate, and its branching indeterminate figure arises from the irregularity and subdivision of these furces. The inode is fpongy, or partly hollow, occupied with branching fibres, bearing numerous little ovate capfules, or receptacles, whose apex appeared to Mr. Sowerby to have an opaque lid. The whole fungus is very durable, remaining unchanged for many years. Its hue is generally a uniform buff or pale tan colour; but Perfoon notices a whitish variety, more compact than the usual kind; and a faffron-coloured one, found by Schrader. We cannot well reduce the Xylostroma to any other genus of this natural order. The Racodium, Perf. Syn. 701, defined as "expandé and soft, resembling cloth in its denely interwoven fbrces," seems to us but a vague affœblage; the frst species being Byffus nigra, which some make to be a Lichen, others a Conflera; the second a Macor.

**XYLOSTROTEN,** formed of εξοστρομα, wood, and στρομα, laid, among the Ancients, an appellation given to Molac or chequered work.

**XYMETHUS,** a town of Africa, in the interior of Cyrenaica. Ptol.

**XYMPATHY,** a word used by some of the old medical writers for sympathy.

**XYNERESIS,** formed of εξο, or στρ, together, and ενεργεια, I ftrive, a word used by Hippocrates, and others of the ancients, to express a firm cohesion or confection of any two things. Some use it to express that firm flattening together, or clenching of the teeth, which happens in convulsions.

**XYNIA,** in Ancient Geography, a borough of Thefaly, on the confines of Perrhebia, near a lake of the same name. Livy.

**XYNOECIA,** formed of εξο, or στρ, with, and οικα, I inhabit, a feast among the ancient Athenians, instituted on occasion of Thefeus's uniting all the petty communities of Attica into one commonwealth; the assemblies of which were to be held at Athens, in the Prytanæum.

**XYPHOID,** in Anatomy, a name given to the cartilage, which forms the inferior extremity of the sternum. See the description of the sternum, in the article Lungs.

Gen. Ch. (corrected from Brown and Gartnér), Cal. Perianth inferior, of three concave chaffy leaves; the outermost hooded, deciduous; the two lateral ones keeled, compressed, curved, acute, converging, permanent. Cor. Petals three, large, spreading, flat, crenate; with narrow claws, as long as the calyx. Nectaries three, feathery, alternate with the petals; suspècted by Brown and Kunth to be barren flaments. Stam. Filaments three, inferted into the claws of the petals, much shorter than the limb, thread-shaped, erect; anthers oblong, incumbent. Pfyl. German superior, obovate, three-lobed; style one, thread-shaped, rather longer than the claws of the petals, three-leafed at the summit; stigmas obtuse, entire, or jagged. Peric. Capsule roundish, of one cell and three valves, with three more or less prominent receptacles, running down the middle of each valve. Seeds numerous, minute, roundish or elliptical, acute.

A genus of perennial herbs, with fibrous roots. Leaves radical, numerous, sword-shaped, or thread-shaped; dilated, equitant, and membranous at the base. Flower-stalk perfectly ample, wrapped in a sheath at the bottom. Head terminal, solitary, its scales membranous, single-flowered, closely imbricated; the outer ones sometimes empty, and unlike the rest. Alterni posterior. Brown. Flowers almost invariably yellow.

Linnaeus was acquainted with but one species, X. indica. Several others have been determined by various authors, inasmuch that Willdenow defines four, and Vahl ten in all. Mr. Brown has fifteen from New Holland alone, and there is a new one from South America. The author just mentioned divides this genus into two sections. Those species which belong to the frst section have a capule of one cell, whose receptacles are separate at the base; of these there are thirteen found in New Holland. The second section is characterized by a capule incompletely divided into three cells, the receptacles being combined in their lower part. Of this there are two New Holland species. It is utterly impossible for us to follow this arrangement, few people having seen half the species in any flate, much less their ripe capsules. We are poftellcd of ten, which appear to be definite, and which can be referred, with tolerable certainty in general, to as many described species. For the remainder we shall cite our authorities.

**XYRIS.**

Linn. Zeyl. 14. Wild. n. 1. Vahl n. 1. (Gladiolus indicus, flore tripetalod; Rudb. Elyt. v. 2. 17. f. 8. Gladiolus lucifi Lucacis malabaricae, e capitato botyioide floriferia; Pluk. Almag. 170. t. 416. f. 4. Kotschettipullu; Rhode Hort. Malab. v. 9. t. 71. Rammotta; Herm. Zeyl. 41.)—Stalk furrowed, with many angles. Head ovate.—Native of the East Indies, and perhaps of Sierra Leone. The leaves are described by Vahl as sometimes a foot long, equaling the flower-flats, lax, acute, almost the breadth of the nail; but he never saw any so broad as in Rhode’s figure. The flower-flats are several, rather more slender than a pigeon’s quill, furnished with six or eight furrows, and twisted in the lower part. Head rather smaller than a Hazel-nut, with roundish scales. Our specimens, gathered by the late Mr. Smeathman at Sierra Leone, have no leaves, but the flat and head answer exactly to the above description. The scales are from twenty-five to thirty in each head, rounded, or nearly orbicular, convex, closely imbricated, obtuse, brown, but little polished, divided lengthwise into three nearly equal flaps, or regions, (as is the case in most of the species that we have seen); the middle region here is slightly hairy or downy, the side ones smooth. The flowers are pale. The head in these specimens is nearly globose; not oblong, as in Gartner’s figure, marked X. indica. A few of the lowest scales are flatter and rather smaller than the rest, apparently always barren, or unaccompanied by flowers. Whatever Mr. Pursh’s X. indicus may be, it cannot belong to this species. He describes the leaves very long and graily, twirled as well as the flats.

2. X. pubescens. Downy-leaved Xyris. Pursh n. 2.—Stalk vilrated, almost cylindrical, enveloped in a downy sheath. Leaves greatly elongated.—Received by professor Desfontaines, from the Weit Indies. Nearly related to X. indica, but differing in several characters peculiar to itself. The roots are long, as thick as the finger, with soft, rather fleathy, nearly simple, fibres, as thick as a raven’s quill; and producing from the crown a great number of soft, flacid, alternate, somewhat imbricated, very smooth leaves, a foot or foot and a half long, half an inch wide, entire, pointed; dilated at the base. Stalks straight, rather slender, twirled at the lower part, where they are each embraced by a cylindrical, rivated, downy sheath, three or four inches long, terminating in a little short acute leaf. **Head of flowers** oval, obtuse, the fize of a large pea, formed of numerous, imbricated, very close, unequal, whitish scales; the outer ones a little dilated, oval, nearly flat, scarcely pointed, the inner narrower, obtuse, rather concave. **Pursh.** See our X. aniceps, which has also a very long leafy-pointed sheath, but it is quite smooth.

3. X. macrocephala. Great-headed Xyris. Vahl n. 2.—“Stalk with one acute angle. Head and scales ovate; the latter grey at the back.”—Native of Cayenne. Described from the herbarium of professor Desfontaines. The leaves are eighteen inches long; as broad as the nail, or broader. Stalks taller than the foliage; round in the lower part; somewhat two-edged further up, with one convex and one acute side. Head when in fruit twice as big as a Hazel-nut, ovate, with obtuse scales. This differs from the reef in the breadth of its leaves, and the size of the head. **Vahl.**

4. X. platycaulon. Broad-stalked Xyris. Pursh n. 4.—Stalk compressed, dilated, rivated, smooth; twirled below; with a lax, dense, abrupt sheath at the base. Heads globose, abrupt at the summit.—Gathered by Commeron in Madagascar. Leaves wanting in the specimens. **Stahl’s** a foot high; two or three lines broad. **Sheath** at least three inches long, smooth, rivated, rather lax, cloven lengthwise, obliquely truncated at the summit. **Head** hardly so big as a pea, flatish at the top, with broad, obtuse, concave, shining, chestnut-coloured scales, the outer ones keeled towards their point. **Poirot.** We have enlarged the author’s specific character from his own description, in order the better to contrast this species with the two following, with which it appears to agree in the flatness of the **flats.**

5. X. aniceps. Small-headed Two-edged Xyris. Lam.-marck Illuir. v. 1. 132. Vahl n. 3.—“Stalk two-edged, smooth. Head nearly globose.”—Native of Madagascar, and Malabar; perhaps also of Guiana. Leaves rather rigid, narrow, but one-third or one-fourth the height of the **flats,** which are several, a foot or more in height, twirled, smooth, by no means iriater. **Head** scarcely so large as a pea, with roundish, convex, hardly emarginate, scales. **Petals** yellow, finely toothed. **Vahl.** A Guiana specimen, communicated by Mr. Rugge, remarkable for the smallness of its **head** in proportion to the herbage, answers precisely in every point to Vahl’s description. Aquatic, or marsh-plants, such as the species of this genus, are known to grow, more than any others, in widely distant and dissimilar parts of the world. We have suspected this Guiana species might be Poirot’s X. pubescens n. 2; but the sheath at the base of the **flats** is not pubescent.

6. X. complanata. Flat-stalked Xyris. Brown n. 1.—“Stalk compressed flat, dilated, nearly straight; carilaginous and rough at the edges, four times as long as the fword-shaped, straight, bordered, roughish leaves. Spike oblong or cylindrical. Scales orbicular, tupid.”—Gathered by Mr. Brown, in the tropical part of New Holland. The **flats** is a line and a half broad. We have seen no specimen.

7. X. fuscra. Rough Xyris. Br. n. 2.—“Stalk two-edged, twirled, with rather acute and rough angles. Leaves linear, roughish. Head ovate or oblong.”—From the same country. The **flats** is barely a line in breadth. **Brown.**

8. X. levis. Smooth Xyris. Br. n. 3.—“Stalk two-edged, smooth, as well as the narrow linear leaves. Head nearly ovate. Scales imbricated every way. Keels of the calyx-leaves fringed.”—Gathered by Mr. Brown near Port Jackson, as well as in the tropical part of New Holland. The **flats** are from fifteen to eighteen inches high.

9. X. americana. Blue American Xyris. Aubl. Guian. 40. t. 14, very bad. Vahl n. 4. Symb. v. 3. 8. Wild. n. 3. Poirot n. 6. (Jupical; Pfl. Bral. 235.)—Stalk two-edged in the upper part. Head ovate-oblong. Scales polished, emarginate, with a small callous intermediate point. **Native of moist pastures in Brazil, flowering in the rainy season, according to Poirot, whose synonym was verified by Vahl, from an inspection of Maregrava’s herbarium. Aublet found the same in wet meadows near the river Macouria, in Guiana, flowering in December; but his figure is made up, as Vahl observes, with the leaves of an Eriocaulon; the scales of the **head,** and the flowers, being moreover very ill drawn. We have never met with a specimen answering to this species. Vahl says the leaves are graily, narrow, and acute, half the length of the **flats,** which is a foot or more in height; round in the lower part, with two prominent lines running down it; compressed in the upper part, and a little dilated at the head. The latter is obtuse, rather bigger than a pea. **Scales** oblong, concave, cloven at the point, with a brownish, rather callous point in the notch. **Vahl.** The **corolla** is said to be blue, of which we know no other influence in this genus.

**Xyris.**

Carolina. *Vahl.* Found in low grassy fields, on a sandy soil, from New Jersey to Florida. Perennial, flowering from June to August. *Heads* small. *Flowers* yellow. It is extremely variable. *Pursh.* Vahl thought this species distinct from the last, in having more rigid leaves, and larger heads, which are acute, instead of being remarkably obtuse. The flowers moreover are yellow, not blue. The leaves vary in length. The heads in Lamark's specimens are longer than those of Richard's. *Vahl.* We have not seen this species, but it seems that more than one may possibly here be confounded.

11. **X. tertia.** Twisted-leaved Xyris. (X. indica; Pursh n. 1, excluding the synonyms.)—Leaves linear, spirally twisted, as well as the stalk, which is two-edged below, quadangular at the upper part. Head globular. Flowers polished, rounded, somewhat emarginate, pointless, with a small silky disc. —Gathered in North America by Kalm. Linnaeus confounded his specimens with *X. indica,* which he knew but imperfectly. They appear, however, to answer exactly to the *indica* of Pursh, who very properly gives an original specific character, instead of copying what did not agree with the plant before him. He found it in overflowed meadows, and small ponds, from Pennsylvania to Virginia; perennials, bearing yellow *flowers* in June and July. He calls the leaves "longissimi graminis." In our specimens they are from one to ten inches long, a line broad, acute, many-ribbed, roughish at the edges, perfectly grassy; the outermost degenerating into broad, short, chéfnut-coloured, pointed, imbricated scales. *Stalks* solitary, about two feet high; nearly round, though two-edged and frilated, at the bottom, as well as very much twirled, even more than the leaves; the upper part is less so, more evidently two-edged; and towards the top there are four, not always equal, angles. *Head* the size of a large white currant, obtuse, of a shining chéfnut-coloured. *Scales* almost orbicular, convex; dilated and thin at the edges; marked at the back, just below the notch, with a pale, greenish, silky foot. Two or three of the lowermost of all are smaller, flatter, a little keeled.

12. **X. pusilla.** Dwarf Broad-leaved Xyris. Brown n. 4. —Stalk two-edged, smooth, like the short, hollow-shaped, two-ranked, equitant leaves. Head orbicular, compressed, of a few shining, somewhat keeled and pointed, *scales.* —Gathered by Mr. Brown, in the tropical part of New Holland. Our specimens, in the herbarium of the younger Linnaeus, were probably given to him when in England, by Sir Joseph Banks and Dr. Solander. The *stalks* are from two to six inches high, pale green, a little zigzag and twirled, somewhat quadangular; sheathed at the base with one or two *leaves,* which, like those that grow from the root, are about an inch long, and two or three lines broad, slightly incurved at the point, of a pale rather shining green, with several ribs, and a finely dotted, or reticulated, surface in the dry state. *Head* the size of a pea. *Scales* orbicular, convex, of a shining chéfnut-brown, pale at the edges; the lowermost equal, without *flowers,* in an early state covering the whole head, and furmished with a brown, green, pointed keel.

13. **X. dentiflata.** Tooth-leaved Xyris. Br. n. 5.—Stalk roundish, smooth. Leaves short, linear-awl-shaped; rough with minute marginal teeth. Head globosely. Scales orbicular, shining, keeled at the summit. —Gathered in the tropical part of New Holland, by Sir Joseph Banks and Dr. Solander, who gave specimens to the younger Linnaeus. This is about the size of the last, or rather taller. The *root* consists of very small fibres. *Leaves* from one to two inches long, not a line broad, their fine reticulations seeming to form the little teeth, at the margin and keel. *Stalk* slender, frilated or angular towards the top. *Head* twice the size of the last, of more numerous, bright-chéfnut *scales,* with thin, pale, often jagged margins, and a little green short keel, or point, not extending beyond the scale. The two lowermost *scales* are barren, as in the preceding, and in a young flato enclose the whole head.

14. **X. paludosa.** Bog Xyris. Brown n. 6.—Stalk more or less angular at the top. Leaves somewhat tubular; that of the stalk longer than the sheath. Head nearly globular. Scales orbicular, shining, imbricated every way. —Found in the tropical part of New Holland, by Sir Joseph Banks and Dr. Solander. We have seen no specimen, nor did Mr. Brown himself meet with this or the last species, any more than with the *pulchiflora* hereafter described.

17. **X. pulchiflora.** Few-flowered Xyris. Willd. n. 2. Phytogr. 2. t. 1. f. 1. Vahl n. 8. Br. n. 7.—Stalk quadranugular. Leaves linear; rough with minute marginal teeth. Head nearly globular. Scales shining, orbicular; spreading at the point, with a short triangular keel. —Gathered by Koenig and Rottler in the East Indies; and by Sir Joseph Banks, in the tropical part of New Holland. The *root* is a small dense tuft of pale fibres. *Stalk* from one to six or eight inches high, erect, fleshy, slender, frilated, roughish. *Leaves* several, erect, sometimes nearly as tall as the stalk, grassy, very narrow, taper-pointed, frilated, roughish, especially at the edges, where they are minutely toothed, or crenate, as in *X. dentiflata* n. 13. *Head* the size of a large pea. *Scales* chéfnut-coloured, with a membranous, dilated, shining margin of a golden yellow, and each tipped with a green, triangular, projecting keel, or point, originating from the brown disk, but not extending beyond the membranous margin, with which it is incorporated. The prominence of this point, giving the head a flag-like shape, is well expressed in Willdenow's, otherwise miserable, figure. The two lowermost *scales* are barren, and closely pressed to the next. *Corolla* yellow.

18. **X. tricuspis.** Bracteated Xyris. Br. n. 8.—Stalk triangular. Leaves linear; their margins, and base of the keel, rough. Head roundish. Scales with a hoary disk, and brown membranous margin; the lower ones oblong, empty, with a linear disk. —Sent from Port Jackson, New South Wales, by Dr. White, in 1792. Mr. Brown found it in the same country, and we borrow from him the above characters of the *leaves,* wanting in our specimens. The *stalk* is a foot and a half high, slender and rufhy, bluntly triangular, even, smooth to the touch, though Mr. Brown remarks that its most acute angle is roughish. *Head* rather ovate.
XYRIS.

ovate than perfectly globose, one-third of an inch in length. Scales elliptical, abrupt, or partly emarginate; their disk elliptic-oblance, convex, not keeled, of a hoary or glaucous hue, finely dotted, not downy; their margin, at each side, about half as broad, membranous, of a thinning brown, paler outwards. Three, four, or more, scales, at the bottom of each head, are distichous of flowers, shorter, much narrower, abrupt, oblong, not elliptical, with a peculiarly narrow disk, and have the appearance of bracts. Corolla rather large, yellow, turning white in decay.

19. X. juncea. Rusty Xyris. Brown n. 9.—"Stalk roundish, slightly compressed, rather zigzag, smooth as well as the awl-shaped leaves. Head globose. Scales ovate, undivided, imbricated every way; their disk of the same colour as the margin. Stigmas many-cleft."—Gathered by Mr. Brown, in the neighbourhood of Port Jackson, New South Wales. The stalk is only eight or ten inches high. We have no specimens answering to the above characters.

20. X. gracilis. Slender Xyris. Brown n. 107.—Stalk thread-shaped, smooth, fearfully twisted. Leaves linear, straight, rough-edged. Head oval, of few flowers. Scales imbricated every way; their disk hoary; margin blackish. Stigmas undivided.—Sent from Port Jackson, in 1792, by Dr. White. Mr. Brown mentions only the fourth part of New Holland, and Van Diemen’s island, as the native country of this species, and yet we cannot refer our specimens to any other mentioned by him. Our plant is about half the size of X. bracteata, with fewer and paler flowers. Head small, elliptical, or obovate. Scales with a broad, hoary, or glaucous disk, like that of the bracteata; but their membranous margin is of a darker brown, and, at the upper part of each scale, quite black, as if burnt. Several of the lowermost scales are smaller, linear-oblong, and of a more uniform brown. The stigmas are long, and undivided. Stalk somewhat compressed, feldom above a foot high; Mr. Brown says a foot and half.

21. X. filiformis. Thread-shaped Xyris. Linn. Hill, p. 135. Vahl n. 9. Poiret n. 9.—Stalk thread-shaped, compressed. Leaves linear-awl-shaped, compressed, two-ranked. Head and scales elliptical; disk and margin uniform, with flight traces of a keel.—Gathered by the late Mr. Smeathman, as well as by Dr. Adam Aszleis, in marady fondy ground at Sierra Leone. The root is small and fibrous. Leaves four or five, feldom more, equitant, erect, linear-awl-shaped, compressed, very narrow, tapering, but rather obtuse at the point; their surface minutely speckled, and more or less evidently reticulated, or dotted; their length, in our specimens, from one to two inches; Vahl says fearfully half an inch. Stalk solitary, fix or eight inches high, very slender. Head the size of hemp-seed, but more oblong, acute at each end, of a copper-brown, not very thinning; the two lowest scales empty, rather pelted, milk oblong, and roundish keeled; the rest elliptical, bluntly pointed, very smooth and even, without any limited disk, but sometimes marked with beautiful concentric veins; their keel fearfully different, except in the form of a short pale elevation, near the apex, but not projecting into a point. Corolla yellow, small.

22. X. flexuosa. Wavy-leaved Xyris. Br. n. 11.—"Stalk thread-shaped, twisted, smooth, as well as the zigzag, slender, slightly compressed, leaves. Head oval, with few flowers. Stigmas undivided."—Found by Mr. Brown, on the southern coast of New Holland. Stalk from six to twelve inches high.

23. X. teretifolia. Cylindrical-leaved Xyris. Br. n. 12.—"Stalk, as well as the leaves, round, straight, and roughish. Head ovate, many-flowered. Scales imbricated every way, torn into many segments."—From the same country. Stalk eighteen inches high. Brown.

24. X. lacer. Jagged-headed Xyris. Br. n. 13.—"Stalk round, smooth. Head nearly globose, many-flowered. Scales imbricated every way, torn into many segments."—Discovered by Mr. Brown, on the south coast of New Holland. We have seen no specimens of this, or the two species immediately preceding.

25. X. fabulata. Awl-leaved Peruvian Xyris. "Fl. Peruv. n. 1. 46. f. b." Vahl n. 10. Kunth n. 1.—"Stalk thread-shaped; roughish at the top. Leaves linear-awl-shaped; their feathes woolly at the margin. Head oblong, about three-flowered."—Native of marhy, cool, highly elevated, mountainous situations, in Peru, flowering in September. Root perennial. Plants growing together in patches. Leaves about an inch long; villous at the base. Stalk slender, about eight inches high. Flowers yellow, two or three only in each head.

26. X. vivipara. Viviparous Xyris. Kunth n. 2.—"Stalk somewat compressed; roughish at the top. Leaves linear-pencil-shaped; their feathes fringed. Head globose, at length leafy and viviparous."—Gathered by Humboldt and Bonpland on the banks of the river Ooonooko, between the mouths of Venturuis and Quivarues, flowering in May. Root fibrous, perennial. Leaves all radical, two-ranked, from two to four inches long, erect, bluntish, fringed, smooth, except a little smoothness at the back; their feathes keeled, fringed, roughish also at the back. Stalks about a foot high, smooth, except some roughish points towards the summit; enveloped at the base with a fringed, keeled, bluntish, smooth, rough-backed feath, an inch and a half long. Head globose, rather abrupt, the size of a pepper-corn. Scales roundish-ovate, bluntish, brownish, coriaceous, smooth, rather transparent at the margin. After flowering, the head throws out from its centre a leafy crown, which becomes a young plant. Kunth.

We are not told whether this leafy tuft originates in the vegetation of one or two of the seeds; or in the germ being supplantet in the flower by a bud; or, which is the leaf likely, in a proflerous elongation of the stalk, independent of the parts of fructification altogether.

27. X. operculata. Imbricated Xyris. Labill. Nov. Hol. v. 1. t. 10. Brown n. 14. Poiret n. 13. Curt. Mag. t. 1158.—Capsule partly three-celled. Stalk round. Leaves thread-shaped. Head obovate. Scales beardless, imbricated in five rows, with numerous empty ones, gradually smaller, at the base.—Sent from Port Jackson, New South Wales, by Dr. White, in 1792. Mr. Brown also observed it there; and Labillardiere in Van Diemen’s island. Neither the figure of the last-mentioned author, nor that in the Botanical Magazine, by any means represents the remarkable character of the five-ranked scales of the head, and the numerous, gradually diminishing ones, distique of flowers, at its base; so that, but for Mr. Brown’s authority, we should have supposet our Port Jackson plant to be exceptionally and widely different. Dr. White’s specimens are without leaves. The stalk is about eighteen inches high, round, or slightly angular, quite smooth. Head obovate, full half an inch long, with five rows of very numerous obovate scales, whose broad convex disk is of a bronze-like hue; the margin brown and brown, more or less jagged, with a deciduous tooth-like fringe. Flowers large, bright yellow. Stigmas obtuse.

28. X. lanata. Woolly Xyris. Br. n. 15.—"Stalk round, smooth. Leaves linear, narrow. Head nearly globose. Scales woolly at the extremity, imbricated in five rows, with several empty ones, gradually smaller at the base."—Gathered by Mr. Brown, on the southern coast of New Holland.

The above great accession of new species throws much light
light on this hitherto little-known, and ill-described, genus of plants. Could they all be compared together, even in a dried state, we have no doubt that their specific characters, and the principles on which they are founded, would derive considerable improvement; and that Xyris, whose generic marks are so well established, would afford a beautiful display of clear and precise specific discrimination. Whether the leaves of any of the species be really toothed, in a living state, we have considerable doubt. Their foliage partsake greatly of the cellular texture, so remarkable in the neighbouring genus *Erica caulon*; with which also they closely accord in *infarscence*, and general habit. Mr. Brown, in his *Prodromus*, has elucidated both these genera, as far as concerns their numerous New Holland species, with infinitely more success than any other botanist; the one genus having previously been scarcely better understood than the other.

A genus of upright shrubs, with opposite, sometimes alternate, leaves. Umbels lateral, either axillary, or between the foyf Falks. Flowers rather large; the limb of the corolla fometimes bearded. Only two species are at present known, both natives of Southern Africa.

1. *X. undulatum*. Waved-leaved Xyfmalobium. Dryand. in Ait. t. 104. Linn. Suppl. Linn. Sp. Pl. 312. Wildl. Sp. Pl. v. 1. 1262. See *Asclepias*, n. 1. Apocynum aficanum, lapathi folio; Comm. Raf. 16. t. 16.—Leaves undulated, naked. Corolla bearded.—Native of the Cape of Good Hope. Sent to Kew garden, in 1783, by Mr. John Graefe. "This is a green-house plant, fowing in July. Mr. Aiton marks it as a *Eropeus*; but Com- melin fays the thick, white, perennial *root* fends up every year, in the early spring, two or three thick, round, green, leafy *flens*. All authors fpeak of the *leaves* as opposite; but in our Linnsean fpecimens, gathered at the Cape by Thunberg, they are alternate, fefile, three or four inches long, ovato-lanceolate, gradually tapering to a blufhi point, with a thick midrib, and numerous interbranching veins; nearly smooth on both fides; undulated and rough-filt at the margin. Umbels axillary, flalked, much shorter than the leaves, with hairy flalks, and linear hairy *bracteae*. Flowers green, their segments denfly beaded at the extremity, with white fhyagg hais. Follicles covered with spreading hairy filaments, an inch long. Every part of the plant, when wounded, discharges a copious milky fluid.

2. *X. grandiforum*. Large-flowered Xyfmalobium. (Asclepias grandiflora; Linn. Suppl. 170. Thurb. Prodr. 47. Wildl. Sp. Pl. v. 1. 1264. See *Asclepias*, n. 26.)—Leaves flalked, hairy. Corolla smooth.—Gathered by Thunberg, at the Cape of Good Hope, but as yet a stranger to our gardens, nor does the Linnean collection contain a fpecimen. The *flam* is faid to be fimpie, erecf, and hairy. *Flowers* large, axillary, flalked; but, as far as we can gather, the umbel is not elevated on a common flalk, as in the foregoing. *Corolla* fpeckled like *Fritillaria Meleagris*, and of a fimilar colour.

*XYSTARCHA*, in Antiquity, the mafler or director of the *xyitus*.

In the Greek gymnasium, the *xyfarcha* was the fect officer: the *firl* was the gymnasifarch. The *xyfarcha* was his lieutenant, and prefided over the two *xyfti*, and all exercises of the athlete therein.

*XYSTIC*, among the *Ancients*, a delegation given to the athlete, because they performed their exercifes in the *xyitus*.

*XYSTRIS*, in Botany, Schreb. Gen. 138. Poiré in Lamarck Dict. v. 8. 822, is one of those genera of pro- fessor Schreber's, to which we have adverted under WHE- LERA, (fee that article,) as being unintelligible to all but those who may have access to the learned author's herba- rium, or to fome record in his manuscripts. The name is Greek, *xystris*, a curry-cumb, or firper.—Clays and order, *Penandria Monogyna*. Nat. Ord. Epacrides of Brown?

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, lanceolate, acute, spreading, hispid, permanent segments, each contracled at the base. Cor. of one petal: tube very short; limb in five deep, ovate, obture, veiny, spreading segments. *Stam.* Filaments five, filigfe-flaped, erecf, spreading at the summit, shorter than the corolla, inserted into the middle of its tube; anthers oblong, erecf. *Pyl.* Germen superior, globose, pointed; filyles two, ca- pillary, erecf, combined in the lower part; Rigmas obtufa. *Peric.* Drupa globose, furrounded at the bafe by short, prostrate hairs, inserted into the middle of the calyx. *Seed*. Nut globose, furrowed, of ten cells; kernels oblong.

Whether this genus be founded on some New Holland fpecimen of the natural order of *Epacridae*, and whether the rigid or prickly habit of the plant fuggifhed the name, can only be matter of vague conjecture. We acknowledge the division of the *flint*, and the hispid segments of the *calyx*, to be exaggerations of the supposed natural order. In total darkness, however, any glimmering of light is welcome, and we will therefore hazard another conjecture, not altogether inconfiuent with the former. As Schreber places *Xyfritis* immediately after the *Jaccinia* of Linnaeus, can it poibly be fupported on *Jaccinia ruifilosa*, of whom fructification no botanif, as yet, has given any fufficient account? There feems an af- fociation of ideas between the habit of *Rufcus*, and the name of *Xyfritis*; and the globose pointed figure of the *fruit*, as copied from Plunier in *Dill. Hort. Elbh* t. 123, fupports as part of the above defcription, though the permanent *calyx* is drawn obtufa, and not apparently hispid.

*XYSTUS*, *xystris*, formed of *xystris*, to pollify, or rub, in the Ancient Architecture, among the Greeks, was a long fpa- cious portico, either open, or covered over; in which the athlete, and others, practifed wrestling and running.

The *xyitus* made a neceffary part of a gymnasium. The athlete, who practifed in it, were thence called *xyfifici*.

*XYSTRUS*, among the Romans, was an alley, or double row of trees, meeting arbor-awife at top, and forming a shade to walk under.
The twenty-third letter in the English alphabet, 

Y

Y is a numeral letter, signifying 150, or, according to Baronius, 159; as in the verse,—

"Y dat centenos et quinquaginta rovenos."

When a dash was added at top, Ý, it signified 150 thousand.

Pythagoras used the Y as a symbol of human life; the foot representing infancy, and the forked top the two paths of virtue and vice, one or the other of which people are to enter upon, after attaining to the age of discretion.

Y, on the French coins, denotes those struck at Bourges.

Y, in Geography, a city of China, of the second rank, in Chan-tong; 317 miles S.S.E. of Peking. N. lat. 35° 10'. E. long. 118° 19'.

Y, a city of China, of the second rank, in Pe-tche-li; 55 miles S.W. of Peking. N. lat. 39° 25'. E. long. 115° 14'.

Y, or EY, a river, or broad piece of water, which pales by Amsterdam, exhibiting the appearance of a creek of the sea rather than of a river.

YA, a city of China, of the second rank, in Se-tchuen, on the borders of Thibet; 840 miles S.W. of Peking. N. lat. 30° 32'. E. long. 102° 20'.

YABAQUE, one of the Bahamas islands, situated in N. lat. 23° 30'.

YABARGULSKAIA, a town of Russia, in the government of Tobolik, on the Irtisch; 120 miles E. of Tobolik.

YABAY, a town of Burmah; 50 miles S.W. of Ava.

YABTONOI, a ridge of the Altai chain in Asiatic Russia, bending in a northerly direction to the vicinity of Ochotlik. The name denotes the mountains of Apples.

YACHT. See SHIP, and Plate XIII. Ship-Building.

YACHTA, in Geography, a fort of Russia, in the government of Irkutz; on the borders of China; 48 miles S.S.W. of Selenginsk.

YACINTE, St. See St. Yacintz.

YACONG TALA, a number of small lakes in Thibet, situated near each other. N. lat. 30° 50'. E. long. 78° 39'.

YADA VA, in Hindoo Mythology, a name of the Hindoo Krishna. It is said to indicate his being of the family or tribe of Yadu.

YADI, in Geography, a river of Russia, which runs into the Oblikaa gulf, N. lat. 68° 25'. E. long. 72° 38'.—Also, a river of Russia, which runs into the Oblikaa gulf, N. lat. 67° 25'. E. long. 72° 18'.

YADKIN, a river of North Carolina, which rises in the F

Allegany
Allegany mountains, and after a course of about 100 miles, changes its name to Pedee, in North Carolina; 9 miles S.W. of Salem.

YADRIN, a town of Ruffis, in the government of Kazan; 122 miles W. of Kazan. N. lat. 55° 34'. E. long. 45° 44'.

YAGONMEW, a town of Pegu; 58 miles S. of Prome.

YAGA. See JAFFA.

YAGARCHOCA, a lake of South America, in the jurisdiction of St. Miguel de Ibarra. It is famous for having been the sepulchre of the inhabitants of Otabalo: upon this place being taken by Huana Capac, the 12th yaca, he, instead of throwing any clemency to them on account of their magnanimity, being exasperated at the noble renitence which they made against his arms, ordered them all to be beheaded, both those who had quietly surrendered, as well as those taken in arms, and their bodies to be thrown into the lake: so that from the waters of the lake being tinged of a bloody colour, it acquired its present name, which signifies "a lake of blood."

YAGATH, in Mythology, a deity adored by the ancient Arabian idolaters, under the figure of a lion.

YAGO, St. in Geography. See St. Tago.

YAGUACHE, or St. Jacinto de Yaguache, a town of Peru, and principal place of a lieutenancy, in the province of Guayaquil; 25 miles N.E. of Guayaquil.

YAGUAS, a town of the island of Cuba; 22 miles S. of Bayamo.

YAGUARIPÉ, a river of Brazil, which runs into the Atlantic, S. lat. 13° 14'.

YAGUARON, a town of South America, in the province of Paraguay; 10 miles S.E. of Assumption.

YAGUEPÉRI, a river of Brazil, which runs into the Negro, 50 miles above Fort Rio Negro.

YAH, in Hindoo Mythology, a name of Pavana, the Hindoo god or regent of the wind; another of whose names is Vayu. See Pavana and Vayu.

YAHANGA, in Geography, a small island in the sea of Japan. N. lat. 43° 8'. E. long. 131° 45'.

YAHEBIRI, a river of South America, which runs into the Parana, S. lat. 24° 22'.

YAIK, a considerable stream of Asiatic Russia, which flows into the Caspian. The name has been recently changed for that of Ural, on account of a daring insurrection of the tribes bordering on the YaiK.

YAITCHNEI, a small island of Russia, in the Pentinftoi fea. N. lat. 60° 30'. E. long. 160° 52'.

YAIWA, a river of Russia, which runs into the Kama, 16 miles S. of Solikamk, in the government of Perm.

YAK, in Zoology, the bos gruntenus of the Linnean system, or ox with cylindric horns curving outwards, very long pendant hair, and extremely villous horfe-like tail, the grunting ox of Pennant, and yak of Tartary, has been lately particularly described by Turner, in his "Embassy to Tibet." He calls it the buffy-tailed bull of Tibet; and in Hindoostan it is denominated foora goy. It is about the height of an English bull, which it refembles in the general figure of the body, head, and legs. He could discover no difference between them, except that the yak is wholly covered with a thick coat of long hair. The head is rather short; the horns tapering from the root upwards, and terminating in sharp points; arched inwards, and bending towards each other, but a little turned backwards near the extremities; the ears small; the forehead prominent; the eyes full and large; the nose small and convex; the nostrils small; the neck short and curved; the withers are high and arched; the rump low; over the shoulders rises a thick mufle, like the protuberance peculiar to the cattle of Hindoostan, covered with a profusion of soft hair: the tail composed of a prodigious quantity of long, flowing, glossy hair; the shoulders, rump, and upper part of the body, clothed with a fort of thick soft wool, the inferior parts having straight pendant hair that descends below the knee, and sometimes trailing on the ground; from the chieft, between the legs, issue a large pointed tuft of frightful hair, somewhat longer than the rest; the legs very short. In all other respects, this animal resembles the ordinary bull. These cattle appear of a large bulk; they have a downcast heavy look, and are, as they appear to be, fullen and fuppicious, and very impatient at the near approach of strangers. Their lowing is not loud, but a kind of feecially audible grunting noise. They are palette in the coldest parts of Tibet, on the short herbage peculiar to the tops of mountains and bleak plains. Their favourite haunt is the chain of mountains that is situated between the latitudes 27° and 28°, which divides Tibet from Bootan, and whose summits are commonly covered with snow. They are a valuable property to the tribes of itinerant Tartars, called Dukbha, who live in tents, and tend them from place to place; they at the same time afford their herdmen an easy mode of conveyance, a good covering, and wholesome subsistence. They are never employed in agriculture, but are very useful as beasts of burden; for they are strong, sure-footed, and carry a great weight. Tents and ropes are manufactured of their hair, and caps and jackets are made of their skins. Their tails are much esteemed; and under the denomination of theas, they are universally used for driving away winged insects, flies, and midges, and are employed as ornamental furniture upon horses and elephants. They supply an abundant quantity of rich milk and excellent butter, which may be kept in skins or bladders through the year, and to the utmost verge of Tartary furnishes a very material article of commercial produce. The orientals highly value a large kind of bezooar that is sometimes found in this animal's stomach. The yak is said to vary in colour, as well as in the length and form of the horns. Those with white tails are most esteemed; and sometimes their horns are as white as ivory.

In India no man of fashion ever goes out or sits in form at home without two "chowrabádas," or bracers, attending him, each furnished with one of these tails, mounted on silver or ivory handles, to brush away the flies. The Chineefes dye them of a beautiful red, and wear them as tufts to their summer bonnets.

Eliah, according to Pennant, is the only ancient writer who takes notice of this fingular species.

YAK, in Geography, a name given by the Olíaks to the Oby; which see.

YAKE DSÁKE, a lake of Tibet, about 12 leagues in circumference. N. lat. 44° 40'. E. long. 95° 24'.

YAKSÁI. See AKSHÁI.

YAKSHA, in Hindoo Mythology, a race of malignant beings of hideous form, into whom the souls of bad men are said to migrate; particularly the souls of fuch as in this life are addicted to forcid and base paffions, or absorbed too much in worldly prosperity. In the plural, they are termed Yakshás; and are affigned as faves or fervants to Kuvera, the Plutos of the Hindoo Pantheon. Another race of beings of a like description is called Rakshás (See the artifice). Raksháni and Yaksháni are the feminines of these races of demons. These names, and some note of their characters
characters and attributes, occur in the articles KUVERA, RAVENA, and SITANTA.

YAKSHNI-DEVI, a name and an inferior manifestation of the Hindoo goddess Parvati. It means goddess of malignant beings; one race of whom are in the masculine termed Yaka, which article, and others thence referred to, the reader desires of information concerning them may consult.

YAKSIMVAR, in Geography, a town of Russus, in the government of Viborg, on the north-west coast of Lake Ladoga; 8 miles S. of Serdopol.

YAKUTSK, a town of Russus, in the government of Irkutsk, on the Lena, which is here about two leagues in width; but it is greatly impeded with ice, and navigable only by a few small boats, chiefly employed in supplying the town with provisions. This town is the capital of a province, to which it gives name: it contains between 500 and 500 houses, mostly of wood, with some stone churches, and is defended by a wooden fort. The belt fables are found near this town and Nerchink: 500 miles N.E. of Irkutsk. N. lat. 62° 5'. E. long. 129° 14'.

YAKUTSK, the Province. The Yakutes, or, as they denominate themselves, Zobka, or natives of this province, are robust, and in general large; they resemble the Tartars in the cast of their features, and there is said also to be a great similarity in the idioms of these two people. Their ancient homestead extended from the Sayan mountains as far as the Angara and the Lena. Perforated by the Burats and Mongoles, they removed down the Lena to their present rude and inclement districts, where they are found in the government of Irkutsk on both sides of that river quite to the Frozen ocean. In the year 1620 they submitted to the Russian conquerors, and at the middle of the last century they numbered upwards of 40,000 bows; but since that time they are considerably increased. Their dress is simple, and nearly the same all the year round; the only difference is, that in winter it is made of skins; over their chemise they commonly wear a large frippled waistcoat with sleeves; their breeches do not extend below the middle of the thigh, but their long boots, called jarii, reach above the knee. In hot weather they wear nothing but the breeches. Polygamy forms a part of the political code of this people; obliged to make frequent journeys, a Yakute has a wife in every place where he stops, but he never abandons them together. Notwithstanding this licence, they are jealous to excess, and the worst enemies of any one who shall dare to violate the rights of hospitality. When summer commences, they leave their winter habitations, and with their families and a small number of horses, make their harvests of fodder for consumption during the frost season. They repair to a considerable distance from their yout, and to the most fertile cantons. In their absence, the horses are left to the care of the servants, and the neighbouring pastures serve for the maintenance of all their herds. Chamos, or forcers, are regarded as interpreters of the gods; they grant their mediation to the stupid Yakute, who implores it with trembling, but always pays for it. In the idolatry of the Yakutes, we find all the absurdities and superstitions practices of the ancient Kamtechaduses, Koriaks, Tchutchis, and other inhabitants of these countries. The funerals are attended with a kind of pomp more or less magnificent, in proportion to the rank and wealth of the defunct. If a prince, he is arrayed in his finest habits, and most splendid arms. The body, placed in a coffin, is carried by the family to the tomb; deep groans announce the solemn procession; his favourite horse, and another the boit in his stead, both richly caparisoned, and led by a valet, or near relation, walk by the side of the corpse. When arrived at the burying-place, they are tied to two stakes, fixed near the grave, and while the latter is interred, their throats are cut over the corpse. This bloody ligation is the homage paid to his attachment to these animals, who are supposed to follow him into the other world, where it is imagined that he will again be able to enjoy them. They are then flayed; the head and hide, in one entire piece, are fixed horizontally upon the branches of trees at a small distance from the grave; and such is the memorial that is erected. A fire is then kindled, and the lait proof of friendship for the deceased is left roasting and eating upon the spot these favoured animals: the feast being concluded the company disperses. The fame ceremonial is observed for a woman, except that instead of a horse, they sacrifice her favourite cow. Their houses, like the yorts of the wandering Koriaks, are circular, spacious, and constructed with poles, fewer in number, but ranged in the same manner, and kept together by a fort of hoops at the top, the whole covered with the bark of the birch-tree, formed into pieces eighteen inches wide, placed in a downward direction. These pieces are edged with a kind of ribband, made of bark, and shaped into feltoons, and the infide of the yort is ornamented in the same manner. The tarte of the ornaments is governed by the caprice of the proprietor, and there is in them a fort of wildness that is sufficiently amusing. The fame decoration is annexed to the chairs and beds of the heads of families. The domestics lie upon the ground on mats or skins, and the fire is lighted in the middle of the house. See YUAGHHERES.

YALE, a town of the island of Ceylon; 56 miles S.S.E. of Candi. N. lat. 6° 52'. E. long. 81° 20'.—Allo, a river of Ceylon, which runs into the sea, on the S.E. side of the island, N. lat. 6° 23'. E. long. 81° 41'.

YALE College. See COLLEGE.

YALEFUL, in Geography, a town of Ceylon, at the mouth of the Yale; 30 miles S. of Yale.—Allo, a town of the island of Ceylon, near the E. coast; 96 miles S.E. of Candi.

YALLAH'S BAY, a bay of the island of Jamaica, on the S. coast, situated to the E. of Yallah's Point.

YALLAH'S Point, a cape on the S. coast of Jamaica; 12 miles S.E. of Kingston. N. lat. 17° 53'. W. long. 76° 21'.

YALLAH'S River, a river of Jamaica, which runs into the sea, a little to the east of Yallah's Point.

YALMAL, a cape on the E. coast of Russus, in the Karlovo sea. N. lat. 75°. E. long. 68° 24'.

YALME, a river of Devonshire, which runs into the English Channel, 7 miles S.E. of Plymouth.

YALOFFS, YALOFFS, Jalefs, or Jalousfs, an active, powerful, and warlike race of negroes, and esteemed the most handfoe of those people, who inhabit a great part of that tract of Africa which lies between the Mandingo states, on the river Gambia to the S., and the Senegal to the N. and E. See JALOFFS.

The Yaloffs differ from the Mandingoos, (see MANDING,) not only in language, but likewise in complexion and features. Their noses are not so much deprected, nor the lips so protuberant, as among the generality of Africans; and although their skin is of the deepest black, they are considered by the white traders as the molt fightly negroes in this part of the continent. They are divided into several independent states or kingdoms; which are frequently at war either with their neighbours, or with one another. In their
their manners, superstitions, and government, however, they
have a greater resemblance to the Mandingoes than to any
other nation; but excel them in the manufacture of
cotton cloth, spinning the wool to a finer thread, weaving
it in a broader loom, and dyeing it of a better colour.
Their language is said to be copious and significant, and
is often learnt by Europeans trading to Senegal. Their
numerals are as follow:

YAMA, in Geography. See JAM.

YAMA, in Hindoo Mythology, is the god of the infernal
regions, corresponding with the Pluto of western heathens.
Yama is a very important deity; his name is of perpetual
recurrance in the sacrificial ceremonies of the Hindoos;
oblations and invocations to him forming a portion of many
of those ceremonies. The Hindoos, as is explained under
our article MARUT, have assigned regents or guardian
deities to each of the cardinal and intermediate points of
the world. Yama is regent of the south, or lower world,
in which the Hindoos place the infernal regions; this corre-
ponding with the Grecian Pluto or Minor. Under our
article MAMI, the great law-giver of that name is sup-
posed to have been the same person as the Minos of an-
tiquity. Yama has many names; and in his character and
functions is found related to many important personages of
sacred and profane history. Among his names are, Dhamma-
rajia, or king of justice; Purijepis, lord of the Puris, or
patriarchs (see PIRIS); and Mimita, meaning death; a
name also of Kala, or Siva. (See those articles.) Sujan-
ya, and Vaivasvata-yama, are others of his names, de-
vided, it is said, the first from a term denoting cemelins or
beauty, the other from his solar origin; Yama being of the
race of the sun, of which some explanation will be found
under our article SURYAVANSA. He is also named Sradha-
dera, or lord of the obsequies, in honour of deceased an-
celors, of which a copious account is given under SRADHA.
As well as the Seventh Mami, Yama bears likewise the
name of Satyaavrota. He is also named Adhibhurota; this
name is said to be derived from a species of wood, by the
attrition of which fire is produced, wherewith to light the
pale on which funeral obsequies are performed to Yama.
Every thing connected with the important element of fire
is peculiarly mystical with the Hindoos. Touching the facri-
cial and other fires, the reader will find many particulars
under our articles PAVARA, SAGNIKA, SAMI, and
others thence referred to. Anbeka is another name of Yama; it means death, or the defroger: thus the compound
Kal-anbeka-yama is Yama, the defroyer of Kal or Time, a
personification of great bolderms and extent. Kal is also a
name of Yama. (See KAL.) Yama has other compound
names, meaning the slayer of all beings, king of deities,
reducer of all things to ashes, the dark-blue deity, of wolf-

Park’s Travels, vol. i.

In connexion with this brief account of the Yaloffs, we
cannot forbear mentioning an anecdote that redounds very
much to the honour of Damel, their king. On occasion of a
war between Damel and Abdulkader, king of Foota Torra,
a country to the W. of Bondon, the latter inflamed with
zeal for propagating his religion, sent an ambassad or to
Damel, accompanied by two of the principal Bahreens,
who carried each a knife, fixed on the top of a long pole.
When they obtained admission into the presence of Damel,
they announced the object of their embassy in the following
singular manner:—" With this knife," said the ambassad or,
" Abdulkader will confecnd to have the head of Damel,
if Damel will embrace the Mahometan faith; and with this
other knife, Abdulkader will cut the throat of Damel, if
Damel refuses to embrace it—take your choice." Damel
coolly replied, that he had no choice to make; he neither
chose to have his head shaved, nor his throat cut: and with
this answer the ambassad or was civilly dismissed.

Abdulkader with a powerful army invaded Damel’s
country. The inhabitants of the towns and villages filled
up their wells, destroyed their provisions, carried off their
effects, and abandoned their dwellings as he approached.
Thus he was led on from place to place, until he had ad-
anced three days’ journey into the country of the Yaloffs.
Several of his men had died with fatigue and hunger by the
way. This led him to direct his march to a watering-place
in the woods, where his men, having allayed their thirst,
lift down, overcome with fatigue, to sleep among the bulrushes.
In this situation, they were attacked by Damel before day-
break, and completely routed. Many were killed, and a
greater number taken prisoners. Among the latter was
Abdulkader himself, who was led, as a miserable captive,
into the presence of Damel. The behaviour of Damel on
this occasion is celebrated, in terms and founds of the highes
approbation, by the family men. When his royal
prisoner was brought before him in irons, and thrown upon
the ground, the magnanimous Damel, instead of setting his
foot upon his neck, and stabbing him with his spear, ac-
cording to the custom in such cases, addressed him in the follow-
ing manner:—" Abdulkader, answer me this question. If
the chance of war had placed me in your situation, and you
in mine, how would you have treated me?" I would have
thrust my spear into your heart," returned Abdulkader
with great firmness; " and I know that a similar fate
awaits me." " Not so," said Damel; " my spear is indeed
red with the blood of your subjects killed in battle, and I
could now give it a deeper stab by dipping it in your own;
but this would not build up my towns, nor bring to life the
thousands who fell in the woods. I will not therefore kill
you in cold blood; but I will retain you as my slave, until
I perceive that your preference in your own kingdom will be
no longer dangerous to your neighbours; and then I will
consider of the proper way of disposing of you." Abdulk-
ader was accordingly retained, and worked as a slave for
three months; at the end of which period, Damel listened
to the solicitations of the inhabitants of Foota Torra, and
refused to them their king.

YALOVA, a town of Natolia, on the sea of Marmora,
once the residence of Dioclesian; 30 miles N. of Brufa.

MALTIOROVSK, a town of Ruffia, in the govern-
ment of Tobolok, on the river Tobol; 168 miles S.W. of
Tobolok. N. lat. 56° 8'. E. long. 66° 32'.

YAM, in Botany, a large lusty root, eatable when boiled
or roasted, of which there are several species, all natives of
their country, and highly useful to voyagers, as they
will, like potatoes, keep for a considerable time without
spoiling. See DISCOREA.
like belly, the variegated being, the wonderful infector of pains, &c.

His abode is in the infernal city of Yampur, whither the Hindoos believe that a departed soul immediately repairs; and receiving a juft sentence, ascends to Swarga, the first heaven, or descends to Narak, the naffy hell; or is re
turned to earth, according to its merits or demerits, where it attains the form of some animal, unless its offences had been such as deferved condemnation to a vegetable or even to a mineral prizon. This extensive theory of transmigra
tion is of a very poetical tendency, affording great scope for the imagination, which the mythical and enthusiastic
turn of Hindoo metaphysicians or theologians has amply indulged in.

Mr. Wilford believes Yama to be the fame with Serapis; and the latter from a Sanskrit term, implying thirst of
blood. In the Puranas, Yama is defcribed as attended by two dogs, named Serbura and Syama; the firft name signifies varied, and it has other appellations meaning flained or spotted. When we add that it was also called Tri-fres, or the three-headed, little doubt can be entertained of its
being the fame with the Cerberus of the Greeks. Syama means Marka. See Serbura, Syama, and Tri-mes.

As Dherma Raja, or the king of justice, Yama is defcribed in the Puranas as having two countenances. "One, called his divine countenance, is mild and benevolent; and tho' alone it fee who abound in virtue. In this form, he is called an emanation of Vifhnu. He is attended by a fervant named Karmala, who conducts the righteous on self
moving cars into the preence of their judge. His other countenane or form is more especially named Yama. He is then deified with large teeth and a monftrous body, and is thus seen only by the wicked. His attendant is named Kalmala, who drags the wicked with ropes round their necks over rugged paths; and at the command of Yama some are beated, some cut to pieces, some devoured by monftrons, and thrown headlong into hell. He is unmer
ceful, hard is his heart, and every one trembles at his fight."

Yama is the name of a celebrated legislator, whose enactmants are still venerated by the Hindoos. For his profound knowledge and justice, he is said to have been made the judge of departed spirits.

In the seeming contradictions of mythology, Yama is found to be identified, or nearly fo, with both Siva and Vifhnu (see tho' articles) as well as with Mino, Kala, and others. This may be reconciled, as in the mythology of Greece, by recollecting that almost all the deities melt into one. Proserpine or Hecate is given to Pluto as a help-mate, being but another form of Diana. Thus Yama has a form of Parvati affigned him, under the name and character of Pataladevi, or goddes of the infernal regions. (See Pataladevi.) In heaven Diana is Luna, and Par
vati is Swardee, or queen of heaven. On earth they are distingufhed by the names of Diana and Bhudevi, the latter meaning goddes of the earth. These similarities or coincidences could be carried to a great extent.

Some of the ceremonies still in ufe as propitiating Yama, or his confort Sakiti, (which fee,) have been found by Sir W. Jones and others, as strikingly refembling tho' of the Eleusinian goddes; and there can be no doubt but the investigation of the mythical fables of the Hindoos has thrown great light, and may throw still greater, on many obfure and unintelligible passages of our ancient poets of Europe.

We do not find any direct representation of Yama, or any minute defcription of his person and attributes, in the mythical works before the public; nor many particulars of his family. We have already noticed him as the off
spring of the fun; this he shares in common with several other of the heroic perfonages of the Hindoos. Yama is indeed one of the many names of Surya, or the fun. The river Yamuna, or Jumna, or rather perhaps the damfel who was poetically metamorphofed into that interesting fream, is fabled as the twin sister of Yama. She is poetically called the "blue daughter of the fun." Days are especially fet apart for certain ceremonies to their honour. On one, Yama is said to have entertained her brother; and the re
membrance of it is prefered in an existing ufe of Hindoo young ladies feafing and making their brothers presents on its anniversary. In the Rig-veda (see Veda.), a dialogue is given, in which Yama endeavours to seduce his beauteous fister; but his base offers are rejected by her with virtuous expoultuation. In some accounts, a divinity named Swadha is defcribed as the goddes of funeral obfequies; and as fuch we fhould expect to find her closely allied to Yama, but know little of the relationship. We have noticed her under the article Swadha. Several other of our articles contain some particulars of Yama. See Kasya, Kri
tantA, Sraddhadeva, Tapas, and Vaivasvat.

YAMAMAK, in Geography. See JAMAMA.

YAMANCHALINSKOI, a town of Ruffia, in the government of Caucaufus, on the Urul; 20 miles N. of Gurfew.

YAMASCA, a river of Canada, which runs into the St. Laurence, N. lat. 46°. W. long. 72° 45'.

YAMASCO, a town of Canada, at the conflux of the Yamasca with the St. Laurence.

YAMBLAK, one of the Aleutian islands; see Jamblo.

YAMBO. See JAMBO.

YAMBURG, a town of Ruffia, in the government of Peterburg, on the Luga. The cloth manufactory at this place was inftituted by Catharine II., prefently after her accession to the throne: it contains 56 looms, and employs 600 perfons. The cloths are fold at St. Peterburg at a low price; 20 miles E. of Narva. N. lat. 59° 15'. E. long. 28° 30'.

YAMEOS, a town of South America, in the audience of Quito, on the river Amazonas; 36 miles W.S.W. of St. Joachim de Omagua.

YAMIMKA, a river of Ruffia, which rises in the government of Tobolsk, and runs into the Iriftich, 14 miles S.S.W. of Koslovo.

YAMINA, a town of Africa, in the kingdom of Bam
barra, near the Niger. This town, according to Mr. Park, was large, covering the fame extent of ground as Sanfanding; but having been invaded and plundered a few years fince by the king of Kaarta, it was, when he was there, half in ruins. N. lat. 13° 46'. W. long. 3° 50'.

YAMON BAY, a bay on the north coaft of the island of Lucan. N. lat. 14° 21'. E. long. 122° 37'.

YAMSCEVSKIAI, a fort of Ruffia, in the government of Kolivan, on the Iriftich. N. lat. 51° 53'. E. long. 77° 30'.

YAMSKAIA, a gulf of Ruffia, in the Penzinfskoi fea, between Cape Pillatschin and the continent. N. lat. 60° 20'. E. long. 154° 14'.

YAMSKOI, a town of Ruffia, near the gulf of Yams
kaia; 2500 miles E. of Tobolsk. N. lat. 60° 12'. E. long. 153° 34'.

YAMUMINTI, in Hindoo Mythology, the name of one
of the wives of the amorous Hindu deity Krishna. Her name seldom occurs.

**YAMUNA**, in Geography, a river of India, which takes its rise, as is supposed, in the great range of mountains called Himalaya. Its source has not been accurately explored, but it probably is not more remote than that of the Ganges, which rises in the southern part of that range. The Yamuna flows through the province of Srinagar, or Serinaur, in a footherly course, nearly parallel with the Ganges, approaching its farther stream to within forty miles, at the village of Garudvara (Gurdwar), in N. lat. 30° 22'; it is then of nearly equal width. The Yamuna enters Hindooftan Proper, in the province of Delhi, varying its distance from eighty to fifty miles from the Ganges. The country between them is called Dooba, a word meaning two waters, or watered by two rivers. It is a very fertile district. The rivers approximate and join at Allahabad, an important fortress and military station under the Bengal government, when the Yamuna, little inferior in magnitude, has its name and waters absorbed in the more celebrated stream. Its length, of course under its own name, is estimated at about nine hundred miles.

For many miles of its course, the Yamuna, or Jumna, as it is more properly called, was considered a boundary to the British territories, dividing them from the polleffions of the Maharrattas. But from its shallowness, being fordable in many places in the dry season, it was not an important military barrier; and for the same reason is of less consequence for the operations of commerce.

The confluence of any two rivers is viewed with holy respect by Hindus, of these two grand streams more particularly. To heighten the mysticlm, (any teryory connection being still more deeply venerated,) it is feigned that a third river, the Saraswat, joins the other two by a subterranean communication at Allahabad. Frequent allusion is made to this occult union by mythological poets, who teach that these three rivers are terrene manifestations of the three great goddeses, Parvati, Lakshmi, and Saraswat; the Sakti, as they are called, or active energies of their respective lords, Siva, Vishnu, and Brahma, who compose the Hindoo triad of divinity. Of these perfonages sufficient will be found in the articles given under their several names in this work. The fable of the "three platted locks," as this supposed union of these rivers is poetically called, often occurs in the writings of the Hindoes: it is noticed in our articles JUNCTIONS, TRIVENI, and ZENNAR. Under SUTTEE, an account is given of the supposed pronemesh of the Hindoes to this crime. At the confluence now under our notice, it not only loses its name, but assumes a meritorious form. Of this, fea more under SUTTEE.

The river goddess Yamuna is made by mythologists to be the fame with Lakshmi, comfort of Vishnu, and twin fiver of Yama, the judge of departed fpirits, and ruler of the infernal regions. Of these perfonages sufficient occurs under their respective names.

**YAMUTHA**, one of the Alentian islands. N. lat. 53° 40'. E. long. 180° 29'.

**YAMYAL KONDA**, a town of Africa, in the kingdom of Yani.

**YAMYAMA KONDA**, a town of Africa, in the kingdom of Tornani.

**YANA**, a river of Ruffia, which rises in a lake, situated in lat. 63° 40', long. 131° 14', and running due north, being supplied by many small streams, empties itself in the Frozen Sea. N. lat. 71° 25'. E. long. 131° 16'. At its discharge it forms five considerable rivers, which issue in a capacious bay.

**YANAM**, a town of Hindoostan, in the circle of Rajamundry; 28 miles S.E. of Rajamundry.

**YANATONG**, a town of Burmah; 40 miles S. of Mellone.

**YANAUCA**, a small island at the mouth of the river of the Amazons; 10 miles N. of Caviana.

**YANDABOO**, a town of Birmah, on the Irawaddy, remarkable for its manufacture of earthenware; 70 miles W.S.W. of Ava.

**YANINSKOI**, a town of Ruffia, in the government of Irkutsk, on the Angara; 160 miles N.N.W. of Irkutsk. N. lat. 54° 30'. E. long. 103° 20'.

**YANFONG**, a town of Corea; 40 miles E.S.E. of Ou-tchuen.

**YANG**, a town of Corea; 13 miles E. of King-ki-tao.

**YANGBONRAW**, a town of Pegu; 60 miles S. of Lundley.

**YANG-CONG**, a river of China, which runs into the Kincha river, near Lo-choui-tong.

**YANG-HO**, a river of China, which joins the San-camho, N. lat. 40° 23'. E. long. 112° 45'.

**YANG-KIN**, a town of the kingdom of Corea; 15 miles S.E. of King-ki-tao.

**YANG-LI**, a city of China, of the second rank; 1157 miles S.S.W. of Peking. N. lat. 22° 54'. E. long. 106° 35'.

**YANG-TCHEN**, a town of Corea, in Tchufin; 150 miles S.S.W. of King-ki-tao. N. lat. 35° 19'. E. long. 120° 14'.

**YANG-TCHEOU**, a city of China, of the first rank, in Kiang-nan, situated on the bank of the royal canal, which extends from the Ta-kiang northwards to the river Hoang-ho, or the Yellow river: it carries on a great trade in all manner of Chinefes works, and is rendered extremely populous, chiefly by the sale and distribution of the salt that is made on the tea-coasts of this jurisdiction and parts adjoining, and which is afterwards carried along small canals made for this purpose, which end in communication with the great canal; 485 miles S.S.E. of Peking. N. lat. 32° 26'. E. long. 118° 54'.

**YANG-TCHUEN**, a town of Corea; 35 miles W.S.W. of King-ki-tao.

**YANG-TE**, a town of Corea; 84 miles E. of Hantcheou.

**YANG-TEE-KIANG**, a river of Afia, which rises in the mountains of Tibet, and after crossing the empire of China, from east to west, empties itself into the sea, 120 miles E. from Nan-king. This river changes its name almost in every province through which it passes. See KINCHA.

The Yang-te-kiang may be considered as equaling, if not exceeding in size, the Yellow River (which lee). The sources of both these rivers are in the same range of mountains, and they approach one another in one part within a few miles. The Yang-te-kiang, according to Mr. Barrow's statement, consists of two distinct branches, which separating from each other about eighty miles, flow in a parallel direction to the southward for the space of 70 miles, and then unite between the 26th and 27th degrees of N. latitude, just at the boundaries of the two provinces of Yunnan and Sechuen. Then striking off to the N.E. directly through the latter of these provinces, collecting the waters of the numerous rivers that descend towards it from that and another province called Que-choo, it continues in this direction about 600 miles, and then enters the province of Hoo-quang, in the
YAN

31st degree of N. latitude. Through this province it takes a serpentine course, and receives the waters of several lakes, with which this part of the country abounds. Leaving Hoo-quang, it pales between the province of Ho-nan and Kiang-fei, and with a little inclination from the E. towards the N., its copious streams glide smoothly through the province of Kiang-nan, and is disembogued into the sea, which bounds China to the E. in the 32nd degree of N. latitude. The distance from thence to Hoo-quang is about 800 miles, which makes the whole length of the river about 2200 miles. The current, where the yachts of lord Macartney's embassy passed it, did not exceed one and a half, but it was much deeper than the Yellow river. There these two great Chinese rivers, taking their sources in the same mountains, passing almost close to each other in a particular spot, separating afterwards from each other to the distance of 15 degrees of latitude, finally discharge themselves into the same sea, within two degrees of each other; comprehending within their grasp a tract of land of above 1000 miles in length, which they contribute greatly to fertilize and enrich, though by extraordinary accidents occasioning unfulful torrents, they may do injury in particular instances. This tract includes the principal portion of the Chinese empire in ancient times; and lies in that part of the temperate zone, which in Europe, as well as in Asia, has been the scene where the most celebrated characters have expelled, and the most brilliant actions been performed, which history has transmitted to posterity. When the gentlemen of the embassy had crossed the Yang-tse-kiang, they found that, instead of a flat country, lakes, and swamps, the ground rose gradually from the margin of the river, enriched with various kinds and tints of culture, interspersed with trees, temples, and pagodas. In the river were islands skirted with shrubbery, and rocks rising abruptly from the surface of the water. The waves rolled like thos at sea, and porpoises are said to be sometimes seen leaping amongst them: several junks were lying at anchor. In the middle of the river is the island called "Chin-fan," (which see.) The ground to the southward of the river gradually rofe to such a height, that it was found necessary to cut down the earth in some parts to the depth of near 80 feet, in order to find a level for the passage of the canal. The land in this neighbourhood is chiefly cultivated with that particular species or quality of the cotton-flax that produces the cloth usually called Nan-kin in Europe. The down enveloping the field, or cotton-wool, is whole in the common plant, but in that growing in the province of Kiang-nan, of which the city of Nan-kin is the capital, the down is of the same yellow tinge which it prefers when spun and woven into cloth. The colour, as well as the superior quality of this substance in Kiang-nan, was supposed to be owing to the particular nature of the soil; and it is asserted, that the seeds of the Nan-kin cotton degenerate in both particulars when transplanted to another province, however little different in its climate. Lord Macartney's Embassy, vol. ii.

YANG-TSI, a town of Corea; 30 miles S. of King-ki-tao.

YANI, a kingdom of Africa, situated to the east of Burfall, and divided into Upper and Lower, on the north side of the river Gambia. See PISANIA.

YANIMAREW, a town of Africa, in the Lower Yani.

YANIMAZCU, a town of Africa, in the kingdom of Yani. N. lat. 13° 30'. W. long. 14° 1'.

YANKEON, a mountain of Thibet; 30 miles N. of Zuenga.

YANKJA, a town of Assyria, near the Tigris, and not far from Bagdad. This place and also Douellia are small straggling towns, every house being surrounded by a separate mud-wall.

YANTAC, a town of Thibet; 28 miles S.W. of Harachar.

YAN-TCHIN, or VAN-TCHIN, a city of China, of the second rank, in Quang-fu; 1177 miles S.S.W. of Peking. N. lat. 23° 1'. E. long. 106° 51'.

YAN-TINCOU, a town of Thibet; 75 miles E.N.E. of Pa-

YANTRA, a word denoting a mystical figure among the Hindoos; also a mathematical instrument used in any science or art of an occult nature. An instrument used in astronomical observations, called Golayanta, or the spherical yantra, is described in the ninth volume of the Asiatic Researches, art. 6, as similar to our armillary sphere. The article now referred to by Mr. Colebrooks, president of the Asiatic Society of Calcutta, is very curious and important. The Hindoos, being so prone to mysticism, can fancy various wifhes in occult figures and practices. Figures similar to the magic squares, abracadabra, &c. of western wizards, are still used and venerated by the knaves and fools of Asia; these are generally called yantra: as are peculiar figures or hieroglyphics, appropriated to certain Hindoo deities, whose followers or sectaries mark their foreheads therewith, and deem them of a sanctifying tendency. The nature of these various yantras, with suitable instructions and warnings as to their formation, uses, and purposes, are taught in a Sanskrit book, entitled "Agamafaltra, or Occult Science." It may be noticed in passing, that the word Agama, meaning in the Sanskrit tongue hidden, mysterious, secret, &c. seems to have had in various languages and regions a similar meaning, as to which it may suffice to refer to our articles OGHAM, O'M, and SHASTA.

Combined with and related to the yantra, are certain imprecations, incantations, charms, philtres, &c. called Mantra and Tantra, which occur frequently in Hindoo writings, and of which some notice is taken in this work under those words.

YAO, in Geography, a city of China, of the second rank, in Chen-fu; 485 miles S.W. of Peking. N. lat. 35° 54'. E. long. 106° 31'.

YAO-NGAN, or YAO-GAN, a city of China, of the first rank, in Yen-nan. The territory of this city is considerable, although it contains but two cities, one of the second order, and the other of the third. It is interspersed with mountains, which are covered with fine forests and fruitful valleys, and produces abundance of fruit; near the city there is a well of salt water, from which they make very white salt; 1175 miles S.W. of Peking. N. lat. 25° 33'. E. long. 101°.

YAO-TCHEOU, a town of Chines Tartary; 380 miles E.N.E. of Peking. N. lat. 45° 43'. E. long. 122° 14'.

YAO-TCHEOU, or YAO-CHIOO-FOO, a city of China, of the first rank, in Kiang-fu, situated on the S.E. bank of the lake Po-yang. It has seven towns of the third rank in its jurisdiction. In this town is a large manufacture of porcelain, from whence, as well as from King-te-ching, it is sent to Nem-chang-foo; 670 miles S. of Peking. N. lat. 29°. E. long. 116° 14'.

YAP, among the Hindoos, is a silent meditation on the names, attributes, and powers of the Deity. Great merit is ascribed to this species of devotion, which is otherwise, though we apprehend least correctly, spelled jai; under which article we find we have sufficiently described it, although reference has occasionally been made to this article;
YAR

ticle; which is therefore thus given, chiefly to point to the more lengthened description.

YAR Island, in Geography, one of the group called Carolines; which see. In this island, a kind of crocodile is the object of their worship. Here are also a number of magicians, who impose upon the credulity of the inhabitants, by leading them to believe, that they have communication with the evil spirit; and by this imposture, they commit with impunity all sorts of crimes. They procure maladies and even death to those whom it is their interest to destroy.

YAPANDAIN, a town of the empire of Birmah, on the Irrawaddy, 40 miles W. of Ava.

YAPIZLACA, or Llanos de Manfo, a province of South America, in the vice-royalty of Buenos Ayres, of great extent, situated to the south of the Vermejo river. This country was formerly called Llanos de Manfo, or the Plains of Manfo, from a captain of that name, who in 1556 undertook to build a town: but when he thought himself in perfect security, he, with all his attendants, was murdered by the Indians; of whom there are several nations. The country is but little known.

YAPOC, a river of Surinam, which runs into the Atlantic, near Cape Orange.

YAPON, in Botany, a species of ilex. See HOLLY.

YARACUI, in Geography, a river of Venezuela, which runs into the Spanish Main, N. lat. 10° 28'. W. long. 68° 40'.

YARANSK, a town of Russia, in the government of Viatsia; 72 miles S.W. of Viatska. N. lat. 55° 36'. E. long. 48° 34'.

YARAY, a town of Africa, in the kingdom of Kuyor; 80 miles S.E. of Amboul.

YARBA, a town of Africa, and capital of a country, called Yarra; 430 miles S.W. of Tombuctoo.

YARD, Virga, a long measure, used in England and Spain; chiefly to measure cloth, fluffs, &c.

The English yard contains three feet. It was first settled by Henry I. from the length of his own arm. See MEASURE.

The English yard is just seven-ninths of the Paris ell; so that nine yards make seven ells. To reduce ells, therefore, into yards, divide. If seven ells give nine yards, how many yards will the given number of ells give?

Yards are converted into ells Flemish, by adding a third part; into ells English, by subtracting a fifth part; or multiplying by 8, and calling off the right-hand figure. Eells Flemish are converted into yards, by adding a fourth. To turn ells Flemish into yards, subtract one quarter.

The Spanish vara, or yard, chiefly used at Seville, is, in some places, called barra. It contains seven twenty-fourths of the Paris ell; so that seventeen ells make twenty-four Spanish yards.

YARD, in Anatomy, the penis, or virile member; serving for the evacuating of the urine and seed.

It is also the common name for the penis in most animals.

Yard of Land, Virgata Terra, or Virga Terra, is a certain quantity of land, but that various, according to the place. At Wimbledon, in Surrey, it is only 15 acres; but in most other counties it contains 20, in some 24, in some 30, and in others 40 or 45 acres.

YARD, in Agriculture. See Farm-Yard.

YARD-Manure. See Farm-Yard, Compost, Dung, Manure, and Manuring.

In order to prevent the vegetation of weeds in this manure, the manure is turned up in the yard in rows when it is about two feet in depth, leaving proper room between each row to put the fresh dung from the stables, cow-houses, and hog-flies. After the manure thus thrown up has got a fair heat, it is again turned over, which moilily destroys or prevents the weeds from growing, when the manure is ready for being taken out upon the land.

The uts and powers of the long and short-yard dung manure are very different in different climates of it.

The opinions and practice of the farmers in the county of Norfolk, in regard to the use of long or short dung or yard manure, are much divided. Comparative trials are wanting to fully ascertain this important point.

It is, however, a prevailing idea in the above country, that long dung is best for strong land, and short for light soils; but that the general practice is that of spreading short in all cafes.

In Eifex, too, it is now the practice of many enlightened farmers to make use of long dung or yard manure with great advantage; though what may be said to be the general custom of the district is to clamp and employ that which is in the shortest state. Some farmers there, however, do not like to see their yard-manure too long in the heaps, as there is loss in turning it. In the practice of duning for wheat, it was there observed, on long and extensive experience, that it should be long freio dung, as the superiority of such dung to that which the farmers so generally prefer, fuel as has been moved and turned over until quite rotten, was, one load of it, worth fix of that of a year old and rotten, as with such dung a crop of wheat is always certain.

In Oxfordshire, and many other counties, the same is the case with many farmers, though the common practice is to mine and turn yard-manure until it is reduced into the short state, and then to apply it to the land.

On this very interesting point of management, the writer of a late work on Agricultural Chemistry has suggested, that a flight incipient fermentation is undoubtedly of use in the heaps of this sort of manure, as by means of it a disposition is brought on in the woody fibre to decay and disolve, when it is carried to the land, or ploughed into the soil; and that this sort of fibre is always in great excess in the refuse of the farm, especially that of the yards; but that too great a degree of fermentation is very prejudicial to such mixed yard-manure, when in the heaps; and that it is better that there should be no fermentation at all before the manure is used, than that it should be carried too far, the excess of fermentation tending to destroy and disfigure the most useful part of the manure.

During the violent fermentation which is necessary for reducing farm-yard manure to the state in which it is termed fitis min or dung, not only a large quantity of fluid, but likewise of gaseous material is lost; insomuch that the dung or manure is reduced one-half, two-thirds, or more of its weight; and that the principal elastic matter dillengaged is carbonic acid with some ammonia; both of which, if retained by the moisture in the soil, would be capable of becoming an useful food or nourishment of plants.

Besides the disfipation of gaseous matter when fermentation is pushed to the extreme, as in the case of short dung, there is another disadvantage attending it in the loss of heat, which, if excited in the soil, is useful in promoting the germination of the feed, and in affilting the plant in the first stage of its growth, when it is most feeble and most liable to disease; and the fermentation of the manure in the
fail must be particularly favourable to the wheat-crop, in preserving a genial temperature beneath the surface late in the autumn and during winter. Moreover, it is a general principle in chemistry, that in all cafes of decomposition, fulfances combine much more readily at the moment or time of their difengagement, than after they have been perfectly formed; and in fermentation beneath the floor the fluid matter produced is applied instantly, even while it is warm, to the organs of the plant, and consequently more likely to be efficient, than in short dung or manure that has gone through the processes; and of which all the principles have entered into new combinations.

The writings of scientific cultivators allege many arguments and facts which favour the application of yard-dung in a fresh or long state. And it is flapped, perhaps there is no subject of investigation in which there is such an union of theoretical and practical evidence and proof.

The main objection against the use of slightly fermented or long yard-dung or manure is, that weeds rife more luxuriantly, and in greater numbers where it is had recourse to: but though seeds thus carried out will certainly sprout, it is but seldom that this can be the case to any extent: and if the land be not clean of weeds, any kind of manure, long or short, fermented or unfermented, will caufe their rapid growth.

The application of yard-dung, or manure in the long flate, is highly advantageous with regard to the quantity or extent of the improvement which may be produced, as nearly four loads of it are mostly required to form one of the short kind.

There is another question connected with this subject, which is not of less interest or importance to the farmer to have decided, which is that of the superior advantage of confuming the straw of the farm by animals, or of having it littered and trodden into dung or manure in the yards. Many of the most enlightened farmers in the firit of the above counties, the writer of the account of the agriculture of it fays, are againft the former of these practices, though a large part of them is in the custom of it: and they have frequently, too, recourse to the method of buying oil-cake, even often at a loss, in order that their straw may be trodden into dung or manure by fattening beasts, which is an excellent management of the yard kind.

Yard-Fall, a term used among our farmers to express a malady to which horses are sometimes subject, which is the hanging down of the penis from its sheath between the legs, the creature not being able to draw it up again. This is caufed by weaknefs of the peculiar muscles which should act in the drawing up; and proceeds sometimes from a violent flip or strain, sometimes from a blow on the back, and sometimes from extreme wearinefs in long journeys.

The method of curing this is, first to wash it with oil of rofe, after this with warm white wine, and finally, to anoint it with a mixture of oil of rofe and honey; it is then to be returned into its place, and kept from falling down again by a little canvas bolster. It is to be thus drefled once in twenty-four hours, till the cure is perfected.

There are some other diítemperatures to which this part is subject in a horse, as the being foil at the end, so that the creature voids its urine in the sheath; in this cafe, the method of cure is to draw out the penis, and cleanse the end of it from any foulefs that may be found there; then it is to be washed with butter and white wine vinegar melted together: sometimes there is a discharge of yellow flinking matter from the penis; this is peculiar to flone-horses, and principally affects them after the time of their courting of mares.

This running is attended with a swelling of the penis, and with a pain in voiding the urine; the creature also finds a difficulty in drawing up the penis into the sheath.

The method of cure is, to dilfolve in a pint of white wine an ounce of roach-alum by boiling; and four or five times a day this is to be ufed, injecting it up into the yard with a syringe, blood-warm. This will prove a certain cure.

Yard-Foul, the filthy, furred state of the yard and sheath in animals of the horse kind, which oftentimes produces difeafe.

It is removed by well washing and cleaning the parts, by the free ufe of soft-soap and water.

Yard, Mattering of, a difeafe in the yards of horses, produced by different caufes, in which matter is formed. It is removed by the ufe of cooling washes, and keeping the parts clean and perfectly free from dirt and nafsnefs.

Yard, Stable. See Stable.

Yard, Straw. See Straw-Yard.

Yards, in a Ship, are long cylindrical pieces of fir-timber, suspended to the masts of ships, &c. to extend the fails to the wind.

All yards are either square or latteen; the former are suspended athwart the masts by the flies, at right angles, and the latter at one-third their length, obliquely.

The proportional lengths of yards are as follow, particularly in the royal navy:—Main-yard, eight-ninths the length of the main-mast; fore-yard, seven-eighths of the main-yard; mizen-yard, six-sevenths of the main-yard; main-topfall-yard, five-sevenths of the main-yard; fore-topfall-yard, seven-eighths of the main-topfall-yard; mizen-topfall-yard, two-thirds of the main-topfall-yard; topgallant-yards to 74-gun ships, two-thirds all under three-fifths of their topfall-yards; royal-yards, half of the topfall-yards; crofs-jack-yard and spritfall-yard, the fame as the fore-topfall-yard; spritfall-topfall-yard and driver-yard, the fame as the fore-topgallant-yard; and the fludding-fall-yards, four-sevenths of their booms.

Proportion of diameters of main and fore yards at the flings is one-quarter of an inch to every foot in their length; mizen-yard, two-thirds the diameter of the main-yard; topfall-yards, five-eighths of an inch to every yard in the length; topgallant-yards, three-fifths of an inch to every yard in the length; royal-yards, half the diameter of the topfall-yards; spritfall-yard and crofs-jack-yard, the fame diameter as the fore-topfall-yard; spritfall-topfall-yard and driver-yard, the fame diameter as the fore-topgallant-yard; and the fludding-fall-yards, one inch diameter to every five feet in the length.

The square yards are of a cylindrical surface the greater part of their length. They taper from the middle, which are called the flings, towards the extremities, which are termed the yard-arms; and the distance between the flings and the yard-arms on each side is divided into quarters, which are distinguished into the first, second, and third quarters, and yard-arms, which are regularly tapered by the following proportions. The first quarter, or that next the flings or middle, thirty thirty-one of the given diameter; the second quarter, seven-eighths; the third quarter, seven-tenths; and the arms or ends, three-fourths. From a middle line struck on the tree or fpar the yard is to be made from, half of the several dimensions above is to be set.
YARDS.

set off, and the yard then fawn to its fiding; it is then
canted, and a middle line struck on one of those sides, and
the middle and the quarters squared up thereon from the
middle line on the firt side, and the fame diameters set off as
before, then fanned and fawn square to the upper fide; it is
then fawn eight-square the whole length.

The main and fores yards (fig. 17. Rigging, Plate II.)
are then trimmed sixteen-square, and rounded from one
quarter on each fide the flings to the outer ends, except on
the aft-side, which must remain eight-square two-quarters
on each fide the middle. The whole is then planed fair and
smooth. In merchant ships they have a fheave-hole in their arms
for the topfart-fllets, and are left square the length of the
fheave-hole; but this method weakens the lower yards.

Topfart-yards (fig. 18. Rigging, Plate II.) being trimmed
sixteen-square, are rounded and planed from the firt quarter
on each fide the middle to their outer ends, and a fheave-
hole cut from their upper fide, its length within each outer
end for the reef-tackles. In fome merchant ships a hole is
cut within the cleats for the top-gallant-fllets, but is better
avoided, as it weakens the yard-arms.

Topgallant-yards (fig. 19. Rigging, Plate II.), royal-
yards, crofs-jack-yards, mizen-yards, fpirt and fpirt-topfart-
yards, fludding-fail and driver yards, are trimmed eight-
square, fixeen-square, and then rounded and planed fair and
smooth from end to end throughout the length.

Battening of Yards.—Main and fores yards, main, fores, and
mizen topfart-yards, have oak batters nailed on their
fleres nearly the fame length and breadth, one inch
to three-quarters of an inch thick; their ends rounded and
fpaped, and the edges chamfered. The fore-fide has no
batters.

Clearing of Yards.—The fling-cleats, a, (fig. 17. Rig-
ging, Plate II.) nailed on the fore-fide of the main and fore
yards, are once and a quarter the given diameter of the
yard in length, with a fhooulder one-third its length; the
breadth one-fourth the length; the thicknes two-thirds
the breadth, made of elm, and nailed once the given dia-
meter on each fide the flings.

Stop-cleats, b, (fig. 17. Rigging, Plate II.) are made
of oak, and nailed within the arms, on the fore-fide and aft-
fide of the lower yards, one inch and a half to every yard in
their length. Their length half the given diameter of the
yard; the breadth one-fourth its length; and its thick-
nesses two-thirds its breadth. Yards for merchant ships have
their cleats sometimes failed from the folid.

Topfart-yards have fpop-cleats, nailed on the fore-fide of
the yard, once the given diameter on each fide of the flings.
Those within the arms, on the fore and after fides of the
main and fore topfart-yards, three inches to every yard in
the length; and mizen topfart-yards, two inches and a quarter.

Topgallant-yards the fame as topfart-yards.

Royal-yard-cleats are once the diameter on each fide
the middle afunder, and twice their length within at the
arms. Crofs-jack-yards have fpop-cleats, nailed on the fore-fide of
the yard, half the diameter on each fide of the flings; therofe
at the arms, one inch and a half within their outer ends to
every yard in length, and nailed on the fore and after
fides.

Mizen-yards have fpop-cleats nailed once the diameter
afunder on the flarboard-fide, and once and a half the given
diameter below the middle of the yard; those at the peak
or outer end, once the diameter within.

Sprit and fpirt-topfart-yards have fpop-cleats nailed on
their under fides; the fpirtflail-yard once the diameter on
each fide the flings; the fpirt-topfart-half the diameter
one each fide: thofe at the arms one inch and a half within
their outer ends to every yard in the length; and they nail
on the fore and after fides contrary to thofe at the flings.

Studding-fail and driver yards have fpop-cleats, nailed
once the given diameter afunder, at one-third the length of
the yard from the inner end; thofe at the arms twice their
length within.

Boat-yard-cleats are once the given diameter afunder at
the flings; thofe in the middle, others one-third from the end,
such as lugs, latteef, and fettees, and the length of the
cleat within at the arms.

Yards are fitted at their outer ends for rigging out
fludding-fails. Main and fores yards have four boom-iron;
one on each of their outer ends, c, (fig. 17. Rigging,
Plate II.) the others at one-third the length of the boom
within, d. The outer boom-iron is compofed of a ring, a
neck, and ftraps.

The ring, through which the boom flides, is of the fame
diameter in the clear as its topmaft-fludding-fail boom;
breadth three-eighths the diameter, and from five-eighths to
three-quarters of an inch thick. In one fide a lignum vitae
collar is fitted, one-third in length the diameter of the boom-
ring. The neck is fquare, and connects the ring to the
ftraps; each neck one inch longer than the diameter of the
ring, and one-fourth its length in fize.

The ftraps are made one inch and a quarter in length to
every three feet of the yard; their breadth once and a
half the breadth of the ring; thicknes at the inner part,
three-eighths of an inch; they increase in fubftance towards
the neck, and are made to the fhape of and let in their
thicknes into the yard-arm. They are bolted, and have
two hoops made to the fize of the yard-arm, one clofe to
the end, and the other near the neck.

Inner boom-iron are made after the fame proportion
as the outer ones, but differ in fhape. The ftraps are made to
compafs the yard at one-third the length of the topmaft-
fludding-fail boom within the end, and the ring is feparated
from the ftrap by a collar; the upper part of the ring opens
with a hinge on one fide, and the heel of the boom is chafed
therein.

Boom-iron fix on the yards thus: the rings are parallel
with the axis of the yard, in a ftraight direction, with a line
fluck upon the yard, in the middle of the fquare, between
the upper and fore fide.

Boom-iron, on the yard-arms of ships in the merchant
service, differ much in fhape. The ring the boom flides
through is connected by a collar to a fquare hoop, that lets
on and nails to the yard-arms, they being left fquare; and
sometimes a round hoop to the fize of the yard-arms. Others
have a ftraight neck, projecting from the ftraps, with a fhooulder
in the middle of the neck, and the part without left fquare.
The boom-ring has a fhank on the under part, with a mor-
tife that fits the neck, and then faddened by a ferew-nut,
or a fping-fockock, that goes on the neck next the ring.

Topfart-yards, main and fore, commonly have boom-iron
at their outer ends, like the lower yards in merchant ships.
In the navy they are mostly fitted with a boom-ring, and a
fping-eye-bolt driven in the middle of their ends, parallel to
its axis; and an iron hoop let in its thicknes and breadth,
and nailed, to prevent splitting the yard-arm. Yards that
have no inner boom-iron have faddles for the heel of the
boom.

Topgallant-yards, main and fore, mizen-yards, fpirt and
fpirt-topfart-yards, have their arms fitted with a ferrule-hoop
and fping-eye-bolts, as the topfart-yards.

Mizen-
YAR

Mizen-topfahl and topgallant yards have hoops like the former let on their outer ends, but no eye-bolts. Driver-yards have a sheave-hole cut through their outer end, and a hoop and eye-bolt.

The main and fore yards of large ships are sometimes made of two trees; they have each tree lined, long enough to scarf four feet beyond the first quarter, next the middle, or flings, which is in all five-eighths the length of the yard, adding four feet. The scarfs line straight, from each quarter next the middle to one-fourth the infallance at the quarter next the butt, and three-fourths at the quarter next the middle, and haunches to about three inches at the butt. Each tree is then fawn as before directed, and completed thus: the scarfs and haunches are trimmed straight, and out of winding on the inside, and a line struck along the middle, and a chain-coak set off, each about two feet four inches long, and one-third the diameter broad; and the butts squared across and down the fides. The coaks are railed one inch and a quarter at the butt, and funk to the fame on the other side of the middle, towards the arm; the other half is then canted thereon, set straight and out of winding, and fayed as the mafs, (which fee, and the Plate of Mafs,) and bolted together fore and aft through the middle, in the butt of every coak; the heads are to be driven from the thimneft part of the scarf, and clenched on a ring, and the haunches nailed.

The yard is then completed as before directed, and the scarfs caulked their length and hooped; one hoop over the butt of each scarf, one in the middle of each haunch, and one over every bolt; then a fihn of fir, two inches thick, and the fame length and breadth as the figure on the affide, is fayed and nailed clofe over all the hoops.

Another method of scarfing yards together made of two trees, which is the strongest, and takes fefs trees than the former, is by providing two trees that will hold the diameter beyond the fishe, and scarf together similar to the former. Then the deficiency of the diameter towards the middle is made good by long fishes of fir, from four to six inches thick, as the fize of the yard may require, extending two feet in length at each end beyond the long square on the affide, and each of fufficient breadth to form the eight-square on the outside. The inner surfaces of the fishes are caoked and fayed clofe upon the yard, the coak extending near the whole length. The yard is then finned as before directed, and hooped and bolted, as in the Plate of Mafs-making.

YARD-Arm is that half of the yard which is on either fide the maff, when it lies athwart the ship. See the preceding article.

YARDS also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. See Dock-Yards.

YARDLEY, in Geography, a village of Worceftershire, which, according to the population return of the year 1811, contained 1918 inhabitants, including 121 families employed in manufactures, and 453 houfe; 7 miles S.E. of Birmingham.

YARE, a river of England, in the county of Norfolk, which rises about five miles N. from New Buckenham, palls by the city of Norwich, and runs into the German ocean near Yarmouth.

YARE. See Segovia Nurva.

Yare, among Sailors, implies as much as, nimble, ready, quick, expeditious. Hence, to be yare at the helm, as some fay, signifies to fet a fresh man at the helm.

YARECA, in Geography. See JARECA.

YAREE, a town of Burmah; 40 miles S.W. of Ava.

YARENSK, a town of Russia, in the province of

Utiug, on the Vitchegda; 92 miles N.E. of Utiug. N. lat. 62°. E. long. 47° 50'.

YARI, a town of Brazil, in the government of Para; 60 miles N.E. of Para.

YARIN, a word used by some of the chemical writers to express the flos aris.

YARKAN, Yarkand, Irken, or Tarkian, in Geography, a town of Cañgar, or Little Bucaria, where the grand gran of the Eluth Tartars chiefly refides. The town is large, and well built of bricks dried in the fun. The environs are fertile, and the palace of the khan large, but not handsome. In 1400 this town was taken and plundered by Timur Bec; 90 miles S.E. of Cañgar. N. lat. 38° 19'; E. long. 78° 19'.

Yarkand, or Tarkand, suggested to be the Oechardes of Potelmo, a river of Afia, which palls by the town of Yarkan, and after a considerable course runs into lake Lop; 100 miles S. of Tourfan.

YARM, or Yarum, a market-town in the W. division of the liberty of Langburgh, in the North Riding of the county of York, England, is situated on the banks of the river Tees, 4 miles S. by W. from Stockton, 44 N.N.W. from York, and 237 in the fame direction from London. In 1811 the houses in the town and parish were 361, and the inhabitants 1431. Here is a next modern church. A market is held on Thursday, and fairs on Thursday before the 5th of April, Holy Thursday, 2d of August, and 20th of October. At Yarm was an hospital, founded before 1185, also a house of Black friars, founded about 1271, by the family of Brus or Bruce, both of which were suppressed by Henry VIII. Over the river Tees at this place is a handfome stone bridge, communicating with the county of Durham. The town, formerly more considerable than at present, still carries on a good trade by water, particularly in corn and lead for the London market. In 1761 the town fuffered severely from an inundation of the river Tees.—Beauties of England and Wales, Yorkshire, by J. Bigland, 8vo. Lond. 1812.

YARMOUTH, Great, an important fea-port, borough, and market-town, in the hundred of Earl Plegg, and county of Norfolk, England, is situated on the E. coaft of England, near the mouth of the river Yare, whence it has its name, 22 miles E. from Norwich, and 124 N.E. from London. The number of houses in the parish, according to the returns of 1811, was 3594, and the inhabitants were 17,077. A market is held here on Saturday, and a fair in Easter week. The town, which fends two members to parliament, was incorporated by James I. It is governed by a mayor, recorder, 7 aldermen, 36 common-council-men, a town-clerk, and other inferior officers. In former times, Yarmouth was a member of the Cinque Ports, and by ancient custom appointed bailiffs, who, in conjunction with the ma- Griffiths of the town, hold a court there during the herring-fair. The corporation poftes also the privileges of courts of admiralty and of record. Yarmouth isingularly situated on a long, narrow, sandy peninsula, having on the E. the German ocean, and on the W. the river Yare, which, after pointing N.E. towards the sea, suddenly bends round to the S. parallel to the shore, and opens into the sea, two miles below the town. The coast near Yarmouth and southward to Lowestoft is the moft easterly part of Great Britain. Yarmouth church lying in E. long. 1° 45' from Greenwich.

The firft mention of this town is in Domesday-book, which renders it probable, that it had its beginning in the early part of the Anglo-Saxon dynasty. When the sand- bank, on which it stands, and which, thrown up by the sea, impeded,
impested, or at least diverted, the course of the Yare, was sufficiently consolidated, habitations were formed on it by the fishermen who returned to the coast. By the influx of foreigners for the purchase and sale of fish the town increased, so as to become the most considerable port on the east coast of England. To provide for its security, Henry III granted to the inhabitants permission to inclose the town with a moat and walls; works which, however, do not appear to have been commenced until 1285, the thirteenth year of his succesor, Edward I. But when war with France broke out in 1545, an additional rampart was thrown up towards the sea, and further extended in 1587. The following year, to guard against the Spanish invasion, outlooks were constructed, the south mouth was raised, and planted with cannon, and a boom was laid across the entrance of the harbour. Coeval with the first fortification of Yarmouth was probably the castle, in the centre of the town. It served for some years as a prison; but in 1621 the whole was demolished. In 1642 the inhabitants of Yarmouth declared for the parliament; but it was only after the independents had gained an ascendency in the state that a garrison was admitted here. During the American war, forts and batteries were constructed, and barricades for a considerable body of troops were erected for the defence of the place. Indebted for its original existence, and subsequent increase to the fishery, Yarmouth very early possessed a very numerous shipping. In the summer of 1310, when Edward II. ordered the several ports of England to send ships to Dublin, to convey troops over to Scotland, Yarmouth furnished fix, while even Bristol and Gloucester, although so conveniently situated for that object, furnished only two between them. To form a fleet to be employed in the siege of Calais, in 1346, under Edward III., Yarmouth sent out forty-three vessels, carrying 1095 mariners; a number of men far exceeding those furnished by any other port in the kingdom; for London itself was called on for only twenty-five vessels, containing 662 mariners.

In 1597, when men for the navy were required in proportion to the tonnage of each port, Yarmouth was the ninth in order; but according to the Cōmbouf-hee books of 1800 it had advanced to be the eighth, the ships of the port being 375, the tonnage 32,957; navigated by 442 men, while Bridol possessed 186 ships, carrying 26,403 tons and 1674 mariners. Yarmouth was early distinguished, and still remains unrivalled, for the herring-fishery. About 1220 the abbots of St. Alban's purchased a large house in Yarmouth, "in order to lay up fish, especially herrings, which were bought in by his agents at the proper season, for the use of his abbey." Prior to 1238, the people of the opposite coast of Europe were in the habit of reftoring to Yarmouth for a supply of herrings. These and other recorded facts shew that the method of preserving that fish, probably by salt, must have been known in England more than 200 years before the pretended invention of Beukels in Flanders, from whom pickling is said to have had its name. (See Herring-Fishery.) The herrings usually appear on the east coast of England about September, when the grand fishings season commences. The boats fitted out for the fishery are decked, and average from forty to fifty tons burthen, with a crew of eleven or twelve men to each. The vessels, with some tons of salt on board, proceed from four to twelve leagues out to sea. Each boat is provided with eighty or a hundred nets, twenty-one yards in length, and eight and a half in depth; all of which, fastened to a long rope, are let down into the sea at dusk, and drawn up at day-light. When falted, the fish are hung up in lofty buildings, and exposed, with small intermissions, for about a month, to the smoke of a wood fire, and thus become red-herrings. Two centuries ago the fishery was also carried on in summer; but in the present times no herrings are found on the coast in that season. In the interval of the fishery, the boats are employed in catching mackerel and cod. Yarmouth trades very largely in the export of corn and malt, and in the woolen stuffs of Norwich. Timber, iron, and hemp, are imported from the Baltic, and ship-building is carried on at this place to a considerable extent.

The formation and the maintenance of the harbour of Yarmouth have required great exertion, ingenuity, and expense; for the present is the seventh recorded to have been made, and its yearly charge amounts to about 2000l., which sum is defrayed by duties exacted from goods brought in. The new works were executed by Josias Johnson, a Dutchman, who had been invited from Holland for the purpose. The principal or north pier is in length 265 yards, and the south pier, which is better constructed, 340 yards: the extent of the harbour between these piers is 1111 yards; and the depth of water, in all states of the tide, being now about twenty-four feet, instead of three feet, as was the case before the erection of the piers, vessels can always lie afloat at their moorings. The well-known Yarmouth roads are formed by ranges of sand-banks, lying out parallel to and at no great distance from the shore. The channels between the banks, some of which are dry at low water, and between them and the shore, are in general narrow, but deep enough for ships of any size. The roads consequently afford a most desirably shelter in stormy weather, on a tract of coast projecting a great way into the German ocean, and peculiarly delitute of accessible harbours. But the concourse of shipping in this station has, on various occasions, produced dreadful disasters, the vessels being frequently driven from their anchors, and wrecked on the banks or on the shore.

The town of Yarmouth is in form an oblong quadrangle, confuting of four principal streets, crofled at right angles by 156 lanes, called rows, fo confined in breadth, that for the conveyance of goods through them, the inhabitants have adopted narrow carts, mounted upon low wheels, and drawn by one horse, the driver flanding in the front of the cart. The town is enclosed by a wall on the north, east, and south sides, in length 2240 yards, which, with the well fide along the river, 2030 yards, make the circuit two miles and 750 yards. Although fo populous a town, Yarmouth forms but one parish, and, until a century ago, had but one church, that of St. Nicholas, which was erected by Herbert Lofinga, bishop of Norwich, in 1123; but it was greatly enlarged in 1525. It confits of a nave, two filies, and a tranfept, and had lately a fpire 136 feet high, a diftinguifhed fea-mark in the midit of a long tract of low and dangerous coaft; but in 1803 it was taken down. The other public buildings of Yarmouth are, the town-hall, a handsome building, with a Tuscan portico, situated near the centre of the quay; the council-room, which also serves for alfembles; the fisherman's hospital, a quadrangle, containing twenty rooms on a floor, each intended for an old fisherman and his wife; the hospital-school for maintaining and clothing thirty boys and twenty girls, at the expence of the corporation; and the charity-school for seventy boys and thirty girls, who are clothed and educated. The quay of Yarmouth is justly the boast of the town, and is one of the finest and the moft extensive in Europe. Its length from the fourth gate to the bridge is 1014 yards, beyond which it reaches 1016 yards farther, making its whole extent a mile and 270 yards. In many places the breadth is 150 yards, and the southern part
is decorated with a range of handsome buildings. By means of a bridge across the Yare a communication is maintained with the county of Suffolk, which stretches up the west bank of the river. As a fashionable watering-place, Yarmouth is well provided with every accommodation, and consequently much frequented. On the beach a bathing-house was erected in 1856, commanding a fine view of the roads and shipping; and in 1778 a new theatre was opened. Opposite to Yarmouth, and for about two miles north and south of the town, the coast is nearly a level common, elevated only from two to three yards above high-water mark. From the edge of the common down to the water is a gentle slope of fine sand, intermixed with loose pebbles called shingles; and as the tides rise but about six feet, the space brought under water is only a few yards. From high-water mark to the turf of the common the sands abound with marine plants, some of them rare and curious, of which an account is given by Mr. Dawson Turner in the Historical Guide to Great Yarmouth, 12mo. 1806.—

YARMOUTH, South, a sea-port, borough, and market-town, in the S.W. half of Well Medina liberty, in the Isle of Wight, and county of Southampton, or Hampshire, England, is situated at the entrance of the little river Yare, on the N.W. coast of the island, 10 miles W. from Newport, and 97 S.W. from London. The town, which is governed by a mayor, twelve burgesses, a steward, a town-clerk, &c. was incorporated by James I., and sends two members to parliament. In 1811 the houses in the borough and parish were 88, and the inhabitants 427. A market is held here on Saturday, and two fairs annually. Yarmouth is built on a bank sloping to the sea, and seems to have been formerly much larger than it is at present. The church is situated in the middle of the town. The market-house has over it the town-hall. Here was a castle, built by Henry VIII. on the site of an ancient church, which had been destroyed by the French. This fortress is defended by some pieces of cannon, and a small garrison. Between Yarmouth and Lymington a packet sails daily.—Beauties of England and Wales, Hampshire, by J. Britton and E.W. Brayley, 8vo. Lond. 1808.

YARMOUTH, a sea-port town of Massachusetts, in Barnstable bay; 50 miles S.E. of Boston. N. lat. 41° 42'. W. long. 70° 10'.

YARMOUTH, a town on the west coast of Nova Scotia; 35 miles W. of Shelburn.

YARMOUTH, North, a town of America, in the district of Maine, and county of Cumberland, with 3293 inhabitants; 9 miles N.E. of Portland. N. lat. 43° 45'. W. long. 70° 8'.

YARMUG, or YARUN, a town of Palestine, in the district of Saplet, on a river of the same name, which runs into the lake of Tiberias, chiefly inhabited by Christians; 24 miles S.E. of Saplet.

YARMUK, a river of Syria, anciently called Marfias, which runs into the Orotetes, near Apamea. In 656 a battle was fought on the banks of the river, between the Christians and the Saracens, in which the former were defeated.

YARN, denotes spun wool. See WOOL, and WOOLEN Manufacture.

YARN, Marking. See MARKING.

YARN, in Rope-Making, is spun from hemp, and is called twenty-five, twenty, and eighteen thread yarn, which differs only in the fineness; the twenty-five being finer than the twenty, &c. It is thus distinguished, because either twenty-five, twenty, or eighteen threads a hook, make a rope of three inches in circumference, and so in proportion.

YARN, Spun, on board a Ship. See SPUN.

YARNALLS, in Geography, a town of Pennsylvania; 20 miles E. of Sunbury.

YAROVOI, a town of Russia, in the government of Tobolsk, on the Irtysh; 52 miles N. of Tobolsk.

YARRA. See JARRA.

YARRINGLES, or YARRINGLE-Blades, a kind of reed, or instrument, with which bands of yarn are wound on to clues, or balls.

YARROW, in Botany. (See ACHILLEA.) Perhaps this old English name originated in the Spanish Terreia, or Terwa, an herb; our Common Achillea Milfolium having been formerly called, in that language, Milbyas Terwa, or Thonfand-leaved Herb, a transliteration of its Latin appellation.

The leaves and flowers of the common yarrow, or achillea milfolium of Linnaeus, which is in flower on our ditch-banks, and in dry pastures, the largest part of the summer, are greatly recommended by some of the German physicians, as mild collaborators, vulneraries, and antiphlogistics, in diarrhoea, hemorrhages, hypochondria, and other affections. They promise, says Dr. Lewis, by their several qualities, to be of no inconsiderable efficacy. They have an agreeable, though weak, aromatic smell, and a bitterish, roughish, somewhat pungent taste. The leaves, having the greatest bitterness and astringency, are chiefly directed for medicinal use; the flowers have the strongest and most pungent smell, are remarkably acid, and promise to be of the greatest efficacy, if the plant has any such efficacy, as an anodyne or antiphlogistic. The virtue of both leaves and flowers is extracted by watery and spirituous menstrua; the astringency most perfectly by the former; their aromatic warmth and pungency by the latter; and both of them equally by a mixture of the two. The flowers, distilled with water, yield a penetrating effital oil, poffieing the flavour of the milfoil in perfection; in confistency somewhat thick and tenacious; in colour very variable, from a greenish-yellow to a deep green and bluish-green, and fine blue, which differences depend in a great measure on the oil in which the plant is produced; the flowers gathered from moist fresh grounds yielding generally a blue oil, and those collected from dry commons a green one, with a greater or less admixture of yellow. The extract obtained by infusipating the yellowish tincture made in rectified spirit, is more agreeable in smell than the flowers, of a moderately warm penetrating taste, somewhat like that of camphor, but much milder, accompanied with a slight bitterish and fulminating quality. The achillea pinnica of Linnaeus, called vneescwerti, or biffard pellitory, is perennial, grows wild on heaths, and in moist shady grounds, and is found in flower from June to the end of summer. The roots of this plant have a hot biting taste, approaching to that of pellitory of Spain, with which they nearly agree in their pharmacetical properties, and for which they have been sometimes substituted in the shops. They are by some recommended internally as a warm stimulant and restorative; but their principal use is as a medicatory and irritant. Lewis.

YARROW, in Agriculture, a plant of the herbage kind, which is common but useful in the pasture-field in many cafes. It has long ago been noticed, by the writer of the "Effays on Rural Affairs," as valuable for cultivation in grazes-lands in different sorts of soil. It succeeds on moist loams, but is most proper for dry burning gravels, sands, and
YAS

and chalks. It is said to possess the singular quality or property of repelling drought on the moist and arid soils; so that if a green spot appears in a burnt-up close-fed pasture ground, it may almost with certainty be concluded to be watered by this plant. In pastures there is not any fort of plant which is eaten down more closely than this, by every species of domestic animal. It has been remarked with surprise, that spots of rich dry land, which were almost wholly filled up with these plants, were eaten down bareer than even white clover. It is a strong-rooted perennial plant, which has many fine leaves, of a highly aromatic smell, and which is considered as not only very acceptable, but uncommonly healthy, or even medicinal, both to sheep and black cattle.

It is found in the belt bullock pastures and grounds, where it is said to be highly grateful to every fort of live-stock of the cattle kind, and particularly so to sheep, which bite it as fat as it grows or rifes: so that on tolerably well-fed pastures or grounds it is rarely suffered to come into flower. The seeds of it are, therefore, to be obtained from some of the spots which well filled up with the plant; and if the soil be well supplied with good mouldy compost, it has been found that the yarrow may be made into a rough hay, from which it is easy to obtain seeds, which are of a peculiar winged form and appearance. It flowers late in the summer, and the seeds may be gathered about the month of October.

It is a plant that has not been observed in abundance in boggy or wet lands; but which, for dry rich soils, devotes the preference to moist others for the purpose of being depauperated. It is a plant that on the whole seems to merit the attention of the stock-farmer, at least in a much greater degree than he has yet bestowed upon it.

YARROW, Water. See Water Violet.

Yarrow, in Geography, a river of Scotland, which rises in a mountain called Yarrow Clough, in the county of Selkirk, forms two lochs, St. Mary's and Lows, in its course, and runs into the Tweed, about two miles below Selkirk.

YARUM. See YARM.

YARUQUI, a plain twelve miles north-east from the city of Quito. This spot was pitched upon as the base of the whole operations for measuring the length of an arc of the meridian, by Ulloa, &c. Near it is a village of the same name.

YARWHELP, or YARWIP, an English name used in some places for the agogebalus of authors. See GODWIT.

YASASCHA, in Geography, a town of Russia, in the government of Irkutsk, on the Kitoi; 68 miles N.W. of Irkutsk.

YASASCHNA, a river of Russia, which runs into the Kolma, at Verchnei Kovimfik.

YASCHAMBOU, a town of Persia, in the province of Adirbeitzan; 198 miles S.W. of Tauris.

YASSA, in Modern History, the name given among the Tartars to a body of laws, ascribed to the famous conqueror Gengis-Kan, which are still observed among the Tartars of Crimea, and other parts of Asia. M. de la Croix has given, in his life of Gengis-Kan, an extract of those laws, comprising twenty-one articles, the first of which incitates the belief of one God, the Creator of heaven and earth, and to whom belong the absolute dispofal and dominion of events.

YASUDA, in Hindu Mythology, the name of the foster-mother of the Hindoo Krishna; it is said to mean the giver of honour.

YASUDERA, the name of the wife of Budha, or Boobh, or deity of the Hindoos, and of other people. See Bhoobh.

YATA, in Geography, a town on the south coast of the island of Catanduanes. N. lat. 13° 52'. E. long. 124° 29'.

YATCHEVERAM, a town of Hindoostan, in the Carnatic; 25 miles S.W. of Nellore.

YATCHEVRA, a town of Corea; 25 miles S.W. of Outehous.

YATCHING, a town of China, in Foo-lien; 15 miles N.E. of Fou-shing.

YATE'S River, a river of Africa, which runs into the Atlantic, N. lat. 8° 8'. W. long. 12° 15'.

YATHKIED, a lake of North America. N. lat. 65° 10'. W. long. 98°.

YATI, the priesthood of the extensive sect of Jainas, in India. (See JAINA.) A yati is sometimes said to be more properly a setze, for it does not appear that he performs any religious rite. It is his duty to read and expound to his disciples the scriptures of the Jainas in their proper languages. See under Sects of Hindoos for a general notice of the Jainas.

The yatis are devoted to religion from their infancy; for with the Jainas the priesthood is not hereditary, as with the orthodox Hindoos. A yati never marries, but sometimes purchases a child, adopts it, and inculcates it in religious duties. Parents sometimes vow or promise their first-born to the deity, in the hope of obtaining the blessing of sanctity in their family. They serve their novicete with their guru, or preceptor, and perform for him many domestic offices. After a proper period, when arrived at a sufficient age and progress in their studies, they are admitted as yatis. The ceremony om occasion is simple. The novice is carried out of the town with music and rejoicing in procession, followed by a crowd of Sravakas, as the laity of the Jainas are called. (See SRAVAKA.) He is taken beneath a tree with milky juice. The pipala, or Indian fig, is usually preferred. A circle is formed on the ground, within which none but yatis are admitted. The hair, or lock, of the novice is pulled out by the root at five pulls; and camphor, musk, sandal, farfion, and sugar, are applied to the scalp: he is then shorn, and placed, with joined palms, the pouture of respect and supplication, before his guru, who pronounces a mantra (see MANTRA) in his ear, and invests him with the drefs of a yati, which consists of a cloth of three cubits for his loins, another of five cubits for his head, a coarse country blanket, called kamly, for his bed, a water-pot, a plate for his viéctuals, a cloth to tie them up in, a long stick to defend him, but not to injure others, and lastly, a broom of cotton-threads to sweep the ground where he sits or lies, to avert the distraction of any insect. The Jainas are the sect that fo especially avoid shedding blood or destroying life; a tenet that leads them to ridiculous excesses, as will be seen under our article JAINA, in which several particulars of the yati are also given.

YATREB, in Geography, the real name of Medina, in Arabia. It is called Medina, or the city, by way of eminence.

YATTENDON, a village of England, in the county of Berks. Here Alfred overthrew the Danes in 876; 4 miles S.E. of Eal Illey.

YATTONG, a town of Burmah; 15 miles W.N.W. of Ava.

YATTONUR, a town of the island of Ceylon; 10 miles S.W. of Candy.

YAUACACA,
YAW

YAUACA, a town of Peru, in the diocese of Lima, on the coast; 20 miles S.S.E. of Nafca. S. lat. 15°.

YUGAR, a town of Burmah, on the right bank of the Irawaddy, opposite to Raynangong.

YUGOS, a town of Peru, in the diocese of Lima; 80 miles S. E. of Lima. S. lat. 12° 40'. W. long. 75° 40'.

YAVI, a town of Peru, in the diocese of La Plata; 85 miles E. S. E. of Lipes.

YAW, in Sea Language, denotes the movement by which a ship deviates from the line of her course towards the right or left in running. See Steady.

YAWL, a small light ship's boat, rowed with four or six oars, used to convey the officers to and from the ship.

YAWNING, Oscillation, an involuntary opening of the mouth, generally indicating a troublesome weariness, or an inclination to sleep. See Lungs.

YAWS, in Medicine, a fever cutaneous disease, which is indigenous in Africa, and has been thence conveyed to the West Indies and America; so called from the resemblance of its eruptions to a raspberry, the word yaw in some African dialect being the name of that fruit. Nofologists have denominated it Frambista, from the French Framboise, which has the same signification.

The nature of this disease has been imperfectly investigated by European practitioners; and as it is perhaps never seen in England, a brief account of it will be here sufficient.

It is not easy to discover the precise character of this eruption, from the varying language of authors. An anonymous writer, who gave the first explicit account of the disease, (see Edinb. Med. Essays, vol. v. part 2. art. 56.) says, they are at first "level or smooth with the skin," but soon "become protuberant like pimples." Dr. Hillary, who has copied much from this writer, describes them as "pimples," though smooth and level with the skin, but soon becoming "protuberant pustules." (On the Diff. of Barbadoes, p. 339.) And Dr. Winterbottom, who has given on the whole the most perspicuous description of the disease, calls them "pustules," from their first appearance. Again, as to the contents of these eruptions, the anonymous author and Dr. Hillary say, that no pus nor any quantity of ichor is found in them, but speek of a little ichor as drying upon the surface; while Dr. Winterbottom say, they are "filled with an opaque whitish fluid," and when they burst, "a thick viscid matter is discharged." There is also some difference of opinion among the writers on this disease respecting the precursiory symptoms, the earlier authors asserting, that the general health is not impaired during the first stages; but others, especially Dr. Winterbottom and Dr. Dancer, affirm, that a febrile state usually precedes it. On the whole, however, it appears to be the most correct account of the malady, which is to be collected from the various descriptions which have been published.

The eruption of the yaws sometimes commences without any precursory symptoms of ill health; but it is generally preceded by a slight febrile state, with languor, debility, and pains of the joints, resembling those of rheumatism. After several days, minute protuberances appear on various parts of the skin, at first smaller than the head of a pin, but gradually enlarging, in some cases to the diameter of a firrrence, and in others even to a greater extent; they are most numerous, and of the largest size, in the face, groins, axilla, and about the anus and pudenda. But the crop is not completed at once; new eruptions appear in different places, while some of the earlier ones dry off. When the cuticle is broken, a foul crust is formed on the surface, from under which, on the larger protuberances, red pungent excrescences often spring up, which attain different magnitudes, from that of a small raspberry to that of a large mulberry, which fruit they somewhat resemble from their granulated surfaces. When the eruption is most copious, these tubercles are of the smallest size; and when fewer, they are largest. Their duration and progress are various in different constitutions, and at different periods of life. Children suffer less severely than adults, and are more speedily freed from the disease. In them, according to Dr. Winterbottom, the duration of the yaws is from six to nine months; while in adults it is seldom cured in less than a year, and sometimes continues during two or three. The fungous tubercules attain their acme, according to the anonymous writer already quoted, more rapidly in the well-fed negroes than in those who are ill-fed and thin; and they likewise acquire a larger size in the former than in the latter. They are not pellucid of much facility, and are not the least of any pain, except when they appear upon the soles of the feet, where they are confined and compressed by the hard and thickened cuticle: in that situation they render the act of walking extremely painful, or altogether impracticable. They never suppurate kindly Dr. Winterbottom says, but gradually discharge a forcible glutinous fluid, which forms an ugly fest round the edges of the excrescence, and covers the upper part of it, when much elevated, with white floughs. When they appear on any part of the body covered with hair, this gradually changes in its colour from black to white, independently of the white incrustation from the discharge. They leave no depression of the skin.

The period during which the eruption is in progress varies from a few weeks to several months. "When no more pustules are thrown out," Dr. Winterbottom observes, "and when those already upon the skin no longer increase in size, the disease is supposed to have reached its acme. About this time it happens, on some part of the body or other, that one of the pustules becomes much larger than the rest, equaling or surpassing the size of a half-crown piece: it affumes the appearance of an ulcer, and instead of being elevated above the skin like others, it is considerably depressed; the surface is foul and flougy, and pours out an ill-conditioned ichor, which spreads very much, by corroding the surrounding found skin: this is what is called the mother or mother yaws." When arrived at its acme, however, the eruption continues a considerable time without undergoing much alteration, often without very materially injuring the functions, and it seldom proves dangerous, except from the milchievous interference of ill-directed art.

The yaws is propagated forcibly by the contagion of the matter discharged from the eruption, when it is applied to the wounded or broken skin of another person, who has not previously undergone the disease. For, like the febrile eruptions, the yaws affects the same person only once during life; but, unlike them, it is not propagated by effluvia. The complaint is sometimes inoculated by flies, in those hot countries, when the skin both of the diseased and the healthy remains uncovered. Hence, Dr. Bancroft says, "none ever receive it whole skins are whole; for which reason the whites are rarely infected; but the backs of the negroes being often raw by whipping, and suffered to remain naked, they scarcely ever escape it." (Nat. Hist. of Guiana, p. 387.) See also Winterbottom, p. 141-3.

In Africa it is usually undergone during childhood. The period which elapses between the reception of the contagion and the commencement of the disease is no where mentioned; but in the case of a Dane, whom Dr. Adams saw at Madeira, the patient had been absent ten months from...
from the West Indies before he felt any indispition. See Memoirs of the Med. Soc. of London.

- With respect to the treatment of yaws, nothing very satisfactory is to be collected from the writings of the practitioners to whom we are indebted for the history of the disease. "The native Africans," according to Dr. Winterbottom, "never attempt to cure it until it has nearly reached its height, when the fungi have acquired their full size, and no more pustules appear." And the practitioners in the West Indies soon learned by experience, that active evacuations retard the natural progress of the disease; and that mercurials, although they superseded it, and cleared the skin of the eruption, yet left the patient still susceptible of, or rather still impregnated with, the virus, which speedily evinced its presence by a reappearance of the symptoms more severe and tedious than before. In truth, the disease, it would seem, like the purulenter and exanthematous fevers of our own climate, will only leave the constitution after it has completed the various stages of its course, and removed the susceptibility of the individual to future infection; and no medicine yet discovered has had any influence in super- feting this action, or in accelerating its progress. Unless, therefore, any urgent symptoms should require alleviation, (which seldom, if ever, happens) it is advisable to dispense with the administration of medicine, and to be content with restricting the patient to a moderate and temperate regimen, during the first stage of the malady. When the eruptions begin to dry, or as soon as they cease to multiply and enlarge, the disease appears to require the same management as other slow and superficial ulcera-tions, accompanied with a cachectic state of the system; viz. a light but nutritious diet, a dry and wholesome air, warm clothing, moderate exercise, and a course of tonic medicine, especially of farfaparilla, or cinchona, with the mineral acids, or with antimonials and small doves of mercury, according to the circumstances of the individual habit. The effects of mercury, however, exhibited so as to excite salivation, as the early practitioners recommend, seem to be of a very questionable nature, especially when it is unaccompanied by the vegetable decoctions; and it is certain that patients have, in some cases, soon recovered under the use of the latter, when the mercurials were omitted. The mercurial treatment, indeed, is often followed by a train of harassing symptoms, called by thenegroes the bonc-ache. "The unhappy sufferer is tormented with deep-seated pains in the bones, especially round the joints, which are occasionally aggravated to a violent degree: the pustules become thickened, inflamed, and painful, and nodes are formed on the bones. When these symptoms have continued for some time, the bones are affected with caries, and even become soft and lose their form." The native Africans employ decoctions of the bark of two or three trees, which are generally purgative, as well as tonic, and likewise wash the fores with them, after carefully removing the crusts. The major-yaw sometimes remains large and troublesome after the relt of the eruption has altogether disappeared. It requires to be treated with gentle elasartories, and soon affumnes a healing appearance under these applications. Stronger caustics are requisite after the cure of the crab-yaws, or tedious excrements, which occur on the soles of the feet.

We may add, that the anonymous writer in the Edinb. Med. Essays, and after him Dr. hillary and others, have deemed the yaws to be the Hebrew leprosy, described by Moses. (Leviticus, chap. xiii.) In some respects, and es- pecially in the appearance of what is called "raw flesh" in the leprous spots, together with whiteness of the hair, the de- scription of the leprosy of the Jews is applicable to the yaws. But the leprosy is described by the great legislator as beginning in several ways, or appearing under several varieties of form, in only one of which this rising of "raw flesh" is mentioned; and the two circumstances, which all these varieties exhibited in common, were a depression of the skin and whitening of the hair. Now this change in the colour of the hair is common to the yaws and to the leucæ; and it is conjoined in the latter with cutaneous depression. It seems pretty obvious indeed, that the term leprosy was used in the Scriptures to denote several diseases of the skin, against which the law of exclusion was enforced, and others to which it did not apply. An instance of the latter occurs in Gehazi, whom we had fill in the employment of Elihas, and even converting with the king, after the leprosy had been inflicted upon him, "and his feed for ever." (2 Kings, chap. v. vi. and viii. v. 4.) See Dr. Bateman’s Practical Synopsis of Cutan. Difeases; and the Works above quoted.

YAXARTEs, or YAKARTEs, the Syr-Daria, in Geography, a river of Russia, that falls into the Aral.

YAXLEY, a small market-town in the hundred of Norman-Crofts, and county of Huntingdon, England, is situated 2 miles N.E. from Stilton, and 73 miles N. by W. from London. It has of late increased in importance from its contiguity to the barracks at Norman-Crofts. The market was for a long time difcontinued, but has been recently revived, and is now held on Tuesdays. It was originally granted to the abbots of Thorney, one of whom, named De Yalkefley, who died in 1794, was native of this town. Here is also an annual fair. The church is a handsome fabric, and particularly remarkable for its lofty and well-proportioned spire, which is seen at a considerable distance on all sides. The population of the parish, in the enumeration of the year 1811, was returned at 1391, occupying 171 houses.

YAYACATLAN, a town of Mexico, in the province of Tlaolaca; 10 miles E.S.E. of Puebla de los Angelos.

YAYAUHQUITOTOL, in Ornithology, the name of an Indian bird described by Nieremberg, remarkable for having two feathers of its tail much longer than the rest, and naked for a great way, but the end ornamented with black and blue hairs. The bird is of the size of the starling, and is beautifully variegated with green, blue, yellow, and grey.

Mr. Ray is of opinion, that this is the bird described by Margrave under the name guaira-guainambi.

YAYNANGHEUM, or EARTH OIL CREEK, in Geography, a town of Burmah, on the Irawaddy, which receives its name from some wells of petroleum, in its neighbourhhood. It is chiefly inhabited by potters; 15 miles S. of Pegoungmew.

YAYYOS, or YAXYOS, a town of Peru, and capital of a jurisdiction, in the archbishopric of Lima, which begins about 48 miles south-east from Lima, and extends about 75 miles in length along the Andes. It abounds in fruit, maize, wheat, barley, &c. and the paltures feed a great number of cattle for the markets of Lima; 80 miles S.S.E. of Lima.

YAZAMATES, a people who inhabited Kuban, after the Sarmites were for the most part given to Europe, five years before Alexander.

YAZOO, a river of the state of Georgia, which runs into the Mississipi, N. lat. 32° 39'. W. long. 91° 10'.

YAZO0, Little, a river of West Florida, which runs into the Mississipi, N. lat. 32° 13', W. long. 91° 10'.

YAZVA,
YAZVA, a river of Ruffia, which runs into the Vifchera, 8 miles E. of Gerdis, in the government of Perm. YBAGUE, a town of South America, in the kingdom of New Grenada.

YCONOMIIUS. See Oeconomus. YDALA, in Geography, a town of Sweden, in Blekingen; 10 miles S.S.E. of Konghback.

YDRIA. See Hydria. YDRINUS, or Hydrinus, a name given by fome to the obfipites, or ferpent-flone.

YDRUS, in Ancient Geography, a mountain of Hilfpania. Jerome.

YE, or Wye, in Geography, a river of Holland, which pafles by Amsterdam, and runs into the Zuyder See, about 6 miles below.

YEVA WATER, a river of Scotland, which runs into the Nith, 2 miles E. of Lochmaben.

YEADON, a township of Yorkshire, in the Weft Riding, with 1693 inhabitants, including 476 employed in trade and manufactures; 3 miles S. of Otley.

YEALME, a river of England, in the county of Devon, which runs into the English Channel, 1 mile N.N.W. of Stoke Point.

YEANGLAW, a town of Birmah; 7 miles S. of Pegomgraw.

YEANING, among Sheep-Farmers, a term used to fignify the act of bringing forth the young in animals of the fheep kind. It is faid that in the polled breeds of fheep the lambs are yeaned with the greateft ease and facility, and in the large-horned breeds with the greateft difticulty and inconvenience. See Sheep.

YEANING-Time, the feaning of yeaning in fheep, which is different in different breeds of them, but probably the moft early in the Dorleftire breed, as they may be managed fo as to lamb at a very early period. In general, however, the management is fuch, that the lambs are yeaned or brought forth from towards the latter end of February to the beginning of the following month, and later in some cafes and situations. When yeaned too early there is often great loss, on account of the inclemency of the feaning, unlefs the ewes have been kept very well for some time before it takes place. Confequently, in all fuch cafes, they fhould, for some weeks at least before the yeaning time, be plentifully fupplied with proper food, fo that the health and Strength of them and that of their young may be promoted and preferved againft this period. Proper feltered situations, yards, and ifpots of ground, fhould also be provided for this purpofe, by which the lives of numbers may be faved. See Sheep.

In all bad cafes of yeaning, the ewes fhould be well supported by good oatmeal gruel and cordial drinks.

YEANLING, a term applied to the young of the fheep kind when newly yeaned. See Lamb.

YEAR, Anxus, in the full extent of the word, is a fystem or cycle of feveral months; ufually twelve.

Others define year, in the general, a period, or space of time, meafured by the revolution of some celefial body in its orbit.

Thus, the time in which the fixed stars make a revolution is called the great year. And the times in which Jupiter, Saturn, the fun, moon, &c. fubmit their revolutions, and return to the fame point of the zodiac, are refpeftively called the years of Jupiter and Saturn; and the folar and the lunar years.

As there is no luminary whole changes and revolutions are fo frequent and remarkable as thofe of the moon, fome have thought that all nations at firft measured and divided time according to the various afspects of this planet. Acci- dentally the Egyptian year originally confifted of a fingle luion; afterwards it included two or three months, and was defined by the flated returns of the feafons. It has been alfo fuppoled, that feveral ages muft have elapfed before the idea of adjufing the length of the year to the courfe of the fun became general, though repeated ob-ervations were made on his motion in the eclipfie. The Indians, the Chaldeans, and Egyptians, who in a very early period applied their attention to astrony, at length found, by comparing the motions of the fun and moon together, that one revolution of the former was equal to about 12 of the latter; and hence was formed a year of 12 luions, in every one of which were reckoned 30 days: and hence alfo, it is faid, arose the division of the eclipfie into 360 equal parts, or degrees.

Years, properly, and by way of eminence fo called, is the solar year; or the space of time in which the fun moves through the twelve figns of the eclipfie.

This, by the observations of Caffini, Bianchini, and de la Hire, contains 365 days, 5 hours, and 49 minutes; which is the quantity of the year affumed by the authors of the Gregorian calendar.

But in the civil or popular account, this year only contains 365 days; except every fourth, which contains 366.

The vicifitudes of feafons feem to have given occasion to the firft infitution of the year. Man, naturally curious to know the caufe of that diverfity, foon found it was the proximity and distance of the fun; and, upon this, gave the name year to the space of time in which that luminary, performing his whole courfe, returned to the fame point of his orbit.

And hence, as it was on account of the feafons, in a great measure, that the year was infituted, their chief regard and attention were, that the fame parts of the year always correspond to the fame feafons; i.e. that the begin-ning of the year should always be when the fun was in the fame point of his orbit; and that they should keep pace, come round, and end together.

This, different nations aimed to attain by different ways; making the year to commence from different points of the zodiac, and even making the time of his progress different. So that some of their years were much more perfect than others, but none of them quite juft; i.e. none of them whole parts did not shift, with regard to the parts of the fun’s courfe.

We may naturally fuppofe that the commencement of the year would be determined by the date of some confiderable event, fuch as the creation of the world, the univerfal deluge, a conjunction of planets, the incarnation of our Saviour, &c.; and of course it has been referred to different points in the eclipfie. The Chaldean and Egyptian years were dated from the autumnal equinox. The ecclefiaftical year of the Jews began in the fpring; but in civil affairs they retained the epoch of the Egyptian year. The ancient Chinefe reckoned from the new moon, nearest to the middle of Aquarius; but according to some recent accounts, the beginning of their year was transferred (B. C. 1740) to the new moon nearest to the winter folstice. This likewife is the date of the Japanese year. Demifchid,
or Gemischid, king of Persia, observed on the day of his public entry into Persepolis, that the sun entered into Aries; and in commemoration of this fortunate event and coincidence, he ordained the beginning of the year to be removed from the autumnal to the vernal equinox. This epoch was denominated Neuruz, viz. New-day, and is still celebrated with great pomp and festivity.

The ancient Swedish year commenced at the winter solstice, or rather at the time of the sun's appearance in the horizon, after an absence of about 40 days. The feast of this epoch was solennized on the 20th day after the solstice. Some of the Grecian states computed from the vernal, some from the autumnal equinox, and others from the summer tropic. The year of Romulus commenced in March, and that of Numa in January. The Turks and Arabs date the year from the 16th of July; and the American Indians reckon from the first appearance of the new moon of the vernal equinox. The church of Rome has fixed new-year's day on the Sunday that corresponds with the full moon of the same feast. The Venetians, Florentines, and Pisans in Italy, and the inhabitants of Treves in Germany, begin the year at the vernal equinox. The ancient clergy reckon from the 25th of March; and this method was observed in Britain until the introduction of the New Style, A.D. 1752, after which our year commenced on the first day of January. See EROCHA and CHRONOLOGY.

They were the Egyptians, if we may credit Herodotus, that first formed the year, which was lunar-folar, making it to contain 360 days, which they subdivided into 12 months. This year was corrected by the Thebans, who added to it five intercalary days. The Medes and Persians, who were anciently a part of the Assyrian empire, adopted the old Chaldean year of 360 days, which they afterwards reformed.

Some missionaries report, that the lunni-folar year was corrected in China; the year of the Indians contained 360 days, and was divided into 24 months. But besides this form of the year, the Indians used another, for astronomical purposes, consisting of 365 d. 15 h. 31' 15"; which Indian days and hours are equal to 365 d. 6 h. 12' 30", according to our mode of computation. Or, as this year is sidereal, if you subtract 2¹ 33' on account of the motion of the stars in longitude, the Indian tropical year will be 365 d. 5 h. 50' 56". The Mexicans received the lunar-folar year from the Indians or Chinefe, and divided it into 19 months of 20 days; adding five days to the last month, and dating the year from March. That the ancient Grecian year was lunar-folar, is evident from many testimonies of Hippocrates, Plato, and Pliny. The Latin year, before Numa's correction of it, consisted of 360 days, 304 of which were divided into 10 months; and to these were added two private months, not named in the calendar. Plut. in Vit. Numa. Serv. et Virgil Georg. l. i. v. 42.

It has been said that Mercurius Trimegillus added five days to the Egyptian year of 360 days. And, on this footing, Thales is said to have instituted the year among the Greeks; though that form of the year did not hold throughout all Greece. Add, that the Jewish, Syrian, Romans, Persian, Ethiopic, Arabic, &c. years were all different.

In effect, considering the imperfect state of astronomy in the ages, it is no wonder different people should disagree in the computation of the sun's course. We are even allured by Diod. Siculus (lib. i.), Platarch in Nama, and Pliny (lib. vii. cap. 48.), that the Egyptian year itself was at first very different from that now represented.

The imperfectness of the lunni-folar year became more and more apparent as the arts and sciences improved; but the necessary correction depended upon a competent knowledge of the solar year. Every nation, by degrees, incorporated the method of intercalating a few days at certain intervals. The author of the discovery is not certainly known: the Egyptians have claimed the merit of it; and the Theban priests have attributed it to Hermes or Thoth. It appears that they were acquainted with the year of 365 days in a very remote period. (Herodot. l. iv. c. 4. Strabo Geog. l. xvii. Synccul. Chron. p. 121.) The length of the solar year was represented in a golden circle fixed upon the tomb of Ozymandes; and this circle was 365 cubits in circumference, laying on each cubit a day of the year inscribed, together with the heliacal risings or settings of the stars. This Ozymandes is said to have flourished either in the 13th or 11th century before the Christian era. For perpetuating the memory of this correction, though inaccurate, the first month of the year was distinguished by the title Thoth, or Sothis, which was the Egyptian appellation of the dog-star, the heliacal rising of which announced the inundation of the Nile. Hence, it is said, originated the fable, invented of the priests of Thebes, that Mercury, or Thoth, regulated the civil year by extending it, as we have already observed, to 365 days; and, in return, the first month was called by his name. See Egyptian Year, and CANONICAL YEAR.

The method of correcting the civil year, by the addition of five epagomenae, was communicated by the Chaldeans and Egyptians to other nations; but it has not been a priori- nated at what epoch the solar year was observed to be almost 6 hours longer than the civil year of 365 days. The priests of Thebes claimed the merit of the discovery (Diod. Sicul. l. i. p. 59. Strabo Geog. l. xvii.); but Herodotus takes no notice of it; nor Thales, who, on his return from Egypt, taught the Greeks to form a solar year of 365 days without any intercalation. Plato and Eudoxus are said to have obtained it, as a secret, from the Egyptians, about 800 years after Herodotus, and to have carried it into Greece; which shows that the knowledge of this form of the year was then recent, and confined to a few of the learned, while the old form was still retained, and the Egyptians used no intercalation until the corrected Julian year was received at Alexandria by the order of Augustus; and even at this time the Greeks and Romans, who resided in Egypt, alone obeyed the imperial mandate. The superfluous nations were required by law to admit any addition to a form of the year which had been so long established among them.

The reformed year of the Chinese consisted of 365 d. 5 h. 20', which were divided into 24 months, each of these equal parts including 15 d. 5 h. 14' 30". (Du Halde, Hyde, Relig. Vet. Perp.) The quantity of the Indian year was somewhat different from that of the Chinese: the lunar year contained 364 d. 22 guris, 1 pull; and the solar year 365 d. 15 guris, 30 pulls, 22½ puts; 60 pulls = 1 pull, 60 guris = 1 day; so that their solar or rather sidereal year consisted of 365 d. 6 h. 12' 7". This mode of computation is used by the Brahmins, by the Moguls, and by other Mahometans in India.

YEAR. Solar, is the interval of time in which the sun finishes his course through the zodiac; or in which he returns to the same point of it from whence he had departed.

This, according to our account, is 365 days, 5 hours, 49 minutes; though some astronomers make it a few seconds, and some a whole minute less; as Kepler, for instance, who makes it 365 days, 5 hours, 48 minutes, 57 seconds, 39 thirds. Ricciolius, and Tycho Brahe, 365 days, 5 hours, 48 minutes, 2 seconds.
The solar year is either astronomical or civil.

Year, Solar Astronomical, is that determined precisely by the observations of astronomy; and is of two kinds, tropical and sidereal or aërial.

Year, Tropical or Natural, is the time which the sun employs in passing through the zodiac, or from one equinox, or one tropic, to the same again; which, as before observed, is 365 days, 5 hours, 49 minutes; or, more accurately, 365 days, 5 h. 48' 48".

This is the only proper or natural year, because it always keeps the same feasons to the same months.

In order to find the tropical year, observe the meridian altitude, \( a \), of the sun on the day nearest to the equinox; then the next year take its meridian altitude on two following days, one when its altitude, \( m \), is less than \( a \), and the next when its altitude, \( n \), is greater than \( a \); then \( n - m \) is the increase of the sun’s declination in 24 hours; also, when the declination has increased by the quantity \( a - m \) from the time when the meridian altitude, \( m \), was observed, the declination will then become \( a \); and as we may consider the increase of declination to be uniform for a day, we have \( n - m = a - m \times 24 \) hours, the interval from the time when the sun was on the meridian on the first of the two days, till the sun has the same declination \( a \); as at the observation the year before; and this time, added to the time when the sun’s altitude \( m \) was observed, gives the time when the sun’s place in the equinoctial plane in the time of the observation the preceding year; and the interval of these times is the length of a tropical year.

If, instead of repeating the second observation the next year, there be an interval of several years, and you divide the interval between the times when the declination was found to be the same, by the number of years, you will get the tropical year more exactly.

Year, Sidereal or Aërial, is the space of time in which the sun, going from any fixed star, returns to the same. This consists of 365 days, 6 hours, 6 minutes, 11½ seconds.

To find the length of a sidereal year. On any day when the sun is at Z on the meridian (Plate XXI. fig. 12.), take the difference, \( Zm \), between the sun’s right ascension when it passes the meridian, and that of a fixed star, \( S \); and when the sun returns to the same part of the heavens the next year, compare its right ascension with that of the same star for two days, one when their difference, \( bh \), of right ascensions is less, and the other when the difference, \( fm \), is greater than the difference, \( Zm \), before observed; then \( bh \) is the increase of the sun’s right ascension in the time, \( t \); and as the increase of right ascension may be considered as uniform for a small time, we have \( bh = bZ \times t \) : the time, \( t \), in which the right ascension is increased from \( b \) to \( Z \) ; this time, \( T \), therefore, added to the time of the observed right ascension at \( b \), gives the time when the sun is at the same distance, \( Zm \), in right ascension from the star, which it was when observed at \( Z \) the year before; the interval of these times is therefore the length of the sidereal year. The best time for these observations is about March 25, June 20, September 17, December 20, the sun’s motion in right ascension being then uniform. Instead of observing the difference of the right ascensions, you may observe that of their longitudes.

If, instead of repeating the second observations the year after, there be an interval of several years, and you divide the observed interval of time when the difference of their right ascensions was found to be equal, by the number of years, you will have the length of a sidereal year more exactly.

The precession being given (see Precession), and also the length of a tropical year, the length of a sidereal year may be found by this proportion; \( 360° - 50°, 25 : 360° :: 365 \text{d.} 5 \text{h.} 48' 48'' : 365 \text{d.} 6 \text{h.} 9' 11''4'' \) the length of the sidereal year.

Year, Anomalous, is the time that elapses from the sun’s leaving its apogee till it returns to it: and as the progressive motion of the apogee in a year is \( 1^°, 75 \); the anomalous year must be longer than the sidereal year, by the time which the sun takes in moving over \( 1^°, 75 \) of longitude at its apogee; but when the sun is in its apogee, its motion in longitude is \( 58' 13'' \) in 24 hours; hence \( 58' 13'' : 11^°, 75 :: 24 \text{ hours} :: 4^°50'' 39'' \), which added to \( 365 \text{ d.} 6 \text{ h.} 9' 11''4'' \), gives \( 365 \text{ d.} 6 \text{ h.} 14' 24'' \), the length of the anomalous year. M. de la Lande determined this motion of the apogee from the observations of M. de la Hire, and those of Dr. Maskelyne. Caffini made it the same. This year is sometimes used by astronomers. See Anomalous Year.

Year, Civil, is that form of year which each nation has contrived for the computation of time: or the civil is the tropical year, considered as only consisting of a certain number of whole days; the odd hours and minutes being set aside, to render the computation of time in the common occupations of life more easy.

Hence, as the tropical year is 365 days, 5 hours, 48 minutes, 48 seconds, the civil year is 365 days. And hence, also, as it is necessary to keep pace with the heavens, it is required that every fourth year should consist of 366 days.

Hence, lastly, the civil year is either common or bissextile.

Year, the Common Civil, is that consisting of 365 days. This, therefore, has seven months of 31 days each, four of 30 days, and one of 28 days; according to the well-known canon:

March 1

Year, Bissextile, or Leap, is that consisting of 366 days; or it has one day extraordinary; which day is called the intercalary, or bissextile day.

This intercalary, or additional day to every fourth year, was first appointed by Julius Cæsar; who, to make the civil year keep pace with the tropical ones, contrived that the fix hours which the former wanted of being equal to the latter, should, in four years, make a whole day, and be added before the twenty-fourth, or to the twenty-third of February, which was their sixth of the calends of March. Hence, as in that year, they reckon this day twice over, or add bis sexto calendar, the year itself came to be called bis sextus, and Bissextile; which fee.

The intercalary day, however, among us, is not introduced by telling the twenty-third of February twice over, but by adding a day after the twenty-eighth of February; which month, in that year, contains twenty-nine days. See Leap-Year.

A farther reformation in this year was made by pope Gregory. See Gregorian Year, and Calendar.

Year, Lunar, is a system of twelve lunar months. See Lunar.

Hence, from the two kinds of synodical lunar months, there arise two kinds of lunar years; one astronomical, the other civil.
YEAR.

Year, Lunar Astronomical, consists of twelve lunar synodical months; and therefore contains 354 days, 8 hours, 48 minutes, 36 seconds; and is, therefore, 10 days, 21 hours, 0 minute, 12 seconds, shorter than the solar year. This is the foundation of the Epact; which fee.

Year, Lunar Civil, is either common or embolismic.

Year, the Common Lunar, consists of twelve lunar civil months; and therefore contains 354 days.

Year, the Embolismic or Intercalary, consists of thirteen lunar civil months; and therefore contains 384 days. See Embolismic.

Thus far we have considered years and months, with a view to the principles of astronomy, on which the division is founded. By this, the various forms of civil years that have anciently obtained, or still do obtain in divers nations, are to be examined.

Year, Ancient Roman, or Latin, was the lunar year, which, as first settled by Romulus, only consisted of ten months; viz. 1. March, containing 31 days. 2. April, 30. 3. May, 31. 4. June, 30. 5. Quintilis, 31. 6. Sextilis, 30. 7. September, 30. 8. October, 31. 9. November, 30. 10. December, 30. In all 304 days, which came short of the true lunar year by 50 days; and of the solar, by 61 days. Hence, the beginning of Romulus's year was vague, and subject to any precise season; to remove which inconvenience, that prince ordered so many days to be added yearly as would make the rate of the heavens correspond to the first month, without incorporating these extra days, or calling them by the name of any month. Censorinus, Varro, and other Roman authors, agree, that the ancient Latin year was divided into 10 months, which appears from a passage in Plutarch, that two intercalary months were added to every year; which two months were not inflected in the calendar. Romulus retained the former names and number of the months; but adapted their quantity nearly to the course of the sun, aligning, as we have flirted, fix of them 30 days, and to the remaining four 31 days each; and he transferred the beginning of the year from April to March; December was the 10th month, as its name implies; after which the two intercalary months were inflected, but no names were affixed to them till the succeeding reign.

Numa Pomphilus corrected the irregular constitution of Romulus's year, and composed two new months, January and February, of the days that were used to be added to the former year. Thus, Numa's year consisted of twelve months; viz. 1. January, containing 29 days. 2. February, 28. 3. March, 31. 4. April, 29. 5. May, 31. 6. June, 29. 7. Quintilis, 31. 8. Sextilis, 29. 9. September, 29. 10. October, 31. 11. November, 29. 12. December, 29. In all 355 days, which exceeds the quantity of a lunar civil year by one day; and that of a lunar alphabetical year by 15 hours, 11 minutes, 24 seconds, but comes short of the common solar year by ten days; so that its beginning also was vague and unfixed.

Numa, however, defiring to have it fixed to the winter solstice, ordered 22 days to be intercalated in February every second year, 23 every fourth, 22 every fifth, and 23 every eighth year, making in all 90 days. But this rule failing to keep matters even, recourse was had to a new way of intercalating; and, instead of twenty-three days every eighth year, only fifteen were added; and the care of the whole was committed to the pontifex maximus, who neglecting the truth, let things run to the utmost confusion. And thus the Roman year floated till Julius Cæsar made a reformation. See Calendar.

For the manner of reckoning the days of the Roman months, see Calendars, None, and Ides.

Year, Julian, is a solar year, containing, commonly, 365 days; though every fourth year, called biflextile, it contains 366.

The astronomical quantity, therefore, of the Julian year is 365 days, 6 hours; which exceeds the true solar year by somewhat more than eleven minutes; which excess, in 131 years, amounts to a whole day. So that the times of the equinoxes go backward, and fall earlier by one day in about 131 or 130 years. And thus the Roman year stood, till the reformation made in it by pope Gregory.

For this form of the year, we are indebted to Julius Cæsar; who, in the contrivance of it, was affiUted by SoQeneses, a famous mathematician, called over from Egypt for this very purpose; who, to supply the defect of fifty-seven days, which had been lost through the fault of the pontifices, and to fix the beginning of the year to the winter solstice, made that year to consist of 15 months, or 445 days; which, for that reason, is used to be called anni confuliun, the year of consulship. See Julian Calendar. Year, Gregorian, is the Julian year corrected by this rule; that whereas, on the common footling, every secular or hundredth year is biflextile; on the new footling, three of them are common years, and only the fourth is biflextile.

The error of eleven minutes in the Julian year, little as it was, yet, by being repeated over and over, at length became considerable; and from the time when Cæsar made his correction, was grown into thirteen days, by which means the equinoxes were greatly disturbed. In the year 1582, the equinoxes were fallen ten days, and the full moons four days, more backwards than they were in the time of the Nicene council; i.e. the equinox, which in the year 435, when that council was held, fell on the twenty-first of March, was in 1582 thrown back to the tenth, and the full moon was removed from the fifths to the frit of April. To remedy this irregularity, which was still increasing, pope Gregory XIII., in the year just mentioned, called together the chief astronomers of his time, and concerted this correction; and, to refile the equinoxes to their place, threw out the ten days that had been got from the time of the council of Nice, and which had shifted the fift of October to the fiftenth. He exchanged the lunar cycle for that of the epacts; and in order to refile the spring equinox to the Nicene standard, subtracted ten days out of the month of October, in that year (1582), making the fourth to be the fiftenth; and by this means, the vernal equinox has been refiled to the twenty-first of March. Moreover, it was endeavoured, by the omission of three intercalary days in four hundred years, to make the civil year keep pace with the solar for time to come. See Calendar.

In the year 1700, the error of ten days was grown to eleven; upon which the Protestant states of Germany, to prevent farther confusion, accepted the Gregorian correction. See Reformed Calendar and Style.

Yet is even the Gregorian year far from being perfect; for we have shewn, that in four centuries the Julian year gains three days, one hour, twenty minutes; but it is only the three days that are kept out in the Gregorian year; so that
that there is still an excess of one hour, twenty minutes, in four centuries, which, in seventy-two centuries, amount to a whole day.

The Gregorian year is now used in most countries in Europe. From the difference between this and the Julian year arises the distinction of the old or Julian, and new or Gregorian Style: which see.

Year, Egyptian, called also the year of Nebonassar, on account of the epocha of Nebonassar, is the solar year of 365 days, divided into twelve months, of thirty days each, besides five intercalary days, added at the end.

Hence, as the Egyptian year in every four years loses a whole day of the Julian year, because it neglects the fix hours, which make a leap-day once in four years, its beginning, in the space of 1460 years, runs through every part of the Julian year; which space elapsed, they meet again; and, therefore, it is justly called the erratic year. And because it returns to the same day of the Julian year after 1460 Julian years, this circle is called the Sothic period. See Canicular Year.

This year is used by Ptolemy, in his Almagest; so that the knowledge of it is of great use in astronomy, for comparing the ancient observations with the modern.

This defultory form was applied by the Egyptians to civil uses, till Antony and Cleopatra were defeated; and the mathematicians and astronomers used it till the time of Ptolemy.

The ancient Egyptians, we are told by Diodorus Siculus (lib. i.), Plutarch (in the Life of Numa), and Pliny (lib. vii. c. 48.), measured their years by the course of the moon. At first, they were only one month, then three, then four, like that of the Arcadians; and then fix, like that of the people of Acarnania. Thofe authors add, that it is on this account they reckon fuch a vast number of years from the beginning of the world; and that, in the history of their kings, we meet with fome who lived 1000 or 1200 years.

But Herodotus is silent on this point: he only fays, that the Egyptian year confifted of twelve months, as we have above represented it. Besides, we learn from Scripture, that from the times of the flood, the year was compofed of twelve months; Cham, confequently, and fion Mifraim, the founder of the Egyptian monarchy, muft have had this custom: and it is very probable his defendants fhould alter it. Add, that Plutarch fpeaks of it with great uncertainty, and as no more than a report; and Diod. Siculus, as only a conjecture of authors whom he does not name; and who, in all probability, might have framed this hypothesis to reconcile the Egyptian chronology to that of fome other nations.

F. Kircher, however, maintains, that besides the solar year, there were fome of the nomes or cantons of Egypt which used a lunar one; and that in the remotef ages there were fome who took a revolution of the moon, that is, a month for a year; and others, who finding the year too short, made it two months, others three, and others four, &c. (Oedip. Egy. tom. ii. p. 252.) A late author obferves, that Varro has afirmed of all nations, what we have here quoted of the Egyptians; and adds, that Laecanamus takes him to talk on that subject. We do not know in what places of Varro, or Laecanamus, he has seen this: all we can fay is, that Laecanamus (Divin. Init. lib. iii. c. 13.), where he gives Varro's opinion, only represents him as speaking of the Egyptians. However, St. Augustine (De Civit. Dei, lib. xv. c. 14.) fays, that the years of the patriarchs mentioned in Scripture are like ours, and not one of ours equal to ten of theirs, as it appears, had been the opinion of fome people.

Upon the Egyptians being subdued by the Romans, they received the Julian year, though with some alteration; for they still retained their ancient months, with the five ἂναται νημειαι, and, every fourth year, intercalated another day between the 28th and 29th of August. Add, that the beginning of their year, or the first day of the month Thoth, answered to the 29th of August of the Julian year, or to the 30th if it happened to be leap-year.

This year, thus reformed, and called the fixed Egyptian year, was called the anus Abincus, as being intituled foon after the battle of Actium.

Year, Ancient Greek, was lunar, confifting of 12 months, which, at first, had 30 days a-piece, then alternately 30 and 29 days, computed from the first appearance of the new moon; with the addition of an embolimic month of 30 days, every 3d, 5th, 8th, 11th, 14th, 16th, and 19th years of a cycle of 19 years; in order to keep the new and full moons to the fame terms or feasons of the year. With this correction, though erroneous, it subsifted until the time of Herodotus and Hippocrates. Solon attempted the reformation of the calendar by the introduction of the complete and defective months; i.e. months of 30 and of 29 days; for two lunations made 59 days, nearly. Thus amended the year became lunar, and was adopted at Athens; but in other states of Greece the ancient form was retained.

Their year commenced with the new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus: 1. Εἰσοδευσις, containing 29 days. 2. Οἰκοδομη, 30. 3. Βοσκήμα, 29. 4. Μακεδονία, 30. 5. Ποσειδια, 29. 6. Ποσελίδα, 30. 7. Γενέα, 29. 8. Αἰγουσία, 30. 9. Εὐφρανία, 30. 10. Νότια, 30. 11. Φαγέπλωθος, 29. 12. Συμφώνια, 30.

The Macedonians had other names for their months; so had the Syro-Macedonians, Smyrneans, Tyrians; so also the Cyprians, Paphians; and fo the Euthynians, &c.

Year, Ancient Macedonian, is a lunar year, only differing from the Attic, in the names and order of the months; the first Macedonian month agreeing with the Attic Μακεδονίας; as the Macedonian year commenced not at the summer solstice, but at the autumnal equinox. The months stand thus: 1. Αὔων, 30 days. 2. Αὐλός, 29. 3. Αὐτοκράτορ, 30. 4. Περίπος, 29. 5. Αὐτοκράτορ, 30. 6. Πανος, 29. 7. Λιπίδας, 30. 8. Διονυσία, 29. 9. Μαχαίριας, 30. 10. Λαός, 30. 11. Γενέα, 30. 12. Συμφώνια.

Year, Modern Macedonian, is a solar year, whose beginning is fixed for the frist of January of the Julian year, with which it perfectly agrees.

This year was particularly called the Attic year; and the intercalary month, after Poidion, was called Ποιδιάς, or letter Poidion.

Year, Ancient Hebrew, is a lunar year, consisting, commonly, of eleven months, which alternately contain 30 and 29 days.

It was made to agree with the solar year, either by the adding of 11, and sometimes 12, days, at the end of the year, or by an embolimic month.

Tradition reports, that Abraham preferred in his family, and transmitted to posterity, the Chaldean form of the year, which originally consisted of 360 days (compare Dan. vii. 25. xii. 7. with Rev. xii. to xiv. xi. 2, 3.), and remained without any correction until the date of the Nabonassar era. If any intercalation was used by the Jews, Mofes
The year of Nifan, during which and, which the Mofes began to use, was the 13th year, or the 4th in the embolimic year, 30. Adar, in the common year, 30. Adar, in the common year, was but 29. In the defective year, Cileu was only 29 days; and in the redundant year, Marchefvan was 30 days.

Though sometimes it contains 13 months; the names, &c. of which are as follow: 1. Muharram, containing 30 days. 2. Safar, 30. 3. Rabia, 30. 4. Rabia, 30. 5. Jamada, 30. 6. Lutter Jamada, 30. 7. Rajab, 30. 8. Shaaban, 29. 9. Ramadan, 30. 10. Shawal, 29. 11. Dulkadah, 30. 12. Duluhejja, 29; and in the embolimic year, 30. An intercalary day is added every 24, 5th, 7th, 10th, 13th, 15th, 18th, 21st, 24th, 26th, 29th, in a cycle of 29 years.

The months commence not from the real new moon, but from its first appearance after conjunction.

The year, Ethiopian, is a solar year, perfectly agreeing with the Attic, except in this, that the names of the month are different. It begins with the Egyptian year, on the 29th of August of the Julian year.

The year, Attic, is the Egyptian year.

The year, Macedonian, is the year, which the Persians began to use in the year 1079, and which was formed by an intercalation made six or seven times in four years, and then once every fifth year.

The yezdegardic year, it may be observed, is the same with Nabonassar's year, differing from it only in the names of the months, and the commencement of the epocha; for whereas the Nabonassaran began on February 26, this began on June 16. As to the galenic year, it is absolutely the first and jufleft of all the civil years yet invented, as being found, by calculation, to keep the solstices and equinoxes precisely to the same days, and answering very accurately to the solar motions; which no other civil year does, not even the Gregorian, for want of so commodious an intercalation. See Per£an Calendar.

The year, Arabic, Mabometan, and Turkifh, called also the year of the Hegira, (which fee) is a lunar year, equal to 354 days, 8 hours, and 48 minutes, and consisting of 12 months, which contain alternately 30 and 29 days.

The year, Syrian, is a solar year, having its beginning fixed to the beginning of October, in the Julian year; from which it only differs in the names of the months, the quantities being the same, as follows:

The year, Olympic, was of a singular form, the first month commenced at the new moon, that the full moon might fall on the 15th day. Four years of 360 days contain 1440 days; 48 lunations are equal to 1417 days, 11 hours, 14 minutes; 349th lunation added to the 4th year makes 1447 days, nearly. By this adjustment, the new moon would have happened on the 8th instead of the 1st of the month. To correct this error, two days were added to the last month of every year, the 4th excepted, when one day was added. By these means, the Olympic year, which consisted of 352 or 367 days, have varied 14 days from the course of the sun in the space of an Olympiad; and, at the end of 70 years, the games would have been transferred to the winter solstice; but for preventing this deviation, a month was intercalated at certain intervals. Notwithstanding this, a considerable error still remained. The Olympic games were regulated by the Cycle of Clostratus; which see. See also Olympiad and Epocha.

The year, Persia, is a solar year, of 365 days, consisting of 12 months of 30 days each, with five intercalary days added at the end.

This year is called the yezdegardic year, to distinguit with it from the fixed solar year, called the gelamian year, which the Persians began to use in the year 1079, and which was formed by an intercalation made six or seven times in four years, and then once every fifth year.
were consecrated to Janus; on which account it was that
they represented him with two faces.
To them we owe the ceremony of wishing an happy new
year, which appears to be very ancient. Before the first
day was spent they not only visited and complimented each
other, but also presented presents, and offered oaths to the
gods for the preservation of each other.
Lucan represents it as a practice of a very ancient standing,
even in his time, and refers it to Numa.
Ovid intimates the fame ceremony in the beginning of his Faht:
"Poffera lux oritur, linguifque animifque favete :
Nunc dicenda bono funt bona verba die."
And Pliny more expressly, lib. xxviii. cap. 1, "Primum
anni incipientis diem latus prefectionibus invicem fauftum
ominantur."
In Russia at the new year is annually held a feast of the
dead, called Radzizl Szabol, on occasion of which every
body visits the grave of his relations, lays some vioculums
upon it, and then hears masses, in payment for which the
priests get the vioculums. In our own country, the ushering
in of the new year, or "New Year's tide," with rejoicings,
presents, and good wishes, was a custom observed, during
the 16th century, with great regularity and parade, and
was more cordially celebrated in the court of the prince as in
the cottage of the peasant. On the first day of the new
year, presents, called new year's gifts, were given and re-
ceived with the mutual expression of good wishes, and par-
ticularly that of a "happy new year." The compliment
was sometimes paid at each other's doors in the form of a
fong; but more generally, especially in the north of Eng-
lnd and in Scotland, the house was entered very early in the
morning by some young men and maidens selected for the
purpose, who prefented the fipced bowl, and hailed you with
the gratulations of the fefon. In the reign of queen Eliza-beth,
the chief officers of state, and several of the queen's household
servants, gave new year's gifts to her majesty, confenting, in
general, either of a loan of money, or jewels, trinkets, wearing-
appearal, &c. The largest sum given by any of the tem-
poral lords was 20l., but the archbishop of Canterbury
gave 40l., the archbishop of York 30l., and the other spiritu-
al lords 2cl. and 1cl. Many of the temporal lords and great
officers, and most of the peeresses, gave rich gowns, petticoats, fmocks, kirtles, silk kaimings, cymbals garters, sweet-
bags, doublets, mantles, some embroidered with pearls,
garnets, &c., looking-glasses, fans, bracelets, calkets tufted
with precious ftones, jewels ornamented with spaxks of di-
monds in various devices, and other costly trinkets. These
presents also consisted of books, and appropriate gifts from
physicians, apothecaries, &c. The queen, though the made
returns in plate and other articles, took sufficient care that
the balance should be in her own favour. In the country,
however, with the exception of the extensive households of
the nobility, this interchange was conducted on the pure
basis of reciprocal kindnes and good will, and without any
view of securing patronage or support; it was, indeed, fre-
quently the channel through which charity delighted to ex-
ert her holy influence, and though originating in the heat-
then world, became sanctified by the Christian virtues.
We shall here add, that the rejoicings on new year's tide
were succeeded by the obfervance of the "Twelfth-day,"
called, from the idea that the Eastern magi, who are faid to
have visited our Saviour on that day, were kings, the "Feast
of the Three Kings." The "Twelfth-cake," distributed on
that occasion, was almost always accompanied by the waaffil
bowl; which fee. Drake's Shakspeare, vol. i.

YEAR.

YEAR, Civil, or Legal, in England, formerly commenced on
the day of the Annunciation, i.e. on the 25th day of
March; though the historical year began on the day of the
Circumcision; i.e. the first of January, on which day the
German and Italian year also begins.
Stowe observes, that William the Conqueror having been
crowned on the firft of January, that henceforth became the
first of the year for historians, &c.; though, in all civil affairs,
they retained the ancient manner of accounting, which be-
gan the 25th of March.
The part of the year between thefe two terms was usually
expressed in both ways, as 1748-9, or 1748-5. But by the act
for altering the style, the civil year now commences with January
1st. See New Style.
Since the Conqueror, the King's prayers, charters, pro-
clamations, &c. are usually dated by the year of the king's
reign.
The church, as to her solemn service, begins the year on
the first Sunday in Advent, which is always that next St.
Andrew's day, or the 25th of November.
The Jews, as most other nations of the East, had a civil
year, which commenced with the new moon in September;
and an ecclesiastical year, which commenced from the new
moon in March.
The month Tifri, which began about the time of the au-
tumnal equinox, was the first month of the Jewifh year, till
it was changed at the time of the coming up of the children
of Israel out of Egypt. For that happening in the month
of Abib, afterwards called Nisan, this month was for this
reason reckoned the first month of the year in all ecclesiasti-
cal matters. Before this period, Tifri was reckoned the com-
memoration of the year, because it was thought that the
world was created and first began at the time of the autumnal
equinox. And for this reason, the Jews do still in their era
of the creation of the world, as well as in their era of con-
tracts, compute the beginning of the year from the firft
of Tifri, and all their bills and bonds, and all other civil acts
and contracts, are still dated among them according to the
fame computation; and from this month also they began all
their jubilees and sabbatical years. And therefore, although
their ecclesiastical year began from Nisan, and all their fe-
fivals were computed from it, yet their civil year was still
reckoned from Tifri, and the first day of that month was
their new year's day; and for the more solemn celebration of
it, the feast of trumpets seems to have been appointed.
The French year, during the reigns of the Merovingian
race, began on the day on which the troops were reviewed;
which was the first day of March. Under the Carolingians
it began on Christmas-day; and under the Capetians, on
Easter-day, which, therefore, varied between the 22nd of
March and the 25th of April. The ecclesiastical year in
France begins on the first Sunday in Advent. But for the
civil, Charles IX. appointed, in 1564, that for the future it
should commence on the 1st of January.
For an account of the change that took place in the year
of France, see French or Republican Calendar. The French
calendar was of no long duration. It was abolished in
the course of thirteen years; and the Gregorian was re-
stored, and ordered to be used in all dates after the 1st of
January, 1806.
The Mahometans begin their year the minute in which
the sun enters Aries. The Persians in the month answer-
ing to our June. The Chinese, and most of the Indians, begin
it with the first moon in March. The Brachmans begin it
with the new moon in April, on which day they hold a feast
called fim COLUTI ARA fudagau, q. d. feast of New-year's day.
The Mexicans, according to D'Acosta, begin the year on
our
If the lease be but for half a year, or a quarter, or any left time, this lease is reputed as a lease or tenant for years, and is so styled in some legal proceedings; a year being the shortest term which the law in this case takes notice of. An estate of this kind, even for a thousand years, is only a chattel, and reckoned part of the personal estate; and, therefore, a lease for years may be made to commence in futuro, though a lease for life cannot.

With regard to emblems, or profits of land sowed by tenant for years, there is this difference between him and tenant for life: that where the term of tenant for years depends upon a certainty, as if he holds from Midsummer to Midsummer, for ten years, and in the last year lows a crop of corn, and if it is not ripe and cut before Midsummer, the end of his term, the landlord shall have it; for the tenant knew the expiration of his term, and therefore it was his own folly to sow what he never could reap the profits of. But where the lease for years depends upon an uncertainty; as, upon the death of the lessor, being himself only tenant for life, or being a husband feared in right of his wife; or if the term of years be determinable upon a life or lives; in all these cases, the estate for years not being certain to expire at a time foreknown, but merely by the act of God, the tenant or his executors shall have the emblems in the same manner as a tenant for life, or his executors shall be intitled to it. But not so if it determine by the act of the party himself; as if tenant for years does any thing that amounts to a forfeiture: in which case the emblems shall go to the lessor, and not to the leasee, who hath determined his estate by his own default. Blackfr. Com. vol. ii.

YEARLINGS, in Rural Economy, a term applied to young near cattle of the heifer kind in the second year. It is observed in the Gloucestershire Report on Agriculture, that until within these few years, it was there esteemed a bad practice to let them be put to early to the bull, but that now it is even thought that this method improves them as milkers; and that from the increased value of flock, it is advantageous to anticipate a year, as a heifer in calf, at two years old, will be worth nearly as much as it would be if kept three. See Live-Stock.

Y E A R N, in Hunting, signifies to bark, as beagles properly do, at their prey.

Y E A R N I N G, in Rural Economy, a term applied to runnet, used for curdling milk in some places. See Dairying and Runnet.

Y E A S T, Yeast, or Burg, the foam or flower of beer, or other liquor in fermentation.

The yeast of beer is used for a leaven or ferment in the making of bread; as serving to swell or puff it up very considerably in a little time, and to make it much lighter, lofier, and more delicate. But when there is too much of it, it renders the bread bitter.

The use of yeast in bread is but of late standing among us: it is not above a century since the avarice of the bakers first introduced it; and then it was only done by stealth. Though Pliny witnesses it to have been used by the ancient Gauls.

The faculty of medicine of Paris, by a decree of the 24th of March, 1688, solemnly maintained it noxious to the health of the people; yet even that censure could not prevent its progress.

Common ale-yeast may be kept fresh and fit for use several months by the following method: Put a quantity of it into a close canvas bag, and gently squeeze out the moisture in a screw-press, till the remaining matter be as firm and stiff as clay.

In this state it may be close packed up in a tight cask, for securing
securing it from the air; and will keep fresh, sound, and fit for use for a long time.

This is a secret that might be of great use to the brewers and distillers here, who, though they employ very large quantities of yeast, seem to know the method of preferring it, or raising nourishment of it; for want of which they obtain a very considerable loss; whereas the brewers in Flanders make a very great advantage of supplying the malt-distillers of Holland with yeast, which is rendered lasting, and fit for carriage, by this easy expedient. Shaw's Lectures.

Mr. Henry has repeatedly prepared an artificial yeast, by impregnating flour and water with fixed air, with which he has made very good bread, without the assistance of any other ferment; and he proposes this method of procuring fresh fermented bread at sea.

The process is as follows: Boil flour and water together to the consistency of treacle; when the mixture is become cold, fill a small cask with it. This cask is to be filled up in the manner represented in Plate XV. fig. 7. Pneumatics, and described under Pyrexia Water, for the impregnation of water with fixed air; and the process is to be conducted in a similar way, except that the cask is to be agitated as often as the mixture rises to about two-thirds of the capacity of the funnel k; and after each agitation, which should continue during several minutes, the unabsorbed air is to be let out, by withdrawing the plug from the orifice m, till that part of the mixture which remained in the funnel has returned into the cask. The orifice at i should also be larger than is necessary in the other operations, on account of the superior viscosity of the mixture. When, after repeated agitation, the mixture which has ascended into the funnel does not subside into the cask, it may be supposed incapable of absorbing more air.

Pour the mixture, thus saturated, into one or more large bottles, or narrow-mouthed jars; cover it over loyally with paper, and upon that lay a plate or board with a weight to keep it steady. Place the vessel in a situation where the thermometer will stand from 70° to 85° and stir up the mixture two or three times in twenty-four hours. In about two days, such a degree of fermentation will have taken place, as to give the mixture the appearance of yeast.

With the yeast in this state, and before it has acquired a thoroughly vinous smell, mix the quantity of flour intended for bread, in the proportion of six pounds of flour to a quart of the yeast, and a sufficient portion of warm water. Knead them well together in a proper vessel, and covering it with a cloth, let the dough stand for twelve hours, or till it appears to be sufficiently fermented, in the above-mentioned degree of warmth. It is then to be formed into loaves and baked.

Mr. Henry adds, that perhaps the yeast would be more perfect, if a decoction of malt were used instead of simple water.

When the operation is finished, the cask, in order to prevent its contracting a disagreeable taint, should be well washed. Henry's Account of a Method of preferring Water at Sea, &c. p. 26, 1781.

YEAST. Chemical Properties of. The nature of yeast has been briefly discussed under the head of Fermentation. Since that article was written, however, some additional experiments have been published on the subject, which deserve to be noticed here.

The active and essential principle of yeast, as observed under the article Fermentation above alluded to, appears to be a species of gluten. When yeast is kept for some time in cylindrical glass vessels, a white substance, not unlike curd, separates and floats upon the surface. If this substance be removed, the yeast loses the property of exciting fermentation. This substance possesses many of the properties of gluten, though it differs from it in others. Its colour is much whiter. It has not the same elasticity, and its particles do not adhere with the same force. It diffuses more readily in acids. Dr. Thomson considers this as the real fermentative principle, and thinks it may be considered as gluten somewhat altered, and rendered much more capable of decomposition. He thinks also that it existed in the raw grain originally, but underwent considerable modifications by the malting process, and perhaps others during the fermentation of the beer from which it separated.

The fame distinguished chemist states, in support of this opinion, the experiments of Fabroni and Thènard. Fabroni, by heating the juice of grapes, and passing it through a filter, separated an adhesive matter, which pollutes the properties of gluten, and deprived of which the juice refused to ferment, though it was fermented as well as usual when this principle was again added. Thènard likewise found in the juices of all the fruits he examined a substance similar to that described by Fabroni, and which, according to him, is absolutely the same with pure yeast. This substance is infusible; does not change vegetable blues, is infusible in water, loses three-fourths of its weight when dried, and is decomposed like animal substances. When eight parts of it were distilled, they left 2.83 of charcoal, and yielded 1.61 of water, 1.81 of oil, and a quantity of ammonia, which, when saturated with muriatic acid, formed 1.46 of muriate of ammonia. The gas obtained weighed 0.33, and consisted of one-fifth of carbonic acid, and four-fifths of carburetted hydrogen, requiring 13 times its bulk of oxygen to consume it. Nitric acid, even when much diluted, converts it into a species of tallow. With potash it forms a soap, while ammonia is diffused. When mixed with sugar and a sufficient quantity of water, fermentation takes place, carbonic acid is diffused, and a vinous liquor formed. By this action, the ferment loses the whole of its azote, and becomes incapable of exciting fermentation when mixed with a new portion of sugar. In further corroboration of this opinion, Dr. Thomson adduces an experiment of Kirchhoff, which he thinks throws considerable light on the nature of yeast. Barley-meal contains both gluten and flour. Pure flour infused in hot water is not converted into sugar; nor does gluten become saccharine matter when heated in the same manner. But if a mixture of pure dried pulverized wheat-gluten and potato-flour be infused in hot water, the flour is converted into sugar. During the process an acid is formed to be evolved. The gluten is little changed in appearance or quantity, and may most of it be separated by filtration. What is singular, however, it is incapable of inducing the same change upon flour a second time.

The following are the constituents of yeast, according to Weltrumb, as quoted by Dr. Thomson. From 15.360 parts he obtained,

[Vol. XXXXIX]
Besides some traces of phosphoric acid and silica. But it is evident, as Dr. Thomon observes, that all these ingredients are not essential, and he considers the gluten only as deferring that appellation.

Some of the French chemists have considered the principle of fermentation to reside in an imperfect species of sugar, which they have denominated the sweet principle, and which they state to exist in combination with real sugar in all fruits containing that principle. This sweet principle they suppose to differ from pure sugar, in being incapable of crystallizing. A familiar example of it we have in treacle or molasses, which, according to them, is the sweet principle of the sugar-cane. This doctrine, however, has not met with many adherents; for, as Dr. Macculloch observes, although chemistry has not hitherto discovered the methods of separating the sugar from the sweet principle, the results of fermentation leave no doubt that the latter conficts of sugar combined with the vegetable extractive matter, or gluten, as it is denominated by most chemists. Thus molasses consists of a certain portion of real sugar, in such a state of combination with a variety of substanves, and the fermentative principle among the rest, that it cannot be made to crystallize, or be otherwise obtained in a separate state. This is demonstrated by the well-known fact, that molasses may be made to undergo the fermentative process, and to yield alcohol, in precisely the same manner as a simple mixture of sugar and yeast. The sweet principle of molasses, therefore, must be in fact nothing else than sugar, unless we suppose two different substanves capable, by the same means, of producing the same result, which is totally unprecedented in chemistry, besides being in itself extremely improbable.

Upon the whole then, in the present state of our knowledge, we are obliged to conclude that the essential principle of yeast, or the real fermentative principle, is either identical with gluten, or closely allied to it. Of its real nature, however, and modus operandi, we are totally ignorant, and shall probably long remain fo.

The yeast of beer is that most generally employed, and is of the utmost importance in the manufacture of bread, and of fermented liquors from malt. If carefully dried and preserved from moisture, it retains its properties for a long time, and it is a pity this practice is not more generally resorted to, as fluid yeast in warm weather soon becomes accecent and putrid, and not only loses its properties, but imparts a most disagreeable flavour to the bread, &c. with which it is mixed. Yeast may be readily dried by first separating its watery parts as much as possible, and afterwards expouing it in shallow vesseLS to the air, or to a gentle heat in a stove. In this way, it may be obtained in thin lamina, and requires only to be preserved in clove vesseLS in a dry place, when it will be always ready for use, by diffusing it in a little warm water. A popular method of preparing yeast is by drying it upon bunches of twigs. See Bread, Brewing, Fermentation, and Wine.

Yeast, Medicinal Properties of. Yeast has been highly extolled as an antifeptic remedy in diseases, when a putrid diahtesis was supposed to prevail; as in low typhus fevers, gangrene, &c. A good method of exhibiting it is, to mix one or two table-spoonfuls of it with a quart of infusion of malt or mild porter, and to take a wine-glaSSful of this mixture frequently. Many practitioners also have spoken highly of the good effects of a fermenting poultice composed partly of yeast, when applied to foul and gangrenous ulcers. The good effects of this remedy, if in reality it possesses any, may probably be attributed to the carbonic acid gas generated by its agency. See Fever.

YEATS, Mrs., in Biography, the celebrated tragic actress, who, in conjunction with Mrs. Brooke, the novelist, a lady of considerable literary merit, undertook, in 1773, at all risks, the conduct and government of the opera, and all its domestic concerns; the enterprize for which they were but faintly qualified. In the first place, Mrs. Yeats, though possessed of strong natural parts, and an inherent spirit of government, knew no language but English, was ignorant and indifferent about music, dancing, painting, machinery, and decorations. She and her husband had saved a considerable sum by their salaries and benefits at our national theatres, and in hopes of accumulation previous to retirement, they quitted employments for which they were extremely well fitted, and in which their success was certain, to govern a most froward family by deputation, at the extreme hazard of being ruined.

Mrs. Brooke, who had resided some time at Quebec, after its conquest, with her husband, the Rev. Dr. Brooke, chaplain to the army in that colony, indeed knew French, had a good taste in books, and wrote in a good fyle; but was ignorant of music, and totally unacquainted with all opera concerns. Yet it was during this female regency, that the best composers, the greatest singers, and the most capital and renowned dancers, were engaged; for during nine years, from 1773 to 1782, we had Saccini, Trutta, and Anfoffi, to compose; Pacchierotti, Anfani, and the Gabrielli, to sing; and Madlle. Heynol, the Veltris, and Le Pasq, to dance.

Mrs. Yeats did not enrich herself by her opera enterprise; but she had the address to escape ruin. And Mrs. Brooke, who risked no property, lost no reputation by imprudence, or the want of talents in the persons she engaged.

YECATY, in Geography, a town of Hindoostan, in Myfore; 20 miles N. of Seringapatam.

YEDCORA, a town of New Mexico, in the province of Hiaqui; 50 miles E. of Riochico.

YEDACOTTA, a town of Hindoostan, in Myfore; 15 miles N. of Dindigul.

YEDAPADY, a town of Hindoostan, in the Carnatic; 8 miles N. of Sankeridurgam.

YELLAGOOD, a town of Hindoosan, in Golconda; 43 miles S.E. of Canould.

YELLAGOOODY, a town of Hindooftan, in the province of Madura; 25 miles W. of Madura.

YELLANG, a town of Burmah; 14 miles S. of Mellane.

YELLOOR, a town of Hindoosan, in Baramaul; 6 miles N.N.W. of Nameul.

YELLOW, a bright colour, reflecting the most light of any after white. See Colour.

The word is formed from the Italian giallo, or the German geel, which signifies the same; or from the Latin galbanus, bright, gay.

There are divers yellow substances that become white, upon wetting and drying them again several times in the sun: such as wax, linen cloth, &c. (See Bleaching.) And the same bodies, if they be already white, and continue a long time in the air without being wetted, turn yellow.

Paper and ivory, applied near the fire, become successively yellow, red, and black. Silk, when turned yellow, is whitened again with the fumes of sulphur.

YELLOW, in Dyeing, is one of the five simple and mother colours. See Colour.

The only materials used by the calico-printers for the production of fine yellows are the quercitron-barke (see Quercus), and the Weld, or Refecla Luibola, which see. In order to obtain calicoes of the finest yellow or more delicate lemon colour, it is necessary to dry the pieces in the open air, as the Rove would not fail to injure such colours; how-drying having a tendency to change a yellow into an orange.

In the operation of dyuing the mordants for these pale yellows, care should be taken that it be not done at a higher temperature than 96° or 100°, as such a high temperature would impair their beauty. But besides, by dyuing at this low temperature, the dyeing may be completed at about 110°, which will give a much livelier colour than if a higher temperature had been employed. For all the different shades of reds and yellows, the mordant employed by calico-printers is the acetate of alumine; which is prepared by a mixture of the sulphate of alumine with acetate of lead, both in a state of solution; so that, on the theory of double decomposition, sulphate of lead is formed, which precipitates while the acetate of alumine remains in solution. Of late this article has been prepared from the pyrolineous acid, by means of lime and alum, in the following manner:

The pyrolineous acid is first passed through a still, to distil it of a portion of the tar which is always dissolved in it; it is then tannated with lime or whiting; and the acetate of lime thus formed is decomposed by a heated solution of sulphate of alumine. The result of this double decomposition is sulphate of lime, which precipitates, and acetate of alumine, which is drawn from the sediment of the calceous sulphate, and preferred for use. Mr. Parkes cautions the manufacturer against the use of lime in the procuces for making acetate of alumine; and he says that the true mode of making it, though more expensive, is that recommended by Berthollet, which consists in decomposing sulphate of alumine by means of faccharum saturni, or acetate of lead. Mr. Parkes mentions a method of producing yellow on calico, which, though not often practised, has nevertheless a very good effect. The process is as follows:—A strong decoction of bark, thickened with gum tragacanth, is to be mixed with a portion of very pure muriate of tin; and this, when printed with the usual management, will produce a colour of great brightness and durability. This mode possesses one very important advantage; viz. that it should be necessary to pad a piece in diluted acetate of alumine to obtain a pale lemon ground, the yellow figures previously done by the above process will not give out any part of their colour to the second mordant; whereas, whenever a strong yellow has been produced in the common way, the pattern is very apt to spread, and to become irregular, and often to stain the ground, when the piece comes to second time into the acetate of alumine. Parkes’s Eff. vol. ii.

Turmeric like-wise gives a good yellow, though not the best.

Woollen cloth, impregnated with a solution of alum and tartar, acquires on being boiled with the watery decoction, an elegant, but not very durable orange-yellow or gold-coloured dye. It is rarely made use of by the dyers, on account of its price, and the perniciousnes of its colour.

There is also an Indian wood that gives a yellow colour bordering on gold. This wood, called fullick, is a species of mulberry-tree, of a deep sulphur-yellow colour, which readily gives out both to water and spirit. The watery decoction dyes prepared of a very durable orange-yellow; the colour is imbied by the cloth in a moderate warmth, without boiling.

The fullé or fullig of the French is a yellow wood or root, very different from our fullick: it gives a fine orange dye to woollen, but the colour is extremely pernicious in the air. This is called extins coriaria, or Venise jumach.

The leaves of many kinds of herbs and trees give a yellow dye to wool or woollen cloth that has been previously boiled with a solution of alum and tartar. There is, indeed, no colour for which we have such plenty of materials as for yellow.

Mr. Hellot observes, in his Art de Teindre, that all leaves, barks, and roots, which on being chewed discover a flight altringency, as the leaves of the almond, peach, and pear trees, alf-bark (especially that taken off after the first rising of the sap in spring), the roots of wild patience, &c. (see Lea), yield durable yellows, more or less beautiful, according to the length of time that the boiling is continued, and the proportions of alum and tartar in the preparatory liquor: that a large quantity of alum makes these yellows approach to the elegant yellow of weld; that if the tartar is made to prevail, it inclines them to an orange; and that if the roots, barks, or leaves, be too long boiled, the yellow proves tarnished, and acquires shades of brown.

Neumann’s Chemical Works, by Lewis, p. 384. 434.

The Chinees are famous for their yellows in dyeing, which never change with washing. They make this dye of the flowers of the acacia, in a manner in which we might ufe several of our productions to a great advantage.

It is thus: they gather the flowers before they are perfectly ripe, and dry them in an earthen vesel over a gentle heat, till they crisp up in the manner of tea-leaves: they then add them to the ripe feeds of the same tree in different proportions; and then boiling them in river water, with alum, they give the yellow in any degree that they please.

They have three kinds of yellow, which they distinguish by the names of Ngo-boang, king-boang, and boang along.

The first of these is the brightest yellow: to dye five or six
fix ells of filk of this colour, they use a pound of the flowers of the acacia, about two ounces of the seeds, and four ounces of alum.

The king-hoong is a somewhat deeper yellow: to dye this, they use the same ingredients in the same proportion as in the former cafe; and when the filk is dry from the dipping in this, they give it a second dipping in a slight tincture of Brazil wood: this brings it to the fine strong yellow we see.

The hoong, or pale yellow, is made of the same ingredients as the first, only instead of four ounces of alum they put in but three ounces: river water is found to be greatly preferable to any other for the extracting of these colours; but even in that there is great difference, some doing the business much better than others.

The Chinese are so expert in judging on this occasion, that they can tell by the taste of water whether it will or will not do; and if it taste faint they know it is faulty; but they dip the pieces twice into it instead of once, and the colour succeeds well.

The flowers of the acacia, when they have been prepared by boiling in this manner, may be kept all the year round, and employed in dyeing as occasion requires, only there is to be longer boiling for the dried flowers than the fresh ones; and it is always found that the fresh flowers give the brightest colour. Obs. sur les Coutum. de l’Afrique, p. 254.

Greens are usually made of yellow and blue mixed. With yellow, madder red, and goat’s-hair prepared with madder, are made the golden yellow, Aurora, panfy, nacreate, Isabella, and chamois colour, which are all casts or shades of yellow.

Mr. Peter Woulfe has given the following receipt for making the yellow dye:—Take half an ounce of powdered indigo, and mix it in a high glass vessel, with two ounces of strong spirit of nitre, which should be previously diluted with eight ounces of water, for preventing the indigo’s being set on fire by the spirit; because two ounces and a half of strong spirit of nitre will set fire to half an ounce of indigo; let the mixture stand for a week, and then digest it in a sand-beat for an hour or more, and add four ounces more of water to it; filter the solution, which will be of a fine yellow colour. If the indigo be digested twenty-four hours after the spirit of nitre is poured upon it, it will froth and boil over; but after standing about a week, it has not that property.

One part of the solution of indigo in the acid of nitre, mixed with four or five parts of water, will dye filk or cloth of the palest yellow colour, or of any shade to the deepest, and that by letting them boil more or less in the colour. The addition of alum is useful, as it makes the colour more lasting: according as the solution boils away, more water must be added. None of the colour in the operation separates from the water, but what adheres to the filk or cloth; and consequently this colour goes far in dyeing.

Cochineal, Dutch litmus, orchil, cudbear, and many other colouring substances treated in this manner, will all dye filk and wool of a yellow colour.

The indigo which remains undissolved in making Saxon blue, and collected by filtration, if digefled with spirit of nitre, dyes filk and wool of all shades of brown, inclining to a yellow.

Cloth and filk may be dyed green with indigo; but they must first be boiled in the yellow dye, and then in the blue. Phil. Trans. vol. 131. part 1. p. 129, &c. See Dyeing.

Painters and enamellers make their yellow of malficot, or, as some write it, malficet, which is ceruffle raised to a yellow colour by the fire; or with yellow ochre. Limners and illuminers make it with saffron, French berries, orca-nette, &c.

Mr. Boyle tells us a most beautiful yellow may be procured by taking good quickfiver, and three or four times its weight of oil of vitriol, drawing off, in a glass retort, the saline menstruum from the metallic liquid; till there remains a dry yellow-white calx at the bottom: on pouring a large quantity of fair water on this, the colour changes to an excellent light yellow.

He says he fears this colour is too costly to be used by painters, and he does not know how it would agree with every pigment, especially oil colours. Works abr. vol. ii. p. 91. See VITRIOL.

Brantão observes, that it was anciently the custom to paint a man’s door yellow, and strew his house with falt, to declare him a traitor to his king.

Yellow and other Colouring Matters of Flowers, in Rural Economy, the different colouring matters thus produced. The nature of the colouring matters of flowers has not yet been much examined into. Such colouring matters are in general very transient, especially those of the blue and red kinds. The yellow colouring matters of this fort are said to be the most permanent. It is noticed by a late writer, that the carthamus contains a red and a yellow colouring matter; that the yellow is easily difolved by water; that from the red, rouge is prepared by a process which is kept secret; that the colours of most flowers are changed by alkalies to green, and by acids to red; that an imitation of the colouring matter may be made by digesting solutions of gall-nuts with chalk; a green fluid is produced, which becomes red by the action of an acid; and that it has its green colour restored by means of alkalies.

Yellow Copper, in Mineralogy, copper pyrites. See COPPER ORES.

Yellow Earth, a soft yellow mineral subfubstance, found at Wehraw, in Upper Luffata, associated with clay and argilaceous iron-dine: it is sometimes used as a yellow pigment. The characters given of this subfubstance do not seem to entitle it to be regarded as a different species from some of the ochreous clays which occur in the coal-strata in England. It is classed by professor Jameron with the lithomarge family, and is thus described by him. Its colour is ochre-yellow, of different degrees of intensity; it occurs mafive; it is dull in the crofs fracture, but glistening in the principal fracture. In the large, the fracture inclines to flaty; in the small, the fracture is earthy. The fragments are tubular, or indefinitely angular. It becomes shining in the freak; it is opaque and very soft, palling into friable; it foils the fingers lightly, and adheres to the tongue; its feel is rather greasy; it is rather light, but the specific gravity is not given. Before the blow-pipe, yellow earth is converted into a black and shining enamel. We have no analysis of this Earth.

Yellow Tellurium Ore, an ore of tellurium, hitherto found only at Ngseyag, in Transylvania. See TELLURIUM.

Yellow Cow-Wheat, in Agriculture. See WHEAT.

Yellow Dead Nettle. See WHEED.

Yellow Devil's Bit. See WHEED.

Yellow or French Berries. See AVIGNON, and LYCIUM.

Yellow Fever, an epidemic disease of frequent occurrence in America and the West Indies. See FEVER, Yellow.

Vessels arriving in Great Britain or Ireland, or the islands of Guernsey, Jersey, Alderney, Sark, or Man, from places where the yellow fever is known to exist, or where it is deemed likely to break out, are subjected by various laws and orders of his majesty in council to the restraint of quarantine; the same as ships arriving from countries subjected
to the Plague, for the details of which, see that article in the Addenda.

**Yellow Hammer,** in Ornithology, the name of a very common English bird, called by authors *emberizus lutus*; and by Linnaeus *emberizus citrinella*; and by some *hortalanus*; and by others *lutes*; and by others *chirroes*. The bill is of a dusky hue; the crown of the head is of a pleasant pale yellow; in some almost plain, in others spotted with brown; the hind-part of the neck is tinged with green; the chin and throat are yellow; the breast is marked with an orange-red; the belly yellow; the lesser coverts of the wings are green; the others dusky, edged with rust colour; the back of the same colours; the rump of a rusty red; the quill-feathers dusky, edged on their exterior sides with yellowish-green; the tail is a little forked; the middle feathers are brown; the two middlemost edged on both sides with green, the others on their exterior sides only; the interior sides of the two outmost feathers are marked obliquely near their ends with white. This species makes a large flat nest on the ground, near a bush or hedge, of moss, dried roots, and horse-hair; it lays six eggs, of a white colour, with dark purple veins; and in winter frequents our farm-yards with other small birds. Pennant.

There is beside this another kind, which is much smaller, and of a browner colour on the back; this is called by some authors *sirina*.

**Yellow Hawkweed,** in Agriculture. See Weed.

**Yellow Jaundice,** in Medicine. See Jaundice.

**Yellow, King's,** is a pure orpiment, or arsenic coloured with sulphur, used for painting in oil and varnish; of an extreme bright colour, and when good a true yellow: when used alone, it will stand well; but mixed with white lead, and several other pigments, its colour flies or changes. It is sometimes mixed with blue pigments, to form a green colour. This pigment may be prepared by mixing sulphur and arsenic by sublimation: taking of arsenic powdered, and flowers of sulphur, in the proportion of twenty parts of the first to one of the second, and putting them into a sublimer, and subliming them in a sand-hearth by means of a furnace particularly adapted to the purpose. When the operation is completed, the king's yellow will be found in the upper part of the glafs, which must be separated with care from any foreign parts adhering to it in the glafs, and levigated into an uniform powder. It may be also obtained from common orpiment by subliming it in the same manner. This pigment may be rendered warmer, or more inclined to orange, by increasing the proportion of the sulphur, and vice versa. Handmaid to the Arts, vol. i. p. 17.

**Yellow Ladies' Bed Straw.** See Weed.

**Yellow Meat,** in Rural Economy, that which is much tinged with a yellow colour. It is said to be a peculiar property in some sorts of animals, of both the sheep and cattle kinds, to afford meat which has a yellow call or appearance.

It is suggested that this defect must be hereditary, as no pasture or particular food can either produce or remove it, as sheep which have been tried in the manner here described and found yellow have been sent to the Thames marshes, kept there a year, and when slaughtered have proved as yellow as gold. It may probably depend upon some physiological principle, which mere examination after death has not yet shown. These remarks are equally applicable to beef as mutton, and are the result of information on the subject derived from a well-experienced Smithfield saleman.

**Yellow, Nepetes.** See Galloolino.

**Yellow Oat-Grafs,** in Agriculture, a sort of grafs which thrives well in meadows and pastures, as well as upon hills where the foil is of a calcareous nature, flowering in the middle of summer. It is a rather coarse grafs, which, though tolerably sweet, is thought by many to be much inferior to the meadow and felce grafses; and which Withering has asserted not to be relished by cattle; but which Swayne thinks one of the best grafses of this kind for the use of the farmer.

The proportional value which the grafs, at the time the feed is ripe, bears to that at the time of flowering, is as 9 to 15.

The proportional value which the grafs of the latter-math bears to that at the time of flowering, is as 5 to 15; and to that at the time the feed is ripe, as 5 to 9.

It is remarked, that this species of grafs is pretty generally cultivated in many districts and parts of this country; and that it would appear from the above details to be a valuable grafs, though inferior to many others. See Avena Flavefenci, Grass, and Grass-Land.

**Yellow Ochre.** See Ochre.

**Yellow Rattle,** See Weed.

**Yellow Scur or Milk,** a disease in lambs, which takes place while they are young, and in which they appear quite dull and faint-lef; their ears instead of being upright lie flat and flumber on their heads; they are very lank in the fides and bellies, and their breathing is very short and unequal. These appearances are succeeded by a purging of a yellowish milky coloured matter, which, in some cases, has come on before the disease is noticed; but at other times, the lambs die without having had any or only a slight discharge of excrement. The body or carcase appears well fed; the excrement in the intestines, which last are sometimes in some degree swelled, resembles in colour that passed at the anus, while the faumach is particularly full of coagulated milk.

It is a disease which never appears or shews itself in hard seafons, but only when the weather is warm, growing, and genial, and there is great plenty of new grafs. In general it does not affect them after they are three weeks old. It is mostly ascribed to their eating more milk than they can digest; and it is even said, that they not unfrequently fall until their faumachs burst.

The lambs being young, and of little value, remedies to prevent or remove the disease are seldom tried; but those of the aromatic cretaceous kind, with a little opium, may often be used with much advantage in preventing and curing the complaint.

**Yellow Vetchling,** in Agriculture, a plant of the tare kind, that may be cultivated by the farmer in many cafes with profit. The writer of the Essays on Rural Affairs flates, that it grows with great luxuriance on flift clayey soils; that it continues annually, for any length of time, to afford a great weight of produfe, which is of the very best quality; that it is equally fit for pasture herbage or for hay, and that it may be applied to one or other of these purpofes at any period as convenient; that it has likewise this advantage, that as it continues to grow with equal strength in the end as in the beginning of the summer feafon, it may admit of being pafured upon in the early spring, when necessary, without endangering the lofs of the hay-crop, which cannot be the cafe with any other plant ufually cul-

tivated, except clover, which is unfit both for early pafure and for hay; and that it is still more valuable, as growing to the greatest perfection on fuch soils as are wholly unfit for producing fum-fcin, the only fort of plant yet cultivated in the
the field, which seems to have qualities approached to those of this plant.

The principal objection to its cultivation is the difficulty of procuring the seeds of it in plenty, which may probably be obviated by proper management. It is, however, an abiding plant, and one which increases fast by its running roots, and which may readily be propagated in this way in the field. See Lavaterus pratensis.

Yellow-Boat Wafh, is a solution of the gum of the French berries in water; and may be prepared by boiling a pound of the berries in a gallon of water with half an ounce of alum, in a pewter vessel, and filtering the fluid; and by evaporating the fluid in the boiler till the colour appears to be of the requisite degree of strength.

This is used as a washing colour in water-painting: it will stand extremely well, and being more diluted, or laid on thicker, will, in consequence of its transparence, give a variety of shades.

Yellow Wafh of Saffron. See Tincture of Saffron.

Yellow Wafh of Turmeric. See Turmeric.

Yellow Breaches Creek, in Geography, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 40° 13'; W. long. 76° 51'.

Yellow Creek, a township of Ohio, in the county of Columbiana, with 491 inhabitants.—Alló, a river of America, which runs into the Ohio, N. lat. 40° 34'. W. long. 80° 44'.

Yellow River, a small river of Ireland, in the King's county, which joins the river Boyne.

Yellow River. (See Hoang.) Mr. Barrow, supposing, without the possibility of exaggeration, that the breadth of the Yellow river, where Macartney's embassy passed it, about 70 miles from the sea, was only three-fourths of a mile, the mean depth five feet, and the velocity of its course four miles an hour, concludes, from these data, that the river discharges into the Yellow sea, in every hour, a volume of water equal to 418,176,000 solid feet, or 2,563,000,000 gallons of water, or 1100 times as much as appears to be furnished by the Ganges. By another computation, he estimates the quantity of mud wafted into the sea by this river in every hour to be equal to 2,000,000 solid feet, or 48,000,000 in every day, or 17,520,000,000 in every year. Supposing the mean depth of the Yellow sea to be 20 fathoms, or 120 feet, the quantity of earth brought down by the Yellow river would, if accumulated together, be sufficient to fill up, even to the surface of the sea, an island one mile square in 70 days. By extending the calculation, a curious inquirer may find in what space of time the Yellow sea itself might be filled up by the successive depostions from the Yellow river alone; for supposing that sea to extend northward from that river, and to include the gulfs of Po-che-lee and Liao-tong, the number of square miles on the surface of this extent would be about 125,000, which, multiplied by the number (70) of days necessary for consolidating one mile square, would make 8,750,000 days, or 24,000 years.

The velocity of the Yellow river at the place where the embassy crossed it was so great, as to require, agreeably to the superstitious notions of the Chinese crew, a sacrifice to the spirit of the river, in order to ensure a safe passage over it. With this view, the master presented a cock, and having wrung off his head, which he threw into the sea, confecrated the vessel with the blood spouting from the body, by sprinkling it upon the deck, the masts, the anchor, and the doors of the apartments, and flung upon them a few of the feathers of the bird. Various kinds of provisions were then ranged across the deck; and when the captain had made three profound inclinations of the body with his hands uplifted, he muttered a few words, as if of solicitation to the Deity. The loo, or brazen drum, was in the mean time beaten forcibly; lighted matches were held towards heaven; papers, covered with tin or silver-leaf, were burnt; and crackers fired off in great abundance by the crew. The captain afterwards made libations to the river, by emptying into it from the vessel's prow the several cups of liquids which he had provided, and concluded with throwing in alof that which held the sail. All the ceremonies being finished, and the bowls of meat removed, the people feasted on it; and afterwards launched with confidence the yacht into the current. As soon as she had reached the opposite shore, the captain returned thanks to heaven, with three inclinations of the body. Sacrifices are also offered to obtain a fair wind, and to avert any impending danger.

Besides these offerings, great exertions were necessary to overcome the violence of the Yellow river, and to transport large yachts in safety to the opposite shore. Embafly to China, vol. ii.

Yellow Sea, an extensive but shallow inland sea between Corea and China, hardly any where exceeding forty-five fathoms in depth, and often not more than twenty; with a bottom of clay or mud: the alluvion, without doubt, of the rivers that are poured into it from the mountains and plains of China. See Liao-tong.

YELOWs, in Animals, is a disease which is incident to horses, neat, cattle, and sheep, in which there is a yellow jaundice-like appearance, especially in the eyes.

It is a disease that takes place in horses in all states of them, but which in those of the young kind is often unaccompanied with fever, or any sort of irritation. It swells itself by a particular yellowness in the eyes and the inside of the mouth, with a considerable degree of conftipation of the bowels in some cases.

The complaint is frequently much relieved by the use of a ball composed of one ounce of aloes in powder, with one drachm of calomel, and half an ounce of Caffile soap, made up with a sufficient quantity of treacle; and the second morning afterwards giving one consolidated of half an ounce each of nitre, refin, and Caffile soap, made up with honey; and if the yellowness should continue in the eyes and mouth, repeating the latter after an interval of four days.

Some, however, advise to have first recourse to bleeding, clysters, and purges; in the last of which intentions the composition directed below may be found useful: One ounce and a half of Indian rhubarb, two drachms of farron, and fix drachms of fucccinine aloes, formed into a ball with yfup of buckthorn. But if the rhubarb should be thought too expensive, it may be omitted, and the same quantity of cream of tartar, and half an ounce of Caffile soap, with four drachms more of aloes, be added. This may be repeated two or three times, giving immediately the remedies directed below: Half an ounce of Ethiopia's mineral, and one ounce of Caffile soap, formed into a ball, and one of them given every day, washing it down with a pint of the following decoction: Madder and turmeric-root, each four ounces; burdock-root sliced, half a pound; monk's rhubarb, four ounces; and liquorice sliced, two ounces; boiled in one gallon of forge-water to three quarts; the liquor then drained off, and sweetened with honey.

In this disease, balls of Caffile soap and turmeric alone are likewise often had recourse to, even to the quantity of three or four ounces or more in the day; and not unfrequently succeed in recent cases.

By means of this fort, the disease for the most part abates
abates in the course of a week or ten days, which may be known by the alteration in the eyes and mouth of the horse; but the remedies are to be continued until the yellowness is wholly removed. Should, however, the disease prove obstinate, and not give way to such modes of treatment, it will be necessary to have recourse to more powerful remedies, such as those of the mercurial purging kind, repeated two or three times at proper intervals, and then to give the balls composed of the substanies directed below: Two ounces of salt of tartar, four ounces of cinnamon or anisomy; three ounces of filings of steel, and soap half a pound, formed with honey into balls the size of a pullet's egg, giving one night and morning in a pint of the above decoction drink.

On the recovery of the horse, some advise two or three mild purges; and if he be strong and fat, to put in a rowel.

He should have mashes and warm water frequently, and be exercised daily, and warmly covered with cloths.

In order to prevent a relapse, the first purging-ball may sometimes be used with great advantage; and a powder formed of the following ingredients be mixed, with the seeds of corn every night for a fortnight: Ethiopis' mineral, nitre, and aniseeds, each half an ounce, mixed together.

Salt-mashes, too, have often been found very useful in the cure of this disorder, and when taken in time rarely fail in relieving the animal.

The yellows in near-cattle is a common disease, arising from obstruction in the gall-duets, and confin in a diffusion of the obstructed bile through the whole body of the animal. It is first distinguished in the white of the eyes, which has a particular yellow appearance; and as it increases, the whole of the skin becomes tinged with the same yellow colour: but the ears, tail, eyes, and mouth, are the parts in which it is the most conspicuous. The animals are affected with great weakness and debility in every part of the diseaf; and there is a little fleas, with indisposition to move, and a want of appetite for their food. When in the pastures, they moly wander about by the sides of the hedges, or other fences, in a lonely manner. Milch cows are particularly subject to the disease in the spring and at the fall of the year; though they are not exempt from having it at all other seasons. The most unfavourable slate of the disease is when it proceeds from an induration of some part of the liver, as there is then but little hope of the disease being permanently removed. As the changing slate of the weather has often a great effect in retarding or hastening the removal of the diseaf, care should be taken to house the animals in all unfavourable feasons.

On the first appearance of the diseaf, it may often be removed by the composition directed below: Salt of tartar, Caffile soap, and grains of Paradise, each one ounce; turmeric-root, and coriander-feeds, in powder, each two ounces; the whole being made into a drink, by pouring three pints of hot ale upon the ingredients in a proper clofe vessel, first fencing the soap in a thin manner, and covering them well up until they become about new milk warm, when two ounces of honey or treacle may be added, and the whole given as a drink. It must be repeated at the distance of every day or two, for two or three times, or as there may be occasion.

When the beast is strong, a little blood may sometimes be taken away with advantage; but it should not be turned out into the pasture the same day.

When the disease does not give way to these remedies, it may be necessary to have recourse to a strong purge or two. After which a drink composed as below may be given: Salt of tartar, one ounce; Caffile soap sliced, two ounces; well rubbed down with an ounce of balsam of copaiva, and then two ounces each of valerian-root, ginger-root, and Peruvian bark in powder added, and the whole given in ale or gruel as above, repeating it every other day.

It is necessary to keep the bodies of the animals well opened through the whole of the diseaf; in which intention a drink compofed as below may often be useful: Barba-
does aloe, in powder, one ounce; castor-oil, four ounces; syrup of buckthorn, two ounces; mixed and given in a quart of oatmeal-gruel when about new milk warm, and repeated until the proper effect be produced, using the first faponaceous drink at the fame time.

When this complaint is removed, the general health of the animals may soon be restored by the proper use of cor-
dial strengthenings drinks, formed of the different aromatic pectoral feeds in the powdered slate.

The yellows is not a very common disease among sheep, and consequently has not been very accurately described; but probably confounded with many other affections to which they are subject. It is supposed by some to be in general confined to the South Down and new Leicesteter breeds, which, from their more tender constitutions, are more liable to complaints.

The appearances of the diseaf are a yellowness over the whole body, but particularly diftinguishable in the white of the eye. The wool, too, has a little of the tinge, and is slightly hard. The paffages of the belly are of a whiffil-
ous appearance; and the urine is found to tinge any thing immersed in it of a yellow hue. Sometimes there is a degree of full-
ness and hardness in the right-fide, about the heat of the liver. The caufes are any thing which has a tendency to obftrude the gall-duets, but they are by no means evident; their effect, however, seems generally to harden the liver, and invariably to impede the paffage of the bile from it into the bowels. In some cafes, small ftones, formed in the gall-
bladder, produce it; and at other times, it is caufed, as in the rot, by the swelling of the glands impeding the flow of the bile in the duets, in which case it is mostly incurable.

The removal of the diseaf is to be attempted by the use of strong purgatives, and fuch remedies as act strongly on the ftemae. A strong folution of purging salts will partly tend to produce this effect; and ten grains of peccacuana, which is kept every three hours in a little warmed ftrong beer, is said to be attended with the most beneficial effects, when continued for five or fix days together, and a dose of purging fals given after it, to give the bowels. Calomel and foap may likewise be often given with great benefit, as well as some of the above faponaceous remedies.

YEMANA, or JEMAMA, in Geography, a country and city of Arabia, which M. D'Anville, probably milled by some map and uncertain accounts, places on a river called Aftan, and which he represents as a stream in Neger, though Niebuhr mentions it merely as a wall or brook, which runs under rains. D'Anville says, that Jemama is in Al Kardje, which is the grand province of Kerje of Niebuhr, on the E. of Hedjaz and Yemen; and in this province, according to the Danish geographer, is the city of Amamé or Imamé, renowned for the prophet Mofeilama, whom the historian Gibbon ascribes to Yemama, and which town is in the dioclet of Suria. But this cannot correspond with D'Anville's Jemama, which is in the province of Ared, D'Anville only by that of Lafta on the E. Niebuhr also informs us, that Aijana, a town of Ared, is remarkable for the new prophet Wahhab; and therefore Gibbon seems to have erred by supposing it to be the same with Yemama, the latter being probably a town of Kerje, not far to the E. of Hedjaz. After all, the province and city of Jemama are
are probably mere fictions, which should be excluded from the maps, together with the river of Altan, which, if it existed, would certainly be followed by the caravans from Lahfa to Mecca, while they seem to prefer a fandy defect.

Pinkerton's Geography.

YEMBA. See Emba.

YEMELLA, a town of Hindoostan, in Golconda; 24 miles E.N.E. of Rachore.

YEMEN, a province of Arabia, comprehending the finest and most fertile part of Arabia, reprefenting, as Gibbon has observed, the Arabia Felix of antiquity, surrounded by the Red sea, or Arabic gulf, and by the province of Hadramaut, Nadjed, and Hedsjas. Yemen is naturally divided into two parts, differing greatly in foil and climate: that bordering on the Red sea is a dry and fandy plain, nearly two days' journey in breadth, and is fcorched by the moft torrid heats: the other, extending immediately beyond this, is a high-lying country, full of precipitous yet fertile hills, and enjoying a much more temperate air. Yemen is, like the rest of Arabia, parcelled out among a number of different sovereigns in unequal portions. Some of them are princes of confiderable power; but many are petty fchiefs, who are, however, perfectly independent: the most confiderable of these princes is the imam, who refides at Sana. There are feveral other independent fates, as Aden, Kaukeban, Kobail or Hafcid-u-Bekil, Abu-Arifch, a large district between Abu-Arifch and Hedsjas, inhabited by free Bedouins; Khaulan, Sahan, comprehending the principality of Saade; Nedsjeran, Kachtan, Nehm, East Khafan, Dejof or Mareb, Jafa, and feveral others. The fafe intermixture of fertile and barren territory, and the fame productions, appear every where through the whole province: the imam, however, seems to be matter of the richest, the moft agreeable, and the moft interesting part of this tract of country. It would not be easy to explain difintly the extents and limits of this sovereign's territories, as they are fo inter- fected by the domains of a number of petty princes. The general division of Yemen into Tehama the Lowlands, and Djebal the Highlands, obtains in the imam's dominion as well as elsewhere. Upon this grand division depends the fubdivision of the kingdom of Sana into thirty governments or counties. Tehama contains five of these governents, and the Highland country twenty-four: the fmall governments are not all alike populous or remarkable. There are in the territory of the imam many fchiefs difperfed among the mountains, who acknowledge not his authority, and are but in a very flight degree dependent upon him. From the expulsion of the Turks in the year 1629, the reign of the imams began; their great ancestor Khalleem Abu Mahomed was the chief author of that revolution. The throne of Yemen is hereditary; if generally approved of by the fubjefts, the eldest legitimate fon of an imam is his rightful fuccifor. But in the depotic governments of the Eait, indeed, no order can be clofely observed, because there are no fundamental laws. The imam is an absolute prince, and the more fo by uniting in his own perfon supreme authority, both spiritual and temporal, over his fubjefts. His jurifdiction in ecclecafical matters, however, extends not over the dominions of other sovereigns of the fame feft: thefe fates have each a muflih, or cadi, for its spiritual life. Although the imam be absolute, he is checked in the exercife of his authority by the fupreme tribunal of Sana, of which he is only prefident: this tribunal, conflifting of a certain number of cadis, polaffes the fole power of life and death. The imam may not order any of his fubjefts for execution, but fuch as have been condemned in confequence of a criminal prosecution before this court.

The cadis are generally efteemed to be perfons of incorruptible integrity, of blameless lives, and devoted to the faithful discharge of their duties: they are not changed here fo often as in Turkey, but hold their offices usually for life. Every petty diftrift in the dominions of the imam has its governor: if not a prince, or one of the higher nobi- lity, this governor is called wali and dola, or fometimes emir, when he happens to be a perfon of low birth. In every little town, a lub-dola, with a small garrifon, confift- ing fometimes of five or fix foldiers, refides to maintain order. The chief of a large village is a fchieff: he of a small one a hakim. Every city in which a dola refides has alfo a cadi, dependent on the chief cadi of Sana; the cadis are fole judge in civil and ecclecafical affairs, nor may the dola interfere to contradift his fentences, or render them ineffectual. The cadis in the provinces, no lefs than in the capital, are in high reputation for wisdom and integrity. The revenue of the imam is fluctuating and precarious.

Niebuhr fhews it at about 500,000 crowns a month. This revenue arises from a land and poll tax, and from duties payable upon articles of merchandise. The military force consists ordinarily of 4000 infantry and 1000 cavalry. These armies ufe no artillery, nor do the Arabs know how to manage cannon. As the imam has no dread of enemies or corsairs upon the Arabic gulf, he has no occasion for a naval force; and his fubjefts are therefore generally un- skilled in navigation. The fishermen venture far to sea in small canoes fearely furnished with oars. The manufactu- res of a people fo little induftry cannot but be very trifling: no fabrics are manufacured in Yemen, nor any edged weapon, except a kind of crooked knives, called jemika. The making of match fire-locks has been attempted here within thefe few years: it succeeds but indifferently.

It is only of late that glafs works have been eftabli{hed at Mocha; some coarse cloth is manufactured here, but not fo much as is required for the ufe of the country: broad cloths are neither made nor worn here. The English brought fome goods of this fort to Mocha, but were obliged to carry them back to India unfold. A country which affords fo few articles for fare cannot have a great trade.

Coffee is almost the fole article exported from Yemen; a valuable commodity, in exchange for which many of thefe things which this country needs from abroad may well be obtained. All the commerce of Yemen is carried on by Mocha, except only the fmall quantities of coffee are exported by Lahore and Hodeids. Agriculture feems to be farther advanced in Yemen than in the other parts of the Eait.

Wheat, in the bel{ cultivated diftricts, is faid to yield an in- creafe of fifty-fold; durra, in the Highlands, 140; and in the Tehama from 200 to 400: and the inhabitants of Tehama reap three succifive crops from the fame field in the fame year. In many parts of Yemen, whole fields are cultivated like a garden, and watered in the rainy feafon by canals from the hills. The inhabitants of the plain are obliged to en- compafs their fields with dykes, that the water may remain for fome time upon the furface of the ground. In the upper parts of Yemen, the inhabitants collect the water neceffary for their fields in dams formed at the foot of the hills. In fome diftricts of Yemen, maize and durra are planted with the hand. The husbandry of Tull and Du Hamel, says Niebuhr, although novel in Europe, is very old in Arabia. In order to guard their fields from depredation of birds and other deftructive animals, the peafants watch them by turns. In the Highlands, he who watches feats himself on a tree; in the Tehama, on a fort of scaffold, with a roof railed over it. Niebuhr's Travels.
YEN, a river of China, which runs into the Hoang, 17 miles S.E. of Yen-tchang.

YEN-CHIN-TCHING, a town of China, in Chantong; 45 miles E.S.E. of Tei-nan.

YENDON, a river of England, in the county of Stafford, which runs into the Churnet.

YENGHI IMAN, a town of Curdislan; 70 miles S.E. of Kerkuk.

YENGL, a town of Corea; 25 miles N.E. of Kang.

YENISSEI, or YENISSEI, or YENIFLEY, a river of Russia, which the Tartars and Mongoles, who inhabit the superior regions of it, above the Tunguika, call Kem, and the Olitaks, Gub or Kheles, figuring the Great river, and which is at first composed of two rivers, the Kambara and the Veikem, originating in the Chihefe Soongaria, or Bucharia, and forming a conjunction in N. lat. 51° 30', and E. long. 111°. About the mouth of the Bom-Kemthuyug it enters upon Russian ground, and henceforth takes the name of Yenifley. After various windings it turns northward, and in N. lat. 70', and E. long. 103° 30', forms a bay containing several islands; and at half, in 3° 30' of length, falls into the Frozen ocean. In autumn, when its water is at the lowest, its breadth, r. 570, at the town of Yenifeilfik, is about 570 fathom, whereas in the spring it is 795 fathom and upwards. The coasts of the Frozen ocean, between the mouths of the Yenifley and Oby, are called the Yuratskoï shore. The more considerable streams taken up by the Yenifley are the following: on the right, the UI, the Tuban, the Kan, and the three Tunguikis, i.e. the Upper, the Middle, or Polskomanna, and the Lower Tunguika; on the left, the Abakan, the Yelovi, and the Turukhan. In its superior regions, the Yenifley flows over a very sandy bed; and its shores, particularly the eastern, are most befet with lofty mountains and rocks. Its course is in general very rapid, though near its mouth it flows so gently, that the current is hardly perceptible. In the neighbourhood of Turukankel and elsewhere it forms some considerable islands; and between the cities of Yenifeilfik and Krafluyarik several cataracts are to be seen. The Yenifley is navigable from its mouth as far as Abakan, and affords abundance of the best fish. Near this river, as well as in some other fleppes of Ruffia, are hone-tombs, which represent in rude sculpture human faces, camels, horfemen with lances, and other objects. Between this river and the Oby, or Ob, is a vail space extending from the north of Tomik to the Arctic ocean, which is regarded as a fleppe, being a prodigious level with no appearance of a mountain, and scarcely of a hill. The fame term is applied to the wider space between the Yenifie and the Lena, between the Arctic ocean in the N., and the river Tunguika, or Angara, in lat. 65°; and to the parts beyond the Lena as far as the river Kolyma or Covima. Tooke's Ruff. vol. i.

YENISSEISK, or YENICEISK, a small town of Ruffia, in the government of Tobolfik, situated on the above described river, the forges of which yield a considerable tax to the Russian revenue. Its jurifdiction is extenfive, and it pays annually a tribute in skins to the crown of Ruffia; 400 miles E.N.E. of Kolivan. N. lat. 58° 16'. E. long. 91° 50'.

YENITE, in Mineralogy, Liverite, Werner, a mineral found in the island of Corfica, which from the great quantity of iron that it contains might properly be called with the ores of iron. It is arranged by Professor Jemfon with the chryfolite family, but it differs greatly in the proportions of its constituent parts from all the other species which he has claffed with this family. The appearance of this mineral refembles hornblende, or rather black epidote:

Vol. XXXIX.

YEN, it occurs both cryftallized and massive. The form of the cryftals is that of a rhomboidal prism, the alternate angles of which meare about 113 and 67 degrees; the prisms are terminated by low four-fided pyramids, the faces of which are on the lateral planes of the prism. It is also cryftallized in rectangular prisms, bevelled on the extremities, and the bevelling planes set on the obtuse edges. These figures are also variously modified by the edges or angles being bevelled. The cryftals are sometimes very minute or acicular, and sometimes half an inch in thickness; they are frequently aggregated in diverging râdis, and sometimes imbedded. The prisms are fliated longitudinally. The structure is imperfectly lanear, with joints parallel to the fides, and to the short diagonal of the rhomboidal prism. The fracture of yenifte is uneven, and imperfectly conchoidal, with a furface between vitreous and refluent. The colour is black passing into brown; it does not change its colour in the ftreke. The hardness of yenite is about equal to that of common felfpar; it is easily.frangible. The specific gravity of yenite varies from 3.825 to 4.061.

It is fulible with cafe by the blow-pipe into a black glafs, which has a metallic aspect, and is attracted by the magnet, but does not posfsed polarifation; it disfolves with borax with a flight ebullition. It is acted upon by the mineral acids, but does not gelatinize with them. When expofed to heat it becomes magnetic. Its colour is changed by heat from black into dark reddish-brown, and it lofes about two per cent. of its weight.

The confluent parts of yenite are,

Yenite decomposes gradually on exposure to the air, and is reduced to a yellowish-brown ochre. According to Bronniant, yenite occurs in differfed cryftals and groups, and in compact kidney-shaped fasses, in a thick bed of a greenish fubfifence nearly refembling yenite, but which has not been accurately examined. It is accompanied with epidote, quartz, and arfhenical pyrites. This bed at Rio la Marin, in Corfica, covers a rock of primitive marble mixed with tale. At the Cap de Calamite, it is accompanied with magnetic iron-oxide, garnets, and quartz.

YEN-KING, in Geography, a city of China, of the second rank, in Pe-techni; 52 miles N.N.W. of Peking. N. lat. 40° 30'. E. long. 125° 30'.

YENLADE, or STRAX, a channel between the Thames and Medway, which separates the island of Graine from the coaft of Kent. It was formerly the ufual passage for vessels to and from London.

YENNE, a town of France, in the department of Mont Blanc, near the Rhone, suppofed to be the ancient Epanna, where Sigismund, king of Burgundy, assembled a council at the end of the fifth century; 14 miles N.W. of Chambery.

YEN-NGAN, a city of China, of the firft rank, in Chen-foo, on the river Yen; 390 miles S.W. of Peking. N. lat. 36° 44'. E. long. 108° 49'.

YEN-PING, a city of China, of the firft rank, in Fochien; 820 miles S. of Peking. N. lat. 26° 40'. E. long. 11° 74'.

YEN-TCHEOU, a city of China, of the firft rank, in Tche-kiang. Near this town are mines of copper, and trees that yield varnish, which give a value to the cabinet-work so much esteemed in Europe; when this varnish is once dry, it never melts again, and will bear boiling water.
The paper manufacture of this place is in equal esteem, and for which they have a great demand. Six towns of the third order are under its jurisdiction; 650 miles S. S.E. of Peking. N. lat. 20° 38'. E. long. 119° 14'.—Also, a city of China, of the first rank, in Chan-tong. The territory dependent upon this capital is inclosed between two considerable rivers, which abound with fish, and make the soil very fruitful. The country is very well cultivated, the mountains are covered with woods, and the air is mild and temperate. There are twenty-seven towns within the jurisdiction of this capital; four of the second order, and twenty-three of the third; 267 miles S. of Peking. N. lat. 35° 44'. E. long. 116° 30'.

YENTCHERU, a town of Hindoosstan, in the circuit of Cuddapa; 20 miles N.E. of Combam.

YEN-TCHING, a town of China, in Chan-tong, where a peculiar species of glafs is manufactured, of which a delicate nature, that it will not endure the inclemency of the air; 15 miles S.E. of Tei-san.

YEOMAN. See Yeovil.

YEOMAN, the first or highest degree among the plebeians of England; next, in order to the gentry. The yeomen are properly the freeholders, who have land of their own; so called from the Saxon gemanes, or geman common.

The word yongman is used for yeoman in the statute 33 Hen. VIII., and in old deeds it is sometimes also written yeman, which, in the German, signifies any-body.

According to Sir Thomas Smith, a yeoman is a free-born Englishman, who can lay out of his own free land in yearly revenue to the sum of forty shillings sterling.

The yeomanry of England are capable of holding lands of their own to a good value; are adjudged capable of certain offices, as constables, churchwardens, jurymen; and are also to vote in elections to parliament, and to serve in the army, and to do any other act where the law requires one that is juris et legalis homo.

The yeomen were famous, in ancient times, for military valour, being particularly expert at the management of the bow; whence the infantry was composed chiefly of them.

They frequently constituted the body-guard of our kings; and in process of time gave rise to the institution of yeomen of the guard.

In many cafes, the law conceives a better opinion of the yeomanry that occupy lands, than of tradesmen, artificers, &c.

By a statute, 2 Hen. IV., it is enacted, that no yeoman shall take or wear a livery of any lord, upon pain of imprisonment, and a fine at the king's pleasure.

YEOMAN is also a title of office in the king's household, of a middle place or rank between a gentleman and a groomsman. Such are the yeoman of the buttery; yeoman of the cellery; yeoman of the wine-cellar, ewry, wood-yard, &c.

There are also the yeoman of the mouth, yeoman of the kitchen, yeomen-porters, &c.

YEOMAN, in Saxon Language, an officer under the boatswain or gunner of a ship of war, usually charged with the storehouse, account, and distribution of their respective stores.

YEOMEN-Warders. See Warders of the Tower.

YEOMEN of the Guard, properly called yeomen of the guard of the king's body, were anciently a body of men of the best rank under gentry, and of larger stature than ordinary; every one being required to be six feet high.

Their number has varied in almost every reign, and formerly consisted of a certain number in ordinary, and an indeﬁnite number extraordinary; and in case of a vacancy in the former, it was supplied out of the latter number. In the reign of king Edward VI. this corps was very numerous. In the reign of queen Elizabeth, the yeomen attending her in her different progresses were occasionally mounted. In the reign of queen Anne, the arms of half this band were arquebuses, which are said by Chamberlain to have been disused ever since the reign of King William; the other half had partisans, and those of both claves had swords. They had their wages and diet allowed them; so that in a MS. of the expenses of the royal establishment for the year 1727, the charges of the table of the yeomen of the guard were 275l. 15s.

But their diet has been discontinued since that reign. Their duty was to wait upon the queen in her flanding-houses; forty by day, and twenty by night. At St. James's, they waited in the ﬁrst room above stairs, called the guard-chamber. It is also their duty to attend the sovereign abroad by land or water.

At present there are but one hundred yeomen in conﬁnant duty, at 39l. 11s. 3d. per annum each; eight of whom are called uffers, who have 100l. per annum each more than the other yeomen; six are called yeomen hangers, and two, yeomen bed-goers, who have the same pay as the uffers; and seventy more not on duty; and of the hundred dies, his place is supplied out of the feventy.

The officers are, a captain, who has 100l. per annum; a lieutenant, at 50l. per annum; an ensign, at 30l.4; and four exons, at 15l. per annum each; and a clerk of the cheque at the same salary.

Their origin is traced to the year 1485, when king Henry VII. ascend ing the throne, immediately after his coronation, instituted a guard of ﬁfty archers to attend him and his successors. They were probably then, as they are now, called the yeomen of the guard.

It is observed, that this is the ﬁrst inﬂuence of any eﬆablished or permanent military guard in England: its kings, till that time, except in times of war and insurrection, contented themselves with the guard of their proper domesticks and retinue. And Hist. Com. vol. i. p. 302.

Most of the writers, however, against standing armies commence that establishment with the ferjeants at arms, who were ﬁrst instituted by king Richard I. Their dress is that which was worn in the reign of king Henry VIII., and which on many occasions was put on by that king; it consisted of a scarlet coat reaching down to the knees, guarded with garter blue velvet, and with badges of the rose and crown on their breasts and backs; their breeches also are scarlet, guarded with blue velvet; their caps are of black velvet, with broad round crowns, adorned with ribbons of the royal colours, viz. red, white, and blue.

The officers and yeomen are at the disposal of the captain; but the captain is at the appointment of the king.

YEOMAN of the Salt Stores. See Acastery.

YEOMANRY CAVALRY, a denomination given to those troops of horse which were levied in the late war among the gentlemen and yeomen of the country, upon the same principle with the volunteer companies. The yeomanry cavalry were to be allowed pay when called out on actual service, and each corps was liable to be put upon duty within its district; all contingent expenses, properly and unavoidably incurred, were to be reimbursed after an investigation at the war-ﬁce. One ferjeant and a trumpeter per troop were to have conﬁnant pay, with the same allowances as ferjeants and trumpeters of regular cavalry. Some accoutrements were to be furnished by the ordinance, or an equivalent
equivalent in money to be given in lieu of them, and 14s. 2d. per man for holliers.

YEOWIL, in Geography, a large and populous market-town in the hundred of Stone, county of Somerset, England, is situated on the confines of the county, at the distance of 9 miles S.S.E. from Somerton, and 122 miles W.S.W. from London. It derives its name from the river Yeo, which rises near Sherborne, and pails this place under a stone bridge of three arches, separating the counties of Somerset and Dorset. The town of Yeovil consists of upwards of twenty streets and lanes; many of the former are of considerable width: the houses in general arerespectable, and many of them are built of stone. Part of the town is called the Borough, and is governed by a portreave and eleven burgesses, out of whom the portreave is annually chosen. Here is a spacious market-house, seventy feet in length, and twenty in breadth, supported by stone pillars, in the centre of which are the remains of an ancient cross. A considerable market is held on Fridays for corn, cattle, pigs, butter, cheese, and flax: here are also two annual fairs. The woollen trade was formerly extensive here, but has decreased: the chief business of the town is the manufacture of leather gloves. In the return of the year 1811, the population of this parish was estimated at 4188: the number of houses is 459. The church, a large, ancient structure, consists of a nave, chancel, two aisles, and transept; the length of the whole is 146 feet; the breadth 50. At the west end is a plain tower, ninety feet high, with a stone balustrade at the top. Differenters have several meeting-houses in the town. Here is an alms-house, founded in the year 1426, by the Rev. Mr. Woburne, minor canon of St. Paul’s, London, and by him endowed with considerable landed property for the maintenance of a master, two wardens, and twelve poor pupils of either sex. He also built a chapel for the use of his poor, and ordained divine service to be performed in it every day.—Collinson's History of Somersetshire, vol. iii. Beauties of England and Wales, vol. xiii. Somersetshire.

YEOUNGZNAIH, a town of Birmah, on the Irawaddy; 36 miles N.N.W. of Rangoon. N. lat. 19° 30’. YEOU-TUN-OUEL, a town of Chinefe Tartary. N. lat. 41° 8’. E. long. 121° 9’. YEOU-YU, one of the small islands in the Chinefe Archipelago; 62 miles S.W. of Macao.

YEOWAH, a town of Birmah; 15 miles S. of Pegongmew.

YEPES, a town of Spain, in New Castile; 17 miles E. of Toledo.

YERAPATT, a town of Hindooflan, in Myfore; 8 miles S. of Dalmacherry.

YERCO, a town of Thibet; 90 miles S.E. of Laffa.

YERE, a river of France, in the department of the Lower Seine, which runs into the English Channel, at Hui.

YERGHEN. See YARKAN.

YERK, in Horfer, a term signifying to strike out backwards. A horfe is said to yerk, or strike with the hind legs, when he flings and kicks with his whole hind quarters, flinging out the two hinder legs near together, and even to their full extent. Horfes of this fort are very dangerous, and fhould be parted with as soon as poifible, whether they are of the farm or the faddle kind.

YERKIE, in Geography, a town of Russia, on an ifland at the mouth of the Volga, where vessels take their departure for the Caffian fea. Here ships formerly entered and cleared, but the ifland is now almost overflowed, and the trade of the place much decayed since 1747; 60 miles S. of Afrachan.

YERMA. See JERMH.

YERMUK. See YARMUG.

YERTNAGOODAM, a town of Hindooflan, in the cirer of Rajamundry; 17 miles S.W. of Rajamundry.

YERVA-MORA, in Botany. See BOSEA.

YERVILLE, in Geography, a town of France, in the department of the Lower Seine; 12 miles N.N.E. of Cambdeby.

YESCOKING CREEK, a river of North Carolina, which runs into Pamlico sound, N. lat. 35° 29’. W. long. 76° 14’.

YESD. See YEZD.

YESTA, a town of Persia, in the province of Larifan; 40 miles N. of Lar.

YESDECAST. See JEDDECAST.

YESID, a town of Persia, in the province of Chuftian, or Kuristan; 18 miles N. of Toftar.

YEST. See YEAST.

YETCHERADAW, in Geography, a town of Hindoofflan, in Myfore; 9 miles E. of Rvdroog.

YETEOPAU, a town of Hindoofflan, in the cirer of Caccole; 15 miles S.W. of Coiffmecotta.

YETHIAN, a river of Scotland, which runs into the German sea, 10 miles N. of Aberdeen.

YETHOLM, or ZET-HAM, a market-town in the district of Kelfo, and shire of Roxburgh, Scotland, is situated nine miles S.E. from Kelfo, on the small river Bowmont, which divides it into two parts, respectively named Town Yetholm and Kirk Yetholm. A weekly market is held on Wednefdays; and two fairs annually. Many tinkers and gypsys reside in this town. The parish extends about four miles in length, and two in breadth; and is bounded on the eaf and fouth by the Englifh border. The surface is hilly, but the hills are covered with verdure, and pafured by a very confiderable number of sheepe. In the population return of the year 1811, this parish is flated to contain 213 houfes, and 1198 inhabitants. King Robert III. granted the barony of Yetholm in the fourteenth century to Archibald Mac Dougall, whose defcendant still enjoys it.—Carllif’s Topographical Dictionary of Scotland, 1813.

YETTUS, in Natural History, a name given by the writers of the middle ages to a species of marble of a deep red, which was used by some as a touch-fohe.

YEU, in Geography, a small and insignificent ifle, situated on the W. coaf of France.

YEVA CHARRE, in Natural History, a name given by the people of the East Indies to a kind of litharge, which is very common in that part of the world, and is fayed to be made partly from lead and partly from zinc.

It is left heavy than our yellow litharge, and of a paler colour. It is ufed as a cauticus in all the occasions of surgery there.

YEVERING, in Geography, a village of England, in the county of Northumberland, where the Scots were defeated in 1415, by Sir Robert Humprevill and the earl of Weftmoreland. Near it is a mountain called Yevering Bell, belonging to those called Cheviot; 6 miles W.N.W. of Wooler.

YEULA, a town of Hindoofflan, in Baglana; 5 miles E. of Bahbelong.

YERVRE LE CHATEAU, a town of France, in the department of the Loiret; 6 miles S.E. of Pithiviers.

YEW, or Elgu, in Botany. (See TAYUS.) De Theis traces thefe Engilh words, whose antiquty cannot be doubted,
doubted, to the Celtic If or Iew, green, alluding to the
evergreen foliage of this tree. The French have retained
If unaltered to the present day.

Iew, as some say, may be derived from the Greek Íëv, to hurt; and probably before the invention of guns
our ancestors made their bows of this wood: they therefore
took care to plant the trees in the church-yards, where they
might be often seen and preferred by the people.

Iew is also a term used by the falt-workers of Lymington,
and some other parts of England, to express the first
rising of a scum upon the brine in boiling.

In the places where they use this term, they add no
clarifying mixtures to the brine, for it ferments in the cisterns,
and all its foulefs sinks to the bottom in form of a
thin mud; they admit only the clear liquor into the pan,
and boil this briskly till it yews, that is, till a thin skim of
falt appears upon its surface; they then damp the fire, and
carefully skim off this film, and clear only the scratch or
calcareous earth, which separates to the bottom.

They do not collect this into scratch-pans, as at many
of the other works, but they rake it up to one side of the pan,
and take it out; they there add a piece of butter, and con-
tinue the fire moderately strong till the salt is granulated.
They keep a brisker fire on this occasion at Lymington
than in most of the other works; so that they will work three
pans in twenty-four hours. See Salt.

Iew-Tree, in Agriculture and Rural Economy, a well-
known evergreen tree, the timber of which is much esteemed
for different uses and purposes in husbandry, and where
toughness, elasticity, and durability, are required.

Trees of this fort may be easily propagated, in moist cafes,
bysowing their berries when divested of the pulp in au-
tumn, as soon as they are ripe, upon a bed of fresh undun-
ged foil, either over the whole or in drills, covering them
over about half an inch thick with the fame earth: but
the latter is the better mode. In the spring, the bed must
be carefully cleared from weeds, and if the season prove
dry, it will be proper to refresh it with water now and
then, which will promote the growth of the seeds; many
of which will come up the same spring, but others will re-
main in the ground until autumn or spring following; but
when the feeds are preferred above ground till spring before
they are sown, the plants never come up till the year after,
so that by sowing the seeds as soon as they are ripe there
is often a whole year savéd.

The plants, when they come up, should be kept con-
stantly well cleared from weeds, which, if permitted to
grow amongst them, would cause their bottoms to be
naked, and frequently destroy the plants when they con-
tinue long undisturbed.

In this bed, the plants may remain two years; after
which, in autumn, there should be a spot of fresh undun-
ged foil prepared, into which they should be removed about
the beginning of October, planting them in beds about four or
five feet wide, in rows about a foot asunder, and fix inches
distant from each other in the rows, observing to lay a little
litter or mulch upon the surface of the ground about their
roots, as also to water them in dry weather until they have
taken root; after which they will require no farther care,
but to keep them clear from weeds in summer, and to train
them according to the purpose for which they are defiged,
—for timber in a straight manner.

In these beds they may remain two or three years, ac-
cording as they have grown, when they should again be re-
moved into a nursery, placing them in rows at three feet
distance, and the plants eighteen inches asunder in the rows,
obseving to do it in the autumn, as before directed, and
continue to trim them in the summer for what they are in-
tended; after they have continued three or four years in
this nursery, they may be transplanted where they are to
remain, always obseving to remove them in autumn where
the ground is very dry; but on cold moift land it is better
in the spring.

These trees are very slow in growing, but there are many
very large trees upon some barren cold soils.

It is observed in the Gloucefhire Report on Agriculture,
that the yew-tree should not be suffered to grow in or
near cow-pastures. The leaves are poisonous to horned
cattle and horses, though the berries are esteemed inoffen-
vive. In January 1825, in confquence of some fences
being broken down by a violent wind during the night, a
number of cows belonging to a farmer in Sandhurst entered
an inclosed shrubbery, where there were many yew-trees
growing, and continued in it till the morning. Soon after
they were driven out, all of them were seized more or
less with a kind of madness, or such acute pains as made
them run about in a very furious manner, sometimes leaping
to a considerable height, then beating their heads against
whatever opposed them, and at last falling instantly dead.
Oftentimes different forts were poured down their throats, as
there was an opportunity of securing them, which seemed
to produce a good effect on some; but notwithstanding
every effort, nine out of thirty died in a few hours after
they were discovered. On their being opened, it appeared
that the whole quantity they had eaten, put together, would
not have filled a peck.

An opinion prevails, that the leaves are not poisonous in
the summer: this, however, is probably erroneous, at least
it is not confirmed sufficiently by fact to justify the farmer
in subjecting his cattle to the experiment. If cattle come
within reach of the yew-tree at that time of the year, they
may perhaps reject it altogether, giving the preference to
other green food, more palatable, and in plenty around
them.

These trees should therefore in all cafes be carefully kept
out of the hedge-rows and all other parts of fields, where
cattle are suffered to feed and pasture.

YEVEAPOUR, in Geography, a town of Hindooftan,
in Lahore; 16 miles S. of Nagorcote.

YEZD, or Yezd, a large and populous city of Perfia,
situated in a sandy defert, contiguous to a high range of
mountains running nearly E. and W. This is the grand
mart between Hindooftan, Bucharah, and Perfia; and is,
therefore, a place of considerable trade. The bazaar is
well supplied, and the city contains 20,000 houfes; besides
thefe of the Guebres, or worthippers of fire, which are eli-
minated at 4000. The Guebres were an induftrious people,
but are greatly oppressed, being taxed at twenty piâfres a-
head, in addition to the various other exactions of the Per-
ftian government. Many opulent Hindoes formerly refided
here; but the late governor, wishing to enrich himself by
plundering their property, they all fled in one night to-
wards Candaar, where they have since estaakihed them-
ftelves. The present khan has, in vain, endeavoured to re-
call them, and there are now only nine Hindoes in Yezd.

The city imports the greatest part of its corn from the
neighbourhood of Ifpahan. Cattle are all scarce, and an
afs will sometimes fall as high as fifty tomans. The ma-
ufacture of filk tilfs is inferior to any in Perfta; and the
numuds or thick felts of Tuft, a small village, distant eight
miles, are equally famous. The fort of Yezd has but a
mean appearance; and the town is defitute of a wall.

That
YEZEĐERDÍC Year, in Chronology. See Per-

That territory which lies between Yezd and Ipahan is the most arid part of Irak. The soil is poor, light, and sandy; and here is a general scarcity of water: the climate also is hot, though not unhealthy. The small towns of Arditián, Nair, Anjutah, and Sezabad are badly built, and contain from 100 to 200 houfes each. M'Kinneir's Persia.

YEZÉDIČAN, in Geography, a river of the Persian empire, in the province of Azerbaijan, which has its source about 60 miles to the E. of the lake of Van, and which, pursuening a N.E. course, paffes under the walls of Yezdican and Kurs, and meets the Araxes a little to the N. of Nuch-

YEZÉDI, the name of a Perián sect, of which several tribes inhabit the mountains of Sinjar, about eight or ten miles from Nisibis. They are numerous in the vicinity of Moful, and are faid to worship, or rather deprecate, the devil, entertaining an idea that he poifles an unlimited power over mankind. They even diflike to hear the name of the evil spirit mentioned in their preference. They are the defendants of those Arabs who followed the banners of Yezid, and fought against Houfein, in the battle of Ker-

YEZNE, or Ynca, a city of Peru, in the province of Ayacucho, situated near the mouth of a fresh-water river of the fame name, which is dry from the beginning of Oc-

YEZNE, or Ynca, an appellation anciently given to the kings of Peru, and the princes of their blood; the word fingifying literally, lord, king, emperor, and royal blood.

The king himfelf was particularly called capas yncas, i.e. great lord; his wife, palas; and the princes feimply yncas. These yncas, before the arrival of the Spaniards, were exceeding powerful. Their people revered them to excels, as believing them to be fons of the fun, and never to have committed any fault. If any perfon offended the royal majesty in the fmallet matter, the city he belonged to was totally demolished.

When they travelled, whatever chamber they lay in on the road was walled up as soon as they departed, that nobody might ever enter in after them. The like was done to the room in which the king died; in which, likewise, all the gold, silver, and precious furniture, were always im-

YOAK, in Agriculture. See Yoke, and Yoking.

YOAK, Jugum, in Antiquity. The Romans made the enemies they subdued pass under the yoke, which they called sub jugum mittere; that is, they made them pass under a yoke in the fatigue of furca patibulares, or galloves, consisting of a pole, or other weapon, laid across two others planted upright in the ground. This done they treated them with humanity enough, and sent them home again. See Furca.

The same measure was sometimes dealt them by their enemies upon the same occasion. Thus Caesar (lib. ii.) observes, that the consul L. Cassius had been killed by the Swifs, and his army defeated, and made to pass under the yoke.

YOAK of Land, jugata terre, in our Ancient Custums, was the place which a yoke of oxen, that is, two oxen, may plough in one day. See Hide, Yard-Land, &c.

YO-CHIN, in Geography, a town of Corea; 10 miles N.E. of Han-tcheou.

YOCKET. See Jockey.

YOCOM CREEK, in Geography, a river of Virginia, which runs into the Potomack, N. lat. 38° 6'. W. long. 76° 36'.

YOCOTE, a town of Hindooftan, in Dowlatabad; 27 miles S.S.W. of Mahr.

YOGESWARA, in Hindo Mythology, a name of the Hindo god Siva; which see. It means lord of ages, or of time; yog, or yog, being vale periods of time into which Hindoo chronologists arrange the past. The addition of Ifwara, the powerful, a name of Siva, seems to give a satisfactory derivation. (See Iswara.) For an account of those periods, see Jougues. Some have derived the name of Yogeswara from lord of yogis, supposing the sect of fanniified beggars so designated as being more immediately under the protection of Siva; but this is in fact nearly the same thing, for yog signifies union or junction, and these periods of time unite all things in the Deity; and the Yogi by intense contemplation effects a similar union. But this metaphysical dogma cannot be explained here. See Kalpa, Yog, and YUG.

YOGI, a description of wandering faits, much repected by many of the natives of India, though by others they are strongly suspected to partake more of the impostor than the enthusiastic. There are many descriptions of these itinerants among the Hinduos; and we are not aware that the distinctions between them have been accurately pointed out. The appellation Yogi means a devout man, devoted to spiritual things, especially to the contemplation of the attributes of the Deity. It is derived from yog or yug, which, among many very significations, means primarily union or junction, and is applied in this sense to one who by intense meditation is united to the divine nature; a mystic in early understood by the initiated and enthusiastic Hindoos, though not recognizable by others. There is a difference, we believe, between the Yogi and Sannyfly, but we cannot exactly say in what it consists. In the latter part of the article SECTS OF HINDOOS, some particulars of these two will be found. Perhaps the Yogi may be the designation of the Vaihnava, and Sannyfly of the Saiva sect. (See Saiva, Vaihnava, and Yogeswara.) Both profess poverty, purity, and austerities. When the latter are carried to any extent, the zealot is honoured with the title of Tapävati, of whatever sect he be. Of such, and their austerities, fee under Tapas.

We sometimes read of female anchorets denominated Yogini; but they are, we believe, merely enthusiastic females, who become ascetics and not the wives of the sanctified males. Among the oriental manuscripts presented to the Royal Society by sir W. Jones, is one entitled "Hatha Pradipaka, or Instructions for the Performance of the religious Discipline called Yoga."

In the Gita, Krishna describes the Yogi as being "more exalted than the Tapävati, the zealot who hurstrily himself in performing penances: he is exalted above the learned in science, and superior to those attached to moral works." This passage is quoted in the latter part of our article SECTS OF HINDOOS, but being erroneously pointed is scarcely intelligible. This article being thence referred to, we take the opportunity of correcting another error or two in it:—In the second column, the name of the Mahrratta Brahman general, Purferam Bhov, is twice spelled Bhon; in the fifth column, the name of Vopadeva, the author of the Sri Bhagavata, is spelled Vapadeva; in the next column, line 21 from the bottom, a comma is wanted after Krishna. Having referred above to the article Tapas, we will here correct an error in that also:—In second column, line 11, for inflexions read inflections.

YOHOGANY, in Geography. See Youngogany.

YOIDES, in Anatomy, the bone of the tongue, commonly called hyoides. See Hyoides.

YOIGT, or joint, in Geography, a town of France, in the department of the Rhone and Loire; 7 miles E. of Roanne.

YOITSBACH, a river of Silesia, which runs into the Queis, near Friedberg.

YOKE, in Agriculture, a frame of wood hollowed out and lined for receiving the neck part of the ox or other cattle in working. Yokes are constructed in different manners, as single and double, in order to be used differently. They are fixed with bows over the necks of the oxen or other cattle when in use; by which means, in the latter fort, the two animals are coupled together, and attached to the plough or other vehicle. See Yoking.

YOKE, in Sea Language, a name formerly given to the tiller, when communicating with two blocks or sheaves affixed to the inner end of the tiller. It is now applied to a small board or bar which fits on the upper end of a boat's rudder at right angles, and having two small cords extending from its opposite extremities to the stern-sheets of the boat, by which it is steered as with a tiller.

YOKED LEAF, in Botany, folium conjugatum, or binatum. See Leaf.

YO-KEOU, in Geography, a town of Corea; 38 miles S. of Haimen.

YOKING, in Agriculture, the practice of putting the animals into the yoke or other fort of team.

In the buffoon of yoking or harnessing oxen for the purpose of draught, different methods have been followed by different farmers. And the modes of harnessing and yoking oxen are even different in different counties, and districts of the same county. The most common practice in the southern parts of this kingdom, is that of working them in harness in the manner of horses; while in the northern counties, the yoke and bows are still much employed. On the continent, as in France, Portugal, &c. the head is the part to which the draught is chiefly attached.

In the first case, the shoulder is made the principal point of draught; but in the second method, the neck and shoulder conjointly have the weight of the draught; and in the last mode, the principle of draught is, in one case the head, and in the other the upper part of the neck and hafe of the horn, which lord Somerville has considered a purchase as great perhaps as can be given to the animal.

It is "effecte by a long leathern strap, wrapped round the
YOKING.

The base or bottom of the horns, and again fastened to the yoke. It has been observed by a writer in the ninth volume of the Agricultural Magazine, that with respect to the second method which has been noticed above, the "usual form of the yoke is a frame of wood fitted over the necks of the oxen, by which they are coupled, and harnessed to the plough. It consists of several parts, as the yoke properly so called, which is a thick piece of wood, lying over the neck; the bow, which compasses the neck about; the flitchings and wreathings, which hold the bow fast in the yoke, and the yoke-ring and ox-chain," which is supposed "a method which is evidently founded on a total mistake in the anatomy of the ox."

And that in the first we have "imitated the gear used with the horse, without considering that the strength and agility of the ox are placed by nature in a different situation. The neck of the ox is a tower of strength; if the yoke is well fitted, he projects part of his form with that prodigious muscular force with which nature has provided him for his own defence; but without attending to her operations, we impose a load of timber on his withers, we lacerate his flesh, and press him down to the earth."

The third or French mode of yoking is thus described in the words of Mr. Hughes. "The labourer passes a piece of wood, of about one-fifteenth of the weight of the English yoke, across the forehead of his cow, having previously neatly hollowed out the extremities of it to fit the mould of the head, and lined those hollows with a piece of woolly sheep-skin, to answer the purpose of a soft pad or cushion. This light and easy yoke he braces to the horns with a small thong of leather, attaches the beam of his plough to the middle part of it, and the animal is completely equipped for his labour."

It has been observed by Lord Somerville, in his Sytem of the Board of Agriculture, that oxen, "whether worked in harness, or in the yoke and bow, as in England, by the joint power of the yoke and horn, as in Portugal, or by the head, as in France, they cannot fail to benefit their employer. As, however, the yoke and bow have prevailed for a considerable length of time, it is probable that the practice may still prevail, in which case the Portugeuse mode of draught will apply with the utmost ease and success to our yoke and bow, so as gradually and imperceptibly to cheat oxen into its use. This in itself is an obvious advantage, because it gives two points of draught instead of one, and thereby relieving each animal of one part of the weight."

"It would be almost superfluous to remark that the strong points of an ox are in his head and neck. It is ordained by nature, that where the strength of an animal lies, there he will resort for defence; the horse to his heels, the man to his arms, and the ox to his head; and in cases of the greatest exertion, the beast ever puts his nose close to the ground."

In objection to the harnessing of oxen, it has been observed in the paper noticed above, that "the article of gear is an oppressive annual charge, from the perishable nature of the commodity employed." The tackle there recommended for twelve oxen would not amount to five-and-thirty shillings, whereas the leather harnes for the fame number of animals, according to the new method, would cost five-and-thirty pounds, and the annual expense of repairs would exceed thrice the original cost of the former." And that "by the French mode of yoking, at least one-third more of the power of the animal is obtained. In the common way, the shoulder being bruised by the unyielding bow, no vigour is exerted, excepting what is imparted by the goad; and the shoulders of the neck are not brought into employment; hence the sublime and gigantic force with which he is endowed is not rendered subservient to the important duties he has to perform for the supply of human subsistence. The cattle proceed in the French team bold and erect; no pain oppresses them, and they chew the cud cheerfully as they pace along the furrow. On the contrary, in this country the painful pressure obstructs the progress of the animals, they lean against each other, scarcely capable of supporting their own weight, and the fine intelligent eye which nature has given them to express the generosity of their temper is clouded with anxiety." That "the trial of this method has at least two recommendations; it may be made at very little expense, and under the fair expectation of success."

The methods of yoking cattle in ploughs are also different in different places; but the only circumstance worthy of being considered is, whether the cattle should be yoked in pairs, or in a line before each other. It may, therefore, be useful to consider the advantages and disadvantages attending each mode, and to compare them.

The most common way of yoking cattle in ploughs is in pairs. There are some disadvantages attending this way that are obvious. In ploughing the furrows betwixt ridges, the land-cattle go upon the ploughed land, and tread it down with their feet: this, especially if the land be wet, poaches and hurts it very much. And there is another disadvantage which is very obvious. When there is but as much of the ridge unploughed as to allow the land-cattle to go upon it with difficulty, they are frequently either going into the opposite furrow, and thereby giving the plough too much land, or, which is worse, they are jollying the furrow-cattle upon the ploughed land.

In order to remove the inconveniences which attend the ploughing with cattle yoked in pairs, some yoke them in a line before each other. It is obvious, that cattle yoked in this manner, going always in the furrow, neither tread upon the ploughed land nor jolli the one another. In these respects, the yoking the cattle in a line before each other seems to have the advantage. It is to be observed, however, that this method is not quite free from inconveniences. When examined, it may, perhaps, be found attended with as great inconvenience as the other. Where cattle are yoked in a line, they go all in the furrow. This makes it necessary to give the plough more land than ordinary, either by the scon or the muzzle; for if this be not done, the head and scon being in the same direction with the beam, and the cattle yoked to the middle of it, the plough will directly follow the cattle without taking any thing off from the land. Now it is inconvenient to be obliged to give the plough land either by the scon or muzzle; for when the scon is turned out of the plane of the beam, it makes the plough heavy to draw; and when the muzzle puts the draught too much to one side of the beam, it prevents the plough from going upright. The yoking of the cattle in pairs is attended with none of these inconveniences; for in this case, the quantity of land which the plough has naturally, when right made, is sufficient to make it take off a proper furrow.

There is another inconvenience that attends yoking cattle in a line, arising from the nature of the animals, which is, that as they like their eafe, they are disposed to throw the burden upon their fellow. This they have a better opportunity of doing when yoked in a line before each other than when yoked in pairs. When yoked in a
line, each pulls by the traces of the one behind him; and therefore, though it may be known when the foremost neglects his work, by the slackening of his traces, it cannot be known when any of the rest neglect their work; for though one of them does this, yet by the pulling of the one before him his traces may be fully stretched. But this is easily discovered when the cattle are yoked in pairs; for then every one of them has a separate draught.

There is still another inconvenience that attends the common way of yoking cattle in a line before each other. When the fore cattle are all yoked to the traces of the hindmost, it is obvious, that as the beam to which the draught is fixed is much lower than his shoulders, by which the red pull, such a weight must be laid upon his back or shoulder, as must render him incapable of giving any assistance. Besides, as the whole force is applied in the direction of the traces of the hindmost, it cannot have such influence on the plough, as when a part of it is in a direction more horizontal. When a body is to be moved forward in any direction, the nearer that the direction of the force applied approaches to the direction of the body, it acts with greater influence; and, therefore, as the plough moves horizontally, and as the direction of the unyoked draught of a plough with the cattle yoked a abreast is more horizontal than the direction of the draught in a plough with cattle yoked in a line, the same force applied will have greater influence.

When these two different ways of yoking cattle in ploughs are thus considered and compared together, it is difficult to determine which ought to be preferred. Each of the two seems preferable to the other in a certain situation. When the land is stiff, and the labour severe, the yoking the cattle in pairs seems preferable, as it is certainly the strongest draught; and when the land is wet, and in danger of being much hurt by the treading of the cattle, the yoking them in a line before each other seems preferable; as thereby they are confined to the bottom of the furrow, which is the firmest part of the land, and prevented from doing harm.

In wet lands and seafords, as long teams answer best, for the most part, collars and trace-chains become of considerable utility in most cafes in yoking of cattle; and in whichever way neat cattle are geared for work, they should constantly have bridles or bit-halters, with blinders, as by such means they are rendered docile, tractable, and easy to manage in the business of team labour. Much information on this subject may be seen in the Corrected Report on Agriculture for the County of Suffolks.

YOKULS, in Geography, the highest mountains in Iceland, perpetually clothed with snow. Of these, Snæfells, hanging over the sea on the S.W. part of the island, is said to be the highest, its height being computed at 6860 feet. The mountains are said to be chiefly sandstone, pudding-stone, with petroflex, slate, and argillaceous schistus.

YOLK, or YELK, in Natural History, the yellow part in the middle of an egg. See Egg.

The chicken is formed out of and nourished by the white alone, till it be grown to some bulk: after which the yolk serves it for nourishment; which itlikewise does, in part, after it is hatched. For a good part of the yolk remains after exclusion; being received into the chicken's belly: and being there reserved, as in a florihoue, is by the ductus internalis, as by a funnel, conveyed into the guts, and serves instead of milk. Willughby's Ornithol. lib. i. cap. 5.

This was even known to Pliny:—"Ipsum animal ex albo liquore ovi corporatur: cibus ejus in luto coctu." Lib. x. cap. 53.

Yolk, in Rural Economy, the peculiar munificent secretion which exudes through the flanks of sheep, and which by intermingling with the pile of the wool renders it soft, pliable, and in proper condition. It has somewhat the same effect on it which oil has upon a thong of leather, when kept in and perfectly faturated with it. The disposition to the production of this sublimate in sheep is favourable to the valuable properties of the wool, and should be attended to by the sheep-farmer in fixing and regulating his flock. It is noticed by a late writer on Agricultural Chemistry, that wool often washed in calcareous water becomes rough and more brittle than usual, as the carbonate of lime has the power of diffusing or decoloring the yolk of it, which is an animal foap that naturally defends it; that the finest wool, such as that of the Spanish and Saxo sheep, is most abundant in yolk; that M. Vauguelin has analyzed several different species of yolk, and has found the principal part of all of them a foam, with a basis of potassa, that is, a compound of oily matter and potassa, with a little oily sublimate in excess; and that he has likewise found in them a notable quantity of acetate of potassa, and minute quantities of carbonate of potassa and urine of potassa, and a peculiar odorofous animal matter.

The same chemical writer has stated, that he found some specimens of wool lofe as much as forty-five per cent. in being deprived of their yolk; and that the smallest loss in his trials was thirty-five per cent.

It is fuggelled in the above work, that the yolk is the most useful to the wool on the back of the sheep in cold and wet seasons; and that probably the application of a little foap of potassa, with excels of grease, to the sheepl brought from warmer climates in our winter, that is, increasing their yolk artificially, might be useful in cafes where the fineness of the wool is of great importance. A mixture of this fort is more conformable to nature, it is thought, than that ingeniously adopted by the late Mr. Bakerwell; but that at the time his labours began, the chemical nature of the yolk of wool was not known. See Wool, Washing Sheep, &c.

Yolk of the Seed, Vitellus, in Botany and Vegetable Physiology, a part first described by Gærtner, and thus named by him, from its supposed analogy with the yolk of an egg.

This analogy, and even the existence of the part in question, have been disputed, as Mr. Brown hints, in Prodr. Nov. Holl. v. 1. 305, by M. Correa de Serra, and by the writer of the present article. We have never at any time communicated on this subject with our learned and sagacious friend, nor the Portuguese minister at New York; so that we are ignorant how far his objections extend, or on what they are founded. Nor does Mr. Brown know more of this matter, than a simple record of M. Correa's opinion, in De Candolle's Flore Frangaise, v. 1. 157. This coincidence, however, from such a quarter, gives us great confidence in our own opinion, which was first offered to the public in Intro. to Botany, chap. 19, published in 1807. On a more attentive and full consideration of the question, the same sentiments were more explicitly detailed and defended in a paper read before the Linnean Soc. Nov. 3, 1807, and printed in that Society's Tracts, v. 9. 204.

Gærtner states the Vitellus, or Yolk of the Seed, to be "difficult from the Cotyledons, as well as from the Albumen, and for the most part situated between the latter and the Embryo." (See Seed, where a reference is made to Vitellus, under which lead the substance of the present article was
The presence or absence of a particular organ is so characteristic of the plant in question as to be regarded as a specific or diagnostic feature.

**Yolk.**

Gartner considers the part of which we are about to treat, as "of all the internal parts of a seed the most singular, and by far the most unfrequent." Its importance therefore cannot be very considerable. The principal diagnostics of the *Vitellus*, according to this eminent botanist, are the following: 1st, "It is most closely connected with the Embryo, so as not to be separable therefrom, without injury to its own substance." 2dly, "Notwithstanding this intimate connection, it never rises out of the integuments of the seed, as the Cotyledons usually do, in germination, so as to become a feminal leaf; but, rather like the *Albumen*, its whole substance is destroyed by the feeding plant, and converted into its own nourishment. And 3dly, If the *Albumen* be likewise present, the *Vitellus* is always situated betwixt that and the Embryo, in such a manner, however, that it may be separated from the *Albumen* with great ease, and without injury." For these reasons, Gartner considers the organ in question as "allied on the one hand to the *Albumen*, on the other to the Cotyledons," but truly distinct in nature from both.

We presume to dissent from this decision of the great writer, whose words have just been quoted, for the following reasons: 1st, The *Vitellus* is certainly not more closely connected with the Embryo than the greater number of Cotyledons, as, any person may find by examining seeds in the first stage of their germination, and as the faithful delineations of Gartner himself every where shew. 2dly, That the *Vitellus* never rises out of the ground, is a circumstance likewise common to many Cotyledons, allowed by Gartner to be such, as in various leguminous plants, as well as in *Resedus*, *Cyamus*, *Tropoolum*, and many others. The difference between Cotyledons which grow up into feminal leaves, and those which remain and decay under ground, is of so little importance as to the classification of plants, that the most natural order of *Papilionaceae*, or Leguminose, contains decided instances of both; *Lupinus* and *Vicia* affording examples of the former mode of growth, *Lathyrus* of the latter. And 3dly, The situation of the *Vitellus*, between the *Albumen*, if the latter be present as a separate organ, and the Embryo, is only a necessary consequence of the more intimate connection between the *Vitellus* and the Embryo, than either of them has with any other part, except that of the Cotyledons and Embryo, which is as strict as can possibly be. Hence we cannot consider the *Vitellus* of Gartner to differ from the subterraneous Cotyledons above-mentioned. We presume their offices must be exactly similar, to perform the necessary functions relative to air or oxygen, till the leaves come forth, and assume those functions in greater perfection, with the co-operation of light. This appears to us more satisfactory than the hypothesis of Gartner, that the organ of which we are treating affords nourishment to the *Embryo*; because this is abundantly supplied by the copious *Albumen* of a multitude of seeds, whole *Vitellus* is very inconsiderable, such as grapes; and it is recurring to two causes to explain what is evidently accounted for by one alone. If the vegetation of corn be observed, the *Vitellus* will be found to dwindle away, with scarcely any change in its very inconsiderable bulk, when the first leaves are unfolded, exactly as happens to the subterraneous Cotyledons of *Lathyrus odoratus*, &c. The same thing very often takes place as specifically in Cotyledons which rise out of the ground. Some which are more permanent, as in crucifom and umbelliferous plants, being only more of the nature of leaves. In grapes, the scale taken by Gartner for a *Vitellus* is mostly so thin and unsatisfactory, as not possibly to contain any material portion of nourishment; ample supplies of which are furnished by the plentiful *Albumen* of those plants. But its expanded figure is very well calculated, like that of these leaves, for honourable analogous to vegetable respiration; and it has the evident aspect of a subterraneous leaf, quickly rendered superfluous by the production of real leaves, and withering away, as the first of those leaves themselves do, when more vigorous ones come forth. It is remarkable, that the real *Vitellus* appears not to be necessary to all plants furnished with this distinct kind of *Albumen*, as *Palmes* and *Orchideae* have it not; while, on the other hand, no influence presents itself of a supposed *Vitellus*, and a real Cotyledon, or Cotyledons, in the same plant. Gartner takes the *Plamula* for Cotyledons in *Rhizophora* (see his t. 45.), as well as in some of the *Scitamineae*; for we cannot conceive the tubular part, embracing the Embryo, in *Anomum*, (see Gart. t. 12, which he erroneously calls *Zingiber*), to be any thing but a Cotyledon, notwithstanding the opinion of our learned friend Mr. Brown, who, like Gartner, terms it a *Vitellus*. The name would be of little importance, if the supposed use of it did not convey, as we presume to think, an erroneous idea; in attributing to these seeds two distinct and separate sources of nourishment. That two such distinct parts exist in this natural order, and perhaps, as Mr. Brown observes, in *Nymphea* and *Nuphar* likewise, we are ready to admit; and we are therefore more satisfied to attribute to each a separate and appropriate office. We have had no opportunity of observing the germination of *Anomum*, or any true scitamineous plant; but as far as we have been able to judge, it appears that the *Albumen* of every seed, when separate from the other parts, is always totally absorbed, or removed, leaving its skin empty; whereas a Cotyledon withers and shrinks in its whole substance, like a decaying leaf. If the albuminous matter, necessary for the temporary nourishment of perhaps every seed, in one form or other, be lodged in the substance of the Cotyledons, as in *Zuma*, the leguminous and cucurbitaceous tribes, and many others, such parts shrink the more, but do not lose any one particular portion of their substance, so as to have only a skin left behind. Perhaps a confusion of ideas has arisen, from the first consideration of this subject, in consequence of the term monocotyledonous as contrasted with dicotyledous. The first had an evident reference to the *Albumen*, in corn, palms, &c.; and when Gartner had emancipated himself from this error, he seems to have transferred the idea to the Embryo, which he calls monocotyledonas, as if he meant by that word to express its own simple form. Prepossessed with this idea, when a separate organ manifested itself, as in the *Scitamineae*, he thought a new appellation requisite. Mr. Brown objected to the term COTYLEDON in this cafe, because he says there is no point of union between the part in question and the Embryo. If such be the case, which we cannot understand, it would be not at all less difficult to conceive how this part could, as a Vitellus, supply the Embryo with nourishment, than it would be to imagine how it could perform any services towards that organ with respect to air, in its capacity of a Cotyledon.

It seems to us, that by considering the *Vitellus* of Gartner as a Cotyledon, all ambiguity respecting the anatomy or component parts of any feed is removed. When the Cotyledons are two or more, the albuminous matter is either lodged in their substance, or forms a separate part. In the latter case, it has no more connection with the Embryo than is absolutely necessary, being in fact not an organic part, but a mere rerervoir of food or nourishment, immediately undergoing a chemical change, after which its whole substance is speedily absorbed. Such is the economy of corn and palms; even the large *Albumen* of the cocoa-nut foam-die, appearing,
appearing, for the evolution and fulfulness of the little Embryo, lodged in a cavity of its bafe; while the Cotyledon of the not very diﬁant genus Zania shrinks indeed considerably, from losing the albuminous part of its fulfulness, but does not disappear; because the remaining part deﬁned to perform the essential ofﬁce of a Cotyledon, repelling air, merely decays when its purpoee is anwered, and Foughs off, like any other dead portion of the vegetable body.

We have already (see Germination) adverted to these two different situations of the albuminous matter. That fulfulness must be present, in some shape or other, for the nourishment of the young Embryo, at the ﬁrst period of its evolution, when so great an alteration of bulk takes place, till it can supply itself from the earth. The idea of this nutritious fulfulness, whether of an oily, mucilaginous, or farinaceous nature, being always, when not a distinct body, lodged in the Cotyledons, throws additional light on the nature and physiology of the last-mentioned parts, and in a very beautiful manner conﬁrms their analogy with leaves. The tap of plants (see Circulation of the Sap) being carried into the leaves, and there acted upon by air, light, heat, and moisture, is returned in the form of various effusions, into the different parts of the vegetable body. Under the inﬂuence of light, the upper surface of their leaves absorbs carbonic acid gas, and the under gives out pure oxygen. But in the dark, leaves absorb oxygen. So the Cotyledons of seeds, in their dark subterraneous situation, being moreover often guarded expressly from light by a brown or even black skin, absorb oxygen, which, as we have said in the article above cited, is known to be necessary to germination. They are already ﬂored with albuminous matter, abounding with the carbonic principle. This, by the action of oxygen, becomes saccharine and milky, ﬁt to be transmitted, through the returning vessels, which the Cotyledons, in common with Leaves, poffefs, into the item of the Embryo; all these important parts having already begun to swell, from the absorption of moifure, and the stimulating effects of heat. Hence we fee why light proves hurtful to incipient germination, and why carbonic acid gas may be given out by feeds during that process. It is evident that the proper functions of Cotyledons are best performed under ground, and that when they rife into the air and light, it is not till after their primary deﬁnation is fulﬁled, and then only because, being fundamentally of the nature of leaves, they are mostly capable of assuming the functions of those organs, with respect to light. Cotyledons of seeds are subterraneous leaves, just like the scales of a bulbous root. Both are ﬂored with albuminous or nutritious matter, and when acted upon by oxygen perform under ground those functions, which leaves perform in the open air, with the afﬁnity of light. It is worthy of notice that the Cotyledons are fo placed, in all feeds, that the oxygen gas must be imbibed by their under surface only, that very fame part which, in leaves, gives out this kind of gas during the day, and probably absorbs it at night. “It would,” as we have elsewhere observed, Tr. of Linn. Soc. v. 9. 213, “have evinced a strange contrariety in the constitutions of two organs otherwise fo analogous, the Leaves and Cotyledons, if the upper surface of the latter, while in the unexpended feed, had been preterted to receive the oxygen gas.”

By taking the Vitellus of Garner for a Cotyledon, we throw no new diﬃculties in the way of the classiﬁcation of plants by this organ. Its form is always, as far as we know, simple and undivided, so that the plants in which it occurs remain only the more steadily ﬁxed in their place of Monocotyledones, as opposed to the Dicotyledones; witnesses Gramina, Sattamine, &c. thus indeed acquiring a right to such an appellation, which they could otherwise barely claim, having, according to Gartner’s principle, no Cotyledon at all.

Yolotou, or Yulduz, or Cyalis, or Chialybl, in Geography, called by the Turks Kerathers, or the Black City, a town of Little Bucharia, situated in a country abounding with springs and ﬁne meadows; 85 miles N.N.W. of Hami.

Yom-Nim-Kien Hotun, a town of Chinefe Tartary, on the E. coast of the gulf of Leao-tong; 263 miles E. of Peking. N. lat. 40°. E. long. 121° 34'.

Yom-Ta-Hotun, a town of Corea; 648 miles E.N.E. of Peking. N. lat. 42° 55'. E. long. 129° 37'.

Yon, a river of France, in the department of the Vendeé, which pails by La Roche fur Yon.

Yonghelahè, a river of the island of Madagascar, which runs into the sea on the west side of the island, S. lat. 23° 30'. E. long. 47° 4'.

Yong-Li, a town of Corea; 30 miles S.E. of Koang-teou.

Yong-Ngan, a city of China, of the second rank, in Quang-fu; 1027 miles S.S.W. of Peking. N. lat. 24°. E. long. 110°.

Yong-Ngao, a small island near the coast of China, in Quang-tong; 20 miles S.S.E. of Mascao.

Yong-Ning, a city of China, of the ﬁrst rank, in Yun-nan, on the borders of Thibet. A little to the E. of this town is a lake; 1005 miles S.W. of Peking. N. lat. 27° 50'. E. long. 100° 24'.—Alfo, a city of China, of the second rank, in Quang-fu; 977 miles S.S.W. of Peking. N. lat. 25° 6'. E. long. 109° 14'.

Yong-Ning, or Yung-ning, a city of China, of the second rank, in Koei-teou; 1027 miles S.S.W. of Peking. N. lat. 25° 55'. E. long. 104° 57'.

Yong-Pe, a city of China, of the ﬁrst rank, in Yun-nan; 1150 miles S.W. of Peking. N. lat. 26° 42'. E. long. 100° 34'.

Yong-Ping, a city of China, of the ﬁrst rank, in Pe-tche-li, on a river which runs into the gulf of Leao-tong. This city is advantageously situated, but its jurisdiction is not very extensive; it contains but one city of the second order, and ﬁve of the third. It is environed by the sea, by rivers, and by mountains, covered for the most part with ﬁne trees: this makes the country less fertile, but the neighbouring bay supplies its want with great plenty of all the necessaries of life. Not far from this city ﬂands a fort named Chun-hai, which is the key of the province of Leao-tong. This fort is near the beginning of the great wall, which is built, for a league together, in a boggy marsh, from the bulwark in the sea; 113 miles E. of Peking. N. lat. 30° 55'. E. long. 118° 34'.

Yong-Sin, a town of Corea; 113 miles E. of Hanzhong.

Yong-Tchang, or Yong-Tchang, a city of China, of the ﬁrst rank, in Yun-nan. This city is large and populous, and is built in the midst of high mountains, on the borders of the province, in the neighbourhood of a savage people, whose genius and manners the inhabitants of this country partake of. The country produces gold, honey, wax, amber, and a vast quantity of ﬁne silk. It has within its districts one town of the second order, and two of the third; 270 miles S.W. of Peking. N. lat. 25° 6'. E. long. 99°.

Yong-Tcheou, a city of China, of the ﬁrst rank, in Hou-quang; 882 miles S.S.W. of Peking. N. lat. 26° 10'. E. long. 111° 15'.
YONG-TONG, a town of Corea; 40 miles E. of Het-Ain.

YONI, in Metaphysics, the name of a mysterious symbol among the Hindoos, which, although contemplated with respect and awe by that superstitious race, is yet of such a nature as not to be discussed without difficulty in the living language of a country which has happily shaken off the trammels of priestcraft; and views with pity, mixed with just abhorrence, the idolatrous propensities of those still retained in mental bondage; accompanied, as we find they were, among many ancient people, by the indecencies of impure rites, scarcely yet superseded, even in Europe, and existing in almost undiminished grossness in the still enlightened regions of Asia.

The reader is suppos'd to be more or less aware of the nature of the origo incident to the worship of such deities as Pan, Priapus, Bacchus, Venus, &c. We do not here inquire particularly into the origin of such rites. In their earlier stages, they were probably an innocent exhibition of gratitude for the experienced bounties of nature. In the East, in India, a concourse of people, both sexes, warmed by exercise and beneficent feelings, at a genial season most likely of the year, found, as is ever the case, their unreserved devotion sublimed into enthusiasm; and hurried by such feelings beyond the scope of unsifted reason, gave themselves up to the extravagances of mysticism, and in the end to excesses which not only Christians, but the decent of every sect and country must unite in reproving. These Bacchic phrenzies were accordingly suppressed or mitigated as to their oftener frivolous and tangible abominations. Nature, in the pharaeology of certain sects, was no longer propitiated through the indulgence of feelings of her own prompting, excited farther by the presence of unequivocal exhibitions. She, still perfonified, was more decently represented by certain symbols sublimated for the earlier types. The cunning priest no longer daring to exhibit their obscurities in flamboyant nudity, permitted only a portion of indecency to remain in the hands and eyes of their deluded votaries, and concealed their origin and meaning in the various mysteries and hieroglyphics denominated Bacchic, Eleusinian, Phallus, Linga, Yoni, Cone, &c. &c. Some notice of these things, and of the ordinary coarse and confusions, will be found under the appropriate articles of our work; also in MYSTERY, MYSTICS, and others thence referred to.

By such people Nature was contemplated chiefly under her attribute or property of fecundity; and symbols of generative allusion were those under which her prolific potencies were exhibited. Those prone, like the Hindoos, to resolve almost every thing into sexual allegory, of course fancied the male and female pudenda omni-arachetypal. Those, in the early days of such perverted devotion, were probably portrayed in India, as elsewhere, without reserve; but were, in most cafes, soon corrected into the comparative decency of the hieroglyphics; and the deluded people were cajoled by mummary and mystery, that became lew'd and lewd understood, and therefore, perhaps, the more revered.

We have said in most cafes; for in Egypt and Greece the grossness of Phallus is known only in the remains of antiquity; in India it doubtles exicts, but defivled of obstrue or confpicious indecility; and too true it is that among Christians was the primeval inflamy of the symbol and usages most tenacious retained. We can but just allude to the discovery of this curious though lamentable fact, by Sir William Hamilton, in the neighbourhood of Naples. His communication, with ample commentary and illustration, has been printed, but very properly not published; concealed, though not suppressed; and we therefore make no direct reference to the sufficiently instructive, though too disgraceful volume, in which this disgusting worship is proved to exist in Christian Europe, and is traced almost all the world over.

Among the Egyptians, Greeks, and Romans, the Phallus and the Cone seem to have been the earliest of the grossest and corrected emblems; the latter contained both the Linga and Yoni, nature active and passive; and similar, familiar, or recondite meanings and allusions were thus readily revived in the minds of the vulgar and the initiated, suitable to the ecstatic or poetic nature of their capacities and feelings. These follies, to give them no harsher name, thus found to have existed among the people just mentioned, and others, have, with great appearance of reason, been suppos'dly derived from the full more ancient usages of India. Much might be said in support of this, were it worth while; and thus far the inquiry will probably be repaid, that it may bring to light many fancy frames of the mind.

If such writers as Colebrooke, Wilford, Faber, and others, who bend their minds to the development and elucidation of Eastern literature and mysteries, continue for a while in the same line of research, we anticipate a confirmation of the usages long entertained, that nearly all the learning, science, and art, as well as the religion of Egypt and Greece, originated in India, or at least with the Brahms; however much they may have been improved or embellished by the hands through which they reached us.

India then, or the country of the Brahms, wherever that was, being in our judgment the region where the superstitious practices now under our consideration originated, we may expect to find its early history teeming with allusions to it. This is indeed the case; though such usages are not, perhaps, found in its earliest works on theology. But as no people have changed so little as the Brahms and their flocks by the innovations of strangers, or the lapse of time, (for frequent submissions by conquerors seem to affect them but little, and perfections ferve only to confirm their prejudices,) we may expect to find their religious institutions and practices more in accordance with those of their early days than the usages of other people who have not disdained to become wiser by the operation of reason and philosophy; and who have been taught to look on the follies of their ancestors with the pity they deserve. In India, we thus find certain hieroglyphics still receiving the external adoration to little their due. There we find the indulgent Brahms still teaching his ignorant supplicant to fall down and worship the Linga and Yoni; symbols, in whatever shape exhibited to the public eye, no doubt fitter for the brothel than the temple. The former of these is the attribute of Siva, the Maha-deva, or great divinity prevailing over reproduction, or regeneration in the abrided; and the other of his consort Devi, or Parvati, the Magna Mater, the Bona Dea of the East.

In preceding articles, we have necessarily touched on the character and attributes of the two just mentioned grand divinities of the Hindoos; and refer our readers to Parvati and Siva for our remarks thereon, and to Linga for a brief notice of the Phallic worship of India. In this article, we propose to discuss that still offered to the Juno, the Venus, the Isis, the many-named all-absorbing goddess of the Hindoos, whose emblem is the Yoni.

Writers on this subject generally, perhaps unavoidably, commix their speculations on the Linga and Yoni. Crude
YONI.

...nature is personified, and called Prakriti; she is declared to be nature, or the earth, the womb of nature; she is thence any thing conceiving or containing, or the power or fact of such faculties. In its first state that power was rather a tendency, an aptitude, and laid dormant until excited by the bija, or vivifying principle, the aura of nature personified in Siva, who in this character is called Parulha, or the primeval male. Here we find nature passive and active; the power or aptitude of nature is symbolized by the Yoni; the vivifying principle by the Linga. Prakriti is found to be one of the names and forms of Parvati, as Parulha is of Siva. Under these names we have taken some notice of their character; but it is not easy, in the short articles to which, in these matters, we must restrict ourselves, to explain fully, were we able, the nature and allusions of these abstract personifications.

The faculty or power of containing, of which the Yoni is the type, is also called Argha by Hindoo mystics. The name is given to a cup or dish, or vessel, in which fruits and flowers are offered in oblation. These vessels, they say, ought always to be boat-shaped; and so they frequently are, but sometimes round, oval, or square; mostly, however, circular. All this is mysterious and profound. The rim of the Argha is more especially the Yoni, while the contents of the vessel represent the Linga, which is sometimes more unequivocally figured by an image of Siva standing erect in the centre of the Argha. Hence one of his names is Arghanatha, or lord of the boat-shaped vessel. We may float a moment here to remark how readily Bryant, Faber, and the race of Noetics, would have recognized the ark, in the arga or arka, or ark, as it may without much licence be written, of the Hindoos. We do not hesitate to hint our belief that many of the fables connected with Colchis, Juno, Io, Ionia, Jonah, &c. are traceable upwards to Hindoo words: many also connected with the names of places or persons, beginning with Col or Kal, or containing its root, that are scattered in unmeaning profusion through the geography and early biogrophy of Europe. But this is not the place to enlarge on this subject.

The Argha, as a type of the power of conception, excited and vivified by the Linga or Phalus, Mr. Wilford (Af. Ref. vol. iii.) supposes to be one and the same with the ship Argo, which, according to Orpheus (Argon. v. xvi.), was built by Juno and Pallas; or, according to Apollonius (b. ii.), by Pallas and Argus, at the instance of Juno. The word Yoni, as it is usually pronounced, nearly resembles the name of the principal Etruscan goddes; and the Sanerkrit phrase Arghanatha Iswara seems accurately rendered by Plutarch (on Isis and Osiris), when he afferts that Oisris was commander of the Argo. That the Sanerkrit words p'kala, meaning fruit, and p'hulla, a flower, had ever the sense of phalus, is not affirmed; but as these are the chief oblations in the Argha, and are confided to be a representation of the Linga, their founds may easily have been transferred. We have seen, too, that Mahadeva himself, the prototype of the Linga, is sometimes placed erect in the Argha: this is to complete a mythical triunion of powers; for Vishnu, the principle of humidity and of conservation, is symbolized by a convexity or emblazon in the centre of the Argha, over which the image of Mahadeva, or the p'hala and p'hulla, as representing the Linga or Phallas, are placed. The idea that the Sanerkrit p'kala or p'hulla may in sense as well as found be cognate with and the source of the Greek phalx, derives strength from the fact that Mahadeva, in his character corresponding with that of Jupiter Marina, or Neptune, bears, like his Roman kinshun, a trident, called Tríphala, and sometimes Tripahla, denoting trisfacration and trisfacrecence. Jupiter Tripbylius is thus identified with the three-eyed Siva, who in this form is named Trilokan and Tríphala.

That the Sanskrit language is very widely spread, and is traceable in various dialects, we have the authority of Mr. Colebrooke for believing. In the names of places, we are inclined to think its extension is proved as much as in any point: and we do not deem the idea very extravagant (says our correspondent) that derives the name of Trafalgar, the scene of the last grand triumph of the British Neptune, from the mythological language of our fellow-subjects of India.

To return to the Yoni or Argha, we have seen that the vessel under the latter denomination is boat-shaped, and a type of the World. In the general Deluge, the generative powers of nature, male and female, reduced to their simplest elements, the Linga and Yoni, assumed this shape for the preservation of mankind. Brahma, the creative power, is represented to have been asleep at the bottom of the abyss. This alludes, we suppose, to the destruction of mankind; man being represented in the abstract by Brahma. The Yoni becoming boat-shaped, the Linga was the mast, and protected by Vishnu rode upon the waters. This, though insufficiently grofs, is doubtless an ariste allegory. Every thing hollow or concave having the property of containing, remind mystics of their type the Yoni or Argha, as aspir- ing obiects do of the Linga. Enthusiasms see these two principles; that is, they fay, nature passive and active, dormant and revivified, everywhere and in every thing,—the earth, the sea, a boat, a well, a pond, the hollow of the hand, clefts in rocks, excavations, caves, commilures of branches, &c. partake of relationship with the one,—mountains, especially if inflated and conical, pyramids, cones of any fort, fire, a mast, a tree, especially if denuded of branches, obelisks, &c. —all these connect themselves with ideas of Mahadeva and the Linga. The earth is typified by a boat; the Argha of the Hindoos, and the Cimbrum of the Egyptians. Ophis is represented in a boat carried by men: in India, Mahadeva erect in the Argha refers to the same allegorv. All over India, the Argha, and Linga of stone inflected in it, is found an obiect of worship. It is strewed with flowers, and water is poured on the Linga, and conveyed off by the rim or Yoni; the foila navicularis or mystical boat of Isis.

Caves, containing to the Ancients a representation of Argo, we have noticed as types of the Yoni, from their property of hollowness or containing, and also from the shape of their mouth. It will be recollected, that the most ancient oracle and place of worship at Delphos was that of the earth in a cave, which was called Delphi; an obsolete Greek word, synonymous, according to Mr. Wilford (Af. Ref. vol. vi.), with Yoni in Sanerkrit. Similar superflutions have prevailed farther westward. Perforations and clefts in stones and rocks were called Cuni Diaboli by early Christians, who usually bestowed the appellation of devils on the deities of the heathens. One of the wonders of the peak in Derbyshire retains an appellation still coarser: but Mr. Wilford thinks improperly; for this wonderful cave, or one he fays very like it, particularly noticed in the Puranas, is declared to be the sacred Yoni. The cleft called Guhya-than, in Nepal, answers fully and literally to the coarse appellation of its relative in Derbyshire, (Gゅya, or Podes,) and is devoutly worshipped by numerous pilgrims from all parts of India. Perforated rocks or stones, as well as the mouths of caves, are mystically contemplated in India. A regeneration is effected by passing through them; or, if the bow be too small, a hand or a foot thrust through, with a sufficient faith, will nearly answer the same purpule.
YONI.

It is difficult to discuss such subjects as thee without feeling a certain degree of contempt, pity, and wonder, at the fooleries of creatures called rational. But when we recollect that many millions, hundreds of millions probably, of our fellow mortals are, or have been, thus milled, and have been similarly milled in all parts of the world, the origin and spread of such ufages become a subject not unworthy the inquiry of the philosopher: as connected probably with the history of stupendous events in faered history, it claims also the attention of the theologian; and the total difufe of all such irrational superlition among ourselves is a matter of gratulation to us as reformed Christians. We are difpuffed, however, to view it in all cases as an invention and engine of priesthood, and not much more to be charged on the religion of the Hindoos and others, than the mummeries practiced at Loretto, Naples, and elsewhere, are justly chargeable on Christianity.

Connected with the symbols and rites of the Yoni, we had prepared to offer some remarks shewing the spread of similar superlitions almost all over Europe, as well as in other regions. And, indeed, although their origin and alhufion are now wholly forgotten, curious obervers may discern in still exifiting ufages occasional relics of this species of devotion even in England. It is inexpedient, however, to indulge in this extended view.

Adoration of ¿rones is found similarly spread through the superlitious ages of all nations. The Hindoos retain it with undiminished bigotry; and will affirm, and indeed go nigh to prove, that such objects, from the faered monolithic subjeat of the Kaiba at Mecca, or the obelisks of fgypt, to the trilithic temple at Stonehenge, with many intermediate, are no other than their Linga, under various forms and denominations. The Battlia of antiquity are nearly related to it. Under Bétylos, Cromleche, Kistvæn, Stonehenge, and other articles of this work thence referred to, the reader may, if defirous, fec the extent of speculation to which the superlition connected with Líthifin, if such a term may be allowed, has given rise.

Clefts in rocks, rent by the hand of nature, may therefore be supposed to be profoundly venerated by fuch enthusiasts as are Hindoo mystics. One of the most celebrated in India, as far as we have heard, is at the promontory on the island of Bombay, called by the Efghish Malabar point. The promontory itself, thrusting its apex into the sea, which there forms a fandy, or junction, (see Junctions,) is Lingar. It proved to be more revered to, and its fpiritual potency much relied on, before its purity and privacy were polluted and interrupted by the presence of strangers, and the increasing population of the island. The unequalled denfity of its present population, and the exfanding prevalence of foreign manners, have leffened the facrity of this spot, now the conftant report and abode of perfons who look on the local fuperlitions with an eye too rational or curious—or severe fhall we say?—to encourage their continuance. Like the Lithic Linga temple of its neighbouring island of Elephanta, as the Efghish call it, the Yoni of Malabar point will soon ceafe to be reorted to. Its fine temple is levelled to the rock whence it arose, and some of its fpolis adorn the Muufuem at the India Houfe. The neighbourhood of Bombay was in former times a grand affembly of Hindoo temples. The great beauty and fulcracity of the fation, the forms of the hills and islands, and other real and fanciond advantages, combined to give it high charms to the tasteful and cunning Brahman. An island rising conically, is we have seen, itself a Linga, its flores a Yoni, the ocean an Argha. The demoralizing effect of this perverted philosophy on the mind of the fimple Hindoo might be exemplified by a citation from our great dramatic poet, slightly altered:

"— And this their life, exempt from public haunt,
Found Lingas in frones, Arghas in running brooks,
Yonis in rocks, and gods in every thing."

Passing through such clefts as we have juft noticed with a placid or expatiatory view is, or rather has been, of extensive prevalence. We could fhow to have been exifled in many parts of Europe. Relics of it still exifit in England. And indeed fuch is the recent rage of theological innovation, and the amazing increafe of credulity, that a zealous fectarian need not deparf of feeing fuch, or ufages equally ridiculous, revived among us. But it would not ftuit the crafty Brahmans to allow rich delinquents to fay advantage as the paffeage through a cleft or Yoni of rock. In certain cafes of defilement, it is required that an image of pure gold be made of the female power of nature, either in the form of a woman or of a cow: in this fhape, the perfon to be regenerated is enclosed, and is protruded through the ufual channel. As this evidently must be excessively expensive, it is of course rarely refforted to. An infance is given in the Hindoo Pantheon, p. 398. of a recent cafe where a Yoni of gold was the medium of regeneration to two Brahman, who had afferted pollution by coming to England. The defilement of a natural birth is done away by the protrusion of the perfon or head through a facred thread called Zurrar. (See that article.) This regeneration is essential to Brahmanical purity, and is also required of the two next tribes. The individuals thereafter are denominated twice-born. The fourth tribe is not allowed to be thus purified, and is therefore confidered as base and unclean. See Sects of Hindoo.

Enough has been faid under this article to fhow the mysterious bearing of its title. It is a fubjeat which, connected with the Linga, meets the observer or inquirer directly or allufively, though not oftener, or very often in an offensive form, at every step he takes in the infegulation of Hindoo literature or antiquities. Reflecting the non-offenfive nor of their appearances, we refer to our article LINGA; of which indeed this may be confidered as a continuation. The subject is inexhaustible, but to us not inviting, though it must have been fo to others. It might not be exaggration, if it appear fo, to fay, that more speculation exits hereon in the languages of India than would fill a volume equal to our whole Cyclopedia! Reference to earlier articles decriptive of the Yoni and its appellation, and allufions enables us to abridge this, which is, however, everywhere bound up with what is faid in thofe articles, and necessarily incomplete. See Kamalayoni, Lileswara, Lotos, Meru, Patra, Radha, Saiva, Sahe, Sani-devi, and Sects of Hindoo. From the article Sani reference is made to this, and we take this occasion to correct an error in the former: in col. 2, line 24 from bottom, for fiction read frition.

Individuals, chiefly of the sect called Saktá, meaning worshippers of the Sakti, or female energy of Mahadevas, the deity of reproduction, propitiate the goddes under the form of the Yoni, the mythical matrix of nature. Of this, see under SAKTA and SAKTI. Such individuals have the feetical appellation of Yonija. In what they differ from the Sakti, if they differ at all, we are not informed. They are not supposed to comperfe but few perfons; but this is a point on which information is obtained with difficulty. Reflectable individuals, if there be any fuch belonging to it, are ashamed to avow being Saktas; and from perfons of a different fpecies information is not to be relied on.

Writings,
Writings, too, on these subjects, are very obscure; their endles Scholia equally fo, and can be critically understood by very few Europeans, even with the affiance of a learned native, who, after all, probably of what he is desired to explain, will, with the utmost delicacy or deceit, gloss over the half-revealed obscenities of his brethren.

The common tendency in the nature of the adoration of the Linga and of the Yoni might, one would think, have united their worshippers in a community of object and view. But such are the anomalies and perversities of the human mind, that it appears to be an historical fact, that the Linghas and Yonias have actually not only disputed and quarrelled respecting the comparative merits of their respective hieroglyphics, or, in other terms, the paramount potentiality of the archetype; but that bloody wars have arisen between them on the question, which, as far as now appears, seems really to have been one of physiology: the only influence, probably, in which such a question hath ever operated as a cause of holy war, manifest as those causes unhappily have been. The Yonias infided, it seems, on a superior influence in the female over the male nature in the production of a perfect offspring. The consequent disputes and warfare the Hindoo writers have, as usual, recited in extravaugant allegories, which we should call obscene, but which they consider as awfully sacred.

"This diversity of opinion," says Wilford, "seems to have occasioned the general war which is often mentioned in the Puranas (see Purana), and was celebrated by the poets of the Welt as the basis of the Grecian mythology: I mean that between the gods led by Jupiter, and the giants, or gods of the earth; or, in other words, between the followers of Iswara (see Iswara) and the Yonias, or men produced, as they afferted, by Prithu, a form of Vishnu (see Prithu and Vishnu); for Nomus (Dionys. b. xxxiv. v. 241) expressibly declares, that the war in question arose between the partisans of Jupiter and those who acknowledged no other deities than water and earth. According to both Nomus and the Hindoo mythologists, it began in India, whence it was spread over the whole globe, and all mankind appear to have borne a part in it.

"These religious and physiological contests were difguised in Egypt and India under a veil of the wildest allegories and emblems. On the banks of the Nile, Osiris was torn in pieces; and on those of the Ganges, the limbs of his comfort If, or Sati, (see Osiris, Isis, Sati, and Sati,) were scattered over the world, giving names to the places where they fell, and where they are still superstitiously worshipped. In Sanskrit books, we find the Grecian ftry concerning the wanderings of Bacchus; for Iswara, having been mutilated through the imprudence of some offended Maniis, (see Muni and Sani-deva;) rambled over the whole earth, bewailing his misfortune; while If wandered also through the world singing mournful dignes in a state of distraction. There is a legend in another book, of which the figurative meaning is more obvious. When Sati, after the close of her exile as the daughter of Dakfi, sprang again to life in the character of Parvati, or mountain-born, (see Merä and Mea,) she was re-united in marriage to Mahadeva. This divine pair had once a dispute on the comparative influence of sexes in producing animated beings, and each resolved, by mutual agreement, to create apart a new race of men. The race produced by Mahadeva was very numerous, and devoted themselves exclusively to the worship of the male deity; but those of their male deities were dull, their bodies feeble, and their complexions of different hues. Parvati had at the same time created a multitude of human beings, who adored the female power only. These were well-shaped, with sweet aspects, and fine complexions. A furious conflict ensued between these Lingacistas and Yonias: the former fixed their ground pretty well at first, but were in the end defeated, and shamefully routed in the battle, through the potency of the sacred Yoni. Mahadeva enraged was about to destroy them by the fire of his eyes; but Parvati interposed; and to appease him, made use of the same artifice that Banbo did to put Ceres into good humour, and shewed him the prototype of the Lotos. Mahadeva smiled, and relented on condition that the Yonias should infantly leave the country.

"It is evident that this strange tale was invented to establish the opinion of the Yonjicistas, or votaries of Parvati or the Yoni, that the good shape, strength, and courage of animals depend on the superior influence of the female parent, whose powers are only excited and put into action by the male aura. But the Lingacistas maintain an opposite doctrine. There is also a fact of Hindoos, by far the most numerous of any, who, attempting to reconcile the two systems, tells us, in their allegorical style, that Parvati and Mahadeva found their concurrence essential to the perfection of their offspring; and that Vishnu, at the request of the goddes, effect a reconciliation between them: hence the novel of Vishnu, by which they mean the as times, is worshipped as one and the same with the sacred Yoni." Wilford, in As. Ref. vol. iii.

YONIJA, the name of a fact of Hindoos, who worship the hieroglyphic of Parvati, called Yoni; which feem.

YONKERS, in Geography, a post-township of the state of New York, in Well Chester county, on the E. bank of the Hudson, above New York island, 20 miles N. of New York, extending near eight miles along the Hudson, and having a mediobreadth of near three miles. The surface is broken, but the lands are cultivated and productive. In 1820 the whole population consisted of 1206 persons, with 39 electors, and 304 taxable inhabitants.

YONNE, a river of France, which rife about four miles S. from Chateau-Chinon, in the department of the Nyevre, passes by or near to Monceaux, Clamecy, Coulanges, Cravant, Auxerre, Joigny, Villeneuve, Sens, Pont fur Yonne, &c. and joins the Seine at Montereau.

Yonne, one of the nine departments of the central region of France, formerly Tonne, E. of Loiret, in N. lat. 47° 50', about 70 miles long, and from 30 to 40 broad, containing 7740 kilometres, or 573 square leagues, and 334,776 inhabitants; bounded on the N.E. by the department of the Anbe, and on the S.E. by the department of the Côte d'Or, on the S. by that of the Nyevre, on the W. by that of the Loiret, and on the N.W. by that of the Seine and Marne. The river Yonne, from which it receives its name, crosses it from S.E. to N.W. It is formed of the Auxerrois, formerly reckoned a part of Burgundy. Its capital is Auxerre. It is divided into five circles, or districts, 34 cantons, and 484 communes. The circles are, Sens, compris sting 57,285 inhabitants; Joigny, 81,933; Auxerre, 103,882; Tonnerre, 47,394; and Avalon, 42,784. According to Haffenfraz, its extent in French leagues is 29 in length, and 25 in breadth: its circles are 7, its cantons 69, and its population consists of 304,909 per sons. In the 11th year of the French era, the total of its contributions was 3,093,024 fr.; and its expenses, administration, judiciary, and for public instruction, 207,915 fr. 66 cents. The soil is various; it has some dry and indifferently fertile tracts, diversified with little hills; the western part is of a clayey soil, covered with woods and pools:
pools: the cantons to the S. and E. are planted with vineyards; and the northern districts is tolerably cultivated. The department, in general, is fertile, producing grain in abundance, with wine, fruits, and excellent pastures.

YOOL ISLANDS, a cluster of small islands in the Pacific ocean, so called by captain Forrest, in the year 1774. In 1788 they were by Mr. Meers called Tattlea islands.

YOO-MIOU, a large town of the Birman empire, situated on a small river, which enters the Irawaddy at a place called Yoo-wa. An extensive tract of country is inhabited by a people called Yoo, who are said to be exceedingly ugly, having protuberant bellies, and white teeth. These Yooos are subjects of the Birman sultan, and observe the same religious worship. They speak the language of Tavy, which is merely a provincial dialect of the Birman tongue.

Symes's Embassy to Ava, vol. ii.

YOPA, a town of Mexico, in the province of Culiacan; 100 miles E.N.E. of Culiacan.

YOPAS, Los, or Tofez, a river of Mexico, which rises in Tlafaca, and runs into the Pacific ocean, N. lat. 17° 10'.

YO-PING, a town of Corea; 33 miles S.W. of King-ki-tao.—Allo, a town of Corea; 28 miles S.E. of Tum.

YORK, the Eboracum of the Romans, is the capital of the great county to which it gives name, the see of an archbishop, who is primate and metropolitan of England, and the second city in rank in the kingdom. It is of unquestionable antiquity, and eminently distinguished in English history by the important political, ecclesiastical, and military transactions which have occurred within its walls, or with which it has been in other ways intimately connected. Seated in the midst of a vast plain, by the side of a river which was navigable for the largest ships of ancient times, and too remote from the open sea to be immediately exposed to predatory invasion, York must have early attracted the attention and become the favourite abode of the chiefs of the northern states, and of their successful invaders from foreign lands. Eboracum was accordingly selected by Roman emperors and commanders as a principal residence during their protracted contests with the ungovernable inhabitants of the northern parts of Britain. The metropolis of a thirc unparalleled in the kingdom for extent, population, and productions, York is placed at the point of junction, although independent of them all, of the three ridings or districts into which the whole is subdivided. The cathedral is situated in N. lat. 53° 59', and in W. long. from Greenwich 1° 7'. The city is divided, by the principal roads, from London, N. by W. 195 miles; from Edinburgh, S.S.E. 201 miles; from Durham, S. by E. 67 miles; from Hull, W.N.W. 38 miles; and from Liverpool, E.N.E. 100 miles. The nearest point of the sea-coast on the E. is at Bridlington bay, distant 33 miles, and on the W. at Lancaster 50 miles. The position of the city is central, with respect to both the limits of the county, and the great body of the population, industry, and commerce, by which it is distinguished. The ancient staiton of Eboracum was confined between the river Ouse on the W. and the collateral stream, the Ouse, on the E., which falls into the Ouse at the southern extremity of the old city. In later times, however, the limits were extended considerably on the opposite sides of both rivers. Such a position, defended on three sides by rivers and marshes, and accessible by an enemy on the N. side alone, although in the midst of a plain, but consequently overlooked by no neighbouring eminence, would, even in the modern art of war, be susceptible of powerful defence; in ancient times it might have been rendered nearly impregnable. In constructing the walls, and laying down the streets, on ground previously occupied by their camps, it was the practice of the Romans to preserve as much as possible the form and distribution of the prior intrenchment. Of this practice frequent instances are found in Britain, as well as in Gaul, and other parts of the continent. The fame, notwithstanding the many changes to which the city has been subjected, may still be traced in York, where evident remains of Roman architecture are yet preferred, and where monuments of antiquity of various cladies have often been discovered.

In its present state, the plan of York forms an irregular pentagon, extending from S. to N. about 1340 yards, and from W. to E. about 1860 yards; the area within the walls is therefore about 300 acres. It is divided into four wards, which take their names from the four gates. Bootham-gate-ward, in the N.W., contains three parishes; Micklegate-ward, on the W. side of the Ouse, contains five parishes; Monk-ward, in the N.E., five parishes; and Walmgate-ward, on the S.E., seven parishes. But the close of the cathedral is not included in any ward. Some of these parishes extend beyond the walls; and the two churches of St. Lawrence and St. Maurice, situated on the outskirts of the city, are still commonly reckoned to belong to it. The number of churches, exclusive of the cathedral, is therefore twenty-three. In former times they amounted to forty-five. Although no regular plan can now be traced in the distribution of the streets, yet some of them are of respectable appearance, having of late years been much improved by widening and paving; and new and handsome buildings, public and private, have been erected. The river Foss, long a piece of flaggated water, has again been rendered navigable, and now materially contributes to the ornament of the city as well as to the health of the inhabitants.

York, still inhabited by many gentry families, maintains its importance in no inconsiderable degree; but in point of population and wealth, it has been far excelled by many manufacturing and trading towns in the county, of comparatively modern foundation. According to the reports of the population of the kingdom in 1811, the inhabitants of York were then only 18,217, and the houses 2743.

CIVIL HISTORY.—York, under its romanized name, Ebro- racum, early appears in British history. In the year 208, the emperor Severus, with his sons Caracalla and Geta, visited Britain; and returning from an expedition against the northern insurgents in the following year, Severus revisited Eboracum, while his troops were employed in constructing across the Ithamus, between the mouths of the Eden and the Tyne, the great wall of defence still known by his name. In this enterprise, he followed the example and completed the fortification of his predecessor Hadrian, which had been formed in the year 121. While Severus's great work was in progress, the emperor died at York in 210; and his successor Caracalla, more intent on the destruction of his en- vied brother Geta than on the enlargement or the preservation of the Roman dominion in Britain, soon afterwards returned to the continent. During his residence in York, Severus issue money, on which he styled himself Britannicus; and also issued a decree respecting the recovery of slaves, which decree is still preferred in the Roman code, dated at Eboracum, on the 3d of the nones of May, in the consulship of Paulinus and Rufus, corresponding to the year A.D. 209.

During his arms against the Caledonians, and other Brit- tons, who struggled for freedom in the north, Constantius fixed his headquarters in York, and there ended his life in 306. York was also the scene of the inauguration of his
... and successor Constantine, who, learning in Asia the indisposition of his father, hastened to York, where he arrived in time to receive his last instructions; and was there proclaimed emperor by the army.

Among the towns specified in the geography of Ptolemy, the Itinerary of Antoninus, and the much later work of Richard of Cirencester, Eboracum is ranked first as a colony, and afterwards as a municipal town. As a colony, or settlement of veteran troops, the inhabitants were citizens of Rome, and governed by the laws of the state. When advanced to the highest station, that of municipality, the inhabitants retaining the privileges of Roman citizens were no longer under those particular laws, but invested with the power of self-government, under magistrates of their own appointment. Besides Eboracum, Britain contained but one other municipal town, Verulamium. In the list of Roman troops stationed in York, the sixth legion, called the victorious, appears to have been there for three successive centuries, down to 446, when the Romans finally renounced all dominion in Britain. The British name of York is liof; but although softened into Eboracum by the Romans, and by their colonies, who copied from them, traces of the original may still be perceived in the Kair-Ebrauc of Nennius and Henry of Huntingdon, and in the Cair-Effroc, or Erof, of the Welsh. In British compound appellations of places, the descriptio part precedes the proper name: in the language of the Saxons a contrary mode prevailed. Hence Cair-Effroc was by them converted into Erof-wyc, and Yevor-wyc, from which the present name of York seems to be derived.

York was the capital of Deira, one of the districts into which the Provincia Maxima of the Romans, or the county of Northumberland, was divided; and there, in the beginning of the seventh century, reigned Edwin, who re-united those kingdoms, and acquired the principal ascendency over Saxon-England. To this prince are ascribed the establishment of the cathedral, and the foundation of the city of Edinburgh (Edwin's burgh), now the capital of Scotland. He also founded a cathedral in York; but in 633 he fell in the defence of his dominions, against the combined attack of the Saxons of Mercia and the Britons of Wales. Offa, who came to the crown in the following year, Northumberland was again united into one kingdom; and afterwards governed by the celebrated Egbert, who, in 827, out of the Saxon heptarchy, formed the great kingdom of England. After a long series of disfactors from Danish invasion, and the internal disorders of the kingdom, York was exposed to utter destruction from the memorable expedition of Harold Hardrad, king of Norway. On the death of Harold of England, an unsuccessful attempt was made by the people of York to place Edgar Atheling on the throne. For this step, William of Normandy besieged the city in 1076, which, after many months, was compelled by famine to surrender. The conqueror inflicted the most horrible vengeance on the inhabitants, the surrounding country was laid waste, and cattle were erected within the walls, to keep the conquered citizens in subjection. With the exception of the contests between the metropolitans of York and Canterbury, little is recorded of the former city until 1137, when the cathedral church, thirty-nine parish-churches, and the greater part of the houses, were accidentally burnt down.

About 1160, one of the first parliaments of England was held there by Henry II.; and in the reign of his successor, Richard I., in 1190, occurred the horrible massacre of the Jews, which was perpetrated and accompanied with circumstances of peculiar atrocity. In 1299, the courts of justice were removed from London to York by Edward I., during his expeditions against Scotland. In his reign this city was chiefly among the sea-ports of England, and required to furnish one ship for his use. In the languid county courts between the houses of York and Lancaster, the former city maintained that it held the castle of the white rose; and in 1483, Richard III. was a second time crowned in the cathedral. The year 1509 was distinguished by the establishment of a printing press in the minster-yard of York, near the place where the royal presses were afterwards erected in 1642, while king Charles refided in the city. Nothing of moment relative to York is afterwards recorded until the 31st year of Henry VIII., when commissioners were appointed there to conduct the suppreffion of the northern monasteries. Adhering to the royal caufe, the city was, in 1544, besieged by the parliamentary forces under Sir Thomas Fairfax. But on the approach of prince Rupert, the siege was raised; and on the 2d of July, the important battle of Marston-moor, about five miles off, was fought, in which the royal party was completely defeated. Returning to the siege, Fairfax, at the end of six weeks, obtained possession of the city, on most honourable terms for the garrison and inhabitants. Notwithstanding the zeal for the royal cause manifested by the citizens of York, their charter was suppressed by Charles II., and never restored. A new charter, however, confirming all the former rights of the city, was granted by his successor James II. in 1685. Down to the 30th of July, 1688, the inhabitants of York continued to express the most determined attachment to James; and on that day, the mayor, aldermen, and commons, congratulated him, in the most energetic terms, on the birth of a young prince.

Civic Government. — The government of York is vested in a mayor, who, like the mayors of London and Dublin, and the provost of Edinburgh, is authorized by the act of Richard II. to assume the title of lord; a recorder, two city-council, twelve aldermen, two sheriffs, seventy-two common-council-men, and six chamberlains. What is styled the privy-council, or the upper house, consists of the lord-mayor, aldermen, and sheriffs, together with those citizens who have passed the office of sheriff. This body, whatever may be its number, is usually called the twenty-four. The mayor, whose office ceases on the 3d of February, is chosen annually from those aldermen who have not borne that office twice, nor within the six preceding years; and during his mayoralty takes precedence of all persons within his jurisdiction. York was early distinguished among the cities of England: in the Domeday-book it appears to be exempted from the payment of geld, except when the fame is paid by London and Winchester, and from paying reliefs. In 1396 King Richard appointed two sheriffs, instead of three bailiffs, for the government of the city, which was then constituted a county within itself. The earliest charters of York now preferred are, one granted in 1109, and another by Henry III., who died in 1222: but both recite preceding charters of Richard I., Henry I., and Henry II. Representatives in parliament for the city of York appear in the summons and returns of the 25th of Edward I. For the parliament called to assemble at Shrewsbury, on the 30th of September 1283, which was but the 11th year of Edward, two representatives were summoned from a number of cities and towns, among which York stands the fourth in order; those before it being London, Winchester, and Newcastle-upon-Tyne. Under the jurisdiction of the lord-mayor, aldermen, and sheriffs, besides the city, is a considerable district on the W. of the river Ouse, called the Ainfley, in which writs are returned, but whose origin and import are now unknown. This tract was once a hundred or wgetnhate of the West Riding of Yorkshire; but in the 27th year...
some text is missing or not legibly visible
flone coffins were found without Bootham-bar; and are now preferred in the cathedral. In 1814 was laid open a beautiful tessellated pavement, within Micklegate-bar, but without the Roman town; but unfortunately a part of it only was preferred; this was the first ever found in York. The walls of the city, which probably succeeded to the Roman fortifications, and which are now in rapid and disgraceful decay, still retain sufficient evidences of their ancient strength and importance. When they were erected is now unknown; but their construction on the Roman foundations is generally ascribed to Edward I, about 1280; in the time of Henry VIII. they were in complete repair. The oldest part of the present walls appears to be that adjoining to Walmgate-bar, at the S.E. corner of the city, on the road to Hull, where the remains of the Red tower are still visible. During the last siege of York, in the civil wars, by Sir Thomas Fairfax, in 1644, these walls were fortified as to require three years to repair them; but since that period they have been shamefully neglected by those whose duty it is to preserve them.

York is distinguished among the cities of England for its ancient gates, or bars, as they are termed. Of these, Micklegate-bar, on the S.W. side of the present city, under which is the road from London, is the most remarkable. It consists of a lofty square embattled tower, with loop-holes, &c. and guarded by an adorned work, with balist-turrets, &c. Bootham-bar, at the N. entrance of the city, not far from the Roman tower, is almost wholly constructed of materials formerly employed in Roman buildings. Monk-bar, on the N.E., and the Walmgate-bar on the S.E., seem to be of equal date, and were probably erected by Edward III. The whole circuit of the ancient walls is nearly two miles and three-quarters.

Castle: Clifford's Tower.—Nearly at the junction of the Ouse and the Foss, on an eminence, is the feite of the ancient castle, accessible only from the city on the N., and strengthened on the other sides by the Foss, carried round it in a deep moat. Prior to the Norman Conquest, York possessed a castle, by some supposed to have flood on the W. side of the Ouse. It is, however, much more probable, that the principal fortresses occupied the position here described, on which William of Normandy erected his castle, which was restored by Richard III. Ceasing to be regarded as a place of strength, it was converted into the prison for the county of York: but becoming ruinous, the whole was, in 1701, taken down, and the present grand structures, still retaining, although very incongruously, the original name, were erected. Within the enclosure of the ancient castle on the N.W. is a high mount, surrounded by a deep ditch, rising 90 feet above the river Ouse, and 30 above the feite of the castle. On the summit stands Clifford's tower, consisting of four segments of circles joined together, and so called, it is said, from the first governor, after its erection by William the Conqueror, to whose castle it served as the keep. In the time of Henry VIII. this tower was in a ruinous state; but on the commencement of the diforders in the reign of Charles I., it was repaired and fortified by the earl of Cumberland, who mounted some pieces of artillery on the platform. In the year 1684, the powder-magazine within the tower exploded, and the building was reduced to its external walls, as now existing. Corresponding to Clifford's tower, on the W. side of the Ouse, is another mount, called the Old Bailey, or Vitus Ballium; and was feite of 90 ancient fortresses.

Public Buildings.—At the head of the public edifices of York is necessarily placed the venerable minster, or cathedral, which, considered in its totality, is unparalleled in England. The earliest erection of a flone edifice for the service of the Christian religion in York is always ascribed to Edwin, king of the Northumbrians. This church was founded about A.D. 628; but it was completed by bishop Wilfrid, after 669, who covered the roof with lead, and filled the windows with glass. This last invaluable substance must have been imported from the continent; for it was not till 674 that glaze-makers were first introduced into England by Benedict Biscop, to glaze the windows of his new monastery at Bishop-Wearmouth. That the cathedral of York suffered with the other parts of the city by the ravages of the Danes in 867 is most probable; but it is not noticed until 1069, when it was destroyed, with a great part of the city, in a conflagration occasioned by the Norman garrison, when attacked by the united Danes and Northumbrians. To punish the refractory people of the city and vicinity, William of Normandy expelled the ecclesiastics, and seized the revenues of the fee: but these were soon restored, and his chaplain and treasurer, Thomas, a Norman, was promoted to the archbishopric. By this prelate the cathedral was rebuilt in a magnificent style; but in 1137 it was again destroyed by fire, together with the abbey of St. Mary, and 39 parish-churches. Having for a number of years lain in ruins, archbishop Roger, the acontious opponent of Becket of Canterbury, began in 1171 to rebuild the choir with its crypt, which he lived to finish. In 1227, his successor, Walter de Grey, erected the transept, with the exception of the N. part, which was the work of John le Romaine, the treasurer, who also raised a central pierre in 1260. In 1291, the fos of the preceding being advanced to the fee, commenced the nave, which, together with the two noble western towers, was completed by archbishop William le Melton. In 1561, the present beautiful choir was commenced by archbishop Thoresby, who contributed largely to defray the charges of the work. More money having been collected than was required, the surplus was, in 1370, employed to construct the present noble central tower, in the place of one erected by John le Romaine. Thus, in the course of 150 years, the cathedral of York was brought into a form nearly as it now appears. It is a grand and interesting edifice; and consists of a nave with side aisles, a large and lofty transept with aisles, a choir with aisles, and a large space east of the choir, called the lady-chapel, with aisles. Beneath the altar is a crypt; on the south side are three apartments called vestries and treasuries; and at the end of the north transept is a fine chapter-house, with a corresponding vestibule. The west end is adorned by two elegantly ornamented towers, whilst another, of larger dimensions, rises at the centre of the transept. All these parts of the church are on a large and magnificent scale; and though not in an uniform style, yet the nave and choir are of corresponding height and width, and very similar in their windows, columns, and other members. The W. front is more richly adorned than any other part of the edifice. Its two towers diminish in dimensions as they ascend, and have been ornamented with several statues, of which now only very few remain. Each tower is surmounted by eight pinnacles; and in the south tower is a set of celebrated bells. In the front are three entrances; that in the centre is divided into two by a pillar. The entire length of the cathedral is above 524 feet; that of the nave, from the west end to the screen at the entrance of the choir, is 250 feet; the length of the choir to the altar-screen 150 feet; and that of the lady-chapel, at the east end, 65 feet. The transept is in length 222 feet. The breadth of the nave, with its side aisles, is 103 feet; that of the nave itself being 53. In the centre of the nave the height to the roof of the

is
The elevation of the central tower or lantern is 213 feet; that of the towers at the W. end 196 feet. The great windows which occupy the principal part of the W. and E. ends of the church are particularly beautiful. The great E. window, especially, is of uncommon dimensions and richness. It was executed about 1405, at the expense of the dean and chapter; and the glass painted, &c. by John Thornton, of Coventry, glazier, who engaged to finish it in three years, and for which he was paid four shillings per week. Spacious, lofty, and light, the interior of this cathedral has a most imposing effect. For although the choir be separated from the body of the building by a screen surmounted by the organ, fill from the W. end the eye ranges over all, quite to the great terminating window in the E. The nave consists of a double range of eight lofty pointed arches, supported by slender clustered columns. A similar arrangement prevails in the choir; but the transept is of a different age, style, and character, to all the other parts of the church.

Great labour has been bestowed in the carving of the stalls of the choir, which are of oak. The screen behind the altar is stone, divided into eight pointed arches, the upper part of which are perforated and glazed. At the entrance of the choir is a very elaborate screen of tabernacle work, perhaps of the time of Henry VI. It is covered with niches, canopies, pediments, pilasters, &c. and contains statues of fifteen English monarchs; i.e. eight on one side of the entrance, and seven on the other side. The whole has been of late years suitably repaired. The central tower, or lantern, as it is usually called, is supported by four lofty arches reposing on strong massive clustered piers.

Among the monuments of prelates and other eminent persons preferred within the cathedral of York, is distinguished that of archbishop Walter Grey in the south transept. It exhibits his effigy in his pontificals, covered by a magnificent canopy, supported by slender pillars. The whole was enclosed with a handsome railing by the late Dr. Markham. But the most elegant of all is the monument of archbishop Bowet, appointed in 1423, of gree height, and in the most florid style of the pointed architecture. A full-length statue, with emblems and an inscription, commemorates the late Sir George Saville. Attached to the south side of the choir is a range of low buildings, styled the vestries; in one of which are preferred sundry emblems of the ancient metropolitan dignity of York cathedral. Among these is a famous antique horn, as it is termed, although formed out of an elephant’s tooth, by the poffession of which the church holds lands of great value, said to have been granted by Ulphus, a Saxon prince of Deira. In the same place is preferred the silver pastoral staff, presented by Catharine of Portugal, dowager of Charles II., to her confessor, who had been appointed popish archbishop by James I. in 1687. Adjoining to the S.W. angle of the transept was a small building, formerly used as a library. A library for the use of the ecclesiastics of the cathedral is believed to have been founded by Egbert the archbishop in 740, and his successor Albert; but the whole was consumed by fire in 1699. By this misfortune no small loss was sustained by the lovers of learning; for according to certain writings of Alcuin, the secretary of Charlemagne, many valuable clasics and other works were contained in it. To supply in some measure its place, another library was collected by archbishop Thomas, the Norman; but that also was destroyed by the flames in 1137. From this period, the cathedral is not known to have been furnished with many books until the private collection, confiding of upwards of 3000 volumes, of archbishop Matthew, was bestowed on it by his relics in the beginning of the 17th century. By various subsequent benefactions, presents, and purchases, a large collection of valuable books and manuscripts has been formed, and placed in what was formerly the chapel of the archiepiscopal palace, on the north side of the cathedral. This building has been lately repaired in a style suitable to that of the church, and commodiously adapted to its present destination. Connected by a short passage or vestibule with the N.E. angle of the transept of the cathedral is the chapter-house, an octagonal room, 63 feet in diameter, and nearly 68 in height. This building differs from many others of the same kind, in having no central pillar to support the roof; but the preture of the arched roof upon the walls is effectually counteracted by buttresses at each external angle. From the similarity of the style of building with that of the nave of the cathedral, founded in 1291, the chapter-house is supposed to have been erected about that time. The buildings belonging to the cathedral were formerly separated from the city by walls; and some remains of the gates of communication may still be discovered. Of those buildings, the principal was the archiepiscopal palace, situated on the north of the church. It was erected by the first Norman prelate appointed in 1070; but after a lapse of about 500 years, the great hall was taken down by the Protestant archbishop Young, for the fake, it is said, of the lead on the roof. Since that time other parts of the palace have been leased out. In former times to the fee of York belonged various places of residence; but now that of Bishopthorpe alone is occupied. This is agreeably situated on the side of the river Oue, about three miles south-west from the city. It was purchased and appropriated to the fee by archbishop Walter de Grey, in the early part of the 13th century; since whole time it has undergone many important alterations and improvements. The principal front and the vestibule are in the pointed style of architecture, and in the interior are several spacious and elegant apartments, besides the chapel and library. In the minster-yard still remains the residence of the dean of the cathedral, a spacious and convenient edifice of respectable appearance.

Of the parochial churches in York, that of St. Margaret in the south-east quarter of the city is remarkable for the porch attached to it, which is of much higher antiquity than any other part of the edifice. It was removed from the church of St. Nicholas, formerly situated without Walmgate-bar, but ruined during the siege of York in 1644. The arch of the porch is semicircular, and exhibits alternately the signs of the zodiac and the emblems of the months. The churches of St. Denys and St. Lawrence have also an appearance of considerable antiquity. Next to the cathedral, the church of St. Michael-de-Belfrey is the largest and the most regular in the city, supported by light pillars and pointed arches. The present building was erected on the removal of the former in 1555. The church of All Saints, on the pavement, is distinguished by its open octagonal tower, erected on a square tower, in which, according to tradition, a large lamp was suspended in the night, to guide travellers over the broad forest of Galtres, which extended on the north and east of the city. York contains places of meeting for various classes of dissenters from the established church; that for the Society of Friends, lately erected, is large and commodious. A handsome chapel for the use of the Roman Catholics was built in 1782.

Of the numerous religious establishments formerly existing in and near York many vestiges still remain. Of these,
the principal was St. Mary's abbey, situated on the bank of the river Ouse, on the outside of the city wall. The foundation of the monastary is of uncertain date; but the church, of which some considerable ruins still remain, was rebuilt in 1270. Having fallen to decay after the general suppression of religious houses, Henry VIII. ordered a palace to be erected out of the ruins, for the residence of the lord-president of the north of England, to be designated the "king's manor." This was enlarged by James I. Previously to the Revolution it became an object of popular outrage; but some years afterwards the king's Mint was established in it, and much gold and silver, distinguished by the initial letter Y, was struck there for William III. The site of the abbey and the manor have long been leased from the crown by lord Grantham and his predece$$ors. Connected with the religious system of former times, it may be noticed, that adjoining to the walls of York, immediately without Micklegate-bar on the London road, is an establishment called the Nunnery. The building was originally acquired in 1686, as a place of education and living for young ladies of Roman Catholic families. The establishment at present consists of the superior and twenty pensioners, who wear the dresses and conform to the regulations of nuns in Catholic countries, with twelve lay-filters, and a chaplain. From fifty to seventy boarders are usually accommodated in the institution. The Guild-hall and the Mansion-house are situated near the river Ouse, in the north-west quarter of the city. The hall, built in 1446, is a noble room, ninety-six feet long, forty-five broad, and twenty-nine feet six inches high. In it are held the law-courts and the courts of municipal justice. The Mansion-house was erected in 1725, and contains every necessary accommodation for the lord-mayor. In the same quarter of the city are the assembly-rooms, the theatre, the subscription library, the principal hotels, &c. As a fortres$, York castle has long ceased to be of importance; it is now occupied by several structures. That on the W. side of the area is the county-hall, rebuilt in 1777, in which the aldermen are held, and other county business is transacted. The centre building is the prison for debtors and criminals; the third building on the E. contains the record-office, and various apartments necessary for the transactio$ of the business of the county. Of all these buildings it is but justice to say, that in their construction external elegance and taste have been properly combined with a due attention to their several definitions. The arrangement and management of the prisons have been frequently the subject of commendation. The new city-gaol, an extensive stone structure near the Old Bailey, on the west side of the river Ouse, and the house of correction, are also deserving of attention. The charitable establishments for the poor and the sick in York are very numerous, and well conducted. Among thefe, the county-hospital and the city-dilpensary are highly commendable. Schools for the education of youth of both sexes are not wanting in York. In 1647 a petition was presented to the crown from the inhabitants of the city and the county, and from other parts of the north, for the establishment of an university in York: but the unsettled state of the affairs of the kingdom then prevented due consideration of the request; nor has it since been renewed; although, for various important reasons, York seems peculiarly adapted for a place of literary and scientific retirement and study. A seminary or college for the education of ministers and lay-gentlemen among Protestant dissenters, which formerly subsisted at Manchester under the successive care of the Rev. Dr. Barnes and Mr. Walker, and was liberally supported by voluntary subscription, was on the death of the latter profe$$esor removed to York, where it is conducted with great reputation by the Rev. Messrs. Wellbeloved, Kenrick, and Turner.

Bridge.—Communication between the original city of York, and the suburb styled Micklegate-bar on the south-west side of the river Ouse, is maintained by a handstone stone bridge, which has lately been erected from the designs and under the direction of Peter Atkinson, eq$. of York. In 1154 the bridge was wood; but in 1268 it was probably of stone; for then was founded on it St. William's chapel, in atonement for the death of several persons on the spot in a fray with the people of the town. In 1564 a flood following an intense frost swept away two arches of the bridge, with the houses built on them.

On the south-ea$t side of York, going out by Walmgate-bar, near the village of Hellington, is an establishment for the reception and relief of persons disordered in mind; which, as for some time, has been the subject of general approbation. This was called the Retreat, founded by the respectable Society of Friends, and originally intended for members of their clafs alone. The first idea of this admirable institution was suggested in 1751, by the unfortunate death of one of their society, at a common receptacle for the insane. In 1794 land was purchased, and the building commenced, on a commanding eminence. The general arrangement, management, and fystem of treatment of the unfortunate patients, have been imitated, as the most perfect of their kind, in various parts of the kingdom and America. See an "Account of the Retreat," 5vo.—Eboracum, or History and Antiquities of York, by Francis Drake, F.R.S. folio, 1736. Description and History of the City and Cathedral of York, 12mo. 3d ed. 1790. Description of York, 12mo. 1816. A Guide to the Cathedral of York, 12mo. 1815, is a rational and judicious vade mecum.

York, Culflon of. See Ratiouahili partes bonorum.

York, in Geography, a county of the United States, in the district of Maine, containing 23 towns, and 41,877 inhabitants.

York, a district of South Carolina, containing 10,032 inhabitants, including 3163 slaves.

York, a county of Pennsylvania, south-west of Susquehanna. It contains 22 townships, and 31,958 inhabitants.

York Borough, a town of Pennsylvania, in York county, containing 28,477 inhabitants.

York, a township of Pennsylvania, in York county, containing 1649 inhabitants.

York, a county of Virginia, with 5187 inhabitants, including 2931 slaves.

York, a town of United America, in the district of Maine, and county of York, containing 3046 inhabitants; 50 miles N.N.E. of Boston. N. lat. 43° 7'. W. long. 70° 40'.

York, a township of Ohio, in the county of Belmont, containing 1349 inhabitants.

York, the capital of Upper Canada, situated on the lake Ontario. It is likely to become a city of great importance, as it possesses great facilities for commerce and navigation. It lies in about 43° 35' N. lat., within an excellent harbour of the same name, made by a long peninsula, which embraces a haven of water sufficiently large for containing a considerable fleet. Vessels may ride safely at its entrance during the winter. On the extremi$ty of the peninsula, which is called Gibraltar Point, are erected commodious block-houses and stores commanding the entrance into the harbour. On the main land opposite
York, New, one of the United States of America, situated, according to the statement of Meish, between 40° 33' and 45° N. lat., and 5° 43' E. and 2° 43' W. long. from Washington; extending from N. to S. 198 miles, and from E. to W. 256; and comprehending an area of 46,000 square miles, or 28,440,000 acres. This state is bounded on the N. by lake Ontario and Canada; on the S. by Pennsylvania, New Jersey, and the Atlantic ocean; on the E. by Vermont, Massachusetts, and Connecticut; and on the W. by Upper Canada, lake Erie, Pennsylvania, and New Jersey. This territory, according to Spafford's "Gazetteer of New York," comprises an area of 46,082² square miles, equal to 29,493,720 acres; but this computation includes all the inland rivers and lakes, one half of lake Champlain, and the St. Lawrence; excluding only all the waters below New York island, and that part of the lakes Ontario and Erie which belong to this state. This statement gives 20.8 persons to a square mile. New York is at present divided into 45 counties, and 452 townships, including four incorporated cities; viz. New York, Albany, Hudson, and Schenectady, as exhibited in the following

* Laid out since the census was taken.

Putnam county was erected in June 1812, from the S. end of Dutchess county, and is formed of the towns of Philip's or Philipstown, Carmel, Frederick, Patterson, and South-East. Courts are held in the Baptist meeting-house in the town of Carmel, and this county lends one member to the house of assembly. The towns are, Carmel the chief, including, in 1810, 2020 inhabitants, the electors being 153; Frederick, with 1811 inhabitants, and 98 electors; Patterson, with a population of 1446, and 110 electors; Philip's, with 1429 persons, and 165 electors; and South-East, in which the population is 1887, and the number of electors 161.

Warren county was erected from the N.W. extremity of Washington, March 12, 1813. It comprises the towns of Bolton, Caldwell, Chester, Hague, Johnstown, Luzerne, Queenbury, and Thurman, the last of which is divided into two towns, called Athol and Warrenburgh. The chief town is Caldwell, with a population of 560 persons, and 60 electors; Athol has 443 inhabitants, and its electors are 20; Bolton has 726, and 30 electors; Chester 937, and 120 electors; Hague 398, and 21 electors; Johnstown 651, and 82 electors; Luzerne 1015, and 85 electors; Queenbury 1948, and 197 electors; and Warrenburgh 887, with 41 electors.

YORK.

The face of this state exhibits a great variety. To the S.E., its surface is agreeably uneven; in the middle, mountainous; to the N.W. undulating; flat towards the lakes; and hilly towards the southern extremity.

Of the mountains in this state, the chain called Catskill, or Catskill, is the largest and most extensive, and this presents a bifurcation of the Apalachian ridge, which at the Highlands occupy a tract of about 16 miles in width, lying obliquely across the Hudson, and penetrated by that river. These ridges preserving their general direction stretch across Dukes county, the eastern parts of Columbia and Renfrew counties, and exhibit some lofty summits. The Taconic hills are lofty and very rugged, and Hoosack and Williamstown are mountains which deserve the appellation. But the Catskill or Catskill mountains present some summits that are higher than any others of the Apalachian chain, if we except the White-hills in New Hampshire. At the Highlands, the summit of Butter-hill is 1432 feet above the level of the river; that called the Crow's-nest 1330; Bell-hill 1301. About 60 miles N., the Round-top is elevated 365 feet above the level of the river; the High peak 3487. These summits are in Windham, Greene county, about 20 miles W. of Hudson, and in full view from that city. A turnpike-road which crosses this range of mountains near those summits, winds up till it reaches the astonishing altitude of 2274 feet. Upon this spot the view is inexplicably grand. The general altitude of the Catskill mountains may be estimated at about 2000 to 3000 feet across Greene county. From Greene they pass into Schoharie county with ridges less rugged; and towards the southern part, their continuity is less distinctly defined. Until after forming the falls of the Mohawk, this range traverses Herkimer county, forming a rugged tract, and diminishing in altitude till they cross the St. Lawrence into Canada, at the Thousand islands. These mountains have obtained from the early Dutch inhabitants the name of Helderberg, or clear mountain, presenting, instead of lofty summits of granitic and schistic mountains, an elevated plain of considerable and very uniform altitudes. Around Lake George, and to the W. of lake Champlain, we find the Peruvian mountains, which furnish the northern sources of the Hudson and form the height of land that separates the waters of the Hudson and St. Lawrence. The highest of these is probably that called White-face, which commands a view of Montreal, at the distance of near 80 miles. The altitude of this summit is little short of 3000 feet from the level of lake Champlain. These mountains obtained the name of Peru from the French inhabitants, in allusion to their supposed mineral treasures. With some few exceptions, the whole country S. of the Highlands is underlaid by rocks of granite, with superstrata of other rocks, which appear in the elevated tracts. There are some tracts of lime-flone and some of sand-flone, but these are so incon siderable in extent as to furnish no objection against denom inating this the granitic region. Some ranges of hills on the W. of the Hudson, composed of sand-flone, are underlaid by granite; and the Catskill mountains are a mass of sand-flone, similar to the Allegheny mountains in Pennsylvania, intermixed with lime; the Helderberg, with some particles of sand-flone, occasionally interposed. N. and E. of the Highlands the rocks are chiefly schistic that form the shahratum, while calcareous ridges of great extent occupy the surface. The hills of the eastern border of Columbia and Renfrew counties are formed chiefly of fragile schistus, intermixed with quartz, and occasional superstrata of lime-flone. On the eastern declivities of these hills lime flone predominates, forming the marble quarries of Stock bridge, Laneborough, &c. in Massachussetts. The northwestern continuation of the Catskill or Catskill presents a kind of calcareous granite, in which the absence of the felspar is supplied by primitive lime-flone, the Peruvian mountains are principally granitic, though ridges of lime flone, flate, flint, and sand-flone, appear in conglomerate masses, and these are most abundant in mineral treasures. The whole level country of the small western lakes is calcareous. The Taconic hills that border the forth-eastern part of Columbia county are granitic.

The rivers of this state are numerous and extensive; and so are its lakes and creeks. The Hudson and the Mohawk are the most considerable rivers, to which we may add the Sacandaga, a branch of the Hudson and Saran river connected with Saron and Brant lakes. The creeks of the Hudson and Mohawk are numerous. The Susquehanna rises in this state; and its western branch, the Tioga, is a river of some note, and claims distinction from several creeks belonging to the former river. The Delaware, which receives several rivers and creeks, forms a part of the western boundary of New York; and the Alleghaney, a principal branch of the Ohio, has its origin in this state, and its creeks, large and small, are too numerous for our recital. The Chatauqua lake discharges itself into Connewong creek. The Cataragus and Buffalo creeks run into lake Erie; Tonawanda and Ellicott's creeks into Niagara river, forming a part of the western boundary of the state. Lake Ontario, half of which is in this state, receives the Genesee, the Oneida, and Black rivers, which convey into this lake the
the waters of several other rivers and creeks. The St. Lawrence washes more than 100 miles of the north-western boundary, and it receives a number of rivers and creeks. Half of lake Champlain also belongs to this state, and it is supplied by several streams. Each river also belongs to this state.

The climate and season must in such an extent of country be very various, so that it is difficult to accommodate any general observation to the whole state. In the eastern territory, or wholly S. of the highlands, where the prevailing winds are southerly through the warm seasons, the weather is very variable; and the changes of temperature, governed by the winds, frequent and sudden. In the northern part of the state, the weather is less variable; but the winters are long and severe, with a clear and settled sky. This region, extending from the southern extremity of lake George, and westward to near lake Ontario and the St. Lawrence, may be distinguished as the region of the "northern climate." That of the "western climate" comprises the great western territory of this state, extending from the Catskill or Catskill mountains to the great lake. Here southerly and westly winds prevail in a considerable proportion throughout the year. A gentle current of air, that may be traced from the Gulf of Mexico, and reaching to a distance of more than 1000 miles, prevails almost constantly from the S.W.; and northerly and easterly winds are almost wholly unknown. In this district, the average temperatures are about three degrees higher than in similar latitudes in the eastern climate. Such is the general character of the western climate of the United States, and the distinction is said to terminate, or nearly so, with the region about lake Ontario. The western climate of this state is therefore warmer than the eastern by about 3° of Fahrenheit; and this is attributed to the greater prevalence of warmer currents of air from the S.W. In the region about Albany, the rigours of winter commence about the 20th of December, and end with February, or about the 10th of March, when the ice usually breaks up in the Hudson. From the middle of March to the end of April, the weather is very variable; the changes of temperature great and sudden, though it be generally rainy, with long-continued storms of easterly winds. May is also a variable month; June assumes a summer character; in July, southerly winds are diminished, and drought prevails; August is more showery, and more uniformly temperate, than any month of the year, and affording health and plenty. The former part of September resembles August, and terminating with mild and pleasanl weather. October is an agreeable month; early frosts occur about the 26th of September, though corn ripens till the middle of October; and from the 15th to the 25th of this month the foliage of the forest-trees is destroyed, and early falls of snow commence about this time. December is usually cold and showery, and storms from the N. and E. are frequent, and of long continuance. It is observed, that a general modification of temperature, favourable to agricultural interests, has occurred within the last 15 or 15 years.

This state affords facilities for inland navigation superior to any other, combining both the objects and the means of intercourse. The connections of the rivers Hudson, Mohawk, Oswego, Delaware, Ohio, Susquehanna, Alleghany, Mississipi, and St. Lawrence, by creeks and streams, and canals with the lakes Oneida, Erie, George, Champlain, Ontario, &c. are peculiarly favourable to internal navigation and commerce. The canal at Rome, which connects the waters of the Mohawk and lake Ontario, and which was completed in 1797, deserves particular mention; and it should be noticed to the honour of this state, that the western inland lock navigation company is formed for the direct purpose of improving the navigation of the western waters; and that the project of a great western canal for connecting lake Erie and the Hudson by a boat navigation is a very important object.

The state of New York has few bays, exclusively of those of Long island, which are very numerous. It has many islands, among which Nassau, or Long island, claims the first place, as it affords more than 100 miles of sea-coast, many excellent harbours, and many advantages for commerce. Its bays are both numerous and large, and it has immediately dependent upon it many subordinate islands. The islands in the bay of New York, as well as that upon which New York itself is situated, and Staten island, and those belonging to the Hudson, Mohawk, Niagara, and St. Lawrence rivers, to lake Ontario, Champlain, George, &c. might be enumerated if our limits would allow. In this connection we might also mention a variety of bridges that serve to facilitate communication and intercourse between the various parts of this state.

The soil and agriculture of New York deserve our particular attention. The soil is of various characters in different parts of the state. In some districts it is deep and warm, and well adapted to grain or grass; in other parts it is of a looser texture, and is found in various proportions with the admixture of vegetable remains; forming a thick vegetable mould, with a small proportion of earth, and called by the farmers in that country "black muck." This is soon exhausted, and as it rests on a subfratum, called "hard-pan" by the farmers, that is cold and flaky, it is incapable of being reforested or reclaimed by any manure or art of husbandry. The west end of Long island is rich, fertile, and highly cultivated; but the eastern part has a large proportion of sandy barren plains. Below the Highlands, the soil is principally dry and warm, having a gravelly or sandy subfratum, or granitic rock. North of the Highlands to the Mohawk, the soil is dry and warm, being either a gravelly or sandy loam in general; and both those which we have mentioned are flanked to be a medium soil. But on the eastern border of the state, the rocks are principally chosie, and a schistous gravel forms most of the soil, which is warm and productive, though not deep. The alluvial flats of Columbia and some part of Rensselaer counties are very extensive and rich; and the valleys, presenting a warm gravelly soil, are also extensive, and furnish much good medium soil. West of Albany are extensive sandy plains, interperfed with marshes, and rather cold and wet till we approach the Helderberg hills. This plain is generally underlaid by clay; but the Helderberg hills are calcareous, and present a better soil, though broken and much diversified.

The agricultural products of this division of the whole territory of the state consists of all the various productions of this country. The west part of Long island, and the counties of West Chester and Dutchess, are well cultivated. The latter is one of the best farming counties in the state. The introduction of gypsum as a manure has marked a new era in the agriculture and rural economy of this region. The west side of the Hudson is considerably behind the eastern. The southern part of Washington county has a warm gravelly medium soil, and abundant crops. Saratoga has much good but more wale land. Its general character is more sandy; and, like that of Albany, rests on clay. Around lake Champlain there is a large extent of clayey soil, extending to the hills that skirt the Peru mountains. With the exception of the alluvial flats, which are extensive and rich, the foil of the country of the Mohawk may be generally

YORK.
generally denominated a fliff loam, till we go wealt of the Cathedall hills at the Little Falls. Here it assumes a new character. The soil of the mountaneous tract of the western region is much diversified; the hills are rocky; the valleys deep and narrow, or spacious and rich. This tract furnishes considerable buck-meat or deep vegetable mould in the valleys. A very large proportion of the soil of this country may be denominated a rich mould, variously intermixed with earth of different kinds; and much of the soil is well adapted for grain and grats. No part of the state is more rapidly advancing in agricultural improvements than this western region. The soil of the level country east of lake Ontario, and along the St. Lawrence, is a warm sandy loam, with a large proportion of the first rate of medium for agriculture.

The rotation of crops lately introduced into this country marks a new era in its agriculture. We shall close this detail with remarking, that the exertions of the agricultural society of this state have been very beneficial, though its publications need more general circulation. The *botanical productions* of this state are numerous and various. Its forest-trees are luxuriant. The region of the western climate is principally wooded with deciduous trees, and of the loftiest growth. Those of the eastern or Atlantic climate are generally deciduous, but less lofty. The most common forest-trees are, oak, maple, beech, walnut, butternut, chestnut, birch, tulia or balsam, poplar, cherry, sycamore or button-wood, ash, elm, fattafras, hornbeam, sash, elder, pine, spruce, larch, fir, hemlock, cedar, and in some parts, locust, laurel, mulberry, black-walnut, cucumber-tree, crab-apple, and common thorn, of many varieties. The state of New York is essentially agricultural. Wheat is the first object of the farmers; and they also cultivate rye, maize, oats, flax, hemp, peas, beans, &c. and most of the domestic grasses are cultivated with success. Fruits are abundant and various; such as apples, affordability of the best quality, peaches, pears, plums, cherries, &c. The garden-fruits are as various as those of any state in the Union.

The *domestic zoology* of the state presents the horse, the cow kind, the merino and other kinds of sheep, which furnish good wool, and swine. The wild animals, not to mention the mammoth, the moofe, and the bison, now extinct in this state, are, the deer, bear, wolf, and fox; and more rarely, the otter, the wolverene, the wild-cat, raccoon, marten, the weasel, hare and rabbit, squirrel and mole, &c. The lakes and rivers supply abundance of fish, such as the salmon-trout, trout, furgeon, chad, herring, pike, and many others. The fayers are in high repute. The number of birds flightarian and migratory is very great. Serpents are found in small numbers, and the rattle-snake does not frequently occur; other snakes are numerous. It is needful to mention the insects, of which the number and variety are considerable.

The *mineralogy* comprehends iron-ore, salt, gypsum, lime-stone, marble, slate, native brimstone, coal, ores of lead, copper, zinc, tin, albeftos, mill-stones, marle and peat, clays, alun, swine-stone, &c. Calcareous petrifactions are very common in the calcareous regions. Silicious sand for the manufacture of glafs, plumbago, a variety of ochres, mica, bitulins, magnetian stones, amiantus, black flints for muffets, molybdana, iron and copper pyrites, emery, magnetic ores of iron, ores of zinc, ores containing silver and anti-mony, and rock crystals, are severally found in various parts of this state. Its mineral waters are held in high estimation.

The *constitution* of this state was adopted by a convention of delegates April 20, 1777, and revised in 1801; and its character is republican. The constitution of the United States was acceded to in this state in 1788. The supreme executive power is vested in a governor and lieutenant-governor, elected every three years by free-holders paying fifty dollars, or both, or the state of 250 dollars; as are the senators also. The supreme legislative powers are vested in a senate and house of assembly, which meet at least once in each year. The senators are elected for four years; the members, or representatives, as they are called, who compose the house of assembly, are elected annually. The number of senators is limited to thirty-two; that of members is not to exceed 150. For the convenience of electing senators, the state is divided into four great districts: the southern, which elects five senators, and comprehends six counties; the middle, eight; the eastern, nine; and the western, twenty-two.

The general election is held annually. A census of the electors is taken every seven years, and the representation apportioned according to the numbers in the respective counties, increasing the number of representatives each year by the addition of two, until they amount to 150. The senators are divided into four clases, elected at different periods, so that some new senators are chosen annually. The governor is commander-in-chief of the militia, and admiral of the navy, of this state: he has power to convene the legislature; to grant pardons and reprieves for crimes, except treason and murder; and can suspend the execution of sentences in those cases till the sitting of the legislature, which alone has a right to pardon. A council of revision consists of the governor, the chancellor, the judges of the supreme court, or any two of them, whose duty it is to revile all bills about to be passed into laws; and if they object in writing to a bill, a re-consideration is taken place, and the same must be amended or approved by two-thirds of both houses before it can then become a law: and this is the negative of the executive power. If the council neglect to return a bill, in ten days it becomes a law, unless the legislature has previously adjourned. A council of appointment consists of the governor, and a senator from each of the four great districts, chosen annually by the legislature. In this council, the governor presides, with only a casting vote. The right to nominate is vested concurrently in the governor and the other members of the council. The list of officers annually appointed by this council is enormous, and consists of most of the subordinate officers of the state.

The chancellor holds courts of equity, and appoints the officers of his court. The supreme court is a court of law. It consists of a chief-justice and four associate judges. County courts consist of a first judge and a number of associate justices. Circuit courts are held in the respective counties by a judge or justices of the supreme court, and the judge and justices of the county. Justices of the peace have cognizance of trials for the recovery of debts to the value of twenty-five dollars; and in New York to the value of fifty dollars. The right of habeas corpus is preferred, and the trial by jury.

The great officers of state are, the governor, lieutenant-governor, a secretary of state, comptroller, treasurer, surveyor-general, attorney-general, council of appointment, commissioners of the land-office, the regents of the university, &c. for the department of state.

Judiciary officers of state, a chancellor, five judges of the supreme court, and a judge of probates.

For the general convenience and the better administration of justice, the whole territory of this state is subdivided into counties, and them into towns.

From the report of the comptroller to the legislature of this state in 1811, the productive funds of this state, in-
York.

...who planted the colony of New York, and who for many years afterwards settled in it, a large proportion of Dutch families, who migrated here from the Dutch Netherlands, and transferred to the societies which they established here, the rural economy of the population of the Netherlands, of Holland, and of the banks of the Rhine. Soon after their arrival, various parts of this state presented buildings resembling those of their native country, and habits of neatness, order, industry, and frugality, which they had practiced from their youth. After the conquest of the English in 1664, Multitudes flocked hither from various nations of Europe, and produced a considerable change in the original and discriminating character and customs of this colony. In 1685 it had a numerous accession of French Protestants. In 1710 it was augmented by about one hundred families of poor Palatines from Germany; fifty or seventy of which settled Germantown on the east bank of the Hudson, and some at Ephesus, now Kingston. Other early German emigrants settled on the Mohawk, in Orange county, on Long island, and in many other parts where their descendants are now found. The early English settled principally at New York and in Long island. The French, at New Rochelle, in Westchester county, and on Staten island. The Scotch fixed themselves, during the more early periods, about Albany, and in Washington county. Massachusetts supplied also the east part of Long island with inhabitants, whose porter form a large share of the present population. But the Dutch were the original proprietors and first colonists, and therefore their possessions were the greatest and the most valuable: nor did they, or the Germans, next to them in number and importance, altogether abandon their discriminating manners and habits. The Revolution, however, produced a material change in this state, and the change, though effected by singular conflicts, was not unfavourable to its general character. The prosperity that succeeded the peace widely diffused a spirit of enterprize and of emigration; and was followed by a surprising increase of population and wealth. Hence arose those various traits of national character, and those diversified habits, manners, and customs, which have distinguished this state. It is observed, that the new character imparted by the influx of emigrants is beneficial to the state; more especially as the New England people have introduced their improved agriculture, their spirit of enterprize, their ingenuity in the arts, and their social habits. In this state, it is said, there are about 100,000 freeholders; and freehold estates are known to produce for their proprietors from 30,000 down to 50 dollars per annum; and this fact is alleged as forming a peculiar feature of the civil habits, manners, and customs of the population of this state.

The English language is chiefly prevalent in this state; though the Dutch and German are in use among people of Dutch and German descent: but these and other dialects are declining, in consequence of the intercourse and influence of a large majority of those who speak English. Some few influences, however, occur, in which public worship is performed in the Dutch, German, and Welsh dialects.

The taste for literature and science is gradually increasing, and is promoted by a variety of publications; and by the progressive improvement of school education, for which a liberal fund is provided, which has been already mentioned. We are informed by the writer of communications, of which we avail ourselves in the compilation of this article, that there are about a hundred printing establishments in this state, and sixty-nine gazettes, besides a very considerable number of other public journals, which contribute to diffuse various kinds of knowledge. The advancement of literature is promoted by...
York.

an institution established in 1787, intitled “Regents of the University of the State of New York;” being a society of twenty-one gentlemen, possessing adequate powers derived from the legislature for superintending colleges, seminaries, and schools. The University of New York is acquiring distinction, and the Columbia college claims high reputation.

In this state there are fifteen banking companies, with a very considerable sum of capital stock, which is paid to have amounted in 1811 to 12,385,000 dollars; and 11 incorporated affarance companies. The manufactures of this state, consisting of woollen, linen, and cotton cloths, leather, paper, hats, iron, &c. are in an improving condition, and are paid to have amounted, in 1811, to 30,000,000 dollars, of which 12,000,000 were produced by household industry and enterprize. If we judge of the commerce of this state by the returns of 1810, it must appear to be very considerable. The domestic exports of that year amounted to 9,928,573 dollars, and the foreign to 6,313,757, making a total of 17,242,330 dollars; and it is said that the port of New York yields about one-fourth of the revenue of the United States, arising from commerce. The exports, exclusive of articles from foreign countries, consist principally of beef, tallow, pork, hams, lard, wheat, maize, rye, butter, cheese, pot and pearl ashes, flax-seed, peas, beans, horser, cattle, lumber, flour and meal, bread and biscuit. The foreign imports are composed of important articles. Wheat, which is the national staple, is exported annually to a very great amount; and about 6,000,000 of bushels on an average, after deducting the supplies for the country, are sent to market from the surplus product of this state. The average annual payments into the treasury of the United States, for duties on imports, tonnage, &c. exceed 4,000,000 of dollars from the district of New York.

The Societies for promoting Agriculture and the Arts in this state are numerous. It has also several Medical Societies; an Historical Society; and also an Academy of Arts lately established at New York. Bible and Missionary Societies are instituted in New York, Albany, and some other counties; and the Charitable and Humane Societies abound. In the city of New York alone there are about forty benevolent institutions; and there are societies of the same kind, as well as those of a literary nature, in Albany, Hudson, Schenectady, Troy, Poughkeepsie, Kingston, Newburgh, Utica, and most of the large towns.

The State Prison, or Penitentiary, is about two miles from the city-hall, in the city of New York, on the E. bank of the Hudson: it was built in 1766-7, and together with its buildings and courts comprises four acres of ground. The immediate government of the prison is committed to seven inspectors. The convicts are all dressed in uniform, the files kept separate, and all are comfortably clothed and fed. Great care is taken of their morals, in the benevolent hope of a reformation.

The Natural Curiosities of this state comprehend the cata-

ncts or falls of Niagara, of the Mohawk, of the Hudson, of West Canada creek, of Black river, Seneca river, Genesee river, and some others of less note. It is probable, that the southern and western parts of this state were occupied by a considerable proportion of Indians at a remote period. So long ago as the year 1535, the country about the lake Onondaga was considered as a favourite situation by the wandering tribes: but their condition was not much known till about the year 1655. At the same time, the Iroquois, or Six, Nations, occupied the countries from Lake Erie to Ontario, the St. Lawrence, around lake Champlain, and the whole of that watered by the Hudson down to the Highlands, were very numerous and warlike. Such was their ascendency, that the Indians of the lower country of the Hudson, on the Connecticut, the Delaware, and Susquehanna rivers, were in a kind of subjection to them. Onondaga was their principal settlement, and the seat of Indian power. Their combination confitited of Onondagas, Oneidas, Mohawks, Cayugas, and Senecas; and it was then so powerful as to be able to send several thousand warriors on distant expeditions.

The first Christian colonists, availing themselves of Indian wars, which they promoted, taught the Indians to despise and abhor those for their hypocrisy and perversity whom they had first considered as beings of a superior order; and thus origin-ated the implacable enmities which not only continued but increased when the French and Britisli became rival nations. About the year 1690, the English erected a strong fort at Onondaga; and in 1696, the French sent a considerable force against the Indian settlement, and succeeded in destroy-ing it. From this time, colonies of each of these nations were planted there at different periods. But we forbear, to pursue their history, and to trace the continued conflicts that served mutually to irritate and increase Indians and pros- fessed Christians. At this time, the principal settlements of the Indians are at Oneida and Onondaga, on the Genesee and Alleghany rivers, Buffalo creek, and Tuscarora, besides other places which we have not room to enumerate in detail. But we must hâllen to finish this sketch of the New York state by a brief abstract of its history.

Soon after the discovery of America, towards the commence-ment of the 16th century, the present state of New York was possessed by the Iroquois, and Canada by the Algosquins, two rival nations of Indians. About the year 1608, the French planted colonies in Canada, which they had laid claim to from having first filled up the St. Lawrence as far as the present Montreal. In 1609 Champlain, the foun-der, discovered lakes Champlain and George, when he de-feated a small party of the Iroquois. In 1608 Hudson, an Englishman, discovered the Eait and North rivers, ascend-ing up the latter as far as the present Albany; and soon after he sold his right to the Dutch. In 1614 the States General of Holland erected a fort at Albany, and granted an exclusive trade on Hudson river to the Dutch West India company; and in 1629, Wouter van Twiller, the first go-vernor, arrived, and took the command of New Netherland, as it was then called. The English, who still laid claim to this country, objected to the sale of Hudson; and in 1663-4, the English king granted the whole to his brother James, duke of York and Albany, afterwards James II. A small armament subdued the colony for England, which then took the name of New York, as did the city also. In 1673 New York was conquered by the Dutch; but restored in 1673-4. The duke's grant was confirmed, and the col-ony aligned to the English by treaty; and this right they held till the Revolution. From the surrender of the prov-ince in 1664 to 1683, the duke of York possessed full so-vereignty. He appointed the governor and the council, who made rules and orders that were acknowledged as laws. These were called the duke's laws; they were collected and arranged about 1674, and a copy of them is deposited among the records of the state. Tho' it is said, which were made in 1683, and after the duke's accession to the throne of England, when the people were admitted to a participa-tion of the legislative power, are defaced or lost. No regard is now paid to any laws made here antecedently to 1691, when the first legislature was organized. In 1691, New York was then divided into nine counties, and the house consisted of seventeen delegates. The second legislative assembly was convened in 1708. We shall not minutely trace
trace the series of events that occurred in this state before the
year 1776, when, on July 4, the thirteen united colonies were
declared independent. This was followed in 1777 by the
formation and adoption of the state constitution by a
convention of delegates, which was revised in 1801. In
1788, New York was evacuated by the British, and general
Washington made his public entry Nov. 25. In 1787 the
precent constitution of the United States was proposed
by the convention, and acceded to by this state in 1788, by
a majority of 30 to 25 votes. General Washington was
elected president of the United States, and Congress met at
New York for the first time under the new federal constitu-
tion, March 4, 1789. In 1797 Albany was made the capi-
tal of the state. In 1801 the legislature divided the state
into thirty counties, and these into towns. An academy of
the fine arts was founded in New York. In 1807 a steam-
boat was established on the Hudson for passengers, between
New York and Albany, and in 1811 their number was 5. In
1809-10, the capitol was built at Albany, at an expense of
115,000 dollars, and was first used by the legislature in the
fall of 1809. New York, New, a county in the American state of the
same name, comprises the island of Manhattan, or York
island, on the E. side, and near the mouth of Hudson
river. It is about 14½ miles long from N. to S., and in
breadth varying from half a mile to two miles; its area is about
213 square miles, or 13,930 acres. It is situated between
40° 42' and 40° 52' N. lat., and 4° 8' E. long, from the
city of New York. It is bounded on the N. and E. by
Haarlem and East rivers, S. and W. by the Hudson, or by
York bay, and the state of New Jersey. The limits of the
county, town, and city of New York are the same; and the only legal subdivisions are the wards, ten in number.
The jurisdiction of the city and county of New York ex-
tends to low-water mark on the opposite shores of the
waters that surround this county. The agriculture of New York county is highly respectable, and its horticulture is in the first style of the country. The whole population of the
county probably exceeds 100,000; by the census of 1810, it amounted to 96,373. This county sends 11 members to
the house of assembly.

York, New, a city of America, the capital of a county of the
same name, is situated on the E. bank, at the confluence of
Hudson and East rivers, at the fourth end of New York
island. N. lat. 40° 42' 40'' W. long. from Greenwich
74° 5' 45''. The compact part of this city extends along the
Hudson about two miles, and along East river, from the
S.W. angle of the battery, near four miles; its circuit is
about 7½ miles. The streets of the ancient part are irregular;
but the northern part has been recently laid out to
greater advantage. Many of the streets are spacious, run-
ing in right lines, and intersected by others at right angles.
The surface has at present a gentle ascent from the Hudson
and East rivers, and commands a fine view on the right
and left of the town, the above-named rivers, and their crowds
of shipping. The principal streets are, Broadway, opening to the N.E., and extending through the whole length of the
city, Greenwich-street, Pearl-street, &c. &c. The usual
tides at New York are about fix feet, and the depth of
water is sufficient for the largest ships; and the harbour,
which is safe and good, is capacious enough for the largest
fleets, and very rarely obstructed by ice. The houses of
this city are well built of brick, and its public buildings
are numerous and elegant. The first of these that deferves
mention is the city-hall, in which are held the courts for the
city and county of New York. This building stands on
an elevated ground, and its structure is ornamental to the city.

The whole number of the churches, or houses for Christian
worship, is 37, besides a Jewis Synagogue. Of these, eight
are Presbyterian, eight Episcopal, four Dutch Reformed,
three Scotch Presbyterian, three Methodist, two for Friends
or Quakers, two Baptist, two German Lutheran, one
French Protestant, one Moravian, one Roman Catholic, two
African. The New York hospital is an extensive establishment;
the cuftom-house adjoins the battery at the S.W.
angle of the city; the gaol and bridewell are opposite to
the Park, and the alms-house is on the same square with the
gaal, bridewell, and city-hall. The college is about mid-
way between the Park and the river Hudson; and St. John's
church, reckoned the most elegant in the city, is in Hudson-
square, farther north. The state-prison is two miles N.
of the battery, on the bank of the Hudson. Here are also a
library and theatre, five market-houses, and many other
buildings that might, if space were allowable, be enum-
rated. There are eight banking-companies in this city; and
their houses and offices, together with those of the insurance,
manufacturing, and other companies, and those of various fo-
cieties, added to the number of edifices that adorn the metro-
polis. The population, which by the census of 1810 was
estimated at 96,373, is supposed to amount to more than
100,000. The city and harbour of New York have been
lately fortified against naval assaults at a very great expanse;
but we should be tedious in minutely describing the works
which have been constructed for this purpose. The number
of charitable establishments, and of schools for education in
this city, is very great, and does honour to the disposition and
liberality of its inhabitants. The markets, which are kept
every day, are well supplied with the productions both of
land and water. The public walks and amusements in the
vicinity of this city afford attraction to its flated inhab-
ants, and to those who occasionally resort hither. The
theatre, reading-rooms, public-gardens, park, and walks on the
battery, afford amusement; and contribute to activity and
health.

The city of New York is governed by a mayor, recorder,
aldermen, and aldermen, who constitute the common coun-
cil. Each ward chooses an alderman and alderman. The
mayor, deputy-mayor, recorder, and aldermen, are ex-officio
judges of the peace, and justices of oyer and terminer; and
the mayor, aldermen, and commonalty, are authorized to hold
a court of record or of common pleas; and this is called the
mayor's court, and deemed of great importance. For the
manufactures, commerce, literary institutions, &c. &c. of the
city of New York, we refer to the account already
given of the state of New York. Melville, More. Saff-
ford's Gazetteer of New York, 1813.

York, New, a poll-town of Virginia; 167 miles S.W.
of Washington.

York Town, or York, a township of West Chester
county, in the state of New York; 45 miles N. of New
York, bounded N. by Duchess county; E. by Somers
and New-York, S. by New-York, W. by Cortland;
length N. and S. 10 miles, and nearly 4 miles wide. The
general surface is hilly, but producive, and well distribu-
ted into arable, pasture, and meadow lands. In 1810, here were
262 taxable inhabitants, 142 electors, and in all 1924
inhabitants.

York Town, a town of the state of Virginia, capital of the
county of York, on the right bank of York river, about
10 miles from its mouth, containing about 800 inhabitants.
In the year 1781, the British army under Lord Cornwallis
surrendered themselves prisoners of war to the united forces
of America and France near this town, and was the occa-
sion of a peace which followed soon after. A marble
column,
YORKSHIRE.

column, with a suitable inscription and trophies, was ordered by Congress to be erected on the spot in commemoration of the event; 8 miles E. of Williamburgh.

YORKSHIRE, a county in the northern part of England, which, for extent, for its number of inhabitants, and for its natural and artificial productions, is far the most productive in the kingdom. It is in general a country of an irregular quadrangle; the longest diagonal extends from N.W. to S.E. about 130 miles, and the shortest from S.W. to N.E. about 90 miles. The area of the county comprehends about 5,060 square miles, or above 3,814,000 statute acres. Yorkshire, taken at its extreme points, is situated between the parallels of 52° 18', and 54° 40' N., and between 2° 40' of W. and 0° 10' of E. longitude from Greenwich. On the N., the E., and part of the S. sides, it is distinctly defined by rivers and by the sea. On the N. it is separated in its whole extent, from the county of Durham, by the river Tees. From the mouth of this river to the entrance of the Humber, the whole E. side is washed by the German ocean. By the eftuary of the Humber and the river Trent, it is separated from Lincolnshire on the S. The limits between Yorkshire, the counties of Nottingham, Derby, and Chelther on the S., and those separating it from Lancashire and Westmorland on the W., are merely conventional, being indicated by no natural feature of the country; the latter, however, in general, coincide with the mountainous range which distinguishes the northern from the southern provinces of England. At a very early period of the Saxon dominion, the great county of York was subdivided into three districts, Jutland, or Jutland, and all under the corrupt name of ridings. These are termed north, east, and west, in reference to their relative positions with respect to each other, and to the capital city of the county. The North Riding is subdivided into 12 wapentakes, the East into 7, and the West into 11 wapentakes; the whole county thus containing 36 wapentakes and 563 parishes. The wapentake, a division adopted in certain northern counties of England, corresponds generally to the centred or hundred of the southern provinces. The whole county comprehends one archiepiscopal city, York, and 59 market-towns, of which 13 are parliamentary boroughs. Of these last in the North Riding are 5, viz. Malton, Northallerton, Richmond, Scarborough, and Thirsk; the East Riding contains three boroughs, Beverley, Heydon, and Hull: in the West Riding the five boroughs are, Aldborough, Boroughbridge, Knareborough, Pontefract, and Ripon. Yorkshire sends thirty members to parliament; viz. two for the county, two for the city, and two for each of the boroughs just named. According to the official reports made in 1811, the number of houses and inhabitants in the county was the following:— In the North Riding 335,679 houses, and 152,445 inhabitants; in the East Riding (York city included), 334,220 houses, and 167,353 inhabitants; and in the West Riding, 129,575 houses, and 653,315 inhabitants. From this statement, Yorkshire, at that period, contained altogether 1,654,592 houses, and 973,113 inhabitants, or an average of 1,65 persons for each square itate mile.

General Appearance, Soil, and Climate.—Yorkshire is an extensive and interesting county; in its geographical features, and geological characteristics, it presents important themes for inquiry and dilinition. Its ancient history, and the numerous antiquities with which it abounds, afford other and not less interesting topics for investigation and comment. The manufactures, commerce, and trade of the county; its mineral productions, and agricultural practices, are also entitled to the most careful and critical develope-

ment of the topographer. It is, however, to be regretted, that neither of these subjects has hitherto been satisfactorily elucidated by a local historian; whence we shall be necessitated to refer to and cautiously analyze several detached and imperfect works, to render a short topographical account of this widely-extended county in any degree useful to the general reader. In the sequel these works will be referred to.

Yorkshire presents a great variety of surface: mountains, hills, vales, moors, fens, rocks, coasts, and rivers, are its component parts; but these are greatly diversified. The North Riding confines principally of two hilly regions, separated by a comparatively low tract, which opens on the S. into the fpacious plain or vale of York. The billy parts are commonly termed, from their position and their nature, the E. and the W. moorlands. Thole on the E. bounded by the river of the river Tees on the N., and by the sea on the N.E., occupy a space of 30 miles from W. to E. by about half as much from N. to S. They coincide in general of bleak heath, interpered with loofe blocks of stone, or with peat-mofs and bog. The whole is delitute of wood, excepting in a few interflecting dales or valleys, where cultivation is practicable. Of these dales a few are of moderate extent, particularly Eskdale and Bielddale, in the eastern parts toward the sea. The western extremity of these moorlands, in the district of Hamilton, produces heat intermingled with large quantities of coarse grafts. Between the N. edge of the moorlands and the river Tees is the fertile district of Cleveland. Several productive valleys intersect the W. moorlands, of which Wenleydale is the most considerable. Watered by the river Ure, the bottom of the valley furnishes rich grazing grounds, bordered on each side by floping inclosed fields, which reach up the hills for more than a mile from the sea. In the East Riding the face of the country, although varied, is less boldly characterized than that in the N. It is divided in the middle into two extensive plains, by the Wolds, a range of hills stretching N. and S. Towards the sea the coast of this Riding is in general low when compared with that of the North Riding; but in several places it rises to cliffs of considerable height, as at and in the vicinity of Flamborough-head. The E.S. part of this Riding confines chiefly a tract of fen and marsh, about 20 miles in length, and four in breadth, which spreads from the sea to the Humber. This part of the Riding, forming the wapentake of Holderness, runs out to the S.E. and S., and terminates its course at the Spurn, a well-known point on the N. shore of the Humber. A succession of easy rilings forms the eastern acent of the range of the Wolds; but on other sides they are steep; and the whole have an agreeable and peculiar appearance. Considered with respect to extent and population, to manufactures and trade, the West Riding is by far the most important division of Yorkshire. Its surface is very irregular, varying from the low marshy tracts in the E. to the rocky mountainous country in the W. The level marshes are the continuation of those already mentioned in the East Riding, and extend wellward almost to the great N. road through Doncaster. Still farther westward lies the middle division of the West Riding, gradually and beautifully swelling into hills, and extending to Sheffield, Bradford, and Otley. Beyond these towns, the country becomes rugged and mountainous, and is composed chiefly of black moors, which terminate in the lofty range of hills bordering on Lancashire. These hilly and mountainous tracts are not, however, without many beautiful and romantic valleys, among which are these watered by the rivers Aire, Nid, and Wharf. Several of the smaller dales are well-
well-wooded and inclosed, and have numerous villages
interfereed.

The soil of Yorkshire is not at least variegated than the sur-
faced. In the E. moorlands of the North Riding, wherever
the ground is covered with ling or heath, the upper soil
is invariably black moor or peat; but the subsoil is various,
and consists of clay, free-stone, and hardened sand. In that
part of the moors called Hamilton, the soil consists gene-

erally of fine loam on lime-stone rock. In the interferting
dales, black moor, earth, land, and grit-rock, more or less,
prevail; but the vale of Cleveland, along the river Tees, is
composed chiefly of strong tenacious clay. Lime-stone, or
a calcareous rock, is the general basis of the W. moorlands;
and the beneficial effects of this subsoil are evident in the
grazes and other useful productions with which the surface
is generally covered. In the extensive tract of plain styded
the Vale of York, which occupies the interior parts of the
county, and comprehends portions of all the three Ridings,
considerable changes of soil are found. In the N. part
towards the river Tees, a rich gravelly loam prevails.
The lopes of the high grounds on the E. and W. are in
some places cold, and abound in springs; but in the greatest
d part the soil is strong and fertile. Of the East Riding, the
most striking feature is the range of hills called the Wolds,
composed of chalk; but the surface is in general a light
free loam, interfered with chalky gravel, often very
shallow. The great plain between the Wolds, the sea, and
the lower part of the Humber, contains many extensive
tracts of fertile cultivable land, especially in the N. and E.
quarters; but the southern districts, towards the river, are
covered with marshes and fens, susceptible, where draining
may be practised, of material improvement. In the com-
stitution of those fens, situated on the W. of the Wolds,
called the Levels, the soil is either clay or sand, with
moorish tracts interfered; but on the banks of the Dar-
went and the Ouse ilrong clay and loam prevail. In the
extensive West Riding foils of every kind are to be found,
from deep strong clay and rich loam to the poorest peat-
earth. Clay and loam, but mingled with some sand and
moor, prevail in the E. district of this Riding, while the
middle division consists chiefly of loam on a lime-stone base.
Similar soils extend through the W. parts, but are fre-

cquently interrupted by tracts of moor of different kinds.

In a country of such extent, and of such variety of soil,
elevation, and exposure, as Yorkshire, an accordant variety
of climate, with regard to temperature, humidity, and falsi-
brity, mult naturally be experienced. The E. moorlands,
advancing high and bold into the German ocean, are
necessarily exposed to the cold, moist, and impetuous winds
from the N. and E. The climate there, however, is rather
difagreeable than unhealthy; for the high grounds are fre-

quently involved in fogs and vapours from the sea. Among
the W. moorlands the climate is still more severe; but its
effects on the productions of the surface are powerfully
counteracted by the calcareous rock of which those moun-
tainous tracts consist. By their distance from the sea, com-
bined with their much greater elevation, the snow remains
on them considerably longer than on the E. moorlands.
But the greatest obstacle to agricultural labours in the W.
parts of the county is the almost incessant rain which falls
among the mountains. On them are accumulated and con-
dened the vapours collected by the opposite winds, which
prevail on the contrary sides of the island. By the humidity
thus produced, no attempt to raise corn-crops among those
high lands can succeed. In the intermediate plains and
gently-swelling tracts of the centre of the county, the
climate is, on the contrary, in general mild and temperate,
in proportion to the remoteness from the mountainous
quarters. The low grounds on the banks of the Darwent,
are, however, so moist, although warm, as to be much
better adapted to pasturage than to corn-land. What is
paid of the climate of the W. parts of the North Riding is
equally applicable to the corresponding portion of the W.;
for there the climate is also rainy, cold, and stormy. At
Sheffield, although on the S. border of the county, the
quantity of rain which falls in a year is about 35 inches.
It is, indeed, found by experience, that the lofty tracts
which separate Yorkshire from Lancashire and Cheshire
are fully as subject to fog, rain, and storms, as any other
portion of England. But notwithstanding these circum-
stances, the air is pure and healthy. The middle and less-

elevated tracts of the West Riding are equally healthy,
milder, and less humid; holding a defirable medium between
the tempestuous blasts of the mountains in the W., and the
dull fogs and damps which usually befet the low marshy
country in the E. On the opposite sides of the Wolds, in
the East Riding, a different temperature is experienced;
for by those hills the W. division is in general sheltered
from the cold damp winds from the sea and the entrance
of the Humber, which prevail over the E. division. On
the Wolds themselves the air is sharp, and the snow remains for
a considerable time on the ground. But the mildness of the
climate in the W. Levels is abundantly compensated, in
regard to falsibrity, by the vapours of the marshes.

Mountains.—The E. moorlands of the North Riding
form a peculiar feature in the county; for they are wholly
detached by their position, and by their subsoil, from the
mountains in the W. Some points of the E. moorlands
rise nearly 900 feet above the level of the sea; but the most
remarkable summit of the whole is Rosebury Topping.
This singular hill, situated midway between Stokelsey
and Guisborough, towards the N.W. edge of the moors,
shoots up in a conical form, to the height of 1488 feet above
the sea. By its detached position and superior elevation, it
commands, in all directions, a prospect at once extensive
and interesting. The hill seems to rest on a basis of alum-
rock, interfered with iron-stone; and its pinnacled summit
indicates to the surrounding country the approaching
changes in the weather; for when the summit is involved
in clouds, rains seldom fail to descend on the neighbouring
low grounds. It is, however, on the W. borders of the
county, that the most elevated mountains are found. These
are a portion of the chain, which, commencing in the S. in
Yorkland, extend northward, with increasing elevation,
through Derbyshire, Lancashire, Welfmoreland, Cumber-
land, and Northumberland, into Scotland. In that portion
of this range which belongs to Yorkshire are several fum-
mits of very considerable elevation above the sea. Of these,
the most remarkable are, Penningant, which rises, according
to barometrical measurement, to the height of 3930 feet;
Ingleborough, 3987 feet; and Whernside, 4052 feet. The
lait mountain is the highest in England; for Crossfell on
the borders of Cumberland is in height only 3839 feet;
Skiddaw, 3530; and Snowden, the highest in Wales, 3568.
Bennies, a detached mountain in the N. of Scotland, and
the most elevated in Britain, rises to the height of 4387
feet. Penningant, situated about 7 miles N. from Settle, is
steep and towering. Ingleborough consists of a basis of
lime-stone, but towards the summit the grit-rock appears.
The E. and S. sides of this mountain are very steep, and of
difficult ascent, on account of a deep morais at the bottom;
but the W. and N. sides, particularly the former, may be
ascended
ancended with ease. Continually receiving vapours from the Irish sea on the W., Ingleborough is seldom free from clouds, and the whole mountain abounds with springs: whence it is covered with verdure, and sheep graze on the mottled elevated parts. In the vicinity appear Pennignant, distant 6 miles to the E., and Whernside 5 miles to the N. On the N.W. are the mountains of Wensmoreland, and on the W. spreads out the low land of Lancashire, bounded at the distance of 24 miles by the Irish sea, of which a great portion may, in clear weather, be deft. In the midst of a circle of hills rises Whernside, on which account, although more elevated, the views from it are not equally interesting with those from Ingleborough. Near the summit are several small lakes or pools, there called tarns, one of which is about 180 yards in length by nearly an equal breadth. In the East Riding, the only hills of note are the Wolds, which exhibit themselves to advantage, in rising out of the low country around them; but at no point are they supposed to exceed 600 feet in height.

Rivers.—Along the whole length of the North Riding, from W. to E., the county is bounded by the river Tees. Rising in the mountains of Wensmoreland and Cumberland, it pursues a very indirect course into the German ocean below Stockton, where it spreads out into an estuary three miles in breadth. The river Tees is navigable for ships of considerable burthen up to Stockton; but the channel is serpentine and intricate, and the current is rapid. Commodious anchorage is, however, found at the entrance, in winds from the W. and S. A few incon siderable streams from the W. moorlands fall into the river Tees; but the great body of the waters of Yorkshire take their course in the opposite direction, and unite with the Humber. On these rivers, the most northern is the Swale, which, rising in the W. moorlands, enlivens the romantic Swale dale, and, after visiting Richmond, bends S.E. until it reaches Boroughbridge, where it unites with the Ure. The latter river, proceeding from the same moors, passeth near to Ripon, and in some part of its course separates the North and West Ridings. Having received the Swale, about six miles below Boroughbridge, the Ure takes the name of Ouse, from an insignificant rivulet which joins it on the W. side. Under this last appellation the combined stream, still farther augmented by the waters of the Nid, traverses the city of York, where it becomes the limit between the West and the East Ridings; and being navigable for large barges up to that city, it receives on its W. side the rivers Wharf and Aire: at last, after a very wandering course to the southward, in conjunction with the Trent, it disappears in the estuary of the Humber. The Aire, already mentioned, a very considerable stream, issuing from the mountains of Craven, facilitates by its waters the important manufactory commerce of Leeds. Receiving on the W. side the current of the Calder, which performs the same service to Wakefield, the joint stream conveys an important accession to the Ouse. Still farther to the S. the Don pursues its course from the W. mountains to Sheffield, where it bends to the N.E. by Rotheram and Doncaster, to its influx into the Aire. Before it be lost in the Humber, the Ouse receives on the E. the Derwent, which, having its sources in the E. moorlands, flows in general S.W. by Malton, across the western parts of the E. district. Two small streams still preserve notice in Yorkshire, not so much for their length of course, as for the variety of water, as for their use utility in forming the principal parts of the county. In the E. moorlands of the North Riding rises the Eke, which after watering Eskdale opens into the German ocean through the

harbour of Whitby. The river Hull traverses the East Riding from N. to S. palling near to Beverley, and, at its influx into the Humber, forms the secure though not capacious harbour of Kingston, which, from the river, is generally also called Hull.

Canals of Yorkshire. See Canal.

Coasts and Harbours.—The sea-coast of Yorkshire, though very extensive, affords but very few harbours of any importance. The mouth of the river Tees, as already stated, is frequented as a place of anchorage in winds from the south and the west. Vessels also often resort to other spots on the coast when the wind blows off the land, such as to Robin-hood's bay to the southward of Whitby, to Filey bay on the north-west, and Bridlington bay on the south-west of Flamborough-head.

The principal harbour on this coast is that of Whitby. (See Whitby.) Scarborough bay is serviceable in westerly winds; and the pier, a noble stone structure, furnishes easy access and safe protection for ships of considerable burthen; for at spring-tides, the depth of water at the entrance is from twenty to twenty-four feet: for want of a back-stream, however, the harbour is in danger of being filled with sand. The entrance of the Humber affords to shipping less protection than from its locality might be expected; for the shores on both sides of Yorkshire on the N.E. and of Lincolnshire on the S.W. are low, and the channel is much incumbered with sand-banks and shallows. Notwithstanding these disadvantages on its north bank, just at the point where the estuary turns its direction from E. to S.E., is situated that much-frequented and important harbour of Kingston-upon-Hull. The natural accommodation of the river has proved very insufficient for the increased shipping belonging to the port, which ranks as the fifth in the kingdom. Docks of great capacity have therefore been excavated, in which vessels lie afloat or dry, as may be required. From this port, the produce of the great manufacturing districts in the interior of the country are exported to foreign parts; and there foreign commodities are transferred to smaller vessels, to be in their turn distributed over the interior of the kingdom. The most remarkable projection of the coast of Yorkshire is the bold and lofty promontory, called Flamborough-head. The cliffs rise perpendicularly over the sea to the height of 100 and 150 yards. They are composed of a mouldering lime-stone rock, of uncommon whiteness; and at the bottom are pierced by a number of caverns, some of them entering a great way into the rock. A new light-house is placed about 400 yards west from the extremity of the promontory. About south by east eleven leagues from Flamborough-head is another point of great consequence to mariners. This is the Spurn-point, which, running out southwards, low and narrow, forms the north limit of the mouth of the Humber. The light-house is situated in N. lat. 53° 41' and E. long. 0° 17'.

Agriculture.—From what has been already noticed respecting the mountainous and the marshy tracts comprehended within the capacious limits of Yorkshire, agricultural improvements in them must be comparatively very limited. In other districts, however, particularly in the spacious plains forming the central parts of the county, every species of amelioration of the soil which the industry of the inhabitants, availing themselves of the natural means within their command, could apply, has been generally brought into action. The farms are of a very unequal extent and rental, conformably to the nature of the soil and to the situation of the farmer with respect to a market. It is remarkable, that in the North Riding leaves are unusual; but although the husbandman labours on fo precie-
rious a possession, changes of occupants of farms are by no means common. In the vale of York one-third of the land is computed to be in tillage, and two-thirds in grass; but in Cleveland, along the south bank of the river Tees, the country is equally divided between corn and pasture. In the environs of Thirsk, where the dairy is the chief object of pursuit, fully three-quarters of the land are devoted to it. In the valleys or dales which intersect the east moorlands, about one-fifth of the surface is in tillage; but in those of the west, a much smaller quantity is usually ploughed: those parts although inclosed are therefore generally in pasture. In few districts of England have improvements in agriculture been more generally or skillfully introduced than of late years in the East Riding. The farms are commonly large, and vary in annual rent from two or three hundred pounds to a thousand; but in the marshy tracts, called the levels, they are mostly small. By drainage there, and in the flat country, in the vicinity of Hull, large tracts, formerly flooded, now produce plentiful crops of corn; the value of the land being thus increased to ten times its former worth. In the hilly range of the Wolds, barley and oats have in many places tied the fupply of wheat. In the West Riding the farms are generally small, but in the environs of the manufacturing towns a great portion of the ground is occupied by the inhabitants for the use of their families. To the eastward of Leeds, Wakefield, and Rotheram, the greatest part of the Riding is cornland; but this tract contains no small proportion of common fields. The soil, however, is good, and improvement may be easily introduced. In addition to grain of all sorts, flax is cultivated in the marshlands to considerable extent; and in the environs of York mustard is now a valuable article of cultivation; though it is still considered as the produce of Durham. The horsetos Yorkshire, and in particular those of the North Riding, have long and universally been famed. Cleveland furnishes an excellent breed for the coach and the plough; the northern parts of the vale of York others for the coach and saddle; and many of both kinds are bred in the southern parts and the marshes. The East Riding also rears horses of peculiar value. A smaller but hardy and useful kind is bred in the dales of the east moorlands: many of an equally serviceable description are also produced in the moorlands on the west. The horned cattle of Yorkshire are of various kinds, adapted to the nature of their pastures, and to the uses for which they are employed. The north parts of the vale of York and the district of Cleveland produce the Tees-water breed, which is ranked among the largest in the kingdom. In the plains where cattle are chiefly kept for the purposes of the dairy, the milk, and not the form or strength of the race, is the main object of attention with the farmer. The sheep, in the various parts of the county are also extremely different in their nature and properties. In the North Riding, the flock has of late years been considerably improved by the introduction of the Northumberland and other breeds. The sheep of the west moorlands are small; but the wool is tolerably fine: those of the east moorlands are still smaller, but with a very coarse wool. Many of the old sheep-walks on the Wolds, in the East Riding, are now broken up, and converted into corn-land. In the West Riding, by the introduction of the Leicestershire breed, the sheep have in many places been highly improved. Those bred on the west moors and hills of this Riding, when brought down early to pasture in the low grounds, become very valuable for food. In many parts of Yorkshire, great satisfaction of the soil has been produced by hollow-draining; irrigation, paring, and burning the surface, have also been advantageously adopted. In certain tracts, bones bruised in a mill are usefully employed in composts for manure. Considering its great extent, the North Riding of Yorkshire contains but a small proportion of woodlands; the whole having been estimated at about 25,000 acres, of which the vale of York, with its boundary hills to the north, contains about 11,000. Large full-grown timber is accordingly very scarce, excepting on the estates of the earl of Carlile, C. S. Duncombe, &c. and some other land proprietors. But the oak-timber of this Riding, produced on hard rocky ground, if not of great size, is solid and durable; and hence the valuable qualities of the shipping built at Whitby and Scarborough. The planting of the Wolds in the East Riding has been successfully begun by several proprietors. In the West Riding, the quantity of oak and ash is very considerable; and both are much used for ship-building, and for the various demands of the manufacturers. Much is also consumed in the coal and other mines. In the vicinity of Sheffield, the duke of Norfolk polishes above 1500 acres of woodland. According to a calculation made in 1799, the wafle lands for the Riding amounted to the value of 400,000 acres, of which one-third seemed to be proper only for planting. No great progress in that operation has, however, yet been made.

Manufactures.—The manufactured productions of Yorkshire, especially of the West Riding, are of the very first importance to the county and to the kingdom, as well as to the multitudes to whom they furnish employment and wealth. The principal inducement for the establishment of those great works in the interior of the country was the plentiful supply of water and fuel for giving motion to machinery, and for the various other operations of the several branches of industry. Leeds, situated on the north bank of the river Aire, has long been celebrated as the centre of the manufacture of woollen cloth; and it is still the great mart for that staple article of the commerce of Yorkshire. (See Leeds, and Woollen Manufacture.) The white cloth is chiefly made at and about Dewsbury, among the hills which separate the valleys of the Aire and Calder, and in the vicinity of Wakefield. The mixed cloth is principally made in the villages comprehended in the parish of Leeds to the westward of the town; in the vale of Calder west from Wakefield; and also in the environs of Dewsbury. In the year 1806, the number of yards of broad cloth manufactured in the West Riding of Yorkshire is rated at 10,079,256, and of narrow cloth at 6,193,317. But in 1810 the broad cloth was only 9,826,048 yards, and the narrow cloth had increased to 6,951,762 yards. In 1811, however, the quantity of both sorts of cloth had comparatively diminished, for the yards of broad cloth were only 8,671,042, and those of narrow cloth 6,180,181; one of the many effects produced on the industry, and consequently on the well-being of the county and of the kingdom at large, by the hostilities in which Britain was then deeply involved on both sides of the Atlantic. The cutlery and plated goods of Sheffield are in all their branches carried to a perfection and an extent of which it is not easy to furnish a satisfactory account. The cutlery, consisting of edge-tools of every description, files, anvils, saws, &c. is not confined to that town, but manufactured in all the neighbouring villages. The plated goods, consisting of tea-sets, coffee-pots, tankards, candle-flicks, and many other articles of household use, are all prepared within the town. In it are also several founderies for iron, brass, and white metal.

Minerals, &c.—Excepting the alum on the borders of the east moorlands, and the lead of the vicinity of Richmond to-
wards the opposite quarter, the North Riding of Yorkshire furnishes but few mineral substances of peculiar value. Copper of good quality, it is true, was wrought about the middle of the last century near Middleton-Tyas; but the works have for some time been discontinued. Copper was also discovered about twenty years ago at Richmond. In the vale of the river Swale, twelve miles above that town, are several very profitable lead-mines. The iron-ore of the cast moorlands has not hitherto been applied to any useful purpose. It appears, however, from ancient records, that it is early as the beginning of the thirteenth century, iron was wrought and forged in Rotherdale. Ayton, a few miles S.W. from Scarborough, is the only place where forges are now established, and those are but inconsiderable. The great alum works are principally situated on the sea-coast on both sides of Whitby, and in the vicinity of Guisborough. See Whiteby and Alum.

Various parts of the North Riding produce coal, particularly in the plain between Eastling and Thirsk; and in the west moors, the coal hitherto discovered seems adapted only to the burning of lime: the north part of the Riding is consequently furnished with that mineral from the adjoining county of Durham. Good free-iron for building appears in many parts of the Riding: a few miles west from Whitby is a quarry from which have been drawn the blocks employed in constructing the new piers of that town. Lime-ore, and a species of marble not inferior to the Derbyshire, are found in different places; and loose blocks of red granite are seen on the surface in certain parts of the west moorlands.

In the East Riding, the chalk of the Wolds is the only mineral substance of importance hitherto discovered or brought into use; but the mineral productions of the West Riding are of peculiar value; for it contains lime, coal, iron, and lead, in great abundance. None of them, however, are found in the low level tracts in the eait division of the Riding. The lime-ore extends all to the westward of a line running northward from Doncaster to Tadcaster. The tracts situated between the rivers Aire at Leeds and Calder at Wakefield are the principal seats of the coal-mines, which abound likewise in the neighbourhood of Bradford, Barnsley, and Sheffield. Near Bradford also, there are very considerable iron-mines. Lead is principally extracted from the mines of Graftington, the property of the duke of Devonshire.

Yorkshire contains several mineral waters of great virtue and celebrity. The chalybeate and sulphuriferous springs of Harrogate have long been in high repute. See Harrogate.

Scarborough, on the sea-coast of the East Riding, has for a long time been celebrated for its mineral springs, which issue from the foot of a lofty cliff on the shore, a little way to the southward of the town. See Scarborough.

Ancient History, Remains, &c. — The great county of York was but a part of the territory of the British tribe, called in Roman history the Brigantes: they are not however mentioned by Caesar. It appears that they were first overpowered by Cæsar, in the reign of Vespasian, in the year 71 of the Christian era. In 78, the Roman arms were carried beyond the river Tyne in Scotland, where Agricola encountered the Caledonians, under Galgacus: but, contrary to the usual practice of the Romans, after a signal victory over the natives, as it is represented by Tacitus, his son-in-law and professed panegyrist, the Roman commander, retreated into the southern part of the country previously subdued. Having established a chain of posts across the narrow illusmus, between the firths of Forth and Clyde, Agricola was in the year 85 recalled by Domitian. From that period, until the arrival of the emperor Adrian himself in Britain in 120, little is known of the transactions in the northern parts of the island. That Adrian should deem it necessary to repair in person to the remote portion of the empire, which then comprehended the richest provinces of the world, is however a proof that the Britons, although overpowered, were by no means reduced to patient subjection. Renouncing, therefore, a great part of the country included within the chain of forts of Agricola, Adrian constructed an earth-rampart across the island, between the mouths of the rivers Tyne and Eden. While these operations were in progress, the emperor fixed his residence in Eboracum, or York; but scarcely had he returned to the continent when the northern Britons, breaking through the second rampart thrown up against them, joined with the Brigantes in an endeavour to regain their independence. To repulse these attempts, Lollius Urbicus was sent into Britain, who, repelling the natives beyond the Roman bounds, constructed a wall and towers on the line between the Forth and the Clyde, first fortified by Agricola. From this event, which happened about 140 until 183, Britain seemed to be tranquil: but then, while the empire was subject to the monter Commodus by the exertions of the natives, and the deficiency of part of the legions themselves, the power of the Romans in Britain was reduced to a very precarious situation. Pertinax, who had served in the island, and who, by his military talents, was fully qualified to restore the discipline and spirit of former times, was soon cut off by the licentious and disorderly, Pretorian guards of Rome; and in 196, Septimius Severus became sole master of the empire. The Caledonians still continuing their efforts to rid themselves of the Roman yoke, Severus, although thus far advanced in life, and very unfit for the service of the field, found it necessary to repair to Britain. (See York.) In 207 he arrived at Eboracum, in the full determination to quell the rebellions spirit of the natives. After an expedition into the northern parts of the island, in which the loss of the Romans is admitted by their own historians to have been prodigious, he fixed his head-quarters in Eboracum; and commanded the rampart thrown up by Adrian between the Eden and the Tyne, to be powerfully strengthened, as Urbicus had done on the northern rampart with a continued wall and forts of stone. Taking advantage of his absence from the frontiers, the Caledonians again had recourse to arms; but in 211, while Severus was preparing in Eboracum to repel their assaults, he died, and his sons and succecssors Caracalla and Geta soon afterwards returned to Rome. Whatever might have been the inclinations of the Brigantes, however gladly they would have combined with their countrymen of the north, yet by the presence of the imperial court, officers, and troops, every effort on their part must have been in vain discovered and repressed. Under Caracalla, Britain enjoyed some semblance of independence: but his affliliation in the midle of his spirited projects enabled Constantius to主体 Britain again to the Roman arms. Dying in Eboracum in 307, Constantius was succeeded in the western portion of the empire by his son Constantine, who was present at his death, and was immediately proclaimed emperor by the legions. For many years, the Brigantes with the other southern provinces of Britain seem to have been submissive to their masters; but in 364, the northern nations renewed their incursions, while the opposite part of the island was harassed by the predatory depredations.
test of the Saxons. Tranquillity was at last restored by Theodorus, whose son of the same name obtained the pur-
ple, and after a short reign died in 393. Diffusion within
and assault from without were now felt hastening on the
overthrow of the mighty empire of Rome; and in the
middle of the fifth century of our era, the Romans finally
relinquished all possession, power, and authority in Britain.
Of their long protracted residence in Yorkshire, many un-
questionable evidences are found in the capital, and in other
parts of the county. The roads established by that exten-
sive people may yet be traced, traversing the country in
various directions. The whole system of the Roman policy
and discipline was certainly directed to the perfection
of their military power.

One great line of probably Roman road, which traverses
the county of York from S. to N., is now called the Watling-
street, (a name apparently Saxon,) which was opened from
the Rutupian port, in the neighborhood of Sandwich, in
Kent, in various directions, all the way to the wall of Se-
verus. Entering Yorkshire near Bawtry, it has been traced
by Doncaster, (Danum, or the fation on the river Don,) over
Scarby and Pigburn Leas, to Barnsford, through Pontefract to Castleford, supposed to be the position of the
ancient Luselium, a little below the junction of the rivers
Aire and Calder. From this point, the road was conducted
by Castle, now Tadcaster, to Eboracum, or York. From
this city it probably followed the N.E. side of the river
Ouse, crossing it near to Iturium, now Aldborough, below
Boroughbridge, and thence by Leeming-lane to Catterick-
bridge, adjoining to which veltiges of Cataraetorum are to
be seen; there turning more to the northward, it passed over
the Tees at Pierce-bridge into the county of Durham.
Another military road is supposed to have been laid out from
Mancunium, now Manchester, in a N.E. direction, by Wake-
field, to join the former line between Doncaster and York.
North-eastwardly from York a road seems to have been
formed by or near Malton, terminating on the sea-coast at
Dunseby, the Dunus bay of Ptolemy. This road is still
called Wade’s caufeway, from the Saxon chief Wada, as
Caden thinks, who resided on the caflle in a caflle, perhaps
originally erected by the Romans. A branch of this road
is supposed to have led to Scarborough, when the sheltered
beach furnished a convenient place for Roman baths.
The straight course of an ancient road may be traced,
although over the high grounds of the Wolds pointing from
York towards Bridlington bay, corresponding probably to
the Sinus Gabrancicorum of the Romans; a branch has also
been observed tending towards Humby and Filey bay.
Another line may also be followed in a direction to
Patrington (Practorium) and the Spurn-point, which seems
to correspond with the Ocellum Promontorium of Ptolemy.
From Lincoln (Lindum colonia) a Roman road may be
traced running N. to the S. bank of the Humber near Win-
tringham, where are still seen veltiges of the flation, ad
Abum. On the N. bank, Drugh indicates the position of
another ancient flation, from which a branch of road proba-
bly communicated with York. This, however, is not the
courte indicated in the itineraries, which point out a much
more convenient course from Lincoln to York, across the
river Trent at Littleborough, the ancient Segelocum.

The veltiges of Roman works and occupation distributed
over various parts of Yorkshire are by far too numerous to
be mentioned in this place; it must therefore be sufficient
to point out two, Cataraetorum and Iturium. About five
miles below Richmond in Swaledale is the present village of
Catterick, so named from the Cataraetorum of the Romans,
of which the veltiges are visible on the S. bank of the river,

Yorkshire.

a little lower down the valley. Iturium exhibits the most
remarkable proofs of Roman habitation. Sixteen miles
above York, and nearly one mile below Boroughbridge, on
the S. bank of the river Ure, is Aldborough, so called in allu-
fion to the old town, to which it has succeeded, named by
the Romans Iturium.

Catterick.—Of these many still remain in Yorkshire, although
in several cases they are either nearly demolished, or by later
alterations, bear but little resemblance to their original
form and structure: in some, indeed, the name alone is pre-
ferrred. Of York caflle, the keep, or Clifford’s tower, is
almost all that is to be seen above the surface of the ground.
Scarborough caflle is situated on a projecting precipitous
cliff, 300 feet above the sea, and cut off by a deep natural
hollow from the high ground behind it. Richmond has long
been distinguished by its extensive caflle, which was erected
soon after the Norman Conquest by Alan, a kinsman of
William the Conqueror, on receiving the vaft possessions
of the Saxon, Edwin, earl of Chester. Crane or Creake caflle,
although belonging to the county of Durham, is situated only
twelve miles N. from York, is of great antiquity; for fo early
as in 685, it was bellowed on St. Cuthbert by Egfrid,
knight of Northumberland. Six miles W. from Doncaster,
are the caflle and village of Conibourgh, or more properly
Coningham. The caflle, one of the most interesting edifi-
ces of the kind in the N. of England, a building of great
extent and strength, is commanded by the high ground on
which the village is placed. The area of the caflle is in
circuit about 700 feet, encompassed by a very deep ditch,
now filled with trees. Of Knaresibough caflle, once a
fortriff of importance, but few remains are now to be seen.
It is believed to have been erected by Serlo de Burgh, who
received the manor as a reward for his services at the Con-
quell. Pontefract caflle, the scene of many transactions of
note in English history, in particular of the murder of
Richard II., is built on a lofty rock. Sheffield caflle, for-
merly of great strength from its situation, between and at
the meeting of the rivers Don and Sheaf, was levelled to
the ground by the parliament in the civil wars. The ancient
castle of Skipton, in the W. part of the county, is stlir in a
habitable state. It now belongs to the earl of Thane; but
was formerly the residence of the powerful family of Clifford,
of which Henry, the fourteenth lord, was, in 1295, created
earl of Cumberland. Near the E. bank of the Darwent,
S.E. from York, are the remains of the magnificent caflle of
Wresfle, supposed to have been erected by Percy, earl of
Worcester, in the reign of Richard II., towards the end of
the 14th century. Originally the caflle formed a quadrangle,
having a tower at each corner, and a fifth over the entrance.
Wresfle was one of the places of residence of the great
earls of Northumberland, where they lived in a style of splen-
dour and magnificence, formed on the model and with the
rate of the royal housefhold. Notwithstanding the zeal evinced
by the earl of Northumberland in the caflle of the parlia-
mnt, the caflle was, in 1652, dismantled. Three sides of
the quadrangle were demolished, and an accidental fire in
1796 completed its destrution. The fite belongs to the
earl of Egremont.

Seats.—To describe the number of admirable structures of
modern times, with which the county of York is adorned,
would require a volume. In this place merely to no-
tice some of the moft eminent seats is all that can be at-
tempted. About 13 miles N.N.E. from York is situated
Caire-Howard, the princely mansion of the earl of Carlisle,
of the illustrious house of Howard. On the fite of the
ancient caflle of Handerkif the present building was erected,
about a century ago, by Sir John Vanbrugh, the celebrated

architect.
Arkitekt of Blenheim. Castle-Howard, in its general arrangement and appearance, bears an evident resemblance to that superb structure, and indicates the genius of that distinguished artist. In extent of front it exceeds Blenheim, and in exterior display of magnificence it is, perhaps, superior. The interior, spacious and lofty, is enriched with a valuable assemblage of paintings by masters of the greatest celebrity; and the collection of antique statues, busts, &c. is peculiarly interesting. The surrounding park and grounds are distributed and ornamented in a way suitable to the grandeur of the structure they enclose. Duncombe-park, the seat of Charles Slingby Duncombe, esq., 22 miles N. from York, also erected by Vanbrugh, is splendid in itself, and splendidly adorned with paintings of the most eminent artists. Hardwood-houfe, the residence of the earl of Hardwood, six miles N. from Leeds, is a magnificent structure, commenced in 1760, in which are combined grandeur of design and ornament, with convenience and accommodation of arrangement. One of the greatest ornaments, not of Yorkshire only, but of the kingdom, is Wentworth-houfe, once the habitation of the distinguished patriot Charles marquis of Rockingham, from whom it descended to his nephew and heir the present earl Fitzwilliam. It is situated in a spacious park, four miles N.W. from Rotherham, and seven N.N.E. from Sheffield. The mansion extends in front about 600 feet, forming altogether a structure of uncommon magnificence. Nor is the interior deficient in appropriate arrangement and splendour. In approaching the house, the attention of the visitor is arrested by a noble mausoleum, raised in 1788, by the present earl, to the memory of his uncle, the marquis. This monument is placed on an eminence, and is in itself 90 feet in height, divided into three parts. The square Doric basement supports a similar structure of the Ionic order, with open arches on the sides exhibiting a facioplagus; the whole surmounted by a cupola. Within the basement storey is a chamber containing a statue of the marquis, by Nollekens. Around the walls are built of eight of his principal political friends, C. J. Fox, sir G. Saville, &c. Wentworth-houfe, erected by the earl of Strafford in 1730, but now the seat of Henry Vernon, esq., is a noble fabric. Towards the southern border of the county, midway between Doncaster and Workhop, is Sandbeck, the superb mansion of the earl of Scarborough, erected nearly fifty years ago.

Ecclesiastical State.—A very important change in the condition of the ecclesiastical establishments in Yorkshire, and over England in general, was introduced by William I. Prior to the Conquest the Saxon prelates, with their archdeacons and other delegates, sat in the courts with the earls and sheriffs for the administration of justice; receiving with the lay-judges a share of the fines imposed on offenders. According to the original charter, however, still preferred among the records of the cathedral of Lincoln, the Conqueror declared, that no bishop or archdeacon should, in future, hold ecclesiastical pleas in the hundred-court, nor suffer any cause of a spiritual nature to come under the cognizance of secular persons. Whoever, therefore, offended against the canons of the church was to be tried by a tribunal, to be appointed by the bishop of each diocese. It was also strictly enjoined on all sheriffs, royal officers, or other lay persons, not to encroach on the episcopal jurisdiction. These regulations were afterwards confirmed, in a general council of the nation, by the bishops, abbots, and all the principal nobility; but those nobles and prelates were then almost all Normans or other foreigners. To this artful separation of the ecclesiastical from the civil jurisprudence, the jealousies, contrarieties, contests, and open ruptures, by which the kingdom was, on various occasions, brought almost to its ruin, must be ascribed. In addition to these difficulties occasioned in this way, the dispute respecting the superiority of the see of Canterbury over that of York was conducted with peculiar animosity, between the Norman prelates of both. In 1070, Thomas, a canon of Bayeux in Normandy, appointed to York, repaired to Canterbury for consecration from the hands of archbishop Lanfranc, who had been previously installed; but refusing to swear obedience to the see of Canterbury, the consecration did not take place. The famous Gregory VII. making it now a rule to confer the pall on no prelate who did not appear in person before him, the two contending English archbishops were required to present themselves in the court of Rome, where the dispute was referred for decision to a synod of the clergy of England. By this council, assembled at Windlor in 1072, a sentence amounting to a compromise was pronounced. The rights claimed by Canterbury were confirmed; but Lanfranc disapproved with the oath of obedience from Thomas of York. In his profession of obedience, however, Thomas acknowledged that the archbishops of York and their suffragans were bound to obey the mandate of the primate of Canterbury, when required to attend him in council, wherever it should be held. On the appointment to York of Thurstan, chaplain and secretary of Henry L. in 1115, the dispute was again revived; but in 1121, Thurstan, who had obtained favour at Rome, was permitted by Henry, whom his pertinacity had irritated, to return to York. It does not, however, appear that he ever made any satisfaction for his reliance to the claims of Canterbury; or that a profession of obedience to that see was ever made by any of his successors. From this time, therefore, York maintained its independence, and, a few years afterwards, had certain suffragan bishoprics placed under its authority. Roger of York, in 1162, procured a bull from Rome, granting him the privilege of crowning the kings of England, poiffessed by some of his predecessors, and of having his crofs carried erect before him throughout the whole kingdom. But in 1165, in the reign of Henry II., the latter privilege was by pope Alexander III. restricted to Roger's peculiar province. Opposing claims were nevertheless advanced on both sides, until Edward III. by influence and management procured from Rome a confirmation of the arrangement he had accomplished between the contending prelates. Then was introduced the caufitical and oily dilution, still preferred, in the titles of the two metropolitans, by which the archbishop of York is styled primate of England, and his brother of Canterbury primate of all England.

The county of York is wholly and immediately under the superintendence of the archbishop, whose suffragans are the bishops of Carlile, Chester, Durham, and the Isle of Man. The latter, styled bishop of Sodor (the southern isles of Scotland) and Man, prefiguring over a diocese not formerly pertaining to England, has no seat in the house of peers. Under the archbishop, ecclesiastical affairs are conducted by archdeacons; an office first introduced into the diocese, as it is said, by Thomas the Norman, appointed in 1070. Fertile and extensive as is the county of York, the number of religious houses erected within its bounds, in former times, was prodigious. There were in all, according to Burton, (Monasticon Eboracense,) "106 ; viz. abbeys 14, priories 44, alien priories 7, cells 13, and houses of friars of various orders 28." Of those establishments the ruins of many houses still exist; some of them exhibiting very picturesque and attractive monuments of ancient devotion and liberalty. St. Mary's abbey adjoining to York gives sufficient indications.
tions of its original grandeur. The abbots of St. Mary's
and of Selby, both of the Benedictine order, were alone en-
titled to wear the mitre on the N. side of Trent. But for
an account of these abbeys, and that of Whitby, the reader is
referred to the description of the several towns in which they
are situated. Of some others, erected in detached situa-
tions, a few may be here noticed. About three miles S.W.
from Ripon are the magnificent and picturesque ruins of Fountain's abbey, of the Cistercian order, founded in
1132; and so named, not from any abundance of springs
of water at the place, but from the village of Fontaines in
Burgundy, where St. Bernard, the great patron of the
order, was born. But the structure, of which the remains
are so great an ornament to the country, was commenced in
1204. Built in the most elegant style of the ancient pointed
architecture, the tower and the walls of the church still
remain; the roof only being ruined. The length of the
church was 371 feet, and that of the transept 186. The
great tower, singularly situated at the N. end of the tran-
sept, is in height 166 feet. The whole edifice may be
considered as one of the finest specimens of the simple but
majestic style of the time of Henry III. and his successor
Edward I. The abbey now forms a peculiar ornament to the
celebrated grounds of Studley-Royal. On the N. bank of
the river Aire, three miles to the westward of Leeds, are
the remains of Kirkstall abbey, founded in 1147, by a colony
of Cistercian monks from Fountain's abbey. The venerable
remains of the Cistercian abbey of Rievaulx, or Rievaulx, are
situated in a valley, about three miles northwards from Dun-
combe-park, from which they appear with peculiar advan-
tage. Of the very ancient monastery of Ripon no part now
exists. The collegiate church, or minster, still an interesting
edifice, was partly rebuilt in the middle of the 14th century.
Roche abbey, situated near lord Scarborough's seat of Sand-
beck, in a deep narrow vale, is now reduced to a few arches,
and a portion of the nave.

the North Riding of Yorkshire, by Mr. Tuke, 4to. 1794.
Ditto of East Riding, by Isaac Latham, Esq. 8vo. 1794.
Ditto of West Riding, by Meffrs. Renne, Brown, and
Sheriff, 8vo. 1794.

Yorkshire Census, in Rural Economy, a term sometimes
applied to a large short-horned breed of these cattle, which
afford much milk, but which is not of the most rich kind,
and which are much produced on the fine pastures in that
district. See Cow and Live-Stock.

Yorkshire White, in Agriculture, a perennial grass that
thrives well in moist situations, and which grows very gene-

eral} on all soils, except those that are of the most barren
and dry qualities. It flowers in the middle of the summer,
and is well calculated for sheep, as it answers uncommonly
well when closely fed down. It is said not to be much
relished by neat cattle, and considered injurious to horsey,
which, in some cafes, are supposed to become affected with
a profuse discharge of urine and general weakness in con-
sequence of the use of it. But should any hay, made from
this grass, be accidentally given to these animals, and pro-
duce these effects, an immediate change of the fodder will
prevent any further bad consequences. Its foliage is
rather soft and woolly.

The proportional value which the grass at the time the
seed is ripe bears to that at the time of flowering, is as 11
to 12.

It is an useful sort of grass in many cafes of laying land
down to pasture and other such purposes. See Holcus
Lanatus.

YO-SANPOO, in Geography. See Sanpo.

YO-TCHEOU, a city of China, of the first rank, in
the province of Hou-quang, situated on the Yang-tse river,
and on the Tong-ting lake. This lake, which reembles a
sea, is remarkable for the greatness of its circuit, which is
more than 210 miles; for the quantity of its water, espe-
cially in certain seasons, in which the two great rivers of the
provinces swelled with rains, discharge themselves into it,
pulling out on the other side feantily diminished; and for its
astonishing quantity of fine fish which are caught therein.
The great number of barks and merchandizes which are
brought thither render it one of the richest cities in the
empire; its districts contain one town of the second order,
and seven of the third; some on the east side of the lake,
and others on the west. The country round is every where
extremely fruitful, and full of different kinds of orange and
lemon trees; 675 miles S. of Peking. N. lat. 29° 23'.
E. long. 112° 35'.

YOUB, El, a town of Algiers; 50 miles S.W. of
Tremeccen.

VOUGH GlaDES, a post-town of Maryland; 173
miles N.W. of Washington.

YOUGHALA, a sea-port, borough, and post-town of the
county of Cork, Ireland, situated at the mouth of the river
Blackwater, in the eastern part of the county. Youghal is
an ancient corporation, and sends a member to the united
parliament. It is one of the towns belonging to the duke
of Devonshire, as heir of the eldest branch of the Boyle
family. It has a considerable corn trade, and is much fre-
quented for bathing. There is a collegiate church, the
wardsenry of which is united to the fee of Cloyne.
Youghal is 115 miles S.W. from Dublin, and 25 E. from
Cork.

YOUHIoGENY, a river of America, which rises in
the north part of Virginia, and runs into the Alleghany, at
Pittsburgh.

Yovis, a town of Africa, in the county of Whidah;
9 miles E.N.E. of Sabi.

YOULE, a river of Madagascar, which runs into the
sea on the west coast, S. lat. 20° 20'. E. long. 44° 40'.

YOUNG, Edward, in Biography, a celebrated poet
and clergyman of the established church, was born at his
father's living of Upham, in Hampshire, in 1684, and removed
from Winchester School to New college, in the university
of Oxford in 1703, and afterwards to Corpus Christi college.
In 1708 he obtained a law-fellowship at All Souls by the
patronage of archbishop Tenison, and at this time poetry
was the chief object of his pursuit. His first performance
in this department was "An Epistle to Lord Landown," one
of the twelve poems created at the same time in 1712; and
this was followed in the next year by his "Lafl Day,"
to which he prefixed a dedication to queen Anne, extolling
the peace of Utrecht. From this circumstance he was re-
garded as a court-writer with a fixed stipend, under which
character Swift alludes to him in his "Rhapsody on
Poetry": "Where Y—— must torture his invention
To flatter knaves, or lose his pension."
YOUNG.

His next production was "The Force of Religion, or Vanquished Love," founded on the story of lady Jane Gray; and in 1714 he inscribed a poem on the death of the queen and the accession of George I. to Addison, who was then secretary to the lords justices. In 1719 he became tutor to the eldest son of the earl of Exeter; but soon abandoning that connection by the solicitation of the duke of Wharton, he graduated doctor of civil laws in this year, and wrote his tragedy of "Buiris, King of Egypt," which was dedicated to the duke of Newcastle, and favourably received; and in the same year he dedicated it in a very complimentary strain to lord chancellor Parker, his poetical "Paraphrase on Part of the Book of Job." In the year 1721 his tragedy, "The Revenge," was exhibited with great applause, and dedicated to the duke of Wharton, whom he avows as his peculiar patron, and from whom he received some pecuniary favours. His patronage, entitled "The Love of Fame, or the Universal Flagon," were separately published, from 1725 to 1728, and as they became popular, he derived from them considerable profit. In 1726 he addressed his poem, entitled "The Infalliment," to Sir Robert Walpole, on his receiving the honour of the Garter; and he availed himself, on the accession of King George II., of his recommending an attention to the navy, to compose two odes, one inscribed "To the King, Pater Patriae," introducing another under the title of "Ocean." Having attained his 44th year, he took orders, and in 1728 was nominated one of the royal chaplains; and this change of his views and pursuits induced him to withdraw from the stage his tragedy of "The Brothers," which was under rehearsal. His next productions were adapted to his new profession; and among these were his "True Estimate of Human Life," exhibiting the dark side of the picture; and a sermon preached before the house of commons on the 30th of January, entitled "An Apology for Princes, or the Reverence due to Government," a subject not inapt to his situation as royal chaplain. In 1730, Dr. Young was presented by his college to the rectory of Welwyn, in Hertfordshire; and in the following year he married lady Elizabeth Lee, widow of colonel Lee, and daughter of the earl of Lichfield. Before this time he had refumed his poetical pen, and written "Imperium Pelagi, a Naval Lyric;" "Two Epistles to Mr. Pope, concerning the Authors of the Age;" and "The Sea-Piece," in two odes, dedicated to Voltaire. By his wife, who died in 1741, he had one son; and this circumstance, together with some other domestic losses that occurred about the same period, increased that melancholy and depression of mind to which he was constitutionally inclined. When he married lady Lee, she had a son, and also two daughters, the eldest of whom, declared by him Narcissa, falling into a decline, went to the south of France, and died at Lyons in 1736. Her husband, Mr. Temple, supposed to be the poet's Philander, died in 1740; and his own lady died in 1741. If he referred to these events in the annexed lines, he must have taken a chronological licence hardly allowable even to a poet:

"Infatiate archer! could not one suffice?  
Thy shaft flew twice, and thrice my peace was slain;  
And thrice, o'errathron moon had filled her horn!"

It is certain that he began to write his "Night Thoughts" in the year 1741; and the occasion, as he declares, was real, and not fictitious. The seventh of these poems is dated in 1744, and the interval must have been occupied in the composition of them. Notwithstanding the sublime strains in which the author expresses his pious feeling, he is not regardful of the patronage of distinguished persons, for to such he inscribes them. On this work Dr. Young bestowed much attention and labour, and he valued it as the chief of his productions. Among his other works, we may mention a poem written as an expression of his loyalty in 1745, and entitled "Some Thoughts occasioned by the present juncture, inscribed to the Duke of Newcastle;" "The Centaur not fabulous, in Six Letters to a Friend, on the Life in Vogue," an overcharged picture of the existing manners; and "A Sermon preached before their Majesties," with a dedication to the king, 1758.

Dr. Young, notwithstanding his genius and piety, and his solicitude to obtain preferment, seems to have been disfavored; and though archbishop Secker expresses his surprise that he had been overlooked by persons in power, he declines any interference in his favour. It should be recollected, however, that the attention which he paid to Frederick, prince of Wales, during his residence with his father, was not forgotten; nor indeed would his junction of the poetical and clerical character be any recommendation to George II. But the reason of his name's being struck out of the list of court-chaplains on the accession of his present majesty is not known; it is the more unaccountable, as he was soon after appointed clerk of the cloister to the prince's dowager of Wales.

In his retreat at Welwyn he maintained a respectable and dignified character; and though the evil of his mind seems to have been gloomy, he was an agreeable and lively companion. The close of his life, however, was rather disconsolate than cheerful. The conduct of his only son, supposed to be the Lorenzo of the Night Thoughts, who is said to have been a rake and free-thinker, afforded him renewed opportunities for reproof and farce. In 1761, he had the occasion of some poems, which have been the occasion of poignant grief; though Mr. H. Croft vindicates his character, alleging that he was only eight years old when his father began that poem. But others have asserted that he was alarmed and grieved on his account; and that, notwithstanding the favourable change which took place in his sentiments and character, his father would not admit him to any interview in his latter years: and even on his death-bed he refused to see him, though he afforded some of his forgiveness, and made him his heir. Towards the end of his life, he pretended to suffer from the influence of a housekeeper, and from some mismanagement in his concerns, and a growing disposition to avarice, he became irritable in temper and deprecating in his spirits. His last production was a poem, entitled "Reformation," printed in 1762, which indicated the decline of his mental powers. His life was prolonged to the year 1765, and he then died in his 84th year. He was interred in the church of Welwyn, and his son erected a monument near the remains of both his parents.

Dr. Young is known principally, if not wholly, as a poet; and his compositions in this department are distributed into fates, tragedies, and night thoughts. His fates are founded on the questionable principle, that the fame of fame is the universal passion of mankind; and as he did not excel in judgment, they are exercises of wit and invention rather than grave exposures of vice and folly. As a dramatic writer, he is charged with not understanding or not adhering to nature, and with indulging his imagination and feeling, and running into exaggeration of character and bombast of expression. The only tragedy that has kept possession of the stage is his "Revenge," the Zanga of which is said to have no competitor for theatrical effect.
effect among the personages of modern tragedies. His “Night Thoughts” are deemed original in design and execution. Whatever were the causes that produced them, they are adapted to excite devout feeling, and to produce moral effect, though they are jutly complained of as in some places unintelligible, and as affording too much scope for criticism. To many readers, the theology on which they are founded and which they express is too awful and severe, and not so well calculated to soothe and pacify the human mind under trouble as the gentleman and more condescending dictates of Christianity. They are sometimes tedious and prolix. They will never be neglected as long as taste and inceptibility of virtuous and religious impressions remain. The lyric attempts of Dr. Young are said to have been singularly unfortunate. From the edition of his works published in his life-time in 4 vols. 8vo., he himself excluded several compositions which he thought of inferior merit.

Young, Patrick (Patricius Junius, Lat.), an eminent scholar, was born in 1584, at the feast of his father, Sir Peter Young, who had been co-tutor with Buchanan to James VI. of Scotland, at Seaton in Lothian. Educated in the university of St. Andrews’s, and accompanying his father to the suite of king James, he was employed for some time as librarian and secretery, by Dr. Lloyd, bishop of Chelfter. In 1605 he assumed the degree of M. A. which he had before taken at St. Andrew’s, and entering into orders, became chaplain at All Souls’ college. During his residence at Oxford he occupied himself in the study of ecclesiastical history and antiquities, and also the Greek language; and upon his removal to London, he obtained a pension of 50l. a year, and was occasionally employed by the king and perfons in power in writing Latin letters. His patron was Montagu, bishop of Bath and Wells, who procured for him the appointment of librarian to the king. In 1617 he was introduced at Paris, by the recommendation of Camden, to the learned men of that city; and upon his return, he assisted Thomas Rhed in making a Latin version of the works of king James. In 1620 he married, and afterwards was advanced to several preferments in the church; and succeeded Rhead in 1624 as Latin secretary. Unknown by any publication, he was nevertheless honoured as a person of distinguished literature, who rendered acceptable and useful services to learned men. In this way, he was the coadjutor of Selden in the examination of the Arundelian marbles; and when they were published by this celebrated antiquary, he dedicated the work to Young. He was also employed in collating the Alexandrian MS. of the Bible with other copies; and as the refult of his labours, he communicated many various readings to Grotius, Uher, and other persons. It was his intention to have edited a fac-simile of this MS., but his design was never executed. He published, however, in 1653, from this MS. the “Epitres of Clemens Romanus,” and he proposed editing the curious MSS. from the king’s library; but the civil wars, and the seizure of the royal library, prevented the accomplishment of his purpose. During the troubles of this period, he fought an asylum with a son-in-law, at Bromfield in Essex, where he died in 1672.

Young is said to have indulged to excess a disposition to oblige, which led him to lend valuable MSS. belonging to the royal library to foreigners and others; and he has been charged with betraying their trust, by not returning MSS. which he removed to his own house in contemplation of the pillage of the library, and there were fold among his other effects. To obviate this imputation, it has been alleged that he purchased for himself many MSS. from Greeks who visited this country. Smith’s Vit. Erudit. Viro. Gen. Biog.

Young is a name borne by many persons connected with and remarkable in some way or other for useful talents in the arts. Charles Young, organist of Catharine-cree church, near the Tower, father of three daughters, who were all public fngers: Cecilia, the eldest, was an elve of Gemmiani, spoke Italian well, sung in many of Handel’s later operas, and was afterwards married to Dr. Arne; the second Miss Young, Isabella, was married to the ingenious and excellent composer Mr. Lamp, who fct the Dragon of Wantley; and the third Miss Young, Elfer, afterwards Mrs. Johns, sung on the stage at Covent-Garden theatre to the time of their deaths. Charles, the father of these ladies, was, we believe, the son of Anthony Young, a musician and musie-feller in St. Paul’s church-yard, commonly called Tony Young, who has been said by some of the family to have let God fare great George our King.” But at the time of the rebellion of 1745, when this air was revived, which Dr. Arne’s mother allured us was written and fet for king James II., when the prince of Orange was hovering over the coat previous to the Revolution; no claim was then made by the descendants of Anthony Young, or of any other composer of this air, which no one durst sing or own after the abdication of king James, without incurring the penalty of treason to king William; so that the song or hymn lay dormant, and the author concealed for near sixty years, before it was applied to king George II.

There is a quibbling gle in the first portion of Purcell’s catch on two persons of the name of Young, father and son, who lived in St. Paul’s church-yard; the one was an instrument-maker, and the other an excellent performer on the violin:

“You ferapers that want a good fiddle well strung,
You must go to the man that is old while he’s Young,
But if this fame fiddle you fain would play bold,
You must go to his son, who’ll be Young when he’s old.
There’s old Young and young Young, both men of renown,
Old fells, and young plays, the best fiddle in town;
Young and old live together, and may they live long,
Young to play an old fiddle, old to tell a new song.”

Another Young, of the same family, the proprietor of a music-shop in St. Paul’s church-yard till the middle of the last century, had a relation, an excellent performer on the violin, known by the name of Chin-Young, from the length of that feature, who led at almost all the concerts within Temple-bar, particularly at the Blue-coat school chapel, Chrilt’s hospital, on a Sunday evening, where there used to be a performance of sacred music.

Miss Young, afterwards the hon. Mrs. Scott, and her sister Mrs. Bartleman, both public fngers, seem to have been the last remains of the musical family of Young. See Generation, Conception, Gestation, Embryo, Fetus, Deliey, Child, &c.

In the army, that regiment, or officer, is said to be the younger, junior, which was latt raised, or whose commission is of late date, whatever be the age of the man, or however long he may have served in other capacities.

Young Plantations, Securing and Sheltering of, in Rural Economy. See Plantation and Sheltering.

Young Frederick’s Island, in Geography, a small island among Queen Charlotte’s islands, in Port Inghram.

Young Nick’s Head, a cape on the east coast of New Zealand, so called from Nicholas Young, a boy on board
the Endeavour, who discovered it in 1760. It forms the south-west point of Poverty Bay.

Young Point, a cape on the east coast of St. Vincent. N. lat. 13° 12'. W. long. 61° 9'.

Young's Island, a small island near the south coast of the island of St. Vincent; 2 miles S.E. of Kingston Bay.

YOUNGE, Nicholas, in Musical History, an Italian merchant, the editor of "Musica Tranfalphina," 1588; Madrigales of four, five, and fixe parts, choven out of divers excellent Authors; with the first and second part of La Virgineua, made by Master Bird upon two Stanzas of Ariosto, and brought to Speak English with the ref. The editor having opporunities of obtaining from his correpodents the neweall and best compositions from the continent, had them frequently performed at his house, for the entertain-ment of his musical friends.

The second collection of the fame kind was published by the fame editor in 1597; in which, among others, there are three madrigals by Crou, three by Luca Marenzio, and fixe by the elder Ferrabocco. These two collections being selected from the works of Palestrina, Luca Marenzio, and other celebrated masters on the continent, leem to have given birth to that passion for madrigals which became so prevalent among us afterwards, and which the composers of our own country endeavoured with such zeal to gratify. The allowance be made for the wretched state of lyric poetry in England at the time the madrigals published in Young's two collections were translated, which was long before the publication of the sonnets of Spenfer or Shakespear, the undertaking seems to have been tolerably executed. Indeed, sometimes with such care and felicity as to transmute the expression of the original words into that of the version. The Italians themselves, at this time, had but little melody or rhyme in their music; but their poetry having been long cultivated, and brought to a much greater degree of perfection than ours could then boast, it indicated to the musical composer traits of melody, more airy and marked, perhaps, than we could derive from the profody or phraseology of our own language. The translator of these madrigals, whoever he was, for the editor does not tell us, feems in general to have imitated the original Italian measure and structure of verfe, as well as ideas; and though they abound with concetti, to which not only Italian poets, but thofe of all the rest of Europe were then fo much addicted, the general tafe of the times was indulged in poetry as well as music, and metre and melody were at once furniished with new models.

However, the perpetual double rhymes in Italian madrigals and sonnets have so much diffireted our translator to supply them in English, that, as the prefervation of the original music obliged him to render his version totidem syllabis, his embellishments on this account are sometimes truly ridiculous. It feems as if the conflant double rhymes in Italian poetry, which throw the accent on the penultima, instead of the final syllable, of a line, gave a peculiar call to the melody in which it is clothed, and rendered it specifically different from that of English songs, in which but few double rhymes occur. The conflant and regular mixture of masculine and feminine rhymes in French poetry may like-wise have had a latent effect on the vocal melody of France, different from that of the other two neighbouring nations. But, after mentioning these indulgences, we shall leave the further investigation of fo futile a subjeqt to philofophers, not only profecied of the neceffary knowledge, but an equal zeal for the cultivation of philology, poetry, and music. No. 7, in Young's second publication of Italian madrigals Englihed, in which the old Saxon termination of the present}

tenfe of the indicative mood of our verbs is conveniently preferred, was doubtlefs not thought the world, as it is applied to feveral compositions in the collection.

"In vayne he feeks for beauty that excelleth,
That hath not fene hir eyes where love fejorneth,
How sweetely here and there the fame the turther.

He knows not how love heareth; and he quelleth,
That knows not how the fighes, and fweet beguileth,
And how the sweetly speaks, and sweetly filmmeth."

These madrigals were celebrated, nearly forty years after their publication, by Peacham, who has pointed out the peculiar excellence of several, particularly thofe of Luca Marenzio, which, he says, "are fongs the mufes themfelves might not have been afhamed to have composed;" and of thofe by Alfonso Ferrabocco, the father, he says, "they cannot be bettered for fweetnefs of ayre and depth of judg-ment." Upon the ditty (words) of one of thofe, "I faw my Ladie weeping," (he fays) Maker Byrd and Alfonfo, in a friendly emulation, exercifed their invention. The words of the Nightingale, and Fayre Sufanna, were fo much admired, that they feem to have been fet by all the belt composers of the times. A few lines of each will perhaps convey to the reader an adequate idea of the poetical beauty of thefe favourite fongs.

The Nightingale.

"But my poor hart with farrowes over-fwellling,
Through bondage vyle, binding my freedom short,
No pleafure takes in thefe his fports excelling,
Nor of his fong receiveth no comfort."

Fayre Sufanna.

"To them the fayd, if I, by craft procur'd,
Do yeld to you my body to abuse it,
I lofe my foule; and if I shall refufe it,
You will me judge to death reproachfully.
But better it is in innocence to chufe it,
Then by my fault tend my God on hye."

Indeed, in more than twenty fets, published between the years 1588 and 1624, during a period of near forty years, including almost four hundred and fifty madrigals and fongs in parts, it would be difficult to find any one of which the words can be perufed with pleafure. The sonnets of Spenfer and Shakespear, many of which are worthy of their au-thors, were indeed not published till about the end of the sixteenth century; but afterwards, it is wonderful, that, except one by Shakespear, none of them were fet by our belt musical composers of their time.

YOUNGOULE, in Geography, a fea-port town, on the west coast of the island of Madagascar. S. lat. 23° 30'. E. long. 47° 4'.

YOUNGSTOWN, a township of the flate of Ohio, in the county of Trumbull, with 776 inhabitanits; 66 miles N. of Pittsburgh.

YOUNGSTOWN, an inconfiderable settlement called a village in Cambria, Niagara county, and flate of New York, 1 mile from Fort Niagara, and 6 from Lewiston, containing about fix or eight houfes.

YOUNKERS, among Sailors, are the younger sailors, otherwife called formeflfoemen; whofe buiness is to take in the top-fails, furl the fails, fling the yards, &c.

YOURS, in Geography. See URE.

YOURI, a town of Africa, in the kingdom of Cafina. N. lat. 16° 15'. E. long. 11° 2'.

YOUTH,
YOUTH, Adolescence. See Age and Adolescence.

The renovation of youth has been much fought after by chemical adepts; and many of them pretended to various secrets for this purpose: but unluckily the death of the pretenders proved a sufficient refutation of their doctrine. Paracelsus talks of the mighty things he could do with his ens primum; and even Mr. Boyle tells us some strange things about the ens primum of balm. (Boyle's Works abr. vol. i. p. 75.) But Mr. Boyle gives these wonderful stories on the credit of a French chemist, and not on his own.

Youth, Juventus, or Juvenitas, in the Pagan Theology, a goddes worshipped among the Romans, who, together with the gods Mars and Terminus, kept her place in the Capitol along with Jupiter, when the other deities were turned out; whence the Romans drew a lucky omen for the durability of their empire. Mem. Acad. Inscript. vol. i. p. 71. eqq.

This state of life was, by the ancients, compared to autumn. In which sense, Horace speaking of one approaching to puberty, says,

"... Jam tibi lividos
Distinguet autumnus racemos,
Purpureo variis coloris."

The moderns, on the contrary, when they speak of one in the autumn of his age, mean one that is upon the decline; and choose rather to use the comparison of the spring, to denote youth.

YOWRY, in Geography, a small island in the East Indian sea, near the north coast of New Guinea, on which a nutmeg-tree was found growing by captain Forrest. S. lat. 15°. E. long. 130° 45'.

YPAWA, a river of Bohemia, which runs into the Elba, near its source.

YPERLEE, a river of France, which rises near Ypres, and runs into the canal of Nieuport.

YPOLOTE, a town on the E. coast of the island of Paraguay. N. lat. 8° 46'. E. long. 118° 21'.

YPRES, or Ypres, a city of France, in the department of the Lys, situated on the river Yperlee, from whence it takes its name. Before the year 800, it was only a château, which was sacked and ruined by the Normans. Baldwin III. comte of Flanders, repaired the château, and built a town about the year 960, which was afterwards enlarged by Thierry, comte of Flanders, and Ferrand, the son of Sanchez, king of Portugal. In the year 1325, the inhabitants revolted with milt part of the neighbouring towns against Louis de Nevers, comte of Flanders, and pulled down the old wall to build a new one, in which they inclosed the faubourgs, which had become so extremely populous, from weavers and other tradepeople, that in the year 1422, the number of perfous amounted to 200,000. In the 14th century, the inhabitants of Ypres, for the most part weavers, were exceedingly troublesome to their neighbours, being unwilling that any people should carry on trade besides themselves. In the year 1383, the rebels of Ghent, afflicted by the English, under the command of the bishop of Norwich, besieged this town with great vigour for six weeks, but were compelled to retire; and the English being obliged to quit Flanders, Philip the Hardy, duke of Burgundy, having become master by a marriage with the heiress of the late comte Louis, enlarged it, and surrounded it with walls. It was erected into a bishopric under the archbishop of Malines, by pope Paul IV. in the year 1559. The town-house is a very large building, forming a square, and is said to have been built by the English, 600 feet in front; it has a very handsome tower, in which were kept their public archives from the year 1342. Besides the cathedral, it has several other churches, and some religious houses. The inhabitants carried on formerly a very great trade in woollen cloth, but by the severity of the duke of Alva, the principal manufacturers were driven to England, from which time that branch of trade declined. At this time they carry on a considerable manufacture of linen of excellent fabric; 4 miles N.W. of Lille. N. lat. 50° 48'. E. long. 2° 53'.

YPSILIOIDES, or lamboides, in Anatomy, the third genuine future of the cranium; thus called from its resembling a Greek γ, or upiron.

Some also call it ypsiloide, lamboides.

There is also a bone at the root of the tongue, called ypsilonides, and hyoides. See HYOIDES.

YQUETAYA, in Natural History, a plant growing in Brazil, long used as a medicine in that country; and lately discovered to the Europeans by a French surgeon.

It has been since found in France; where, being cultivated and examined by Marchant, it appears to be no other than the common water-betony, or scorpiularia aquatica.

It has this remarkable property, that it takes away from fena all its ill taste and smell; which property of correcting the infusion of fena was before wholly unknown.

To use this plant, it must be dried ten or twelve days in the shade, and afterwards exposed to the sun, till quite dry.

YRAME, in Geography, a town of Arabia, in the province of Yemen; 100 miles N.N.E. of Aden.

YROUER, in Geography, a town of France, in the department of the Yonne; 5 miles S. of Tonnerre.

YRSEE ABBEY, a princely abbey of Germany, in the circle of Swabia, founded in the year 1182. The territory includes the village of Yrsee, and seven others. In 1802, this abbey was given among the indemnities to the elector of Bavaria; 3 miles N.W. of Kaufbeuren.

YRVILLAC, a town of France, in the department of the Finillerie; 3 miles S. of Landerneau.

YRUN, a town of Spain, in Guipuscoa; 2 miles S. of Pontevedra.

YRVON, a river of Wales, in the county of Brecknock, which runs into the Wye, at Builth.

YS, in Ichthyology, a name given by Athenæus, and some other of the Greek writers, to the fish called mutis and fatis by others. It is the carpificus of later writers. See GOAT-FISH.

YSAMBARA, a word used by some as a name for hellebore, and by others to express a species of poison prepared in Spain, of which hellebore is an ingredient.

YSARD, in Zoology, a name given to the chamois.

YSCHE, in Geography, a river of France, which runs into the Dyle, 6 miles S. of Louvain.

YSENDYCK, or ISENDYCK, a town and fortress of Flanders, situated on the side or arm of the Scheldt, called the
YTT

the Blie; it was built near a town called Gafterneffe, swallowed up by an inundation of the sea some centuries ago, whose inhabitants came to ealhllift themselves at this place. The Dutch made themselves masters of it in the year 1664, and since that time it has been strongly fortified, which is much affihed by its situation, being surrounded by morasfles, which they can lay under water at pleasure; 8 miles E. of Stavanger. N. lat. 51° 21' E. long. 5° 28'.

YSIPTORM, in Ancient Geography, a place of Aifa, in Armenia, which had a Roman garrison.

YSNI, in Geography. See ISNY.

YSOPUS, a term used by some to express the chemical art of separation.

YSPAR, a name by which some of the chemical writers call iron.

YSSANDON, JEAN, in Musical Biography, born at Leffart, in the Compté de Foix, wrote "A Treatise on Practical Music, divided in Two Parts." This book is very scarce, and deferves to be reprinted. It was first printed by Ballard in 1582. Laborde.

YSSEL, in Geography. See Issel.

YSEN Geaux. See Issengaux.

YSTAD, or YSTAD, a sea-port town of Sweden, on the south coast of the province of Schonen, from whence a packet fails to Straflund. It was formerly well fortified, and contained two churches. The harbour is neither large nor safe; 26 miles S.E. of Lund. N. lat. 55° 22'.

YSTLA, a town of North America, in the province of Mexico.

YSTWITH. See ISTWITH.

Y-CHANG, a town of Corea; 35 miles W.N.W. of Kang-tcheou.

YUCHIU, a town of Corea; 15 miles S.S.W. of Ou-tcheou. —Also, a town of Corea; 55 miles N. of King-ki-tao.

YTHAN, a town of Scotland, a few miles N. of the Don, that joins the sea, about two miles from Aberdeen, which falls into the German ocean. The Ythan is a stream formerly celebrated for its pearl fisheries, of which some relics are now found.

YTHING, a river of Wales, which runs into the Wye, 3 miles N. of Builth.

YTERON, a small island in the gulf of Bothnia. N. lat. 65° 4'.

YyTRA BERGON, a small island on the W. side of the gulf of Bothnia. N. lat. 61° 48'. E. long. 17° 13'.

YyTRA, or Iyttra, in Chemistry, is a peculiar elementary substance usually considered as an earth.

Yttria has been hitherto met with in a peculiar mineral named Gadolinite, so named from professor Gadolin, who first analysed it, and in Yytrio-tantalite, both minerals found only in Sweden. See those articles.

Yttria has the appearance of a fine white powder, without taint or smell. It does not affect vegetable blues. Its specific gravity is considerably higher than that of the other earths, being not less, according to Ekeberg, than 4.842.

Yttria is insoluble in water, yet, like alumina, it is capable, according to Klaproth, of combining with nearly one-third of its weight of that fluid when precipitated from a plate of solution by the muriatic acid. In solutions of the pure alkalies it is likewise insoluble; but in the carbonate of ammonia, and indeed in all the alkaline carbonates, it dissolves readily. It combines with acids, and forms with them fatis, which, as far as they are known, are described below.

Yttria is not affected by light, and probably does not combine with oxygen. According to the experiments of Klaproth, it does not combine readily with sulphur.

Sir Humphrey Davy found, that when potalmum was passed through red hot yttria, it was converted into potash, while grey metallic particles were perceived mixed with the alkali, which were considered to be the metallic basis of the earth or yttrium. Nothing further, however, is known respecting this metallic basis.

The Salts of Yttria are but little known. The following only have been examined.

Nitrate of Yttria.—This salt was first formed by Ekeberg, and has been more lately examined by Vauquelin. It may be prepared by dissolving yttria in nitric acid. The solution has a sweet astringent taste, and can scarcely be made to crystallize. Exposed to the air, it deliquesces. When sulphuric acid is poured into the solution, crystallts of sulphate of yttria are instantly precipitated.

Carbonate of Yttria.—This salt may be formed by precipitating yttria from its solution in acids by means of an alkaline carbonate. It is white ta肥料e insoluble powder, composed, according to Klaproth, of

| Carbonic acid | 18 |
| Yttria | 55 |
| Water | 27 |

According to Vauquelin, however, it loses only 32 per cent. when calcined.

Phosphate of Yttria.—Vauquelin formed this salt by mixing a solution of the phosphate of soda with the sulphate, nitrate, or muriate of yttria. The phosphate of yttria precipitated in the form of gelatinous flakes.

Sulphate of Yttria.—Sulphuric acid dissolves yttria readily. As the solution proceeds, the sulphate crystallizes in small brilliant grains. Ekeberg states these crystals to be flat fix deposits, formed by the acid compressed. Dr. Thomson obtained these in the form of long slender rhombohedral prisms. Their colour is amethyst-red; their specific gravity 2.791. They are soluble in about 32 parts of water at 60°. A red heat partly decomposes them. Oxalic acid, prussiate of potash, and infusion of nutgalls, occasion a precipitate in the aqueous solution of this salt. It is decomposed by the phosphate of soda. The sulphate of Glucina is readily distinguished from this salt by its being colourless, lighter, and more soluble in water. According to Berzelius, the sulphate of yttria is composed of

| Sulphuric acid | 50.0 |
| Yttria | 50.0 |

Arseniate of Yttria.—When yttria is dissolved in arsenic acid, and the solution boiled, arseniate of yttria precipitates in the form of a white powder. Arseniate of potash also precipitates yttria from acids.

Chromate of Yttria.—Chromic acid dissolves yttria cold in considerable quantity, and with effervescence. The solution has an astringent and pungent taste, and, like most of the chromates, has an orange-red colour, passing into yellow. The solution is quite neutral. When evaporated, it forms minute prismatid and cubic crystals. It is very soluble in water.

Acetate of Yttria.—Yttria dissolves readily in acetic acid, and the solution on evaporation yields crystals of the acetate of yttria, the form of which is usually that of thick fix-sided plates,
plates, obliquely truncated. Their colour is amethyst-red, and they are not altered by exposure to the air.

**Succinate of Yttria.**—Yttria is not precipitated from its solution in acids by the succinates, unless the two salts be concentrated, in which case small cubic crystals fall, which are the succinate of yttria.

**Oxalate of Yttria.**—When oxalic acid, or the oxalate of ammonia, is dropped into a solution of yttria in an acid, a white insoluble powder falls, which is the oxalate of yttria. According to Vauquelin, this salt is composed of

| Oxalic acid | 57.5 |
| Yttria      | 42.5 |
| **Total**   | **100** |

**Tartrate of Yttria.**—Yttria is precipitated from its solution in acids by the tartrate of potash, but the precipitate is dissolved by the addition of water.

Dr. Thomson infers, from the analyses above-mentioned, and more especially from the analysis of the sulphate and carbonate by Berzelius and Vauquelin, that the combining weight or weight of the atom of yttria is 50, oxygen by 10, and consequently that it is composed of

| Yttrium    | 80  |
| Oxygen     | 20  |
| **Total**  | **100** |

and the weight of the atom of yttrium will be 40.

With respect to the facts of yttria in general, it may be said, that many of them are little soluble; that they are capable of being precipitated from acids by the phosphat of soda, the carbonate of soda, the oxalate of ammonia, the tartrate of potash, and the profulate of potash; and lastly, that the solution of yttria may be distinguished from the solution of lime by its greater solubility, and by its sweet taste.

**YTTRIUM.** The metallic base of yttria. See *Ytria sapra.*

**YTTRO-TANTALITE,** in *Mineralogy,* Tantale yttri-fere, Brongniart, an ore of tantalum, combined with the newly-discovered earth called yttria, and found at Yttberby, near Roslagen, in Sweden. The colour of yttro-tantalite is a dark iron-black; when pulverized it is greyish; it occurs in nodules, about the size of a hazel-nut, and also crystallized in oblique fine-fided and four-fided prisms. It occurs also in granular distinct concretions. Its fracture is compact or finely granular, and it has a shining metallic lustre. Yttro-tantalite scratches glass, but yields with difficulty to the knife. The specific gravity of this mineral is 5.13. It decrystallizes with the blow-pipe, but at length melts into a greenish-yellow flag. According to Vauquelin, the constituent parts are,

| Oxide of tantalum | 45  |
| Oxide of iron and yttria | 55  |
| **Total**         | **100** |

Yttro-tantalite is nearly allied to gadolinite, the other mineral in which yttria is found, and occurs with it at Yttberby, in a bed of green-red felspar in granite.

**Y'TZAIMPATLI,** in the *Materia Medica,* a name given by some to the cavanilla, or *bordeum caelestum,* the caustic Indian bark?

**YU,** in *Geography,* a city of China, of the second rank, in Pe-tche-li; 87 miles W. of Peking. N. lat. 39° 52'. E. long. 114° 14'.—Allo, a city of China, of the second rank, in Ho-nan; 442 miles S.S.W. of Peking. N. lat. 35° 22'. E. long. 113° 38'.—Allo, a city of China, of the second rank, in Ho-nan; 377 miles S.S.W. of Peking. N. lat. 34° 16'. E. long. 113° 14'.—Allo, a river of China, which rises in Ho-nan, 12 miles N. of Pi-yang, and joins the Hoai, 20 miles E.S.E. of Sin-tai. Allo, a river of China, which rises about 26 miles W. from Ngan-fou, in Kiang-fu, and runs into the Kan-kiang, 7 miles N.E. of Lin-kiang.

**YUCATAN,** a province of Mexico: it is a peninsula, surrounded on the W. and N. by the gulf of Mexico, between the bay of Campeachy on the S.W., and that of Honduras on the S.E., having the little province of Tabasco on the S.W., and that of Vera Paz, in the audience of Guatimala on the S., where it is joined on the continent by an isthmus not 120 miles broad. The climate is pretty warm in summer, which begins about April, and ends in September. It rarely rains here during the winter season, though the weather is tolerably cool, except in January and February, which are almost as hot as in the middle of summer. It is, however, very healthy, especially a large mountainous tract, extending from Salamanca on the W., to the eastern boundary, and where the natives live to a great age. The southern side of this ridge is ill-peopled, and worse cultivated, for want of water; but the north part is very populous, being rendered pleasant by gentle breezes, though the sun is very hot. The days and nights are nearly equal all the year. The soil when properly cultivated produces great quantities of corn, cotton, and indigo. All sorts of cattle, wild-beasts, honey, wax, and fowls, are here in great plenty; and on the coasts are found large pieces of amber; but as no mines were ever discovered in this country, the Spaniards are not fond of making settlements here, so that it abounds mostly with Indians, subject to the Spaniards, who employ them in making salt, in the bay of Campeachy. This peninsula has very few rivers, but wells without number, and considerable lakes; and wherever they dig up the land, abundance of shells are found, which with the lowness of the country, and shallowness of the sea about it, has induced many to think that the greatest part of it was once under water. The capital of Yucatan is Campeachy, in the bay of which, and of Honduras, the former lying on the west, and the latter on the east side of this province, the English cut their logwood.

Gen. Ch. Cal. none. Cor. bell-shaped, in six deep, ovoid, very large, equal, moderately spreading segments, connected by their claws. Pericarps none. Stam. Filaments fixed, inserted into the base of the corolla, very short, swelling upwards, reflexed; anthers minute, roundish. *Pfl.* P Germen
YUCCA.

Germen superior, oblong, bluntly triangular, with fix furrows, rather longer than the glumes; stipe none; stigma obtuse, with three furrows, its lobes cloven, the centre pellucid. Peric. Berry oblong, bluntly hexagonal, flexily, perforated at the summit, of fix cells; three of the partitions thicker than the three intermediate ones. Seeds very numerous, in a single row, separated from each other by transverse membranes, roundish-ovatate, flat, depressed, attached, by their pointed base, to the inner angle of the cell.

Obi. We have, like Schreber, adopted Gartner’s idea of the fruit, which Linnaeus does not appear to have seen in perfection, and which Dillenius confides himself to have judged of from the unenlarged germen only. Analogy might well lead these authors to presume it to be a capsule, which, from the structure of the germen, might be judged to consist of three cells. This idea was moreover supported by an account which Ray had somehow obtained from the East Indies; where indeed no Yucca grows wild, and therefore this account cannot implicitly be trusted. Gartner received, from professor Hermann of Strasbourg, the ripe fruit of Yucca drogonis; and this being the only authentic instance of the feed-veil of any one of the genus pecting under the investigation of a critical botanist, we must rely on it as affording the only certain type of the genus in this particular. Jaffén appears to have followed Linnaeus; but the discovery of the true nature of the fruit, rather favours his opinion above-mentioned, of the affinity of Yucca to his Bromelia. This is a handsome perennial genus, more or less caulecent, with numerous long, simple, rigid or coriaceous, pungent leaves; and copious, paniced, white, liliaceous, very elegant though generally inodorous flowers. Some of the species are tolerably hardy in our gardens, but they do not very readily or confiantly blossom.

1. Y. gloriosa. Common Adam’s-needle. Linn. Sp. Pl. 456. Wild. n. 1. Art. n. 1. Pursh n. 4. Curt. Mag. t. 1260. Andr. Repof. t. 473. (Y. five Jucca, peruana; Ger. Em. 1743. Yucca indica, folia aloes, flore albo; Barret. t. 100.)—Caulecent. Leaves lanceolate, straight, furrowed; their edges smooth and entire.—Native of Peru and North America. On the sea floor of Carolina, flowering in July and August; the whole plant about ten feet high. Flowers white. Pursh. The stem in our gardens is seldom two feet in height, somewhat branched, thick, tough, crowned at the summit of each branch, if divided, with a profusion of crowded leaves, spreading in every direction, each a foot and a half or two feet long, tapering to a hard spinous point; contracted in the lower part, but dilated at the very base, where they half clap the stem: their upper surface is of a fine green, smooth, furrowed longitudinally, especially towards the end; the under paler, and more even; the edges quite even and smooth. Terminal compound, erect, composed of perhaps an hundred drooping flowers, not much inferior in size and beauty to those of the White Water-Lily, but more cream-coloured, tinged at the base and points with crimson, deliquit of scent. Partial flacks about an inch long, round, smooth, with a pair of membranous bracts at the base. Stigma in three divisions, spreading, clove, lobes. We cannot but think, notwithstanding Mr. Ker’s opinion, that Andrews’s figure belongs to this species, and not to alofisols. This is evinced by the furrows and margin of the leaves, as well as by the structure of the stigma; though we must allow the whole representation to be less happy and characteristic than that in the Magazine.

2. Y. recurvifolia. Drooping-leaved Adam’s-needle. Salv. Parad. t. 31. Pursh n. 3.—Caulecent. Leaves linear-lanceolate, furrowed, recurved and drooping; their edges at length somewhat filamentous.—Native of the sandy shores of Georgia, where it was found by M. Leconte, flowering in July and August. ‘The flowers are of a greenish-yellow, with a tinge of purple. Stem about three feet high. Pursh. This species is recorded in the Paradisus Londinensis, as having flowered, in the late Mr. Swainson’s garden at Twickenham, in 1805; yet it is not admitted by Mr. Dryander, or Mr. Alton, into the Hortus Kewensis, or its Epitome. The flowers are said by Mr. Salisbury to have a strong smell, mixed with something like a citron flavour. The three inner segments of the corolla is a little the broadest. Stigma most like the leaf. The edges of the leaves split off in a few disjointed filaments, in the manner of T. filamentoa, though far less remarkably. We have seen no specimen. Mr. Pursh having observed this, as well as the gloriosa, in a living state, in North America, chiefly induces us to admit it into our list of species; garden plants being always less to be trusted in any doubtful question.

3. Y. alofisola. Aloe-leaved Adam’s-needle. Linn. Sp. Pl. 457. Wild. n. 2. Art. n. 2. Pursh n. 5. Curt. Mag. t. 1700. (Y. arborescens, folis rigidioribus rectis ferratis; Dill. Eth. 435. t. 323.)—Caulecent. Leaves linear-lanceolate, even, straight; their edges bordered with fine cillous notches.—Native of South America, according to most authors; of the coast of Carolina and Florida, flowering in August. Pursh. It was introduced, more than a hundred years ago, into the English and Dutch gardens, and is generally treated as a green-house shrub, though said to succeed and flower better, in mild seasons, in the open ground. The stem is generally simple, and rises to the height of fifteen to eighteen feet, even in our conservatories, being for the most part naked, round, three or four inches in diameter, marked with scars where leaves have been. The upper part, for the space of a foot or more, is thickly beset with leaves, spreading in every direction, the lower ones pointing downwards, the upper ones nearly upwards, a few in the middle only being horizontal. The leaves are all straight, narrower and flatter than in Y. gloriosa, and distinguished by their crenate edges, as well as even surface. The panicle also is more dense and cylindrical, from two to three feet high. Flowers white, externally tinged with purple. Stigma abrupt, of three shorter, less dilated and spreading, lobes. Mr. Ker truly remarks, in the Botanical Magazine, that this species will thrive for many years with very little earth, in pots not more than a foot deep. Its flowering is a rare occurrence, and after that event, the head decays at the top, throwing out lateral shoots, and the plant becomes branched; but its elegant simplicity is destroyed, and we believe no more flowers, at least in our gardens, are ever produced.

4. Y. drogonis. Drooping-leaved Adam’s-needle. Linn. Sp. Pl. 437. Wild. n. 3. Art. n. 3. (Y. drogonis folio, ferrato reflexo; Dill. Eth. 437. t. 524. Tacori. Clus. Exot. 48.)—Caulecent. Leaves linear-lanceolate, even, reflexed, crenate. Segments of the corolla spreading, somewhat recurved.—Native of South Carolina, according to Mr. Alton, who marks this species as a hardy shrub, flowering in October and November. We have never seen an authentic specimen of the flowers, but in the very admirable plate, communicated to Dillenius by his friend Sprekelson of Hamburg, and published in the Hort. Eth. as above, the corolla is represented with more lanceolate, flat, spreading...

tos at the edges. On the thores of Virginia and Caro-

lina, and in the western parts of the same countries, flower-

ing in July and August. Pursh. A hardy perennial in our

gardens, flowering, though not very constantly, in autumn.
The leaves are numerous, a foot long, spreading in the form of a
rofe from the crown of the root; their points spinous,
but flint; their surfaces both frifated, a little glaucous,
rough to the touch with minute harsh prickers; their edges
beef with long recurved threads. Flower-stalk solitary,
creft, from four to five feet high, round, smooth, leafles,
bearing several flattered, oblong, membranous, reddish-
brown bractees, such as allo accompany the partial flarks.
Panicle compound, lax and spreading, of numerous large
and handifome, pendulous, cream-colored, bell-shaped
flowers, reprefented of much too yellow a hue in the Botani-

cal Magazine. Their fegments are taper-pointed. Fil-

eaments rough, or glandular, with very small anthers. Stigma

with spreading, somewhat recurved and cloven, lobes, like

*T. glorifera*.

Pursh n. 2.—Sterile none. Leaves linear, elongated, rigid,

sparingly flammenous at the edges. Fruit obovato-cylindri-
cal.—Gathered by Mr. Nuttall, on the banks of the Mif-
fouri, flowering in July and August. Perennial. Leaves

very narrow. Stalk from two to three feet high. Fruit

large. Pursh. This appears not yet to have been brought
to England.

The name of *Yucca* may be found applied, by the older
botanifts, to feveral plants which have no botanical affinity

to the present genus; fuch as Morifon’s fect. g. t. 23. f. 3,
where the leaves are digitate; and *Iatropha Manihot of Lin-

næus. (See *Jatropha.*) Such plants agree in the elec-

dent quality of their flefly roots, which when grated and

washed, yield a fanaeous fubftance, of which the natives

of America and the Weft Indies appear to have made a

kind of bread, long before our European corn was intro-

duced among them.

*Yucca*, in Gardening, contains plants of the fucculent,

evergreen; shrubby, hardy, and tender kinds, in which the

species cultivated are, the common Adam’s-needle (*Y. glo-

riofoa*), the thready Virginian *yucca* (*Y. filamentosus*),

the aloe-leaved *yucca* (*Y. aloifolia*), and the dragon-tree-leaved

*yucca* (*Y. draeonis*).

These are all fucculent evergreen shrubs, fome of

them having a flefly nature and great regularity of

growth.

Method of Culture.—These plants are all capable of being

raised by offsets or fuckers, from the roots and heads of

the old plants, as well as by seed.

The offsets and fuckers may be taken off any time in the

spring or summer feafons, being laid in some dry place for

a few days, till the fowied part caufed by the feparation

from the plant is dried and healed over; when they may be

planted out feparately in pots of light fandy compoft, and

be placed in a shady fituation till they have taken root in a

perfection manner. When affifted by a hot-bed, they often

fucced better.

The feed obtained from abroad should be fown in the

spring in pots of light earth, plunging them in a hot-bed,
in which the plants soon come up; and when they are two

or three inches high, they fhould be pricked out feparately

in small pots of light fandy mould, replanting them in the

hot-bed to forward their growth, affifting them with mod-

erate waterings and frefh air daily, and hardening them by

degrees to the full air, fo as to be let out in June to remain

till October, when they fhould be removed into the green-

houfe for the winter.

Some plants of all the forts fhould constantly be preferred

in pots.

They are all very ornamental; the two first after they

have been hardened, in the dry borders, where the foil is

light, and where the fituation is warm and feltered; and

the others in green-houfe collections, among other potted

plants.

*YUE*, in Geography, a city of China, of the fecond rank,
in Yun-nan; 1105 miles S.S.W. of Peking. N. lat. 25°

27'. E. long. 103° 22'.

*YUEN*, a river of China, which runs into the lake Tong-
ting, 17 miles E. of Tchang-te.—Allo, a city of China,
of the fecond rank, in Hou-quang; 850 miles S.S.W. of

*YUEN-KIANG*, a city of China, of the fift rank, in

Yun-nan, on the Ho-ti river; 1250 miles S.W. of Peking.

N. lat. 23° 37'. E. long. 101° 44'.

*YUEN-TCHEOU*, a city of China, of the firth rank,
in Kiang-6; 750 miles S. of Peking. N. lat. 24° 50'. E.

long. 114°.

*YUEN-YANG*, a city of China, of the firth rank, in

Hou-quang, on the river Han; 517 miles S.S.W. of

Peking. N. lat. 32° 50'. E. long. 116° 29'.

*YVERDUN*, or *Ifferten*, a town of Switzerland, in

the Vaudois, and capital of a bailiwick, in the canton

of Berne, fiftuated on the lake of Neufchâtel, otherwife called

the lake of Yverdun, at the mouth of the river Orb, which

divides into two branches, forming a good port, and an

ifland, on which the town is fiftuated. The two fauxbourgs

communicate with the town by bridges. It is ancient, and

in the Theodorean table called "Caflrum Ebredunenfis," and

"Ebredunenfis," by which it is understood to have been a

place of firength. The Romans maintained here a *prefetius

Barcariorum*, and there yet exifls a fociety of boatmen, of

ancient fanding, and numerous, who have a particular po-

lice, privileges, and laws of navigation. From the Romans

it paffed to the kings of Burgundy, and afterwards to the
dukes of Zahringen. In the year 1259, it was taken by

Peter of Savoy, who reduced it by famine, and it continued

in
in that family till the year 1536. In this year, the troops of Berne, when they had reduced the rest of the Vaudois, laid siege to this town, and after a few days, became masters, since which Yverdun has been subject to Berne. The police is administered by a great and little council, composed of thirty-six members, the president of whom has the title of banneret. It has a large and strong castle, flanked with four towers, built in the 12th century, by Conrad, duke of Zähringen: other public buildings are, a college for the instruction of youth, an hospital, divers magazines, &c. and in the town-house is a library, formed not long since by contribution. The environs were formerly a moraet, which has been drained, and is now become good and fertile land. Near the town is a fulphureous medicinal spring, and in the year 1735, a building, for the purpose of bathing, was erected by the magistrates. In the middle of the last century, a company was formed, for the purpose of making a navigable canal from the lake of Yverdun to the lake of Geneva, but it was never finished. The bailiwick is one of the most considerable in the canton of Berne, containing about 25 parishes and 20 lordships, and is about 15 miles in length. The fertility is moderate: the wine is not of the best quality; 34 miles S.W. of Berne. N. lat. 46° 48'. E. long. 6° 14'.

Yves, or Ivo, in Biography, bishop of Chartres, was born in the 9th century, of a noble family, in the territory of Beauvais, and studied theology under Lanfranc, prior of Bec. Being made abbot of St. Quentin, he opened a theological school, which became famous; and having superintended this institution for fourteen or fifteen years, and maintained a regularity among those who attended it conformable to the ancient canons, he was justly regarded as one of the chief founders of the order of canons-regular. Upon the death of Geoffrey, bishop of Chartres, he was chosen as his succesor, and the election was confirmed by Urban II. in 1091. The discipline he maintained in his see was exemplary, and in the duties of it he was employed for 25 years, his episcopate and his life terminating in 1116. Besides sermons, a brief chronicle of the kings of France, and two collections of ecclesiastical decrees, he has left 267 epistles, from which may be learned the manners of the times in which he lived. Of these we have a summary by Dupin. A collection of his works was printed at Paris in 1647. His name is highly respected in the church of Rome, and pope Pius V. issued a bull in 1570, empowering the canons-regular of Latran to celebrate an anniversay for "the bleffed Yves." Dupin. Moreri.

Yvetot, in Geography, a town of France, in the department of the Lower Seine. This was once a place of consequence, and the capital of a kingdom; 18 miles N.W. of Rouen.

Yufts, or Russia Leather, as it is called in England, are the chief products of the tanneries in Russia; and the principal places in which they are prepared, next to Moscow and Petersburg, are, Arfamos, Kof- troma, Yaroslav, P'cove, Kazan, Vologda, Nihney-Novgorod, Vladimir, Ekatarinenburg, &c. Mr. Tooke has described the processes by which they are prepared: -- The raw ox-hides are first laid in running water, or in large tan-pits full of water dug in the earth for that purpose, to soak for a whole week; but in summer not so long. During this time they are daily taken out of the water, and scraped at a scraping-bench, or wooden horse. Having now been duly steeped, they are put into a lea, thus prepared: In other vats, likewise dug in the ground, and under cover, they mix two parts of good ashes with one part of unflacked lime, in boiling water, and sink the wet hides in this lea on a grating, which being suspended by cords, can be raised or let down at pleasure. In this vat the hides are laid again for about a week, though in warm weather less, in cold perhaps even longer. The sign that they have lain long enough in the lea is, that the hair can without difficulty be rubbed off with the hand, so that none remains. If the hides, after the expiration of a week, are not in that condition, fresh ashes are put into the lea, and the skin skunk in it. But if at length the hair be sufficiently loose, the hides are entirely taken out of the lea, and all the hair scraped off on a stretching-block, by means of blunt iron scrapers with two handles. The hair is washed clean, and sold for domestic uses. The hides, thoroughly cleansed from hair, are suspended in vats of clean water on a running stream, where they remain three days, diligently turning them to and fro, in order to purge them from the ashes and lea; afterwards they are hung up, and left to drain. The hides must now be scraped on the flesh side. To this end they employ either the aforefaid scraping-iron, or others sharper in various degrees. After this treatment, the hides are trampled. But calves-hides have another sort of preparation, which the yufts-tanners, in the interior towns of the empire, who mollify practife it, call rakefa. This preparation is performed with the white excrement of dogs dried, which is diffused in boiling water, and to a hundred hides about four vedros full of excrement is the rule. If here the right proportion with the water be not found, the hides corrupted in this slime, the object whereof seems to be the complete freeing of the skin from the salts that adhere to it from the lea. The hides are left to lie twice twenty-four hours. With this is sprinkled a four gruel of oatmeal with warm water, and to three offmies, or eightths of a cheverik, three or four vedros of dregs of the common quas, which the people make of meal and a small portion of malt, put in the thin gruel, that it may quickly four with the hides. To ten hides, the tanners usually reckon forty pounds of meal.

After the hides have foured, which is done in large vats, they are laid in other vats, and well steeped for two or three days in a strong tan-juice, for, thoroughly boiled from good bork. When this is done they are brought straight to the tan. In the tan-pits, in which often some hundreds of hides are lying, is poured half water and half tan, or water boiled with tan, and a grating is hung in with cords, having one hide after the other spread upon it, thick ftrewd with good fine-pounded tan, and the grating conflantly let deeper into the pit, till it be nearly full; yet so that the tan-liquor is always above the hides, which are then again sprinkled over with tan. In this tan the hides continue to lie a week; those of full-grown animals longer. On being taken out, they are washed and trampled on, which two workmen in a summer’s day can perform with three hundred hides. The next day they are laid, in the manner above-described, in fresh tan. Thus they generally get four times successively fresh tan, and are every time rined clean. In the last tan they lie three weeks, or longer, are then finally washed, hung up, and, when they have tolerably drained, delivered to those workmen whose busines is it, in particular workshops, to dry, drefs, and wax the yufts, and to deliver the goods finished. It is to be observed, that the Russian yufts-tanners seldom use oak-tan, and never willingly. The choicest and best tan is that of the tchernotal, as they call it, or the black willow; and also the young bark peeled off from other shrubby willows, which are collected by the boors, dried in bundles, and brought in cart-loads to market. To ten hides, the tanners compute one and a half fathom of these bundles of willow-bark,
bark, as they are laid one upon another for sale, through all the towns. It must not, however, be imagined that the excellence of the Ruffian dyers depends on this; for in Siberia, where there are no oaks, and but few willows of any size, they tan yuts with only birch-bark, which are not much worse than the Ruffian. The bark is made small by either ordinary tan-mills, turned by horses or by water; or the Tanner himself, in many towns where there are no mills, causes it, at unnecessary expense and labour, to be pounded in wooden mortars, or excavated blocks, with pelles, almost like those in the tan-mills, by day-labourers.

The dyeing of the yuts is performed in two ways, and of two colours. The commonest and most natural custom of giving the colour to the hides is, by fewing them together in pairs, the hair side inwards, while they are yet moist, round the edges, with rubies or stripes of bark, thus forming them into a bag or pack; into this pack the colours is put, the pack well shook, and the superfusious dye let to run out, whereupon the skins are dried. From this method of dyeing them, it seems to proceed that the yuts are called and taken by pairs. The other process, whereby much trouble, time, and colour are saved, and the edges of the skin entirely preserved, is the following: Each skin is hung upon a horse over a long trough, so that the hair side, which must be flained, appears outwards, pouring the dye upon it out of the dye-kettle, till the whole skin is dyed. The two colours given to the yuts are red and black. The red dye is thus prepared: Pound brahill-wood (fandall) in the pounding-mill, or with hand-pelles, as fine as the tan, and boil it in kettles. Previous to the dyeing, steep the skins in alum-water. It is calculated, that to each small yut-skif a half, and to a large one a whole pound of logwood is put. But the latter are mostly coloured black. To a hundred yuts to be dyed red, four pounds of alum is sufficient. For dyeing black the brahill-wood is likewise used; but in the red dye, to a hundred skins three pounds of good iron vitriol is dissolved. After the first tincture the skins are dried, and afterwards on tables done over again with the same dye and rolled up, that they may thoroughly imbibe the dye. For heightening the colour this tincture is sometimes thrice repeated. When the skins are now tolerably dried, by hanging, that the colour may not fade, with the flesh side outwards, the yuts, still somewhat moist, are smeared over on tables that have ledges. There was a time when it was commanded by authority to use nothing but dolphin and feal-blubber for smearing them; but by that the yuts are harsher, and have not that yut smell, which foreigners prize so much, unless the birch-tar, taggot, prepared in Ruffia, at least be mixed with it. At present this birch-tar alone is used for smearing. This done, the skins are cleaned from all impurities that may remain, and are sent to the dressing-house, where skilful workmen scrape them first with scraping-irons, having two handles, with the edge cross-wise on a stretching-bench, that a soft thin leather remains with a clear glossy surface, free from all impurities. Other workmen then take the clean-scraped yuts on large clean tables, sprinkle them on the flesh side with a gentle shower of fresh water from their mouths, and lay them slightly rolled up to moisten. This done, the skins are taken separately one after another, folded together, and worked and calendered in all directions, to make them soft and pliant. They are then curried with a kind of wooden curry-comb, with sharp irons fixed in leathers, like a card for carding wool, the skin being folded with the hair side outwards, by which the whole surface of the yuts acquire the cross-strokes or trellis-like marks they are always seen to have. Some work the skins with the hands first dry, not sprinkling them till they are mangled with the card. Lastly, those skins which are too harsh and stiff to the feeling, are more or less sprinkled with linseed-oil, and thus are ready for the merchant.

In this connection we shall introduce from the same author an account of the Ruffian method of preparing and dyeing their faflain, maroquin, or Morroco leather, which are dyed at Atrachan of three colours, red, yellow, and black. The treatment of the red faflains, which are the most famous, is usually as follows:—The raw hides are first laid in large vats, and have river water poured upon them, in which they are left to soak for three or four times twenty-four hours. They are then taken out, the water is drained and squeezed from each skin, and are scraped one by one on the stretching-bank with scraping-irons, uraki, quite gently on the flesh side, in order to take away the grosser impurities, but principally for opening the skin, and to qualify it for the ensuing operation.

They now proceed to make the hair fall clean off, chiefly by the application of lime. To a hundred hides is floured in about half a buhel of unfalke lime in vats with river water, and the hides are laid in so that the lime may as much as possible be equally distributed over all of them. The Atrachan Tartars let the hides lie in this lime-pit frequently three weeks, but it is well known, that their faflains are far harsh and liable to crack, and even corroded by it, that they are fit for nothing, and can only impede upon an inexperienced purchaser. They then take out skins, wash them, and carefully scrape off the hair, now become loose, with wooden scrapers. It often happens, that the hair is not perfectly loosened by the first lime-ley, but that many tender fubboles and small hairs are left remaining. In this case, the hides must be put into fresh lime-ley, and be left perhaps two weeks in it; the hair then comes off, and the hair side of the skin gets a green and very white appearance, but the substance is then also very soft, and the faflains, by this corrosion of the lime, are very little durable in comparison of other kinds of leather.

The method now for taking the lime again out of the hides, is the second treatment with dog-excrement, or white gentian, which is carefully collected for this purpose. This excrement, which is indispensably necessary, is pounded, put into a narrow not very large vat, warm water poured upon it, the mafs thoroughly floured, and the cleansed hides are put with it into another vat, so as that the dissolved album grecum is spread and inminated over and between every skin. In these ingredients, the skins must lie only twenty-four hours, or if the quantity of album grecum prove not rich, somewhat longer. The proportion here to be observed cannot be accurately ascertained; for the faflain-makers are guided generally by eye-measure, and observe only that the water be very thick and turbid, and consequently acid enough. The hides come out of this corrosive much foffter and thinner than they were, and are now freed from the force of the lime; but no time must be lost in endeavouring to extract the corrosive likewit, that the hide may not be even more ruined by it than by the lime. They are generally very careful that the hides lie not too long in this corrosive, which they judge of by their eye from the pliancy and suppleness of them. As soon as the skins are lifted out, the unclean moisture is carefully and forcibly pressed out, and they are laid without loss of time in a vat, wherein wheat-bran is floured to a tolerably thick gresul with warm water; in this they lie again about thrice twenty-four hours, whereby all the former defects are completely remedied, and the substance of the skin
formally absorbed all the dyeing particles, and only some what of a pale moisture remains. The leathers being thus for the first time tained are quickly squeezed out, hung up flingly across poles, and when they are all done, they are directly taken for the second time, and imbued in the same manner with dye, and this treatment is repeated for the third and the fourth time; so that each skin gets four ladles of the dye. From the fourth dye the skins are no more preiffed out, but hung up entirely wet, to be venti lated, upon poles.

After the dye, the skins are once more curried with the leaves of the tan-tree, which the Armenians call belge. The crushed or pounded dry leaves, which the Altrachan faffian-makers get from the Terek, are flurred in broad troughs to a thick gruel with river water, and the coloured skins laid in it, between each of them, leaving a sufficiency of the leaf-ooze; the tanner then goes barefoot into the troughs upon the skins lying on one another. In this tan, or quas, as the workmen call it, the faffians lie eight days and nights, adding fresh tan every other day; so that four tans are necessary.

Here it must be observed, that some Armenians who pre pare faffians, for enhancing the quality of the red colour of their faffians, to half a pound of cochineal add two lote, or rather more of forrel, (or lutor, or later, as they call it,) in the dye-kettle, but it is usually omitted in Altrachan, on account of its high price; for which reason the Altrachan faffians are excelled by the Turkifh in beauty of colour. Secondly, it is to be known, that instead of the leaves of the tan-tree, bruifed nut-galls are held to be still more service able for giving the faffians the tan. By this means, the colour is fo durable as never to pass away but with the leather; whereas the faffians prepared with the tan-tree begin soon to be discoloured. But the nut-galls are likewise too dear in Altrachan to be customarily used by the faffian-makers. The Kazan Tartars colour their faffians with red wood, and tan them with the shrub uva urfi, but it makes the worst faffians of all, as they presently fade.

When the faffians are lifted out of the tan, till the last work remains. They are first left some time in the air to dry, they are afterwards scraped on the stretch-bank with sharp scrapers on the fleece side, quite smooth and clean, then washed in running water, each skin duly stretched with pegs all round the edges, and thus left till they are dry.

The skins must now be smoothed on the hair side with a wooden instrument for that purpose; and lastly, they are laid on a thick felt, where, with an iron password that has blunt points, those little pittings, which the faffians are generally seen to have, are impressed on the same side. And thus they are ready for sale, without being smeared with linseed oil, as is mentioned in Gmelin's travels, which would infal libly spoil them.

The yellow faffians are little made in Altrachan, as the demand for them is much less, and there are but few faffian-makers who know much of the matter. The dye which they make use of for this purpose is of the berries of a tart of rhamnus (perhaps lycoideis), which are brought from Persia under the name of ulofchar, and usually bought for fix to nine rubles the pound. The Kazan Tartars colour their ordinary yellow faffians with the flowers of the yellow camomile, which they gather under the name fare tfchetschiak, i.e. yellow-flower.

In preparing the yellow faffians, they observe in Altrach an the following difference of treatment: 1. They make no use whatever of honey in the preparation. 2. They never
never at all put the hides into the salt brine. 3. Instead of the honey-preparation and the pickling, they lay the hides before the dyeing, in the foregoing manner, in the tan of the leaves of the kitzial tan-tree, leaving them in it eight days. 4. For preparing the dye, they have no need of the herb tchagan, but the berries alone are boiled in clear water, of which to four Russian vedros of water about ten pounds are requisite, and heighten the colour afterwards with three lots of alum to every pound of berries. The dyeing is performed in the same manner as has been related with the red, and after the dyeing there is no need to lay the saffians in the tan, as having before received it. Nothing more is necessary than to ferment them, to work them thoroughly, to polish and to ornament them. The yellow saffians usually are folded at one ruble twenty kopeeks; but the red at somewhat more, on account of the dearness of the feds, generally one ruble eighty kopeeks.

YUG, or YOG, the more correct mode of writing the word jogas, by which the Hindoos distinguish the poetical or mythological ages of the world. We have noticed these wild speculations under the more popular word jogas; to which, to GENTOOS, KAKI, KALPA, and YOGESWARA, we refer those deffours of further information hereafter.

YUGASIRI, in Hindoo Mythology, is the name of the wife of Va'ruves, an incarnation of Siva. See those articles.

YUHAGHIRS, in Geography, a Russian tribe, which occupies the northernmost part of the territory of the Yakutes, bordering on the Frozen ocean, from the Yama to the Kolyma. They were known to the Russian conquerors as early as the Yakutes; but on account of their wild and impaffable deferts, could not be brought into entire subjeftion until the year 1639. They had never seen a horse, though that species of animals was found among the Yakutes; and therefore they appear to have been for a long time confined to their cold, fenny, and mountainous deferts. The whole people, at the revision before the last, says Mr. Tooke, paid taxes only for about 1000 heads; but it was too easy for them in their deferts to evade the payment, that their entire population may be computed at a much higher number. See YAKUTSK.

YVIAS, a town of France, in the department of the North coasts; 4 miles E.E. of Ponthieu.

YVICA. See YICA.

YUKANLOOT, a town of Candahar; 10 miles E.E. of Sufia.

YULDUZ. See Yolotou.

YUMA, or YUMBA, or Long Island, one of the Bahama islands; about 50 miles in length, of very unequal breadth. N. lat. 23° 20'. W. long. 74° 50'.

YUMA, in Mythology. See Tscheremisses.

YUMAR, the name of the object of worship among the Votkais; similar probably to Yuma, Yummel, and Yummals, among other tribes of the ancient Finns.

YUMBA BAY, in Geography, a bay on the E. coast of the island of Hispaniola, S. of Cape Spada.

YUMETOS, a cluster of small islands, among the Bahama islands, about 20 miles S.W. from Yuma.

YUMFONG, a small island, near the coast of China, about three miles from the island of Tieng-ming. N. lat. 31° 42'. E. long. 121° 17'.

YUMMALA, in Mythology, an idol deity of the Finns, who had a rich temple in Permia, or Bierma, supposed to have extended from the White Sea to the mountains of Ural. This temple was decorated with a profusion of gold and jewels. See PERMANS.

YUMMEL, an appellation by which the Lieflanders and

Eathanians worshipped the true God; in subordination to whom they only admitted inferior deities as beneficent and malicious spirits.

YUN, in Geography, a city of China, of the second rank, in Yun-nan; 1262 miles S.W. of Peking. N. lat. 24° 32'. E. long. 99° 35'.

YUN, or Tong-po, a city of China, of the first rank, in Yun-nan; 1135 miles S.W. of Peking. N. lat. 26° 44'. E. long. 100° 34'.

YUNA, a river of Hispaniola, which runs into the So- mana bay.

YUNCHA, a town of South America, in the province of Tucuman; 60 miles S. of St. Jago del Eftero.

YUNG-KANG, a city of China, of the second rank, in Quang-fi; 1140 miles S.S.W. of Peking. N. lat. 22° 56'. E. long. 107° 26'.

YUNG-NGAN-POU, a fortress of China, in Chen-fi, on the borders of Tartary; 110 miles N. of Ling-tao.

YUNG-NING, a city of China, of the second rank, in Chian-fi; 300 miles S.W. of Peking. N. lat. 37° 35'. E. long. 110° 30'.

YUNGUS, or Yungus Vitus, in Ancient Geography, a place of Gaul, on the route from Reims to Treves. Anton. Itin.

YUN-HING, in Geography, a city of China, of the first rank, in Ho-nan. The country, within its defert, is very large, and is partly flat, and partly mountainous, especially to the north and south; it is watered by several rivers, which render the soil very fruitful. There are two towns of the second rank, and twelve of the third under its jurisdiction; 430 miles S. of Peking. N. lat. 33°. E. long. 113° 52'.

YUN-LEAN-HO, a canal of China, formed of the river Pay-ho, or rather the river itself made navigable from Hiam-ho to Tien-tsin, in the province of Pe-tche-li, for the purpose of conveying corn towards Tong-tcheou and Peking. The name in the Chinese language is faid to mean corn bearing.

YUN-NAN, a province of China, bounded on the N. by Se-tchen and Thibet, on the E. by Quang-fi and Kei-tcheou, on the S. by Laos, and on the W. by Ava and Pegu; about 300 miles in length, and 250 in breadth. This province is reckoned one of the most fertile and opulent in China. Its inhabitants are brave, robufl, affable, and fond of the sciences, which they cultivate with succefs; its rivers, gold, copper, and tin-mines; its amber, rubies, sapphires, agates, pearls, precious finones, marble, mufk, silk, elephants, horfes, gums, medicinal plants, and linen, have procured it a reputation which renders it respectable to the Chinefe. Its commerce is immenfe, as well as its riches, which are faid to be inexhaustible. This province contains 21 cities of the first clas, and 55 of the second and third. Sir George Staunton estimates the population at eight millions.

YUN-NAN, a city of China, of the first rank, and capital of Yun-nan, situated at the north extremity of a lake. It was formerly celebrated for its extent, and the beauty of its public edifices. Here were seen magnificent buildings, vast gardens, tombs, triumphal arches, and elegant squares; but the Tartars, in their different invasions, destroyed all these monuments; and the city at preient contains nothing remarkable; it is, however, the residence of the governor of the province. It comprehends in its district four towns of the second clas, and seven of the third; 1152 miles S.S.W. of Peking. N. lat. 25° 06'. E. long. 102° 28'.

YUNTAI, an island near the coast of China, in the Eastern
ZABERN, Conrad de, in Biography, born in Germany about 1450, was a very learned man, and much respected for his morals. He wrote two treatises on music; the first of which is entitled "De Monochordo," and the second "De Modo bene Cantandi." He was much beloved by the emperor Frederick III.

ZEBERN, in Geography. See Bergzabern.

ZABI, or ZABA, in Ancient Geography, a place of Africa, in Mauritania Stiftenis, on the route from Cartage to Caflarea, between Arz and Macri, Anton. Ita.

ZABII, or ZABIS. See ZABANS and ZABISM.

ZABIN, in Geography, a town of Lithuania; 30 miles N.E. of Minik.

ZABIRNA, in Ancient Geography, a river of Afa, in Melopotamia, which discharges itself into the Tigris.

ZABLOTOW, in Geography. See Sablotow.

ZABLOWICZE, a town of Lithuania; 86 miles E.S.E. of Pinfk.

ZABOLA, a town of Transylvania; 10 miles N. of Cronstadt.

ZABORE, a town of Russia, in the government of Irkutsk; 36 miles S.S.W. of Kirensk.

ZABREZEH. See Hohenstadt.

ZABULIAN, See Sabulest.

ZABULON. See Zebulen.

Zabulon, Tribe of, in Ancient Geography, was bounded on the N. by the tribes of Apher and Nahphali, on the S. by the torrent of Kifon, on the E. by the sea of Galilee, and on the W. by the ocean. Almost all the towns of this tribe were on the plain of Galilea.

Zabulon, a town of Judea, situated on the plain of Galilea, in the tribe of the same name, according to Joshua and the book of Judges. Josephus says, that Cestius, though he admired its beauty, took, pillaged, and burnt it. It was situated S.E. of Potemans.

ZABUR, a country of Afa, in Babylonia, in which was the town of Seclucia.

ZABUS, Zabatus, or Zerbis, (Great Zab or Zab) a river, which is the same with the Lycus, flowed from a source towards the 35th degree of latitude, and directed its course first to the N.W., then to the W., afterwards to the S.W., and finally to the S., discharging itself into the Tigris, about lat. 35° 45'. Xenophon says, that this river, at its entrance into the Tigris, appeared to the Greeks comparable to the Tigris itself. See Zab.

Zabus Minor, or Caprus, (Lesser Zab, or Altan-Sen) a river of Afa, which had its source E. of Arbelles, and ran towards the S.W., discharging itself into the Tigris, over against Cane, below or S.S.E. of the greater Zabus. See Zab.

ZACA, in Geography, a town of Egypt; 17 miles N.E. of El Arish.

ZACANTHA, in Ancient Geography, a town of Hifpania, in Iberia, said by Steph. Byz. to have been taken by Hannibal, and to have been called Zacythus or Saguntum.

ZACAPA, in Geography, a town of Mexico, in the province of Vera Paz; 42 miles S. of Vera Paz.

ZACAPULA, a town of Mexico, in the province of Chiapa; 130 miles S.E. of Chiapa de Izapa.

ZACATECAS, a province of Mexico, bounded on the north by New Biscay, on the east by Guadaluca, and by the south by the provinces of Mechoacan, Guadalajara, and Chiametlan, and on the west by Chiametlan and Culuaca. It is well inhabited, and abounds with large villages. Part of it lies in the temperate and part in the torrid zone; it is about 100 leagues in length, and 45 in breadth. The western part of it is an arid tract, and would not be inhabited were it not for the mines, which were formerly reckoned the richest in America; but the eastern part abounds with corn, and fruits of various kinds, and its forests are full of deer.

ZACATECAS, the capital of the fore-mentioned district, the importance of which has declined with the mine. It formerly contained about 12,000 families of Spaniards and mixed breeds, though confining chiefly of one street, in a deep passage between high rocks, crowned with cottages. Luis de Potosí on the S.E. is said by Alcedo to contain only 1600 families of Spaniards, Malatotoes, and Indians, though it has six magnificent churches. The ridge of St. Peter, five leagues from the city, contained rich mines of gold and silver; but they are now in part exhausted, and the fuel has become scarce. The opulence of this city has in course declined, and the chief trade is in gutta-percha and tanned leather.

ZACATECAS. See St. Louis de Zacatecas.

ZACATLAN, a town of Mexico, in the province of Thatela; 30 miles N. of Puebla de los Angeles.

ZACATULA, or Zacatula, a town of Mexico, in the province of Mechoacan, on a river of the same name, near the Pacific ocean; 93 miles S. of Mechoacan. N. lat. 18° 35'. W. long. 105°.

Zacatula, a small but fertile province in the dominion of Mexico.—Alfo, a river of Mexico, which runs into the Pacific ocean, near the town of Zacatula.

ZACARRIA. See Tevo.

ZACCHIA, Paolo, in Biography, an eminent physician, was born at Rome in 1585, and in the progress of life was distinguished by his learning, and by his skill in music, painting, poetry, and eloquence, as well as in the more appropriate sciences relating to his own profession. He was physician to Pope Innocent X., and celebrated among his contemporaries by various publications; of which the principal is intitled "Questiones Medicis legales, in quibus omnes materiae medicae que ad legales facultates videntur pertinentes, proponitur, pertrafauntur, refutuntur," a work which has been often reprinted. He was also the author, in Italian, of two esteemed works, "Del Vitto Quadragesimale," 1637, the subject of which is the regimen of diet in Lent; and "De Mali Ipochondriachi," 1639, a diffuse treatise on hypochondriacal affections. He died in 1659, aged 75. Haller. Eloy. Gen. Biog.

ZACCONI, P. Lodovico, of Pefaro, author of an ample treatise of music, entitled "Prattica di Musica," the first part of which was printed at Venice, 1592, and the second in 1596; a publication in which the author not only proposes to give instructions for the regular composition, but the accurate performance of every species of music. The idea is splendid; but the world has been too frequently deceived by the titles of books, that authors are obliged to abate in their promises, in proportion as the expectations of the public are diminished. If arts and sciences could be acquired by the dead letter of fient instruction, every who could read, in Italy, might, during the times under consideration, have been a musician. But though no ingenuous occupation was perhaps ever yet completely taught by books, without a master, or by a master, without books, yet they are excellent helps to each other. It is hardly possible for a didactic work to satisfy all the doubts that arise in an inquiring mind during solitary meditation; particularly in the first stages of a student's journey through the rugged roads of science. But when he has made some progress, if he should be separated from his guide, the way becomes daily so much more straight and smooth, that by the
the help of these kinds of charts, he will be enabled to advance with tolerable speed and facility by himself.

Zacconi's work, though sometimes dry and tedious, contains much useful and practical knowledge. And as he is almost the only Italian writer on the subject of music who has not bewildered himself in inquiries concerning the systems of the ancient Greeks, or the philosophy of sound, he has had the more leisure for analyzing the art, and facilitating the student's progress. This author regarded Okenheim, Joquin, Isac, Brumel, Mouton, and Senefelio, as古人 compared with Willaert, Morales, Cipriano, Zarlinio, and Palestrina; and these last, ancient with respect to himself and contemporaries; and says (lib. i. cap. x.), that as the ancient Greeks and Romans produced their musical effects by mere melody, united with poetry, and Joquin and other early contrapuntists, by notes of different lengths, harmonized and worked into perpetual fugue; so the more modern, though the rules of harmony are the same, by a different disposition of concords, inversions, and other contrivances, produce a greater variety of effects.

He likewise observes (cap. xxiii.), that "every age has vainly thought its music brought to as great a degree of perfection as was possible; but it was always found that the next age continues to change, and fill to think the same. Okenheim, the master of Joquin, and even in the days of Joquin, John Mouton, his scholar, had the fame ideas of their own improvements; yet, since their time, music has not frowd fill, but made great advances towards perfection, being more light and pleasing."

The change in musical modes has continued to our own time, and will doubtless continue to the end of all time; for melody, being a child of fancy and imagination, will submit to no theory or laws of reason and philosophy; and therefore, like love, will always continue in childhood.

Zacconi's chief labour and merit in the third book have been the explanation of the moods, and correction of errors in the notation of old composers, to which his work will serve as a useful collection of errata. In Book I. he dwells much on the superiority of the finging and fingers of his own time, over all that preceded them; and has a long chapter upon the manner of graceing and embellishing a melody, where he tells us, "Che file ti tenghi nel far di gioria; delli de i moderni passaggi, come si farfichino le cantilen•;" and speaks of acconciature, as the modern Italian do of rifiorament•, or graces. The divisions, however, into which he breaks passaggi, in order to embellish them, if adopted by an opera-singer of the present times, would not like a modern fine lady appearing at court in the furbelsow and flounces of queen Elizabeth, or a fine gentleman in the peruke of sir Cloudley Shovel.

ZACHARIAS, or SOCHAN, in Geography, a town of Hinder Pomerania; 14 miles E. of Stargard. N. lat. 52° 13'. E. long. 15° 28'.

ZACHAREVSKAIA, a fort of Russia, in the government of Ekaterinoslav, on the Konjika; 28 miles W. of Mariopol.

ZACHARIAS, Justus Frederick William, in Biography, was born at Frankenhausen in Thuringia, in 1726; and during the course of his elementary education at his native place, he distinguished himself by various poetical pieces. In 1743 he went to Leipsic to study jurisprudence, but directing his chief attention to the belles lettres, he produced his mock-heroic poem, entitled "Regomittedo," which Eichorn, in his History of Literature, says, was the commencement of heroic-comic poetry among the Germans. In the following year, he was admitted as an associate by the young men who contributed to the work published under the title of "Amusements of Reason and Wit." From Leipsic, where he remained about three years, he removed to Gottingen, where, attracting the notice of professor Klaproth, he was recommended by him to be a member of the German society. In 1748 he was appointed tutor at the Caroline college at Brunswick, and in 1761 he became professor of poetry in that institution; to which, in the succeeding year, were annexed the offices of inspector of the typographic and book-selling establishment belonging to the Orphan House, and director of the Brunswick Intelligence. From 1768 to 1774, he was editor of the New Brunswick Gazette; in 1775 he was appointed to the Exarchate of St. Simeon, at Brunswick; and he died in the month of June, 1777, in the 51st year of his age. His biographer states, that "he possessed a very fertile and vivid imagination, with a fine talent, improved by observation and acquaintance with the world. As a poet, he composed with uncommon facility, and tried his talents in almost every species, but was the most successful in the descriptive and heroic-comic. His burlesque poems were distinguished from every thing of the kind that had before appeared in Germany." A collection of Zachariah's poetical works was published at Brunswick in 1763-1765, 9 vols. 8vo. Gen. Biog.

ZACHARIAH, or Zachariah, one of the minor prophets, who commenced the exercise of his gift in the 8th month of the 2d year of Darius, the son of Hystaspes; and on account of the precision and clearness of his predictions, he has been intitled "the man among the minor prophets." The most remarkable of his prophecies are those that relate to the advent of the Messiah, and to the destruction of Jerusalem. Dupin.

ZACHARIAH, Pope, a native of Greece, succeeded Gregory III. in 741; at a time when the Roman territory was threatened with an invasion by Luitprand, king of the Lombards, and when the sons of Charles Martel were too much engaged by domestic broils to undertake its defence. The pope, therefore, tried how far he might avail himself of the authority of religion in averting the storm; and by a solemn embassy and personal visit, he not only obtained peace, but induced Luitprand to return to the Roman see four cities which he had taken from it. He also interposed, in 743, with Luitprand on behalf of the exarch of Ravenna, and prevailed with him to desist from an invasion of the exarchate, and to grant peace, as well as to give back the fortress of Cefena to the exarch; and in the same year he held a council at Rimini, to settle some matters of discipline, particularly such as related to the clergy. During the pontificate of Zacharias in the year 746, Carlogan, the eldest son of Charles Martel, who had surrendered his dominions to his brother Pepin, went to Rome, and assumed the monastic habit, with which he was solemnly invested by the pope. Rachis, the succesor of Luitprand, who, upon his acccession to the throne in 747, was peaceable disposed towards the pope and the Romans, took up arms against them; but his hostile purposes were averted by the remonstrances of Zacharias, and those of some of his principal clergy and nobility, who visited his camp, in order to obtain peace; nor were they successful merely in this object; but the refolt of their interview was Rachis's resignation of his crown, the assumption of the monastic habit conferred upon him by the pope, and retirement to the monastery of Monte Cacone, where Carloman refided. In 752 Pepin applied to the pope for permission to seize the crown of France, and to set aside Childeric III. the pope consented, and Childeric was provided for in a monastery. Zacharias, having displayed talents in the exercise of his office, which gave
him rank among the greatest of the popes, and having esta-
lished an efficient character by his liberality to the poor, 
and by his munificence in public works, died in 752, in the 
11th year of his pontificate. Some of his decrees and 
epistles, and also his translation of the dialogues of St. Greg-
ory from Latin into Greek, are extant. Bower.

"ZACHAROVA, in Geography, a fort of Ruffia, in the 
government of Irkutsk; 32 miles N.N.E. of Kirenik.

"ZACHAU, a town of Brandenburg, in the Middle 
Mark; 10 miles E. of Brandenburg.

"ZACHAW, Frederic Wilhelm, in Biography, an 
able musician and organist at Halie, in Saxony, was born at 
Leipzig in 1665. He had the honour and good fortune to 
have Handel for his scholar. He is still celebrated by the 
Germans as a maister, who had established an admirable 
school of music at Halie, and as one who was deeply skilled 
in all the arcana of composition and performance.

"ZACHEO, or DESECHIO, in Geography, a small island 
in the West Indies, between Hifpaniola and Porto Rico; 
about 27 miles N.E. of Mona.

"ZACHTLEVEN, Cornelius, in Biography, was born 
at Rotterdam in 1666, and became an admirable painter of 
scenes of humour, imitating the style of Bourdeau; but in 
subjects of a more sober description, which he also painted, 
such as farm-houses, kitchens, and the recreations of vil-
lagers, &c. he chose the more light and agreeable style of 
Teniers for his model; and in that style attempted to 
embody the fame description of persons and compositions. 
In neither, however, of his imitations did he attain an equal 
degree of spirit or of truth with his prototypes. His works 
are well composed, and the touch with which they 
are executed is bold and free; they are not often met with, 
but are thought deserving of a place in the best collections.

"ZACHTLEVEN, Herman, was the younger brother of 
Cornelius, and was born at Rotterdam in 1690. He is 
said to have been the pupil of Van Goyen, but did not 
follow the style of that master. His principal occupation 
appears to have been in painting views of the banks of the 
Rhine and the Meule. These he executed in a very neat 
manner, but with a mean and common-place style of depiction 
and imitation. The tones and hues of his pictures are 
generally cold, but fresh; and as he appears to have had 
great knowledge of aerial perspective, his distances are well 
proportioned, and the forms drawn with great care and minute-
ness. He never left Flanders, though it has been asserted 
that he went to Italy. His drawings are numerous, and 
are carefully preserved in the best collections. He died in 
1685, aged 76. Both he and his brother Cornelius em-
ployed the etching-needle, and left several neatly executed 
plates, from designs of their own.

"ZACINTHA, in Botany, whether so called by Mat-
thiolius, the author of the name, because this plant was 
originally found in the Isle of Zante, or for what other rea-
on, does not appear.—Matth. Valgr. v. 1. 457. t. 466. Schreb. 
t. 269. Poiret in Lamarck s. 8. 851. Garin. s. 157. —

Gen. Ch. Common Calyx double; the outermost short, 
erect, of several lanceolate leaves, marginated at the edges; 
inrior larger, simple, furrowed, of eight permanent, li-
near, acute, converging leaves; at length swelling and very 
prominent at the base. Cor. compound, imbricated, uni-
form; florets equal, perfect, of one petal, ligulate, linear, 
s abrupt, with five stamens. Stam. Filaments five, capillary, 
very short; anthers united into a cylindrical tube. 
"Pfl.

"ZACONDA, a town of Africa, in the country of Anel, 
where the Dutch built a fort. It was a considerable town 
at one time, till in a war between the people of Ante and 
Adom, it was burnt down by the latter; since which it has 
ever been thoroughly repaired.

"ZACUTO, or Zacutus Lusitanus, in Biography, a 
physician, was born at Lisbon in 1575, and educated at Sal-
amanca and Coimbra. In his 20th year he took the degree 
of doctor, and settling in his native city, practiced with 
reputation for thirty years. As he was a descendant of 
Jewish parents, his dread of the Inquisition, after the edict 
of Philip IV. against the Jews was issued in 1624, induced 
him to retire to Holland, where he openly professed the 
religion of his family, and maintained a character highly 
respectable, both in his profession as a physician, and in his 
mental conduct. He died at Amsterdam in the year 1642; 
and left behind him a collection of works, amounting to 
2 vols. fol. The principal of his works are, "De Medi-
corum Principum Historia," lib. vi. in which he approves 
himself a strenuous advocate of Galen and the Greek phy-
sicians; "Praxis Historiarum Morborum," lib. v. and 
"Praxis Medica admiranda," lib. iii. In all his works he 
blends acuteness of observation with a certain degree of 
superficialities.
superstitious credulity; but they are nevertheless consulted and quoted. Haller. Eloy.

ZACYNTHUS, in Ancient Geography, an island of the Ionian sea, W. of that part of the Peloponnesus on which is the island Chelonis. It is now called Zante. Strabo makes its compass 160 stadia. It had many forts, and was very fertile. In this isle was a town of the same name, situated in the eastern part, with a citadel. According to Dionysius of Halicarnassus, it derived its name from Zacynthus, son of Dardanus, who, accompanied by a number of Phrygians, settled here. According to Thucydides, the first Greeks known in this island were Achaeans, who came hither from Achaia. It palled under the dominion of Philip, king of Macedon, who surrendered it to Amynander, king of the Thessalians, who sold its government of it to Philip of Megalopolis, by whom it was transferred to Hierocles of Sicily. After the defeat of Antiochus at Thermopylae, Hierocles sold it to the Achaeans. Livy says, that the town and citadel were assaulted and captured by Leuvinus; and Pauniani informs us that it was called Paphis. According to Scylax it had one port; and Pliny says that it was very fertile, and that its port was named Hyrie; but P. Mela distinguishes Hyrie from Zacynthus.

ZACYNTHUS, a town of Africa, in Libya. Steph. Byz. Zacynthus, an epithet used by the ancients to a liquid bitumen, from the island Zante.

ZAD, in Geography, a name given to the Niger of Africa, in Bornou, which is described in Horneman's Journal as flowing callwards. Its breadth was given to him for one mile, and he was told that it flowed towards the Egyptian Nile, through the land of the heathens. The course here given is directly towards the Congo; and it is said, that Zad is the name of the Congo at its mouth, and that it is the name of the Congo for at least 650 miles inland.

ZADADRUS, in Ancient Geography, a river of India, on this side of the Ganges; which received the waters of the Hyphasis and Adris, according to Ptolemy.

ZADAN, in Geography, a town on the west coast of the island of Cother. S. lat. 21° 55'. E. long. 119° 9'.

ZADAOX, a river of Portugal, which runs into the Atlantic, near Setuval.

ZADELSDORF, a town of Saxony, in the circle of Neufkald; 3 miles S.E. of Auma.

ZADONZK, a town of Russia, in the government of Voronez, on the Don; 52 miles N. of Voronez. N. lat. 53° 4'. E. long. 39° 14'.

ZADRADARIA, in Ancient Geography, a very large town of Asia, the capital of Hyrcania, according to Arrian.

ZADRAMA, a town of Arabia Felix, the capital of the Cincadopolites. Steph. Byz.

ZADRUN, in Geography. See Hatyan.

ZADRIS, in Ancient Geography, a town of Asia, in the interior of the Colchide. Ptol.

ZADURA, in the Materia Medica of the ancients, a name given to a foreign root, which was round and smooth, and of the colour of ginger.

It was at that time imported from the Indies, and greatly esteemed in pestilential cafes.

ZETIA, or Zetta, a town of Arcadia, N. of Megalopolis. It had two temples, one of Ceres, another of Diana.

Z.EZAR, in Geography, a town of Spain, in the province of Murcia; 22 miles N.W. of Murcia.

ZAF, in Geography, a town on the coast of Byzantium; 55 miles S.E. of Melilla.

ZAFARANBOLI, a town of Natolia; 28 miles S. of Amashch.

ZAFFABEN, a word used by some of the chemical writers to express putty.

ZAFFER, ZAFFRE, or SAFFRE, in Chemistry, is the residuum of cobalt, after the sulphur, arsenic, and other volatile matters of this mineral have been expelled by calcination: so that it is a kind of calx or oxyd of cobalt, mixed with a portion of felseous matter, of a grey or reddish colour; in which flake it is imported from Saxony. It is used to produce a very fine blue colour, when it is melted with fusible and vitrifiable matters.

The blue colour produced by the vitrification of zaffre proceeds from the earth or calx of a semi-metallic substance contained in cobalt, called by chemists regulus of cobalt. This is proved by melting zaffre with a reducing flux, like any other roasted ore, by which means the regulus will be obtained. The fcoria in this fusion has also a blue colour, proceeding from a portion of the calx of the regulus that is not reduced, but is vitrified together with the fcoria. The calx, therefore, or metallic earth of the regulus of cobalt, is the fceafe of the blue colour produced by zaffre.

But as this is contained in cobalt in various quantities, some zaffres produce more blue than others. The heterogeneous fixed matters contained in cobalts contribute, according to their quantity, not only to the greater or less intensity of the blue colour, but also to its lustre and beauty; and, therefore, those who manufacture zaffre from cobalt make frequent effays of the roasted ore, by mixing it with vitreous matters, in order to discover the intensity and beauty of the blue colour.

Good cobalt calcined would form too deep a blue, and almost a black glass, if it were not previously mixed with a certain quantity of vitreous frit. In the manufacture of zaffre, therefore, the calx of cobalt, the strength of which has been determined by previous effays, is mixed with such a quantity of sand, or of powdered flints and quartz, that with the addition of some saline flux, a deep blue glass may be formed. See Cobalt.

The zaffre that is commonly sold, and which comes from Saxony, is a mixture of oxyd of cobalt with some vitrifiable earth; it is of a grey colour, and some zaffres are clearer than others, according to the intensity of the colour which they are capable of producing.

Zaffre is employed in the manufacture of pottery and porcelain, for painting the surface of the pieces of ware, upon which it is applied, together with some saline flux, previously to the baking or glazing, that the same fire may vitrify this colouring material.

The blue of zaffre is the most solid and fixed of all the colours that can be employed in vitrification; it suffers no change from the most violent fire. It is successfully employed to give shades of blue to enamels, and to the crystal glasses made in imitation of some opaque and transparent precious stones, as the lapis lazuli, the turquois, the sapphire, and others of this kind.

To prepare zaffre for use in the glasa-trade, put it in groats pieces into earthen pans, and let it stand half a day in the furnace; then put it into an iron ladle to be heated red-hot in the furnace; take it out while thus hot, and sprinkle it with strong vinegar: and when cold, grind it on a porphyry to an impalpable powder, then throw this into water
water in glazed earthen pans; and when it has been well stirred about, let it settle and pour off the water: repeat this washing often, and the foulness of the saffron will be thus wholly separated. Dry the powder, and keep it for use.

ZAFFRAM, a word used often by authors to express saffron, but sometimes as the name of other things of a yellow colour; thus ochre was called by this name.

ZAFFRAMEN, a word used by some medical writers to express saffron.

ZAFRA, in Geography, a town of A fixture Turkey, in the government of Marash; 15 miles S.W. of Tarfus.

—Allo, a town of Asiantic Turkey, in the government of Trebizond, on the Black sea; 50 miles N.W. of Trebifond.

—Allo, a town of Spain, in Extremadura; 22 miles E. of Xeres de los Caballeros.

ZAFRANIA, in Colours, a term used by the Greeks to express the yellow of saffron. The barbarous writers of the after-ages translated it into the Latin crocitas, or saffron colour.

The later Greek writers only use it, and they have taken it literally from the Arabians, Avicenna, and Serafio. This was a term used by them to express the colour of the fine hole-armenic of Galen, which they tell us flayed paper to a fine and beautiful gold colour.

ZAQA, in Botany, Poiret in Lamarck Dict. v. 8. 831. (Zaga, Pethon, or Corallaria latifolia, Rumph. Ambon. v. 9. 175. t. 110.)—This is one of those trees, whose hard red seeds are used for ornament, in the form of necklaces, bracelets, &c. by the natives of tropical climes, and even by the inhabitants of the most polished countries of Europe, as fashion, from time to time, is pleased, in her capricious wisdom, to ordain. Such are the beautiful red and black seeds of Abrus precatorius, of which there is a perfectly white variety, of rare occurrence. Such also are those much larger seeds, of the same combination of colours, produced by the Weit Indian genus Ornaria. (See that article.) The Zaga of Rumphius and Poiret is evidently a papilionaceous plant, with pinnate leaves, composed of about three pair of elliptic-oblong, entire, flaked, rather large leaflets, with an odd one. Flowers in panicked terminal clusters. Legume elliptic-oblong, pointed, hard and smooth, each containing one, rarely two, hard, thinning, round seeds, all over of the colour of red coral, larger than those of Adenanthera pavonia, being as broad as the fore-finger nail, and destitute of the defined circumscribed area, for which the seeds of the Adenanthera are remarkable.

ZAGALA, in Geography, a town of Spain, in Extremadura; 25 miles S. of Alcantara.

ZAGAN, a town of the principality of Georgia, in the province of Kasket; 3 miles N. of Tetis. —Allo, a town of Peris, in the province of Irak; 12 miles S.W. of Hamadan.

ZAGARA, a mountain of Greece, in Livadis, anciently called Helicon.

ZAGATHAI, a name given from the second son of Zingis to Great Bucharis; which fee.

ZAGATIS, in Ancient Geography, a river of Asia, in the Colchide, according to Arrian, who fixes its mouth between Atanx and Anchianke Regia.

ZAGAWA, in Geography, a city of Africa, in Bornou, on a river which runs into the same lake, where the Niger is by some supposed to be let. N. lat. 19° 10’. E. long. 25° 50’.

ZAGGOS, a mountain of Africa, in which are some mines of salt; 100 miles S. of Algiers.

ZAGHARA, a town of Africa, in Bornou.

ZAGI. See ZEOI.

ZAGOLLONITIS, in Ancient Geography, a country of Asia, in Cappadocia. Strabo.

ZAGING, in Geography, a town of Austria; 3 miles N. of St. Polten.

ZAGIRA, in Ancient Geography, a town of Asia, in Paphlagonia, at a small distance from the sea. Ptol.

ZAGLIA, in Geography, a town of the island of Corfica; 8 miles S.E. of Calvi.

ZAGORA, a town of European Turkey, in Romania, on a lake which communicates with the Black sea; 12 miles S.W. of Burgas.

ZAGORA, in Ancient Geography, a town of Asia, in Paphlagonia, on the coast of the Euxine sea, between Caur and the mouth of the river Halys, according to the Peripus of Arrian.

ZAGOROLO, in Geography, a town of the Popedem, in the Campagna di Roma; 5 miles W. of Palestrina.

ZAGOROW, a town of the duchy of Warlaw; 20 miles S. of Kalich.

ZAGRA. See AGRAM.

ZAGROS, MOUNT, a mountain of Peria, in the province of Irak, along the brink of which extends the district of Kurrend, from the vicinity of Holwan to the village of Gour. It is covered with forests of oak, and inhabited by an extraordinary race of men, among whom fubful customs similar to those of the Kadmufa in Syria, described by Volney. It is said that in their nocturnal festivals, the garments of the fair sex, at the expiration of a certain period, are thrown into a heap, and jumbled together. The lights are then extinguished, and the clothes being regularly distributed among the men, the candles are re-lighted; and it is settled by the rules of the society, that the lady must patiently submit to the embrace of the perfon who has become possessed of her drefs, whether father, fon, husband, or brother. The lights are then once more extinguished, and all of this licentious tribe pays the remainder of the night in the indulgence of the most promiscuous lust.

ZAGRUS, or ZAGRUS MONS, in Ancient Geography, a mountain of Asia, in Media. It made a part of mount Taius, commencing in Armenia, and extending as far as the Chaloutide, between Media and Adiabene. Pliny. It is reckoned by Ptolemy one of the most confiderable countries in Media. According to Strabo, it was this chain of mountains which touched the Niphates, and separated Media from Babylonia.

ZAGU, in the Materia Medica, the name given by some authors to the fago-tree, the todda pauna, or palma fructre priniforme.

ZAGUANANAS, in Geography, a river of considerable length in New Mexico, which flows from the same sources with the Rio Bravo, and joins the Colorado; which see.

ZAHARA, in Geography, a town of Spain, in the province of Seville. In 1407, this town was taken from the Moors; about two years after the Moors retok the town, but not being able to reduce the citadel abandoned it. In 1481, it was surprised by the Moors, in a dark stormy night; most of the inhabitants were put to the sword, and the red feit slaves to Grenada; 36 miles S.E. of Seville. N. lat. 36° 50’. W. long. 5° 33’.

ZAHARA. See SAHARA.

ZAHIA, a word used by the Arabian physicians to express a sort of dyfentery, in which there was a very large
ZAIRA KAKONGO, an island in the Atlantic, at the mouth of the river Zaire.

ZAIRAGIA, or ZAIRAGIAN, a kind of divination in use among the Arabs; performed by means of divers wheels, or circles, placed concentric to one another, and noted with several letters, which are brought to ansver to each other, by moving the circles according to certain rules.

This is also called zarib, because of the circles of this machine, which are called mutazariat, lafak, &c. are intended to correspond to the orbs of the planets, and the atmospheres of the several elements.

ZAIRED, or SAIRE, in Geography, a river of Africa, which rises in the country of Matamba, about S. lat. 10°, and takes a northerly course to lat. 3°, in the kingdom of Congo; after which it takes a south-westerly direction, and runs into the Atlantic, S. lat. 6°. E. long. 13° 20'.

It has been an important question, with regard to which geographers have entertained various opinions, what are the course and termination of the Niger. The ingenious geographer, Mr. Rennell, on comparing the various accounts of the progress of the Niger beyond Houfia, declared his opinion to be, that its waters had no communication, either with the river Nile, as was thought, or with the seas, as others imagined; but that they were spread out into a great lake in Wangara or Ghana, and evaporated by the heat of the sun. (See NIGER.) Mr. Park, the late African traveller, directed his particular attention to this subject, and was induced to conclude that the Congo would be found to be the termination of the Niger from the following considerations: 1. The total ignorance of all the inhabitants of North Africa respecting the termination of that river. If the Niger ended anywhere in North Africa, it is not easy to account for this total ignorance, and for their generally describing it as running to the Nile; and in fact, to a country with which they had not any acquaintance. A second consideration has been already suggested under the article ZAD. A third is deduced from the general supposition that the river of Dar-Kulla, mentioned by Mr. Browne in his "Travels," was the Niger, or at least that it communicated with that river; and this, it is said, would be exactly the course which the Niger ought to take in order to join the Congo. 4. The quantity of water discharged into the Atlantic by the Congo cannot be accounted for on any other principle, but that it is the termination of the Niger. If the Congo derived its waters entirely from the S. side of the mountains, which are supposed to form the belt of Africa, one would naturally suppose, that when the rains were confined to the N. side of the mountains, the Congo, like the other rivers of Africa, would be much diminished in size; and that its waters would become pure. On the contrary, the waters of the Congo are at all seasons thick and muddy. The breadth of the river, when at its lowest, is one mile, its depth is fifty fathoms, and its velocity five miles per hour. 5. The annual floods of the Congo commence before any rains have fallen south of the equator, and agree correctly with the floods of the Niger, calculating the water to have flowed from Bambara at the rate of three miles per hour. Mr. Park, during his residence in Scotland, became acquainted with a Mr. George Maxwell, formerly an African trader, who was well acquainted with the whole western coast of Africa, more especially S. of the equator, and had published a chart of the river Congo. Mr. M. had been led by a variety of circumstances to conjecture that the source of the Congo lay considerably inland, and far to the north; and from a perusal of Mr. Park's travels
he concluded, that the Congo and the Niger were one
and the same stream. Mr. Maxwell's reasoning confirmed
Mr. Park in his opinion; and in this opinion he persevered
to the end of his life.

Since the discoveries of Mr. Park, it is very generally
allowed that the course of the Niger is from west to east;
and his opinion with regard to its termination in the Congo,
or, as it is sometimes called, the Zaire, has received a con-
siderable degree of confirmation from the account of the
Congo given by Mr. Maxwell. "Before ever the Niger
came to be the topic of conversation," says Mr. M., "it
struck me, that the Congo drew its source far to the north-
ward, from the floods commencing long before any rains
took place S. of the equator; since it begins to swell per-
cently about the latter end of October, and no heavy rains
fell in before December, and about the end of January, the
river must be supposed to be at its highest. At no time,
however, can the rains to the southward of the line be com-
pared with those in the Bight of Guinea, where ships are
obliged to have a house erected over them during these
months."—"If the Niger has a sensible outlet, I have no
doubt of its proving the Congo, knowing all the rivers be-
tween Cape Palmas and Cape Lopas to be inadequate to the
purpose; nor need the immense course of such a river fur-
prise us, when we know that the river St. Lawrence, con-
templated in size compared with the Congo, encompasses the
whole of North America, flowing through a chain of lakes.
But instead of seven or eight lakes, the Congo may be sup-
posed to pass through seventeen or eighteen; which will
solve any difficulty as to the floods of the Niger not imme-
diately affecting the Congo." He adds, the river Niger,
compared with other rivers, must rank as the third or fourth
in magnitude. Considering the force of the current it pro-
duces in the sea, carrying out floating islands fifty or seventy
leagues from the coast, the Amazon or Plata only can cope
with it. At the distance of 600 miles from its mouth, the
Congo traders report that it is as large at the place from
which they came, and that it went by the name Enzaddi, as it
does among all the nations upon the coast. If the shallow
water opposite to Suenda should be thought to detract from
the assumed size of the Congo, it should be considered, that
the river there is spread out ten miles in width, the middle
channel of which has never been accurately founded. "It
has long been my opinion, that Leyland's or Molyneux's
island at Embomma, (a settlement on the banks of the
Congo, distant thirty leagues from its mouth,) either of
which might be rendered as impregnable as Gibraltar, at a
very small expense, could be a choice station for establishing
an extensive commerce with the interior of Africa. Indeed,
if the idea of the Congo being the outlet of the Niger
prove fo upon trial, we may consider it is an opening de-
gned by Providence for exploring those vast regions, and
civilizing the rude inhabitants." The Congo appears from
other testimonies to be a river of the finest clays, and larger,
probably, than the Nile. The waters of the Congo, it is
said, may be distinguished at sea more than thirty leagues
from the coast; and the water is fresh at the distance of thirty
miles. If these accounts are thought to be exaggera-
tions, it is a general opinion among navigators that this
river has a wonderful size and force. All accounts con-
cur in representing that the stream of the Congo is of a
more uniform height, and subject to much less variation from
the dry and rainy seasons, than any tropical river which is
known; and that on a comparison with such rivers, it may
be considered to be in "a perpetual state of flood." The
average rising of the Ganges in the rainy season is rated by
major Rennell to be thirty-one feet, being almost the same
with that of the Nile; whereas, the difference between the
highest point of the Congo about February, and the lowest,
in September, is only about nine feet; and the river, at the
latter period, has all the appearance to a stranger of being
in full flood. It is this remarkable peculiarity which distin-
guishes the Congo from other great rivers of a similar de-
scription, and which leads to important conclusions with re-
gard to its origin and cause. "In support then of the hy-
pothesis which identifies the Congo with the Niger, the fol-
lowing arguments deduced from the preceding facts and ob-
servations may be alleged: 1. The great magnitude of the
Congo. 2. The probability that this river is derived from
very remote sources, perhaps considerably north of the
equator. 3. The fact, that there exists a great river N. of
the equator (the Niger), of which the termination is un-
known, and which may, perhaps, form a principal branch
of the Congo.

"Such being the evidence in favour of the hypothesis
respecting the Congo, the objections must be admitted to
be weighty and formidable; the principal of these are,
1. That it supposes the course of the Niger to be through
the vast chain of the mountains (anciently Montes Lune),
the great central belt of Africa."—"It is difficult to un-
derstand how the Niger could penetrate this barrier, and
form a passage southward. 2. The course of the Niger,
emanated from its source in the mountains of Senegal, (fup-
poing it to be the same river with the Congo,) and to flow
by Wangara and Cadhna, through the centre of Africa into
the Atlantic,) would be considerably more than 4000 miles.
But the course of the Amazon, the greatest river in the old
or new world, is only about 3500 miles; and although the
existence of a river considerably greater than any yet
known may be within the limits of physical possibility, yet
so improbable a supposition ought not to be adopted upon
flight or conjectural reasoning, or upon any thing much
short of distinct and positive proof."

The editor of Mr. Park's Travels, &c. in 2 vols. 8vo.
1816, which we are now citing, very laudably expresses a
hope, "that this distinguished river, which hitherto has been
only known as one of the greatest marts of the Slave Trade,
may at length be rendered conducive to objects of civiliza-
tion and science; and that some use will now be made of
this great inlet into Africa, for the purpose of exploring a
part of that continent which as yet is entirely unknown; or,
at least, of obtaining more complete and authentic informa-
tion relative to the Congo itself, which must unquestionably
be considered as a very curious and interesting subject of
inquiry."

Another opinion with regard to the termination of the
Niger has been advanced by M. Reichard, a German geo-
grapher, and published in the "Ephemerides Geogra-
phiques," at Weimar, in August 1808. This opinion is,
that the Niger, after reaching Wangara, takes a direction
forth the south, and being joined by other rivers from that
part of Africa, makes a great turn from thence towards the
south-west, and pursues its course till it approaches the
north-eastern extremity of the gulf of Guinea, where it
divides, and discharges itself by different channels into the
Atlantic; after having formed a great Delta, of which the
Rio del Rey constitutes the eastern, and the Rio Formoso,
or Benin river, the western branch. This hypothesis,
thought it diminishes the distance which the Niger has to
flow in its course to the Atlantic, does not remove the ob-
jection arising from the Niger's being conceived to penetrate
the Congo mountains. But we must not pursue this subject
any
any farther. For the lengths of the course of the most noted rivers, see River.

ZALESCHE, in Geography, a town of Austrian Poland, in Galicia; 32 miles S. of Lemberg.

ZALEUCUS, in Biography, a philosopher and legislator of Greece, and founder of the Laconian state, flourished in the 7th century B.C. He was of obscure birth, and lived in servitude as a shepherd; but his extraordinary abilities and merit attracted notice even in his humble station, and advanced him to the government. His laws were deemed severe, but being adapted to the circumstances and manners of the Locians, their constitution was for several ages highly celebrated. His discipline was rigorous, so that he prohibited the use of wine, otherwise than as a medicine; Vol. XXXIX.

ZAM, in Geography, a town of Grand Bucharia; 85 miles N.W. of Balk.

ZAMA, a town of Peru, in the diocese of Arequipa; 30 miles N. of Arica.

ZAMA, in Ancient Geography, a town of Africa Propria, 5 journeys from Carthage. This town, to which ancient authors give the title of royal and a fortesis, is famous in the wars of Jugurtha and Juba, and more especially on account of a battle between the Carthaginians under Hannibal and the Romans, commanded by Scipio, in the year 551 of the Republic. At the time when this town was in a flourishing state, it was assigned to Numidia. Cornelius Nepos says, that it was 300 miles from Aduometum. Appian says 3000 stadia. It was situated on a plain, and owed its strength to its fortifications more than to its situation. Hirtius says, that it was the ordinary residence of king Juba, where he had his wives, children, and treasures. Pliny says, that it became a Roman colony.

ZAMFARÁ, or ZANFARA, in Geography, a town of Africa, and capital of a kingdom of the same name; 170 miles E.N.E. of Waganga. N. lat. 18° 20'. E. long. 16° 15'.

ZAMIA, in Botany, from ἵππως, damage, or loss. This name, which first occurs, as the appellation of a genus, in the Gen. Pl. ed. 6. of Linnaeus, is taken from Pliny, who uses it for such cones of the fir as “split while they are upon the tree,” and, as he says, “require to be taken off, that they may not injure the reft.” This should seem to apply to the male catkins, however Pale the physiology of Pliny, and the practice founded upon it, may be. Our Zamia answers to his, merely in the cone-like form of its fructification, which, being male on one plant, and female on another, exhibits in the former the appearance of lofs, or sterility, like the male catkins of the fir.—Linn. Gen. 574. Suppl. 68. Schreb. Gen. 778. Willd. Sp. Pl. v. 4. 845. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 410. Brown Prodr. Nov. Holl. v. 1. 348. Pursh 648. Jaff. 16. Poiret in Lamarck Dict. v. 8. 831. Lamarck Illust. t. 892. Gartn. t. 3.—Clais and order, Dioecia Polyandria. Nat. Ord. Filicet, Linn. Juff. Cycadeae, Perloo, Brown.

Gen. Ch. Male. Cal. Catkin ovate, telfellated-scales horizontal, obtuse, thickened towards the end, permanent. Cor. none. Stam. Filaments none; anthers numerous, sessile, crowded on the under side of each scale, especially towards the extremity, elliptical, smooth, of two valves and one cell, splitting lengthwise.

Female. Cal. Catkin ovate, telfellated: scales horizontal, obtuse, more or less peltate, permanent. Cor. none. Pfl. Germens two, ovate, sessile, horizontal, inflexed, on the under side of each scale, near the extremity; style very short, somewhat conical; stigma obtuse, undivided, pellucid. Peric. Drupa roundish, somewhat angular, of one cell. Nut hard, roundish or elliptical, of one cell.

Obf. Mr. Brown, to whom we are obliged for the remark of the filey being finally pervious, records an idea of the late Mr. Dryander, that the American Zamia, which confitute the original genus, having more perfectly peltate scales to the male catkin, and the anthers assembled in two diffiñct masles might possibly form a diffiñct genus from the Cape and New Holland species; more especially as in these American plants, the leaffets are each manifefly articulated with a projection from the main rib of the leaf; whereas in the others they are either very obscurely jointed, or perfectly decurrent. We conceive, however, that they all together compose a very diffiñct genus, which cannot, without violence to nature, be divided. It is nearest akin to Cycas, but differs essentially in the female part of the fructification being a catkin, whose scales bear two germens underneath; instead of an assemblage of fronds, or leafy receptacles, bearing an indeterminate number upon their margins. The herbage is perennial, generally without a flem. Leaves abruptly pinnate, singularly hard, rigid, and often spinous; rarely lobed. Catkins radical, faltimore.

It being extremely difficult to obtain and to compare good specimens of the different species, as well as to detect and define their effential characters, authors have not very clearly described them. Jacquin has published magnificent figures of several; but their most satisfactory marks require to be sought at an earlier period of their growth, and in more minute parts, than he has generally exhibited.

1. Z. cycadifolia. Sago-palm-leaved Zamia. Jacq. Fragm. 27. t. 25, 26. Willd. n. 1.—Leaffets very numerous, two-ranked, linear, entire, with fimpie spinous points; common stalk femicifylindrical, channelled, downy. Catkin of the fruit elongated, fomewhat cylindrical.—Native of the Cape of Good Hope. Cultivated in the Imperial gardens at Schoenbrun, but not mentioned by Mr. Aiton as known to our English collectors. The thick globular fheal head of the root, near a foot in diameter, bears numerous fpreading pecife leaves, very much reembling, at first fight, those of Cycas revoluta. The flate of each is, in its naked part, two feet long, as thick as a fwan’s quill, all over downy, as is also its leafy portion, and the young leaffets themselves. The full-grown leaffets are from 50 to 80, rigid, parallel, acute, pungent, each about three inches long; the lowermost gradually fhortef, and rather more dilant. The ripe fruits, brought from the Cape, is ovate-oblung, about fifteen inches in length, and five in diameter, brown, each fcale bearing two ovate, angular, orange-coloured drupas, about an inch long, their points direéted towards the base of the fcale. Nut not much smaller, ovate, angular.

2. Z. pungens. Needle Zamia. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 478. ed. 2. n. 1. Willd. n. 2. Poiret n. 3. (Palma fofofifera ægyptia, folis leviourbus, frutibus nigro; Till. Hist. 129. t. 45.) Commonly fpreadmg, ftraight, rigid, pointed, entire; their outer margin rounded at the base; common stalk nearly cylinderical, unarmef.—Native of the Cape of Good Hope, from whence it was brought by Mr. Maffon, to Kew garden, in 1775, but has not yet flowered. The leaffets are very thick and coriaceous, much fewer than in the preceding species, mostly opposite, four orfive inches long, and one broad; their under surface somewhat frifated; the upper smooth and fhining; margin quite entire; point fimpie, spinous, fout and rigid.

3. Z. tridentata. Three-toothed Zamia. Willd. n. 3.—Leaffets linear, obfcurly furrowed, smooth, with three spinous teeth at the end; common stalk femicifylindrical, channelled.—Suppofted to be a native of the Cape of Good Hope. The leaffets are fourteen to fifteen pair, linear, tapering at each end, with two lanceolate, pointed, terminal teeth, and a third situated a little lower at the outer edge. Common stalk smooth. Willdenow. No other author appears to know this species. We have specimens in the herbarium of the younger Linnaeus, without name, indication of their native country, or any traces of fructification, which anfwerv
ZAMIA.

answer to the above characters; except the leaflets being more numerous, sometimes with a simple spiny point only, on the same stalk with others that have two or three, very rarely four; and in one instance the leafstalk is the common leafstalk is flabby with soft hairs. Each leaflet is two or two and a half inches long, thick-edged and slightly revolute, entire, except the above-mentioned points; smooth on both sides; furrowed beneath; tapering at the base, and somewhat decurrent at its insertion. See n. 15.

4. Z. angustifolia. Narrow-leaved Zami a. Jacq. Coll. v. 3. 265. Lc. Tar. t. 636. Willd. n. 4. Poiret n. 6.—Leaves linear, elongated, entire, obtuse, with two terminal callous points; common stalk fleshy-cylindrical. Fruit ovate, pointed.—Native of the Bahama islands; cultivated at Schonbrunn, where it was raised from seed, and borne flowers and fruit, the catkins being about eight months in going through their different stages. The root is scarcely bigger than a large radish; its ovate crown enclosed in a few pointed, very broad, scales. Leaves about a yard high, with slender stalks and leaflets; the latter drooping, a span long, and two lines broad. Cattins three inches long, on stalks about the same length; the male ones most slender, and nearly cylindrical. Fruit three inches long, on a thick ovate, or elliptical figure, with a blunt point. Drujas concealed, red.

5. Z. tenuis. Slender Zami a. Willd. n. 5.—Leaflets linear, obtuse, somewhat revolute; tapering at the base, with one or two oblique teeth near the extremity; common stalk triangular, smooth.—Native of the Bahama islands. Willdenow fav a living male plant. Leaflets about fourteen pair; the upper ones furnished, near the point, with one or two very inconspicuous teeth. An intermediate species between the latt and the following; agreeing nearly with Z. angustifolia in the form of its leaflets, but they are broader, and their stalk is triangular; the leaflets are narrower than those of the following, neither are they minutely serrated towards the point; but the stalks are similar.

6. Z. media. Intermediate Zami a. Jacq. Hort. Schoenbr. v. 3. 77, t. 397, 398. Willd. n. 6. Poiret n. 7.—Leaflets linear-lanceolate, obtuse, flat; obscurely serrated towards the point; common stalk triangular, smooth.—Native of the West Indies; cultivated at Schoenbrunn. The crown of the root is as big as the fist. Leaves two feet long, besides their naked stalk, which is half as much. Leaflets from fourteen to twenty pair; five inches long, and one-third or half an inch broad, flat, for the most part entire, except a few slender dull serrate teeth towards the extremity, which is bluntish, and without any spiny termination. Female cattins on short thick stalks, ovate, with a blunt point. Fruit oval, brown, rough, three inches long. Jacquin. That author confers the present species as alluded on the one hand, to his angustifolia (see n. 4.), and on the other to intergrifolia, n. 8. Still we cannot question it being specifically distinct from both.

7. Z. debilis. Lax-leaved Zami a. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 478. ed. 2. n. 2. Willd. n. 7. (Palma prunifera humidus non spina, infusa Hifpaniole, frutetui iujubino simili, officulo triangulo; Commel. Hort. v. 1. 111. t. 58.). Leaflets lanceolate, acute, pointlets, serrated towards the point; common stalk triangular, smooth.—Native of the West Indies, from whence it is said to have been imported, in 1777, by the late Mefiara. Kennedy and Lee. It flowers in the flower, in July and August. The leaflets are five or six pair, half an inch broad; though only two and a half or three inches long, and are distinguished from all the foregoing by their conspicuous serratures, all indeed near the end, the greater part of the leaflet being entire: the upper side is smooth and shining; under furrowed or frutet. Commelina originally raised this species from seed in the Amsterdam garden, and was informed that the fruit was reddish, growing partly underground.

8. Z. intergrifolia. Dwarf Zami a. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 478. ed. 2. n. 3. Willd. n. 8. Pursh n. 1. Poiret n. 5, excluding the reference to Commelina. Jacq. Coll. v. 3. 261. Ic. Tar. t. 635. Lamarck t. 892, copied from Jacquin. (Z. punila; Linn. Sp. Pl. 1659, excluding all the synonyms.)—Leaflets smooth, frutet, lanceolate; rounded, obtuse, and finely serrated at the end; tapering at the base. Common stalk smooth, somewhat quadrangular.—Native of East Florida, from whence it was introduced into the English gardens, by the celebrated John Ellis, efq. in 1768. Jacquin says it grows also in Hispaniola. The crown of the root is sometimes as thick as a man's arm, dividing below into several stout branches and fibres. Leaves usually about eighteen inches long; sometimes twice as much. Leaflets from ten to twenty pair, opposite or alternate, each two and a half or three inches long, varying in breadth from one-quarter to three-fourths of an inch, entire, rather shining, strongly serrated on both sides, with many parallel ribs; the extremity rounded and pointlets, with a greater or less number of flight tooth-like serratures in proportion to its width. Cattins on short stalks, ovate, clothed with dark brown pubescence; the male ones about two inches long. Fruit three inches long, elliptical, pointed, downy; its scales finally widely separating, each of them peltate and angular, supported by a rather slender angular stalk, above an inch in length, and remaining long after the fruit is fallen. Each cattas is elliptical, about half an inch, or more, in length, with a small quantity of sweet orange-coloured pulp, and a large, rather pointed, nut. The leaflets are too strongly serrated in Lamarck's plate; and rather broader and more luxuriant than usual in Jacquin's, otherwise admirable, representation. The male cattins are very frequently produced; the female ones we know only from dried specimens, and the works of Jacquin.

9. Z. muricata. Prickly-stalked Zami a. Willd. n. 9.—Leaflets oblong, pointed, smooth, frutet; serrated from the middle to the extremity; common stalk spinous.—Gathered by Humboldt and Bonpland, in South America, near Porto Cabello. Leaflets about four pair, six inches long; tapering at the base; frutet and ribbed on both sides; sharply serrated in their upper half. Footstalk channelled, armed with very short, blunt, scattered spines. Willdenow.

10. Z. furfuracea. Broad Rusty-leaved Zami a. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 477. ed. 2. n. 4. Willd. n. 10. Poiret n. 2. (Palma americana, folis polygonati brevioribus, leviter serratis, et nonnulli spinosis, trunco crasso; Pluck. Phyt. t. 103. f. 2. and t. 309. f. 5. P. americana, crassii rigidissimi folis; Herm. Parad. 210. t. 210. Palmifolia frutet clavato polypyrene; Trew Ehret, 5. t. 26.)—Leaflets elliptic-oblong, pointlets; coarsely serrated from the middle to the extremity; frutet and hairy beneath; common stalk spinous.—Native of the West Indies. Plunenat faw it in the royal gardens at Hampton-Court in king William's time. It is still preserved in our flowers, flowering towards autumn. The crown of the root is often a foot in diameter. Leaves from one to two feet long, exclusive of their prickly stalks. Leaflets usually eight or nine pair, three or four inches long, and one or one and a quarter broad, very rigid and coriaceus; shining, and roughish to the touch, on the upper side; more

R 2 furrowed,
furrowed, and clothed with flabby, chalky pubescence, which gives them a ruddy or tawny hue, underneath. Their ferratures, or teeth, are numerous, obtuse, very irregular. Catkins ovate, hoary and downy, about three inches long, on a stalk about the same length. Hermann says this plant produces a white infidel gum.

11. Z. spiralis. Spiral Zamia. Salisbury. Prod. 401. Willd. n. 11. Alt. n. 5. Brown n. 1.—Leaflets numerous, linear, very smooth, somewhat curved, with a few spinous teeth at the extremity. Catkins smooth, with pointed scales; those of the male ones wedge-shaped. —Native of New South Wales, from whence seeds were sent, in 1791, by Dr. John White, to the writer of this, and plants were raised from them in the following year, by the late Mr. Fairbairn, in Chelsea garden, being the first introduction of this species into Europe. The whole cone, filled with these nuts, was about half as large as a man's head; the nuts themselves about the size of small chestnuts. They were said to be eaten roasted by the natives of New South Wales, but on being tried by our English settlers, occasioned sickness. Their flavour is certainly inferior to a chestnut, and even to the nuts of Cycas revoluta, ripened in the bishop of Winchester's stove at Farnham castle. The plants soon grew to a considerable size, and according to Mr. Aiton, this species flowers in the stove, in July and August. The leaves are very smooth, of a fine green, a yard or more in length, spreading, each composed of from thirty to forty pair of long narrow leaflets, tipped with from three to five spinous teeth. Footstalks said to be somewhat spiral. The catkins are stalked, cylindrical, about five inches long, and two in diameter, lirrated, smooth, not downy nor hairy; scales of the male ones obvate-wedge-shaped, an inch long, with a short, broad, sharp, acute, rounded, pubescent point; their upper face smooth and naked; under nearly covered with an uninterrupted heart-shaped assemblage of crowded, oval athers, the size of poppy-seed; scales of the female catkins stalked, gibbous, two-edged and depressed, larger than the male ones, each tipped with an erect, sword-shaped, pungent, smooth point, an inch long, and, as the fruit ripens, extended to three inches, the gibusb flasky part of the scale being then also much enlarged. Germens two, ovate, sessile, close together, at the inner edge of this flasky part of the scale, and directed horizontally inward. Drupes roundish, gibbous, an inch or more in half an inch in diameter, orange-coloured, with a rather thin pulp, at leaf in the dried state, and a large, ovate, hard nut, not burling, whole kernel, after keeping twenty-five years, is horny, imbricated, and as hard as the shell. Mr. Brown supposes there may be two species confounded under Z. spiro-lata; one found in the neighbourhood of Port Jackson, to which our description and synonymy entirely belong, and which is from two to four feet high; the other, often ten feet in height, noticed by Mr. Brown on the southern coast of New Holland, and which we have never seen. Mr. Brown remarks, that in both, the catkins, usually solitary, sometimes grow two together.

12. Z. longifolia. Tall-leaved Zamia. Jacq. Fragm. 28. t. 29. Willd. n. 12. Poiret n. 10.—Leaflets numerous, elliptic-lanceolate, pointlets, entire, clothed with flabby down. Scales of the male catkins wedge-shaped, with abrupt quadrangular points. —Native of southern Africa, above a hundred miles from the Cape of Good Hope. Cultivated at Schoenbrunn. The crown of the root is scaly, a foot in diameter, smooth. Leaves slightly spreading, from five to seven feet high; their stalks quadrangular, without spines; leaflets from forty to fifty or sixty pair, two-ranked, three or four inches long and one broad, coriaceous; frizzled beneath; clothed on both sides, as well as the leafy part of their common stalk, with a cobweb-like down, easily rubbed off; the lower ones only somewhat pointed. This species has not flowered in Europe; but the male catkin, brought from Africa, and represented in Jacquin’s magnificent plate, is elliptic-oblong, near two feet in length, and five inches in diameter, brown, smooth, composed of innumerable wedge-shaped scales, covered underneath with anthers, and each tipped with a quadrangular, or pyramidal, abrupt, prominent point, without any of the spinous termination seen in the last.

13. Z. lanuginosa. Woolly-scaled Zamia. Jacq. Fragm. 28. t. 35, 31. Willd. n. 13. Poiret n. 9.—Leaflets lanceolate, smooth, spinous-pointed, with a few unilateral spinous teeth. Radical scales woolly. —Native of southern Africa, from whence a single plant was brought long ago to the Imperial stove at Schoenbrunn. After twelve years’ culture, it had made but slow progress, and shewed no signs of fructification. The root consists of numerous, very thick, tapering radicles; its crown being as large as a man’s head, and covered with imbricated, deltoid, pointed scales, two or three inches broad, all clothed with soft, dense, hoary wool. Leaves a yard high, or more, dark green, very smooth and shining, with armed quadrangular stalks, and from twenty-five to thirty pair of linear-lanceolate leaflets, each four inches long, with a short spinous point; their margins all entire, except being often furnished with one, two, or three broad, spinous, tooth-like lobes, always at the lower edge of each leaflet, by which this species is at first sight readily distinguished. Professore Willdenow fupposed it might not be distinct from Z. cycada (see our 17th species); but we see no reason to concur in that opinion.

14. Z. hovisii. Grey Thorny Zamia. Jacq. Fragm. 27. t. 27, 28. Willd. n. 14. Alt. n. 6. Poiret n. 8.—Leaflets lanceolate, glaucous, acute, spinous-pointed, with a few unilateral, lanceolate, spiny teeth. Radical scales smooth. —Native of southern Africa, a hundred miles above the Cape of Good Hope. Cultivated at Schoenbrunn, and introduced into the English green-houses, in 1800, by John Liptrap, esq., who propagated, for several years, a splendid collection of exotics at Mile-end; but it does not seem to have bloomed either here or in Germany. The feal crown of the root is as large as the preceding, but the scales are not woolly. The leaves and their stalks are all over finely glaucous, which distinguishes the plant from the rest of its genus. The leaflets, as well as their lateral parts, are long, and more pointed, than in Z. lanuginosa; the points and bases green, as the whole surface becomes when rubbed. A ripe female cone, brought from its native country, is fifteen inches long and eight thick, brown, tessellated, and warty, but not spinous. Drupes orange-coloured, oval, each with a thick, elongated, obtuse point, in the place of the style. Nut oval, somewhat triangular. This species is, as Willdenow observes, very nearly related in size and general habit, to the last, but differs in its smooth crown of the root, and glaucous colour of the herbace.
Linnaeus, downy; with age, the plant acquires, like the palm tribe, a thick scaly stem, as tall as a man. The leaves are from a span to two feet long, of rather numerous and crowded leaflets, each two or two and a half inches in length, and one-quarter or one-third of an inch in breadth; smooth and even above; flirated beneath; the younger ones, or rather those of young plants, tipped with a sharp tooth or two, besides the terminal spine. Common flax is smooth. Cut-

Llam was, indeed, though, and the town may be tender of houses in great, by the male a span long; its scale fomewhat triangular, very obtuse, rugged, smooth; flat on the upper side; keeled underneath, and covered with 

zamolxis, in Biography, a celebrated person among the Scythians, was, as some have supposed, a slave of Pythagoras, who, having attended him into Egypt, obtained his freedom, and taught his master's doctrine among the Getæ. It has been also said, that in order to enforce the belief of the immortality of the soul, he dug a subterranean apartment, and concealed himself in it for three years; but re-appearing as one risen from the dead, he there established his authority as a teacher. But Herodetus, who relates this fabulous story, as a common tradition, gives it no credit, but expressly says, that so far from being a Pythagorean, he flourished at a much earlier period than Pythagoras. The general testimony of the ancients furnishes reason for concluding, that Zamolysis was a Thracian, who, at a very remote period, taught the Scythians the doctrine of the immortality of the soul, and that after his death, they enrolled his name among the divinities, with whom they assured themselves they should associate in the invisible world. Herodetus relates, that at certain festivals, they chose several persons by lot, who were to be deputed as meilengers to Zamolysis; and that they put them to death, by throwing them up into the air, and catching them, as they fell, upon the points of their spears; and this story is thought to be the more credible, because it is well known, that the practice of offering human sacrifices prevailed among the Scythians and the Thracians. Herodetus. Brucker. Ensfield, vol. i.

ZAMORA, in Geography, a town of Spain, in the province of Leon, on the Duero; the see of a bishop, suffragan of Compostella. In the year 967, this town was taken by the Moors and destroyed; but afterwards rebuilt and fortified. It is now a frontier town against Portugal, and place of arms. The streets are narrow, and the general appearance of the town is gloomy; 120 miles N.W. of Madrid. N. lat. 41° 50'. W. long. 6°.—Alfo, a town of Algiers, founded in honour of a Mahometan saint. Here is a small garrison; 28 miles W. of Seteef. —Alfo, a town of Mexico, in the province of Guadalajara; 80 miles N.W. of Mechoaca. N. lat. 20° 54'. W. long. 103° 40'.—Alfo, a town of South America, in the audience of Quito, on a river of the Amazonas. In the neighbourhood are some gold mines; 200 miles S. of Quito. S. lat. 4°. W. long. 78° 40'.

ZAMOSCIE, or SAMOSTK, a town and fortresses of Austrian Poland, in Galicia, built by the famous great chancellor, John Zamovsky. It has a flatly cathedral, and several other churches, a decayed university, a charitable foundation called Mons Pietatis, and several valuable privileges; but the fortifications are now in a bad condition. The proprietor of this town, &c. aided himself prince Zamofie. It now belongs to Austria; 60 miles N.W. of Lemberg. N. lat. 50° 31'. E. long. 23° 15'.

ZAMPALA, a river of Mexico, which rises in the province of Tlaxcala, and runs into the gulf of Mexico, N. lat. 19° 40'.

ZAMPALA, Chempala, or Zempala, a city of Mexico. When Cortez landed in the year 1519, the chief or lord of this place, who was tributary to Montezena, offered his service to the Spaniards. It was at that time a large city and exceedingly populous, the lowest account reckoning the inhabitants at 20,000 or 30,000. It was the capital of a country called Totonacapan, now the N.E. part of the province of Tlaxaca; 90 miles E. of Puebla de los Angelos. N. lat. 20° 10'. W. long. 97° 50'.

ZAMPERINI, ANNA, in Biography, of Venice, arrived in England in 1767, as a buffa linger, a parte eguale, with the
the Guadagni, sister to the great finger and actor Guadagni, who had been here in early youth.

The Zamperini was a very pretty woman, coquetish, and an affected finger. Her first appearance on our stage was in La buona figliaola Maritata of Piccini, of which the music was so difficult to perform, and not easy to hear, that it was never sufficiently repeated for the public to be familiarly acquainted with it. They were glad, therefore, as well as the performers, to return to La buona figliaola, for their own relief from a too serious attention.

The finger of Guadagni, an elegant finger, and graceful actress, the original performer of the part of Cocchina in Italy, being superfeeded in that part by the Zamperini, occasioned a great rupture between Guadagni just arrived here in 1789 for the second time, and the honourable patentee and imprimario of the opera; which generated faction and a party spirit that destroyed the comfort of the opera, serious and comic, at a time when the public, in a state of tranquillity, would have been more delighted than at any other period.

We never heard the Zamperini sing serious music, but are told by M. Laborde (Effai fur la Nef), that "having a natural talent for music, and great spirit and fire in her action, though her excellence of performance was principally manifested in comic operas, yet the fung equally well in the serious. After performing with great applause in London, Liebhen, and Italy, she quitted the stage, and was well married."

ZAMPIERI, DOMENICO, called Domenichino in the History of Painting, was born at Bologna, in 1581, and placed when very young under the tuition of Denis Calvert; but being ill treated by him, he prevailed upon his father to permit him to enter the school of the Carracci, at the time when Guido and Albano were both students there. He soon distinguished himself, but more by his care and affability than by brilliance of talent. He here attached himself to Albano, and, when he left the Carracci, they travelled together to Parma, Modena, and Reggio, to study the works of Correggio and Parmeggiano, and soon afterwards they both went to Rome. In that city his first patron was cardinal Agucchi, who employed him in his palace, and commissioned him to paint three pictures for the church of S. Onofrio, from subjects of the life of S. Jerome. His former master, A. Carracci, also employed him for some time to assist in his great work at the Farnefe library; and he painted from his own designs, in the loggia in the garden, the Death of Adonis, when Venus springs from her car to assist her unfortunate lover.

As the health of A. Carracci became rapidly impaired, and he was necessitated to refuse many commissions offered to him, he recommended them to his scholars; and had the satisfaction of seeing Guido and Domenichino employed by the cardinal Borghes to paint the frescoes in S. Gregorio, which have subsequently become so celebrated, and of which the Flagellation of S. Andrea by the latter is so justly admired. The cardinal Farnefe also employed him to paint some frescoes in the chapel of the abbey at Grotto Ferrata; among them is that picture of the Cure of the Demonic Youth, which has been compared with and by many preferred to the one of Raphael in the Transfiguration. Another cardinal, Aftrobrandini, availed himself of the established renown of Domenichino, and engaged him to paint in fresco, ten pictures of the history of Apollo, in his villa at Frascati, which added greatly to his reputation. Soon afterwards he completed the work which more than any other has served to immortalize his name, his well-known picture of the Communion of S. Jerome, painted for the principal altar of the church of S. Girolamo della Carita. This fine production ranks with the best of any age. It is said, with a great fancy on truth, that the arrangement of its composition was borrowed of Agostino Carracci, who painted the same subject for the Certosa at Bologna. But if Domenichino did borrow the thought, he has amply made amends by the mode in which he has adorned it. It received its due meed of applause at the time, and was ranked as the work next in value to the Transfiguration by Raphael; but while the merit of its author thus excited the admiration of the public and most of the artists of Rome, it elicited in the minds of several, and among them of Lanfranco, the bitterest spirit of envy and malignity, which was actively exerted against him. He was reviled as a plagiarist, and the execution of his pictures condemned as heavy and ungraceful; and in spite of their powerful effect, the influence of his adversaries so far prevailed, that for a time he failed of commissions, and had serious thoughts of changing his profession for that of sculpture. The celerity and freedom with which Lanfranco invented and painted, and all those machinists who applauded the means of art above the end, were opposed to the flow and uncertain power of invention possibled by Domenichino. But upon this subject Lanzi justly observes, that if Domenichino had had the good fortune which he merited, he would, like the Carracci in Bologna, have soon triumphed over his adversaries, admitting that he was an imitator, but not a servile one, and that if his works were more flow in their birth than those of his enemies, they merited a much longer existence. "The public," he adds, "is just in its judgment, but before its tribunal a good cause is not sufficient of itself unless able pleaders give it credit. Domenichino timid and solitary, master of little, had not then sufficient means to protect himself against the torrent which overwhelmed him, and report seemed to verify the remark of the cardinal Agucchi, that his worth would not be duly appreciated until after his death. Impartial politeness does him justice, and there is now no gallery which is regarded as complete without some specimen of his talents."

The virulence of these perfections disfigured and disturbed Domenichino so much, that he returned to Bologna, and there he tranquilly passed some years in the delightful practice of his art. Among the most renowned of his productions about this period are his pictures of the Martyrdom of S. Agnes, for the church of that saint, and the Madonna della Raffaia, both large works, and of sufficient merit to attract the infipidity of the French, and for a while they adorned the walls of the Louvre; but they are now returned to their original destinations. When malice and envy had exhausted themselves, and fame added fresh laurels to the brow of Domenichino, he was invited back to Rome by pope Gregory XV., who appointed him his principal painter, and architect to the pontifical palace. The cardinal Montotto engaged him to paint the vault of S. Andrea della Valle, where he represented the four Evangelists with Angels; and in the chapel of cardinal Bandini, in the church of S. Sylvestro, in the Quirinal, he painted four pictures, which rank amongst his best: the subjects are, Ester before Ahasuerus, Judith with the Head of Holofernes, David playing and singing before the Ark, and Solomon and his Mother Bathsheba seated on a Throne. The former are certainly two very high clas of art, and though lacking the simplicity and grandeur of M. Angelo or Raphael, yet they are full of rich and fine forms, particularly those of the angels, &c. which accompany the figures. The latter are not of so elevated a style, but are more familiar, and wrought with fine colour: they are engraved by Jacomo Frey.
Frey. About the same time he painted four of the cardinal
Virtues in the angles of S. Carlo Catenari, which have been
preferred to us by the graver of G. Andran.

Domenichino not only excelled in historical painting, in
works both great and small, but he has also left us many
landscapes of extraordinary excellence in point of tone;
feldom can so much be paid of their compositions. They
are generally feckled in fenery, of a grave and dignified cha-
racter, and are executed with boldness and freedom, and en-
riched with figures. A very fine one may be seen in the
collection of the marquis of Stafford. He is universally
esteemed as the best among the disciples of the Carracci, and
Nicolo Poufbin is said to have preferred him before them:
but that favour, if we except the Communion of S. Jerome,
his works will scarcely be found to support. M. Fufeli
has remarked, that "expression which had languished after
the death of Raphael seemed to revive in Domenichino;
but his facility was not supported by equal compre-
henion, elevation of mind, or dignity of motive." His forms
are by no means fo pure or graceful, or his actions fo na-
rural and unconstrained, as those of that divine painter. His
invention does not appear to have been vivid, but his fluid
was unremitting, and with all his defects he well deferved
the title of a great painter, and certainly has not since been
equaled. He died in 1641, aged 60.

ZAMPOGNA, in the Italian Majuscue, is used to denote
any instrument that sounds like a flute; and particularly a
bagpipe, being an assemblage of divers pipes of different
sizes. It is also taken for a common flute.

ZAMRECOTTA, in Geography, a town of Bootan;
34 miles S.E. of Damfong.

ZAMZERVIRIZI, a town of the principality of Georgia,
in the province of Carduel; 15 miles S.W. of Gori.

ZANA, a river of Peru, which runs into the Pacific
ocean, S. lat. 7°.

ZANATHA, in Ancient Geography, a town in the in-
terior of Arabia Petraea. Ptol.

ZANCHI, Basiilio, in Biography, an elegant Latin
poet, was born at Bergamo in 1501, and pursued his studies
under Giovita Rapiolo with so much ardour, that at the age
of seventeen he made a collection of Latin poetical epistles,
which was afterwards published. Before he had attained
the age of twenty he visited Rome, and was much noticed
by the poets of that city. According to the practice which
then prevailed he changed his baptismal name Pietro into
L. Petreius; but afterwards, returning to Bergamo, and
entering, in 1524, among the canons-regular of Lateran, he
assumed that of Basili; devoting his attention to sacred
literature, and publishing some works on the scriptures. In
the progress of his life he frequently changed his residence;
and was every where receiv'd, on account of his learning and
talents, by the principal scholars of the age. Under
the severe decree of pope Paul IV. inflicted in 1558, which
commanded, under the threatened penalty of the prison or
galleys, all the religious to return to the cloisters to which
they belonged, Zanchi was imprisoned, and fell a sacrifice
to the rigour of confinement. One of his biographers says,
that he had few equals in the sweetness, and fewer in the
elegance of his poetry; specimens of which occur in his
eight books of poems, one of which bears the title of
"De Horta Sophis," and describes the most remarkable
facts and doctrines of the Catholic religion. Some of his
poems are inferred in the "Delicia," and the "Carmina
Poetarum Italorum." He also published a kind of Lexi-
con, entitled "Latinum Verborum ex variis auctoriis

ZANCHI, Girolamo, an Italian Protestant, was born in
1516 at Alzano, in the territory of Bergamo, and entered
among the canons-regular of Lateran at the age of fifteen,
in which conncction he remained for ten years. But Peter
Martyr having communicated to him, and others of his fra-
ternity, the opinions of the reformers, he departed with
him from Italy in 1550, and went to Geneva. From Ge-
neva he removed to Stralsburg upon an invitation to supply
a vacancy in the professorship of sacred literature, which
he accepted in 1555, and which he occupied for about eleven
years. Having signed the Augsburg confession, with some
restrictions, he was aggregated to the chapter of St. Thomas,
in Stralsburg. Although his disposition was moderate and con-
ciliatory, he was engaged in some disputes with the zealous
Lutherans, who determined to procure his expulsion. With
this view, they acquired his signature of a formulary, to
which he assented in the following terms: "Hanc doctrinam
formulam ut piam agnofco, etiam remipcio." The am-
biguity of this declaration was not satisfactory to his adver-
faries, and he was therefore induced to resign, and to accept
an invitation to a church in Chiavenna. The articles with
regard to which he was perswaded by the Lutherans were
predetermination, the perseverance of the saints, the eucharist,
ubiquity, images, antichrist, and the end of the world.
Having refused at Chiavenna from the year 1563 to 1568,
he removed to the theological chair at Heidelberg, when he
took the degree of doctor. When Frederick III., who was
a zealous Lutheran, succeeded the elector palatine, and
removed the Heidelberg professors, Zanchi declining offered
settlements at Leyden and Antwerp, took a place in count
John Caumir's college at Newstadt. Upon the restoration
of the expelled professors, Zanchi, on account of his age,
was declared "emeritus;" and having lost his fight, died
at Heidelberg in 1590.

Highly esteemed among Protestants in general on account
of his learning and invincible attachment to their principles,
John Sturmius affirmed of him, "that he should not be at
all anxious for the caufe of reformed religion, if Zanchius
alone were to dispute in the council of Trent against all the
fathers present." Bayle.

ZANCLE, in Ancient Geography, a town of Sicily, on
the S.W. which separates this island from Italy. According
to Herodotus, the Meffenians, driven from the Peloponne-
sus by the Lacedæmonians, transplanted themselves into Sicily,
took possession of Zancle, and gave it the name of Meliana,
whence Meffina.

ZANDENDORF, in Geography, a town of Germany, in
the margrave of Anfaph; 2 miles S.W. of Cadolzburg.

ZANDHOP, a town of Pruflia, in Ermeland; 16 miles
S.E. of Heilberg.

ZANE, a town of Virginia; 9 miles S.S.E. of Win-
chill.—Also, a township of Champaign county, in the
district of Ohio, with 645 inhabitants.

ZANES, in Ancient Geography, a town of Upper Media,
fortified by Julinius, so as to render it one of the strongeft
bastions of the empire.

ZANESVILLE, in Geography, a township of the state
of Ohio, in the county of Muhlington, on the Scioto, with
2154 inhabitants.

ZANETTI, Antonio, in Biography, of Venice, maefro
di capella to the duke of Modena, the latter end of the
17th and beginning of the 18th century, for whom, and for
the theatres in Venice, he produced fix or seven operas that
were much esteemed in those days.

ZANETTI, Francisco, was born in the year 1740,
maefro di capella in the cathedral at Perugia in 1770. He
had previously passed some time in London, where some
elegant and easy sonatas of his composition were published
by
by Brenner. He left his place in the church at Perugia, by having appeared on the Alberti stage at Rome, as a singer in an opera of his own composition, and that, merely to supply the place of the principal tenor, who had run away, and to prevent the piece from being stopped: he however married afterwards a pretty woman, who sung well, and indemnified him for the loss of his place.

Since his marriage he has composed several succesful operas, in which figura Zanetti has performed the principal female part, particularly one at Milan in 1789, in which he was much applauded, as well as her husband's music. He has composed much natural and pleasing music for instruments; as fix violin trios, fix quintets for three violins, and two violoncellos, &c.

ZANFARA, in Geography. See Zambara.

ZANGARISA, a town of Naples, in Calabria Ultra; 6 miles N.E. of St. Severina.

BAGNESAIR, or Sanguseer, a fea-port of Hindoostan, in Concan, with a good harbour, but not much frequented; 15 miles S. of Severndroog. N. lat. 17° 38'. E. long. 72° 54'.

ZANGUEBAR, a name given to a large territory of Africa, bordering on the Eastern sea, including many kingdoms; the name is said to import "the coast of the negroes," the inhabitants being blacks, with curled woolly hair; extending from two degrees north to the twenty-first degree of south latitude. The principal kingdoms on the coast have been separately spoken of and described. Of the country in general little is known; the whole tract is represented as barren and unhealthy, the lands lying low, and intersected with rivers, lakes, thick woods, forests, and marshy grounds. The fruits of it are very unwholesome, their rivers, for the most part, covered or choked up with weeds, bushes, and thicket; all which fo vitiated the air, and corrupt the products of the earth, and render the inhabitants fo sickly and indolent, that they receive little or no benefit from its produce. The Bedouin Arabs are the only people who make advantage of it by breeding multitudes of cattle, and living mostly upon their flesh and milk; whilst the negroes, or Zanges, content themselves with feeding upon wild beasts and fowl, which swarm all over those parts. To supply the want of corn, pulse, roots, and other wholesome food, of which they are destitute, the Divine Providence hath interposed, by the help of which they can purchase all the necessaries and conveniences of life from other parts: but this is the very circumstances that makes them so extremely jealous of letting strangers penetrate into the inland; more especially since the Portuguese have made themselves masters of such a number of places along this coast. They are in their nature fierce and froward, ignorant and brutish, without religion, especially the negroes; upon which last account they have the name of Caffers.

As for the Bedouins, they have some kind of religion, or rather observe a variety of superstitious rites, but are no lefs ignorant and uncivilized than the Caffers; yet they chiefly herd among themselves, and live at a great distance from the coasts, and by the sides of lakes and rivers, for the convenience of pasturage for their numerous herds. They go all naked, both Caffers and Arabs, excepting that they wrap a piece of cotton cloth round their middle, which defcends a little below the knee; but those who live along the coasts are somewhat more civilized, affect a little more finery in their drefs, and instead of cotton cloth cover themselves with the skins of wild beasts, more or less rich, according to their rank, with the tails of animals trailing behind on the ground; they likewise adorn their necks, arms, and legs, with a variety of beads, bugles, and other trinkets, of amber, jet, glass, and other materials, which they purchase from the merchants with their gold, furs, ivory, and other commodities. There are among these coafers a great number of Mahometans, but a much greater number illib. among the islanders along the coast; they being for the most part defended from those Arabs who were banished out of their country. The countries are, Melinda, Mongala, Jubo, Mosfambique, and some others.

ZANHAGA, or ZANZAGA, or Zenbaga, a province of Africa, in the country of Sahara, bordering on the Atlantic.

ZANIA, in Ancient Geography, a town of Afa, in the interior of Media. Ptol.

ZANNA, the name of a medicinal earth, described by Oribauus: he says it is found in Armenia, in that part which borders on Cappadocia; and that it is very drying, and of a pale colour, and easily diffused by water, falling into a fine powdery like lime.

It is called by the natives zarina, and the mountain from which it is taken is near the city Bagasuana. It is of a drying and altering nature.

ZANNICHIELLI, John Jerome, in Biography, a physician and naturalist, was born at Modena in 1662, and settling in the medical department at Venice, he published a work on the preparation of chemical medicines, entitled "Promptuarium Remediorum chymicorum." In 1702 he was created, by a patent of the duke of Parma, doctor of medicine, surgery, and chemistry. He afterwards formed a museum of natural history, and made many journeys in order to collect fossils and other subjects for this repository. Some of his excursions were undertaken by public authority, as he was designated by the chamber of health, physician-naturalist to all the states of Venice. He died in 1729. During his life-time he published several tracts relating to botany and lithology, and after his death his son John James edited from his MSS. "Opuscula Botanica Pothumia," 1730, and "Italia della Piante che nascono nel lidi intorno à Venezia," 1735, being a description, with figures, of the plants on the Venetian shores. Haller. Eloy.

ZANNICHELLIA, in Botany, was so named by Michelli, in compliment to John Jerome Zannichelli, an eminent apothecary at Venice, who spared no expense or labour, even at an advanced age, in the study of botany, on account of which he undertook several hazardous and difficult journeys. He was particularly devoted to the observation of marine productions, as well animal as vegetable. In pursuit of these he was Michelli's companion and guide, among the islands and shores of the Adriatic; and has wrote an account of the plants there to be found; which, with the history of some of his mountain tours, were printed after his decease. Zannichelli published a pamphlet on the medical qualities of Rufus, as well as various chemical and geological works. He died in 1729, aged 67. His son, John Jacob Zannichelli, wrote on the properties of the horde-chefnut, as well as an account of his own and his father's musem. — Mich. Nov. Gen. 70. t. 34. Linn. Gen. 476. Schreb. 616. Willd. Sp. Pl. v. 4. 181. Mart. Mill. Diet. v. 4. Ait. Hort. Kew. v. 5. 229. Sm. Fl. Brit. 955. Prodr. Fl. Græc. Sibth. v. 2. 225. Pursh 4. Joff. 19. Poiret in Lamarck Diet. v. 8. 836. Lamarck Illutr. t. 741. Gært. t. 19. (Graminifolia; Dill. Gen. 168.)—Clas and order, Monoclea Monandria. Nat. Ord. Inundate, Linn. Natâtes, Joff.

Female, close to the male. Cal. Perianth of one leaf, inferior, hollow, swelling, oblique, with two or three nerves. Cor. none. Pfl. Germs from four to eight, filaked, oblong; styles as many, simple, rather spreading; stigmata ovate, peltate, flat, spreading outwards. Peric. none. Seeds as many as the germs, naked, filaked, oblong, compressed, a little incurved, beaked with the permanent styles, tuberculated at the back, with a simple coriaceous coat.

Obf. Schreber speaks of some solitary, dispersed, male flowers, furnished with a single-leaved calyx, whose orifice is oblique, acute at the posterior part, and entire. He follows Gartner in considering the coat of each seed as a capsule; but the latter allows there is fearlessly any internal coat or integument, to the kernel, and the outer one is defective of valves; so that although the style be permanent, we rather follow Linnaeus than other authors; and we conceive that if the existence of a naked seed be admitted in any instance, it must be in the present; there being only a simple covering to the embryo, which is indescribable.

1. Z. palustris. Marsh Horned-Pondweed. Linn. Sp. Pl. 1375. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1844. Pursh n. 1. Mill. Illust. t. 77. Fl. Dan. t. 67. (Z. palustris major, folii graminei acuti, flore cum apice quadrilatari, embryonis syphoelis integris, et vaceulo non barbate, capulis feminis ad coliam dentatissi.) Mich. n. 1. t. 34. f. 1. Potamogeton filiformis, gramifoliosa, ramosa, ad genucula polyceratos; Pluk. Phty. t. 102. f. 7.) —Anther of four cells. Stigmas entire. Native of ponds, ditches, and rivulets, in Italy, as well as other parts of Europe, from Sweden to Constantinople, flowering in summer. It is found also in Virginia, near the sweet springs, according to Clayton and Pursh. The root is annual. Stem slender, floating, branched, round, leafy, and smooth, with the habit of a Potamogeton. Leaves linear, grasy, felifill, narrow, acute, and entire, two or three inches long. Bractea membranous, tubular, axillary, including a pair of green flowers, one male, the other female. Anther tawny. Seeds blackish when ripe, when rugged or toothed at the back.

2. Z. dentata. Toothed Horned-Pondweed. Willd. n. 2. Poiret n. 2. (Z. palustris minor, folii graminei acuti simillima, flore minimo cum apice bicaulipar, embryonis syphoelis circuncrescenti, et vaculo barbato, capulis feminis ad coliam dentatis; Mich. n. 2. t. 34. f. 2.) —Anther of two cells. Stigmas toothed. Found in the neighbourhood of two-Fleves, with the foregoing, as well as in mountain pools in the adjacent country. Rather smaller than the first species, with shorter leaves; but most essentially different in having only two cells to the anther, and remarkably toothed stigmata. The seeds also are tuberculated all over, not merely toothed at the back, or keel.

Loureiro has a Z. tuberosa, Fl. Cochinch. 543, to which he attributes an ovate-oblong single-seeded berries. It grows in the waters of Cochinchina, and has tuberous perennial roots, radical, sword-shaped leaves, spiked flowers, the calyx of the female in six deep segments. We agree with M. Poiret that it would be too hazardous to admit this species without examination. Loureiro had probably never seen a real Zanichellia.

ZANOE, in Ancient Geography, a town of Palestine, in Vol. XXXIX.
and Malebranche. But being desirous of studying the works of Aristotle and Plato in the original language, he applied with diligence to acquire a knowledge of the Greek, so that he became able not only to read but to write it. Thus furnished, he obtained leave to give lectures in philosophy; in the course of which he instituted a comparison between the systems of Descartes and that of Newton, avowing a decided preference to the latter; more particularly as it respects optics and astronomy. It was by his advice, and under his direction, that Algarotti undertook to compose a popular treatise on light and colours. Declining to go to Padua for the purpose of giving lectures, he was appointed librarian to the Institute at his native place, and afterwards secretary, in which office he drew up in Latin an account of the transactions of the academy, with a history of its institutions, which he continued till the year 1766. This work was rendered peculiarly pleasing and instructive by the clearness of his arrangement, and the excellence of his style; in both which respects it seems to have formed himself on the model of Fontenelle. To these transactions he was himself a contributor; communicating a method of squaring different spaces of the hyperbola, and several important discoveries with regard to the circle, sphere, and circumfering figures. Of these discoveries he transmitted an account to the Academy of Sciences at Montpellier, of which, as well as of the Royal Society of London, and the London Institution, he had become a member. He also discovered a method of separating indeterminate quantities, detected several errors in philosophy, and prosecuted a variety of experiments; on these and other subjects he delivered papers to the Bologna Institute, which were published in his commentaries. Several of his papers on the central forces were also inserted in the Transactions of the Academy. His theorem on the means of determining the velocity of a body drawn or repelled from its centre, in any point of its orbit, were held in high estimation by Paul Frisius, who availed himself of it in the composition of his work on universal gravity. On the subject of the "Vis viva," which in his time engaged particular attention, he wrote three dialogues in Italian, distinguished for perspicuity and elegance. In these he adopted the opinion of Descartes in opposition to that of Leibnitz, who conceived that this force was not to be estimated from the velocity, as he asserted, but from the square of the velocity. The properties of numbers likewise engaged his peculiar attention; and he shewed, that if any multiple of the number 9 be taken, the sum of the figures forming that multiple will be also a multiple of 9. In his speculations on moral philosophy, he defended the Peripatetics against Maupertuis; and his adversary Anfaldi, in his "Vindicatio Maupertuianae," accused him of depreciating the Catholic religion, as he ascribed too great influence to the Stoic philosophy in alleviating the misfortunes of human life. This controversy gave occasion to many publications. Zanotti was a poet as well as a mathematician and philologist, and wrote verses both in the Tuscan and Latin languages; aiming, in imitation of the most celebrated poets of Italy, to blend the suavity of Petrarch with the energy and vigour of Dante. Many of his Italian poems were published by Eufalio Manfredi; and some of his Latin elegies were edited by J. Antonio Vulpi; who says of them, that Catullus himself would not have been ashamed to acknowledge them. Both his Italian and Latin poems were afterwards published separately, first at Florence, and latterly at Bologna; and in this edition are contained imitations of Tibullus, Ovid, and Virgil, as well as of Catullus. After the death of Beccaria, Zanotti, whose modeLy was no lefs conspicuous than his talents and acquisitions, accepted the office of president of the Institute, which he deemed peculiarly honourable, as it was a token of esteem conferred upon him by his countrymen. Among the learned men with whom he maintained intercourse of friendship or correspondence were the famous anatomist Morgagni, Voltaire, and pope Benedict XIV. He died in the month of January 1777. For an account of his works, which, besides those to which we have already referred, were numerous, we refer to "Pabroni Vita Italorum Doctrinae excellentium," and for an abstract of their titles, and time and place of publication, to Gen. Biog.

Zanotti, Giovanni Pietro, was born at Paris, though of Italian parentage, in 1757. He was sent young to Bologna, and became a pupil of Lorenzo Paffinelli. Under that master he acquired an agreeable tone of colouring, a mellow pencil, and an intelligent acquaintance with the principle of the chiaro oscuro. He painted several altar-pieces for the churches at Bologna, of which the most esteemed are, the Incredulity of St. Thomas, in the church of S. Tommaso del Mercato; the Refurrection, in S. Pietro; the Nativity, in La Purita; and a large picture in the palazzo publico, representing the ambassadours from Rome wearing fidelity to the Bolognese. He held a great part of his life at Cortona, where he also distinguished himself by several pictures painted for the churches, particularly Christ appearing to the Magdalen, Christ bearing his cross, and the Presentation of the Infant Jesus.

Zanotti was a laborious and intelligent writer on art. Of his numerous publications the most considerable is his "Storia dell' Academia Clementina di Bologna," published in two vols. 4to. in 1739. He died in 1765, aged 91, Bryant's Dict.

Zanotti, L'Abate Giancalisto, of Bologna, a disciple of Padre Martini, was born in 1770, of whose composition at the annual performance of the musical students, who were members of the celebrated Philharmonic Society in Bologna, founded in 1666, we heard a dicit, in which there were all the marks of an original and cultivated genius. The movements and even passages were well contrived; and to make use of the language of painters, there were diffcnnible in it not only light and shade, but even mezzo tints. He proceeded from one thing to another by such easy and inextricable gradations, that it seemed wholly the work of nature, though conducted with the greatest art. The accompaniments were judicious, the ritornels always expressed something, the melody was new and full of taste, and the whole was put together with great judgment, and even learning. We have very seldom been more pleased or completely satisfied than by this production; and yet the vocal parts were but indifferently executed, for there were then no great fingers at Bologna. We expected to have heard of future works by this most promising young composer, who was one of the maestri di capella in the church of San Petronio; but as that has not happened, we fear he did not long survive this performance.

ZANOW, in Geography, a town of Pomerania; 6 miles E.N.E. of Coflan.

ZANTE, an island in the Mediterranean, near the coast of the Morea, about 12 miles in length, and six in breadth, chiefly inhabited by Greeks, till lately under the Venetians, who appointed a governor, called proveditor, and two counsellors. The Greeks have 40 churches, besides convents, and a bishop; the Roman Catholics have three convents and a bishop. By the treaty of Campo Formio, Zante was given to France; but in 1799 it was taken by the united fleets of Russia and Turkey, and in the year 1800 connected with other neighbouring islands, to form a republic of the Seven islands, named the Ionian, which are to pay a tribute to the
the Porte, and guaranteed both by the Turks and Russians. Corfu, Cephalonia, and some others lately in the possession of Venice, were of this number. The island produces excellent wine, and that species of grapes called currants, olives, figs, melons, peaches, and other choice fruits : towards the coasts, the island is in general mountainous, but level in the interior parts. It is much subject to earthquakes. N. lat. 37° 40'. E. long. 21° 4'.

ZANTE, a town and capital of the island of Zante, situated on the N.E. side, with a harbour safe and commodious for vessels of any size. The town stretches between the harbour and the foot of a mountain about a mile in length, but narrow ; the streets are not paved, and the houses in general low. On a mountain above the town is a citadel, which commands the harbour, and contains a little city within its walls. It is to be ascended with difficulty, is strong, and well supplied with stores, and furnished with a garrison. This is the residence of the governor and officers. Zante is the see of a Greek and Latin bishop. There are several churches, and the Jews have a synagogue; 21 miles S.S.W. from the town of Chirena in the Morea. N. lat. 37° 40'. E. long. 21° 8'.

ZANTHENES, in Natural History, a name given by the ancients to a feffile substance found in Media. Pliny quotes Democritus for saying, that if rubbed in palm wine and fermented, it became soft as wax, and yielded a very sweet smell.

ZANTHER, in Geography, a town of Pomerolia; 10 miles S. of Marienburg.

ZANTHOXylum, Linn. Gen. 519. See Xanthoxylum.

Zanthoxylum, in Gardening, contains plants of the hardy and tender exotic shrubby kinds, in which the species cultivated are, the Canada tooth-ache-tree, or Hercules's club (Z. clava Herculis), and the Chinefe tooth-ache-tree (Z. trifoliatum).

The first is a plant of the tree kind, of which there is a variety; the ash-leaved tooth-ache-tree, with oval-oblong foliules, and prickly mid-ribs.

And the leaf is a woody branching plant.

Method of Culture.—These plants may be increased by seeds and layers. The seeds should be sown in the spring, either in an east border, or in pots placed in the morning sun all the summer, being sheltered in a frame in winter; and in the spring following removed to the full air till October, giving proper waterings all the summer; and towards winter be placed again under shelter from frost till March, when the young plants may be potted separately; and thus continued for a year or two, being sheltered in the winter, when they may be transplanted into the shrubbery, where they are to remain.

The layers of the young wood may be laid down in autumn or early spring, and when they have struck root be taken off and managed as the seedlings.

They also pucced by cuttings in spring or summer, planted in pots, affited by a hot-bed, in which they soon strike, when they should be inured to the full air; and the young plants will be fit for planting out in the autumn, or the spring following.

The first is a very ornamental plant in the borders and other dry parts of shrubberies, and the latter among potted plants in the green-house collections.

ZANTOCH, in Geography, a town of the New Mark of Brandenburg; 8 miles E. of Landberg.

ZANZALUS, in Biography. See Baradœus.

ZANZIBAR, or Zangibar, in Geography, an island of Africa, in the Indian sea, near the coast of Zanguebar, governed by a king, who is tributary to the Portuguese. S. lat. 6°. E. long. 41° 15'.

Zanzour, a town of Africa, in the country of Tripoli; 15 miles W.N.W. of Tripoli.

ZAOE, a town of Egypt, on the left bank of the Nile; 13 miles N. of Benifuil.

ZA-OSTROG, a town of Morlachia, near the coast; 15 miles S.E. of Macarika.

ZAOZERSKOI, a town of Russia, in the government of Novgorod, on the Sula; 28 miles W. of Tcherepovetz.

ZAPATA, or Sepata, a kind of seaf, or ceremony, held in Italy, in the courts of certain princes, on St. Nicholas's day, in which people hide presents in the shoes orippers of those they would do honour to; in such manner, as to put them on the morrow, when they come to drefs.

The word is originally Spanish, cateto; and signifies a shoe, or slipper.

It is done in imitation of the practice of St. Nicholas; who used, in the night-time, to throw purses of money in at the windows, for portions to poor virgins in their marriage. F. Meneville has described these zaptas, their origin, and different uses, in his Traité des Ballets Anciens et Moderns.

ZAPATERO, in Geography, a small island of Mexico, in lake Nicaragua, near the west coast; 32 miles S.E. of Grenada.

ZAPATILLA LAGOON, a bay on the east coast of Yucatan. N. lat. 18° 52'. W. long. 89° 32'.

ZAPETRA, in Ancient Geography, a town of Asia, in the mountains of Comagene, upon a small river, which discharged itself into the Euphrates, S. of that town.

ZAPPENDORF, in Geography, a town of Bavaria, in the bishopric of Bamberg; 9 miles N. of Bamberg.

ZAPHOR, a name given by some writers to Zaffir; which fea.
Z A R

1499, by the Venetians, in whose hands it afterwards continued. Zara is surrounded on all sides by the sea, except that it has a communication eastward with the continent, by means of a draw-bridge, commanded by a fort. It is reckoned one of the best fortifications in Dalmatia, and deemed almost impregnable. The citadel is divided from the town by a very deep ditch, hewn out of a rock. The harbour, which lies to the north, is capacious, safe, and well guarded. The rain is carefully preferred in cisterns, to supply the want of fresh water. In the cistels resides the governor or provost of Dalmatia, whose office is only triennial. It now belongs to the kingdom of Italy; 28 miles N.W. of Scardona. N. lat. 44° 22′. E. long. 15° 39′.

Zara Vecchia, Old Zara, or Biograd, or Alba Maritima, a town of Dalmatia, now little better than a village. In the time of the Romans it was a place of considerable figure, and received a new set of inhabitants by a numerous colony of that people. In the middle ages it was called Belgrad, or Alba Maris, and more anciently Blandonia. According to some it was ruined by Attila; but we know with more certainty that it was destroyed in the war between the Venetians and the Hungarians, by the doge Ordelafo Falieri. Some banditti afterwards mixing with the inhabitants that remained, the republic, to check their excceses, ordered a general massacre of the robbers, in which the ancient inhabitants were not spared. Here was also a bishop's see, which, on the demolition of the town, was removed to Scardona; at present its inhabitants confit only of a few peasants; 18 miles S.E. of Zara.

Zara. See Schedesje.

Zara, in Ancient Geography, a town of the Moabites, taken by Alexander Jannaeus.—Allo, a town of Asia, towards Armenia, upon the route from Arabifum to Satala, between Eumene and Dagolaffum. Anton. Itin.

Zaraisk, in Geography, a town of Russia, in the government of Riazan, on the Ofer; 24 miles S.W. of Riazan. N. lat. 54° 30′. E. long. 38° 24′.

Zarama, in Ancient Geography, a town of Asia, in the interior of Media. Ptolemy.

Zaranda, a name anciently given to the Euphrates. Ptolemy.

Zarang, the Zorang of Ptolemy, in Geography, a populous city of Persia, in the province of Segesta or Segesta, situated pleasantly on the banks of the Hermand. This was the customary residence of Jacob Ben Lath, the conqueror of the caliph of Bagdad, and stood a long time against Timur, by whom it was at last taken. Zarang is supposed to be the same with the present Dofhak, the old name having been lost in the revolutions to which this province has been subject for more than a century, and to which its present destination may, in a great measure, be attributed. For a further account of it, see Segesta.

Zaranis, in Ancient Geography, a town of Asia, in the interior of Media. Ptolemy.

Zarate, in Geography, a town of South America, in the province of St. Martha; 15 miles S. of Teneriffe.

Zarayos, or Sharayos, a supposed lake of America, in the course of the river Paraguay, which only exits during the annual inundations, that are on a far grander scale than those of the Ganges, and may be said to deluge whole provinces.

Zarca, a town of Egypt, on the east branch of the Nile; 10 miles S. of Damietta.

Zarchas, or Tcharkas, a town of Persia, in the province of Chorasan, or Khorasan; 150 miles N. of Herat.

Zarcoia, a town of Persia, in the province of Segesta; 12 miles W. of Zarang.

Zardam. See Sardam.

Zare, a town of Persia, in the province of Chorasan, or Khorasan, on the north side of a lake so called; 70 miles S. of Herat.—Allo, a lake of Persia, in the province of Segesta; 60 miles N. of Zarang. See Zarreh.

Zared, in Ancient Geography, a torrent beyond Jordan, on the frontier of the Moabites. This torrent had its source in the mountains, E. of the country of Moab, and proceeding from the E. to the W. discharged itself into the Dead sea. The Israelites passed it 35 years before their departure from Kadesh-Barnea. Numb. xxxii. 12. Deut. ii. 12, 14.

Zarephath. See Sarepta.

Zareshe-Sheker, or Sarat-Arer, a city of Rebun, beyond Jordan. Jos. xiii. 19.

Zareth, or Zarath, a people comprised under the name of Scythians, on this side of the Imaus, south of mount Maffei and Alani. Pol.

Zarex, a port of Laconia, on the Argolic gulf, S. of Cyphanta. Near this port was a temple of Apollo, with a statue of this god, holding in his hand a lyre. To the south, and parallel to the coast, was a mountain called Zarex.

Zarfa, in Botany, a name given by Leo Africanus, and others, to the lotus, or nettle-tree.

Zargarida, in Ancient Geography, a town situated on the bank of the river Heraufus, in the interior of Lower Mesia, a little above Tamassava.

Zarjaspa, or Zarjaspe, a town of Asia, in Bactriana, watered by a river of the same name, which discharged itself into the Oxus. Strabo. It was also called Bactra. Steph. Byz.

Zarif, a word by which some of the chemical writers have expressed tin.

Zarik, in Geography, a town of European Turkey, in the Moros; 22 miles E. of Misitra.

Zarima, a town of South America, in the province of Quito; 220 miles S. of Quito. S. lat. 3° 36′. W. long. 79° 36′.

Zarion, a town of South America, in the government of Buenos Ayres; 300 miles N.N.W. of Buenos Ayres.

Zarlino, Giuseppe da Chioggia, maestro di capella of St. Mark's church at Venice, and the most general, voluminous, and celebrated theorif and writer on music in the Italian language during the 16th century, was born in 1520, and author of the following musical treatises, which, though separately printed, and at different periods, are generally bound up together in one thick folio volume:—

1. "Institutioni Harmonica;" Venice, 1553, 1562, 1573, and 1589; 2. "Dimostrazioni Harmonie," Ven. 1571, and 1589; and 3. "Sopplimenti Musicali," Ven. 1588. We do not know of the dates that these works were written, nor if they were written as an author at the age of 18; and from that period till he had arrived at 49, he was continually revising and augmenting his works. The
The musical science of Zarlino, who died in 1590, may be traced in a right line from the Netherlands: as his master Willaert, the founder of the Venetian school, was a disciple of John Mouton, the scholar of the great Josquin. A commentary upon the voluminous writings of this author would occupy too large a portion of our work; and to refer the reader to the analysis of his several treatises by Artusi would be doing him little service, as the writings of Artusi would be difficult to find. There are few musical authors whom we have more frequently consulted than Zarlino, having been encouraged by his great reputation, and the extent of his plan, to hope for satisfaction from his writings concerning many difficulties in the music of the early contrapuntists; but we must own, that we have been more frequently discouraged from the pursuit by his proxility, than enlightened by his science; the most trivial information is involved in such a crowd of words, and the fulpene which it occurs is so great, that patience and curiosity must be invincible indeed to support a musical inquirer through a regular perusal of all his works.

He begins his Institutes with a panegyric upon music, in the usual strain; then we have its division into mundane and humane, faithfully drawn from Boethius; after this, there is a great waste of words, and parade of science, in attempting to explain the several ratios of greater and less inequality, proportion, and proportionality, &c. where, in his commenting on Boethius, we have divisions of musical intervals that are impracticable, or at least inadmissible, in modern harmony.

In his account of the ancient system, he discovers much reading; and that which is he chiefly wishes the reader should know.

In describing the diatonic genus, in which the tetrachord is divided into tone major, tone minor, and major fectone: 3, 3, 3, for which division, commonly called the lydian, or intense of Ptolemy, he contidentally proceeds, we have the substance of his dispute with Vincenzio Gallei, which will be mentioned hereafter. The second part of his Institutes is chiefly employed in measuring and ascertaining intervals by means of the monochord, and an instrument called the myself. This is said to have been invented either by Archytas of Tarentum, or Eratosthenes, for the purpose of measuring the interval. Whether the practical musicians of antiquity applied these calculations or imaginary divisions to their flutes and lyres, we know not; but of this we are most certain, that the greatest performers of modern times are Ariftoxianists, and make the ear the only instrument of calculation; which, by means of harmony, and the constant opportunities of comparison which the base or other accompaniment affords them, during performance, is rendered a much more trufly guide than it could be in playing a single part. It feems, however, as if the ancient instruments, upon which all the tones are fixed, had more need of the assistence of calculation and mathematical exactness in regulating their intervals than those of the violin-tribe at present, which, except in the open string, which often lead the performer to erroneous intention, depend on the strength and dexterity of the musician's hand, and accuracy of his ear, during performance. See an ingenious and useful work, called "Essay upon Tune," published at Edinburgh, 1781; where the imperfections in the scales of modern instruments are clearly shewn, and remedies for correcting them preferred.

The elements of counterpoint, and fundamental rules of composition, which chiefly concern the practical musician, are given in the third part of the Institutes; and there are more ample, and illustrated with more examples, than in any preceding writer; particularly the laws of canon and fugue, for which no instructions have been given by Tranchutus, though they were in such high favour during his time. P. Aaron and Vicentino have indeed started the subject, but the pursuit of it was left to Zarlino.

In the fourth part of the Institutes we have a short historical account of the inventors of the federal ecclesiastical modes: it is, indeed, a mere skeleton of allusions or conjectures without proof, more derived from traditional than written evidence. Here likewise gives instructions for composing in all these modes, in which he religiously keeps within their legal limits, and submits to all the restraints which antiquity had prescribed.

Padre Martini, figlio di contrapunto, in recommending the study and imitation of ancient masters, has well described the difficulties they had to encounter; where, after confronting the ecclesiastical scales with the secular, we have the following passage: "From an attentive and comparative view of these scales, any one desirous of learning the art of counterpoint for the service of the church, will see what diligence and efforts were necessary to unite the different qualities of canto-fermo and canto-figurato; and by carefully examining the examples given of both, will discover what artifices were used by ancient masters to avoid such sounds as differed from the canto-fermo, and with what paraphory they admitted such accidents as canto-figurato requires, particularly in the third and fourth tones; where, instead of modulating into B mi, the 5th of the mode or key, as is constantly practised at present, they have passed to the key of A in the fourth tone, and C in the third, by which means they have been able, dexterously, to unite the different qualities of canto-fermo with those of canto-figurato."

He gives excellent rules for composing motets and madrigals; but it is remarkable, that he advises the composer to make the tenor proceed regularly through the sounds of the mode he shall choose; and above all, that this part be so much the more smooth, regular, and beautiful, as the rest are to be built upon it; whence, says he, its sounds may be called the nerves and ligaments of all the other parts, for which he has given the cantilena, or principal melody, as the subject, as by modern composers, to the sopranos, or highest part; that calibrati were not so common as at present, and that the tenor being the kind of voice most rarely found, and more generally, the voice of him than that of any other pitch, was judiciously honoured with the principal melody.

Zarlino says, that to great was the rage for multiplying parts in musical compositions, that some masters, not content with three or four, which sufficed to their predecessors, had increased them to fifty; from which, he truly observes, nothing but noise and confusion could arise. However, in another part of his book, he tells us, that Adriano Willaert had invented masses a Due Cori, over a tre, or, as some call them, a Cori Spezzati, which had an admirable effect. We know not how Okenheim dispofed his thirty-six parts in the motet already mentioned; but they would have furnished nine choirs of four voices each. In the large churches of Italy, where the performers are divided into two bands, placed in opposite galleries, all the imitations and solo parts are distinctly heard, and when united in at least eight real parts, completely fill the ears of the audience with all the charms of congregated sound.

ZARMISOGETUSIA REGIA, in Ancient Geography, a capital town of Dacia, upon the river Sargetia. When this city became a Roman colony, it joined to its ancient name "Colonia Ulpia Traiana," or that of "Angula Dacica."
ZEAA.

roundish, flat-tipped, longer than the glumes; angular and comprossed at the base.

Of. Two out of the four valves of the female corolla appear to belong to an abortive flower. Schreber.

Female, Calyx a glume of two valves. Corolla of four valves. Style one, thread-shaped, pendulous. Seeds solitary, imbedded in an oblong receptacle.

1. Z. mays. Common Maize, or Indian Corn. Linn.

Sp. Pl. 1378. Willd. n. 1. Ait. n. 1. Pursh n. 1. (Fruentum indicum; Camer. Epit. 186. F. aflaticum, turicicum et indicum; Ger. Er. 81, 82. Morif. fect. 8. t. 13. f. 1, 2, 3.)—Leaves entire. — Native of America. Cultivated there, as well as in the southern countries of Europe. One of the largest of the family of corn or grasses. Root annual, of innumerable fibres. Stem erect, somewhat branched, round, flat, jointed, leafy, from five to ten feet high. Leaves sheathing, lanceolate, concave, acute, ribbed, two or three feet long, and three or four inches broad. Male flowers in numerous, aggregate, terminal spikes, each three or four inches long, greyish, downy, with purple anthers. Female ones below, in a generally simple, cylindrical spike, covered by the large sheaths of the upper leaves. Styles fix or eight inches long, very numerous, of a thinning yellowish or reddish hue, hanging down like a long filken tassel. Seeds white, yellow, red, or purplish, forming a heavy, tesselated, cone-like, naked spike, from fix to ten inches long. There are innumerable varieties, in the size, figure, colour, and qualities of the grain, which, though valuable for many purposes, and yielding an abundant crop, is far inferior to wheat as a bread corn. It requires a richly manured soil. Mr. Pursh mentions a variety, brought lately by governor Lewis from the Mandan nation, on the Missouri, which promises to be particularly valuable, as ripening earlier than any other fort, and yielding an excellent produce. See Maize.

2. Z. Curagua. Chili Maize. "Molina Chil. German edition, 107." Willd. n. 2.—Leaves serrated. — Native of Chili. Annual. Smaller in all its parts than the foregoing. Molina. Of the qualities or history of this species, we have no further account.

Ze, in Gardening, contains a plant of the hardy herbaceous annual kind, of which the species cultivated is the maize, or Indian corn (Z. mays).

It has a large strong, herbaceous stalk, which sometimes rises to the height of ten or twelve feet; and there are varieties with yellowish-white seeds, with deep yellow seeds, and with purple-blue seeds. This plant is mostly cultivated in the garden and pleasure ground for the sake of its singular tall growth.

Method of Culture.—These plants may be raised by sowing seed in the spring, as March or April, in a dry warm situation, where the plants are intended to remain, in patches of two or three seeds or more in each, about an inch and a half deep: when the plants are come up, they should be thinned out to one or two of the strongest. But to have the plants more forward, fo as to produce ripe seed-spikes more effectually, some should be sown in a hot-bed at the same time, and when the plants are three or four inches high, be forwarded by prickings them out upon another hot-bed, either under a deep frame, or an awning of hoop arches, to be covered with mats occasionally, allowing them plenty of free air; and when they have sufficient growth, as in May, they may be transplanted, with balls of earth about their roots, into the full ground in the borders or shrubbery clumps, in warm sunny situations, being well watered; and when the summer proves warm and dry, they often produce perfect heads, and the seed ripens in a good manner.

As the plants mostly run up in tall stalks, it is proper to support each with a tall neat stake, especially where much exposed to wind and rain.

These plants in the different varieties have a fine effect in the back parts of borders, clumps, and other places, in warm sheltered situations.

It is observed by a late writer, that he has planted a small quantity of this sort of grain in his garden, and it turned out superior to his expectations; and he is of opinion, that this crop may be raised to advantage in the field on some light soils, particularly the poor lands of Norfolk and Suffolk, or on any hot burning lands; as the countries where it grows naturally are light hot soils. And he adds, that he prefers the drill method of culture for it in this country; as the small hillocks in planting the seeds separately make the land unightly and improper for other crops. But to raise the greatest produce in corn, the hills are, he conceives, the best way; however if the crop is intended chiefly for fodder, then drills are best. The seed is to be put about an inch deep in the ground. And that when the corn first appears above the surface, the hillocks or drills must be examined, to see whether it all comes up properly; and if it has not, there must be fresh seeds put into the vacant places to prevent a loss in the crop. And as soon as the plants take root in the ground, the crop should be examined again to see whether any have died away, or the birds have taken the feed. The plants must also be thinned to two on a hill, and good plants substituted for weak ones.

In the cultivation while growing in the hill-way, the hoe must be used at every operation to the plants, and earth be given to them, as the land cannot be made too light for this crop; but when in drills, the corn must be hoed in the same manner as garden peas.

He also further observes, that when the corn gets out of the milk, the blades below must be all pulled off while green; tie them up in small bunches, about the size of a birch-broom, and hang them on the top of the stalks of the corn; for at the same time that the blades are pulled, the tops must be cut off, and let up in round bunches to dry, and tied round the topmost part to keep them from falling: when these are dry, they must be harveted. The blades are generally ready in four or five days, but the tops take longer; when these blades and tops are properly harveted, they are excellent food. And it is fuggled, that as these proceeds will be finished about the end of August, the land might be ploughed and then fown with rye. If seeds were required, he is of opinion that it would be very proper to sow the seeds at that time on this poor hot land; as the warm seafon would be over, and the seeds would have sufficient time to take root before winter. If only rye was wanted, he would eat it with sheep in the spring or during the winter. But the stalks must, he fays, stand, for the corn to ripen after the rye is fown; and the corn ought to hang on the stalk till it is hard. In America, it is often December before the white corn can be pulled, or September for the yellow corn: if it is pulled before it is hard, and the cob is perfectly dry, it will mould and spoil, and the corn will be apt to rot, therefore great care should be taken not to pull it too soon.

This sort of corn is, it is faid, given to horses, cattle, and hogs, without shelling, and only husked in the ear; but when given to fowls, or intended for fale, it is rubbed off by burning a cob in the fire till hard, and then rubbing the corn with
with it. It is a sort of grain which is sometimes given to pigs, but more frequently when ground to fowls. Count Rumford has slain in his Essay on Food, that this is perhaps the most nutritious grain, except wheat, either as human sustenance, or as provender for brute animals. See MAIZE.

**Zea**, in *Geography*. See ZIA.

**ZEAGONG**, a town in Birmah ; 12 miles N.N.W. of Raymangong.

**ZEAZ, ZEALUS, ZEALOT**, the exerxe of a warm animated affection, or passion, for any thing.

Some will have jealous zeal to be properly a mixed or compound fenfation, where one affection is railed or inflamed by another. On these principles, jealousy may be defined an affection arising from love and indignation, which cannot bear a thing to be given to another, that a perfon defires for himself, or on whom he loves and favours. Others make it confit in an eager fludy, or defire, to keep any thing inviolate; or a fervour of mind, arising from an indignation againft those who abuse or do evil to a perfon beloved.

The Greek philosophers make three specie of zeal. The firft, of envy; the second, of emulation, or imitation; the third, of pity, or devotion; which last makes what the divines call religious zeal.

Jophesph speaks much of a party, or faction, called the Zealous, or Zealots, which arose among the Jews during the war with Vespasian and Titus. Lib. xiv. cap. 6. Antiq. and lib. iv. cap. 12. de Bello Judaico.

**ZEALAND, or ZEELAND**, (in Danish *Sieland,* in Geography, the largest island belonging to the kingdom of Denmark, bounded on the north by the Scag-gerac, on the eft by the Sound, on the fouth by the Baltic, and on the weft by the Great Belt; about 65 miles in length from north to fouth, and where wideft 60 from eft to weft, though in some parts fearely 30, and in no part above 20 miles from the fea; reckoned about 700 miles in circumference. The coaft is much interfeated with large bays; and within the country are feveral lakes, which, as well as the rivers, abound in fhad. The country is pleafant; the foil is generally fertile, and produces corn, chiefly barley and oats, more than fufficient for the inhabitants, with excellent paffures; and in moft parts is plenty of wood, except towards the centre of the island, where the inhabitants generally ufe turf for fuel. The fields are fpread by mud-walls; the cottages are of brick or white-wafhed: land-hills are fometimes destruive on the coaft; and the beet protection from their ravages, fays Catteau, is the elymus anemia. Copenhagen is the capital. N. lat. 55° 2' to 56° 6'. E. long. 10° 58' to 12° 45'. See DENMARK.

**ZEALAND, State of**, one of the former United Dutch States, and now part of the recently effablished kingdom. It contains of islands which are formed by thefe branches and outlets of the Scheldt, called Zeewuwfe Stromen, or Sea Streams; on the north it is bounded by Holland, eft-ward by Brabant, southward by Flanders, and weftward by the North Sea: its name sufficiently indicates its natural position and situation. The islands of Walcheren and Schouwen, on the western coaft, are defended againft the violence of the sea, by downs or sand-hills, and on the other fides, like the reft of the islands of Zeeland, by vaft dykes, which, at the bottom, have a breadth of 25 German ells, and at the top are fo wide, that two carriages may pafs abreaf: the height is alfo proportioned to their thicknefs; notwithstanding which, in high tides and fury weather, the waves in many places force a paffage, or even flow over them: the firft formation of these dykes muft have been attended with immense ex pense, the very repair and maintenance of them requiring large sums. Emanuel van Meteren, in the fixteenth book of his Commentaries, fays, and confirms it by the attentions of the workmen employed in them, that the dykes in this province alone, if placed in one direction, would form a length of 40 miles, each mile to be reckoned at 1400 rods, and that the ex pense of one rod with another was a pound Flemifh, or fix Dutch gilders. Thus the charge of the outward dykes taken together amounts to 340,000l. Sterling. Through the inhabitants of the other provinces, and foreigners in general, complain of the air being heavy, difagreeable, and unhealthy, yet no people look better, or enjoy a more confined clmate of health, than the natives who are born and bred up in it. The foil too is very fruitful, and famed for its excellent wheat, as likewise for madder, the cultivation of which furnifhes out great employment for the inhabitants of Zeeland: it abounds also in good fruits, and its rich paffures are covered with flocks of fine fhEEP. The waters around the islands fupply them with plenty of fhi, particularly with oylters, lobifters, and muffes, of an uncommon fize and goodnefs. Zeeland en-joys Likewise an affine of all kinds of provisions, but fuel is very fcarce there, especially turf, which, being brought from other provinces, bears a high price; great quantities of English coals are ufed here. In the whole province are 121 towns and villages, some of which are very large. The inhabitants are reckoned the moft wealthy in all the Netherlands, which is, in a great meafure, owing to their traffic by fee, and for this, indeed, they have every conveniency that can be defired. (See HOLLAND.) The right bank of the Scheldt, called the East Scheldt, divides this province into two quarters, viz. into that on the eft and that on the weft of the faid river. The quarter on the Weft Scheldt is compofed of five islands, viz. Walcheren, South Beveland, North Beveland, Wolferidyk, and St. Joofland. The quarter of the Eaft Scheldt contains four islands, viz. Schouwen, Duveland, Tholen, and St. Philip's Land.

**ZEALAND, New,** two islands in the South Pacific ocean, firft discovered by Tafman, a Dutch navigator. In the year 1642, he traversed the eftern coaft from lat. 34° to 43°, and entered the ftrait called Cook's Strait; he was at-tracted by the natives foon after he came to anchor in the place, to which he gave the name of Murderer's Bay, and never went on shore: he gave the country the name of Staaten Land, in honour of the fates-general, and it is now generally diftinguished in our maps and charts by the name of New Zealand. As the whole of this country, except that part of the coaft which was feen by Tafman from on board his ship, had from his time to the voyage of the Endeavour, in the year 1770, remained altogether unknown, it was by many fupposed to be part of a fouthern continent. It is, however, now known to confit of two large islands, divided from each other by a ftrait or paffage, which is about four or five leagues broad. The northernmost of these islands is called by the natives Euthemmewau; and the fouthernmost Tory, or Tavi Poommoo. The latter is the name of a lake, and signifies the water of green tale. This lake is situated in the northern part of the island, and the country adjoining it only is known to the natives under this name. From my obervation, fays captain Cook, and from other information, it appears to me, that the New Zealanders muft live under perpetual apprehenfions of being destroyed by each other; there being few of their tribes that have not, as they think, sufianed wrongs from fome other tribe, which they are continually upon the watch to revenge; and perhaps the defire of a good meal may be no small incitem ent. They will even preferve their enmity from father to
and the son never loses sight of an injury done to his father. The method of executing their horrible design is by killing upon their enemies in the night; and if they find them unguarded, (which however is but seldom the case,) they kill every one indiscriminately, not even sparing the women and children: the dead bodies they either devour on the spot, or carry them home for that purpose. If they are discovered before they can execute their bloody purpose, they generally retreat; and sometimes are pursued and attacked by the other party in their turn. They never give quarter, or take prisoners. This perpetual state of warfare renders them so circumstantial, that they are never off their guard, either by night or day. According to their system of belief, the soul of the man whose flesh is devoured by the enemy is doomed to perpetual fire; while the soul of him whose body has been rescued, as well as those who die a natural death, ascend to the habitation of the gods. They do not eat the bodies of their friends who have been rescued. Their common method of disposing of the dead is by burying in the earth; but if they have more of their slaughtered enemies than they can eat, they throw them into the sea. They have no such things as morals, or other places of public worship; nor do they ever assemble together with this view. But they have priests, who alone address the gods in prayers for the prosperity of their temporal affairs. Whatever principles of their religion may be, they are strongly inclined from their infancy: of this I had a remarkable instance in the youth who was first destined to accompany Taweharaoa. He refrained from eating the greatest part of the day on account of his hair being cut; though every method was tried to induce him to break his resolution; and he was tempted with the offer of such viands as he was known to like best. He said, that if he ate any thing that day, the Eatoa would kill him; however, towards evening the cravings of nature got the better of the precepts of religion, and he ate, though but sparingly. Notwithstanding the divided and hostile state in which the New Zealanders live, travelling foreigners who come with no ill design are well received, and entertained during their stay: which, however, it is expected will be no longer than is requisite to transact the business that they come upon. Polygamy is allowed amongst the people: the women are marriageable at a very early age; and one who is unmarried is but in a forlorn state: the can with difficulty get a subsistence, and is in a great measure without a protector, though in continual want of a powerful one. The New Zealanders seem to be perfectly satisfied with the little knowledge they are masters of without attempting in the least to improve it; nor are they remarkably curious either in their observations or inquiries. Towy Poemamoo is for the most part a mountaneous, and to all appearances a barren country, and thinly peopled. Ealeimauheu has a much better appearance; it is indeed not only hilly, but mountainous, yet even the hills and mountains are covered with wood, and every valley has a rivulet of water; the soil in these valleys and in the plains, of which there are many that are not overgrown with wood, is in general light, but fertile, and fit for every kind of European grain, plants, and fruit. From the vegetables that were found here, there is reason to conclude the winters are milder than in England, and the summer not hotter, though it was more equally warm; dogs and rats are the only quadrupeds that were seen, and of the latter only a few. The inhabitants breed the dogs for the sole purpose of eating them. There are fruits and whales on the coast, and a sea-lion was once seen. The birds are, hawks, owls, quails; and there are long-birds, whose note is wonderfully melodious. There are ducks and

flags of several forts, not unlike those of Europe; and the gauntlet, which is exactly the fame. The sea-coal is visited by abalrobises, shear-waters, pintados, and penguins. The flies are, flesh-flies, butterflies, beetle-flies, sand-flies, and mufquitoes; and the neighboring sea abounds with fish, which are equally delicious and wholesome food. Captain Cook seldom came to anchor but they caught enough, with hook and line only, to supply the whole ship's crew; and when they fished with nets, every mesh in the ship, except those who were too indolent, fished as much as supplied them when at sea some time after. The fish was not less various in kind than plentiful in quantity; there were many sorts they had never before seen, but the sailors readily gave names to all of them. The highest luxury which the sea afforded was the lobster, or sea cray-fish. Here were also several species of the skate, or hingray: soles, flounders, and shell-fish, were abundant. This country abounds with forests filled with very large, straight, and clean timber. There is one tree about the size of an oak, which was distinguished by a scarlet flower, that appeared to be composed of several fibres; the wood of which was hard and heavy, excellently adapted to the use of the mill-wright: and another which grows in swampy ground, very straight and tall, and bears small bunches of berries resembling that of a yew-tree; the wood of which is very tough, and thick enough to make masts of any size: about 420 species of plants were found; all of which are unknown in England, except garden night-shade, cow-thistle, two or three kinds of fern, and one or two sorts of graits. They found wild celery, and a kind of cresses, in great abundance on the sea shore, and of eatable plants raised by cultivation, only coconuts, yams, and sweet potatoes. There are plantations of many acres of these yams and potatoes. The inhabitants likewise cultivate the ground; and the Chinese paper mulberry-tree is to be found, but in no abundance. There is only one shrub or tree in this country which produces fruit, and that is a kind of a berry almost tinelefs; but they have a plant which answers all the uses of hemp and flax. There are two kinds of this plant, the leaves of one of which are yellow, and the other deep-red, and both of them reemble the leaves of flags; of these leaves they make lines and cordage, and much stronger than any thing of the kind in Europe. These leaves they likewise split into breadth, and tying the slips together form their fishing-nets. Their common apparel by a simple process is made from leaves, and their finer by another preparation is made from the fibres. This plant is found both on high and low ground, in dry mould, and deep boggs; but as it grows largest in the latter, that seems to be its proper soil.

The men of this country are as large as the largest Europeans. Their complex is brown, but little more so than that of a Spaniard. They are full of flesh, but not lazy or luxurious, and are stout and well shaped. The women prefer not that delicacy which distinguishes the European ladies, but their voice is singularly soft, which, as the drefs of both sex is similar, chiefly distinguishes them from the men. The men are active in a high degree; their hair is black, and teeth are white and even. The features in both sex are regular; they enjoy perfect health, and live to a very advanced age; they are of the gentlest dispositions, and treat each other with the utmost kindnefs, but they are perpetually at war, every little distress being at enmity with all the rest, and towards their enemies they are implacable, never giving quarter. They have neither black cattle, sheep, hogs, nor goats; so that their chief food being fish, and that not at all times to be obtained, they are
in danger of dying through hunger: they have a few, and but a very few dogs; and when no fish is to be got they have only vegetables such as fern-root, clams, yams, and potatoes, to feed on; and if by any accident these fail them, their future health depends upon their skill for their shocking custom of eating the bodies which are slain in battle, for he who fights through mere hunger will not scruple to eat the adversary he has killed. The inhabitants of New Zealand are modelled and revered in their behaviour and conversation. The women, indeed, were not dead to the loiter impressions; but their mode of content was, in their idea, as harmless as the content to marry with us, and equally binding for the stipulated time. If any of the English addressed one of their women, he was informed, that the content of her friends must be obtained, which usually followed on his making a present. This done, he was obliged to treat his temporary wife at least as delicately as we do in England. They anoint their hair with oil, melted from the fat of fish or birds. The poorer people use that which is rancid, so that their smell is very disagreeable; but those of superior rank make use of that which is fresh. They wear combs, both of bone and wood, which are considered as an ornament when stuck upright in the hair. The men tie their hair in a bunch on the crown of their head, and adorn it with the feathers of birds, which they likewise sometimes place on each side of the temples. They commonly wear short beards; the hair of the women sometimes flows over the shoulders, and sometimes is cut short. Both sexes, but the men more than the women, mark their bodies with black stains called Amoey; in general the women have only the lips, but sometimes mark other parts with black patches; the men, on the contrary, put on additional marks from year to year, so that those who are very ancient are almost covered. Exclusive of the Amoey, they mark themselves with furrows: these furrows make a hideous appearance, the edges being indented, and the whole quite black. The ornaments of the face are drawn in the spiral form, with equal elegance and correctness, both cheeks being marked exactly alike, while the painting on their bodies resembles filagree work, and the foliage in old chafed ornaments, but no two faces or bodies are painted exactly after the same model. The Indians likewise paint their bodies, by rubbing them with red ochre, either dry, or mixed with oil. Their drefs is formed of the leaves of the flax, split into strips, which are interwoven, and made into a kind of matting, the ends which are seven or eight inches in length hanging out on the upper side. One piece of this matting, being tied over the shoulders, reaches to the knees; the other piece, being wrapped round the waist, falls almost to the ground. These two pieces are fastened to a string, which, by means of a bodkin of bone, is passed through, and tacks them together. The men wear the lower garment only at particular times. What they consider as the most ornamental part of their drees is the fur of dogs, which they cut into stripes, and few on different parts of their apparel. As dogs are not in plenty, they dispise these stripes with great economy. They have a few drees ornamented with feathers; and one man was seen covered wholly with the red feathers of the parrot. The women never tie their hair on the top of their head, nor adorn it with feathers; and are less anxious about drees than the men. Their lower garment is bound tight round them, except when they go a-fishing, and then they are careful that the men shall not see them. The ears of both sexes are bored, and the holes stretched so as to admit a man's finger. The ornaments of their ears are, feathers, cloth, bones, and sometimes bits of wood: a great many of them use nails, which were given them by the English for this purpose; and the women sometimes adorn their ears with the white down of the albatrosses, which they pluck before and behind the hole, in a large bunch. They likewise hang to their ears by strings, chifsels, bodkins, the teeth of dogs, and the teeth and nails of their deceased friends. The arms and angles of the women are adorned with shells and bones, or any thing else through which they can pass a string. The men wear a piece of green tale, or whalebone, with the resemblance of a man carved on it, hanging to a string round the neck.

The houfes are from sixteen to twenty-four feet long, ten or twelve wide, and fix or eight in height. The frame is of eight ficks of wood, and the walls and roof are made of dry grass, pretty firmly compacted. Some of them are lined with bark of trees, and the ridge of the houfe is formed by a pole, which runs from one end to the other. The door is only high enough to admit a person crawling on hands and knees; and the roof is floping. There is a square hole near the door, serving both for window and chimney, near which is the fire-place. A plank is placed near the door, adorned with a fort of carving, and this they consider as an ornamental piece of furniture. The side walls, and roof, projecting two or three feet beyond the walls at each end, form a fort of portico, where benches are placed to sit on. The fire is made in the middle of a hollow square in the floor, which is inclosed with wood or stone. They sleep near the walls, where the ground is covered with straw for their beds. Besides the fern-root, which serves them for bread, they feed on albatrosses, penguins, and some other birds. Whatever they eat is either roasted or baked, as they have no vessels in which water can be boiled. No plantations of cocus, potatoes, and yams, were seen to the southward, though there were many in the northern parts. The natives drink no other liquor than water, and enjoy perfect and uninterrupted health. When wounded in battle, the wound heals in a very short time, without the application of medicine; and the very old people carry no other marks of decay about them than the loos of their hair and teeth, and a failure of their muscular strength, but enjoy an equal share of health and cheerfulness with the youngest.

The canoes of this country are not unlike the whale-boats of New England, being long and narrow. Those of the larger fort seem to be built for war, and will hold from 30 to 100 men; one of these measured near seventy feet in length, six in width, and four in depth. It was sharp at the bottom, and consisted of three lengths, about two or three inches thick, and tied firmly together with strong plaiting; each side was formed of one entire plank, about twelve inches broad, and about an inch and a half thick, which were fitted to the bottom part with equal strength and ingeninity. Several thwarts were laid from one side to the other, to which they were securely fastened, in order to strengthen the canoes. These vessels are rowed with a kind of paddles, between five and six feet in length, the blade of which is a long oval, gradually decreasing till it reaches the handle; and the velocity with which they row with these paddles is surprising: their fails are compoied of a kind of mat or netting, which is extended between two upright poles, one of which is fixed on each side. Two ropes fastened to the top of each pole serve instead of fleets. The vessels are loaded by two men, having each a paddle, and sitting in the stern; but they can only fall before the wind, in which direction they move with considerable swiftness.

T 2

These}
Thee Indians use axes, adzes, and chieles, with which left they likewise bore holes. The chieles are made of Jasper, or of the bone of a man's arm; and their axes and adzes of a hard black flone. Their tillage of the ground is excellent, owing to the necessity they are under of cultivating, or running the risk of starving. A long narrow flake, sharpened to an edge at bottom, with a piece fixed across, a little above it, for the convenience of driving it into the ground with the foot, supplies the place both of plough and spade. The soil being light, their work is not very laborious, and with this instrument alone they will turn up ground of fix or seven acres in extent. Their fish-hooks are of shell or bone; and they have baikets of wicker-work to hold the fish. Their warlike weapons are, spears, darts, battle-axes, and the patoo-patoo, in which they chiefly confide. This is fastened to their wrists by a strong frap, lest it should be wrested from them; and the principal people generally wear it sticking in their girdles, considering it as a military ornament and part of their dress, like the poinard of the Aitifac and the sword of the Europeans.

The spear, which is pointed at each end, is about twenty-six feet in length, and they hold it in the middle, so that it is difficult to parry a push from it. Whether they fight in boats or on shore, the battle is hard to hand; their contents must be bloody. The war-dance confits of a great variety of violent motions and hideous contortions of the limbs, during which the countenance and tongue perform their parts. This horrid dance is always accompanied by a song, every strain of which terminates with a deep and loud figh.

The employment of the men is supposed to consist in cultivating the ground, making nets, catching birds, and fishing; while the women are engaged in weaving cloth, procuring fern-roots and shell-fish, and dressing food. With regard to religion, they acknowledge one superior being, and several subordinate. Their mode of worship could not be learned, nor was any place proper for that purpose seen. There was indeed a small square area, encompassed with stones, in the middle of which hung a basket of fern-roots on one of their spades. This they said was offered to the gods, in the hope of a plentiful crop of provision. The inhabitants of the southern district said they disposed of their dead by throwing them into the sea; but those of the north said they buried them in the ground; captain Cook's crew, however, saw not the least sign of any grave, or monument; but the body of almost every inhabitant bore the marks of wounds which they had given themselves, in token of grief for the loss of their friends and relations. Some of these scars were newly made, which is a proof that their friends had died while the ship's crew were there, yet no one saw any thing like a funeral, as the indefers conceal every thing respecting the dead with the utmost caution. A great finitude was observed between the drees, furniture, boats, and nets of the New Zealanders, and those of the inhabitants of the South sea islands, which furnish a strong proof that the ancestors of both were natives of the same country. The language of New Zealand and Otahihe is radically the same; and that of the northern and southern parts differs chiefly in the pronunciation. S. lat. 34° to 45°. W. long. 181° to 194°. Cook's Voyages by Hawksworth, vol. iii.

ZEAMAH, a river of Algiers, which runs into the Mediterranean, 6 miles S.S.E. of Cull.

ZEAN, a town of Hindoostan, in Doob; 20 miles S. of Canoge.

ZEB, or ZIN, a town of Syria, near the sea-coast, an-

ciently called Achaph, Achzib, and Ecchipa; 9 miles

from Acre.

ZEBBAIDE, a town of Persia, in the province of Far-

sián; 80 miles E. of Shiras.

ZEDAINNEH, a village of Syria, built on the spot

where it is said by some that Cain flew his brother Abél;

14 miles N.W. of Damascus.

ZEBE, or Zaan, in Ancient Geography, a town which

once formed a part of Mauritanian Sittanís; it was situated

at the foot of the chain of mount Atlas.

ZEBEE, in Geography, a river of Abyssinia, which runs

into the Indian sea.

ZEBEEER, a town of Arabian Irak; 12 miles W. of

Balforah.

ZEBEN. See ZEBEN.

ZEBET, a word used by some of the chemical writers to

express wood.

ZEBID, in Geography, a city of Arabia, in the province

of Yemen. Zebid was once the place of a sovereign's residence, and the most commercial city in all Tehama; but since the harbour of Ghalefa was choked up, its trade has been transferred to Beit el Fakhî and Mocha, and this city now retains nothing but the shadow of its former splendour. Viewed from a distance, it appears to some advantage, by means of the mosques and kubbets, of which it is full. Several of these mosques were erected by different pachas, who refused here during the short period while this part of Arabia was in the possession of the Ottoman Porte. Zebid had once eight gates; of these only five are now standing, and the river is gradually breaking down a part of them. The walls of the old city are demolished, and the very ruins are sold by poor people, who gather out the stones, and fell them for building new houses. The present buildings occupy about one half of the ancient extent of the city. Zebid is still distinguished for an academy, or university, for the Sunnâis, as that of Damar is for the Seidés, in which the youth of Tehama, and a part of Yemen, study such sciences as are cultivated among the Mussulmen. This is besides the feat of a dola, a muniti, and three cadis; 52 miles N. of Mocha. N. lat. 14° 12'. E. long. 43° 15'.

ZEBIO, a mountain of Italy, which sometimes emits flames; 6 miles S. of Modena.

ZEBLICIUM MARBREUM in Natural History, a name given by several authors to a loft green marble, variegated with black and white; and though the authors who have described it have not observed it, yet it no way differs from the white ophites of the ancients. See OPHITES.

ZEBÖIM, in Ancient Geography. See SEBOIM.

ZEBRA, in Zoology. See Equus Zebra.

ZEBU, a name given by M. de Buffon to a variety of the bos taurus of Linneus, or bison of other writers, or the camel. This variety resembles the Indian ox, or bos Indicus, but is extremely small, being found in some parts of India of a size scarcely larger than a great dog. In colour it differs like the common calf, being either grey, brown, white, &c., or variously spotted. The Indian ox, which is found in many parts of India, as well as in the Indian and African islands, and particularly in Madagascar, is of a reddish colour, of a very large size, and is distinguished by a very large protuberance over the shoulders. See BULL, in Geography. See SIRO.

ZEBULUN, or ZABULON, in Scripture Geography, one of the Jewish tribes in Lower Galilee, on the S. of the tribes of Asher and Naphthali, having the Mediterranean on the W., the sea of Galilee on the E.; separated on the N. from Asher by the river Japhethel, and on the S. from Ilia-
The Curcuma Zerumbet of Roxburgh, with small bulbs, and palmate tubers pale straw-colour; leaves green-petioled, broad-lanceolar, with a purple cloud down the middle; and flowers shorter than their bractea, is the Amomum Zerum-
beth of Retzius; which see. This is a native of various parts of India, and its flowering-time the hot season, before the leaves appear. The pale colour of the roots, crimson carmin and ferruginous maroon down to the centre of the leaves, which is a constant mark in this elegant species, readily point it out from every other. The dry root appears to be the zedoaria of the shops in England. See Astatic Researcher, vol. ii. p. 332—334.

The root is brought over in oblong pieces, about the thickness of the little finger, and two or three inches in length; or in roundish ones (the zerumbeth of the Paris Pharmacopoeia), about an inch in diameter; it is of an ash colour on the outside, and white within. The difference of these, in strength, if any, is very inconsiderable, and therefore the college allows both to be used indiscriminately.

This root has an agreeable campshoraceous smell, and a bitterish aromatic taste. It impregnates water with its smell, a flight bitternes, a considerable warmth and prun-gency, and a yellowish-brown colour. The reddish-yellow spirituous tincture is in talle stronger, and in smell weaker, than the watery. In dilution with water, it yields a thick, ponderous effential oil, smelling strongly of the zedo-ary, in talle very hot and pungent: the decoction, thus deprived of the aromatic matter, and concentrated by infip-itation, proves weakly and disagreeably bitter and sub-acrid. A part of its odorous matter rifes also in the inipification of the spirituous tincture; the remaining extract is a very warm, not fiery, moderately bitter aromatic, in flavour more grateful than the zedoary in subsitance.

Zedoary-root is a very useful warm fhotacitic: and has been commended in colics and hysterick affections, for promoting the menfes, &c. It has been employed by fome as a fuccedaneum to gentian root; but from the above analyfis it appears to be not entirely similar to that fimple bitter; its warm aromatic part being the prevailing principle, in virtue of which its spirituous extract (the most elegant preparation of it), has been made an ingredient in the cordial confection of the London Pharmacopoeia. Lewis's Mat. Med.

Carthenfer, who ascribes its virtues to a campshoraceous volatile oil, considers it as a general remedy for most of the chronic diseases with which human nature is affected; but as the camphor contained in it can avail but little, and its effects as a bitter or aromatic are so very inconsiderable, this root is now deemed to poiffes very little medicinal power, and might be safely expunged from the materia medica. Cullen.

Woodville.

The zedoary wath, which is a cooler yellow than faffron, though full as bright, and valuable for many purposes in painting with water-colours, may be prepared by boiling an ounce of the root in a quart of water, till the water is sufficiently tinged to make a ftrain on paper, of a full yellow colour; and infining the liquor through a linen fifter. This wath may be dried in fhelves, and will again difolve and spread kindly with the addition of water.

Zeedlintz, in Geography, a town of Sifeia, in the principality of Neife; 3 miles N. of Ottmachau.

Zedere. See Sufferdam.

Zefr, a word by which fome of the chemical authors express pitch.

Zefrio, in Geography, a mountain of Naples, in Cala-
bria Ultra; 10 miles N.N.E. of Bova.

Zegedin, or Szeged, a town of Hungary, near the conflux of the rivers Maros and Thielle. It is strong, and a place
a place of some trade, particularly in cattle. In the year 1503, all its defence was a moat and rampart; but falling some time after into the hands of the Turks, they erected a brick fort. In 1686, the Imperialists dispossessed the Turks of it; 68 miles N. of Belgrade. N. lat. 46° 15'. E. long. 10° 55'.

**ZEGGO,** a town of Africa, in the country of Melli, in the road from Kongo to Casha; 100 miles N.W. of Malel. N. lat. 14°. E. long. 8°.

**ZEGHAMA,** a town of Dar-Fur; 60 miles N. of Coblé.

**ZEGHEN,** a town of Fezzan; 65 miles N. of Moursouk.

ZEGI, ZAGI, a word used by Avicenna and others to express all the several vitreous minerals. See Chalctitis, and Colchothar.

**ZEGMA,** in Geography, a town of Asiatic Turkey, in the province of Diarbekir, on the Euphrates, opposite to Romkala.

**ZEGUTI,** a town of Imirezia; 20 miles S.W. of Catisa.

ZEGZEG, a city of Africa, and capital of a country of the same name, situated to the east of Agades; 370 miles N.E. of Casha. N. lat. 20° 45'. E. long. 16°.

**ZEHDENICK,** a town of Brandenburg, in the Ucker Mark, on the Havel. In it is a convent for ladies of noble descent, consisting of a dominion and six fritters. It carries on a large trade in wood and corn: in the pastures, near the town, iron-ore is met with in great abundance, and accordingly there is a mill here for that purpose, which is driven by the Havel. At this place likewise is a foundery, where bombs, grenades, bullets, mortars, pots, weights, and even small cannon are cast; 28 miles S.S.W. of Prenzlau. N. lat. 52° 58'. E. long. 13° 22'.

**ZEHIN,** a town of Brandenburg, in the New Mark; 40 miles E. of Oderburg.

**ZEHERECH,** a word used by some of the chemical writers to express flowers of brafs.

**ZEHISTA,** in Geography, a town of Saxony, in the margrave of Meissen; 3 miles S. of Pirna.

**ZEHRENDORF,** a town of Brandenburg, in the Middle Mark; 3 miles S. of Zolten.

**ZEIDOURSE,** a district of Algiers, between Tremecen and Oran.

**ZELI,** a town of Bavaria, in the bishopric of Bamberg; 12 miles W.N.W. of Bamberg. N. lat. 50° 4'. E. long. 16° 45'.—Allo, a town and castle of Germany, which gives name to a county; 4 miles N. of Leuchtirch.

**ZELLA,** or ZELLA, or Syla, a sea-port town of Africa, in the kingdom of Adel, situated on the coast of the Arabian sea, at the mouth of the Hanazo, or Hawah, which forms a bay, called the Bay or Gulf of Zelita. It receives a governor from the dola of Mocha. N. lat. 10° 45'. E. long. 44° 20'.

**ZEILSHEIM,** a town of the duchy of Wurzburg; 4 miles N. of Volckach.—Allo, a town of the duchy of Wurzburg; 4 miles E.N.E. of Arnstein.

**ZEINDEROD,** or ZENDEROD, a river of Peria, in the province of Irak, which has its source in the Kohizard, or Yellow mountain, where an aqueduct may yet be seen, by which Abbas the Great attempted to unite its waters with those of the Karoon. The Zenderood passes through the city of Ifpanah, and is said to be absorbed in the irrigation of the neighbouring territory, or to lose itself in a lake, 15 miles S.W. of Larifian. On this river are three bridges, two of which are in good repair; particularly that of the Char Bagh (four gardens), so called from its connecting the upper and lower Chaur Bagh, the name given to a spacious avenue, which runs from the royal square to the foot of the mountains E. of Ifpanah.

**ZEISELMAN,** a town of Austria; 3 miles E. of Turnau.

**ZEISPERG,** a town of Austria; 3 miles E.N.E. of Crems.

**ZEITHAYN,** a town of Saxony, in the margrave of Meissen, famous for a pleasaunce-camp which King Augustus II. made there, in 1730, at the expense of five millions of rix-dollars. On the spot which was used for this camp, and the exercising of the army, are erected six large pyramids; and medals have likewise been struck upon it, and a grand representation thereof engraved on copper; 8 miles W.N.W. of Groffenhayn.

**ZEITLOSS,** a town of the duchy of Wurzburg, on the river Sinn; 10 miles N. of Grumunden.

**ZEITON,** a town of European Turkey, in Thesfly, on a gulf to which it gives name. Here are about 400 Christian families, but the greater part of the inhabitants consists of Turks; 48 miles S.S.E. of Larifian. N. lat. 39° 6'. E. long. 22° 58'.

**ZEITON,** a gulf or bay of the Egean sea, on the E. coast of Thefaly, N.W. of the island of Negronepont.

**ZEITONQ,** a town of Persia, in the province of Fars or Farifian, containing about 2000 inhabitants, and situated in a pleasant valley, fertilised by both the branches of the river Tab, which here form a junction. Zeitoon is about fifteen miles distant from Behaban, the capital of the mountainous district of Khogilfa, which extends from the valley of Ram Hormuz to the vicinity of Kazerou.

**ZEITOUN,** a town of Asiatic Turkey, in the government of Divas, on the Kizilermak; 33 miles W. of Samioun.

**ZEITRABA,** a term used by some of the chemists to express any thing that is fluxile.

**ZETZ,** in Geography, a town of Saxony, in the bishopric of Naumburg, anciently the site of a bishop, founded by the emperor Otho I. afterwards transferred to Naumburg, after this town had been sacked and almost destroyed by the Vandals in the year 682; 15 miles E.S.E. of Naumburg. N. lat. 51° 3'. E. long. 12° 2'.

**ZEKELHEB,** a town of Hungary; 8 miles N.W. of St. Job.

**ZELA,** a town of Persia, in the province of Segeltan; 25 miles S.W. of Ferah.

**ZELA, ZELA,** or Zela, in Ancient Geography, a town of Thrace, afterwards called Flaviopolis.—Allo, a town of Afa, in Cappadocia Pontus, near the Lycus. It was celebrated by the defeat of Triarius, the Roman general, and afterwards by that of Pharnaces. Here was a famous temple, represented upon some medals, consecrated to the goddess Anaitis, a Persian divinity, whose pontiff was very powerful under ancient kings; but in process of time his authority and revenues were diminished. The town and the ministers of the temple were dependent on Pithodiris, who possessed a part of the territory; other parts were ceded to the pontiffs of Zela and Comanes, and the rest was annexed to the Roman province. According to Strabo, Zela and its territory were situated to the left of the river; the sacred lands of the temple, and the domains of the pontiff, were in the environs of the town. He adds that it was fortified and built in the retreatment of Semiramis; and in the first times it had only some huts near the temple; but Pompey made it a town.

**ZELAH,** or SELA, a city of Benjamin (Jos. xvii.38), where Saul was buried in the tomb of his father, Kish. 2 Sam. xvi. 14.

ZELAN,
ZELEN, in Geography, a mountain in the county of Tyrol; 20 miles N.E. of Trent.

ZELANDY, a small island in the East Indian sea, near the W. coast of Sumatra. N. lat. 6° 53'. E. long. 98° 14'.

ZELANICA, a cape on the N. coast of Nova Zembla. N. lat. 78°. E. long. 77° 24'.

ZELATE, a town of the country of Candahar; 30 miles N.E. of Candahar.

ZELEBI. See Scheleby.

ZELEFFA, a town of Africa, in the country of Tunis; 10 miles S.E. of Cairo.

ZELEH, a town of Aegiatic Turkey, in the government of Sivas, anciently a town of Pontus, and called Zela. Near this place the Romans, under Trajanius, were defeated by Mithridates; and Pharmaces, son of Mithridates, was afterwards defeated by Julius Caesar; 21 miles W.S.W. of Tarsit. See Zela.

ZELEIA, in Ancient Geography, a town built, according to Homer, at the foot of mount Ida. It was watered by the Tarisus, and had to the S. the lake Aphlithmus. According to Strabo, it had also in ancient times an oracle, but in his time it was not consulted.

ZELEM, in the Materia Medica of the Ancients, a name given by Avicenna and others to a fruit common in Africa in their time, and much esteemed by the people of that country, and called there by some piper nigrorum, the black people's pepper, or negro-pepper. Avicenna tells us, that the zelem was a fattish seed, of the size of a chich, and of a high flavour, in colour yellow on the outside, and white within, and that it was brought from Barbary. He adds, that there was another plant, properly called fulus alasteen, that is, piper nigrorum. This, he says, was a feed contained in pods like kidney-beans, and was black, and of a pungent and acrid tafe.

ZELLENIN, in Geography, a small island in the Frozen ocean, near the S.W. coast of Nova Zembla. N. lat. 70° 50'. E. long. 50° 24'.

ZILENOIKOLOK, a fort of Ruffia, in the government of Caucasus, on the Ural; 44 miles N. of Curiev.

ZELLES, in Ancient Geography, a town of Hispania, in Bocata, upon a ftrait which separated Hispania from Africa, according to Strabo. This author reports, that the Romans transported the inhabitants into Mauritania, together with others drawn away from Tingis, established the town of Julia Joga.

ZELETAWA, in Geography. See Scheletha.

ZELEZENSKAIA, a fort of Ruffia, in the government of Kolivan, on the E. side of the Irtisch. N. lat. 53° 25'. E. long. 75° 40'.

ZELITO, or Zilito, a fort of South America, in the harbour of Carathenga.

ZELL, a town of Austria; 14 miles N.N.W. of St. Wolfgang.—Alto, a town of Bavaria, in the bishopric of Bamberg; 10 miles W. of Bamberg.—Alfo, a town of Germany, in the principality of Culmbach; 12 miles S.S.W. of Hof.—Alfo, a town of the duchy of Wurzburg; 3 miles N. of Schweinfurt.

ZELL. See Liebenzell.

ZELL am Ham, a town of Germany, on the Mofelle; 25 miles N.E. of Treves. N. lat. 50° 4'. E. long. 7° 47'.

ZELL am Ingel, a town of the archbishopric of Salzburg, on the Zeller See; 30 miles S.S.W. of Salzburg.

ZELL am Zellerthal, a town of the archbishopric of Salzburg, on the Ziller; 50 miles S.W. of Salzburg.

ZELL am Hammerbach, a town of Germany, situated in the vale of Hammerbach. The town was imperial, and affeiled twenty-one florins till 1802, when it was given to the margrave of Baden; 9 miles W. of Freudenfalt. N. lat. 48° 34'. E. long. 8° 7'.

ZELLA, in Ancient Geography, a town of Africa, which was ruined during the war of Caesar against Scipio. Strabo.

ZELLANG, in Geography, a town on the W. coast of the island of Celebes. S. lat. 4° 20'. E. long. 120° 41'.

ZELLE, or Altenzell, a town of Saxony, in the circle of Erzgebirg; 2 miles W. of Noffen.

ZELLE, a city of Westphalia, in the principality of Luneburg. This is a fortified and well-built town, situated on the Aler, which is here navigable, and behind the New Town is joined by the Pulfee. The town itself, in conjunction with the suburb of Fritzenweife, consists of 564 houses; but including the other suburbs, summer-houses, and buildings without the gates, the number of them amounts to about 1400. At this place was held the high court of appeals for the several territories of the electoral house of Brunswik-Luneburg, together with the chancellery and chief tribunal of the principality of Luneburg. Here also stands the provincial house for the diets of the principality, together with one of its superintendencies, and a special superintendency which is administered by the general superintendant, who is always first minister of the town church. The other public edifices in it are, the Guildhall, the riding-house, the mews, and the armoury. The magistracy is possessed of the lower jurisdiction in the town, and likewise in some parts of the suburbs. At this place, too, are manufacturers and artificers in various branches, particularly in gold and silver. The prince's seat, near the town, is walled and moated in, and was the residence of the Zelle line of Brunswik-Luneburg; which failed in 1705. It was built by duke Henry, in the year 1485, and afterwards improved; 40 miles S. of Luneburg. N. lat. 53° 42'. E. long. 10° 14'.

ZELLENBERG, a town of France, in the department of the Upper Rhine; 9 miles N. of Colmar.

ZELLERSEE, a lake of Germany, in the archbishopric of Salzburg; 28 miles S.S.W. of Salzburg.

ZELLERFELD, a town of Weftphalia, in the Harz Forest; fiver to the value of 20,000 imperial crowns is annually coined in this town; 6 miles S.S.W. of Giflar.

ZELLERNDORFF, a town of Austria; 3 miles S.E. of Schrattental.

ZELLOHENF, a town of Austria; 10 miles N.W. of Grein.

ZELLIA, in Ancient Geography, a country of Upper Panonia, inhabited by the Slav.

ZELLIN, in Geography, a town of the New Mark of Brandenburg; 13 miles N.W. of Cuffrin.

ZELLINGEN, a town of the duchy of Wurzburg; 8 miles N. of Wurzburg.

ZELLITZ, a town of the duchy of Stiria; 8 miles W. of Marburg.

ZELON, a town of Thibet; 27 miles S.W. of Laffa.

ZELOTTI, BATTISTA, in Biography, was born at Verona in 1532. He was a pupil of Titian, according to Vafari, and a fellow-student with Paolo Veronese, with whom he co-operated in several important works at Venice. He particularly excelled in freresco, and that induced Paolo to court his alliance in many of the great works in which he was engaged. In consequence many of his works are given to Veronese, and thence in the hall of the Council of Ten, in the palazzo S. Marco, have been engraved by Le Febre as the works of that master. His picture of the Holy Family, in the Carara collection, is painted with the strength and warmth of Titian, and others of his works in
oil are deservedly esteemed and admired, particularly the Converion of St. Paul, and Christ with his Disciples in the Fishing-boat, in the cathedral at Vicenza. He fell short of the grace and taste of Veronese, yet his invention was not lacking in energy; his touch is free and animated, and his compositions managed with skill and judgment. He died in 1592, aged 60.

ZELPHI. See Zenda.

ZELPITSCH, in Geography, a town of Iliria; 10 miles N.E. of Mitterburg.

ZELTURINSKOI, a fort of Ruffia, in the government of Irkutsk; 72 miles S.S.E. of Tunginskoi.

ZELUIA, a town of Lithuania, in the palatinate of Novogrodek; 25 miles N.W. of Smolni.

ZEM, a river of Albania, which runs into the Moraca, 12 miles W. of Cattaro.

ZEMA, a word used by many of the old writers for a decoration or apazom.

ZEMARAIM, or SEMARAIM, in Ancient Geography, a city of Benjamin near Bethel. Joth. xviii. 22.

ZEMARITES, an ancient people of Syria, mentioned by Strabo, who places them on a plain, two leagues to the N. of mount Libanus, and gives them the term of Simyra.

ZEMASARUM, a word used by some of the chemical writers as a name for cinnabar.

ZEMBLA, Nova, Novaya Zemlia, or New Land, in Geography, a Russian island, or rather a group of five islands, with the intervening channels always filled with ice, situated in the Frozen or Northern Ocean. Of the numerous islands in this ocean, Novaya Zemlia and Kalgeva are the most considerable; but both are uninhabited, and frequented only by fishermen and hunters. The former is indeed well supplied with water; but is rocky, unfertile, and destitute of wood, furnishing vegetation only for a few flustered bushes and polar plants. It abounds, however, with rein-deer, white bears, white and blue foxes; and the flores swarms with mores, walruses, and various kinds of fish. Its magnitude is estimated at 950 versts in length, 520 in breadth, and 3090 in circumference, without following the finnouts, and 425,509 German miles of superficies, according to Mr. Storch. On the northern side it is entirely encompassed with ice mountains; and to the south is the sea of Kara, Kara, or Karkoge, in which the tide flows about two feet nine inches. Among the animals of this island there is one of fresh water. From the middle of October till February the fun is not at all visible; but they have the advantage of numerous and strong north-lights and of much moon-light. In summer they have no thunder-storms. The snow falls in many places to the depth of four arshin. For two months, viz. June and July, the fun never sets. Between this island and the main land is the famous passage known by the name of Vaggrat's or Waygat's straits.

ZEMECH, a word used by some writers as a name for lapis lazuli.

ZEMENIE, in Geography, a town of European Turkey, in Romania; 16 miles S.W. of Gallipoli.

ZEMIA, Zymeis, among the Athenians, is sometimes taken in a large and general sense for any kind of punishment; but more frequently for a pecuniary mulct or fine laid upon the criminal, according to the degree of his offence.

ZEMLIANSK, in Geography, a town of Ruffia, in the government of Voronez; 44 miles N.N.W. of Voronez. N. lat. 52° 12'. E. long. 38° 42'.

ZELMIN, or SEMLIN, a fortress of Selavonia, at the union of the Save and the Danube, oppolite Belgrade. Here is a lazaretto, where travellers and merchandise from the Levant are detained to prevent infection. The number of inhabitants is about 1200 Rachiens, Greeks, Jews, Armenians, and Turks: during a fire at Zemlin, Joseph II. emperor of Austria, assisted in person to suppress it.

ZEMME, a town of Grand Bucharis, on the Gihon; 60 miles S. of Bucharia.

ZEMOKARTLI, a town of Turkish Armenia, in the government of Cars; 50 miles N. of Ardanoudi.

ZEMORGET, or ZEMOGITE, a small island in the Red sea, 30 miles from the coast of Egypt. This island was called by the ancients "Ophiodes," from the abundance of serpents, and the island of topazes from the number of those precious stones found there. N. lat. 23° 25'. E. long. 53° 5'.

ZEMOVAH, a town of Pegu; 50 miles S. of Prone.

ZEMPHYRUS, in the Materia Medica of the Ancients, a name give to a precious stone, the fragments of which they use as a cordial and pudoric.

It appears by their accounts, that this stone was blue; and hence many have too hastily judged, that it was the lapis lazuli; but in truth it was the fapphir.

The word zemphyrus is no where used but in the writings of the later Greeks, and it is plainly formed, as most of their names of things are, on the Arabian word expressing the fame thing. This Arabian word is fephir; and this, in Avicenna and Serapio, is always used as the name of a fapphir, never as that of any other gem. We find also by their accounts, that this fapphir was not the fapphir of the ancient Greeks, but the fine blue polluid gem we now know by that name; for the fapphir of Theophrastus, and the other old writers, was only a kind of lapis lazuli.

ZEMPLIN, in Geography, a town of Hungary; 16 miles N.E. of Patak.

ZEMPOALA. See ZAMPALE.

ZEMZEM, the holy well of Mecca, which see.

ZENANICH. See Selenieh.

ZENATI, a river of Algiers, formed by the union of two streams, which soon after changes its name to Seboue.

ZENDA, a general term coined by Paracelsus, by which he and his followers express extraneous or equivocal generation, or the production of bodies without a feminal principle. The word zuranda is used to express this particular fort of generation of men, and zelpi in regard to other animals.

ZENDAVESTA, by contraction Zend, and, as it is vulgarly pronounced, Zundasfoow and Zund, in Antiquity, denotes the book ascribed to Zoroaster, (see his article,) and containing his pretended revelations; and which the ancient Magians and modern Persees, called allen Gours, observe and reverence in the same manner as the Christians do the Bible, and the Mahometans the Koran, making it the sole rule of both their faith and manners. See Magi, Persees, Gebres, &c. See also Gentoos.

The word, it is said, originally signifies any instrument for kindling fire, and is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of those who read it.

Zendavella is compounded of Zend, denoting the letters of the book, and Avekly, signifying the language in which it was written. See PERSIA, LANGUAGE OF.

M. Anquetil du Perron, to whom account we shall refer more at large in the sequel of this article, has taken pains, in the 37th volume of the work cited below, to prove that Zoroaster lived under Hyfaspes, the father of Darius, in the sixth century before Christ.

The Zendavella, or Zend, contains the system of doctrine and duty, which is said to have been supernaturally communicated.
municated to Zoroaster, and which his followers hold in very extraordinary veneration. A copy of this book is kept, says Dr. Prideaux, to this day in every oratory and fire-temple, and portions of it are read at stated times by the priests to the people: and to this they appeal as the standard of the good and evil of their actions. This work, scribbled among other numerous writings to Zendavesta, or the Persian Zoroaster, and esteemed by his followers as of sacred authority, is said to have been written in the Persian language, and to have consisted of two parts; one of which contains their forms of devotion and order of ceremonies, the other the precepts of religion and morality. A compendium of it, called the Sadda or Sadder, is read to the people on every sacred day by their priests. There is, however, much reason to question, whether this book be of such ancient date as the time of Zoroaster; and it has been suggested as probable, that it was written about the time when many Jews and Christians resided among the Persians; that is, about the 4th or 5th century. In proof of its being later than the time of Zoroaster, but written since the days of Mahomet, it is alleged, that the word $f$hiatam occurs in it, which is peculiar to the Arabs; or in other oriental languages it is written $fatam$, or $fatan$.

Dr. Hyde gives us the following account of it. The Zend is the general name of the book, which is also called the book of Abraham; and it consists of twenty-one or twenty-two separate parts, with distinct names. Its contents were originally written on twelve hundred skins; and the ancient copies of it, like the original, are in the pure old Persian language; but the later copies are in the same language, mixed with modern Peric or Arabic words, serving to explain such as were becoming obsolete. Some parts of the Zend contain the original text, and others contain Zendavesta's second thoughts subjoined, for more fully explaining his doctrine. Some writers suggest, that Zendavesta first intended to compile his book in four parts, viz. the Zend, containing the liturgy and chief doctrine of his religion, and the Pazend, or commentary upon the former; and that the farther additions were occasioned by the opposition of adherences, and unforeseen circumstances that occurred. The character in which the Zend is written is that of the old Peric, called Pehlevi; and the Pazend character differs in a small degree from this.

Dr. Hyde has given a catalogue of the several parts of the Zend, each of which is called nos or nafs.

In process of time, when the old Peric language became antiquated, and little understood, one of their deputies or bishops (about A.D. 1300) composed the Sadda, which is a compendium, in the vulgar or modern Peric tongue, of those parts of the Zend that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroaster, serving as an authoritative rule of faith and practice for his followers. This Sadda is written in a low kind of Peric verse, and, as Dr. Hyde informs us, it is bonorum et malorum farrago, having many good and pious things, and others very superfluous and trifling.

The Zend contains a reformed system of Magianism; teaching that there is a Supreme Being, eternal, self-existent, and independent, who created both light and darknes, out of which he made all other things; that there are in a state of conflict, which will continue till the end of the world; that then there shall be a general retribution and judgment; and that just retribution shall be rendered unto men according to their works; and that the angel of darknes with his followers shall be con-

Vol. XXXIX.

digned to a state of everlasting darknes and punishment, and the angel of light with his disciples introduced into a state of everlasting light and happiness; after which light and darknes shall no more interfere with each other. The Zend also enjoins the constant maintenance of sacred fires and fire-temples for religious worship, the distinction of clean and unclean beasts, the payment of tithes to priests, which are to be of one family or tribe, a multitude of washings and purifications, remembering those of the Jewish law, and a variety of rules and exhortations for the exercise of benevolence and charity.

Dr. Prideaux charges the Zend with allowing the worst kind of incense; and Dr. Hyde also intimates that it was allowed by Zoroaster, till it was at length abolished; but no authority has been cited to justify this charge.

The above-mentioned doctrines of the Zend are accommodated to the eastern taste by a great intermixture of fable.

In this book there are many passages evidently taken out of the Scriptures of the Old Testament, particularly out of the Psalms of David: the author represents Adam and Eve as the first parents of all mankind, gives in substance the same account of the Creation and Deluge with Mofes, differing indeed with regard to the former by converting the six days of the Mosaic account into fix years, comprehending in the whole three hundred and sixty-five days; and speaks also of Abraham, Joseph, Mofes, and Solomon. Moreover, Dr. Baumgarten (Univ. Hist. Suppl. vol. ii. p. 326, &c.) affirms, that this work contains doctrines, opinions, and facts, actually borrowed from the Jews, Chrisilians, and Mahometans; whence, and from other circumstances, he concludes, that both the history and writings of this prophet were probably invented in the later ages, when the fire-worshippers under the Mahometan government thought fit to vindicate their religion from the fupposition of idolatry.

The Zoroaster, says the abbe Foucher, (see Zoroaster,) who was the author of the Zend, is represented by him as an apostate Jew, a facile philosopher, and an obsequious angel-courtier, who ingulphed himself into the favour of Darius Hyftafpes; and he says that his great design was to reconcile the Hebrew with the Persian religion by a mixture of the leading and essential doctrines of each, to revive the credit of the Mosaic law, and to accommodate, by proper colouring, the Jewish religion to the weaknes and prejudices of the Medes and Persians, by taking from it that exclusive character that rendered it offensive to other nations, and mixing with it the reveries and visions of the ancient Zoroaster. See Hyde's Religio Veterum Perfaran. Prideaux's Conn. of the Old and New Testament, vol. i. p. 317, &c. edit. 9. Univ. Hist. vol. ii. p. 206, &c. fol.

The account more lately given both of the Persees and Zend, by M. Anquetil du Perron, differs in several particulars from that of Dr. Hyde. This gentleman made a voyage to India, and employed himself between the years 1755 and 1761 in studying the Peric and Sanskrit languages, and in collecting and translating manuscripts, many of which he brought with him, and deposited in the king of France's library. His account was read to the Royal Academy of Sciences at Paris, and a translation of it was published in the Gentleman's Magazine for 1762, and also in Dodgley's Annual Register for 1762, part ii. p. 101—127. Of the Persees or Parfes, the disciples of Zoroaster, he says, a very numerous body has been established more than nine hundred years in Guzerat, to which place they came fugitives from Kerman, A.D. 767, on account of the Mahometan
homenet perfections, where their genius for commerce and industry, which are their known charactearistics, procured for them very considerable settlements. Concerning the hierarchy of the Parfles, this writer observes, that their ministers of religion are divided into five classes, viz. erbeds, mobeds, deftours, deftour mobeds, and deftouran deftours, or deftours of deftours. An erbed is a person who has submitted to the purification directed by the law, who has read, during four days without interval, the Zendateh and the Venddad, and who is instructed in the ceremonies of the worship established by Zoroafer. If the erbed afterwards continues to read publicly the Zend works, which constitute the liturgy, and to perform the ministerial functions, he becomes a mobed, though he does not understand the Zendavesta; but if he contents himself with studying the law, the Zend, and the Pehlvi, or Pehlavi, without exercising the ministerial functions, he is called a deftour.

The deftour mobed is he who unites the qualifications of the mobed and deftour; and the deftouran deftour is the principal deftour of a city or province, who decides calef of conscience, and determines points of law, and to whom the Parfles pay a tithe of their revenues.

As for the Zend writings, which the Parfles attribute to their legislator, and for which they have the same veneration as the Jews have for their Hebrew text, M. du Perron inclines to think, though he does not affirm, that they are really the works of Zoroafer, whose reputation has been acquired by laws that have subsisted two thousand five hundred years.

The Zend, ascribed to Zoroafer, was divided, as we are told by modern authors, into twenty-one nofis, or parts; seven of treat of the creation and history of the world; seven of morality, and civil and religious duties; and seven of phytic and astronomy. Among the Parfles it is an universally received tradition, that Alexander the Great condemned these twenty-one volumes to the flames, after having caused them to be translated into Greek. Those which escaped are, the Venddad, the Zendateh, the Vishpered, the Jelchis, and the Nenechis, in Zend, and some other Pehlvi translations of Zend originals. The Parfles have also a great number of prayers, which they call nerengs, and which in general are written in modern Perfic, with Zend characters, which they affect to use in all writings that treat of religion, though composed in modern Perfic. The writings of Zoroafer, which still remain, speek of the creation of the universe, of the terrestrial paradise, and the dispersion of mankind; of the cause of the fpeect paid to fire, of the origin of evil, natural and moral; of the angels appointed to the government of the universe; of several particulars relating to the end of the world, and the resurrection, &c. &c. They also contain precepts with respect to the latter times, some excellent moral precepts, and a very extensive ceremonial code.

The Zend, according to Du Perron, is not the name of Zoroafer's writings, but merely of the characters, though generally used to signify the language itself, in which they were written: the language of the original text is called Avesta, and is a dead language, and was entirely unknown to the Parfles before the time of Zoroafer, who, he apprehends, brought it from the mountains; and is totally different from the Pehlvi or ancient Perfic, spoken in the time of Zoroafer. He farther supposes, that the works of Zoroafer, till extant in the Pehlvi, were translations made into that language during the life of this legislator, or soon after his death.

The Zend, which Dr. Hyde makes to be the name of a work, is, according to Du Perron, the name of a language, which is a dialect or corruption of the Avesta, and almost extinct, except that a few words of it are preserved in the Pehlvi translation. The characters of the Avesta and Pehlvi are different; the former, which are properly the Zend letters, being much the neatest; the Zend has no peculiar alphabet, but adopts that of the Zend or Pehlvi indifferently. (On this subject, see Language of Persia.) For M. du Perron's account of the eighteen MSS. of which he brought duplicate copies with him, and an abstract of their contents, we must refer to the Ann. Reg. &c. ubi supra.

This writer has published a translation of the Zendavesta, with remarks and illustrations, &c. in 3 vols. 4to. at Paris, in 1771.

The Zend, as Sir W. Jones fuggelts (Works, vol. iii. p. 115, 8vo.), bore a strong resemblance to Sanskrit, and the Pehlvi to Arabic, being a dialect of the Chaldaic. Sir W. Jones, from a perusal of two vocabularies, exhibited in this work, one in Zend, and another in Pehlvi, and derived from a collection of traditional pieces in modern Perfic, was convinced in his opinion, concerning the Chaldaic origin of the Pehlvi; and in preparing the Zend glossary, he was surprized to find, that fix or seven words in ten were pure Sanskrit. M. Anquetil, he says, most certainly, and the Persian compiler most probably, had no knowledge of Sanskrit, and could not therefore have invented a lift of Sanskrit words: it must therefore be an authentic lift of Zend words, which had been preferred in books or by tradition; and hence it follows that the language of the Zend was at least a dialect of the Sanskrit, approaching perhaps as nearly to it as the Pracrit, or other popular idioms which are known to have been spoken in India 2000 years ago. As soon as M. Anquetil published the above-mentioned work, Sir W. Jones immediately discovered that the work was spurious, and by no means to be attributed to Zoroafer; and in consequence of which he published in the same year, "Lettre à M. A — du P — dans laquelle il compris l'Examen de la Traduction des Livres attribués à Zoroafer." This letter is contained in the 10th volume of his works, ed. 8vo.

In Germany this version of M. Anquetil has met with more success, and has not only been translated into German, but applied to the purposes of explaining the New Testament. This use of it has been suggested by Michaelis, and exemplified in the illustration of the introduction to St. John's gospel, and particularly of the term "word," which is used in the Zendavesta in the same sense as by St. John and the Gnostics for the name of a perfon, and determines the proper translation of ζωὴν. (Michaelis von Marth., vol. i. p. 161.) Several other persons, besides Sir W. Jones, have questioned the authenticity of the work which M. Anquetil has translated, or its being a genuine remain of Zoroafer.

Mr. Richardson, in his "Dissertation on the Language, Literature, and Manners of the Eastern Nations," originally prefixed to his Persian, Arabic, and English Dictionary, 1778 (chap. i. sect. 2.), is very severe, both on Dr. Hyde and M. du Perron. Those fragments of the supposed works of Zoroafer, which Dr. Hyde has given us under the title of Sadder, are, he says, the wretched rhymes of a modern Parfi deftour or priest, who lived about three centuries ago; whilst the publications of M. Anquetil du Perron carry palpable marks of the total or partial fabrication of modern times. The Zend language, he says, is not genuine; and M. du Perron has produced no discovery which can stamp his publication with authority.

He adds, the specimens of old Perfic in Hyde's ReligioVeterum
Veterum Perfarum are simply modern language in ancient characters.

In the "Memoirs of the Royal Society of Gottingen for 1799," i.e., "Commentationes Societatis Regia Scientiarum Gottingensis," &c., we have a memoir by M. Christopher Meiners, who enters into a critical examination of the authenticity and antiquity of the books published by M. Anquetil du Perron, as genuine writings of Zoroaster; and alleges many plausible arguments to prove them recent and pious. He shews, that they contain a multitude of fables, totally unknown to the ancient Persians, and contrary to the spirit of their laws and religion; and also many opinions and ceremonies, which had their rise in ages after Zoroaster. The dissertations of professor Meiners, relating to the Zendavesta, are printed in the 8th volume of the Novi Commentarii Soc. Reg. Gotting.; and in the 1st and 3rd volumes of the Commentations.

Some have thought that the truths which are observable in Zendavesta, Vendidad Sadi, and other writings of the eastern nations, were derived from the disciples of Nestorius, who were found very early on the coasts of Malabar. But this, Mr. Bryant thinks, is a groundless supposition; because the religious facts, among which these writings have been preferred, are widely separated, and most of them have no connection with Malabar or the Christians of that quarter. And besides, the Brahmins and Banians adhere closely to their own rites, and abhor all other persuasions; and they are influenced by customs and ceremonies, which prevent their intercourse with other people. In their writings there occurs no trace of Christianity, or of its founder; and hence Mr. Bryant infers, that whatever truths may be found in the writings of these people, they were derived from a higher source, and by a different channel. See Anal. of Anc. Mythology, vol. iii. p. 599, &c.

We shall terminate this article with adding, that Dr. Hyde presented the copy of part of the Zend writings in his possession to the university of Oxford; and that the whole Zend was afterwards brought from India by Mr. Frazer, and is lodged with his other oriental MSS. in the Radcliff library at Oxford.

ZENDERO, in Geography. See GINGIRO.

ZENDEROU. See ZEINEROOD.

ZENDGIN SERAI, a town of Grand Bushire; 30 miles S. of Samarcand.

ZENDOFF, a town of the duchy of Sturia; 12 miles E. of Landipperg.

ZEINECHDON, a term used by the Arabian physicians for a preparation of arfenic, for external use; seeb being their name for arfenic.

ZENEXTOR, one of the many names by which the chemists have called mercury.

ZEGAN, ZENIGAN, or ZINJAN, in Geography, a town of Perfia, in the province of Peria, said to have been fortified many years before the Christian era, and at one time to have contained 20,000 houses. It was entirely destroyed by Timur Bëc when he first passed through that part of Peria; but being informed that it had long been the seat of learning and science, on his return from Turkey he in part rebuilt it. Since that time it has been frequently sacked and destroyed by the Tartars and the Turks. It contained in the 17th century about 2000 houses. It is a large, and now apparently a prosperous town, capital of the extensive district of Kuch, which is 71 miles down an uneven country, full of deep ravines, from hence to the banks of the Rizilok.
ZENITH.

as to its direction, when viewed by a spectator; yet as it has reference to the apparent place of a heavenly body, it is not fixed, because the earth's motion is continually carrying the spectator's eye in a circle that produces the optical effect of an apparent circumpolar revolution of the celestial bodies. Whatever point of the hemisphere is at any moment vertical to an observer on any part of the globe, that point is the zenith for the time then passing, and will again be the zenith, or very nearly so, after an interval of one complete rotation of the earth; and, therefore, strictly speaking, in every place there are as many successive zeniths in this period, as there are appreciable points in the circle generated in the heavens by the superior end of the vertical line carried round by the globe in rotation.

Because every point of the horizon is just 90° distant from the exzilting zenith, in every place, and at all times, it will be readily apprehended, that the complement of the altitude of any heavenly body will, at any instant, be the angular distance of that body from the zenith of the place of observation; but as this distance varies inversely with the altitude, it is more properly called the co-altitude than the zenith-distance, the former being a variable, and the latter a limited quantity. The zenith-distance of any star is properly the complement of its meridian or greatest altitude in any given place, and as the latitude of the place varies, so will the zenith-distance of the same body, but inversely; the distance of the zenith to the pole being always the complement of the latitude. Hence it is obvious, that when the zenith-distance of a star is observed by any instrument that measures it accurately, the latitude of the place may be inferred from the tabular polar distance of that star, as well as from the declination, which is its complement; and, therefore, it is a matter of no importance in theory, whether the altitude or zenith-distance of a body transting the meridian be taken, for the purpose of ascertaining its place in the heavens, when the altitude of the observer is known, or for the purpose of determining the latitude of the place, when the declination, or polar distance of the body, is known. Accordingly, in the circular instruments that have been recently introduced into observatories, and that will revere in position, it is usual to number the divisions and subdivisions so, that when they read altitudes with the graduated plane facing the east, they read zenith-distances (on the meridian) when the fame is made to face the west, and vice versa; so that not only are the opposite errors of collimation of the telescope and of the bubble or plumb-line thus corrected, but when atmospheric refraction is allowed for, the sum of the two readings, or of the averages of several, will be exactly 90°, or otherwise 180°, if the observations be truly taken, and the instrument duly adjusted for zero and collimation; which check is of great practical importance in the delicate operations of the astronomer.

Zenith-Sector is an astronomical instrument, by means of which the angular distance of a star is accurately measured from the zenith point of any given place towards the north or south. The first instrument made use of for this purpose was contrived by Dr. Hooke, with a view of determining the annual parallax of a fixed star, agreeably to the gullion of Galileo. The telescope, which Dr. Hooke, in the year 1669, made the essential part of his instrument, was thirty-six feet long, the principle of achromatism not being at that time practically applied, so as to allow of considerable power with a short focal distance of the object-glass; but the length of the radius of his arc of measurement promised advantages over every other instrument, which justified the conception and execution of the plan, though its accomplishment failed of corresponding success. Indeed, the nice arts of constructing achromatic telescopes, and of dividing the arc of a circle with extreme precision, had neither of them yet been perfected. From the Cutlerian Lectures we learn, that the first observation with this instrument was made on the 6th of July of the above-mentioned year, on the star denominated γ Draconis, which, on that evening, was found to pass at the distance of 2° 12′ to the north of the zenith of Gresham college; which was also found to be the case on the 9th of the same month; but on the 6th of August next following, the distance was only 2° 0′; and on the 21st of October after only 1° 48′, or 1° 50′; whence it was concluded, that the measurement of a zenith-distance taken by this instrument was liable to an error of 24′, or perhaps more; and it was considered, therefore, that the instrument was quite incompetent to the purpose for which it was intended. But an original idea once suggested, as the basis of useful speculation, is not readily abandoned, even under an apparent want of successful application. The Hon. Samuel Molyneux afterwards availed himself of the manual skill of the ingenious Graham, and by the assistance of Dr. Bradley put up a zenith-sector at Kew, in the year 1725, which turned out to be much more accurate than its predecessor, though the focal length of the object-glasses of its telescope was only 244 feet. With this instrument, and with one of about one-half its focal length, were made two of the most important discoveries in astronomy that have graced the annals of this science; viz. the nutation of the earth's axis, and the aberration of light in its passage from the heavenly bodies. As the history of astronomical discoveries, and that of astronomical instruments, are mutually illustrative of each other, and as a detail of the minuscule is always interesting, that connect great refults with primary measures, that might otherwise be considered as insignificant, we will make no apology for introducing here Dr. Bradley's own account of his proceedings, as inferred in the Philosophical Transactions of London, No. 406, p. 149 of the Abridg.

"The following observations," says the author, "were begun by the honourable Samuel Molyneux at Kew, continued and repeated by myself at Kew and Wanstead, in hopes of verifying those that Dr. Hooke formerly communicated to the public, concerning the parallax of the fixed stars. (London, 1674.) Therefore the same star was made choice of by Mr. Molyneux, almost the same method followed and his instrument constructed upon principles nearly the same, but greatly exceeding the doctor's in exactness, which was chiefly owing to our curious member (of the Royal Society) Mr. George Graham, to whom the lovers of astronomy are also indebted for several other exact and well-constructed instruments. Mr. Molyneux's apparatus was completed and fitted for observing about the end of November, 1725; and on the 3d day of December following, the bright star in the head of Draco (marked γ by Bayer) was for the first time observed, as it passed near the zenith, and its situation carefully taken with the instrument. The like observations were made on the 5th, 11th, and 12th days of the same month; and there appearing no material difference in the place of the star, a farther repetition of them at this season seemed needless; it being a part of the year wherein no sensible alteration of parallax in this star could soon be expected. It was chiefly, therefore, curiosity that tempted me (being then at Kew, where the instrument was fixed) to prepare for observing the star on Dec. 17th, when, having adjusted the instrument as usual, I perceived that it passed a little more southerly this day.
ZENITH.

day than when it was observed before. Not suspecting any other cause of this appearance, we first concluded, that it was owing to the uncertainty of the observations, and that either the stars or the accompanying stars, or both, were not as we had supposed; for which reason we proposed to repeat the observation again, in order to determine from whence this difference proceeded; and upon doing it on Dec. 20th, I found that the star passed still more southerly than in the former observations. This sensible alteration was more surprising than that, in it was the contrary way from what it would have been had it proceeded from an annual parallax of the star; but being now pretty well satisfied that it could not be entirely owing to the want of exactness in the observations, and having no notion of any thing else that could cause such an apparent motion as this in the star, we began to think that some change in the materials, or of the instrument itself might have occasioned it. Under these apprehensions we remained some time; but being at length fully convinced, by several trials, of the great exactness of the instrument, and finding by the gradual increase of the star's distance from the pole, that there must be some regular cause that produced it, we took care to examine nicely, at the time of each observation, how much it was: and about the beginning of March, 1726, the star was found to be 20' more southerly than at the time of the first observation. It now, indeed, seemed to have arrived at its utmost limit southward, because in several trials made about this time, no sensible difference was observed in its situation. By the middle of April, it appeared to be returning back again towards the north; and about the beginning of June, it passed at the same distance from the zenith as it had done in December, when it was first observed.

"From the quick alteration of this star's declination about this time, (increasing a second in three days,) it was concluded, that it would now proceed northward, as it before had gone southward of its present situation; and it happened as was conjectured; for the star continued to move northward till September following, when it again became stationary, being then near 20' more northerly than in June, and no less than 30' more northerly than it was in March. From September the star returned towards the south, till it arrived in December to the same situation it was in at that time twelve months, allowing for the difference of declination on account of the precession of the equinox.

"This was a sufficient proof that the instrument had not been the cause of this apparent motion of the star; and to find one adequate to such an effect seemed a difficulty. A motion of the earth's axis was one of the first things that occurred itself upon this occasion; but it was soon found insufficient; for though it might have accounted for the change of declination in γ Draconis, yet it would not at the same time agree with the phenomena in other stars; particularly in a small one almost opposite in right ascension to γ Draconis, at about the same distance from the north pole of the equator; for, though this star seemed to move the same way as a motion of the earth's axis would have made it, yet in changing its declination but as much as γ Draconis in the same time, (as appeared upon comparing the observations of both made upon the same days, at different seasons of the year,) this plainly proved that the apparent motion of the stars was not occasioned by a real motion, since, if that had been the cause, the alteration in both stars would have been near equal.

"The great regularity of the observations left no room to doubt, but that there was some regular cause that produced this unexpected motion, which did not depend on the uncertainty or variety of the seasons of the year. Upon comparing the observations with each other, it was discovered that in both the fore-mentioned stars, the apparent difference of declination from the maxima was always nearly proportional to the versed sine of the sun's distance from the equinoctial points. This was an induction to think, that the cause, whatever it was, had some relation to the sun's situation with respect to those points. But not being able to frame any hypothesis at that time, sufficient to solve all the phenomena, and being very desirous to search a little further into this matter, I began to think of erecting an instrument for myself at Wanstead, that, having it always at hand, I might with the more ease and certainty inquire into the laws of this new motion. The consideration, like-wise, of being able by another instrument to confirm the truth of the observations hitherto made with Mr. Molyneux's was no small inducement to me; but the chief of all was the opportunity I should thereby have of trying in what manner other stars were affected by the same cause, whatever it was. For Mr. Molyneux's instrument being originally designed for observing γ Draconis, (in order, as I said before, to try whether it had any sensible parallax,) was so contrived as to be capable of but little alteration in its direction, not above seven or eight minutes of a degree; and there being few stars within half that distance from the zenith of Kew bright enough to be well observed, he could not, with his instrument, thoroughly examine how this cause affected stars differently situated with respect to the equinoctial and solstitial points of the ecliptic.

"These considerations determined me; and by the contrivance and direction of the fame ingenious person, Mr. Graham, my instrument was fixed up, Augst 19, 1727. As I had no convenient place where I could make use of so long a telescope as Mr. Molyneux's, I contented myself with one of but little more than half the length of his, (viz. of about 12½ feet, his being 24½,) judging from the experience which I had already had, that this radius would be long enough to adjust the instrument to a sufficient degree of exactness; and I have had no reason since to change my opinion: for from all the trials I have yet made, I am very well satisfied that when it is carefully rectified, its situation may be securely depended upon to half a second. As the place where my instrument was to be hung in some measure determined its radius, so did it also the length of the arc, or limb, on which the divisions were made to adjust it; for the arc could not conveniently be extended farther than to reach to about 6½ on each side my zenith. This indeed was sufficiently, since it gave me an opportunity of making choice of several stars, very different both in magnitude and situation; there being more than two hundred inserted in the British Catalogue, that may be observed with it. I needed not to have extended the limb so far, but that I was willing to take in Capella, the only star of the first magnitude that comes so near my zenith.

"My instrument being fixed, I immediately began to observe such stars as I judged most proper to give me light into the cause of the motion already mentioned. There was variety enough of small ones, and not left than twelve that I could observe through all the seasons of the year; they being bright enough to be seen in the day-time, when nearest the sun. I had not been long observing, before I perceived that the motion we had before entertained of the stars being farthest north and south, when the sun was about the equinoaxes, was only true of those that were near the terrestrial colure; and after I had continued my observations a few months,
months, I discovered what I then apprehended to be a general law observed by all the stars, viz. that each of them became stationary, or was farthest north or south, when they passed over the zenith at fix of the clock, either in the morning or evening. I perceived likewise, that whatever situation the stars were in with respect to the cardinal points of the ecliptic, the apparent motion of every one tended the same way, when they passed my instrument about the same hour of the day or night; for they all moved southward while they passed in the day, and northward in the night; so that each was farthest north, when it came about fix of the clock in the evening, and farthest south, when it came about fix in the morning.

"Though I have since discovered, that the maxima in most of these stars do not happen exactly when they come to my instrument at those hours; yet not being able at that time to prove the contrary, and supposing that they did, I endeavoured to find out what proportion the greatest alterations of declination in different stars bore to each other, it being very evident that they did not all change their declination equally. I have before taken notice, that it appeared from Mr. Molyneux's observations, that Draconis altered its declination about twice as much as the fore-mentioned small star almost opposite to it; but examining the matter more particularly, I found that the greatest alteration of declination in these stars was as the sine of the latitude of each respectively. This made me suspect that there might be the like proportion between the maxima of other stars; but finding that the observations of some of them would not perfectly correspond with such an hypothesis, and not being able to the uncertainty and error of the observations, I deferred the farther examination into the truth of this hypothesis, till I should be furnished with a series of observations made in all parts of the year, which might enable me not only to determine what errors the observations are liable to, or how far they may safely be depended upon, but also to judge whether there had been any sensible change in the parts of the instrument itself.

"Upon these considerations, I laid aside all thoughts at that time about the cause of the fore-mentioned phenomena, hoping that I should the more easily discover it, when I was better provided with proper means to determine more precisely what they were.

"When one year was completed, I began to examine and compare my observations; and having pretty well satisfied myself as to the general laws of the phenomena, I then endeavoured to find out the cause of them. I was already convinced that the apparent motion of the stars was not owing to a variation of the earth's axis. The next thing that offered itself was an alteration in the direction of the plumb-line, with which the instrument was constantly rectified; but this, upon trial, proved insufficient. Then I considered what refraction might do, but here also nothing satisfactory occurred. At last I conjectured that all the phenomena hitherto mentioned proceeded from the progressive motion of light, and the earth's annual motion in its orbit. For I perceived that if light was propagated in time, the apparent place of a fixed object would not be the same when the eye is at rest, as when it is moving in any other direction than that of the line passing through the eye and object; and that when the eye is moving in different directions, the apparent place of the object would be different."

The author then proceeds to deduce from his observations the relative velocities of light, and of the earth in its annual orbit; shews what variation in the right ascension and declination of stars differently placed may arise out of the aberration of light; and concludes that light, agreeably to such deductions, must travel from the sun to the earth in about 927.5 of time. (See Aberration, Light, and Stars.) The discovery of the earth's motion was not, however, published until the year 1737. See Nutation.

After our readers have seen what important discoveries and deductions have been derived from Graham's zenith-tractor in the hands of a skilful astronomer, they will be naturally disposed to become acquainted with its construction, which we will now proceed to describe.

Zenith-tractor by Graham.—The zenith-tractor that we have said Graham made for Mr. Bradley, afterwards Dr. Bradley, was removed to Greenwich, where the proprietor became astronomer royal, and is the same instrument which Dr. Maikelyne used with great success in adjudging, by comparison, the zero of the large quadrants. It still remains at Greenwich, and is yet capable of measuring zenith-distances to the accuracy of half a second, according to Bradley's original report, or even less. Fig. 1. of Plate XXXIII. of Astronomical Instruments, is a representation of the essential parts of this instrument: A B represents the iron tube of the vertical telescope, which is suspended by two small metallic cylinders projecting at right angles from the inferior end, one of which is seen at a, and the other is hidden by the tube. These cylinders, which constitute the axis of motion, revolve in a pair of Ys, attached to the fold wall facing the north, and also occasionally to another pair fixed to a wall facing the south; which additional pair allows the ends of the cylinders, or axis of motion, to be reversed in position. The brass bar CD is fixed to the same wall to which the pair of Ys are attached, at opposite sides of the room, and bears a cock to which the micrometer-screw E is fixed, which measures the fractional portion of a minute on its head b; and the second screw e is made to relieve it. The ends of these screws press against fluids inserted into the tube of the telescope, while the weight F pulls a string round the fixed pulleys G and H, by means of a pliable cord, attached to the tube at the point d, and keeps the telescope home. The graduated arc IK contains 125°, each subdivided into twelve parts, or five minute spaces, and is fixed exactly at right angles to the tube, over the point where the wires intersect the field of view. This arc was originally of brass, but Sisson put on an arc of steel, containing gold pins to receive the divisions of division. A plumb-line suspended from the superior end of the tube, over the centre of one of the cylinders a, and having an adjusting screw e, to bring the point of suspension to the upper dot, falls near the face of the arc, and indicates the distance from zero at the middle of the arc; if the plumb-line covers one of the dividing dots of the scale, when a star near the zenith is cut by the horizontal wire, then the quantity is read by the plumb-line and arc alone; but otherwise the fractional portion is ascertained by means of the micrometer-screw, which is made to press against the tube until the suspended line coincides with the next nearest dividing dot of the scale. The value of the micrometer-head, which is divided into thirty-four equal parts, was ascertained by trying how many revolutions of the screw would measure a degree, or other portion of the arc, exactly; and on an average of several trials made in different parts of the arc, it was ascertained, that one revolution was not precisely 34°, but 33° 528', and one of its divisions on the head, therefore, only 9° 4892', instead of 10°, as was intended by the maker. The instrument had originally a single lens for its object-glass; but at the request of the late Dr. Maxkelyne, Mr. Dollond substituted
situated an achromatic object-glas, which has modernized the instrument, and put it nearly on a level with the new instruments which have lately been constructed and erected in the Royal Observatory by Troughton, on the best principles. If the zenith-sector had been made to reverse in position in the same situation, i.e. without being carried across the room, its use would have been more convenient, and the observations more certain. As much as the fame distance would have been preferred between the axis of motion of the telescope, and the point acted upon by the micrometer-crew, without any refuling allowance. Besides, the instrument would have been less liable to accidents; and reversed observations might probably have been made on the fame evening. When Bird afterwards made a zenith-sector for the Oxford Observatory, he noticed these inconvieniences, and obviated them by making the tube of the telescope turn round in its own place, so that the positions of the axis can be reversed by an azimuthal motion that carries the plumb-line round at the fame time; and when the plumb-line will cover the dot at zero during this whole motion, the telescope is truly vertical.

The adjustment for collimation is effected by an apparatus that serves the wires in the eye-piece, as in the transit-instrument, and may be thus effected: Let the graduated arc face the east, and view a star passing in or near the zenith, the proper time for doing which may be known from the star’s right ascension, by means of a fidereal clock, or by conversion of solar into fidereal time, and note the distance from zero when the plumb-line is quiet, which it will soon be if the plummet is immersed in a goblet of water, and mark down this quantity as read partly by the divisions on the scale, and partly by the micrometer-head; which call the eastern measure with N. or S. annexed, accordingly as the star passes to the north or south side of the zenith point; then reverse the position, and on a succeeding night, which will be 5°56' sooner on every successive night, measure the zenith-distance of the same star in like manner with the graduated scale facing the west; and call it the western measure; then if the two quantities thus measured be similar, the collimation for zenith-distance will be true; but if otherwise, one half of the difference of the two readings will be the error of collimation, which may be either corrected by the proper apparatus at successive trials, or which is perhaps better, may be allowed for in each observation. When the instrument has been used for several observations, it will be still better to take an average of all the observed errors, as ascertained by different stars, and to apply it with its proper sign in future single observations, so long as the instrument remains in all respects unaltered. It is hardly necessary to observe, that in using this instrument, when a star is very near the zenith of any place, the micrometer alone, without reference to the graduated scale or arc, will give the true measure. How the altitude of any place may be very accurately determined from the measured zenith-distance of a star, of known declination, will be seen presently.

**Zenith-sector by Ramdjen.**—While the trigonometical survey of England was carrying on, it was found desirable to have a portable zenith-sector to assist in measuring an arc of the meridian, and as Ramdjen had one in an half-finished state, that had been ordered by the duke of Richmond, the parties were prevailed on to have this finished for the purpose, which was nearly done in Ramdjen’s life-time, in the year 1801, and completed in April 1802 by his successor Berge. It was first tried at Greenwich, and then removed to the Isle of Wight, where the operations began, and from whence they were continued northward from Station to Station, as described in the “Trigonometrical Survey,” by captain William Mudge, and published from time to time by Mr. Faden, of Charing-Crofts. The original account of this complex instrument has reference to fix large plates, and is too long for us to copy. (See vol. ii. p. 6. & seq. of part ii.) Fig. 2. of our Plate XXXIII. of Astronomical Instruments, gives a reduced perspective view of this instrument. From an examination of which a better idea will be formed of its general construction than by any detailed account we can give of its parts without the additional plates.

Captain Mudge says, “that Mr. Ramdjen has here obviated the inconveniences attendant on the use of former sectors; and has also diminished, in a very considerable degree, the errors unavoidably resu[ling from their imperfect construction. The principles, he adds, on which he has founded the several improvements, consist in the means of uniting the sectorial tube to its axis, so as to ensure the permanency of the length of its radius, when erected for observations; more accurate methods of adjusting the instrument vertically; and an easy way of placing the face of its arc in the plane of the meridian.” The frame exhibited in our figure consists of two parts; the external fland of mahogany, which supports the apparatus to which the sectorial tube is attached; and an inner frame, containing that apparatus with the tube itself. The fland, or outer frame, is in the shape of an obtuse pyramid, having a base six feet square, and its vertex three. It unites strength with simpidity of construction. The inner frame, within which the sector is suspended, is supported at top in every lateral direction, while its lower extremity is terminated by a cone reposing in a metallic concavity, on which it turns in azimuth; and it can be kept in any position by a clamping apparatus acting with an azimuth circle, made fast to the bottom of the external frame. The telescope of the sector has an object-glass nearly eight feet long, with an aperture of four inches, near which is made fast the tranverse axis of motion, similar to that of a transit-instrument. The wires of the eye-piece of the telescope are illuminated by reflected light, entering the axis in the usual way; and a plumb-line, with the ghost apparatus for adjustment to zero, is made a leading feature in the construction. The arc is divided into 15°, which was the concluding work done by Berge, and each degree is subdivided into 5' spaces, as in Graham’s instrument. A second telescope, of 29 inches focal length, is attached to the long tube, and moves in the plane of the divided arc to any given elevation, but partakes of the azimuthal motion when the lower vertical telescope is turned round; so that this 29-inch telescope horizontal angles are measured, by the help of the azimuth circle, which therefore is divided for this purpose. Besides these essential parts, there are various appendages and bracing parts, rendered necessary by the size of the instrument, particularly a microscopical tube reaching up to the upper dot of the plumb-line, and bent at both ends into a horizontal position for convenience of the observer. This contrivance required reflectors, both of the light, and of the image of the piece of mother-of-pearl that is bifected by the wire, constituting the plumb-line. The micrometer measures minutes and seconds in the usual way, and the plummet is immersed in a small vessel of water to prevent vibration. We mention these particulars generally, not only because their particular uses and modes of application have been previously described, when we explained other instruments, such as Circles, Equatorials, Transit-Instruments, &c.; but because this instrument has furnished hints to others who have copied in part, or wholly, several
several of Ramsden's contrivances. It was moreover necessary to introduce various weights, pulleys, cords, springs, \&c. to facilitate and keep steady the motions of the different acting parts, which, together with the reading microscopes, lamps, rods, and adjusting screws, give the instrument the appearance of great complexity.

The manner of adjusting the instrument for observation is thus performed, according to Mr. Mudge's own words; viz. "The feet of the external stand should be first carefully brought into a horizontal plane; and when they are so, the azimuth circle will be necessarily parallel to it, having its centre under the middle of the opening in the mahogany frame screwed on the top of the stand. This being done, and the instrument set up, the plane of the arc should be brought parallel to one of the sides of the stand, in which situation the internal frame is to be clamped to the azimuth circle, and the wire brought to its proper distance from the limb, by means of the adjusting screw attached to one of the slides, which carries the concave receptacle and conical point. The dot at zero should then be brought exactly under the plumb-line, as seen through the magnifier, and the point on the micrometer-head, at which its index stands, noted. The instrument is then to be turned half round, and if the same dot on the arc still continues bisected, it will afford a proof of the internal stand being upright in one direction. But if the dot should not continue bisected by the plumb-line, it must be made to do so, and the revolutions, or parts of a revolution, counted; half of which is to be turned back on the micrometer-head. The same dot, zero, is then to be brought under the plumb-line (wire), by means of the other adjusting screws, beneath the azimuth circle. If the stand is pretty accurately set up, one operation is sufficient for bringing the interior frame upright in one direction, viz. either in that of the meridian, or the one at right angles to it. The arc is then to be turned round 90°, and the same operation gone through. This being properly done, the interior frame is made perfectly upright. The next step to be taken is that of placing the long level on its axis above, and rectifying that axis by means of the Y plate screws. If this be done carefully, the bubble will remain between the pointers of the level, whatever position the sector may be placed in. Having thus rectified the instrument, by making the internal frame upright, and the axis horizontal, the only remaining point to engage attention is, placing the plumb-line at a proper distance from the arc: this is done by means of the screw acting on the spring jutf under its point of suspension. If great care be used in going through these several adjustments, the instrument may, at any future time, be accurately adjusted for observation by turning the proper screw belonging to the azimuth circle, and bringing the arc to its usual distance from the wire."

In order to shew the accurate results that may be obtained from an instrument of this description, and also the care that is necessary in using it, and in clearing the observations of errors arising from natural causes, we will subjoin a few Tables that were found useful in the grand trigonometrical operations, by means of which, in the years 1802 and 1806, the meridian arcs were compared with the corresponding terrestrial measurements.

**Table shewing the Runs of the Micrometer-Screw over every Five Minutes in the First Degree on each Side of Zero.**

\[ X = 2 \]
ZENITH.

Besides these observations, various others were taken of different stars in Draco, Cygnus, Ursula Major, Hercules, Perseus, and Auriga, from an average of all which the final results were obtained; but before the true or mean zenith-distances can be exactly known, the apparent measures must be corrected by certain equations for aberration, nutation, semi-annual solar equation, precession, and refraction; the Tables proper for which are chiefly given under our article Declination.

It was deemed sufficient for our purpose in this place to confine ourselves to the consideration of the observations made on γ Draconis alone, which being a star of the second magnitude, and very near the zenith of London, and of the southern parts of England, was considered as the best object. We will therefore subjoin the reduction of the observations made on this star by way of illustrating their application in practical astronomy.

Reduction of the Observations contained in Table I.

In obtaining the latitudes of the two last places, the declination of γ Draconis is diminished 3° to bring it to the year 1806, and in all the cases where S is annexed to the zenith-distance, it is added to the declination. The reductions are made to the first of January of the respective years, and the latitudes come out very nearly the same as those determined from terrestrial measurement, and also from an average of all the observed stars.

"From the observations made at the station in Delamare forell with the zenith-flector in 1806, combined with those at Dunmore, 1802, taken with the same instrument," says the author of the Survey, "it is found, that the difference in latitude of those is 2° 36' 12.2" (by γ Draconis alone in our examples 2° 36' 11.73"), making a difference of 1" between the calculated and observed amplitudes, which, fetting aside the consideration of the spherical figure of the earth, is at the rate of 1" in a second in one degree. Perhaps, under the consideration of each meridional line being obtained independently of the other, and admitting that neither of them can be measured with perfect accuracy, together with the chances of the amplitudes being in some small degree either in excess or defect, we may consider the result as sufficiently consistent and satisfactory, and may take 60823 fathoms, in latitude 52° 34', or the centre of England, as the length of 1°."* Trigonometrical Survey, vol. iii. p. 332, &c.

ZENITH-MICROMETER is an instrument of very recent date, and is scarcely yet known to the generality of astronomers. It differs from the zenith-flector in this respect; that the measures taken with it are all taken within the tube of the telescope, whereas those taken by the zenith-flector are all external: consequently the range of the zenith-micrometer's scale is confined to the extent comprised within the field of view, which will always be inversely as the magnifying power of the glasses used; hence the greater the power of the telescope, the smaller the number of stars that will pass within the range of the micrometer-screw; but then corresponding accuracy may be expected from the great powers and delicate construction of modern micrometers; and what is wanting in the extent of the scale will be made up by superior precision. The telescope, which constitutes the basis of the zenith-micrometer, may be either of the reflecting or refracting construction; and within a short space of time one of each description has been constructed; the former by Troughton, for the Greenwich observatory, and the latter by Dollond, for the use of those geodetic commissioners, who are employed by the English government to ascertain the proper line of demarcation across the American lakes. We will give a short account of each of these instruments, such as will enable our readers to form an opinion of their respective merits, as prototypes for future imitation.

Zenith-Micrometer by Troughton.—It is probable that the first
first idea of a zenith-micrometer occurred to Mr. Troughton, and certain that he was the first who executed one, and gave it its name. It was in 1806 that he proposed it to Dr. Maldeyne, and in 1812 that he erected it at the Royal Observatory, as an appendage to the mural circle.

The telescope of this instrument is a Newtonian reflector, the tube of which forms the vertical axis, through which axis a plumb-line passes centrically from end to end; and, therefore, is not made to vibrate by turning. The tube or axis, 10 feet long, and 5 inches diameter, at the lower end terminates in a pivot, while the upper end is received by a right angle, against the sides of which it is gently pruned by two springs; contrivances which produce free and steady azimuthal motion.

All the zenith instruments require for collimation two positions, which in the sectors are called face east and face west; two at 180° distance from each other are equally necessary for the micrometer, and in that under consideration are indicated by the contact of stops, without regarding any divisions.

The large mirror at the lower end, as well as the pivot, are perforated, in order that the plumb-line may pass freely through them, the latter sublimating the plummet in a water vessel several inches below. The axis of the mirror is somewhat inclined to that of the tube, for the purpose of placing the plane mirror out of the way of the plumb-line, which latter, as before observed, occupies the centre. The rays of light, thus rather obliquely reflected up the tube, are turned into a horizontal direction by the plane mirror, and come to a focus a little beyond the side of the tube, where, with appropriate adjustments, is fixed a double micrometer for measuring zenith-differences.

When the instrument is floated with the micrometer toward the south, one of the moveable wires is made to bisect a star a little before it comes to the centre of the field of view; then the instrument is turned to the opposite side of the micrometer towards the north, which may be done in three seconds, and then the other moveable wire is made to bisect the star. It is evident now, that the opening between the wires is double the zenith-difference of the star, and if the axis was truly vertical, the middle between them is the point zenith. The revolutions of the screws are counted in the field of view, and the parts to the third decimal figure read off upon the micrometer heads, which revolutions and parts are to be reduced to angular measure.

The plumb-line is suspended from a fixed point at the upper end, and near the lower end is a rectangular arrangement of microscopes with adjustments, which, together with the adjustments of the pivot, accomplish the means of bringing the axis and plumb-line coincident with each other, and of affuring the vertical position of the former.

The conception of this instrument was not confined to a reflecting telescope, it was seen that a refracting one would succeed equally well: in the latter case, the pivot at the lower end must be perforated to receive the eye-glasses, and the plumb-line should be exterior to the main tube, but included in a smaller one to protect it from the action of the wind. In the case of the Greenwich instrument, of which the foregoing is a description, the reflector was preferred on account of its allowing the central portion of the plumb-line, which, being free from vibration, shortens the time required for adjustment; a consideration indeed of very little value; for it is now known (but was not then) that instruments properly contrived, and used with care, which they now are at our national establishments, seldom or never want re-adjustment. A better caue for adopting the reflector was, that the horizontal view is more easy than the vertical one, especially as in the former the hands and whole body are unembarrassed, and fit for action. But whichever construction of the telescope is employed, we know that Troughton considers the zenith-micrometer as one of the most elegant of his inventions.

Zenith-Micrometer by Dollond. — The zenith-micrometer which is represented in Plate XXXIII. by figs. 3, 4, 5, and 6, has great advantages in the simplicity of the construction and use, that former instruments for the same purpose do not posses, and is portable: the plan was proposed by Mr. Pond, the astronomer royal, and the instrument executed by Mr. Dollond for transatlantic measurements. It is drawn from a scale of two inches to the foot, and is represented without a flat or support. It can be applied to either, as occasion may require. The component parts are the; viz. an achromatic refracting telescope A A, (fig. 5, 4,) of 42 inches focal length, with an aperture of 2½ inches; a micrometer B, with two screws, each moving a separate wire through the field of view, which is extended in two degrees. The transverse axis C is 18 inches long, and glazed for a telescope, with cross wires that adjust, so that when the principal telescope A is taken out, (and for which there is a provision,) the line of collimation may be truly adjusted to the pivots, and when replaced will be correctly at the angles to the principal telescope. The use of the axis being formed into a telescope, is, for the purpose of placing the instrument correctly in the meridian, by a mark that must be found to the east, and also by another to the west, so that when the star has been observed with one of the micrometer wires, and the instrument is changed for the purpose of observing the same star with the other micrometer wire, it may be correctly replaced, the mean of the two observations being the correct zenith-difference. The instrument is also furnished with a plumb-line D, and with a dot in E, the image of which is brought to the place of the plumb-line by a lens; this is known by the name of the mill adjustment. The plumb-line is suspended from a piece at F. The two screws G G are used for bringing the dot carried by the telescope, to coincide with the plumb-line; and is observed to be by the lens at H. This contrivance affords one of the greatest advantages of the instrument, as it enables the observer, at the moment before he observes the conjunction of the star with the micrometer wire, to ascertain the correct position of the instrument by the plumb-line; for the correctness of the observation will depend on the accuracy with which the plumb-line is made to coincide with the dot; and by this method the error of division is done away. The level (fig. 6.) is used for levelling the axis, and the circular piece (fig. 5.) with the Ys a a attached, in which the pivots of the transverse axis rest, may be applied to a mahogany-framed plumb, or on a stone pier, or bracket: it is represented as it was made for a mahogany stand (which had adjusting screws at the feet); it consists of two strong brass plates, and is furnished with a circular motion for bringing the instrument into the meridian, which motion is given by a pinion b; and it is made fast by the four screws e, e, e, e. The two adjusting screws G G, (fig. 3.) must also be attached to a bracket or framed piece in the stand; and the support for the water, in which the plummet is immersed, may also be applied to this bracket. The wires are illuminated through the axis in the same manner as in the transits-instrument. The value of the micrometer-screws is to be found in the usual manner, and reduced into seconds.

The foregoing are the distinguishing properties of this instrument,
infirment, and as the method of using it may be understood sufficiently from what we have said of the zenith-ßector, from which it differs only in the small range of its scale, it will be unnecessary to give any further explanation of either its adjustments or practical application.

Other Instruments.—Besides the zenith-ßectors and zenith-micrometers, which we have above described, there are other instruments, which may be used as substitutes for these, at the same time that they may be used for their own respective purposes. Of these, the tranfit-circles of large dimensions, particularly those which move with their pivots supported by ﬂone piers, claim our principal notice. As the professed use of these circles is to ascerten both right ascensions and declinations at the same time, and as zenith-distances are only complements of altitudes taken in any latitude, it is obvious, that those instruments that measure altitudes accurately, atall elevations, will also measure zenith-distances, or their complements; and in fact, the divisions are now numbered in such way, that altitudes and zenith-distances are read alternately in the reversed positions. Of this description is the excellent circle of Mr. Groombridge at Blackheat; but the large circle at Greenwich, not having a plum-line or level used, nor being capable of reversion, is not of the same clafs; though a very superior instrument for its own purpose of measuring polar distances from the exact polar point, without any reference to latitude, altitude, or zenith-distance.

We have also before us an 18-inch tranfit-circle with a 34 feet telescope, very lately made by Mr. Thomas Jones, of Charing-Crofts; the axis of which is supported by a califon frame, that very conveniently admits of measures being taken in or near the zenith, as well as in any other degree of elevation. This instrument comprises many new and useful contrivances, but they cannot be described under this head, conﬁdently with our general plan of dividing our subjécts.

Zenith is a word used by some writers to express the ﬁrst appearance of the menes in young women.

ZENKABAD, in Geography, a town of the Arabina Irak; 22 miles S. of Sherban.

ZENKOY, a town of Russia, in the government of Tchernigov; 140 miles S.E. of Tchernigov. N. lat. 50° 19'; E. long. 34° 14'.

ZEN, a river of Franconia, which runs into the Rednitz, near Vacha, in the margrave of Aspach.

ZEN. See LANGENZEN.

ZENNAR, the name of a mythical word worn by Brahman, and by many individuals of other tribes of Hindoos. So prolix and minute are the authors of the Ordinances of the Hindoos, that rules for almost every occurrence of life, however trifling, have been laid down. Not that any thing connected with the zennar has been deemed trifling by those who ordained it, by those who wear it, or those who revere it. On the contrary, the individuals to be so distinguished, the mode of manufacturing the sacred article, and its invetiture, with many particulars, have occupied the attention of lawgivers, and are attended to with great respect by their obedient followers.

Brahmans afert to consider the zennar as of highly mysterious and sacred import, and do not consider an individual as fully a member of his tribe until he have assumed this holy emblem. A Brahman should be invested with it at the age of eight years, by the hands of his father, who, with his Guru, or spiritual preceptor, twirls that ﬁrst put on. A Kshtetriya receives it at eleven, from a Brahman. A Vaiyeya at twelve years of age. A Sudra is on no account permitted to wear it. A description of these four grand divisions, comprising the whole race, will be found under SECTS OF HINDOOS.

The zennar must be made by a Brahman: it is composed of three threads, each measuring ninety-six hands, twined together, and folded into three; then twined again so as to consist of nine threads: these are again folded into three without twirling, and each end fastened with a knot. It is put over the left shoulder next the skin, and hangs down the right thigh as low as the fingers can reach. Of these cords a Brahman wears four; the other privileged tribes but three. Some writers call this the Brahmanical, or priestly, oracerodotal thread; but not, it would appear, in strict correctness; it not being confined to the priestly tribe, but worn, as we have seen, by three out of the four sects of Hindoos.

In the Institutes of Menu (see Menu), c. 11. v. 36. the revered legislator ordains, that "in the eighth year from the conception of a Brahman, in the eleventh from that of a Kshtetriya, and in the twelfth from that of a Vaiyeya, let the father invest the child with the mark of his clafs."

The two next verses allow, on particular occasions, the assumption of the sacriﬁcial thread, as it is often called, in the ﬁfth, sixth, or eighth years respectively; or it may, in like manner, be delayed until the individual be double the age mentioned in verse 36. "After that, all youths of these three clafses, who have not been invested at the proper time, become outcasts, degraded from the Gayatri, and contemned by the virtuous," v. 39. Of the Gayatri, see under our article O'M.

In ancient books, the three ﬁrst clafes, from being thus invested with this sacriﬁcial thread, are called twice born: a regeneration being effected by this mythical second birth. But it has been thought, that in later times, the Brahman only has the advantage of being thus born again. The term twice born is very common; a third birth is sometimes mentioned: this, we believe, is at the decease, or the burning of the body. "The ﬁrst birth is from a natural mother; the second, from the ligation of the zone; the third, from the due performance of the sacriﬁce: such are the births of him who is usually called twice born, according to a text in the Veda. Among them, his divine birth is that which is distinguished by the ligation of the zone and sacriﬁcial cord; and in that the Gayatri is his mother." Menu, ii. 159, 170.

This cord is never taken off; even when sleeping and bathing, it is worn and disposed of in a particular manner. When worn out, it is committed to the water with due and appropriate ceremony, and another is as duly put on. It is seen on the most ancient of Hindoo sculptures, and on many of the ﬁgures; for insance, in the cavern temple at Elephant. (See MAHAKAL.) It has several other names; among them Janvi, or Jahnui, Maurvi, &c. The latter is applied to the cord of the military tribe, being made from the leaves of a species of hyacinth, called murva, of which bow-strings are also made: the Brahman's cord is made of cotton. The name Jahnui given to this sacred, triple, mythical, regenerating thread, has been derived from Jahnui, an ascetic, who, in a very extravagant way, gave a second birth to the equally sacriﬁced, triple, mythical, regenerating river Ganga (the Ganges), which is hence called Jahnui. Of this we have taken some notice under JAHNU; and of the triple union of the Ganga, and other sacred rivers, under TRIVENI.

Brahmans, and their enthusiastic followers, are very mystical concerning regeneration, and have divers modes of effecting the second birth, in cases where the purity derived from the ligation of the zone, or invetiture with the sacriﬁcial thread,
thread, hath been lost by the contaminations of unlawful sects, as from accidental deslements. Of this, see under our article YONI.

ZENO, in Biography, called the Elean, in order to distinguish him from Zeno the Stoic, was a native of Elea, in Magna Graecia, and said to have been the adopted son of Parmenides, whose disciple he was, flourished about the year 463 B.C. and chose to live in his native city rather than at Athens, for the sake of maintaining his independence. He is represented as a zealous friend of civil liberty, and as having lost his life in his opposition to a tyrant. It is said, that having been detected in a conspiracy against the petty tyrant of the place of his nativity, he endured the most cruel torments, because he would not betray his accomplices; and that at length his countrymen, routed by his fortitude, fell upon the tyrant and stoned him to death. To him the invention of the dialectical art has been erroneously ascribed.

According to Aristotle, Zeno taught that nothing can be produced either from that which is similar or dissimilar; that there is only one being, and that is God; that this being is eternal, homogeneous, and spheroidal, neither finite nor infinite, neither quiescent nor moveable; that there are many worlds; that there is in nature no vacuum; that all bodies are composed of four elements, heat and moisture, cold and dryness; and that the body of man is from the earth, and his soul an equal mixture of these four elements. He argued with great subtlety against the possibility of motion. If Seneca's account of this philosopher deferves credit, he reached the highest point of scepticism, and denied the real existence of external objects.

Upon the whole, his sentiments seem to have been so fluctuating and unstable, and his method of arguing so fallacious, that it is not certain whether he allowed or denied a properly divine nature. Molheim, not improperly, applied to the doctrine of Zeno the words of Terence:—

"In certa hac, si tu postules
   Ratione certa facere, nihilio plus agas,
   Quam si des operam, ut cum ratione infanias."

"Things thus uncertain, if by reason's rules
   You'd certain make; it were as wise a task
   To try with reason to run mad."  — Colman.

Bayle depreciates the practical philosophy of Zeno, on account of his vindication of the warmth with which he refuted reproach, by saying, "If I were indifferent to censure, I should also be indifferent to praise." His works, though unknown to the moderns, were held in high estimation among the ancients. Diog. Laert. Bayle. "Brucker by Enfield, vol. i.

Zeno, the founder of the Stoic sect, was born about the year 366, before Christ, and died, as it is said, in the 11th year of the 129th Olympiad, or 264 B.C. For an account of him, see the article Stoics.

Zeno, Roman emperor of the East, was a descendant of an Ifaurian family of distinction, and at first bore the name of "Traflacillus." Being a commander of the Ifaurian troops in the service of Leo I., he married Ariadne, a daughter of the emperor, who created him a patrician, and raised him to the chief command of all the armies in the East. Upon the death of Leo in the year 474, the empire was transmitted to his grandson by Zeno and Ariadne, and Zeno, by the influence of the dowager-empress Verina, was appointed his colleague, and when the young emperor died, Zeno policed the whole imperial power. But Verina, being incensed by his scandalous conduct, formed a conspiracy against him, so that Zeno was obliged to seek refuge, first at Chaledon, and afterwards in Ifauria, his native country. Baithicus, the emperor's brother, who had assumed the empire, became so unpopular, that Zeno was restored, and the degenerated emperor perished in prison. About this time the western empire terminated; and Zeno, accompanied by deputies from the Roman senate, which he recognized as the vestige of universal empire, and requested the title of patron to Odoacer, proclaimed king of Italy, was flattered with the title of sole Roman emperor, and commenced an amicable correspondence with Odoacer. The remaining period of his reign was both turbulent and inglorious. The insurrections against his government were numerous, and his temper, which was naturally feverus, was thus rendered more hasty and cruel towards those whom he considered as his enemies. The irritability of his disposition proved eventually a collateral cause of his death, by aggravating a disorder in his bowels, which proved fatal in the year 491, at the age of 65, after a reign of seventeen years and three months. His widow Ariadne married very soon after his death. His reign was famous for the conciliation of faith, called the Henoticus, or Henoticus, (which see.) Gibbon's Hist. Rom. Emp. vol. vi. vii. viii. Zeno, in Geography, a river of Italy, which runs into the Taro, opposite Fornovo, in the duchy of Parma.

ZENOBIA, Queen, in Biography, was a native of Syria, in the third century, who claimed descent from the Macedonian kings of Egypt. This female was celebrated for the beauty of her person, the harmoniousness of her voice, her mental talents and literary acquirements, and her distinguished heroism and valour, as well as her modesty and chastity. "Her manly understanding," says Gibbon, after recording her personal beauties and excellencies, "was strengthened and adorned by study. She was not ignorant of the Latin tongue, but professed in equal perfection, the Greek, the Syriac, and the Egyptian languages: she had drawn up for her own use an epitome of oriental history, and familiarly compared the beauties of Homer and Plato, under the tuition of the sublime Longinus." She was allied by marriage to Odonatus, king of Palmyra, and delighted in those exercises of war and the chase to which he was devoted. Many of his victories have been ascribed to her military skill and valour. After the death of her husband, about the year 267, she assumed the sovereignty of the East, and governed with equal vigour and policy; so that by her successes in warlike expeditions, as well as by the wisdom and firmness of her administration, she aggrandized herself in Asia, and her authority was recognized both in Cappadocia and Bithynia, when Aurelian succeeded to the Roman empire. Envious of her power, and determined to dispossess her of some of the rich provinces that were comprehended within the extent of her dominion, he marched at the head of a powerful army to Asia, and having defeated the queen's general Zabdas, near Antioch, she retreated to Emesa, whither she was pursued by Aurelian. Under the walls of that city another engagement with Zenobia, which was commanded and animated by herself, took place, in which the emperor was again victorious. The queen, thus unfortunate, withdrew the relics of her vanquished forces to Palmyra, her capital; and was pursued thither by Aurelian. The favourable terms that were offered to Zenobia being refused, the city was besieged; which, after long resistance, the queen determined not to surrender; but as the apprehended famine within the walls, she mounted a swift dromedary, and hastened towards the Euphrates, with a view of seeking an asylum in the Persian territories. But being overtaken in her flight, she was brought back to Aurelian, who
who received her with a stern countenance, and questioned her how she could dare to refit the emperors of Rome. She replied, "Because I could not acknowledge as such a Gallienus and others like him; but I recognize by that title you who know how to conquer."  At Emelia, the fate of Zenobia was submitted to the judgment of a tribunal, at which Aurelian predisposed; and the Roman soldiers demanded her death. She, in a manner unworthy of her former fame, saved her own life by throwing the blame of her renunciation on her ministers and councillors; Longinus was one of these, who, with several others, was put to death, in the year 273.

Zenobia was referred to grace the triumph of Aurelian; and on the appointed day the procession, on foot, a magnificent chariot, which she had designed in the days of her prosperity for a very different kind of entry into Rome. She was encircled, it is said, with chains of gold, and almost funked under the weight of jewels with which she was adorned. Afterward she was treated with humanity by the victor; and had assigned to her an agreeable residence near the Tiber, where she passed the remainder of her days as a Roman matron. Whether she contracted a second marriage with a Roman senator, as some have affirmed, is uncertain; but however this be, her favoring for Vhaballat withdrew into Armenia, and plethoraed a small principality granted to him by the emperor, and her family was not extinct in the fifth century. Gibbon's Hist. of Rome, vol. ii.

Zenobia, a place of Italy, near the palace of Adrian, assigned to queen Zenobia for her residence.

ZENOBII ISELIAE, the name of seven islands in the Indian ocean, upon the coast of Arabia Felix, at the entrance of the Sathale gulf. Ptolemy.

ZENODOTIUM, a town of Asia, in the Euphrates, upon the banks of the Euphrates, five miles from fort Mambri, and on this side of the small town of Sura. According to Procopius, it was founded by Zenobia, wife of Odonatus, prince of Palmyra. After it had been ruined, Juttinian re-established it, and repopulated it, and made it one of the bulwarks of the empire. After having rebuilt the town and fortified it, he embellished it, constructing magnificent churches, public baths, galleries, and lodgments for the soldiers. It was situated S.E. of Nicsephorium.

Zenobia, a place of Italy, near the palace of Adrian, assigned to queen Zenobia for her residence.

According to Procopius, it was founded by Zenobia, wife of Odonatus, prince of Palmyra. After it had been ruined, Juttinian re-established it, and repopulated it, and made it one of the bulwarks of the empire. After having rebuilt the town and fortified it, he embellished it, constructing magnificent churches, public baths, galleries, and lodgments for the soldiers. It was situated S.E. of Nicsephorium.

Zenobia, a place of Italy, near the palace of Adrian, assigned to queen Zenobia for her residence.

Zenobia, in Ancient Geography, a town of Asia, in the Euphrates, upon the banks of the Euphrates, five miles from fort Mambri, and on this side of the small town of Sura. According to Procopius, it was founded by Zenobia, wife of Odonatus, prince of Palmyra. After it had been ruined, Juttinian re-established it, and repopulated it, and made it one of the bulwarks of the empire. After having rebuilt the town and fortified it, he embellished it, constructing magnificent churches, public baths, galleries, and lodgments for the soldiers. It was situated S.E. of Nicsephorium.

After having rebuilt the town and fortified it, he embellished it, constructing magnificent churches, public baths, galleries, and lodgments for the soldiers. It was situated S.E. of Nicsephorium.
shaped fragments; it yields easily to the knife. The specific gravity is from 2.158 to 2.197. Before the blow-pipe it intumesces, and forms a jelly with acids. It may be distinguished from needle zeolite by its inferior luster, fibrous structure, and low degree of transparency and hardness, and also by its want of regular crystallization.

**Needle Zeolite, Mefotype, Háyý; and prismatic mefotype of some mineralogists.** Its colours are, greyish, yellowish, or reddish-white; it occurs both massive and crystallized. The crysRals are acicular-rectangular four-sided prisms, terminated by low four-sided pyramids, the faces of which are set on the lateral planes of the prism. Sometimes there are only two terminating planes, forming an acute bevelment, fett on obliquely. The rectangular prism is sometimes truncated on the edges, forming an octahedron, with four large and four small planes. The lateral planes of the crystals are longitudinally striated, but the acuminate planes are smooth. Sometimes the crystals are diverging, and sometimes promiscuously aggregated. The crystals are externally shining or splendent, internally glistening; the luster is vitreous, inclining to pearly. The structure is lamellar, with joints parallel to one of the sides of the prism; also at right angles to the axis, and parallel to the two diagonals of the prism. Of these, the first cleavage only is generally visible. The crofs fracture is imperfectly conchoidal; the luster between vitreous and pearly. It is transluent or transparent, with double refraction. It yields to the knife, but feraches calcareous spar, and is brittle. The specific gravity varies from 2.17 to 2.27. This mineral, like the preceding, intumesces before the blow-pipe, and gelatinizes with acids. It becomes electric by heat; the extremity of the crystal, terminated by a pyramid or bevelment, fleshes positive the bottom of the crystal negative electricity. According to Vaquelin, the constituent parts of mefotype are:

| Silex | 50.24 |
| Alumine | 29.50 |
| Lime | 9.46 |
| Water | 10 |
| **Total** | **99.2** |

Needle zeolite, or mefotype, is distinguished from radiated zeolite, or stilbite, by its vitreous luster, distinct prismatic concretions, and greater transparency and brittleness. The latter has also more of a nacre luster.

**Radiated Zeolite, Stilbite, Háyý,** is generally of a yellowish or greyish-white colour, and rarely pales into reddish-white or red. It occurs massive in angular pieces, and globular, and also crystallized in broad, rectangular, four-sided prisms, rather acutely terminated by four planes set on the lateral edges of the prism. Of these planes two adjoining ones are more inclined to the axis of the prism than the other two. The summits of the terminating planes are sometimes more or less deeply truncated. Sometimes the prism is so thin as to form a long hexagonal table, bevelled on the shorter terminal planes. The crystals are aggregated in diverging radii, and frequently so closely joined to each other, that the pyramidal terminations of each crystal are only visible. The broader lateral planes of the crystals are smooth, and the smaller longitudinally striated. The structure is lamellar, with joints in one direction, parallel to the axis of the prism. The surfaces of the broader lateral planes are splendent and pearly; internally the luster is more or less shining, and is nearly flat. The crystals are transluent, or semi-transparent. The diverging radii of the aggregated crystals are more or less broad, passing from fibrous to foliated. It is brittle, and the fragments are wedge-shaped and splintery. Stilbite feraches calcareous spar. The specific gravity of this mineral is from 2.13 to 2.46. It intumesces before the blow-pipe, yielding a phosphoric light; it becomes white when laid on a glowing coal; it does not gelatinize with acids. The constituent parts are:

| Silex | 49.98 |
| Alumine | 29.50 |
| Lime | 16.95 |
| Water | 16.50 |
| **Total** | **97.52** |

**Foliated Zeolite, Stilbite, Háyý.**—The colours of this mineral are nearly the same as those of the preceding, being chiefly yellowish and greyish-white, and rarely milk-white, snow-white, reddish-white, or red; it sometimes is yellowish-grey, and pinchbeck-brown. It occurs both massive, disintegrated, globular, amygdaloidal, and crystallized. The form of the crystals is a low, very oblique, four-sided prism; sometimes truncated on the acute lateral edges, and also on the angles of the acute lateral edges. Sometimes all the angles are truncated. It occurs also in low fix-sided prisms, and equi-angular fix-sided tables; also in eight-sided prisms. The crystals are generally small; the lateral planes are transversely striated, and the terminal planes are smooth. It has a pearly luster, which is either shining or splendent. The pinchbeck-brown variety has a fémé-metallic luster. It has a foliated and slightly curved structure, with a single cleavage, parallel with the terminal planes of the prisms. Sometimes a conchoidal crofs fracture may be observed. It is brittle, and the fragments are angular and blunt-edged, and sometimes tabular. The massive varieties are strongly transluent; the crystals are transluent, semi-transparent, or transparent. It yields to the knife, but feraches calcareous spar. The specific gravity of this mineral is 2.2; and, like the preceding mineral, it intumesces and melts before the blow-pipe, giving out a phosphoric light; it does not form a jelly with acids. According to Meyer, the constituent parts are:

| Silex | 58.3 |
| Alumine | 17.5 |
| Lime | 6.6 |
| Water | 17.6 |
| **Total** | **100** |

According to Vaquelin,

| Silex | 52.6 |
| Alumine | 17.5 |
| Lime | 9 |
| Water | 18.5 |
| **Total** | **97.6** |

All these zeolitic substances, classed as mefotype and stilbite by Háyý, pass by imperceptible gradations into each other, and occur, as we have before observed, in basaltic and volcanic rocks.

The easy fusibility of zeolites was at one time regarded as rendering their occurrence in volcanic rocks a subject of difficult explanation; but the experiments of Sir James Hall, referred to under Systems of Geology, demonstrate the
the possibility of crystalline arrangements taking place under compulsion in substances that would be disintegrated by heat under the common prelude of the atmosphere. It is probable, however, that many zeolitic substances which occur in bafsalt or lava have been infiltrated into the cavities at a later period, and are even forming at the present day in ancient lavas and basalts.

Some of the minerals claffed with the zeolite family have been described in our preceding volumes. See Aphy-lite, or Ichthyoptalmite.

Analcime, or Cubite, formerly called by Werner cubic zeolite, is generally white, sometimes reddish-white, or red. It occurs sometimes massive, but more generally crystallized in perfect cubes, or with the angles more or less deeply acuminated, or in twenty-four-sided crystals, like those of the leucite, having each of the fides equal and similar. The structure presents slight indications of cleavage, parallel with the fides of a cube. The fracture is compact and flatly conchoidal, paffing into fine-grained, uneven. It is translucent, semi-transparent, or transparent, and has a fihing lufr, between vitreous and pearly. It is sufficiently hard to fcratch glafs, but is easily frangible. The specific gravity of cubicite is 2.44. It becomes electric by rubbing. Before the blow-pipe it melts into a transparent glafs. According to Vauquelin, the conffituent parts of this mineral are,

This mineral occurs most frequently in cavities in rocks of the trap formation, accompanied with zeolite; but it is sometimes found in metallic veins in ichthite rocks, accompanied with various ores, and with calcaceous fpar and quartz. The name analcime was given to it by Haiy, figuring a body with little power, on account of the feeble electricity excited in it by friction.

Chabafite, Chabafite, Haiy, is nearly allied to cubite, but was formerly claffed with it. The crystallization is different; the form is not perfectly cubic, but slightly rhombohedral, the angles of the rhomboid being 94° and 86°, either perfect, or with the obtuse lateral angles truncated, and sometimes both the fix obtuse lateral angles and fix obtuse angles are truncated. The crystals are transparent or tranflucent. The lufr is vitreous, and externally fplen-dent, internally glifhing; the fracture is imperfectly conchoidal, or fine-grained, uneven. It fcratchs glafs little. The specific gravity of this mineral is 2.7. It is fusible into a white fpong enamel. According to Vauquelin, the conffituent parts are,

The situation in which this mineral occurs is nearly the fame with that of analcime. The name was given it by Haiy, from chabazion, an unknown stone mentioned in the poems of Orpheus.

Launonite, Zeolite efflorescent, Haiy.—Its colours are, yellowish-white, snow-white, and greyish-white. It occurs massive and crystallized in octahedral prisms, with edges apparently rounded; the summit of the crystals are chri- dental. The crystals are small, lining drifty cavities. The structure is lamellar, and has a two-fold cleavage; it is transparent or tranflucent when fresh; but on exposure to the atmosphere soon becomes opaque, losing its hardnefs, and yielding to the prelude of the finger. When fresh it fcratchs glafs. The specific gravity is 2.23. Bournon. It forms a jelly with acids. Before the blow-pipe it inte-neces, and is changed into a white enamel. According to Vogel, the conffituent parts are,

This mineral, which agrees in its principal characters with zeolite, was first found in Brittany, by M. Gillet Laumont, after whom it has been named by Werner. It has been found also at Patitly, in Renfrewshire, in amyg- daloid, accompanying cubicite. Launomite difintegrates fo rapidly, that for its prefervation it requires to be kept in well-closed bottles.

Crofs-Stone, Hormotome, Haiy, occurs in small crystals: the form is generally a broad rectangular prism, terminated on each extremity by four rhombic faces, with their acute angles fet in the lateral edges of the prism. Sometimes the edges of the rhombic faces are bevelled in one direction. But the name crofs-stone is derived from the frequent occurrence of two prisms interfeting each other, having one common axis. The broader planes by this interfeting project, and form the figure of a crofs when the prism is viewed at the end, or in the direction of the axis. The colour of crofs-stone is generally a greyish-white, which passes into fmode-grey; it is sometimes a yellowish-white, paffing into cream-yellow, and red. It is tranflucent or tranflucent, with a lufr between vitreous and pearly. The fracture is uneven, or imperfectly conchoidal. It is suppored, by professor Jamefon, to have an imperfectly foliated structure. It fcratchs glafs feebly. The specific gravity is 2.53. Before the blow-pipe it emits a yellowish phosphoric light, and melts with intumeefence into a colour-les glafs. It does not gelatinize with acids. This mineral differs from other members of the zeolite family, by containing barytes as an ingredient in its composition. According to Klaproth, its conffituent parts are,

I Dipye, Haiy; Schmelzstein, Werner.—Its colours are, light pearl-grey, greyish-white, or reddish-white. It occurs massive and crystallized, in aggregated, flen-der, octahedral, acicular prisms. The structure is lamellar, with joints parallel to the fides, and to the diagonal of a rectangular prism. The lufr is intermediate, between vitreous and pearly: it is tranflucent. This mineral is sufficiently hard to fcratch glafs; but is very frangible. The specific gra-

vity
It is said by Brongniart to occur in felsite, along with iron pyrites, near Mauleon, in the Western Pyrenees.

The other members of the zeolite family are described in the preceding volumes. See NAITROLITE and WATELITE.

ZEOPHILOS, a word used by Quercetan as the name of an antimonal medicine.

ZEOPHYRUM, in the Materia Medica, the name of the *tritium fylvium, or hordeum nutum, as it is called by some authors, the naked barley.

ZEPHANIAH, a canonical book of the Old Testament, containing the predictions of Zephaniah, the son of Cushi, and grandfather of Gedaliah; being the ninth of the twelve latter prophets. He prophesied in the time of King Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was contemporary with Jeremiah. He prophesies chiefly against Judah, who continued very corrupt, notwithstanding the king's pious zeal for reformation, and the good example he gave to his subjects.

ZEPHAT, in Ancient Geography. See SEPHTAT.

ZEPHIRA, in Geography, a small island in the Grecian Archipelago, near the N. coast of Antiparos.

ZEPHIRE, in Ancient Geography, an island situated on the coast of that of Crete, before the promontory Samounium. Mela.

ZEPHIRON, or ZEPHIRONIA. See ZEPHIRON.

ZEPHYRI FETUS, a term used by Hartman, and some other writers, to express a mole, or false conception.

ZEPHYRINUS, *Popis, in Biography, succeded Victor in the Roman see in the year 201. A perfecution at the commencement of his papacy obliged him to conceal himself, and when he was at liberty to exercise his functions, he was engaged in the suppression of prevalent heresies, which disturbed the latter years of his pontificate. He died in the year 218 or 219. Bower.

ZEPHYRION, in Ancient Geography, a promontory of Asia, on the confines of Cilicia Propria. According to Strabo and Ptolemy, this promontory and that of Sarpedon formed the mouth of the river Calycadnus.—Alfo, a town at the extremity of this promontory.—Alfo, a promontory of the Ille of Cyprus, towards the S. W., at the extremity of a peninsula, which on the W. incloses the gulf, at the bottom of which was Paphos.—Alfo, a promontory of Italy, on the eastern coast of Bruttium, between the promontory of Hercules and the town of the Locri. Strabo.—Alfo, a promontory of Africa, in the Cyrenaica, upon the coast of the Pentapolis. Ptolemy. Strabo distinguishes two promontories of this name on the coast of Cyrenaica.—Alfo, a town of Asia, on the coast of Paphlagonia.—Alfo, a town of Asia, in the interior of Cappadocian Postus. Arrian gives it a port, and rates it to be 120 stadia from the town of Arrenthias, and 30 stadia from the town of Tripolis.—Alfo, a promontory on the coast of Egypt, between Campé and Alexandria, where was a chapel of Venus Arinnae, and hence the took the name of Zephyrida. Alfo, a promontory of Asia Minor, on the coast of the strong and the vicinity of the town of Myndus. Strabo.—Alfo, a town of the Tauric Choreneus; situated on the sea-coast, N. E. of the Nether. Pliny.—Alfo, a promontory on the eastern coast of the isle of Crete.

ZEPHYRION Jugum, a sacred mountain of Hilparia, upon which was a fortres. ZEPHYRUS, or ZEPHYR, Zepher, the west wind; a wind blowing from that cardinal point of the horizon opposite to the eith. The poets personify it, and represent Zephyrus as the mildest and most gentle of all the deities of the woods: the character of his personage is youth and gentleness.

It is also called *Favonius, and *ocidum; and, by many, has been confounded with the Africus. See Wind.

ZEPS, in Geography, a town of the duchy of Warsaw; 20 miles E. of Wladislaw.

ZERA, a town of Italy, in the Veronese; 7 miles S. of Verona.

ZERANIA REGIO, in Ancient Geography, a country of Thrace. Steph. Byz.

ZERBITA, in Geography, a town of South America, in the government of New Grenada; 30 miles W.S.W. of Pamplona.

ZERBST, a town of Germany, in the principality of Anhalt Zerbst. It is the residence of the prince, and the largent and handsomest town in the whole principality of Anhalt. The residence-house here is remarkably grand. In the town are two Lutheran churches, one of which is used by the Calvinists, together with an university, common to all the princes of Anhalt, and founded in 1594, out of a school: it has a rector, with three Calvinist and one Lutheran professor. The principal trade is in beer, with manufactures of gold and silver; 8 miles N.N.W. of Deisau. N. lat. 52° 5'. E. long. 12° 10'.

ZERDA, in Zoology, a name given by the Moors to an animal which inhabits the desert of Sahara, extending beyond mount Atlas.

This is the canis coro of Linneus, with a straight tail, a palish or yellowish-white body, with long upright ears, internally rofe-coloured. It is the fennec of Bruce, and a beautiful African and Asiatic animal, and is principally found in Arabia.

Pennis attaches it under the genus of dog; and describes it as having a pointed vifage, long whifkers, large bright black eyes, very large ears of a bright rofe colour, internally lined with long hairs, and orifice fo small, as not to be visible, probably covered with a valve or membrane; legs and feet like thofe of a dog, and taper tail; its colour is between a straw and pale brown; its length from nose to tail ten inches, its ears three inches and a half long, tail fix, and height not five. It burrows in the sandy ground, and is fo exceeffively swift, that it is very rarely taken alive; feeds on insects, especially locusts; fits on its rump; is very vigilant; barking like a dog, but with a thriller found, and chiefly in the night; and is never observed to be sportive.  

M. Bulfin describes this animal, that it is found to the south of the Palus Tritonides, in Lybia; that it has something of the nature of the hare, and something of the squirrel; and that it lives on the palm-trees, and feeds on the fruits: hence probably it derives its name fennec from *fennec, a palm-leaf. Bruce's Travels, vol. v.

ZERDUHST, in Biography. See ZOROASTER.
ZEREA, in Geography, a town and fortress of Perșia, in Farîlțan; this town was taken by the troops of Timur Beq, with great slaughter; 18 miles N.N.E. of Schiras.

ZEREB, a town of Perșia, in the province of Segellên; 130 miles N.W. of Zarang.

ZEREWICA, a town of Lithuania; 5 miles S.W. of Slonim.

ZERB, a town of Kudîštân; 25 miles W. of Gu-lamerik.

ZERICHUM, a name given by some of the chemical writers to arsentic.

ZERKI, in Geography, a town of Kudîštân; 30 miles S.W. of Beltsis.

ZERKWITZ, a town of Lusfatia; 2 miles W. of Lubbënaun.

ZERMA. See SURMA.

ZERMAGNA, a river of Dalmatia, which runs into the Adriatic, opposite Pagò.

ZERMONY, a town of Lithuania; 10 miles N.W. of Lida.

ZERNA, a mountain of Carinthia; 3 miles N.W. of Millatt.

ZERNA, a word used by some of the chemical writers to express an ulcerated lepra or impetigo. The chemical authors use it also as a name for the foulneflles which they call the lepra metalorum, or leprofises of metals.

ZERNEMBIL, or TSCHERNEMBIL, in Geography, a town of the duchy of Carniola, on a small river which runs into the Kulpa; 4 miles S.S.W. of Rudolfswerth. N. lat. 45° 50'; E. long. 15° 45' 32''

ZERBIENSIUM COLONIA, in Ancient Geography, a colon of Dacia, founded by Trajan.

ZERNETZ, in Geography, a town of Switzerland, in the Upper Engadine. In the late war it was taken by the French, and soon after retaken by the Autrians; 8 miles N. of Zulz.

ZERNITZ. See Czernetz.

ZERO, a river of Italy, which runs into the sea, 7 miles N. of Venice.

ZERO, denotes the point from which the scale of a thermometer is graduated. Thus Celsius's and Reaumur's thermometers have their zero at the freezing-point, while the thermometers of Fahrenheit has its zero at that point at which it stands when immerged in a mixture of snow and common salt. In Wedgwood's pyrometer, the zero corresponds with 107° of Fahrenheit's, each degree of which is equal to 100° of Fahrenheit. Consequenty 180° Fahr. = 100° Celsius. = 80° Reaum. = 150° De Lille = 44° Wedgw. See THERMOMETER.

ZEROGERE, in Ancient Geography, a town of India, on this side of the Ganges, E. of the river Namadus. Ptolemy.

ZEROWITZ, in Geography, a town of Bohemia, in the circle of Bechin; 3 miles W.S.W. of Potchaken.

ZERREH, or ZERRAH, Lake of, a lake of Perșia, in the province of Seîlant or Segellên, into which the river Heermann, or Hindmûnd, (the ancient Etymander,) navigable for boats from Bolt to Zarang, flows through the centre of it, from the mountains of Huzzara, beyond Ca- buh. This lake is said to be 50 farfuns in length, and 6 in breadth, or about 100 miles long, and zo broad at the widest part. It is principally formed by the waters of the rivers Heermann and Ferrah, and in the dry season resembles more a marsh than a lake, being covered with rufhes and reeds. In the middle the water is fresh; but brackish towards the shore, as the sandy plains which surround it are impregnated with salt. The lake is full of fish and wild fowl; and in its centre there is a fortified town, called "Kookhozerd," built on a high island, where the treasure of the principal families of Seîlant used to be deposited when the province was invaded. It is said that on the borders of this lake is a town named "Naffarabad," which is describ'd as being four days' journey for a loaded camel, W. of the city of Doolhak, the present capital of the province.

ZERTA, or SERTA, the Zerte, or Serte, in Ichthyology, a fish caught in the rivers of Italy, and some other places, of the figure of the chub, and called by authors capito anadromus, and the alike. It seldom grows to more than ten pounds weight, and at times lives in rivers, at times in the sea; and is esteemed a very well tasted fish, especially a little before the feaon of Its spawning, either fresh, salted, or prepared in various ways by pickling, &c.

The zerte is that species of cyprinus described by Gesner and others under the name of capito anadromus. See CYPRI-

NUS VIMBA.

This is the silvery-blueish carp, olivaceous above, with the dorso, caudal, and anal fin bluefish, the red reddish, and the nose protrubent. It is a native of Germany, Russia, Sweden, and other parts of Europe, inhabiting rivers, and migrating into the Baltic sea.

ZERVINKA, in Geography, a town of Servia, on the Danube; 10 miles N.W. of Belgrade.

ZERUS, in Ancient Geography, a town of Thrace, on the route from Dyrrachium to Bylace, between Dyme and Plotopoli. Anton. Itin.

ZERUMET', in Botany, a name first used by Serapio, and apparently either of Arabian or Indian origin. It belongs to one of the aromatic roots of the natural order of Scitamina, the produce of the East Indies, but rather to a Kempteria, than to the species of Ginger to which Linnæus has applied it. (See ZINGIBER.) Dale has very judiciously observed on this subject, Pharmacologia, 275, that in the present instance, as well as innumerable others, the Arabian writers are too brief, as well as vague, in their descriptions, and so contradictory amongst themselves, that we can scarcely tell whether they were acquainted with any particular object or not.

Wendland, Jacquin, and Poiret, (Lamarck Diét. v. 8. 857,) have most unaccountably made a genus of Alpinia nutans, and called it Zerumbet; but this cannot on any principle be maintained.

ZERYTHUS, in Ancient Geography, a town of Thrace, which had a cavern of the same name, and which the ancients called Zerynthium Antrum. This cavern was consecrated to Hecate, to whom they sacrificed dogs. Suidas.

ZEREN, in Geography, a town of Arabia, in Yemen; 36 miles S.E. of Ghezlar.

ZESMETZ, a town of Bohemia, in the circle of Chrudim; 8 miles N. of Chrudim.

ZESSEL, a town of Silicia, in the principality of Oels; 5 miles N.E. of Oels.

ZEST, the woody thick skin quartering the kernel of a walnut. Some physicians prefer this zest, dried, and taken with white wine, as a remedy against the gravel.

The word is also used for a chip of orange or lemon-peel; such as is usually squeezed into ale, wine, &c. to give it a flavour; or for the fine thin oil that spufts out of that peel on squeezing it.

Hence, to zest an orange or lemon, among confectioners, is to cut the peel from top to bottom into small slips, as thin as possible; or, to zest, is to squeeze the peel over the surface of any thing.
ZET

ZESTOLUSIA, a term used by some medical authors to express bathing in warm water, by way of distinction from phlebolypha, or bathing in cold water.

ZETA, or Zetecula, a little closet, or withdrawing chamber, with pipes running along the walls, to receive from below either the cool air, or the steam of warm water.

The word is formed either from *ζευς, to be warm: or of *ζεῦς, vivens, to live, on account of the use made hereof for love and enjoyment.

ZET, or Zetta, (Mansil) in Ancient Geography, a town of Africa Propria, situated near the sea, E. of Vicus Augusti.

ZETETE, Zetetides, among the Athenians, were officers appointed upon extraordinary occasions, to inquire after the public debts, when, through the neglect of the receivers, or by other means, they were run up to large sums, and began to be in danger to be lost, if not called in.

ZETETICZ, Zetetides, formed from *ζεῦς, to seek, or zetetic method, the method made use of to investigate or find the solution of a problem.

The ancient Pythagoreans were sometimes called Zetetici, q. d. sectares.

ZETIN, in Geography, a town of Croatia; 28 miles W.N.W. of Novi.

ZETLAND, or Shetland, the name of a cluster of islands, situated in the Northern ocean, between the 59th and 62d degrees of N. latitude, and a very little to the W. of the meridian of London. The most southern part is nearly 100 miles N.N.E. from the northern county of Scotland. These islands exceed one hundred in number, of which only thirty-four are inhabited; the others, coating chiefly of rocks and lands, are unfitted for human support. By different writers, they have been named Hetherland, Hialtan, Zetland, Shetland, and Shetland; which names, Dr. Edmondston says, "are of Norwegian origin, and are supposed to be descriptive of their form or appearance." The most correct and approved orthography is that of Zetland. The general appearance of these islands is bleak, bare, and rocky; but some interior parts of the main-land are cultivated, clothed, and cheerful. In many places on the coasts, rocks of immense size are seen to rise above the foaming waves, some of which are at considerable distance from the shores. Some of these are also perforated by vast natural arches; in other parts there are deep caverns and subterranean recesses. Two of these are called the Scarna, one of which extends above 300 feet in depth. Almost all the large islands are deeply interfected by tortuous bays, or voes, as they are provincially called, which afford facilities for internal communication, and excellent harbours for vessels. Several of them are commodious, and well sheltered from dangerous winds. Some of the islands have lakes, the largest of which is not more than two miles in length. The highest hill is Mons Ronaldi, in the parish of Northmavine; the height of which, from barometrical measurement, is 3944 feet above the level of the sea. Some of the headlands are lofty and grand, one of which, Noss-head, is above 600 feet in height.

According to the population reports of 1811, the following is the enumeration of houles and inhabitants, and the names and number of parishes. The total number of houles 8230, inhabited by 9238 families, 16 houles building, and 101 unoccupied. The whole population was 46,153, consisting of 20,151 males and 26,002 females. The parishes are, 1. Aithiing and Sandting; 2. Breffay, Burra, and Quarfi; 3. Delting; 4. Dunroinshies, Sandwick, Cunnibrough, and Faria filie; 5. Lerwick and Gulberwick.

ZEU

As the chief histories and topographical peculiarities of the Zetland islands have been fully detailed under the words MAINLAND, LERWICK, and Scallaway, the reader is referred to each word respectively.—A View of the ancient and present State of the Zetland Islands, by A. Edmondston, M.D. 2 vols. Svo. 1809.

ZETLAND Islands, Foula or Fula, the most western of the Shetland islands, and is supposed to be the "Ultima Thule" of the ancients. It is about three miles long and one and a half broad, nearly twenty miles distant from any land, W. of the clusters of Orkney and Shetland, to which it is politically annexed: it affords excellent and extensive pasture for sheep; and is inhabited by 26 or 27 families.

ZETTERITZ, a town of the principality of Cumbach; 11 miles S.W. of Cumbach.

ZETUS, a word used by some of the chemical writers as a name for vitriol.

ZEVACO, in Geography, a small island in the Pacific ocean, near the coast of Veragua. N. Lat. 8°. W. long. 81° 46'.

ZEVEN. See Cloester Seven.

ZEVENAER. See Sevenar.

ZEUF, or GAER, a town of the kingdom of Balt; 100 miles S.E. of Balt.

ZEUETIE, Zuyten, among the Athenians, the third class of the people, or those who had an estate of two hundred mediambi.

ZEUETIES, in Botany, an ancient name, adopted by Brown, but no other applicable to the present genus, than as far as concerns its reedy habit. The Zuytites of Pliny was a large Breton reed, so called from *ζεῦς, a yoke, because it was bound together, in portions of different lengths, to make the pastoral pipes; as wheaten straws are, by our shepherds' boys, to this day; but the West Indian grass, of which we are now to give an account, has not even this coincidence with the original.—Brown, Jam. 341.

Gen. Ch. Common Calyx a glume of two valves; the outer one broadest, concave, abrupt and jagged, ribbed; membranous at the edges; the inner narrower, harper and keeled. Male Florae two, smallish, on a common stalk the length of the solitary female floret, within the common calyx. Perianth none. Cor. Glume of two ovate-oblong, compressed, blintish, awnless, equal valves. Stam. Filaments three, capillary, the length of the corolla; anthers oblong, cloven at each end.

Female within the larger glume of the common calyx, fife. Perianth none. Cor. Glume of one oblong concave valve, twice the size of the calyx, bordered towards the top with a dilated membrane, awned; the avn terminal, capillary, straight, half as long again as the glume. Pjil. Germen oblong; style divided; stigmas long, flaggy. Peric. none. Seed solitary, oblong.

Obf. Schreber remarks, that this grafs differs so entirely, in every character, from Apfield, with which Linnaeus combines it, that they are totally irreconcileable. We should refer both, with all other true Gramina, as in Fl. Brit. to the clasf Triandria.

Eff. Ch. Common Calyx of two valves, with three flowers; the female one fife; the males flalked. Corolla
of the males of two heartless valves; of the female of one awned valve. Style divided. Seed oblong.

1. Z. americana. Jamaica Yoke-grass. Willd. n. 1. (Z. argenteus, ramosus, minor, rufescens; paniculā
sparsē terminalis; Browne Jam. 341. t. 4. f. 3. Apulda Zeuges; Linn. Sp. Pl. 1487. Amen. Acad. v. 5.
not 6). 412. Swartz. See. 383.—Native of Jamaica. Found by Dr. Browne at Cold-pring, in the mountains of New Lignanea, in a rich foil, and shady situation. His original speciments are in the Linnæan herbarium. The root is said to be perennial. Stem two feet high, much branched, ascending, round, jointed, polished, brownish, leafy, rather slender. Leaves alternate, on slender stalks, each with a long leafless base, reclinate, or nearly pendulous, ovate, acute, entire, smooth, many-ribbed, from an inch to an inch and a half long, and from half an inch to an inch broad. Pedicels terminal, from the sheaths of the uppermost leaves, compound, spreading, with smooth slender branches. Glumes green, filiated, smooth. The habit is no less foreign to the genus Apulda than the generic characters.

ZEUGMA, Zeugma, literally denoting a joining together; from ζυγμα, I join, a figure in Grammar, whereby an adjective, or verb, which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

Thus Terence, "Utinam aut hic furcus, aut hec muta facta sit." So Virgil, "Hic illus arna, hic currus fuit." In which cases, the words facta sit agreeing primarily with hic muta, are also made to agree or extend to hic furcus: and the verb fuit is not only referred to hic currus, which it properly respects, but farther to hic illus arna.

Of this species of ellipsis, which differs from the ellipsis properly so called, in that the word which is to be understood, once or oftener, has been already mentioned, Melleur des Port Royal enumerate three sorts; viz. when we repeat the noun or verb in the same manner it has been already expressed; or when the word expressed cannot be repeated without receiving some alteration in gender, case, number, or person; or when, after a word which includes the whole, a distribution of the parts is made without repeating the verb. Latin Gram. vol. ii. p. 183.

The Latins, it may be here observed, take a liberty in constructions, which some of the nicer critics among the moderns, particularly the French, will not allow in the modern tongue.

ZEUGMA, (Rowm-Kala,) in Ancient Geography, a town of Asia, or a place on the right bank of the Euphrates, S.E. of Samotlata, and over-again Apamea.

ZEVICO, in Geography, a town of Spain, in the province of Leon; 10 miles S.E. of Palencia.

ZEVIO, a town of Italy, in the Veronese; 10 miles S.S.E. of Verona.

ZEVKETI, a town of the principality of Gurid; 25 miles S.E. of Puti.

ZEULEN, a town of Bavaria, in the bishropic of Bamberg, on the Rotach; 21 miles N.N.E. of Bamberg. N. lat. 60° 17'. E. long. 11° 16'.

ZEULENRODA, a town of Saxony, in the county of Reulin, containing two churches and 350 houses. Here is a manufacture of stuffs, and a considerable one of stockings; 10 miles W. of Greitz. N. lat. 50° 30'. E. long. 11° 11'.

ZEUS, in Ichthyology, a genus of fifth, of the order of the thoracids; the characters of which are, that the head is compressed and declining: the upper lip is arched by means of a transverse membrane; the tongue is awl-shaped; the branchiostegous membrane has seven perpendicular rays; the lowest placed transversely; the dorsal fins, in most species, furnished with projecting filiform rays; and the body is compressed, broad, thin, and of a bright colour. The species enumerated by Gmelin and Shaw are the following:

VOMER. Silvery dory, with the second ray of the dorsal fin very long. Bloch. (See VOMER.) Its shape is rhomboidal, length fix or eight, or more, inches, body thin, without scales, tinged on the upper parts with a blueish cast, mouth with small teeth. Native of the American and Indian seas, and sometimes seen in those of the north of Europe: edible, but not much esteemed.

GALLUS. Silvery dory, with the tenth ray of the dorsal and second of the anal fin longer than the body. Shape and length, and body, like those of the former; back tinged with a greenish hue, head large, mouth wide. Native of the American and Indian seas, efluent: when first taken grunting, like the gurnards. The abactatua of Marcgrave.

FABER. Gold-green, fuliginous dory, with a dufky central spot on each side of the body, or with a rounded tail, brown spot on the middle of the sides and two anal fins. Linnæus. This is the common dory (see Dorek), which is a native of the Mediterranean, Northern, and Atlantic seas. Its head is large and long; length generally twelve or fifteen inches, and weight ten or twelve pounds; mouth wide, lower jaw longer than the upper, teeth small and sharp, eyes large, body covered with small scales, and marked by a curved lateral line, which declining pretty suddenly from the gill-covers, pusses on to the tail; back arched, and furnished with a row of strong, small prickles, continued along the curve of the abdomen; two very strong and sharp spines at the base of the pectoral fins. The introduction of this fish, as excellent food, to the tables of the higher ranks, is of no remote date; Mr. Quin being considered as the founder of its peculiar reputation in the polite circles. This fish is of a very voracious nature, preying on smaller fishes and their spawn, as well as various kinds of sea-insects, the smaller shell-fish, &c. It emits a noise like that of the gurnards and scorpens, when first taken, by violently forcing out the air from its gill-covers.

APER. Reddish dory, with rough scales and even tail; a small species about three inches long, resembling the common dory in habit; snout protubering, and turning upwards; no perceptible teeth; eyes large, with white irides; two dorsal fins, the anterior having five strong and sharp spines, the first low and scarcely visible, the second four times longer, and the third very long and thick; the second dorsal fin composed of twenty-three soft rays; the vent-fin having twenty-five rays, the pectoral fins about fourteen, and the ventral fin. This fish generally refines at the bottom, and is accidentally taken after great storms: it is not eatable, being small, coarse, and of an unpleasant colour. It is a native of the Mediterranean.

INSIDIATOR. Silvery dory, with sides speckled with black, and narrow extensile mouth; shape rhomboidal; smaller than Z. ciliaris; colour bright-flivory, blueish-green above, and speckled with black points; body without scales; lower lip retráctile, and mouth capable of forming a tubular snout, for ejaculating a drop of water against such insects as happen to alight on or fly about the aquatic plants near the shores of the waters it inhabits, and thus obtain its prey. A native of the rivers and fresh-waters of India.

CILIARIS. Silvery dory, with some of the rays in the dorsal and anal fin excessively long; body rhomboidal, thin, without scales, and of a bright-flower colour, with a blueish or
or greenish cast on the back, and small and looping; lower jaw longer than the upper; teeth small and sharp; several of the last rays of the dorsal and anal fin extending farther than the tail itself, the long and flexible filaments of which count de Cepede imagines attract small fishes, which mistake them for worms, the dory himself concealing among sea-weeds, &c. and waiting for its prey: the count also conceives that these may serve to fatten the fish by coiling round the stems of sea-plants, &c. A native of the Indian seas; but not esteemed as food, being small and coarse.

**Luna or Opah.** Dory with somewhat lamunated tail; the body being generally either red, green, or purple, with oval white spots. This is a superb species, and found, probably wandering, from the warmer regions, in the Mediterranean and Northern seas, the largest species of the kind, being between four and five feet in length, in colour varying from a bright silvery-green ground to a bright gold colour, and variegated on the sides with pretty numerous and moderately large oval white spots, while the fins and tail are bright scarlet; the skin seemingly deftite of scales and perfectly smooth.

Specimens of this fish have been occasionally thrown on the British coasts, one of which is described under the article Opah. A dried specimen of this fish may be seen in the British Museum.

**Quadratus.** Grey dory, with transverse dusky or a cinereous body, and even tail. This fish, found in the sea that washes the coast of Jamaica, is described by Sir Hans Sloane, as five inches long and four broad in the middle, narrowing from thence gradually to the head and tail; mouth small, but with rows of small, sharp teeth; tongue round and cartilaginous; pupil large and black in a white circle; five fins; tail almost square; whole body clothed with grey or ashen-coloured scales, having three or four transverse black lines; with a very crooked line from head to tail.

**Zeus,** a species of scorpaena. See Scorpaena Porcus.

**Zeuxis,** in Biography, a celebrated ancient painter, who is said to have been a native of Heraclea, either in Greece or Magna Gracia, and to have commenced the practice of his art in the fourth year of the 95th Olympiad, B.C. 397. According to Quintilian, he is the first artist who understood the proper management of lights and shades, and to have excelled in colouring; but ambitious of imitating the strength and grandeur of Homer's manner, he is charged with giving unfinished bulk to the heads and melodrēns to the limbs. Notwithstanding he allowed every perfection, he attained distinguished excellence; and in the prosecution of it he was attentive even to the minutest circumstance. Many instances occur in his history to this purpose.

In his picture of Helen, executed for the Crotolians, as an ornament for their temple of Juno, he determined to combine every quality that might constitute a perfect beauty; and with this view he selected five of the handomest females of Crotola, and transferred to his picture, from their naked charms, an affenblage of all that were most perfect in their kind. This figure has been exhaled as the finest specimen of art existing; and under it the painter, not unconscious of his merit, inscribed the lines of Homer, in which Pham expresses his admiration of the beauty of the real Helen. Every one who saw it, before it was placed in the temple, paid the painter a fee, which, added to the liberal recompence of the Crotolians, amply repaid him for his skill and labour. This enabled him to gratify his vanity by making presents of his pictures, for which no adequate price could be given. To such a degree was he enriched by his art, that he was able to indulge his vanity by appearing at the Olympic games with his name embroidered in golden letters upon his mantle. Among his most famous performances are enumerated a Jupiter on his throne, with the other gods standing round;—a Hercules in his cradle, straining the serpents, Alcmena and Amphitryon witnessing the exploit with terror;—a Penelope, with an expression con forming to her character;—a Cupid crowned with roses, for the temple of Venus at Athens;—a Martyr's bound, afterwards placed in the temple of Concord at Rome; and a group of Centaurs. The time of his death is not known; but as to the manner of it, the following whimsical anecdote is recorded: after having painted an old woman, whilst he was attentively surveying it, he was seized with such a violent fit of laughter, that he died on the spot. Pliny Hist. Nat. Gen. Biog.

**Zeya,** in Geography, a river of Austria, which rises near Ernfrung, and runs into the March, 6 miles E. of Ziferdorf.

**Zeyl.** See Zeil.

**Zeyland,** a small island near the coast of Lapland. N. lat. 70° 10'.

**Zeyring,** a town of the duchy of Styria; 6 miles N.W. of Judenburg.

**Zezeare,** a river of Portugal, which rises in the coast part of Elremadura, and runs into the Tagus, at Tancos.

**Zezerine,** or Kiervanz, a small island in the Persian gulf, hardly half a mile in length. N. lat. 28° 8'.

**ZFoken,** a town of Saxony, in the circle of Erzgebirg; 8 miles N.W. of Grunhain.

**Zha,** a river of Africa, which forms the coast boundary of Fez, and runs into the Mulloaiah.

**Zhehol,** Zieho, or Gebo, a town of Chinese Tartary, in the country of the Mandhrs, not far beyond the great wall, and summer residence of the emperor of China; 120 miles N.E. of Peking.

**Zia,** an island in the Grecian Archipelago, anciently called "Cos" and "Hydra," about 16 leagues in circumference. The inhabitants are Greeks, who have a bishop. The soil is fertile, and they have a good breed of cattle, with plenty of wild fowl, especially partridges and pigeons. The chief manufactures are, flilk, camlets, and a fort of cloaks made of goats' hair. Among the productions of the island may be reckoned the velani, a species of acorn abundant in this island. Of four considerable towns or cities in this island, the only one at present remaining is Carthea, or Zeta, containing about 2500 houses, with a harbour capable of receiving vessels of considerable burden, and where a whole fleet may ride in security from every gale, in every depth of water, and in very good anchoring ground. The entrance into this creek or arm of the sea is very faje by keeping it, according to the sea-phare, open; but when once within it, ships of whatever burden may ride where they please to an anchor; 10 miles E. of Cape Colonni. N. lat. 37° 30'. E. long. 24° 24'.

**Zia,** Ziba, or Siba, in Ancient Geography, a city beyond Jordan; 5 miles W. from Philadelphia.

**Ziatek,** in Geograph. See Saatz.

**Zib.** See Zeb.

**Zib,** a town of Arabia, in the province of Hedjjas; 20 miles S.S.W. of Madian.

**Zibatskoi,** a fort of Russia, in the government of Kolivan, on the Irtisch. N. lat. 54° 44'. E. long. 92° 20'.

**Zibel**
ZIELENZIG, in Geography, a town of the New Mark of Brandenburg; this town belonged in a considerable degree to the knights of Malta; 18 miles S.E. of Cultrin. N. lat. 52° 30'. E. long. 15° 16'.

ZIENWALD, a town of Saxony, in the margrave of Meissen; 4 miles S.S.W. of Lauenstein.

ZIEREKOWITZ, a town of the duchy of Storia; 4 miles E.S.E. of Windisch Feilritz.

ZIERENBERG, a town of the principality of Heife Caffel; 11 miles N.W. of Caffel. N. lat. 50° 22'. E. long. 9° 20'.

ZIERA, in Botany, was so named by the writer of the present article, in memory of the late Mr. John Zier, F.L.S., who, as Dr. Sims records in the Botanical Magazine, "having been appointed to a professorship in a Polish university, was preparing to leave this country, but was prevented by a chronic disease, which terminated in death."

That Mr. Zier was "a learned and industrious botanist, we are more ready to confirm by our own testimony. He was no lea meritorious in his private character, and bore with modesty and patience those privations, which too often belong to literary merit in a foreign country, especially where canting and time-serving are out of the question. We have been informed that Mr. Zier was the coadjutor of Mr. William Curtis (see that article), in part, at least, of the celebrated Flora Londinensis; taking upon himself the technical Latin descriptions, while Mr. Curtis was engaged in those practical observations, experiments, and scientific distinctions, which make the peculiar merit of the work.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four deep, ovate, rather acute, equal, permanent segments. Cor. Petals four, ovate, pointed, somewhat coriaceous, downy, equal, longer than the calyx, alternate with its segments. Stam. Filaments four, alternate with the petals, awl-shaped, simple, smooth, infixed, much shorter than the corolla, each inserted into a globular gland, projecting above their base at the inside; anthers terminal, rounded, with a minute point. Pfyl. German superior, roundish, four-lobed, blyle terminal, erect, columnar, the length of the flaments, deciduous; stigma capitulate, four-lobed. Peri. Capules four, connected at their inner edge, each comprized, abrupt, of two valves and one cell. Seeds solitary, oval, comprized, each enclosed in a hoary elatic tupe of two valves.

We are acquainted with four species of this genus, consisting of shrubs, natives of New South Wales, with opposite, fliine, and tente leaves, and white flowers. It is allied to Boronia, (see Rutaceae,) as well as to Crowea, Eriostemon, Correa, Phebalium, and Melicope, to which we refer the reader. Ziera is essentially characterized by the infection of each of its frutes into the outside of one of four large glands, standing on the receptacle, at the base of the germs; as well by the simplicity of those frutes, in the other part of their fructification. All the species abound with resiny dots on their leaves, flanks, and calyx, lodging an essential oil, whose qualities are more or less acidic and aromatic.

1. Z. lanceolata. Lanceolate Ziera. Brown MSS. (Z. Smithii; Andr. Repof. t. 606. Curt. Mag. t. 1395; Ait. Epit. 376.)—Clusters axillary, repeatedly three-forked. Leaflets lanceolate, flat, acute. Branches and flanks warted. —Sent from Port Jackson, New South Wales, by Dr. John White, in 1795. It is said by Mr. Aiton to have been introduced into the English gardens in 1803, where it proves a tolerably hardy green-variably shrub, flowering in the spring and early part of summer, and may be increased from cuttings. The stem is bulky, of humble growth, being scarcely three feet high, with round, purplish, leafy branches, rough with glandular warts, and when young, beprinkled with minute, flary, rigid pubescence. Footflarks warty, channelled, near an inch long, suffrute of flipples, each bearing three lanceolate, flat, entire, smooth, fingle-rubbed leaflets, contrasted at each end, the middle one rather the largest, being two inches, or two and a half, in length. Panicles opposite, axillary, often two together, somewhat leafy, repeatedly forked, many-flowered, various in length, spreading, slightly downy; their flanks quadrangular, purplish. Flowers white, each about the size of a Privet-blossom, with yellow anthers. Capules brown, dotted with glands. Tunic of the seeds white and fining.

We agree with Dr. Sims in expressing an expressive specific appellation to one taken from the name of a botanist, and, therefore, as the genus in question was not established on this species more than the rest, all, except the last, having been equally considered, we are happy to let the example of an alteration, in which we can have no other motive than propriety and common advantage. We have called this species multiflora; but we consider the synonym in the Botanical Magazine as a publication of the unexceptionable name given by Mr. Brown.

2. Z. lanceolata. Smooth Ziera. —Clusters axillary, three-forked, coriaceous. Leaflets linear, revolute. Branches and flanks very smooth. Gathered by Dr. White, near Port Jackson, New South Wales. The branches of this pretty species are quadrangular, and very smooth, like every other part, except the petals. Leaves smaller than the foregoing, with somewhat of a glaucous hue. Footflarks about half a quarter of an inch long. Leaflets scarcely an inch, acute, polished, strongly revolute, dotted with glands, and somewhat tinged with purple. Flowers a little larger than the last, and much fewer, the panicles being always solitary, much leaf compound, and situated chiefly towards the upper part of each branch. The flanks are acutely quadrangular, and very smooth. Calyx brown or reddish, taper-pointed, likewise quite smooth. Petals downy on both sides, like a piece of woollen cloth.

3. Z. pauciflora. Few-flowered Ziera. —Stalks axillary, with one or three flowers. Leaflets linear-obovate, somewhat revolute. Branches and flanks hairy. Segments of the calyx lanceolate, taper-pointed. —Sent from Port Jackson, with the former, by Dr. White, in 1795. A small shrub, with slender, round, scarcely quadrangular, branches, which are more or less copiously clothed with erect bristly hairs. Leaves about half the size of the last; their leaflets dilated upwards, and obtuse, a little crenate towards the end; copiously dotted, rarely hairy, on the upper side; sometimes very hairy beneath, but occasionally quite smooth even in that part. Flowers very small, often quite solitary, on an axillary flalk, with a pair of small acute bracteas; sometimes there are three flowers on each flalk. Segments of the calyx broad at the base, but tapering suddenly into a long point. Petals minutely dotted with tufts of flary hairs, giving them a warty, or granulated, aspect. Capules tuberculated, sometimes hairy, curiously reticulated at the inside. Seeds black, rather opaque, with a fining, white, at length convoluted, tunic, whole edge is minutely fringed.

The hairy and nearly smooth varieties of this plant look different at first sight, but we cannot detect a specific distinction.

4. Z. cyrtoides. Downy Ziera. —Stalks axillary, three-forked, leafy. Leaflets obovate, entire, downy on both sides. Branches and flanks downy. —Native of New South Wales, from whence we obtained a specimen through the favour of Earl St. Vincent in 1805. Whether this be Mr. Brown’s arborosa, mentioned by Dr. Sims, we have at present no means of knowing, and therefore we are obliged to describe it by a name which appears to us very expressive.

Every part is clothed with fine dente soft pubescence, appearing filled and entangled under a high magnifier. Branches round. Footflarks half an inch long. Leaflets about an inch in length, entire, slightly revolute; their upper side peculiarly soft and velvet-like; the under moist hoary. When held against the light, they appear full of pellicid dots. Calyx very downy; its segments broad and ovate. Petals about twice as long, and of the same shape, downy. We have not seen the ripe fruit.

ZIESAR, or ZIEESAR, in Geography, a town of the Middle Mark of Brandenburg; 18 miles S.W. of Brandenburg.

ZIETZ, a town of the Middle Mark of Brandenburg; 10 miles S.W. of Brandenburg.

ZIEZAR, a town of Spain, in the province of Murcia; 22 miles N.W. of Murcia.
The species are,

Pursh. Root bulbous. Leaves a span long, concave, spreading. Stalk two feet high, bearing several, gradually diminishing, leaves, and terminating in a panicle of several greenish-white flowers, the size of Veratrum album, each of whose petals is marked, near the base, with a double glandular, apparently nectariferous, depression. Stamen distinct from the petals. Seed tunicate. We know not whether they be fo in any other Helonia.

H. elegans. Elegant Helonia. (Zigadenus elegans; Pursh n. 2.)—Leaves linear, flat, erect. Stalk nearly naked. Bracteas linear. Petals acute.—On the waters of Cokahlaifkit river, near the Rocky Mountains, found by governor Lewis, flowering in July. Radical leaves erect, linear, very long, smooth, ribbed, flat. Stalk taller than the foliage, about two feet in height, round, fimple, bearing one or two short leaves. Clusters many-flowered, occasionally branched at the bottom. Bracteas as long as the partial falks, membranous, ribbed. Flowers white, the size of Melanthium virginicum. Petals ovate, acute, with something of a claw, marked at the base with two vermillion spots. Filaments shorter than the corolla. Stigma three, reflexed. Pursh.

ZIG, in Ancient Geography, a people of Asiatic Sarmatia, on the bank of the Tanais. Pliny.

ZIGALOVA, in Geography, a town of Ruffia, in the government of Irkutik; 16 miles N.W. of Tутура.

ZIGAN, a mountain of Algiers; 18 miles S. of Conflantina.

ZIGANS, a town of Ruffia, in the government of Irkutik, on the Lena; 1472 miles E. of Tobolsk. N. lat. 67°. E. long. 125° 22'.

ZIGERA, or ZIGHEA, in Ancient Geography, a town of Africa Propria, between the town of Thabrac and the river Bagradas. Ptolemy.

ZIGER, a word used by some of the old writers to express a very fine kind of caffa, extremely aromatic to the taste, and of a purplish-black colour.

ZIGERE, in Ancient Geography, a town of the interior of Thrace, on the borders of Lower Mædia.

ZIGET, in Geography, a town of Hungary, situated between the streams of a small river, which unite below the town, and flow after run into the Drave. It is on every side surrounded by a moras, and defended by moats, walls, and battions; 44 miles S.E. of Czincsa. N. lat. 46° 8'. E. long. 17° 56'.—Alba, a river of Hungary, which runs into the Drave, 12 miles S. of Zigel.

ZIGIRA, in Ancient Geography, a town of Asia, in Assyria, towards the N., and at a great distance from the Tigris. Ptol.

ZIGURELLA, in Ichthyology, the name by which some have called the julis, a small but beautiful fish, common about Genoa, and in some degree approaching to the nature of the turdus or wraze.

It is a species of the labrus, according to Arcted, and is distinguished by the name of the palmaris labrus, with two large teeth in the upper jaw. See Labrus.

ZIGZAG TREFOIL, in Agriculture, a term sometimes applied by farmers to the perennial red clover, marl grafs, or wild red clover. See Clover and Trifolium Purpurascens.

ZIKLAB, or SICALAB, in Ancient Geography, a city which Achæ, king of Gath, gave to David, while he took shelter among the Philistines (1 Sam. xxvii. 6.), and which afterwards always belonged to the kings of Judah. Josua had allotted it to the tribe of Simeon. (Josh. xix. 5.) Eufebius says, that it lay in the southern part of Canaan.

ZILA, in Geography, a river of Moldavia, which runs into the Pruth, 35 miles S.E. of Jassy.

ZILEH, a town of Turkis Armenia; 30 miles S.S.W. of Arzianog.

ZILGA, a river of Ruffia, which runs into the Oka, N. lat. 53° 4'. E. long. 101° 14'.

ZILIS, in Ancient Geography, a town of Africa, in Mauritania Tingitana, marked in Anton. Itin. 24 miles from Tingis, between Tabernæ and Ad Mercuri. This was a colony established by Augustus, exempt from the jurisdiction of the kings of Mauritania, and dependent upon Bactria in Hifpania.

ZILKEFEL, in Geography, a town of the Arabian Irak; 18 miles S.W. of Hellic. ZILLEBA, a town of Arabia, in the province of Yemen; 35 miles E. of Loheia.

ZILLER, a river of Tyrol, which runs into the Inn, 2 miles above Rattenburg.

ZILLY. See Cilly.

ZILMISSUS, in Ancient Geography, a hill of Thrace, on which was a temple dedicated to the god Sabadeus. Macrobius.

ZILTAN, in Geography, a town of Africa, in the defert of Barca; 150 miles W. of Angela.

ZIMARA, in Ancient Geography, a town of Asia, in the Greater Armenia, at the foot of mount Capotis, in the place where the Euphrates has its source.

ZIMARA, in Geography, a town of Asiatic Turkey, in the government of Sivas; 55 miles E. of Sivas.

ZIMBAOA, or ZIMBA, a town of Africa, in the kingdom of Sofala, and capital of Mocaranga. S. lat. 16° 42'. E. long. 33° 40'.

ZINBRA. See Zowamore.

ZIMENT-WATER, or COPPER-WATER, in Natural History, the name by which some have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal.

The most famous spring of this kind is about a mile distant from Newfor in Hungary, in the great copper-mine called by the Germans ferna grundt.

The water in this mine is found at different depths, and is received into basins, for the purpose of separating the copper from it; in some of these it is much more salted with this metal than in others, and will make the spumous change of iron into that metal much sooner. The most common species of iron used in the experiments are, hornhed, nails, and the like; and they are found very little altered in shape, after the operation, except that their surfaces are more raised.

The water appears greenish in the basin where it stands; but if a glass of it be taken up, it looks clear as crystal: it has no smell, but a strong vitriolic astringent taste, infomuch that...
that the lips and tongue are blistered and scorched upon
tasting it.

The miners are well acquainted with the virtue of this
water in changing the metals; but they also use it as a
medicine: whatever sickness they are seized with, they first
attemp its cure by a large dose of this water, which usually
both vomits and purges them very briskly. They also use it in disorders of the eyes, in some of which
it must be of great power; but in others, it is very im-
proper; so that upon the whole they do more harm than
with it.

The copper produced from these waters is valued by
the people much beyond any other copper, as being much more
ductile, and running easier in the fire: the people in the
neighbourhood have many vessels of it; but it is to be
observed, that its ductility and hardness increase after it is
taken out of the water; for while immersed in it, it is
friable.

It is observed, that after great rains the springs are
always fuller than at other times, and the virtues of the water
considerably less.

A small quantity of oil of tartar being added to a pound
of this water, the whole becomes turbid, and on filtration
leave a large residuum in the filter, which dried, weighs
about two scruples and a half; and when warm water is poured
upon this and filtered, six grains of yellowish earth will be
left in the filter; and the greenish solutiion being again
evaporated to a pellicle, and the operation being several
times repeated, somewhat more than two scruples of a blue-
green vitriol will be separated in small crystalls.

A small quantity of oil of tartar being added to a pound
of this water, the whole becomes turbid, and on filtration
leave a large residuum in the filter, which dried, weighs
about two scruples and a half, and is found to be a cupreous
vitriol, with a small mixture of a neutral salt. If a pint of
this water be put into a bottle, and a small piece of iron
thrown into it, bubbles will appear on the iron, which will
gradually be changed to a copper colour. On the second
day, the water will be turbid, and afterwards whitish, and
white filaments will gather about the bottom and sides of the
glafs, and about the iron, which will appear throughout of
a coppery colour. From these experiments, we may
easily understand what the true nature of the water is; that
it contains a large quantity of vitriol of copper, which it
probably owes to a soluion of that metal, by means of the
acid of the common pyrites and water: when this is known,
the effects are not difficulty accounted for, there being no
real change of one metal into another; but the true state of
the cafe being, that the particles of one metal are disdolved
and carried away, and those of another metal deposited in
their place. A water thus impregnated is a menstruum
capable of dissolving iron, and in the soluion of that metal
becomes so weakened as to let go the copper it before con-
tained in small parcells. This is seen to be the cafe, by
examining the changed metal while it lies in the water, the
copper then appearing not a soft malleable and even mafs,
but a congeries of granules closely placed together, and
resembling the small granules, or ovs, in the spawn of fishes;
and it is very friable and fragile while in this state.

This solution of one metal, and deposition of the particles
of another in its place, is a thing very familiar in chemistry,
and is seen every day in numerous instances; but in none so
familiar as in a like cafe, or solution of iron and copper in
the same menstruum. Thus, if a piece of copper be dis-
solved in aqua fortis, and when this solution is perfected a
piece of iron be thrown into the liquor, the same thing will
be seen that is in this spring, for the iron will be dissolved,
this visit gave him an opportunity of publishing an account of his "Conversations" with that celebrated prince. He was induced also, by the notice that was taken of him, to undertake a defence of the character of Frederick against the censures of Count de Mirabeau. The severe criticisms to which these writings exposed him, and the part he took in the conversations that agitated the continent with regard to the principles that produced the French revolution, irritated his feelings and disquieted a mind like his peculiarly susceptible of contumely and reproach. His political and religious principles led him to view with jealousy and detestation those societies which, in his judgment, and in that of others of similar sentiments, aimed at the subversion of established forms and authorities, and to declare war against them. Such were his abhorrence and dread of them, that he addressed a memoir to the emperor Leopold, recommending the suppression of them by force; and he subjected himself to a prosecution for a libel by a charge brought against a person by name for an unavowed publication. His mind had arrived to such a state of irritation, that the approach of the French towards Hanover in 1794 almost subverted his reason. Dreading the consequences of their arrival, he abounded in food, waited to a skeleton, and died absolutely worn out in 1795, at the age of 66.

"Such," says his biographer, "was the melancholy end of a man whose moral and intellectual qualities rendered him in a high degree the object of private friendship and public esteem." Tiffiot's Life of Zimmerman. Gen. Biog.

ZIMOVE, in Geography, a village of Ruffia, in the government of Irkutsk, where is a column-house; 52 miles S.E. of Barguzinsk.

ZIMOVE Tchijko, a town of Ruffia, in the government of Irkutsk; 16 miles S.W. of Vitimkoi.

ZIMOVE Tafischnoo, a winter habitation of Ruffia, on the N. coast of Baikal lake, in the government of Irkutsk. The word Zimovoe, in Ruffian, means a house or inn, built at a distance from a town, for the accommodation of travellers, where are generally found a warm room, fresh bread, and a kind of liquor called quafe. N. lat. 55° 20'. E. long. 109° 14'.

ZIMOVE Zaminskoi, a town of Ruffia, in the government of Irkutsk, near lake Baikal; 76 miles S.E. of Vercholenk.

ZIMOVSKAIa, a town of Ruffia, in the country of the Cofacks, on the Choper; 48 miles W. of Arkadanikia.

ZIN, Sin, or Senna, in Ancient Geography, a city S. of the land of promise. (Numb. xxxiv. 4.) See Sina.

ZINARI, in Geography, an island in the Grecian Archipelago. N. lat. 36° 59'. E. long. 26° 10'.

ZINARIA, a word used by the Arabsians for a kind of vitiated bile, called arcurious bile.

ZINC, in Chemistry, the name of a metal, in Latin zincum. The ancients do not appear to have been acquainted with this metal. Cadmia was the name by which they seem to have known one of its ores, which was so called from Cadmus, who, it is said, taught the Greeks how to form braze by its means. It is first mentioned by Albertus Magnus, but it is doubtful if he had ever seen it. The word zinc first occurs in the writings of Paracelsus. This metal has been also called spelter.

Zinc has never been found in Europe in a state of purity, and chemists were late in discovering a method of extracting it from its ores. Henkel seems to have been one of the first who effected this about the year 1720, and he was soon followed by others. Zinc is of a brilliant white colour, with a shade of blue, and seems to be composed of a number of thin plates adhering together. It imparts a perceptible smell and colour to the skin when rubbed by it for some time; hence it is rather soft. Its specific gravity is said to vary from 6.86 to 7.1, the lightest being esteemed the purest. When hammered, it becomes so brittle that it may be reduced to powder in a mortar.

Zinc may be drawn into wire. According to Mufchenbroek its tenacity is such, that a wire of .7-inch in diameter is capable of supporting a weight of about 26 lbs.

Zinc melts at a temperature of about 680°, according to Dr. Black. If the heat be increased it evaporates, and may be easily distilled over in close vessels: upon this property of zinc, Von Swab's method of extracting it from its ore was founded. When allowed to cool slowly, this metal crystallizes beautifully in small bundles of quadrangular prisms disposed in all directions, which, if exposed to the air while hot, assumes a blue changeable colour.

When exposed to the air, zinc soon tarnishes, but it scarcely undergoes any other change. When kept under water, its surface becomes black, the water is decomposed, hydrogen is emitted, and the oxygen combines with the metal. If heat be applied, these changes go on more rapidly; and if the steam of water be made to pass over zinc at a high temperature, it is very rapidly decomposed.

When this metal is kept melted in open vessels, it soon becomes covered with a grey pellicle of oxide. If the heat be very strong it takes fire, and burns with a brilliant white flame, and at the same time emits a great quantity of very light white flakes. This is merely the oxide of zinc. It was well known to the ancients, and received from them many whimsical names, such as pompolyxs, &c. Among the alchemists it was known by the names of nihil album, lana philtrophia, flowers of zinc, &c.

Zinc appears to combine with only one proportion of oxygen, which has been flated by different chemists to vary from 24.16 to 25 of oxygen to 100 of the metal. According to the first of these determinations, the weight of the atom of zinc will be 41.39; according to the second 40. Dr. Thomson has decided upon 41.25 as the most probable weight of the atom.

Zinc combines readily with chlorine, and forms a chloride of zinc. It may be prepared by dissolving zinc in muriatic acid, or by exposing the metal to the gas, when the two combine by a species of combustion. The chloride may be also obtained by dissolving zinc- filings with the oxy-muriate of mercury, or corrosive sublimate; and thus obtained, it was formerly denominated the butter of zinc. When thus prepared, it sublimes on the application of heat, and crystallizes in needles; but according to Dr. Davy, when the common muriate is heated in a glass tube, it does not sublime even at a red heat, but remains in a state of fusion. Exposed to the air, it soon deliquesces. According to Dr. Davy's analysis, it is composed of

But if we suppose it to be composed of an atom of zinc and
ZINC.

and an atom of chlorine, and the atom of zinc to weigh as
above, its constituents should be

Zinc readily combines with iodine by heat. The compound, or iodide, is white. It is volatile, and crystallizes in
fine quadrangular prisms. It deliquesces in the air, and is
very soluble in water. The solution is colourless, and does not crystallize. Gay Lussac has shown, that this
compound consists of one atom iodine, and one atom zinc, or by weight of

No compound of zinc with fluorine is as yet present
known. Zinc does not combine with azote nor hydrogen;
nor are we acquainted with any compound of this metal with boron and silicon.

Zinc may be combined with phosphorus by dropping
small bits of phosphorus into it while in a state of fusion.
Phosphuret of zinc is of a white colour, and possesses a metal
lic lustre, which more refracts than zinc. This is
somewhat malleable. It emits the odour of phosphorus
when filed or hammered, and if exposed to a strong heat it
burns like zinc. Phosphorus also appears to combine with
the oxide of zinc, and to form a peculiar compound.

Sulphur cannot be combined artificially with zinc; but
if melted with the oxide of zinc a peculiar compound is
formed. A similar compound is formed when sulphurised hydrogen in combination with an alkali is dropped into a
solution of zinc. It is at first white, but becomes darker
on drying. Dr. Thomson considers this compound as a
phosphuret of zinc. Mr. E. Davy ascertained, that when
the vapour of sulphur is passed over zinc in fusion a yellowish compound is obtained, similar in appearance to blende.

One of the most common ores of zinc is blende, described
below, and which is a phosphuret of zinc, composed, according
to Dr. Thomson’s experiments, of

</table>

Hence he considers it as a compound of one atom zinc,
and one atom sulphur.

The alloys of zinc and the metals of the fixed alcalis are
specifically decomposed by exposure to the air or immi
ration in water. We are not acquainted with the alloys of
zinc and the metallic bases of the alkaline earths.

Zinc may be combined with arsenic by distilling a mixture
of it and arsenious acid. With iron, zinc combines
with difficulty; the alloy when formed, according to Lewis,
is hard, somewhat malleable, and of a white colour, like
silver. M. Jolin has shown, that zinc may be used instead of tin for covering iron plates; a circumstance which
demonstrates an affinity between the two metals.

Zinc does not appear capable of combining with nickel
or cobalt by fusion. The alloys of zinc with manganese,
cerium, and uranium, are unknown.

For the other alloys of zinc, see the different metals;
particularly for the most important of them or brasses, see
Brass and Copper.

Salts of Zinc.—Almost all the acids act with energy on
zinc, in consequence of its powerful affinity for oxygen.
The salts of zinc, therefore, are very easily formed, and
on account of their being but one oxide of zinc are not
much liable to variation.

Nitrate of Zinc.—The nitric acid attacks zinc with such
energy, that it is commonly necessary to moderate its action
by diluting it with water. Even then much heat is
evolved, and a strong effervescence is produced by the
escape of nitrous oxyd gas. The solution is transparent
and colourless, very caustic, and yields by evaporation flat,
flattened, tetrahedral prisms, terminated by four-sided pyramids.
These crystals attract moisture on exposure to the air, and
are soluble in water and alcohol. When heated they melt,
and if thrown on burning coals, detonate with a red
flame.

Carbonate of Zinc.—Caledine, one of the ores of zinc, is
a native carbonate of zinc, as described below. This salt
usually exists in the form of a white powder, and may be
obtained by precipitating zinc from its solution in acids by
an alkaline carbonate.

Phosphate of Zinc.—The phosphoric acid unites in two
proportions with the oxyd of zinc. The neutral phosphat
is a tafelte white powder insoluble in water. The bi-
phosphate is soluble in water, if not exposed to too great a
heat. It does not crystallize, and it is strongly acid.

Sulphate of Zinc.—Concentrated sulphuric acid scarcely
acts upon zinc without the affiatence of heat; but when
diluted it acts upon the metal very strongly, and hydrogen
is given out in abundance. In this case, the water is
decomposed, its oxygen combines with the metal, while its
hydrogen escapes. The solution, when concentrated, yields
crystals in abundance.

This salt, formerly known under the name of white
vitriol, was discovered in Germany, about the middle of
the 16th century. When quite pure, it is perfectly white.
The form of its crystals is that of flat quadrangular prisms,
terminated by four-sided pyramids. At a temperature of
62°, it diffuses in about 1.4 times its weight of water. In
boiling water, it diffuses in any quantity whatever. The
constituents of this salt are,

<table>

</tr>
</tbody>
</table>

When heated, the crystals part with their water, and if
the heat be strong, the whole of the acid likewise separates,
and leaves the oxyd of zinc in a state of purity. See
VITRIOL, White.

Muriate of Zinc.—See Chloride of zinc, supra.

Sulphite of Zinc.—This salt exists in the form of crystals,
soluble in water, but insoluble in alcohol. On exposure to
the air, they are soon converted into the sulphate of zinc.
Fourcroy and Vauquelin describe a hypo-sulphite of zinc,
which affines the form of four-sided prisms, terminated
by four-sided pyramids. They are soluble in water and alcohol.

Borate of Zinc is a white, insoluble powder. It may be
formed by pouring borate of soda into the nitrate or muriate
of zinc.

Arseniate of Zinc is a white insoluble powder, and may be
formed by mixing solutions of the alkaline arseniates with the
sulphate of zinc.

Acetate of Zinc.—This salt exists in the form of rhom-
bohial or hexagonal plates of a tafelte appearance, and is not
very soluble in water. Solutions of this salt form an excel-
ent external application to inflammations.

Oxalate of Zinc.—This salt is a white powder, little soluble
ZINC.

n water, and may be formed readily by double decom-
position.

Tartarate and Citrate of Zinc. — Both these salts exist usu-
ally in the form of powders, and are but little soluble in
water. They may be procured, like the oxide, by double de-
composition.

The other salts of zinc are of very little importance or
interest, and do not therefore merit to be enumerated here.
The salts of zinc may be distinguished in general by their
forming colourless solutions in water, by their yielding
white precipitates with prussiate of potash, sulphuretted hy-
drogen, and the alkalies, and by the characteristic circum-
stance that zinc is not precipitated in the metallic state by
any other metal.

Uses of Zinc and its Compounds. — Neither this metal nor
its compounds, if we except brass, are much employed in the
arts nor in medicine. A chief use of zinc is in the formation
of galvanic apparatus, and in electrical experiments. (See
Galvanism and Electricity.) As it is not a poisonous
metal, it has been recommended instead of tin and lead for
domestic purposes; but the ease with which it is oxidized
makes it very unfit for all sorts of culinary apparatus.

The strong affinity of zinc for oxygen renders it of
great use as a chemical agent for precipitating other metals
from a state of solution in the metallic state. The oxide of
zinc is used in medicine, both internally as a tonic, and
externally mixed with hog’s-lard as an ointment. The native
carbonate is also used in the same manner as an external
application. See Unguentum Calamine, and Unguentum
Zinci.

The sulphate and the acetate are the only salts of zinc used
in medicine; for the properties of which, see above.

Zinc, Ores of, in Mineralogy. The ores of zinc are gen-
erally associated with lead-ores, and exist abundantly in va-
rious parts of England; particularly in veins in the moun-
tain lime-stone of Derbyshire, Durham, Cumberland, York-
shire, Somersethire, and North Wales. The ores of zinc
are either oxides, carbonates, or sulphures of zinc, and are
principally known as calamine or blonde. There is an ore
of zinc hitherto found only in North America, called by
Dr. Bruce red zinc-ore; it occurs in several of the iron-
munes in Suffolk county, New Jersey.

Red Zinc Ore is of a blood-red or aurora-red colour: it
occurs massive and disseminated. The fresh fracture is lining,
but becomes dull after long exposure to the air, and is cov-
ered with a pearly crust; the principal fracture presents
a foliated fracture; the croz fracture is concentried. It is
opaque or translucent on the edges; it yields a brownish-yel-
low or orange streak; it is brittle. The specific gravity is
6.22. It is insufible without addition by the blow-pipe, but
melts into a transparent yellow bead with borax. When
pounded and mixed with potash, and exposed to heat, it melts
into an emerald-green mass, which, on solution in water,
yields the same colour; but on the addition of the mineral
acids is immediately changed to rofe-red. This ore is sol-
uble in the mineral acids. Its constituent parts are,

\[
\begin{align*}
\text{Zinc} & \quad 76 \\
\text{Oxygen} & \quad 16 \\
\text{Oxys of manganese and iron} & \quad 8 \\
\end{align*}
\]

Bruce’s American Mineralogical Journal, p. 69.

According to Dr. Bruce, this ore possesses advantages in
the manufacture of brass over those generally used; for
without any previous preparation, it affords with copper
brazes of the very fineel quality, pollelning a high degree of
malleability, and suited for the most delicate workmanship.
Red zinc-ore is characterized and distinguished from red
silver-ore and red lead-ore by its insufibility; the latter
melting into a blackish flag before the blow-pipe. Red orpine,
with which it might be confounded, is distinguished from
red zinc-ore by its volatility, and the garlic smell which it
yields. This ore of zinc has greater specific gravity than
red copper-ore, and its solution in acids is colourless; but
those of red copper are green. Calamine is divided by some
mineralogists into four kinds, sparry calamine, compact
calamine, earthy calamine, and electric calamine.

Sparry Calamine: Zinc Carbonate, Haüy. — Its colours
are greyish and yellowish-white, and sometimes green and
reddish-brown. It occurs massive, botryoidal, cellular,
flaflake, and crystallized, in acute and obtuse rhomboids,
and in longish quadrilateral tables: the crystals are small.
The lustre of sparry calamine is between refrinous and vitre-
ous. The fracture is imperfectly lamellar, and sometimes
radiated. It is translucent, or more or less transparent; it
yields easily to the knife. The specific gravity is 4.3. It is
insufible before the blow-pipe, and loses about 34 per cent.
by ignition. With muriatic acid it effervesces, and is dis-
folved. According to Smithson, the constituent parts of
this ore from Derbyshire are,

\[
\begin{align*}
\text{Oxid of zinc} & \quad 65.2 \\
\text{Carbonic acid} & \quad 34.8 \\
\text{From Somerfethire,} & \\
\text{Oxid of zinc} & \quad 64.8 \\
\text{Carbonic acid} & \quad 35.2 \\
\end{align*}
\]

Compact Calamine: Zinc Carbonate, Haüy. — Its colours
are, greyish, greenish, or yellowish, and often brown, from
an intermixture with iron. It occurs massive, botryoidal,
diffuse, flaflake, reniform, and mamillated; it has a dull,
feebly glintening, refrinous lustre. The fracture is uneven
and coarse-grained, or splintery, and sometimes even a
flatty conchoideal. It sometimes occurs in concentric la-
mmellar concretions: it is opaque. Its chemical characters
and constituent parts are the same as of the sparry calamine,
these minerals being only varieties different in form from
each other.

Earthly Calamine: Zinc Carbonate, Haüy. — It is of a
greyish or yellowish-white colour, sometimes snow-white;
externally it is frequently covered with a tint of yellowish-
brown. It occurs massive, and coating other minerals; it is
opaque, and has an earthy fracture; it yields to the nail,
and adheres to the tongue. The specific gravity is 3.58. Ac-

\[

\text{Oxid of zinc} & \quad 71.4 \\
\text{Carbonic acid} & \quad 13.5 \\
\text{Water} & \quad 15.1 \\
\end{align*}
\]

Electric Calamine: Zinc Oxide, Haüy. — Its prevailing
colours are, greyish, blueish, or yellowish-white; external-
ly it is sometimes brownish or blackish. It occurs crys-
\[\text{tals are six-sided prisms, with dehedral summits, or acute}
\text{octahed-}
ZINC.

octahedrons; sometimes truncated on the summits. The crystals are small, and either solitary, or radiating in groups, like zeolite. The luster is shining, glassy, and vitreous; the structure is imperfectly lamellar, or divergingly fibrous. It is sometimes opaque, and sometimes translucent or transparent: it yields to the knife, but is much harder than common calamine. The specific gravity is 3.4. When gently heated it is strongly electric; it is infusible, and looses about 12 per cent. by ignition. It is soluble in muriatic acid with effervescence: the solution gelatinizes on cooling. According to Klaproth, its constituent parts are,

Calamine sometimes occurs in what are called supposititious crystals, as if it had been moulded over crystals of other minerals, and the internal crystal had disappeared. In Derbyshire, the working miners are of opinion, that the calamine destroys the lead-ores when they occur together; or, as they express it, the calamine eats up the lead. That some processes of decomposition or change takes place where these ores are associated there can be no doubt; but by what means this is effected we are at present ignorant. See Venis, Metallic.

Calamine, commonly called lapis calaminaris, when cleaned and roasted, is used for the fabrication of brafs, forming a compound with copper. (See Brass.) Its uses in the making of brafs is of very high antiquity, being mentioned by Ariflotle.

Calamine is also the most valuable ore from which metallic zinc is extracted.

The uses of calamine were not known in England before the reign of queen Elizabeth, and even so late as the year 1700 it was commonly carried out of the kingdom as ballast by the ships which traded to Holland. The calamine raised in Derbyshire about the year 1720 amounted to 1500 tons. Sixty years before that time the quantity got did not exceed 40 tons, the greater part being thrown away through ignorance of its nature and value.

The dressing of calamine consists principally in picking out all the pieces of lead-ore, lime-flone, iron-flone, heavy spar, and other minerals mixed with it in the mine. The picked calamine is then calcined in proper furnaces, and looses by calcination between a third and fourth part of its weight, which is the carbonic acid. In great works, where calamine is prepared for the brafs-makers, after its calcination, it is carefully picked again, the accidental ingredients being rendered more durable by the action of fire. It is afterwards ground to a fine powder, and washed in a gentle stream of water, to free it from earthy particles with which it may be intermixed; the fine being lighter are carried off by the water: it is then made up for use.

A ton of the crude Derbyshire calamine, as dug from the mine, is reduced, by the various processes it undergoes before it becomes fit for use, to about twelve hundred weight. Part of the zinc is lost in calcination, particularly if too strong a fire be made: this is evident by the flame visible over the furnace. It would be practicable to use calamine without calcining it, for the carbonic acid would be expelled by the heat applied in making brafs; but then there would be seven or eight hundred weight put into the brafs pots which would be of no use in the operation: it is therefore better to get rid of so large a quantity of unserviceable matter, and thereby avoid also an increased expense of carriage from the calamine-furnace to the places where the brafs are made. Watson's Chemical Ells, vol. iv.

Blende comprises various sulphurets of zinc, differing in the proportion of their constituent parts, and the admixture of other mineral substances.

Yellow Blende, or Phosphorescent Blende: Zinc Sulphure Jaunis, Brongniart. — The prevailing colours of this ore are yellow, passing into green, and sometimes blue, and opal. It occurs massive, disseminated, and crystallized. The crystals are generally small, middle-sized, and closely aggregated, and it is difficult to determine the precise figure, which appears either the rhomboidal, the dodecahedral, the octahedral, or the tetrahedral. Yellow blende is translucent, passing into transparent, and has a splendid adamantine lustre. It yields to the knife, and affords a yellowish-grey or yellowish-white streak: it is brittle. The specific gravity rather exceeds 4; according to Kerton, it is 4.1.

It decrepitates before the blow-pipe, and becomes grey; but is infusible either alone or with borax. By friction it becomes phosphorescent, and, according to Bergman, acts as powerful in this respect in water as in air.

Fosketed Brown Blende: Zinc Sulphure Brun, Brongniart. — It is of a reddish or yellowish-brown, passing into blackish-brown and dark red. It occurs massive, disseminated, and crystallized. The form of the crystals is a rhombohedral dodecahedral, either perfect or truncated on the alternate lateral angles and edges, or an octahedral, either perfect or truncated. It occurs also in tetrahedrons, perfect or truncated, and in rectangular four-sided prisms, six-sided prisms, and acicular crystals. Sometimes the crystals are joined, forming a twin crystal. The luster is shining or splendent, and either reinosus, adamantine, or semi-metallic; it has a straight lamellar structure, with a cleavage in six directions. It is more or less translucent; it yields to the knife, and affords a yellowish-grey or yellowish-brown streak; it is brittle, and easily fractureable. The specific gravity of this ore varies from 3.7 to 4.

It is infusible, and yields an hepatic odour when digested in sulphuric acids. The constituent parts of blende are given as under; but some varieties of foreign blende contain silex, arfenc, and manganese, which may be regarded as accidental.

Fibrous
ZINCHI, or ZICHI, in Ancient Geography, a people of Asiatic Sarmatia, upon the coast of the Euxine sea, and separated from the Scythians by the river Acheus. Arrian.

ZINCKGRABEN, in Geography, a town of Bavaria, in the bishopric of Bamberg; 5 miles E. of Lichtenfels.

ZINDIKITES, a seat among the Mahometans; so designated from their leader Zindik, whom Grotius makes to be one of the magi, and a follower of Zoroaster.

The Zindikites believe no providence nor retribution: they allow no other God but the four elements; and, in this sense, they affect, that man, being a mixture of those simple bodies, returns to God when he dies.

ZINDINSKAIA, in Geography, a fort of Ruflia, on the confines of China, in the government of Irkutsk; 80 miles S. of Selenginsk.

ZINETUS, a word used by Paracelsus as a name for one of the brases-like marcasites.

ZINGANE-IS-KELESI, in Geography, a town of European Turkey, in Romania; 6 miles S. of Burgas.

ZINGAR, a word used by some of the chemical writers for verdigrise; and by others for the flores, or flowers of copper or brass.

ZINGHA, in Geography, a town of Africa, in Whidah; 20 miles N.W. of Sabi. ZINGI, in the Materia Medica, the name of a seed, sometimes also called the anilum Reullatum, or flarry-headed anise.

ZINGIBER, in Botany, of Dioscorees, a name which the Greeks seem to have taken, when they obtained the plant itself, from the Arabs. Gartner, dextrified with Linnaeus's application of the ancient name Anomum, to a genus of the Scitamineae, under which they both of them confounded very different things, still confounded Zingiber in its place, as undoubtedly belonging to one or other of the species. But since this tribe, and its generic distinctions, have been cleared up by Mr. Roffce, it becomes necessary to discriminate between Anomum and Zingiber, and consequently both names are employed.—Roffce Tr. of Linn. Soc. v. 8. 347. Dryand. in Alt. Hort. Kew. v. 1. 5. (Anomum; Lamarcch ill. t. 2. f. 3.)—Cliffs and order, Monandria Monogynia. Nat. Ord. Scitamines, Linn. Brown. Canis, Jull. Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, thrashing, membranous, splitting at one side. Cor. of one petal: tube twice the length of the calyx, a little swelling upwards; outer limb ringlet; the upper lip divided; lower in two deep, equal, deflexed segments; inner limb a large, spreading, three-lobed lip, of which the middle segment is the largest, all of them more or less wavy and crenate. Stem. Filament one, erect, oblong, extended beyond the anther in an awl-shaped incurved beak, involuted at the edges, embracing the style; anther attached by its back, below the beak of the filament, oblong, of two close, parallel, linear lobes, meeting round the style, curving in front. Pfl. German inferior, roundish, small, crowned with a pair of glands; style thread-shaped, embraced by the filament, and feebly extending beyond its beak; stigma small, concave, fringed, projecting a little beyond the point of the beak. Peric. Cape? —

Eff. Ch. Anther two-lobed. Filament elongated beyond the anther, with an awl-shaped, channelled beak, embracing the style. Outer limb of the corolla ringlet; inner a three-lobed lip.

Obf. Juffieu had already, after Adanson, remarked a difference between the inflorescence of the Ginger and the Cardamom tribes, though both have been comprehended by all botanists under Anomum. In the former, the flowers compose a dense spike, supported by a radical flalk; in the latter, they are panicked at the base of the stem. So important a difference in habit, between plants whose general structure is so uniform and simple, might lead us to look for some generic difference in the parts of fruitification. This Mr. Roffce has detected in the filament, according to the
the principle which runs through all his generic definitions of this tribe, and which is supported throughout by the in- 
fluence, as well as the parts of the flower in general. 
Nothing more perfect has ever been accomplished in fyle- 
matic botany. See Scitamineæ.

Ait. n. 1. (Z. majus; Rumph. Amboin. v. 5. 176. t. 66. 
Pl. v. 1. 6. Jacq. Hort. Vind. v. 3. 31. t. 75. " Infichi; 
Rheed Hort. Malab. v. 11. 21. t. 12." )—Bracteas ovate, 
acute. Segments of the outer limb of the corolla linear, 
revolute. Middle lobe of the lip entire.—Native of the 
East Indies; naturalized in Jamaica. A flower plant 
in England, flowering in September. It appears to have 
been cultivated here by Edward lord Zouch, before the year 
1605. The root is perennial, tuberos, fibrous, with long 
flout fibres, well known for its hot, gratefully aromatic, 
flavour, and cordial qualities. The whole herb is smooth, 
and partakes of the flavour of the root. Barren flens 
several, erect, herbaceous, wand-like, leafy, about three feet high. 
Leaves alternate, linear-lanceolate, acute, entire, single- 
ribbed, spreading, with long, close, sheathing, abrupt foot- 
flanks. Flower-flasks radical, a foot high, clothed with tu- 
bular sheathing bracteas. Spike solitary, erect, club-rounded, 
enveloped in broader, shorter, less pointed, crowded bra- 
tease, each accompanied by a solitary, fleshy flower, twice its 
own length, of a delicate texture and short duration. The outer 
limb of the corolla is of a very pale yellow, or straw 
colour, revolute; the upper segment rather the broadest. 
Lip, as well as the incurved point of the filament, spotted 
with crimson. We have never been able to procure any 
specimen or account of the fruit, which is perhaps in 
consequence of the great increase of the roots, not often 
perfeated, or if produced, it is most probably overlooked 
by the cultivators, who may find it expedient for the ad- 
vantage of their crop, to cut away the flanks before they 
run to feed.

Ait. n. 2. Sm. Exot. Bot. v. 2. 105. t. 112. (Z. ipu- 
rhium; Koenig in Ketz. Obf. falc. 3. 10. Z. latifolium 
fitylabre; Herm. Lugd.-Bat. 636. t. 637. Amomum Ze- 
Hort. Vind. v. 3. 30. t. 54. Lampium; Rumph. Ambo- 
in. v. 5. 143. t. 64. f. 1. " Katou-infichi-kua; Rheed 
Hort. Malab. v. 11. 27. t. 13." )—Bracteas ovate, obtuse. 
Segments of the outer limb of the corolla straight. Mid- 
dle lobe of the lip cloven, slightly wavy. Rib and teeths 
of the leaves smooth.—Native of the East Indies. The 
roots are said to be bitter, without the flavour and pungency 
of the true Ginger; but the young foliage, according to 
Rumphius, is used in Amboyna as a pot-herb. This spe- 
cies is not uncommon in our floses, being eafy of culture, and 
flowering frequently at the end of autumn. Many persons 
who grow it think themselves posfefled of the real Ginger. 
The habits of the two plants are indeed very familiar, but the 
barren flens of the present species are rather the taller, 
being four or five feet high, with elliptic-lanceolate leaves; 
filky beneath when young. Flower-flasks eighteen inches 
or two feet high, thick and firm. Spike ovate. Flowers 
pale yellow, without scent, each lasting but a few hours. 
Upper segment of the outer limb ovate, erect, concave: 
two lower ones lanceolate. Lip yellow, its large central 
lobe emarginate.

3. Z. Cafumunar. Cafumunar, or Haary Ginger. 
" As Xob. in Aftatic Referaches, v. 11. 347. t. 7." Sims in 
Curt. Mag. t. 1426. Ait. Epift. 376. (Cafumumarum; 
Dale Pharmac. 275. Cafumunar; Lewis Diff. ed. 4. 
Vol. XXXIX.)

112.—Bracteas ovate, rather acute. Segments of the 
outer limb of the corolla straight. Middle lobe of the lip 
cloven, dilated, crisped, and creenate. Rib and teeths of 
the leaves hairy.—Native of the East Indies, from whence 
it was feft by Dr. Roxburgh to this country, and flowered 
in August 1811, in the flove of James Vere, eqq. at Ken- 
fington Gore. The roots had long ago been introduced into 
the Materia Medica as a powerful stimulant and tonic, 
in hysterie, paralytic, and other nervous disorders, poffef- 
sing a warm bitterish flavour, with the smell of Ginger; 
but they have long gone out of use. Their shape is lefs 
elongated and compressed than that of Ginger, and more an- 
nulated, tuberos or knotty. Herbage molt like the last spe- 
cies, but disfigured by the hairy sheet and mid-rib of the 
leaves. Flower-flasks not above fix or eight inches high. 
Spike ovate, brownish. Corolla pale yellow, dilatigufed 
from Z. Zerumbet by the greatly dilated, inverely heart- 
shaped, crisped and creenate, middle lobe of its lip; the two 
side lobes being erect and entire, not larger than in Zerum- 
bet. The plant is said to be propagated by cuttings of the 
root.

v. 1. 7. Banks Ic. Kempf. t. 1. Dajooka, vulgar Mioga; 
Kempf. Am. Exot. 826.)—Bracteas ovate, acuate. Spike 
neary fesse. Segments of the outer limb of the corolla erec- 
tae, acuate. Middle lobe of the lip concave, entire.—Found 
near Nagasaki, and in other parts of Japan, flowering in 
September. Thunberg, Kempfer speaks of this as an eateable kind of Ginger, with a mild 
flavour. The leafy flesms are from one to two feet, or more, 
in height, and with the foliage resemble thofe of the three 
foregoing species. The flower-flask is radical, and remark- 
fably fhort, or scarcely any. Spike ovate, with numerous, 
large, white, pointed, fariated, concave bracteas; the outer 
one largef, concealing many within. The flowers smell 
faintly like Butter-bur, and have a yellow, very concave, 
undivided lip, and a white limb. Filament greenth-white, 
beaked, embracing the thread-shaped style, according to 
the generic character, as is faithfully defcribed by Thunberg, 
who fpeaks of the fruit as a nearly ovate, obtuse capule, 
with three cells and three valves, and numerous minute feeds, 
inferred into the central column.

(Amomum rofam; Roxb. Coromand. v. 2. 15. t. 126.) 
Bracteas lanceolate, coloured. Spike nearly fesse. 
Segments of the outer limb of the corolla revolute. 
Middle lobe of the lip flat, entire.—Native of moif valleys in 
Hindooftan, flowering in the rainy feafon. The Telingas 
call this plant Bumacatchey. Root creeping, cylindrical, 
branched, not knotty. No aromatic or other quality is re- 
corded concerning it, or any other part of the plant. 
Leafy flesms two or three feet high. Spike nearly fesse at 
the root, ovate, two or three inches long. Bracteas loofely 
imbricated, erect, lanceolate, acuate, of a fine rofe colour, 
as are also the calyx, and the narrow revolute segments of 
the outer limb of the corolla. The lip is white, obovate, 
entire, not concave, but somewhat reflexed. Beak of the 
filament yellow. No account is given of the fced-voefel.

Ait. n. 4.—" Bracteas ovate, coloured. Segments of the outer 
limb of the corolla ecrat. Middle lobe of the lip divided," 
Native of the East Indies. Introduced into the Englifh 
floses, by the right honouable Sir Joseph Banks, in 1796, 
and obferved by Mr. Roscoe in the Botanic garden at 
Liverpool. It flowers in September.

ZINGIBER, in the Materia Medica. See Ginger.

A a ZINGIS,
ZINGIS, otherwise JENGHIZ-KHAN, or Genghiz-khan, in Biography, the founder of the Mogul empire, was the son of Biiyuk, or Jefukai, a chief or over-seer between hordes of Moguls in the Tartarian range between China and the Caspian sea, and born about the year 1161 or 1165, his first name being Temugin. In the year 1205 he was installed in the Mogul empire, and declared his purpose of giving a new code of laws to the nation; the object of which was the preservation of peace at home, and the conduct of war abroad. The penalty of death was denounced against murder, adultery, perjury, and the theft of a horse or ox, which were the chief articles of Tartarian property. The nation was interdicted all servile labour, the performance of which was assigned to slaves and strangers, and was consecrated to the sole profession of arms. The weapons which they were appointed to use were bows, cymetars, and iron maces; and the troops were distributed into divisions of hundreds, thousands, and tens of thousands. The soldiers and officers were made individually responsible for the safety and conduct of one another; and it was an established rule, that peace should never be granted without previous conquest. With regard to religion, Zingis established universal toleration. As for himself, his only article of faith was the existence of one God, the creator and governor of all things; but his Mogul and Tartar subjects were idolaters, Jews, Christians, and Mahometans, all of whom were allowed to practise their several rites without molestation, and without any difference of privileges. Having thus settled the affairs of the proper Mogul empire, he successively, by his own arms, and those of his lieutenants, reduced the different tribes of the desert, and rendered himself the undisputed monarch of the pastoral nations who pitch their tents from the wall of China to the Volga. For a sketch of his conquests, we refer to the article of the Mogul Empire. These conquests were attended with many acts of savage cruelty. In his invasion of Kitay, the northern empire of China, he took 90 cities, destroyed by fire a number of towns and villages, and massacred many thousands of people; at the same time obliging the Kin emperor to purchase peace at the price of a Chinfe prince, 500 youths and maidens, 3000 horses, and a large tribute in gold and silk. At his departure, he inhumanly ordered all the children whom he had taken in four provinces to be butchered. In a second expedition he laid siege to the capital city Yen-king, now called Pekin, which, after a long resistance and grievous suffering by famine, was stormed by the Moguls, with the conflagration of the imperial palace; and after the depopulation of China, its five northern provinces submitted to the dominion of the Mogul conqueror. In the bloody conflicts between Zingis and Mohammed, sultan of Khairim or Charasim, all the rich and populous cities and countries of Transoxiana, Khairim, and Khorasan, were taken or laid waste by the Moguls. Mohammed died a fugitive in a desert island of the Caspian sea; but his son, Gelaleddin, boldly resisted the invader, and checked his progress, till overpowered by numbers on the banks of the Indus, he was under a necessity of spurring his horse into that rapid river, the opposite side of which he reached in safety. Zingis, admiring his heroism, and forbidding the pursuit of him, said to his sons, "Any son might with to spring from such a father." Nevertheless he ordered all the sultan's male children to be killed. After the defeat of Gelaleddin, Zingis, remaining for some time in Khorasan, pursued his customary operations of sacrificing lion's flesh to his horse before the country. Returning to Bokhara, or Bucharia, in 1223, he investigated the antiquities of Balk and the doctrines of Zoroaster, and held conferences with the Mahometan doctors; the result of which was his ascent to their tenets, the necessity of a pilgrimage to Mecca excepted. In 1224 he held a grand diet in the plain of Tonkat, which, though seven leagues in length, could scarcely contain the tents of all the distinguished persons that were assembled. In the following year he pitched through Tartary to the borders of northern China, and subjugated the kingdom of Hyia or Tangut. In the province of Shen-fi, on the mountain of Lu-pan, whither he went in order to pass the summer heats, he was taken ill; and as he perceived his end approaching, he summoned the generals of his army, before whom he declared his fourth son regent, till the arrival of his brother Octai, whom he appointed his successor in the dignity of grand khan of the Moguls and Tartars. Recommending unanimity, and advising the conduct of the war against Kin, he expired in August 1227, at the age of 65 years. His remains were interred with great pomp under a beautiful tree which he had fixed upon in returning from a hunting expedition. He had many wives, and left a numerous progeny. "This emperor," says one of his biographers, "possessed the civil and military qualities necessary for the founder of a mighty monarchy, together with a penetrating and inquiring mind, which, with superior culture, might have placed him in the list of truly great princes. His memory now survives as that of one of the great conquerors whose deeds have astonished the world, to which they have proved the most terrible of scourges. His simple laws were long the rule of the countries he governed, and are still religiously observed by the Crim Tartars." D'Herbelot. Gibbon's Hist. Univ. Hist. Gen. Biog.

ZINGST, in Geography, a small island in the Baltic, near the coast of Pomerania, and a little to the west of the island of Uedem. N. lat. 54° 29'. L. long. 12° 50'.

ZINIA, a name given by the old chemical writers for verdigris.

ZINJAT, a word used by the old chemical writers to express either the action of fermentation, or any thing that is capable of exciting it in bodies.

ZINK. See ZINC.

ZINKOW, in Geography, a town of Poland, in Podolia; 32 miles N. of Kaminiec.

ZINN, John Godfrey, in Biography, an anatomist and botanist, was born in 1726, studied under Haller at Gottingen, and became botanical professor in that university. His first experiments were undertaken in order to ascertain the renewability of different parts of the brain; he then proceeded to the examination of the eye, which produced his celebrated work, intitled "Description Anatomica Oculi Humani, Iconibus Illustrata," Gotting. 4to. 1755. Botany was also the subject of his assiduous study, the result of which appeared in several papers, and in a catalogue of the plants in the academical garden and vicinity of Gottingen, arranged according to the system of Haller. His premature death happened at the age of 32, in April 1758. He was a member of the Academy of Sciences at Gottingen, the Institute of Bologna, and the Royal Society of Berlin. Haller, Eloy.

ZINNA, in Geography, a town of the duchy of Magdeburg; 18 miles N. of Wittenberg.

ZINNA, in Botany, was so named by Linnaeus, in honour of Dr. John Godfrey Zinn, professor of physic and botany at Gottingen, author of a Catalogus Plantarum Horti Academici et Agri Gottingensis, printed there in 1757. This work, making 3 volumes, is classed after Haller's method. Its author has, besides, published various botanical and physiological treatises, and would probably have contributed much more to the advancement of science, had he not been cut off, at the early age of 32, in 1758. Haller, whose
whole disciple and succcssor he was, speaks of him with much complacency; but it is easy to see that his favour was greatly conciliated by Dr. Zinn's preference of his system to that of Linnaeus. One principle of the learned Swedish botanist is indeed very justly approved, that plants nearly related on the whole ought not be separated on account of a difference in one particular part. Yet in the application of this rule he surely has wandered widely from the truth, in wishing to unite Geum, Comarum, Potentilla, Tormentilla, and Fragaria. Such it seems was the avowed opinion of Zinn, in his Preventto, published in 1755; but he has not followed it in his work above-mentioned. In that volume occurs, if we mistake not, the first figure of a Zinnia, under the name of a Rudbeckia; though the author justly declares it to constitute an indubitably new genus.—Linn. Gen. 437.

Gen. Ch. Common Calyx cymato-cylindrical, smooth, imbricated, with numerous, oblong, erect, permanent scales. Cor. compound, radiated. Florets of the elevated disk several, all perfect, funnel-shaped, five-cleft, internally vio- lous; the ralse of the radius from five to ten, ligulate, roundish or oblong, abrupt, larger than the disk, permanent. Stam. in the perfect florets, Filaments five, very short; anthers united into a cylindrical tube. Pífl. in the perfect florets, Germin oblong, with two very unequal awns; style thread-shaped, cloven half way down; figmas two, erect, obtuse; in the female florets, Germin oblong, triangular, without awns; style capillary, cloven half way down; figmas two, recurved. Peric. none, except the unchanged calyx. Seeds in the perfect florets, solitary, oblong, quadrangular, comprefled. Down of two points, one of them arowed. In the female florets solitary, pointless, crowned with the permanent pæcil. Recept. chaffy, with tongue-shaped, channelled, deciduous scales, the length of the calyx. Eff. Ch. Recenrelate chaffy. Sced-down of two erect unequal awns. Calyx imbricated, somewhat ovate. Florets of the radius from five to ten, permanent, undivided.

1. Z. pauciflora. Yellow Zinnia. Linn. Sp. Pl. 1569. Wildl. n. 1. Ait. n. 1. (Bidens calyce oblongo Ígmoano, fenumibus radiis caroliâ non decúidi coronatis; Mill. Ic. v. 1. t. 64. Rudbeckia flolia oppositís hibríus ovato-acutís, calyce imbricato círdínico, radií petálíis píllíatís; Zinn. Gott. 409. t. 1. Chrysofönem peruviam; Linn. Sp. Pl. ed. 1. 920, excluding the synonym, which is wrong, and a heap of confusion; see Feuillé 766.) —Flowers fesile. Leaves somewhat heart-shaped, fesile, clasping the Rem. —Native of Peru. Cultivated by Miller, but not commonly preferred in our gardens like the following, being less hardy, and not so ornamental. The root is annual. Stem erect, three or four feet high, branched, angular, leafy. Leaves opposite, defexed, two or three inches long, acute, roughish, entire, rough-edged, with three principal ribs; their base broadish-heart-shaped. Flowers solitary at the ends of the branches, nearly or quite fesile, with the uppermost pair of leaves close to the base of the calyx; disk brownish; radius yellow. We perceive a difference between several species and figures of this plant, but cannot trace an absolute or conftant specific diftinction between them. In the Linnaean specimen, the small number of florets justifies the specific name, and the flower itself is quite fesile. This is undoubtedly Miller's plant, though the radiant florets are much more numerous in his figure, and the whole flower larger. A specimen under this fame name of pauciflora, given us by

for Joseph Banks, from Jaccuin's herbarium, is what Zinn's figure exactly repreffents. The leaves are shorter, more rounded and heart-shaped, and the flower is large, with more or less of falk. Its radiant florets are numerous, broad, and yellow. How far these characters are permanent, culture and repeated observations must determine. We are rather inclined to confide the Linnaean specimen, raised in the Upfal garden, is a farded one, the flowers perhaps being rendered diminutive by their latcncs. It is most probable that a portion of the fame seed was fent by Jüffieu to Lin- naeus and to Miller. The plant indeed flowered at Upfal before the year 1753, when Miller says he received his seeds, because it is defcribed, in the firft edition of Sp. Pl. printed that year, from the garden specimen now before us.

2. Z. multiflora. Common Red Zinnia. Linn. Sp. Pl. 1269. Willd. n. 2. Ait. n. 2. Pursh n. 1. Curt. Mag. t. 149. Linn. Dec. 25. t. 12. Jacq. Obs. fac. 2. 19. t. 40. —Flowers falked. Leaves opposite, ovato-lanceolate. —Native of North America. Found on the banks of the Multiflóri, flowering in July and August. Annual. Rays yellow, orange, and sometimes brick-red. Pursh. The latter colour is most common in the gardens of Europe, where this plant is treated as a rather tender annual, like the different species of Tagetes, being best raised on a hotbed, and planted out so as to flower in the autumn. A yellow variety, almost equally common, is less singular and striking in colour. We are not by any means certain that this variety may not be sometimes taken for the foregoing; yet the plant of Zinn and Jacquin, of which we have just given an account, is too different in the great breadth of its leaves to be confounded with the present species. The Z. multiflora has a more hairy stem than the pauciflora, much narrower and elongated leaves, with three ribs; their surface roughish to the touch. The flowers stand each on a hollow, deeply furrowed, terminal falk, from one to two inches long, much thicker than the stem, and gradually swelling upwards. The disk is conical and acute, composed of reddish or tawny florets, accompanied by the prominent, dark-green, or blackish, scales of the receptaél ; the radius consists of ten or more broad, elliptical, usually emarginet florets, of a deep brick-red, and very smooth, above; pale, greenish, and rough beneath; reticulated with veins, and finally becoming rigid, or membranous.

3. Z. verticillata. Whorl-leaved Zinnia. Andr. Repof. t. 189. Wildl. n. 3. Ait. n. 3. —Flowers falked. Leaves whorled, ovato-lanceolate. Radiant florets very numerous. —Native of Mexico. Raised by Meffrs. Lee and Kennedy at Hammerfsmith, about the year 1789. We cannot fuppofe this to be any thing more than a luxuriant variety of the last. Annual plants, pampfered with manure, and every possible advantage of cultivation, are liable to acquire aggregate leaves, double flowers, and many other characters, which do not appear in a state of nature. Thefe is the buflines of the gardener to encourage, and of the botanist to beware of. Having seen no specimén of this plant, we can only judge by the figure, in which we cannot discover any specifc distinctions. These flowers indeed are rendered very splendid, by their multiplied radius of a deep scarlet, and their disk fesile broader, and less conical, or pointed, than in either of the foregoing species. This last charafter, if conf tant, is more material than any which has been mentioned.

fringed.
fringed. Tubular florets with a hairy disk.—Native of Mexico; said to have been brought to England from Madrid, in 1796, by the late marchioness of Bute; whose botanical acquisitions in Spain, made with no less intelligence than taste, have eminently enriched the gardens of England. This is also a tender annual, flowering from Midsummer to the end of Autumn. The *herbage* is flouter, the *leaves* broader, and much more hairy to the touch, like a file, than in any other of the genus. *Flowers*, in a cultivated state at least, as large as the half, with a conical, but rather obtuse, *disk*; the prominent orange-coloured feales of the *receptacle* have many finely-fringed *segments*; the upper surface of the yellow *tubular florets* is densely fraggy; the *radius* consists of numerous, spreading, *ovariform florets*, of a deep lilac, or light purple, colour, *leaves* harsh, or *scarios*, after flowering than in the *multiflora*.

5. *Z. tenuiflora.* Slender-flowered *Zinnia*. Jac. Ic. Rar. t. 590. Wild. n. 5. Ait. n. 5. Curt. Mag. t. 555. (Z. *revoluta*; Cavan. Ic. v. 3. 26. t. 251.)— *Flowers* flaked. Leaves opposite, ovato-lanceolate, pointed. Calyx cylin- drical. *Radiant florets* linear, revolute.—Native of Mexico. Rared here, 1799, by the late captain Woodward, at Vauxhall. This very distinct *species* requires the same treatment as the rest. They may all, perhaps, succeed, in favourite gardens, as hardy annuals, but are best raised with artificial heat in the spring. The present has much narrower leaves than the last, which moreover are nearly smooth. The *flowers* are the smallest of their genus, and distinguished by their bright red, narrow, revolute *radiant florets*, very rough at the edges; the tubular *florets* are yellow, roughish in their disk.

*Zinnia*, in Gardening, contains plants of the annual flowering kind, in which the species cultivated are, the fewflowered yellow *zinnia* (*Z. pauciflora*), and the manyflowered red *zinnia* (*Z. multiflora*).

These are both plants of the annual flower kind.

*Method of Culture.*—These annual plants are increased from seeds, which should be sown on a flight hot-bed in the early spring, as March; and when the plants are a few inches high, they should be pricked out on another bed previously prepared to receive them, where they should remain till the advance of summer, when they may be taken up and planted out in the borders of the pleasure-ground, where they blow and complete their seeds for the year following.

They have a fine effect in their leaves and flowers in these situations.

**ZINNORE**, in Geography, a town of Hindooftan, in Guzerat, on the Nerbuddah; 30 miles N.E. of Baroach.

**ZINTEN**, a town of Prufia, in the province of Nanten, near which the Poles were defeated in 1520; 30 miles S.S.W. of Königberg. N. lat. 54° 23'. E. long. 20° 20'.

**ZINTI**, a town of South America, in the viceroyalty of Buenos Ayres, and archbishopric of La Plata; 90 miles S. of La Plata.

**ZINU**, a province of South America, in the viceroyalty of New Grenada, situated to the north of Choco, and well of Carthagea.

**ZINU**, or *Sinu*, a town of South America, and capital of a province, on a river of the same name, which runs into the Spanish Main; 90 miles S. of Carthagea. N. lat. 8° 58'. W. long. 75° 48'.

**ZINWALD**, a town of Bohemia, in the circle of Leitmeritz; 18 miles N.W. of Leitmeritz.

**ZINZENDORF**, Nicholas Louis, in Biography, was born at Drefden in May 1700, and was educated under the inspection of his grandmother, who was a pious woman, accustomed to the perusal of the Scriptures. He was thus led into an early acquaintance with the principal doctrines of the Christian religion, and manifested a peculiar taste for spiritual songs. Under professor Franke at Halle, he became a great admirer of Goeze and his compatriot. The world was such, that he indited them rather than he could write them. Such, however, was his proneness to dissipation, and particularly gaming, that he squandered away not only his money, but all his effects. From his youth he was fond of forming religious societies, and it is said that he had established seven associations of this kind between the year 1710 and the year 1716, when he left Halle. One of his companions in forming these institutions was Baron Frederick von Wattenwille, in intercourse with whom he first conceived the idea of attempting the conversion of the heathens. With this view they bound themselves by an oath, and determined to employ others in accomplishing this design who were properly qualified for the office. This resolution seems to have taken its rise from a baptized native of Malabar, who had been brought to Halle by the missionary Ziegenbalg. In 1710 Zinzendorf removed to Wittenberg, where he was diligently to his studies; and in 1719 he quitted Wittenberg, in order to gratify his relations by pursuing his travels. On his tour he remained for some time at Utrecht, prosecuting his studies in history and jurisprudence; but his chief attention was directed to theology, as he had formed a purpose of becoming a preacher. From Holland he proceeded to Paris, where he associated with his friend, Henry, prince of Reuss, and endeavored to spread his doctrine among the Catholic nobility, by some of whom they were treated with respect, while others contemptuously denominated them Janenfits and Pietists. At this time he was introduced by Father de la Tour, general of the Society of the Oratory, to the archbishop of Paris, and attempts were made, without effect, for gaining him over to the Catholic church. During his abode at Paris he formed an acquaintance with several other persons of distinction. From Paris he proceeded through Switzerland to Germany in 1720, and having arrived at Hersdorf, in Lusatia, he found his grandmother still living, and employed himself in communicating instruction to the domestics, and corresponding with his friends. Soon after, retaining his purpose of becoming a preacher, he went to Drefden, and having received his property from those with whom it had been entrusted, he purchased the lordship of Bertholdsfeld, in Lusatia, and marrying a sister of the prince of Reuss, distinguished for her piety and virtue, he inclined to his her whole property, that he might not be incumbered and diverted from the prosecution of his design by the cares of the world. About the year 1722 he indulged the notion of a purer church discipline, of which he observed some traces among the Bohemian and Moravian brethren, who, from their earliest connection with the Waldenfes and true followers of John Huf, had formed a peculiar religious community. The Christians of this description had undergone from the year 1458 to 1627 several persecutions, so that they were almost exterminated from Germany; but a small number of them remained, under oppression, in Moravia; and about the year 1720 the sect revived; so that they held frequent meetings, read the Scriptures with their old books of hymns, celebrated in secret the holy sacrament, and introduced, at least in their houses, the ancient church discipline. One of their number, of obscure condition, obtained an introduction to count Zinzendorf, who gave them leave to settle on his estate at Bertholdsfeld. Availing themselves of this permission, a small number of them, confiding of three men, two
women, and five children, came hither from Moravia, in Whitenside, 1722, and erected on a hill, in a wild marshy district, a wooden habitation, exposing themselves to the derision of the adjacent inhabitants. They were so poor that the countefts lent them a cow to supply milk for their children. However, they gradually gained new converts; and when the count and his consort visited this new settlement of the Moravian brethren in the month of December, he gave them a cordial welcome, and falling upon his knees, pronounced a benediction on the infant colony. Such was the origin of the village of Hernhut. (See HERNHUTERS and MORAVIANS.) The count, whilst he afforded them protection, left them at full liberty to think for themselves; more especially as he found, upon examination, nothing improper in their doctrine. From this time, count Zinzendorf, in connection with some other persons similarly disposed, took pains in giving instruction to his subjects, and educating their children; avowing himself a true Lutheran, but willing that his people might remain totally ignorant of the disputes that subsisted among Protestant divines. In 1723 he published a small catechism, entitled "The Pure Milk of the Doctrine of Jesus," which, he says, cost him more labour than all his other works. The count, devoted to the profession of the work he had undertaken, refined sometimes on his estate in Lusatia, and sometimes at Dresden, but declined every offer of a place at court. He employed himself in the composition and occasional publication of books adapted to his design; one of which, being a periodical work, and entitled "The German Socrates," was suppressed by order of the council, probably because it censured the prevailing indifference about religion, and called upon his fellow-citizens to live in a manner more agreeable to what their religion required, or entirely to renounce it. In 1727 he quitted Dresden, that he might be nearer his favourite object Hernhut, and that he might be at leisure to devote his whole time and attention to the improvement and increase of his congregation. With this view he made a tour through the greater part of Germany, occasionally preaching, and endeavours to gain converts. In 1731 he extended his tour to Denmark, and being present at the coronation of Christian VI., who conferred upon him the order of Dannebrog, which five years afterwards he resigned, because he thought it improper to accept the insignia of his flock with the infirmity of his order. In this tour he acquainted himself with the state of the Danish missions in the East Indies and Greenland; and on his return he took measures for carrying into execution the design he had formed at Halle with his friend Watteville. From this commencement, in the year 1732, arose that missionary fyllem of the Moravians which has since been so widely and so wonderfully extended. Between 1732 and 1766 nearly 4,000 negroes in the Danish islands were baptized; and in 1768 the congregation of New Hernhut and Lichtenfels, in Greenland, amounted to 764 persons. When the congregation at Hernhut had increased in 1732 to 300 persons, the Saxon court became alarmed, and appointed a commission for the purpose of examining their doctrine and principles. Although they were found to be inoffensive, the count was forbidden to bring any more new emigrants from Moravia; and soon after he received an order to sell his estate and property, which was a kind of sentence of banishment from his country. He also perceived a coldness and prepare in the disposition of his friends. Accordingly he quitted Hernhut, and repaired to his friend count Reufs at Eberforh. He now thought seriously, as he had done twenty years before, of entering regularly into the church; but the countefts and his friends diffused him from adopting this measure. With a view of becoming tutor to the children of Richter, a merchant at Stralsund, to which he was urged by his pecuniary circumstances, he was examined for orders, and having obtained a flattering testimonial, was formally ordained at Tubingen. But a change taking place in the circumstances of Richter, this plan did not succeed. In 1735 he made an attempt to visit Sweden, but was forbidden to enter the kingdom by an order of government; and this occasioned the composition of one of his most important works, entitled "A Letter to the King of Sweden in regard to the general Belief of himself and Congregation," which he widely circulated, and which produced various plans for extirpating the Moravian brethren from the empire. In the same year he visited Switzerland, and in 1736 he and the countefts made a tour to Holland, where, at the desire of the princes dowager of Orange, he founded a new colony at Yffeldlein, called Heerendyck, which was afterwards removed to Zuylt. On his return he found at Cassel a copy of a Saxon reformatory, by which he was forbidden the territories of that electorate, and banished from his native country. He was thus reduced to the necessity of making various excursions; and on his return he was invited to a conference with the king of Prussia, who was so well satisfied with his doctrine and character, that he advised him to be regularly ordained. For this purpose he recommended him to the chief court preacher Jablonfky, by whom he was consecrated bishop of the Moravian congregation in May 1737. In this year he visited London, and established the brotherhood in England. Here he became acquainted with John Wesley, and maintained a dispute with him on the impossibility of men's attaining moral perfection, for which the English preacher contended. Although he obtained permission to return to Hernhut, it was on condition of his making certain declarations with which he could not comply, and therefore he became a voluntary exile; and was forbidden ever to enter Saxony. In the year 1738 he undertook his first voyage to America, in the course of which he composed a work entitled "Jeremiah a Preacher of Righteousness." Upon his arrival at the island of St. Thomas, he found that all the missionaries had been thrown into prison, but he immediately procured their release, and liberty for his congregation to assemble. After his return he visited Holland and Switzerland, wrote in his own defence against the accusations of his German enemies, and held public assemblies at Geneva. In 1742 he made a second voyage to America, and preached alternately with their own minister to the Lutheran congregation at Germantown, in Pennsylvania, and built for them a place of worship. In a Latin speech at Philadelphia he laid aside the title of count, and assumed the name of Von Thuifeken, which belonged to his family. The Quakers generally styled him friend Lewis. He also established the celebrated colony at Bethlehem, and made a tour among the Indians, who received him favourably, and, as a token of their friendship, gave him the wampum belt. In America, however, he suffered much abuse and calumny. In 1743 he returned to Europe; and having proceeded to Riga with a view of settling some differences among his followers at Livonia, he was arrested, conveyed to the frontier, and ordered never to enter the imperial territories any more. In 1747 he obtained permission to return to Saxony, after an exile of ten years; and the king, having received from one of the Moravians a considerable sum of money for the cattle of Barby and districts of Doben, issued a declaration that the society should be allowed, in every part of his territories, the same privileges which they had enjoyed at Hernhut. In 1748 he
he succeeded in obtaining a commission, which, after particular examination, declared the members of the Moravian community to be true adherents to the Augsburg confession. In the following year he visited England, and obtained an act of parliament for the protection of his followers in the British dominions in America. In 1757 he made his last tour to Switzerland, and from thence proceeded to Holland. In 1760 he died at Hernhut, after an illness of four days, and his funeral was attended by 2000 of his followers, and as many spectators; and his coffin was carried to the grave by thirty-two preachers and millionaires, some of whom had come from Holland, England, Ireland, North America, and even Greenland. Count Zinzendorf was somewhat above the middle size; and his countenance combined fer- riousness with animation. In early life his manners were elegant, but as he withdrew from intercourse with the world, in more advanced life they became stiff and reserved. To money he was perfectly indifferent, and as he gave to every mendicant, he was often pennyless. His disposition was lively, but he was capable of long-continued and intense application. His memory was prompt and comprehensive, but as he was of a lively imagination it was not very retentive. In his style he bid defiance to all the rules of grammar, and his ambiguous mode of expression subjected him to many inconveniences, so that his meaning was often mistaken and misrepresented. To persons of the lower order he was condescending, and in his intercourse with all mild and candid. In his temper he was irritable and passionate, but placable and forgiving. His activity in doing good and serving others was indefatigable and unbounded; he often promised, it is said, with the best intentions, beyond his ability of performance; and he is charged with having used art and stratery to carry on his own purposes, and to gain converts to his cause. Molbein, &c. Gen. Biog.

For a further account of the tenets and partisans of the sect with which he was connected, and of which he was, according to his own statement, a reformer, and not a founder, we refer to the articles Hernhuters, Moravians, and Unitas Fratrum.

ZINZIBER, Ginger. See Zingiber and Ginger.

ZINZIBER Rubrum, Red Ginger, a name by which some authors have called the officinal caffumara-root.

ZINZIBER Canum, Dog's Ginger, in Botany, a name given by some of the old writers to the *pericaria urens*, or biting arfart; a plant which is very hot, and pungent to the taste, and grows in watery places. It had the name of hydroper, water-pepper, among the Greeks, and was called *zinziber canum*, or dog's ginger, by Avicenna and others, from its heat, and from an opinion that it would poison dogs that eat of it.

The Arabian name is *zinzibili alekel*.

ZINZIBER Canum is also a name given by some authors to the *capsicum*, or Guinea-pepper. Ger. Emac. Ind. 2.

ZINZIG, or ZINZIG, in Geography, a town of France, in the department of the Roer; 18 miles N.W. of Coblenz. N. lat. 50° 33'. E. long. 7° 12'.

ZINZILLA, a name by which some medical writers have called that species of the herbes, which we usually call the flings.

ZINZOAOCZA, in Geography, a town of Mexico, in the province of Mechoacan, anciently the residence of a cacique.

ZÖBERIS, in Ancient Geography, a river of Asia, in Hyrcania, which discharged itself into the Rhadge, according to Quintus Curtius. Diodorus Siculus calls it Stiboeas.

ZIOLO, in Geography, a town of Italy, in the Paduan; 10 miles S.E. of Padua.

ZION, in Ancient Geography. See Sion and Jerusalem.

ZIPH, a town of Palestine, in the tribe of Judah. (Joh. xv. 24.) St. Jerom says, that in his time they fled the village of Zipf, 8 miles from Hebron eastward. David for some time concealed himself in the wilderness of Ziph. (1 Sam. xxiii. 14, 15.) There was another city called Zipf, near Maon and Carmel of Judah. Joh. xv. 55.

ZIPHRON, or ZEPHIRNA, a city N. of the land of promul, now unknown. Numb. xxxiv. 9.

ZIPOETIUM, a town of Asia Minor, in Bithynia, near mount Lyperus, and which had been founded by king Zipotus. Steph. Byz.

ZIPPORIS, a name which the ancients gave to the town of Sefera or Sauffori. It was the strongest place in Galilee, and its position might be regarded as the key of the province, according to Josephus.

ZIPSERCHLOSS, in Geography, a town of Hungary; 6 miles E. of Leutsch.

ZIRBALIS HERRNIA, a term used by medical writers to express that kind of rupture which is caused by a defect of the omentum into the frcutom.

ZIRBUS, the name by which the Arabian physicians have called the omentum.

ZIRCON, in Mineralogy, Jargen de Ceylon, Romé de Lisle, Zircon, Haüy, a gem originally found in the island of Ceylon, in the sands of rivers, along with spinel, faphire, termaline, and iron-fand. Zircon, the gem called the hyacinth, and zirconite, are regarded by most mineralogists as varieties of the same species. They are essentially composed of the earth called zircon, (see Zirconia, in Chemurgy), with filex, and a minute portion of iron, which may be regarded merely as the colouring matter. The primitive form of the crysals of zircon, according to Haüy, is an octahedron, composed of two four-sided prisms, whose fides are isofaces triangles. The inclination of the planes of the fame pyramid to each is 124°,12; the inclination of the fide of one pyramid to thofe of the other 82°,50. The angle of the summit is 73°,44. The common forms in which it occurs are rectangular four-sided prisms, rather flatly terminated by four-sided pyramids, the planes of which are set on the lateral planes of the prifm under equal angles. The above figure is often truncated in the lateral edges. The angles of the prifm, in junction with the pyramid, are often bevelled, and sometimes the prifms are terminated by four planes at each end, two of which at each end form very obtuse angles, and are set on the lateral planes of the prifm. The crysals are generally small, and occur loofe or imbedded. The surface of the crysals is sometimes rough, and sometimes smooth and fhining; that of the grains is uneven, and glitening internally. Zircon is splendid or fhining, with a luftre intermediate, between adamantine and refinous. The ftructure is imperfeftly foliated, with the folia parallel to the lateral edges of the prifm. The fracture is flatly conchoidal. The prevailing colour of zircon is grey; it is sometimes white, green, and brown, and occasionally yellow, blue, and red. The colours are pale; it is sometimes transparent, but more frequently semi-transparent or translucent: it refracts doubly. Zircon is harder than quartz, but softer than the diamond. The specific gravity varies from 4,5 to 4,7. It is infufible without addition by the blow-pipe.

According
According to Klaproth, the constituent parts are,

Zircon:

Zircon has been found in rolled masses of scienite by professor Jamefon in Scotland, in the county of Galloway; and has since been met with in granite near Cuffel, in Dumfriesshire.

Zircon has been found in South America, and in the province of New Jersey, in the United States.

Zircon and hyacinth are characterized by their great specific gravity. Common zircon has been frequently confounded with the diamond, but the specific gravity alone would be sufficient to distinguish them; that of the diamond not exceeding 3.5. The hyacinth has often been confounded with other minerals. The oriental hyacinth of Romé de Lille is orange-coloured sapphire. The occidental hyacinth of Duteus is yellow-coloured topaz.

Cruciform hyacinth is cross-stone; brown volcanic hyacinth is vesuvian; white hyacinth of Somma is meionite.

The hyacinth of Deffentis, mentioned by Saulsure, is a variety of garnet.

Common zircon is frequently cut and polished by the jewellers as a gem. The greyish-white and yellowish-white varieties are the most prized, on account of their resemblance to the diamond. The darker coloured varieties may be deprived of their colour by heat. It is cut into the same forms as the diamond, and exhibits faintly the same play of colours, and is not frequently found as an inferior kind of diamond. The hyacinth is also employed by jewellers in various kinds of ornaments; but pale garnets and rock crystals are frequently sold for hyacinths.

Zirconia, or Zircon, in Chemistry, the name of a peculiar earth, hitherto only met with in the minerals termed hyacinth, and zircon or jargons. See the preceding article.

Zirconia exists in the form of a fine white powder, which feels rather hard when rubbed between the fingers. It has neither taste nor smell. It is infusible but the blow-pipe; but when heated violently in a charcoal crucible it undergoes a fort of imperfect fusion, and acquires a greyish colour and porcellaneous appearance. In this state it is very hard, and its specific gravity is 4.3.

Zirconia is insoluble in water, but has a considerable affinity for that liquid. It does not combine with oxygen, azote, or any of the simple combustibles, but appears to have a strong affinity for many metallic oxys, especially for that of iron.

It is insoluble in alkaline solutions, neither can it be fused with them by the afflance of heat, but it is soluble in the alkaline carbonates. Sir H. Davy subjected this earth to the action of galvanism, and obtained evidences of its containing a metal as its basis. To this metal he gave the name of zirconium. Nothing satisfactory is known respecting its nature.

No very accurate analysis of the faults of this earth have been yet made. From some experiments of Klaproth and Vauquelin, Dr. Thomson fixes the weight of its atom at 46.25; though it is probable that this is not to be absolutely relied upon.

Salts of Zirconia: Nitrate of Zirconia.—This salt may be formed by pouring nitric acid on newly precipitated zirconia. It always contains an excess of acid, and does not crystallize. It is decomposed by heat, and most of the vegetable acids, except perhaps the acetic.

Carbonate of Zirconia is a white infusible powder. It may be formed by double decomposition with the alkaline carbonates, and solutions of zirconia in acids.

Sulphate of Zirconia.—This salt exists in the form of a white powder, but may be obtained in small needle-formed crystals. It has no taste, and is infusible in water. It is easily decomposed by heat.

Acid of Zirconia.—This salt has an astringent taste. It does not crystallize. It is very soluble in water and alcohol.

The other salts of zirconia are mostly white insoluble powders, very little known, and apparently possessing very little interest. With respect to the general properties of zirconia and its compounds, it may be remarked, that the alkalies and alkaline earth separate this earth from its combinations with acids. The salts of zirconia have an astringent, harsh, disagreeable taste, similar to some of the metallic salts. They are most of them insoluble in water. Those which are soluble yield white precipitates when sulphuric acid, carbonate of ammonia, oxalate of ammonia, tartrate of potash, and infusion of nut-galls, are dropped into their solutions. These properties sufficiently distinguish this earth from *alumina* and *ytria*. For further particulars respecting this earth, see the articles above referred to.

**ZIRCONITE.** See ZIRCON.

**ZIRCONIUM,** the metallic basis of zirconia. See ZIRCONIA supra.

**ZIRIANKA,** in Geography, a small river of Ruffia, which runs into the Enifei, near its mouth.—**Alfo,** a town of Ruffia, on the Niznei Tungufka. N. lat. 16° 10'. E. long. 106° 54'.

**ZIRICZEE,** a town of Holland, one of the most ancient in Zeeland, and capital of Schouwen, built and surrounded with walls in the year 859, by a person named Ziringus, from whom it is called. It was the ancient residence of the counts of Zeeland, and was at that time a place of much more consequence than it is at present, the port being filled with sand. The inhabitants carry on a considerable trade in grain, salt, and fish; the town is large and populous, and has several good buildings; the church, called the "Munster," dedicated to St. Levinus, is a handsome structure. N. lat. 51° 40'. E. long. 30° 48'.

**ZIRKNA,** a river of Syria, which runs into the Mediterranean, 8 miles S. of Tortura.

**ZIRKNITZ.** See CIRKNITZ.

**ZIRKWITZ,** a town of Silefia, in the province of Oels; 14 miles N. of Breflaw.

**ZIRL,** or **GIRL,** a town of the county of Tyrol, on the Inn; 7 miles W. of Innsbruck.

**ZIRNOE,** a town of Ruffia, in the government of Saratow; 32 miles S.W. of Saratow.

**ZIRO,** Lo, a town of Naples, in Calabria Citra; 9 miles E. of Umbratian.

**ZIROVAIA,** a small river of Ruffia, which runs into the Penzinkatai gulf, 32 miles S.W. of Oklank.

**ZIRUA,** a small island in the Mediterranean, near the coast of Tunis. N. lat. 33° 39'. E. long. 11° 39'.

**ZIRWITZ,** a town of Silefia, in the principality of Oels; 3 miles E. of Trebnitz.

**ZIRZING,** a town of Austria; 6 miles E. of Steyregg.

**ZIS,** a river of Africa, which rives in the Atlas, passes by Sugulmefia, and lofts itself in the fands, in the country of Taflet.—**Alfo,** a mountain of Africa, between Sugulmeffia and Fez; 40 miles S.S.E. of Fez.

**ZISEL,** in Zoology, a name given by Buffon to the earlefs mammot, or *mus citellus* of Linnaeus. See CITELLUS.

**ZISKA, John,** in Biography, a distinguished leader among the Hussites, was the son of a Bohemian gentleman, named "De Trecznu," and celebrated for military valour in his youth. Ziska, denoting "one-eyed," was an appellation, which he bore in consequence of having lost one eye in a combat, on occasion of the perfidious execution of John Huls and Jerome of Prague, at the council of Conflance. Their followers took up arms, and invited Ziska to be their commander. In 1519 he accepted the invitation; and, having assembled a body of peasants, he soon disciplined them so as to be equal to veteran troops. From a fortdres which he constructed on an elevated situation, and called Thabor, the Hussites derived the name of Thaborites. At the siege of Rabi he lost his other eye; but though totally blind, he executed his office as commander with great vigour and success. At Aufig on the Elbe he gained a complete victory over the Catholics, and left 9000 of them on the field, retaliating the severities which they inflicted on the Reformers, by demolishing their churches, committing their priests to the flames, massacring those who were prisoners, and laying waste their country, and thus rendering his name formidable. Having made himself master of the new town of Prague, it was invested by the emperor Sigismund and other princes: but Sigismund, being defeated with great slaughter by the Thaborites, was obliged to retreat into Moravia, while Ziska laid siege to Wifhrafen. When the emperor with a fresh accession of forces renewed the attack, he lost his whole army, and the town surrendered to Ziska. He also dispersed an army of crusaders commanded by an archbishop; and in 1422 he again routed the army of Sigismund. In the mean time the Hussites renounced their allegiance to Sigismund, and chose for themselves a king; but this measure was disapproved by Ziska and the Thaborites, because they were inclined to a republican government; and the new king was compelled to abdicate his crown. Such were the reputation and importance which Ziska acquired, that Sigismund proposed to him terms of accommodation; but in his journey to hold a conference with the emperor, he was seized with the plague, which terminated his life in 1524. Although the story of his having ordered his flesh to be given to the birds and beasts, and his skin to cover a drum, for the purpose of founding dismay to his enemies and courage to his friends, be fabulous, it is certain that the Bohemians regarded his memory with superstitious veneration. Un. Hist. Gilpin. Gen. Biog.

**ZISPATA,** in Geography, a bay of the Spanish Main, on the coast of South America; 80 miles S. of Carthagena.

**ZISTERSDORF,** a town of Austria, with a citadel. In the year 1704, this town was miserably laid waste by the Hungarian rebels; 20 miles N.E. of Vienna. N. lat. 48° 28'. E. long. 16° 43'.

**ZITARA,** a town of South America, in New Grenada, and capital of a district, to which it gives name, in the province of Chocos; 120 miles S.W. of Santa Fe de Antiquia. N. lat. 6°. W. long. 76° 30'.

**ZITHA,** or SITHA, in Ancient Geography, a town of Asia, in Mesopotamia, on the bank of the Euphrates. Ptolemy.

**ZITTAU,** in Geography, a river of Germany, which runs into the Saal, 4 miles S.S.E. of Bernburg.—**Alfo,** a town of Lufatia, on the river Neffe. This town is considered as one of the belt in Lufatia, and fortified in the ancient manner; it contains two churches within the walls, and three without, with three hospitals and an orphan-house; 17 miles S. of Goritz. N. lat. 50° 43'. E. long. 14° 56'.

**ZITWA,** a river of Lithuania, which runs into the Niemen, 20 miles S.E. of Lida, in the palatinate of Wilna.

**ZIVAGEE,** or ARCHACHER, a town of Hindooftan, in Cancon, on the Pirate coast; 30 miles S. of Severandroog.

**ZIUF,** a town of Africa, in the kingdom of Tunis.

**ZIVOLO,** in Ornithology, a name by which some authors have
have called the smaller species of yellow-hammer, from its prominent note, which is only ziz, ziz.

It is of the size of the common sparrow; its beak is thick and short; its breast and belly yellowish, spotted with brown; and its head, back, wings, and tail, of a dullgy-brown, but two of the tail-feathers on each side have a variegation of white.

The difference between the male and female in this species is, that the male is yellow, and has some yellow spots on its neck and sides, which are wanting in the female. It is almost always seen on the ground, and feeds on seeds, &c. It seems but little if at all essentially to differ from the common yellow-hammer; and Mr. Ray has some suspicion that they are the same species.

ZIWICA, in Geography, a town of Austrian Poland; 35 miles S.W. of Cracow.

ZIZA, in Ancient Geography, a town in the interior of Arabia Petraea. Ptol.

ZIZANIA, in Botany, an ancient name, ζηανος of the Greeks, synonymous with the infelix lolium of the Latins, as well as with our Darnel, and belonging to an unprofitable weed, of the tribe of Gramineae, which greatly injured the crop of corn, and into which Corn itself was supposed to degenerate. (See Lolium.) Our translators of the New Testament call it θηανος. Ano was another Greek name for Darnel, and is still used for Lolium temulentum in the Morea. Zizania was merely adopted, as an unoccupied classical name, by Gronovius and Linneus, for the present genus, which yields an inferior sort of grain, used by the inhabitants of some parts of North America. We cannot applaud this application of ancient names, to plants to which they could not possibly have originally belonged, though Linneus often practised it. Gærtner has successfully opposed this principle, but did not always change things for the better.—Linn. Gen. 491. Schreb. 639. Willd. Sp. Pl. v. 4. 394. Mart. Mill. Dict. v. 4. Pursh 65. Alt. Hort. Kew. v. 5. 278. Juss. 33. Poiret in Lamarck Dict. v. 8. 863. Lamarck Illitr. t. 768. Gærtt. t. 82. (Elymus; Mitchell in Ephem. Nat. Cur. v. 8. append. 210.)—Clads and order, Monocotyledon Hexandria. Nat. Ord. Gramina, Linn. Juff.

Gen. Ch. Male, Cal. none. Cor. Glume of two lanceolate, membranous, ribbed, clasping valves, one rather larger than the other, and most pointed. Nectary of two ovulate oblong scales. Stam. Filaments 6 to 8, capillary, very short, equal; anthers pendulous, linear, notched at each end, shorter than the corolla.

Female in the same panicule, larger, Cal. none. Cor. Glume of two valves, cloaked, except a vacancy at each side just above the base; the outer valve largest, concave, long, straight, rigid, revolute at the edges, embracing the inner at each side, and terminating in a long straight awn; the inner narrower, lanceolate, involute at the edges. Nectary of two acute scales. Stam. sometimes prenent, though minute and imperfect, with small incomplete anthers. Pist. Germen superior, oblong; styles two, spreading, capillary, short; stigmas feathery, projecting between the valves of the corolla. Seed foliary, oblong, even, polished, naked, unconnected with the glumes.

Eff. Ch. Male, Calyx none. Corolla of two valves; the outer one pointed.

Female, Calyx none. Corolla of two unequal cloaked valves; the outermost largest, revolute at the edges, with a terminal awn. Styles two, divaricated. Seed foliary, enclosed in the plaited corolla, but unconnected with it.

n. 1. Lambert Tr. of Linn. Soc. v. 7. 264. t. 14. (Z. clavulosa; Michaux Boreal. Amer. v. 7. 75. Wild. n. 3. Z. palustris; Linn. Mant. 295. Wild. n. 4. Schreb. Gram. v. 2. 54. t. 29.)—Panicle pyramidal, compound, with numerous male flowers, in the lower part; spiked and female above.—Common in all the waters, from Canada to Florida, flowering in July and August, and known by the name of Zizania, or Wild Rice. Pursh. Sir Joseph Banks introduced it into this country in 1765, and still cultivates it abundantly in the ponds of his delightful villa of Spring Grove. The seeds were obtained from Canada in jars of rice. Mr. Lamert is of opinion, that this grain might be cultivated in many shallow lakes of Ireland, and turn to considerable advantage. The root is certainly annual; not, as Mr. Pursh marks it, perennial; and consists of numerous, long, flout, hairy fibres. Stems several, or two or three feet high, round, jointed, hollow, leafy. Leaves grassy, long, narrow, smooth, with long, close, fribled, smooth sheaths. Stipula short, somewhat pointed, membranous, deciduous, entire. Panicle two feet, or more, in length, erect, and terminating in a compound, close, straight, spiked cluster, of numerous female flowers; the lower part consisting of still more numerous, drooping male ones, of a smaller size, with green or purplish glumes, and yellow anthers, composing an elegant spreading allelage, of compound breadth. We have from Mr. Prafer a mutilated specimen, of what Michaux and Willdenow call clavulosa, a name well expressing the appearance of the female flower-flakes, after the flowers are gone; being larger than in the common specimens. Other writers consider this is not even a variety of the plant in question, and we submit to their opinion. Linneus, who cultivated the Z. aquatica at Upfal, confounded with it originally a Jamaica species, which he afterwards distinguished. But he by inadvertence, in his Mannifia above quoted, applies the name of palustris to his original aquatica, and cites Browne's Jamaica, who has two Zizania, neither of which appears to be this North American grai. We shall attempt to fet this matter right under the next species.

2. Z. effusa. Jamaica Wild-Rice. (Z. aquatica; Linn. Syll. Veg. ed. 13. 714. ed. 14. 853. Wild. n. 1. Z. n. 1; Browne Jam. 349. A rundo graciol, folis e viridi ceruleis, loculis minoribus; Sloane Jam. v. 1. 110. t. 67.)—Panicle loose, much branched. Male and female flowers interposed.—Common in all the waters, or lagoons, of Jamaica. Sloane calls it the Trumpet reed. The stems are as thick as the little finger, and appear to be several feet high. Leaves longer and broader than in the foregoing, with a strong mid-rib. Panicle large, with numerous, whorled, repeatedly compound branches; whose ultimate divisions are quite capillary, and very smooth. We have seen but a few damaged flowers. This is unquestionably a very distinct species from the last, though it does not appear that Linneus ever described it as such. He did not, in fact, distinguish between the names of aquatica and palustris, but used one at one time, and another at a different period, for the same plant, to which he misapplied Browne's syno-

nym. This has caused great confusion, to remedy which we are obliged to choose a new name, which has some meaning attached to it.

B
ZIZIZ

is described as rather thick. *Panick* long and large, much branched. Permanent corolla tumid, and, as well as the seed, somewhat ovate, with very short awns. We have seen no specimen of this species, but the ovate tumid glomer, with the familiar form of the seed, which gave occasion to the specific name, appear to constitute a very clear distinction between this and both the preceding, nor is the figure of Slowick, which we have referred to our *effusif*, any means reconcilable to the present plant.

4. *Z. fluitans*. Floating Wild-Rice. Michaux Boreal.-Amer. v. i. 75. Willd. n. 5. Pursh n. 3.—*Spikes solitary, axillary, about four-flowered; the upper ones male. Clumes bearded.*—On the banks of lakes Champlain and St. Lawrence; perennial, flowering in July. Of humble stature, with slender, branched, floating stems. Leaves floating, linear, flat. Spike brittle-shaped; the lower ones female. All the glumes are deftillate of awns. *Michaux, Pursh.*

5. *Z. terricrnis*. Land Wild-Rice. Linn. Sp. Pl. 1408. Willd. n. 5. (Katou-Tsjolam; Rheede Hort. Malab. v. 12. t. 60. R a i H i l l. Pl. v. 3. 617.)—Panicle nearly simple,—Native of South America, on the coast of Malabar. Stems round, leafy, jointed. Leaves long and narrow, green, rigid, sharply pointed. Flower-flaiks slender, from the sheaths of the leaves. *Glumes leafy, bearing round, blackish, glabrous buds*, (we presume *seeds*). They are fruited with the juice of Bette-lin and, applied to the tongue, are supposed to cure the thirst to which children are subject. *Ray.* We have seen no specimen. Linnaeus described this species from the *Hortus Malabaricus* alone, and we prefix its genus may, at least, be doubtful.

ZIZDRA, in Geography, a town of Ruffia, in the government of Kaluga; 60 miles S.W. of Kaluga. N. lat. 53° 43'. E. long. 34° 54'.

ZIZERIA, a word used by Apicius, and some other authors, to express the inauthentic name of the gallinaceous kind, often used in decoctions for gluts, &c.

ZIZERS, or ZITZERS, in Geography, a town of the Grifons, in the Cadce league; 6 miles N. of Coire.

ZIZEVON, a town of Perius, in the province of Far-sitan; 23 miles E.S.E. of Schiras.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, cylindric, very long, strongly, bristly, with five minute marginal teeth, and bearded in the orifice. Cor. of one petal, ringent: tube cylindrical, the length of the calyx: limb minute; its upper lip ovate, flat, reflexed, undivided; lower spreading, broadest, in three round equal segments. Stam. Filaments two, simple, spreading, about the length of the corolla; anthers oblong, dilatant. *Pil. German superior, four-cleft: style brittle-shaped, the length of the corolla: stigma cloven, pointed, inflamed. Peric. none, except the calyx remaining unchanged, a little gibbous at the base. Seeds four, oblong, obtuse, gibbous at one side, angular at the other, very much shorter than the calyx.

The plants of this genus are slender, generally aromatic herbs, or diminutive shrubs, of humble growth, with the habit of *Thymus*, or *Clinopodium*; but distinguished by their long and slender calyx, as well as much capillary tube of the corolla, even more than by having only two flowers. Their texture is hard and rigid, and they inhabit dry funny situations. The leaves are opposite and undivided. *Flowers* whorled or capitate, red or purplish. *Root* mostly annual; sometimes perennial, and rather woody.

A hardy annual, flowering in July and August, sometimes kept in botanic gardens. Miller seems to be the first perfon who raised this plant in England. The root is fibrous, branched and zigzag. Stem erect, three or four inches high, when cultivated much taller, square, leathly, usuful with two opposite spreading branches, besides the central part, clothed all over with fine, short, curved, hoary pubescence. Leaves hardly an inch long, entire, hoary, roughish at the edges, furrowed with parallel veins. Foot-flaiks one-eighth as long as the leaves. *Bracteae* four at the top of each branch, nearly sessile, like the leaves, but larger, more pointed and fringed; somewhat heart-shaped at the base; about the length of the flowers, which are numerous in each head. Calyx half an inch long, furrowed, bristly, a little wavy, with tender, sharp, purple teeth. Corolla with a white, downy, zigzag tube, and pale purplish limb. Stumens prominent, about as long as the lower lip, with blueish anthers. We scarcely perceive any aromatic flavour in the dried plant. Plutekeet was much misinformed as to this Ziziphora being of West Indian origin.

2. *Z. hispanica*. Spanish Ziziphora. Linn. Syt. Nat. ed. 10. 853. Sp. Pl. 31. Amen. Acad. v. 4. 263. Willd. n. 2. Vahl n. 2. Ait. n. 2.—Flowers axillary. Leaves obovate, pointed, many-ribbed.—Gathered by Leaffing in Spain. Root annual. The *fem* is three or four inches high, crows-branched and bulby, downy with minute recurved hairs. *Branches leafy. Leaves* a quarter or one-third of an inch long, fringed; tapering at the base; marked on both sides with conpicious glandular dots: the lower ones smaller, and somewhat create. Flowers two or three together, sessile. *Calyx* tapering upwards, strongly furrowed, hispid, about the length of the leaves. Corolla externally downy. Linnaeus considered the branches as spikes and the leaves as bracteas, but we can see no reason for this than in any of the following species. The leaves in the original specime still retain a powerful smell of Pennyroyal.

3. *Z. spicata*. Spiked Ziziphora. "An Hift. Nat. Madr. v. 4. 254." Vahl n. 3.—"*Flowers* in racemo spike, imbricated. *Bracteae* ovate, acute, ribbed. *Leaves* lanceolate, somewhat toothed."—Native of Spain. Annual. Stem from ten to eighteen inches high, throwing out from the base a branch or two as tall as itself. Leaves ribbed; the lower ones flaked; the upper filfe. *Flowers* several, on short filaks, standing near together. *Bracteae* broad, entire, acute, fringed. Perhaps a mere variety of *Z. hispanica*. Yet it seems to differ in having the *leaves* lanceolate, narrower than those that accompany the flowers, which are ovate, not obovate. *Vahl.* We have seen no specimen;
specimen; but this description seems to make the in-
fluence of the present species really spiky rather than
whorled, though it does not alter our opinion as to the
left.

Vahl. n. 3. Vahl n. 4. Ait. n. 3. (Acinos fyracia, folio
mucronato, capulis hirtis; Moril. v. 3. t. 454. fect. 11. t. 19.
fr. 3; also A. syraca, tenuifole capulis, capulis hirtis; ibid.
fr. 4.)—Flowers axillary. Leaves ovato-lanceolate, taper-
pointed, acute, entire.—Native of Syria. Sent to Moriton
from Aleppo, by the Rev. Dr. Huntington. We presume,
from a remark of Moriton under a plant immediately
following, that the two varieties here indicated, as well as a
third, with a smoother calyx, his fl. 2, were all sent in
seed, and that he raised the plants. If so the introduc-
tion of this species should be dated before the time of
Miller. The root is annual. Stem a span high, with many
square, downy, leafy branches. Leaves an inch long, nearly
serif, strongly ribbed, downy, dotted, entire, more or less
fringed with strong white hairs. Flowers flanked, mostly in
pairs, almost together. Calyx about half the length of
the leaves, hoary with fine recurved pubescence, more or
less intermixed with long, prominent, hoary hairs; its lower
part swelling much, as the seeds ripen. Corolla pale, hairy
externally, with a dilated throat.

Vahl. n. 4. Vahl n. 5. Ait. n. 4. (Clinopodium fupinum
incanum; Amm. Ruth. 51.)—Flowers axillary. Calyx
hoary. Leaves ovate, flapped, somewhat serrated.—Native
of Siberia. Introduced into England by the late Dr.
William Pitcairn, in 1786. Mr. Aiton marks it as a
perennial. The flims are diffuse, branched, bluntly quadra-
gerual, finely downy. Leaves scarcely aromatic, though dotted
with pellucid spots, many-ribbed, rough-edges, and some-
what fringed, from half to three-quarters of an inch long,
on footstalks about half or a third as much. Flowers all
axillary, three, four, or more, together; on downy foot-
stalks, half the length of the footstalks. Calyx cylin-
drical, strongly ribbed, not downy, but beset with numerous,
prominent, horizontal hairs. Corolla hairy, its limb larger than
in the first and second species, scarcely so long as the third,
of a light purple, or lilac, especially the lip. Anthers large,
ovate, purple.

Caucas. v. 1. 18. —Flowers axillary. Leaves linear-lanceo-
late, liriate, obtuse, entire.—Native of mount Caucasus
and its neighbourhood, among lime-stone rocks, or about
the flory banks of torrents, flowering in June and July.
We received specimens of this, and all the following species,
from the Chevalier de Steven. The root is annual, long,
tapering and zigzag. Stems one or more, more-or-less divided,
except at the bottom, ascending, near a span long, not
composed of opposite branches crowding each other, as in
Z. tenotior, to which the author of the Flora Taurico-Cau-
casic confederates this plant very nearly allied. Without
adverting to the greater size of the corolla, which is very likely
to vary, and to the pubescence of the calyx, which certainly
does, the leaves appear to be much narrower and more
obtuse; not acute or spinous-pointed. The whole herb
smells strongly, but pleasantly, of Penny-royal, and its leaves
are dotted as in the tenotior. One of our specimens has
broader leaves than the other, and rather shakes our opinion
of its being a distinct species.

Taur.-Caucas. v. 1. 18. (Serpyllum orientale, folio pulegii
vulgaris; Tourn. Cor. 13.)

8. Bieberl. ibid. (Serpyllum orientale, folio pulegii cer-
vini; Tourn. Cor. 13. Herb. Tourn.)

Clutters terminal, capititate, somewhat leafy. Leaves
lanceolate, naked, even, obtuse. Stems rather flabby,
ascending.—Native of the greyly hills of Caucasus, flower-
ing from June to August. Of open fields in Georgia,
about Tolbi; communicated by the Chevalier de Steven.
The flims are rather woody, their branches hoary, with fine,
recurved, downy hairs. Leaves smooth, with copious pel-
licid dots, and the flavour of Penny-royal. They have a
mid-rib, but no lateral ribs, veins, or furrows. Flowers
flanked, crowded at the summit of each branch into a close
tuft, some of the lowermost being axillary. Flower-flanks
round, clothed with fine and hoary pubescence, as are
also the strong ribs of the calyx, whole teeth are fringed
with long white hairs. Limb of the corolla rather large,
and flamen prominent. The variety K, which is all we have
seen, is laid to differ only in having narrower, perfectly
entire, leaves, which are also more crowded than in a. If
there be any affinity between the two varieties, neither of
them can possibly be the Z. serpyllacea of Curt. Mag. t. 906.
See the following species.

Taur.-Caucas. v. 1. 18. (Z. serpyllacea; Sims in Curt.
Mag. t. 906. Ait. n. 5. Z. Poulichkini; Sims in Curt.
Mag. t. 1093. Ait. n. 6.)—Clutters terminal, capititate,
athomely leafy. Calyx densely hairy. Leaves ovate, ob-
tuse, notched. Stems procumbent.—Native of mountainous
parts of Georgia, towards Caucasus, flowering from July
to September. Introduced into this country by Mr. Lod-
diges. The root is perennial, and rather woody, as is the
lower part of the spreading, nearly prostrate, hairy, purplish
flims. Leaves ovate, flapped, about a quarter of an inch long,
roundish-ovate, ribbed and veiny, dilantly serrated, dotted,
roughish with short hairs, especially the ribs beneath.
Flowers numerous, crowded into very dense oval heads.
Calyx in our specimens quite concealed by very long, dense,
spreading, hoary hairs, much more remarkable than in any
other known species. Limb of the corolla rather large.
Stamens more or less prominent, though variable in length,
with large anthers. The colour of the flowers may very
well vary between the two extremes represented in the Bot-
anical Magazine. The smell of the herb may also be variable.
We cannot but think the original opinion of our judicious
friend Dr. Sims far preferable to that which induced him to
separate the above two plants. Let us be wrong however,
it is proper to announce that our specimens of Z.
dasyantha, from the Chevalier de Steven, has little or no scent,
and agrees well with Z. Poulichkini. The Flora Taurico-
Caucasica speaks of a variety, found in the elevated fields
of Georgia, in which the leaves are rather narrower, and the
hairs of the calyx shorter, as well as fewer. The author
believes this to be closely related to Z. bifanus, see n. 2,
of which perhaps he had not examined an authentic specimen.
No two species of this genus, or any other, can be more
dilinct, than the Linnæan bifanus, and the plant of which
we are treating.
**ZIZIPHUS.**

Gen. Ch. Cal. Perianth inferior, of one leaf, nearly flat, in five spreading, ovate, equal, coloured, deciduous segments. Cor. Petals five, minute, obovate, between the segments of the calyx, but much shorter, opposite to the filaments, spreading horizontally. Stam. Filaments five, short, lying over the petals, and not half so long; anthers roundish, of two lobes. Pkt. Germin superior, orbicular, depressed; style one, very short; stigmas two or three, obtuse. Peric. Drupa oval, or roundish, pulpy, of one cell. Seed. Nut solitary, the shape of the drupa, of one or two cells, with solitary kernels.

Eff. Ch. Calyx flatish, in five deep segments. Petals five, opposite to the filaments. Drupa superior. Nut of one or two cells.

Obst. We have already (see Rhamnus and Paliurus) declared our determination of separating all these genera, though, like Willdenow and some others, the writer of this has united Ziziphus and Paliurus, in the Prodrumus Fl. Græc.; an error which will be corrected in the Flora Græca itself. With respect to some of the species, we can only rely on those who have described the fruit, on which the distinction chiefly depends. They are all shrubby, and for the most part thorny, with alternate, simple, undivided, deciduous, strongly ribbed leaves, and small, axillary, tufted, sometimes racemose and partly terminal, flowers, of a yellow or greenish colour, and inconspicuous appearance; their calyx more flat, for the most part, than that of Rhamnus. The fruit is in most instances edible, or medicinal. In a few instances, the petals are wanting.

Sect. 1. Thorns or prickles none.

1. Z. lineata. Veiny Jujube. Willd. n. 1. (Rhamnus lineatus; Linn. Sp. Pl. 281. Amen. Acad. v. 4. 308. Olsbeck t. 210. t. 7. Engl. ed. v. 1. 353. t. 7.)—Stem erect, unarmed. Leaves roundish-ovate, obtuse, wavy, Clusters terminal; their lower flowers axillary.—Gathered by Olsbeck, on the French island, in the river of Canton, flowering in September. A bushy shrub, often as tall as a man, with copious, alternate, round, leafy, finely downy branches. Leaves alternate, on short stalks, of a roundish, abrupt, often marginate, figure, half an inch long at most, smooth on both sides; dark green above; paler and yellowish beneath, with very elegant, oblique, parallel, red veins. Flowers about the ends of the branches, flaked, partly axillary, partly collected into terminal smooth clusters. Calyx a little concave, or bell-shaped, at the base; its segments lanceolate, as are likewise the petals. Anthers black before they burst. Drupa small, oval, armed, on the orbicular permanent base of the calyx.

2. Z. volubilis. Twining Jujube. Willd. n. 2. Ait. n. 1. Pursh n. 1. (Rhamnus volubilis; Linn. Suppl. 152. Walt. Carol. 101. Jacq. Coll. v. 2. 236. 1c. Rar. t. 356.)—Stem twining, unarmed. Leaves ovate, acute, somewhat wavy. Umbels axillary and terminal, flaked.—In deep swamps, near the sea-coast, from Virginia to Carolina, flowering in June. Flowers small, greenish-yellow. Fruit oblong, yellowish, half covered. It affords the highest trees of Cupressus difflacha, in the Dismal swamp, near Suffolk in Virginia, and is known there by the name of Supple-Jack. Purf. The branches are round and smooth. Leaves flaked, drooping, one and a half or two inches long, and near one broad, acute, and tipped with a small point, smooth, with oblique parallel veins, more numerous than in the last; their under side rather the palest. Flowers small, pale. Drupa small, blackish, of a long oval shape. Nut of two cells in the wild state, according to Walter, though Jucquin, in the cultivated plant, found only one. Lamarrck, in an observation at the end of this genus, though he allows this species to have the proper fruit of Ziziphus, gives his reasons for keeping it in Rhamnus; thence are the concave calyx, and the want of a fleshy disk, or, in Linnaean language, "receptacle of the flower." Probably the same remarks would apply to the preceding species, which Lamarrck also excludes from Ziziphus. We are ready to allow that they both have more of the habit and foliage of Rhamnus, and their frutus are so small, it may be difficult to say whether they are drupa or fruticos. Not having had an opportunity of investigating this point ourselves, we must rely on those who have.

3. Z. peruviana. Peruvian Jujube. Lamarrck n. 12.—Stem unarmed. Leaves elliptic-ovate, sparingly and minutely toothed, somewhat angular, rather fleshy, smooth. Petals acute, longer than the calyx.—Native of Peru. Long cultivated in the public garden at Paris, from whence the younger Linneaus procured a specimen, and where Lamarrck saw it flowering for many successive years, but without producing fruit, which led him to suppose the flowers might be dioecious. The plant itself appears now to be no longer in existence there, no mention being made of it in professor Desfontaines's Tableau de l'Ecole de Botanique au Jardin du Roi, ed. 2. printed in 1815. This is an evergreen, branching, loosely spreading frutus, about three feet high, smooth in every part. Branches a little zigzag, nearly round. Leaves scattered, flaked, from an inch to a half inch, generally ovate, blunt, or sometimes pointed, thick and somewhat fleshy, of a glaucous green, with a mid-rib, and a few scattered veins, none of which seem to be visible but in a dried state, and then but slightly. The margin is irregularly angular, each angle tipped with a glandular tooth. Our specimen has no flowers. Lamarrck says they are small, axillary, two or three together, or solitary, flaked, yellowish-white, widely expanded, flat or cleft. Petals oval, pointed, flat, larger than the calyx.

4. Z. marginata. Notched Jujube. Swartz Ind. Occ. 1954.—Stem erect, unarmed. Leaves roundish-ovate, marginate. Umbels axillary, flaked. Petals none.—Gathered by Mr. Fahlberg, in the west Indian island of St. Bartholomew. The frutus is fleshy, with round, erect, rigid branches, whose bark is grey and smooth; their extremities angular. Leaves flaked, alternate, but approaching each other in pairs, so as to become nearly opposite, rather membranous, very smooth on both sides, an inch or an inch and a half long, entire, the extremity only being slightly marginate. Footstalk short. Umbels opposite. Stalks the length of the footstalls, thickened as the fruit advances. Partial ones from three to six, rather longer, fingle-flowered. Calyx concave, with a spreading limb, in five acute segments, divided as it were into two cavities. Petals none. Filaments very short, inserted below the divisions of the calyx. Anthers ovate, embraced at each side by the hollows in the segments of the calyx. Stigmas two, obtuse. Drupa roundish-ovate, smooth, the size of Alphice, crowned with the permanent style. Nut of two cells, with solitary kernels. Swartz.

Seet. 2. Branche prickly.

5. Z. Lotus. Lotus Jujube. Willd. n. 4. Lamarrck n. 2. Ait. n. 3. (Z. sylvestris; Tourne. Inf. 627. Shaw Afric.)
ZIZIPHUS.

—Prickles in pairs; one of them hooked. Leaves elliptic-oblong, slightly crenate, three-ribbed, smooth on both sides.—Native of Africa, especially of the kingdom of Tunis, in a tract called Cerret, which was formerly the centre of the Latothong. The Arabs know this plant by the name of Seedna. It has the habit of a Rhamnus, and the flowers of the Common Jujube. But the fruit is smaller, rounder, and sweeter; the size of Sloes, with a large flone. This fruit is borne on every part of the branches, like Gooseberries; whereas that of the Common Jujube grows only on the flender annual shoots, thrown out from the ends of the branches. The Z. vulgaris is 20 feet, or more, in height, with a large furrowed stem, twisted branches, knotty at the extremities, and larger oblong leaves; but the Lotus is scarcely three or four cubits high, with numerous shoots from the same root, which are smoother, staintiger, and paler, or whitish; the leaves small, round, and more rigid. The fruit is ripe, and fit for eating, in December and January."

Such is Dr. Shaw’s very intelligent account; to which we may add, that the prickles grow on the pairs, both of them very straight, slender, and sharp; but when young, but in process of time one becomes thick and hooked, the other much elongated, remaining quite straight. The leaves are at most an inch long, perfectly smooth, naked; and green, on both sides; their three ribs sometimes separate, sometimes more or less combined.

Lamarck n. 11. (Rhamnus Napaea; Linn. Sp. Pl. 282. Rh. n. 87; Linn. Fl. Zeyl. 36. Jujuba indica spinosa, folio et fructu longiori; Pluk. Almag. 190. Prunus zeylanica spinosa, &c.; Pluk. Phyt. t. 216. f. 6. Vidara litorea; Rumph. Amboin. v. 2. 119. t. 37.)—Prickles generally in pairs, hooked. Corymbs axillary, many-flowered. Leaves ovate, acute, finely serrated, smooth on both sides. Fruit elliptical.—Native of Ceylon, Amboyna, and other islands of the East Indies. We know this only by the specimens in the Linnaean herbarium, which does not quite agree with the description in the Flora Zeylanica, the leaves being neither oblique, unequal, nor bluntish, but exactly as represented by Plukener and Rumphiius. The branches are somewhat zigzag, round, or a little angular, with a smooth whitish bark; rough with mealy down when young, like the flower-buds, flalks, and young leaves. Prickles stout, recurved, dark brown. Leaves an inch, or an inch and a half long, elliptic-obtuse, acute, tipped with a small glandular point, finely and bluntly serrated, strongly three-ribbed; paler and yellowish beneath. Footstalks quarter of an inch long, a little down. Flowers very numerous, in dense, compound, downy or mealy, corrymbose clusters, on short axillary flalks. Drups like an olive, elliptical, or somewhast ovate; its flavour acid and astringent. Rumphiius says, this fruit is seldom eaten but with salt, or as a sauce to fish or other food, for the purpose of exciting an appetite. Lamarck unites this species, or at least its synonyms, with the Rhamnus Spinosa-Chrifti of Linnaeus, of which we shall speak hereafter; see n. 15.

7. Z. Jujuba. White-leaved Indian Jujube. Willd. n. 6. Lamarck n. 6. Ait. n. 4. (Rhamnus Jujuba; Linn. Sp. Pl. 282. Rh. n. 89; Linn. Fl. Zeyl. 36. Manifaxis; Sonnerat Nouv. Guin. 134. t. 94. Malum indicum; Rumph. Amboin. v. 2. 117. t. 36. Perinoddi; Rhede Hort. Malab. v. 4. 85. t. 41.)—Prickles solitary, deflexed. Corymbs axillary, many-flowered. Leaves roundish-ovate, obtuse; downy and snow-white beneath.—Native of the East Indies. A flowe plant in England, flowering in April and May. When wild, it makes a tree of a moderate size. The branches, flower-buds, flalks, and backs of the leaves, are all white with fine, dense, entangled, rather hairy, pubescent. Form and size of the leaves much like the last, but rather rounder and more blunt; the margin crenate, or bluntly serrated; upper side very smooth, of a fine green. Infrutescence like the last. Flowers white; sometimes fix-cleft and hexandrous. Style divided. Drupa globular, or somewhat heart-shaped. Nut ruggied, with two green kernels. Sonnerat reckons this fruit among the best that are the produce of New Guinea. Rheede speaks of it as "agreeably acid," and more oliveshaped than in Sonnerat’s figure. Cultivation perhaps may account for these differences. Hence we presume Z. mauritiana, Lamarck n. 7, may be but a variety of this.

8. Z. Xylpyrus. Wooden-fruited Indian Jujube. Willd. n. 7.—"Prickles solitary, recurved. Leaves ovate, rather acute, somewhast heart-shaped; downy beneath. Flowers corrymhits."—Native of desert places, at the bottoms of hills in the East Indies. A tree, scarcely taller than a man. Branches hoary. Leaves broadly-ovate, in some few heart-shaped, not frequently oblique; unequally serrated; dark coloured above; clothed beneath with very fine white down. Prickles few, small, solitary under each footstalk. Flowers in axillary flalked corymbs. Calyx downy. Drupa dry, inipid, slightly astringent, larger than a cherry. Nut ruggied. Retains, Willd. Posibly this may be Z. rugosa; Lamarck n. 8, for which that author cites Frutex spinosus, &c.; Pluk. Phyt. t. 29. f. 7.

Lamarck, n. 5. Mill. Dict. ed. 8. n. 3. (Rhamnus Oenophila; Linn. Sp. Pl. 282. Rh. n. 88; Linn. Fl. Zeyl. 35. Jujuba aculeata, nervosi folis, infra sericeis, flavis; Burm. Zeyl. 131. t. 61.)—Prickles solitary, conical, recurved. Leaves unequally ovate, or half-heart-shaped, acute; silky beneath.—Native of Ceylon. A small tree, with downy branches, and short, thick, hooked prickles. Leaves two inches long, very obscurely serrated; remarkably unen or oblique at the base, the three ribs also being much nearer one margin than the other; the under side finely silky and yellowish; the upper also silky while young, but in a less degree. Flowers in little dense, silky, axillary tufts.

10. Z. ignanco. Lizard Jujube. Lamarck n. 4. (Rhamnusignacuus; Linn. Sp. Pl. 282. Jacq. Amer. 74. Jujube americana spinosa, loti arbors foliis et facie, fructu rotundo parvo dulci; Commel. Hort. v. 1. 141. t. 73.)—Prickles in pairs, unequal, divericat. Leaves ovate, pointed, serrated, smooth on both sides. Clusters axillary, monocious. Petals wanting. Fruit roundish.—Native of the West Indies, as well as of the neighbouring continent, in bushy, rocky, or flomy places, where the Lacerta ignana, reported to be fond of this fruit, is likewise frequently to be met with. This is an inegquent trailing shrub, with round, zigzag, scarcely downy, branches. Leaves thin, pliant, three-ribbed, very smooth, two or three inches long, sometimes more, Jacquin says eight inches, though rarely, in which case they are more elliptical. The prickles are long and flender, in pairs under each footstalk; one of them always straight; the shortest sometimes curved, but not remarkably. Flowers small, yellow, according to Jacquin delitute of petals. Drupa roundish or ovate, yellow, twice the size of a pea, with a sweet pulp, and a rugged nut, of one cell. Willdenow seems to have omitted this species entirely.

11. Z.
11. Z. scoparia. Chinee Jujube. Lamarrck n. 3. Def.- font. Tabl. 231.—"Young branches prickly, downy; old
ones unarmed. Leaves ovate-oblong, sharply serrated.
Petals reflexed under the calyx."—Cultivated in the public
garden at Paris, and said to be a native of China. As
this point is uncertain, how much better might the name of
cryptopetalas have been chosen! Lamarrck describes the pre-
frent species as a frub, only three or four feet high, losing
its tender, unequal, bitle-like prickles as the branches ad-
VANCE in age. Leaves of a very pale green, crowded, three-
ribbed, rather smaller than those of Z. vulgaris hereafter
defined; we presume they are quite smooth. Fruitflaks
short and downy. Flowers small, whitish, axillary, solitary
or in pairs, remarkable for having their petals so perfectly
reflexed, and concealed by the calyx, as not to be visible
when we regard the flower vertically. Lamarrck.

12. Z. rotundifolia. Round-leaved Jujube. Lamarrck
n. 9. (Jujuba, five Ziziphus, zeylanica rotundifolia crenata
minor, folis subus lananoginis; Pluk. Phyt. t. 197. f. 2.
Burme. Zeyl. 132.)—Prickles in pairs; one of them re-
curved. Leaves roundish-oval; downy beneath."—Native
of Ceylon. Leaves small, perhaps hardly an inch long,
rather more rounded than in Phukemts figure, slightly
toothed; smooth above; cottony beneath; on very short

n. 10.—Prickles in pairs, frright. Leaves roundish-oval,
somewhat toothed, smooth on both sides. Branches acutely
angular."—Described from the herbarium of Juffieu, with-
out fertilisation. The angular branches strikingly distin-
guish this species from all the rest. They are woody,
smooth, zigzag, square, with prominent acute angles.
Leaves three-ribbed, an inch and a half broad, on short
footstalks. Lamarrck. Nothing is recorded of the native
country of this plant.

n. 1. Ait. n. 5. Sm. Fl. Greec. Sibth. t. 241. (Z.;
part 2. 24. t. 59. C. L. Willch Obf. 5. Jujube Arabum,
five Ziziphus Dodonaei; Ger. Em. 1501.)—Prickles in
pairs, unequal. Leaves ovate, abrupt, bluntly ferratted,
smooth. Flowers in axillary tufts. Fruit elliptical.—
Native of the fouth of Europe. Gathered by Dr. Sibthorp
about Megara, and on mount Parnassus. It has been cul-
vatated in England ever since Parkinson's days, but requires
the shelter of a green-house, and though it may sometimes
bloom, never bears fruit. Pliny says the Jujube-tree was
brought in, his time, from Syria into Italy. When wild it
attains the fize of a small tree, with round, smooth, glaucous
branches, zigzag and leafy when young. The prickles make
no appearance on the young leafy shoots, but the following
year they become strong thorns, one of them an inch long,
the other much shorter, and sometimes, not always, recur-
cved, as Willich well observes. Leaves rather crowded,
deciduous, on short flarks, ovate, somewhat tapering into
a broad blunt point, frequently emarginate; their edges
copiously though bluntly ferratcd; both surfaces smooth;
the under paler, strongly three-ribbed; their length an inch
and a quarter or an inch and a half. Flowers yellowish, on
short flarks, in little axillary tufts, not much longer than
the footstalks. Petals obtuse, half the length of the calyx.
Stigmas two or three. Drupa the size and shape of an olive,
blue-red, sweet, mucilaginous, esteemed good in forenes
or inflammation of the mouth and throat, but are out of use
in our present practice. Pallas's plant has been quoted be-
the true Z. vulgaris, of which we cannot help feeling some
doubt, a comparison of that plate with the old wooden cut
of Camerarius, may serve to shew how superior the artistis
of thofe earlier times were to some of our modern delineators
and colourers.

n. 10. (Z. africana; Mill. Dict. ed. 8. n. 4. Rhamnus
Spina Chiri]; Linn. Sp. Pl. 282. Oenoplia spinata; Gluf.
Hitt. v. 2. 313. Nabca, Palurus Athenezi credited; Alpin
Agypti. 16. t. 19. Jujbee five Zizyphus africana, macron-
ata folis; spinis gemellis; Pluk. Almag. 199. Phyt. t. 197.
fl. 3.—Prickles in pairs, frright. Corymbs axillary,
flaked, many-flowered. Leaves ovate, finely ferrated,
smooth on both fides. Fruit globofe.—Native of Ethiopia
and Paleflus. Seeds collected near Jerusalem, by Hassel-
feld, produced the plant described by Linnaeus, a wild
specimen of which, fent also by Hasselquift, is preferred in
the Linnaean herbarium. Miller also raised this species
from Syrmin seeds, fo that it is entitled to a place in Hort.
Kew. Respecting Phuknet's synonym, we feel no doubt.
The cut of Alpinus as much refembles Z. Napecu, n. 6, in
the foliage, but the globofe fruit agrees bet with the species
before us. The prickle are hardly visible on our fpecimen,
which is a young luxuriant leafy branch, in flower. They
perhaps acquire their full proportion on older branches, as
in Z. vulgaris, n. 14. The leaves are scattered, of a broad-
oveate, somewhat roundish, obtuse figure, two and a half
or three inches long, and two wide, strongly three-ribbed,
with tranverse veins, minutely and slightly serrate rather
than ferratted, very smooth and even on both fides; paller
beneath. Footstalks scarcely an inch long; downy on their upper fide.
Corymbs forked, downy, many-flowered, each on a folicary
axillary flalk, shorter than the footstalk. Bradteas wsh-
haped. In our only expanded flower, the segments of the
calyx, as well as the petals and fannus, are strongly reflved,
quite under the base of the calyx. The drupa is said to be
the fize and shape of a Sloe.
grotes, and each grotesch is divided into 18 pfenings. The florin also contains 24 floracks, 90 schilling, or 270 pfenings. A florack is worth 12 grofen, or 36 schilling; a grochen, 3 schilling; and a schilling, 3 pfennings.

ZMEINOGORSKAIA, in Geography, a fort of Russia, on the river Porobalik; 200 miles N. of Kolivan. N. lat. 51° 10'. E. long. 82° 10'.

ZMILACES, in Natural History, a name given by Pliny to a stone found in the river Euphrates, resembling marble, and of a bluish-green colour.

ZMILAMPIS, the name of a gem, described by Pliny and the ancients, which they tell us was very like the Proconnesian marble, except that in the centre of the stone there was always a blueish spot, resembling the pupil of an eye.

The Proconnesian marble of the ancients was of a fine clear and elegant white, variegated with irregular black veins. Pliny's description is so short, that it has been supposed from him that the zmilampis was a sort of marble; he only says of it, that it was like the Proconnesian marble, but blue in the middle. Many had inferred from this, that he meant no more by it than that this was a stone, which had blue veins instead of the black ones in the Proconnesian kind. But when we examine the rest of the ancients, and find that it was a small stone, found in the river Euphrates, and worn in rings, and that its blue spot was like a pupil of an eye, we may easily determine that it was one of those gems which we call acicus beli, or bellocesto; of which there is a vast variety found in the rivers of the East Indies, and many have a fine opaque white ground, and a blueish or greenish spot for the pupil.

ZMILANTHES, a name given by Solinus and some others to a gem called by the more correct writers zmiliampis.

ZNAMENSKOI, in Geography, a town of Russia, in the government of Tobolk, on the Irtych; 28 miles N.N.W. of Tara.

ZNAYM, a town of Moravia, in the circle of the same name, near the river Teyai. This town was built about the year 1222, at a little distance from another town, laid waffle by the Bohemians. It contains a citadel, four cloisters, and a college; the circle borders on Austria; 68 miles S.W. of Olmutz. N. lat. 48° 48'. E. long. 15° 51'.

ZNENDEI, a river of Russia, which runs into the Vitim, N. lat. 53°. E. long. 115° 14'.

ZNIN, a town of the duchy of Warsaw; 20 miles N. of Gnefna.

ZNONIRAD, a town of Croatia; 36 miles S. of Bihać.

ZOAGLI, a town of Genoa; 20 miles E. of Genoa.

ZOANA, in Ancient Geography, a town of Asia, in the Lesser Armenia, upon the route from Hatala to Arbusitis, between Tonofa and Gundufa. Anton. Inan.

ZOANNES, a name given by Strabo to a people half-favag, that inhabited the mountains of the Colchide.

ZOAR, ZOAR, SEGAR, or BELA, a city of Pentapolis, on the southern extremity of the Dead sea. It was preferred by destruction from fire by means of the intercession of Lot. (Gen. xiv. 2.) Its name before this circumstance was Bela; but when Lot requested it to be spared as a place of refuge for himself, he represented it as a small place; and hence it had the name Zoar, or Segor, which, in Hebrew, signifies small or little. The Romans kept a garrison at Zoar. St. Jerom observes, that the name Bela was given to this city, because, as soon as Lot left it, an earthquake caused it to be swallowed up; bela in Hebrew signifying to swallow up. Jerom also says, that the Hebrews think that Zoar bears also the name of Shalitha. (1 Sam. ix. 4.) They pretend that this city has been often demolished by earthquakes.

ZOAR, in Geography, a town of Arabia, in the province of Hedjaz, on the south coast of the Dead sea, at the mouth of the Safa; 30 miles N. of Karaz.

ZOAR. See TSOR.

ZOARA, a town of Africa, in the country of Tripoli; 62 miles W.N.W. of Tripoli.—Also, a town of Africa, in the country of Barca; 140 miles S.W. of Tolometa. N. lat. 25° 35'. E. long. 115° 56'.

ZOBAYA, a town of Mexico, in the province of Guatimal; 30 miles N. of Guatimala.

ZOBIR, a town of the Persian empire, in the pashalic of Bagdad, about 10 miles W. of the city of Baflora, situated on the dry canal of the Djuze Zade, supposed to be the former bed of the Euphrates. It is by some laid to be the ancient Bafra, and derives its present name from Zobrefan, who was defeated and slain in the battle of the Camel, fought near this place.

ZOBELN, a town of the duchy of Courland; 20 miles E. of Goldingen.

ZOBERA, a town of Arabia, in the province of Yemen; 35 miles S.E. of Chamir.

ZOBERN, a town of Saxony, in the Vogtland; 8 miles W. of Oel unfitz.

ZOBIN, a town of Germany, in the principality of Oettingen Wallerstein; 6 miles W.N.W. of Nordlingen.

ZOBING, a town of Saxony, in the margravate of Meiffen; 15 miles S. of Deffau.—Also, a town of Auffria; 3 miles N. of Crems.

ZOBLITZ, a town of Saxony, in the circle of Erzgebirg. This place consists of 110 houses, and the inhabitants furnish principally by working the ferpent-stone, which is found here, into pitchers, bowls, tea and coffee dishes, mortars, cups, &c. The ferpent-stone is dug just above the town, and farther on to the east of it is found a red species, which is reckoned among the finest, and for that reason was also considered by the foreigner as his property, together with a yellow, green, grey, and black stone. In the electoral red quarry is also found abelhos of divers colours and granites; 17 miles S. of Freyberg. N. lat. 50° 36'. E. long. 13° 11'.

ZOBOWITZ, a town of Pomerelia; 14 miles S. of Dantzic.

ZOBTEN, a town of Sileia, in the principality of Schweidnitz; 9 miles E.N.E. of Schweidnitz. N. lat. 50° 48'. E. long. 16° 41'.

ZOBTENBERG, a mountain of Sileia, situated in a country otherwise level, 2,424 Paris feet above the level of the sea, near Zobten.

ZOCCO, ZOCOLO, ZOCHE, or SOCHE, in Architectura. See SOCLE.

ZOCCELAR, in Geography, a town of Croatia; 2 miles S.W. of Bihać.

ZOCHINACZTLIS, in Botany, a name by which some authors have called the flos auricula, a flower of New Spain, used in making of the Spanish chocolate.

ZODIAC, ZODIACUS, in Astronomy, a facia, or broad circle, whose middle is the ecliptic, and its extremes two circles parallel to it, at such distance from it, as to bound, or comprehend, the excursions of the sun and planets.

The word is formed from the Greek ζώoς, animal, by reason of the constellations in it, which have the forms of animals given them; others derive it from ζωή, life, from
an opinion, that the planets have a great influence on animal
life.

The sun never deviates from the middle of the zodiac; i. e. from the ecliptic: the planets all do more or less.
Their greatest deviations, called latitudes, are the measure
of the breadth of the zodiac; which is broader, or narrower,
as the greatest latitude of the planets is made more or less.
Accordingly some make it 16, some 18, and some 20
degrees broad.

The zodiac intersecting the equator obliquely makes an
angle with it of 23 degrees and a half; or, more pre-
cisely, of 23° 27'; which is what we call the obliquity
of the zodiac, and is the sun's greatest declination. See
Ecliptic.

The zodiac is divided into twelve portions, called signs;
and those divisions, or signs, are denominated from the con-
fellations which anciently possessed each part. But the zodiac being immovable, and the stars having a motion
from west to east, those constellations now no longer cor-
respond to their proper signs; whence arises what we call
the precession of the equinoxes.

When a star, therefore, is said to be in such a sign of the
zodiac, it is not to be understood of that sign, or constellation,
of the firmament, but only of that twelfth part of the
zodiac, or decadometer of it.

Cassini has also observed a tract in the heavens, within
whose bounds most of the comets, though not all of them, are
observed to keep, which, for this reason, he calls the zodiac
of the comets.

This he makes as broad as the other zodiac, and marks
it with signs, or constellations, like that; as Antinous, Pe-
garus, Andromeda, Taurus, Orion, the Lesser Dog, Hydra,
the Centaur, Scorpio, and Sagittary.

ZODIAC, Hindoo. The early investigators of Hindoo
mythology, which comprehends not only their almanacs,
but every science, and almost every art, of which the Hindoos
have any knowledge, were surprized to find that the days
of the week were named, as with us, after the planets, and
in the same order. It was natural enough to suppose
that the Hindoo almanac was borrowed from the Arabians.
The few Brahmas who at that time had access to Euro-
peans of science, supposed the fame of us, when they dis-
covered the similitude of fable and of name. But it has
been made manifest by the investigations of later writers,
that the Hindoo zodiac is of very great antiquity. Such
of our readers as may be desirous of extended information
hereon, are referred to the dissertations of Sir William Jones
and Mr. Colebrooke; on the Hindoo zodiac, in the 2d
and 9th volumes of the Asiatic Researches; and to the
Hindoo Pantheon. In both works, plates of the Hindoo
zodiac are given from different authorities; and in the
latter work separate engravings also of the personified
planets. We will extract from it a fort of table, shewing
the English and Sanskrit names, and the vehicles assigned
to the several planets by the latter fabulists.

Under the Sanskrit names of the planets we have given
short articles descriptive of their mythological and histori-
ical attributes and allusions. To them (Surya, Soma, &c.)
we therefore refer for farther particulars, and to the article
Vahan for an account of the vehicles assigned to them and
other mythological personages of Hindoo fable.

ZODIACAL LIGHT, a brightness resembling that of the
milky way, but less bright, and which is sometimes per-
ceived in the heavens, at certain times of the year, after
sun-fet, or before its rise. Some have supposed, that this
phenomenon is the same with that which the ancients called
tails, a term by which they denoted a meteor, or impres-
sion in the air like a beam. Thus Pliny (lib. ii.) says, "emi-
cient trabea, quos docos vocant." The form of this light
resembles that of a pyramid, lying lengthways in the zodiac,
within which its point and axis are always enclosed, its base
being towards the sun, and placed obliquely with respect to
the horizon. In the torrid zone, the zodiacal light is fre-
quently, or almost continually, seen. At or near our latitude
it may be seen about the time of the equinoxes. The best time
for seeing it is about the 1st of March, at 7 o'clock in the
evening, when the twilight is ending, and the equinoctial
point in the horizon. This phenomenon was first discovered
by Defcartes, and by Childrey about the year 1659. It
did not engage general attention till it was described and
named by M. Cassini the elder, in 1683. It was after-
wards observed by M. Fatio, in 1684, 1685, and 1686, and
by M. Kirch and Eimmart, in 1688, 1689, 1691, 1693,
and 1694. See Mairau, Suite des Mem. de l'Acad. Royale
des Sciences, 1731, p. 3.

In 1707, April 3, it was observed by Mr. Derham in
Eves. It appeared in the western part of the heavens,
about a quarter of an hour after sun-fet, in the form of a
pyramid, perpendicular to the horizon. The base of this
pyramid was judged to be the sun. Its vertex reached 15°
or 20° above the horizon. It was throughout of a dusky-
red colour, and at first appeared pretty vivid and strong,
but faintest at the top. It grew fainter by degrees, and
vanished about an hour after sun-fet. This solar atmo-
sphere has also been seen about the sun in a total solar
eclipse, a luminous ring appearing about the moon at the
time when the eclipse was total.

M. Fatio
M. Fatio conjectured that this appearance arises from a collection of corpuscles encompasing the sun in the form of a lens, reflecting the light of the sun. M. Caffini supposed that it might arise from an infinite number of planets revolving about the sun; so that this light might owe its existence to these bodies, as the milky way does to an innumerable number of fixed stars. It is now, however, generally supposed, that it is matter detached from the sun by its rotation about its axis. The velocity of the equatorial parts of the sun being the greatest would throw the matter to the greatest distance, and on account of the diminution of velocity towards its poles, the height to which the matter would there rise would be diminished; and as it would probably spread a little sideways, it would form an atmosphere about the sun something in the form of a lens, whose section perpendicular to its axis would coincide with the sun's equator. And this agrees very well with observation. There is, however, a difficulty in thus accounting for this phenomenon. It is very well known that the centrifugal force of a point of the sun's equator is a great many times less than its gravity. It does not appear, therefore, how the fun, from its rotation, can detach any of its gross particles. If they be particles detached from the sun, they must be sent off by some other unknown force; and in that case they might be sent off equally in all directions, which would not agree with the observed figure. The cause is probably owing to the sun's rotation, although not immediately to the centrifugal force arising therefrom.

The zodiacal light, according to M. de Mairan's ingenious and plausible hypothesis, is nothing but the solar atmosphere, a rare and nebulous fluid, either luminous by itself, or made by the rays of the sun surrounding its globe; but in a greater quantity, and more extensively about its equator than any other part. As it always accompanies the sun, it is natural to ascribe it to a solar atmosphere, extending beyond the orbit of Mercury, and sometimes even beyond that of Venus. Accordingly, the zodiacal light has been supposed to be a fiction of this atmosphere, which, being extremely flat at its poles, cannot be conceived to partake of the sun's monthly motion. Dr. T. Young (Lectures, vol. i. p. 502.) observes, that the only probable manner in which it can be supposed to retain its figure, is by means of a revolution much more rapid than that of the sun's motion. To that purpose, M. de la Lande remarks, that it seems now to be generally believed, that the zodiacal light is the atmosphere of the sun; for it always accompanies the luminaries; and the equator of the sun is in the direction of this light; consequently he fays, that in all probability the zodiacal light is an atmosphere situated round the sun, in the direction of its equator, and flattened by its rotary motion. Astron. Paris, 1771. § 845 to 846.

The zodiacal light is more or less visible according to circumstances; but the solar atmosphere is not always visible by means of this light, though it be always seen about the globe of the sun in total eclipses.

One of the most essential circumstances for the perception of the solar atmosphere by the zodiacal light is its having sufficient length on the zodiac; for without this its brightness is entirely hid from us by the twilight.

M. de Mairan fays, it may be proved from many observations, that the sun's atmosphere sometimes reaches as far as the earth's orbit, and there meeting with our atmosphere produces the appearance of an aurora borealis.

The length of the zodiacal light varies sometimes in reality, and sometimes in appearance only, from various causes.

The oblique position of this light, little different from that of the plane of the ecliptic, does not permit us to see it distinctly, and sufficiently elevated above the horizon; but some time after sun-set, towards the end of the winter, and in spring, or before sun-rising in autumn, and towards the beginning of winter. Several causes hinder our seeing it, any more than the milky way; such as moon-light and strong twilights, among others.

M. Caffini often mentions the great resemblance of the zodiacal light to the tails of comets. M. Fatio has made the same observation; and M. Euler has lately endeavoured to prove them owing to similar causes. Decouverte de la Lumière Celeste que paroit dans le Zodiaque, art. 41. Lettre à M. Caffini, printed at Amsterdam, 1686. Euler, in Mem. de l'Acad. de Berlin, tom. ii.

The figure of this solar atmosphere must be lenticular, or that of a flattened sphereoïd. M. de Mairan gives us a draught of its appearance and projection.

The extent of the zodiacal light from the sun to its point is seldom less than 45, sometimes 150 degrees in length; M. Pingré being on the torrid zone saw it 120 degrees; and its breadth varies from 8 to 30 degrees.

This light seems to have no other motion than that of the sun itself.

M. Euler observes, that if the sun has an atmosphere, the force of the impulse of light issuing from that globe must drive particles of that atmosphere before it; but as gravity is very strong at the sun, this impulse would never drive those particles beyond the limits of their atmosphere, were it not for the centrifugal force arising from the sun's motion round its axis. This being opposite to the action of gravity, diminishing its effects, the impulse of the light may considerably dilate the figure of the solar atmosphere, from what it would be if it arose from the gravity and centrifugal force of its particles only; and this dilatation will be very considerable near the sun's equator, and very small towards its poles. The action of light thus diminishing the action of gravity, M. Euler attempts to calculate how far this diminution of gravity may increase the extent of the sun's atmosphere about its equator. He finds a cubic equation, the roots of which express the semi-axis, or greatest amplitude of this atmosphere. He adds, that this equation having three real roots, it is possible that the solar atmosphere may become a ring surrounding the sun's globe, as the ring of Saturn surrounds the body of that planet. As the electric fluid is now generally acknowledged to be the cause of the aurora borealis, which M. de Mairan ascribes to the solar atmosphere, which produces the zodiacal light, and which is thrown off principally and to the greatest distance from the equatorial parts of the sun, in consequence of his rotation on his axis, and extending visibly, in the form of a luminous pyramid, as far as the orbit of the earth, falls into the upper regions of our atmosphere, and is collected chiefly towards the polar parts of the earth, in consequence of the diurnal revolution, where it forms the aurora borealis; it is no improbable conjecture, that the sun may be the fountain of the electric fluid, and that the zodiacal light, and the tails of comets, as well as the aurora borealis, lightning, and artificial electricity, are its various and not very dissimilar modifications. See Theory of Electricity.

ZODZISZKI, in Geography, a town of Lithuania, in the palatinate of Wilna; 52 miles E. of Wilna.

ZOEGEA, in Botany, was so named by Linnaeus, in honour of his pupil and correspondent Dr. John Zoega, who visited Iceland, and communicated thence, as well as from the neighbouring ocean, many new or rare plants, especially of the cryptogamic tribes, to the great Swedish naturalist. Dr. Zoega wrote a Flora Islandica, which has been

Vol. XXXIX.
been several times printed, with Olafsen's, and von Troll's, accounts of that country. In the latter book this _Flora_ is a mere catalogue, Linnæan names, the synonyny and descriptions being omitted. He wrote also a mineralogical work on Zeolites. The plant which bears his name was raised in the Copenhagen garden, from Siberian seeds, and communicated by himself to Linnæus.—Linn. Mant. 15. Schreb. Gen. 577. Willd. Sp. Pl. v. 3. 2276. Mart. Mill. Diét. v. 4. Ait. Hort. Kew. v. 5. 143. Jaff. 174. Poir in Lamarck. Diét. v. 8. 868. Gært. v. 2. 452.—Clafs and order, Syngenesia Polygama-syriframus. Nat. Ord. Compojiae capitée, Linn. Cinareaceph, Jull. Gen. Ch. Common Calyx ovate, imbricated, of numerous lanceolate, fringed scales; the inner ones linear-lanceolate, chaffy, longelt. Cor. compound, radiant. Florets of the disk numerous, perfect, of one petal, with a slender tube, and a limb in five deep, lanceolate, erect segments; those of the radius fewer, neater, of one flat, ligulate, abrupt, sharply five-toothed petal. Stam. in the florets of the disk, Filaments five, short; anthers united into a cylindrical tube. Pet. in the same florets, German short; style capillary, very long, erect; stigma short, clvned: in the radiant florets, German a rudiment only, without style or stigma. Peric. no other than the unaltered closed calyx. Seeds in the florets of the disk, solitary. Down bristly. In the radius none. Recept. bristly. Eff. Ch. Receptacle bristly. Seed-down of simple bristles. Florets of the radius ligulate. Calyx imbricated. Obf. Linnæus justly observes that this genus is very intimately related to Centaurea (see that article). Indeed the only difference consists in the flat, or ligulate, not tubular, florets of the radius. How far that distinction is sufficient, some persons have doubted; especially as the presence of the radiant florets themselves in Centaurea, has been thought but a casual occurrence, equivalent to double flowers in other natural orders. As long, however, as the Syngenesia family continues to be characterized at all by the different figure of the florets, _Zoega_ must remain separate from Centaurea.

1. Z. Leptaure. Yellow Zoega. Linn. Mant. 117. Suppl. 383. Willd. n. 1. Ait. n. 1. L'Herit. Stirp. Nov. 57. t. 29. (Z. aleppica; Jacq. Col. v. 1. 89. Lc. Rar. t. 177.)—Native of Siberia, according to a manuscript correction of Linnæus in his own Mantillia; other authors say, of the Levant. It appears to have been cultivated in Mr. Blackburne's celebrated garden at Oxford, Lancashire, before the year 1779, when the catalogue of that rich collection was printed. This plant is a hardy annual, flowering in July and August. The stem is much branched, spreading in every direction, leafy, angular and roughish, twelve or eighteen inches high. Leaves alternate, dilatant, roughish, entire; the lower ones pinnatifid; the rest undivided, obtuse, tapering down into a footstalk. Flowers solitary, on long terminal stalks, large, near two inches broad. Scales of the calyx delicately fringed with tawny bristles. Corolla of a shining golden yellow.

Another species is described in the Supplement by Linnæus himself, under the name of _Z. capensis_. This is _Rehbiana pedunculata_ of L'Heritier. See Willd. Sp. Pl. v. 3. 2136, and is the same thing as _Aphanasia pulita_. Linn. Suppl. 362.

2. _Zofala_, in Geography. See _Sofala_.

3. _Zoffany_, Johan, in Biography, was born at Frankfurt, about the year 1735. He came to England as a painter of small portraits when he was about 30 years of age. After passing some time with very little encouragement, he at length was fortunate enough to attract public attention by a portrait of the Earl of Barrymore, and thenceforward enjoyed considerable favour and encouragement. The most considerable of his productions at this period were portraits of the most celebrated dramatic performers in their favourite characters; as Garrick, in Abel Drucker, Sir John Brute, and lord Chalkstone, &c.; Foote, in major Sturgoen; and Jacob, as Jacob Gallop; Foote and Welton, as Dr. Laft and the President, in the Devil on Two Sticks; Parmors, Moody, Bransby, Aiken, and many others, whose likenesses he preferred most admirably, with all the variety of expression required for the characters they personified. One picture he painted of the members of the Royal Academy, in the hall of the Academy devoted to the study of the living figure, round which they here assembled, and it received universal applause.

He had the honour to be employed by his majesty, and painted portraits of the royal family; and he was engaged by the queen to paint for her a view of the Tribune of the Gallery at Florence. He was somewhat of a humoursift, and it is said of him, that whilst he was engaged painting in the Florentine Gallery, the emperor of Germany visited the grand duke, and coming up to Zoffany in the Gallery, was much pleased with his performance, and asked him his name; and on hearing it, inquired what countryman he was; when he answered, an Englishman. Why, said the emperor, your name is German. True, returned the painter, I was born in Germany, that was accidental; I call that my country where I have been protected.

Soon after his return from Italy, he went to the East Indies, where he was much employed, and acquired a considerable fortune; but it disappeared upon his return home, and was only restored by a second adventure to the fame hot-bed of wealth and difeafe. He again returned to England, but with diminished powers: yet he still continued to paint, and, among other works, produced an elaborate picture of the back ing the wine vaults at the Tuileries, in 1792; a disgusting display of the atrocities of that eventful period. He lived to a very advanced age, but was reduced exceedingly in intellectual powers for some years before his decease, which happened in 1808. He was a member of the Royal Academy.

4. _Zoffingen_, in Geography, a town of Switzerland, in the canton of Berne, on the Wigger. It was at one time imperial, after which it put itself under the count of Habsburg. In the 13th century it was subject to the house of Austria, from which it was taken by the Bernois, in the year 1415, and is the principal place of a bailiwick, with considerable privileges; 26 miles N.N.E. of Berne.

5. _Zogno_, a town of Italy, in the department of the Serio; 5 miles N. of Bergamo.

6. _Zogocara_, in Ancient Geography, a town of Asia, in Greater Armenia. Ptol.

7. _Zogor_, in Geography, a town of Thibet; 16 miles W.S.W. of Zuenga.

8. _Zoahaub_, one of the districts of the province of the Lower Kurdfan, in the pachalic of Bagdad, which has a separate hakem or governor. See _Soltiman_.

10. _Zohra_, a town of Egypt, on the left bank of the Nile; 5 miles N.N.E. of Minet Ebn Kasr.

11. _Zoika_, a town of Ruflia, in the government of Archangel, near the mouth of the Petchora; 160 miles N.E. of Mezen.

12. _Zolius_, in Biography, a carping critic belonging to the clafs of grammarians, was a native of Amphipolis, and lived.
lived in the time of Ptolemy Philadelphus, about the year
B.C. 270. His natural disposition to depreciate eminent
characters is said to have been strengthened by the course
of his education, as a disciple of Polycrates, who wrote an
accusation against Socrates. This disposition, which he was
in the habit of indulging, gave occasion to his being deno-
minted the rhetorical dog; rhetorical, as his style was ele-
gant, and dog, from his practice of snarling. Both his
person and mind are very unfavourably exhibited by Ælian;
who says of him, that being once asked, why he spoke ill of
all mankind,—he replied, “because I cannot do ill to
them.” Ambitious of gaining reputation, he endeavoured
to acquire it by degrading others; and valued himself
by having established a kind of claim to the title of “Homer-o-
maflx,” or the fcoeur of Homer. Suidas informs us
that he wrote nine books of grammatical remarks upon this
poet. Plato and Æocrates, as well as Homer, were objec-
tes of his critical severity. Zoilus was the author of several
works; particularly a history commencing from the theo-
gony, and continued to the death of Philip of Macedon,
and a history of his own city. His attack upon Homer
seems to have been an unpardonable offence, and threw a
shade over every other good quality he possessed; for if we
may credit Dionysius of Halicarnassus, he testified that
he was actuated by the love of truth, and he ranks him with
Arilotté, and other eminent philologists. But his virtues
and talents, whatsoever they were, could neither secure him
from poverty whilst he lived, nor guard his memory from
reproach. Vitruvius reports, that when he visited Alex-
andria, he recited his writings against the Iliad and Odyssey
of Homer to king Ptolemy, which gave the king such en-
fence, that he would take no notice of him; and afterwards,
when urged by inducement, he solicited charitable afliance,
Ptolemy repulsed him with this contemptuous refutation;
that if Homer, who had been dead 1000 years, could by
his works give maintenance to many thousand people, a
writer fo much his superior might fairly maintain himself.
It is further said, that the king was so much displeased
with his conduct, that he treated him as if he had been guilty
of paricide; and that he was put to death, as some say, by
crucifixion, and as others by flaying; and according to
another account, he was burnt alive at Smyrna. Vitruvius
adds, “that whatsoever of these was his fate, he well de-
ferred the punishment.” The penalty, however, if this
statement be true, seems to have been much more than ade-
quate to the offence. Ælian Hist. Var. V. Æol. Hift.

ZOISTE, in Mineralogy, Epidote, Häüy, a mineral so
called by Werner after baron Von Zeis of Laybach.

Common ZeiSte.—Its colours are yellowish and blueish-
grey; it occurs massive and crystallized in very oblique
four-sided prisms. The crystals are middle-sized, and deeply
flaked longitudinally. The structure is lamellar, and the
joints parallel with the axis of the crystal. The internal
lumena is sphenoidal; the luflour of the crosf fracture is glist-
thening, and between pearly and resinosous; it is translu-
cent, hard, and easily fragrable. The specific gravity is 3.31
According to Klaproth, the constituent parts are,

Friable Zoíste is of a reddish-white colour, spotted with
pale peach-blossom red; it occurs massive. The fracture
is intermediate, between earthy and splintery; the frag-
ments are very sharp-edged, and translucent on the edges; it
is rather hard and brittle. The specific gravity of this mineral
is 3.3. According to Klaproth, its constituent parts are,

Zoíste was first found in Carinthia, but has since been
discovered in various parts of the continent of Europe,
and at Glenelg in Inverness-shire. It is nearly allied to tremolite,
with which it was at first arranged.

ZOTTIUM, in Ancient Geography, a town of the Pelo-
pomeus, in Arcadia; 15 stadia from Tricoluns. Steph.
Byz.

ZOK, Sokor, in Geography.— See Sokor Zok.

ZOKOL, a town of Servia; 16 miles S. of Sabatz.—
Alfo, a town of Bofnia; 45 miles E. of Boftoneri.

ZOL ENGERS. See Engers.

ZOLCA, in Ancient Geography, a town of Asia, in
Galatia, which belonged to the Paphlagonians, and was
situated on the coast of the Euxine sea. Ptol.

ZOLDO, in Geography, a town of Italy, in the Bellu-
nes; 18 miles N.W. of Belluno.

ZOLDORF, a town of Bohemia, in the circle of Bole-
law; 6 miles W.N.W. of Jung Buntzel.

ZOLERI, a town of the county of Tyrol; 8 miles
S.S.E. of Trent.

ZOL-HUYS. See Tol-huys.

ZOLLERN, a castle of Germany, situated on a moun-
tain, in the principality of Hohenzollern, to which it gives
name; 10 miles S. of Tubingen.

ZOLLICKOFEN, a town of Switzerland, and prin-
cipal place of a district, in the canton of Berne; 2 miles
N.W. of Berne.

ZOLNOK, a town of Hungary, on the river Tysylv;
46 miles W.S.W. of Debrecin.

ZOLOGEV, a town of Russia, in the government of
Charcov; 24 miles N.N.W. of Charcov. N. lat. 50° 20'.
E. long. 35° 44'.

ZOLTITZKA, a town of Russia, in the government of
Archangel, on the east coast of the White sea; 60 miles
N. of Archangel.

ZOLONOSCHKA, a town of Russia, in the government
of Kiev; 72 miles S.S.E. of Kiev. N. lat. 49° 30'.
E. long. 31° 58'.—Alfo, a river of Russia, which runs into
the Dnieper, near Zolotonoscha, in the government of
Kiev.

ZOLOTTA, or Szelotta, a silver coin of Turkey,
containing 50 paras, the para being = 3 alpers.

ZOMBA, in Geography, a town of Africa, in the
kingdom of Congo; 70 miles E. of St. Salvador.

ZOMBAR, a town of Hungary; 40 miles S. of Co-
bofla. N. lat. 45° 56'. E. long. 19° 12'.

ZOMERAW, a town of Prufia, in Oberland; 12 miles
N.E. of Bisfhofswerder.

ZOMUCHANA, in Ancient Geography, a town of Asia,
in Arma. Ptol.

ZONA, or Zona Usaros Regia, a very fertile country
of Peru. It was so called because its revenue was designated
for the accommodation of the queen. Plato.

ZONA, a word used by some authors for that species

Cc 2 of
of lizards, which others call the *zinsilla*, and we term the *finglet.

**ZONCHIO,** in *Geography*, a cape of European Turkey, on the coast of the Morea; 12 miles N.N.W. of Navarin. N. lat. 37° 12'. E. long. 21° 30'.

**Zonchio,** a sea-port town of European Turkey, in the Morea: the harbour is large, but not commodious; 8 miles N. of Navarin.

**ZONCOLUCAN,** a mountain of Mexico, in the province of Guazacac.

**ZONDAGS,** a river of Africa, which runs into the Indian sea, N. lat. 31° 20'. E. long. 25°.

**ZONDORO,** a town of Hungary; 26 miles S.W. of Cefchau.

**ZONE,** *Zona*, q. v. *belt*, girdle, in *Geography* and *Astronomy*, a division of the terraqueous globe, with respect to the different degrees of heat found in the different parts of it; formed by the two tropics and two polar circles, which divide the surface of the earth into five parts.

The zones are denominated *torrid*, *frigid*, and *temperate*.

**Zone, Torrid,** is a fascia, or band, surrounding the terraqueous globe, and terminated by the two tropics.

Its breadth, therefore, is 46° 56'. The equator running through the middle of it, divides it into two equal parts, each containing 23° 28'.

The ancients imagined the torrid zone uninhabitable.

**Zones, Temperate,** are two fasciae, or bands, environing the globe, and contained between the tropics and the polar circles. The breadth of each is 45° 4'.

**Zones, Frigid,** are segments of the surface of the earth, terminated, the one by the antarctic, and the other by the arctic circle; or included between these circles and the poles. The breadth of each is 46° 56'.

The difference of zones is attended with a great diversity of phenomena.

1. In the *torrid zone*, the sun passes through the zenith twice a year; and his recedes from the equator towards the pole, which is above the horizon, is twice a year equal to the height of the pole.

2. In the temperate and *frigid* zones, the least height of the pole exceeds the greatest distance of the sun from the equator; and, therefore, to the inhabitants of it, the sun never passes through the zenith; yet if, on the same day, the fun rises, at the same time, to a greater height, the height of the pole is the least, since the inclination of the circles of diurnal revolution to the horizon is least.

3. In the temperate and *torrid* zones, the sun rises and sets every natural day, because the distance of the sun from the pole always exceeds the height of the pole; yet every where but under the equator, the artificial days are unequal, and the inequality is the greater as the place is lefs distant from the frigid zone.

4. Where the temperate zones terminate on the *frigid*, the height of the pole is equal to the sun's distance from the pole, when in the neighbouring tropic; and consequently, once a year, the fun, in its diurnal motion, performs an entire revolution, without going down under the horizon.

5. Every where, in a *frigid* zone, the height of the pole is greater than the least distance of the sun from the pole; and therefore, during some revolutions of the earth, the sun is at a distance from the pole less than the pole's height; and, during all that time, does not set, nor so much as touch the horizon. Where the distance from the pole, as the fun recedes from it, exceeds the height of the pole, or latitude of the place, the fun rises or sets every natural day.

**Zone, Circulus* or girdle, part of the ecclesiastical dres of the Roman Catholic minister. The use of it being derived from the church of Rome, it was called *Zona Romana*.

**Zone, Ciliary,* in *Anatomy*, the black impression of the ciliary processes on the vitreous humour. See *Eye*.

**Zones, Greater and Smaller, of the Iris,* arterial circles produced by the Anastomoses of the arteries. See *Eye*.

**ZONGHAN,** in *Geography*, a town of Cochimachina, near the sea. N. lat. 14° 30'. E. long. 108° 48'.

**ZONGO,** or *Morena,* a river of Africa, which runs into the Atlantic, near Old Benguela.

**ZONITES,** in the *Materia Medica of the Ancients*, a name given to a kind of totty, called *allo placitis*. It had the latter name from the Greek *zónitikos a curr*, it being formed by way of crust on the sides of the furnaces. The latter name *zonites* was given from its being formed of several coals, which, when broken transversely, had the appearance of belts or zones. See *Taphani,* and *Tomo*.

**ZONITIS CADMIA,** a name given by some authors to a kind of *cadmia fornacum*, from its usually surrounding the upper parts of the furnaces like a girdle or belt.

**Zonitis,** in *Entomology*, a genus of the *coleoptera* order of insects, the characters of which are, that the antennæ are fetaeous; the palpi four and filiform, and shorter than the whole jaw; and the lip emarginated. There are two species; *viz.*

**Chrysomelana.** Yellow, with wing-sheaths having a point in the middle, and the apex black: found in Egypt and the East.

**Flava.** Reddish, with wing-sheaths yellow, and black at the apex.

**ZONNAR,** a kind of belt, or girdle, of black leather, which the Christians and Jews of the Levant, particularly those of Asia, and the territories of the grand signior, are obliged to wear, to distinguish themselves from the Mahometans.

The word is corrupted from the vulgar Greek; a contraction of *zónaros or zóna girdle*.

It was Motavakkil X. kaliph, of the family of the Abbasides, that first enjoined the Christians, &c. to wear the zonnar.

The ordinance to this effect was published in the year of the Hegira 235.

Hence, as most of the Christians of Syria, Mesopotamia, &c. are either Nestorians or Jacobites, those sectaries are often called *Orihians of the girdle*.

**ZONOSBIO,** in *Geography*, an Indian town, belonging to the Seneca tribe; 2 miles N. of lake Seneca.

**ZONS,** a town of France, in the department of the Roer, situated on the Rhine, with a castle: at this place a river-toll is paid; 13 miles N.N.W. of Cologne. N. lat. 51° 4'. E. long. 6° 43'.

**ZOOGRAPHY,** formed of *ζωος animal,* and *γραφεi* describe, denotes a description of animals.

**ZOOLATRIA,** *ζωολατρις* composed of *ζωος* an animal, and *λατρις* worship, a species of idolatry, in which divine worship is offered to animals.

**ZOOLOGIA,** *ζωολογια,* composed of *ζωος* life, or *ζωος animal,* and *λογος* speech, discourse, a discourse or treatise upon animals, or living creatures.

Zoology makes a considerable article in natural history, comprehending what relates to the form, structure, method of living, feeding, propagating, &c. of the divers species
species of brute creatures, and the descriptions of every kind. This makes one of the three kingdoms, as they are called, of natural history; the vegetable and the mineral being the two others: in these, however, there is this difference made by writers, that while vegetables and minerals are treated of together, as all of a piece in each, the subjects of zoology are divided, and it is made to compose, as it were, several kingdoms. Whoever is to write on plants and minerals, calls his work a treatise of botany, or mineralogy; and we have no words to express any subdivision of them into kingdoms; but in zoology we treat, as different subjects, the different parts of it; and the history of birds is separated from the rest under the name of ornithology; that of quadrupeds, under the name of tetrapodology; and we have for the rest, the words entomology, amphibiology, and the like, expressing those things which are properly but the parts of zoology, as so many distinct and separate studies.

This may easily be amended by our considering the animal world as we do the vegetable and mineral, and dividing it, as we do the others, into its proper families; it will then be found that there are no better divisions than those of the families of these things, and that the authors may as well set up separate studies under the names of entomology, amphibiology, and the like, as those.

A natural division of the subjects of zoology, on this principle, will afford fixed several families of its subjects.

1. The hairy quadrupeds. 2. The birds. 3. The amphibious animals, such as serpents, lizards, frogs, and tortoises. 4. The fishes. 5. The insects. And, 6. Those lowest order of animated beings, the zoophytes. Arเตd's Ichthyol. See Quadruped, Bird, Fish, &c.

ZOOMBO, in Geography, a town on the west coast of Celebes. S. lat. 3°. E. long. 110° 10'.

ZOUMINERALIA, a word used by some writers to express certain substances which are of animal origin, yet have somewhat of the nature of stones, as pearls.

ZOOPHORIC COLUMN. See COLUMN.

ZOOPHORUS, or Zophonius, in the Ancient Architecture, the same thing with the freeze in the modern. It was thus called in Greek, because anciently adorned with the figures of animals: from ζοων, animal, and ζωος, I bear.

The Greeks sometimes also call the zodiac zoophorus, because of the signs and constellations in it.

ZOOPTHALMUS, in Botany, a name given by the ancient Greeks to the sedum majus, or common great house-leek.

It had this name from the Greek ζοων, an animal, and ζωοςια, an eye, as expressing a resemblance to the eyes of large animals, in the round and radiated growth of its clusters of leaves. They also called it ambrosia.

ZOOPHYTON, Zoophyte, Zoopotes, compounded of ζοων, animal, and ζώος, plant, q. d. plant-animal, in Natural History, a kind of intermediate body, supposed to partake both of the nature of an animal and a vegetable.

In the Linnean system, the zoophytes, which constitute the fifth order of worms, (see VERMES,) are composite animals, resembling a flower, and springing from a vegetating stem. This order contains 15 genera, as the TUBIFERA, MADREPOura, MILLIPORA, Cellepora, IAS, ANTIPATERIA, GORGONIA, ALCYONIA, SPONGIA, FLEURA, TUBULARIA, CORALLINA, SERTULARIA, PENNATULA, and HYDRA; see each respectively. The species enumerated and described in Gmelin's Linnean system are 489.

The fetus, while in the womb, appears to many to be a real zoophyte, growing to the mother by the funiculus umbilicalis, as plants do to the earth by their stem. See FETUS, and EMERGO.

Concerning the zoophyte called borama, see AEGUS SCYTICUS.

ZOOHYTAE-Marygold. See MARYGOLD.

ZOOPTERAE, Chemical Composition of. See SHELLS and VERMES.

ZOOTOMY, Zoos, compounded of ζοων, animal, and τομη, I cut, the art, or act, of dissecting animals, or living creatures.

Zootomy amounts to the same with anatomy, or rather comparative anatomy. See ANATOMY.

ZOPARITUS, in Ancient Geography, a town of Asia, in Meltene, on this side of the Euphrates. Ptol.

ZOPH, in Geography, a town of Syria; 25 miles S. E. of Jerusalem.

ZORN, a district in the N. part of the government of Diarbekir.

ZOPHA, a town of Friul, in Pomerelia; 10 miles S. W. of Marienburg.

ZOPHOCIDELUS, in Botany, a word used sometimes as an epithet with the word chamleon, and sometimes figuratively as the name of a plant, in both cases expressing the black chameleon-thistle, which the ancients carefully distinguished in their writings from the white kind; the former being a poisonous plant, the other not.

ZOPHORIC. See ZOOHYTAE.

ZOPHORUS. See ZOOHYTAE.

ZOPISSA, Zopiss, naval pitch, a kind of mixture of pitch and tar, scraped off from the ships that have been a long time at sea. See Naval Pitch.

The word seems formed from ζωος, bull, I boil, and νέφος, pitch; q. d. concordant pitch.

This matter, by being gradually penetrated by the salt of the sea, becomes impregnated with its qualities; and, being applied to the body externally, is found resolutive and digestive.

ZOPPO, in the Italian MYCO, is applied to all those counterpoints described under the article OBLIGATO, &c. Thus they say, contra-punto alla zoppa, a lame or hopping counterpoint; because, in these, a note is placed between two others, each of half its value in time. When this comes to be played or sung, the voice or instrument seems to proceed by unequal leaps or skips, like those of a lame person. See the example here annexed.

There are contra punto alla zoppa sopra il soggetto, as well as fatto il soggetto, i. e. above and below the subject. See SOGGETTO.

ZOPPOLA, in Geography, a town of Italy, in Friul; 13 miles N. N. W. of Concordia.

ZOQUES, a district of Mexico, in the province of Chiapa, bordering on Tabasco.

ZORABA, a word used by some of the chemical writers to express vitriol.

ZORAH,
ZORA, in Geography, a town of Africa, on the coast of Barca. N. lat. 30° 45'. E. long. 18° 30'.
ZARAMBUS, in Ancient Geography, a river of Asia, in Carmania. Ptol.
ZORBI, or Little Zerbst, in Geography, a town of Saxony, in the circle of Leipzig, with a citadel; 15 miles S. of Deltau. N. lat. 51° 40'. E. long. 12° 18'.
ZORECZA, a town of Lithuania; 80 miles E.S.E. of Pinkf.
ZORGE, a town of Saxony, belonging to the abbey of Walkenried; 6 miles N.E. of Walkenried.
ZORGE, a river of Thuringia, which runs into the Helm, 5 miles W. of Nordhausen.
ZORIGA, in Ancient Geography, a town of Asia, in the Greater Armenia, to the left of the Euphrates, and at some distance from it. Ptol.
ZORILIS, in Zoology, a species of weasel, having the back and sides marked with short stripes of black and white, the tail tinged with yellow; the tail long and bushy, partly white, and partly black; the legs and belly black. This animal inhabits Peru, and other parts of South America: its pelliferial vapour overcomes even the panther of America, and stupefies that formidable engine. Pennant. See Viverra.
ZORITA, in Geography, a town of Spain, in New Castile; 12 miles N.W. of Huesca.
ZORLESCA, a town of Italy; 8 miles S.S.E. of Lodi.
ZORN, a river of France, which rises near Saverne, in the department of the Lower Rhine, passes by Brumath, and enters a canal which communicates with the Rhine, 8 miles N. of Strafburg.
ZORNOD, a town of the New Mark of Brandenburg, where the king of Prussia defeated the Russians in the year 1758, near Cuftrin.
ZORNIA, in Botany, received that name from the late Prof. Gmelin of Gottingen, the compiler of a very faulty edition, at least as to the botanical department, of the Systema Naturae of Linneaus. He chose this appellation for one of Walter's anonymous genera, which he himself knew nothing of. It has been adopted by Michaux and Pursh, and seems intended for the commemoration of Mr. John Zorn, an apothecary of Kempten, in Bavaria, who was born in the year 1730, and may possibly be still living. He has published five volumes in octavo of Icones Plantarum Medicinalium, each volume containing one hundred plates, with a Latin and German text. Thesefigures are coloured in the Nuremberg file; at which place the work appeared, between the years 1779 and 1784. There was, moreover, a Dr. Bartholomew Zorn of Berlin, who published there, in 1714, Botanologia Medica, a thick German quarto, with six plates. He edited also, in 1763, the Herbarium portatil of Thomas Pancerius, and according to Dandridr. Bibl. Banks, v. 5. 406, died in 1717, at the age of 78.—Gmel. Syöf. Nat. v. 2. 1996. Michaux Borcel-Amer. v. 2. 76. Pursh 484. Poiret in Lamarck Dict. v. 8. 872. (Anonymo n. 279.) Walt. Carol. 181.—Claus and order, Diadephia Desandria. Nat. Ord. Papilionacei, Linn. Leguminose. Juli.
Obfl. The habit of this genus is so peculiar, and so unlike Hedyasarum, much more resembling Stylomasynes, (see the above articles,) that we are very glad of any characters that may serve to keep it distinct, and we hope the above may suffice. The plants are herbaceous, with one or two pair of conjunct leaves, without an odd one. Flowers small, in axillary spikes, with large leafy bracts. The species have not yet been well discriminated. We shall endeavour to explain them, with the help of original specimens.
Raii Hift. v. 3. 404.—Leaflets two, lanceolate, uniform. Branches ovate, ribbed, fringed, imperfectly reticulated, shorter than the legume, marked with glandular dots. Prickles of the legume rough.—Native of the East Indies, in a sandy soil. Root annual, tapering, warty. Stems several, diffuse, from four or five inches to a foot long, round, fider, zigzag, smooth, leafy, with short alternate branches. Leaflets simply conjunct, alternate; leaflets from half an inch to an inch long, elliptic-lanceolate, entire, blinfith, tipped with a small point, unequal at the base, smooth on both sides, not quite seifile at the extremity of the common footstalk, which is about the length of the leaflets, cylindrical, smooth, with a longitudinal furrow above. Stipules half-arrowshaped, ribbed, entire, pointed at each end. Flowers yellow, in axillary, solitary, falked, lax, bracted; spikes longer than the leaves, each spike of from three to eight alternate flowers. Branches one pair to every flower, twice or three-, two-ranked, converging, flat, ovate, acute, entire, strongly fringed, three or five-ribbed, bespined with reflexed dots, elongated at the base into a short oblique spur, permanent, their surface smooth. Legume near an inch in length, longer than the branch, of about four semi-ribicular joints, finely reticulated, and beset with spreading brown, barbed prickles, which are rough with minute reivered hairs, but we cannot perceive that the surface of the legume itself is downy, at least not invariably. The reflexed dots scattered over the branch seem peculiar to this species. Those parts are full as much fringed in this as in the H. conjunctum of Willdenow, though his definitions indicate otherwise.
2. Z. reticulata. Reticulated Zornia. (Hedyarum diphyllum z; Willd. Sp. Pl. v. 3. 1178. A; Lamarck Dict. v. 6. 424. H. diphyllum; Swartz Offl. 285. H. n. 10; Browne Jam. 301, excluding the synonyma. H. minus diphyllum, florue luteae; Sloane Jam. v. 1. 185.)—Leaflets two, lanceolate; the lower ones elliptical. Branches ovate, as long as the legume, strongly reticulated and fringed, without glandular dots. Legume and its prickles downy.—Native of the dry sandy parts of the savannahs of Jamaica. Our specimens are from Browne himself. The root, though said to be annual, is somewhat woody. Herb larger than the leaf, and most unquestionably specifically distinct. The leaves are straight, a foot long, scarcely branched. Leaflets an inch
inch or an inch and a quarter in length; those of the lower leaves half an inch broad. *Spikes* many-flowered, thrice as long as the leaves. *Flowers* yellow; the standard sometimes purplish. The *bracteas* afford a clear specific distinction, in their strongly-marked, elevated, vein reticulations, and the total width of reflex or glandular dots, though their whole surface is minutely granulated, as it was, like those of the foregoing species. *Legumes* have three or four joints, and their surface, as well as their prickles, is downy. They are almost entirely covered by the *bracteas*.

3. *Z. conjugata*. Ovate Zornia. (Hedyfarum conjugatum; Willd. Sp. Pl. v. 3. 1178. H. diphyllum; Linn. Sp. Pl. 1053. H. n. 291; Linn. Zeyl. 135. H. bifolium; H. foliolis ovatis, filiculhis apferis, geminis, inarticulis; Burm. Zeyl. 114. t. 90. f. 1.) *Onobrychis maderafpatana diphyllus*, filiculhis apferis; Pluk. Phyt. t. 102. f. 1.) —Leaflets two, ovate, uniform. *Bracteae* ovate, ribbed, fringed, imperfectly reticulated, shorter than the legume, without glandular dots. *Legume* fringed; its disk and prickles smooth.—Native of Ceylon and Tranquebar. This species approaches the lath in size, but differs in many essential points. The *leaflets* are ovate, not so long as their common *footstalk*. *Bracteae* more pointed and elongated at the base, ribbed, but not strongly reticulated; their substance quite delile of pellucid dots, though some of them occasionally bear little black opaque prominences, which seem the effect of injury, or are perhaps a minute parasitical fungus. *Legumes* considerably longer than the *bracteas*, though each consists of scarcely more than two orbicular joints, full twice the size of either of the preceding species, from which they differ in the smoothness of their disk and prickles, though fringed at the edge. The *flowers* are yellow.

4. *Z. latifolia*. Broad-leaved Zornia. (Hedyfarum diphyllum; Aubl. Guian. 774, excluding all the synonyms.) —Leaflets two, roundish-ovate; the lower ones orbicular. *Bracteas* linear-lanceolate, ribbed, somewhat hairy, longer than the downy legumes.—Gathered in Guiana by Aublet, whom we have specimens, which abundantly show his plant to be different from any of the foregoing, and justify him in saying that, with respect to it at least, Plukener's figures are bad. This has a woody, but perhaps annual, root, and several prostrate stems, from six inches to a foot long, straight, round, downy. *Footstalks* also downy, rather longer than the *leaflets*, in which the lower leaves are about half an inch in length, nearly orbicular, obtuse; in the upper gradually more elongated, ovate, or ovato-lanceolate, acute; all of them somewhat hairy or silky, especially beneath, where also they are a little glaucous. The narrow *bracteas*, very differently shaped from any of the three preceding species, are the distinguishing characteristic of this; they have three very strong crowded ribs, originating from their point of inception, below which is a blunt elongation downwards, most like that of *Z. reticulata*; they are somewhat hairy, as well as slightly fringed. *Corolla* yellow. *Legumes* of only two joints, unless any have been broken off, which is not apparent; the prickles downy, and the disk quite woolly. Willdenow speaks of a supposed variety of *Hedyfarum diphyllum* from Porto rico, which is larger than the common kind, and whose *leaves* are "fligetis beneath;" by which expression is probably meant briliy, or hairy. This, if not our *Zornia latifolia*, must be a hitherto non-descript species, of which we have not materials to give a definition.

5. *Z. heterophylla*. Various-leaved Zornia. (Hedyfarum tetraphyllum; Thunb. Aét. Nov. Uspal. v. 6. 44. t. 3. Prodr. 132. Willd. Sp. Pl. v. 3. 1203. Lamarck Dict. v. 6. 405, variety 2.) —Leaflets three or four, lanceolate. *Stipulas* half-arrowshaped. Base of the *bracteas* elongated and acute.—Gathered by Thunberg in the interior part of the country, above the Cape of Good Hope, near Galgebergh, flowering in November and December. The *flowers* are herbaceous, decumbent, thread-shaped, smooth, a foot or more in length. *Footstalks* rather longer than the *leaflets*, which are three or four together, elliptic-lanceolate, acute, entirely an inch long. *Stipula* much elongated at the base, acute at each end. *Spikes* axillary, many times longer than the leaves, (at least the lower spikes,) and consisting of ten or twelve *flowers*, concealed by the ovate three-ribbed *bracteas*, each of which is elongated at the base into an oval appendage, nearly half its own length. *Legume* longer than the *bracteas*, of four joints, said by Thunberg to be rough, but in what manner, or degree, is not mentioned: his figure represents them smooth and globose, which is evidently an inaccuracy.

6. *Z. tetrphylla*. Four-leaved Zornia. Michaux Borealis. Amer. v. 2. 76. t. 41. Pursh n. 1. (Z. braBeas; Gmel. n. 1. Anonymus braBeas; Walt. Carol. 181. Hedyfarum tetraphyllum; Lamarck Dict. v. 6. 405, n.) —Leaflets four, lanceolate. *Stipulas* ovate. Base of the *bracteas* somewhat elongated, oblong.—Native of sandy fields in Lower Carolina. Perennial, flowering in July and August. About a foot high, much branched. *Flowers* yellow. *Purp. We have here ventured to distinguish this from the last-difcribed species, by the characters afforded in the plates cited, without our having even seen a specimen of either. We are fully aware of the hazard of such a proceeding; but as it is highly probable that a Cape plant will hardly prove, on comparison, the same species as a Carolina one; and the species of this genus very nearly resemble each other, and have been much confused, we propose the above character. If the figure of Michaux be exact, as to the *stipulas* and *bracteas*, there can be no doubt on the subject, and it was drawn by no less an artist than Redouté. The *stipulas* are there represented perfectly ovate, without any spur, or elongation, at the base, and not half the usual size in this genus. Thone of Thunberg’s plate are like the rest of the species. This is the most important difference, though the short and blunt spur of the *bracteas* is very striking also. The *flowers* seem larger in these two last, than in any of the foregoing.

On reviewing the whole genus, we cannot but repeat that the abruptly-compounded *leaves* afford a most important mark of difference, compared with *Hedyfarum*, nor are the yellow *flowers* in this case, entirely unworthy of consideration. There is moreover a close resemblance between all the species of *Zornia*, as to induce a perfusion of their constituting a very natural genus. The fame may be said of *Stylosanthes*, to which we have already referred the reader as being next akin to *Zornia*.

Which of the above six species, or rather which of the first four, is entitled to a place in the *Hortus Kewensis*, we cannot presume to determine. In v. 4. 340. of that work, Dr. Houtlouin is recorded as having sent to Miller, before the year 1733, something which has always passed for *Hedyfarum diphyllum*. This must have come from South America, or the West Indies, and was therefore not *Nelam-mari* of Rheedie, our *Zornia angulifolia*; nor the *conjugata*, a plant of Ceylon. It must have been either the West Indian *reticulata*, or more probably perhaps the South American *latifolia*. ZOROANDA, HAZOUR, in Ancient Geography, a place of
of Asia, on a part of mount Taurus, called Nicephates, where the Tigris opened a subterraneous passage, N.W. of Amida.

ZORASTER, Zerdust, or Zardush, in Biography, an eminent Eastern philosopher, concerning whom, as well as the age in which he lived, learned writers have entertained very different opinions. Some have ascribed this title, the derivation of which is uncertain, to many eminent persons; whilst others have maintained that there was but one Zoroaster, and that he was a Persian. Others have said that there were six celebrated founders of philosophy of this name. Ham, the son of Noah, Motes, Obris, Mithras, and others, both gods and men, have by different writers been ascribed to have been the fame with Zoroaster. Many different opinions have been also advanced concerning the time in which he flourished. Aristotle and Pliny fix his date at 6000 years before the death of Plato; Hermippus says, that he lived 5000 years before the Trojan war; but these are idle tales, which should, without doubt, be classed with the report of the Chaldeans, concerning the antiquity of their astronomical observations. According to Laertius, he flourished 600 years before the Trojan war; according to Suidas 500 years. We shall in the sequel of this article detail the opinions of some of our principal modern writers on this subject. According to Brucker, the most probable hypothesis is, that there was a Zorosaster, a Perfo-Median, who flourished about the time of Darius Hytapas, and that besides him there was another Zoroaster, who lived in a much more remote period among the Babylonians, and taught them astronomy. The Greeks and Arabians are agreed concerning the existence of the Perian Zoroaster; and the ancients unanimously ascribe to a philosopher, whom they call Zoroaster, the origin of the Chaldean astronomy, which is certainly of much earlier date than the time of Hytapas; so that it seems necessary to suppose a Chaldean Zoroaster distinct from the Persian. Concerning this Zoroaster, however, nothing more is known, than that he flourished towards the beginning of the Babylonish empire, and was the father of the Chaldean astrologists and magi. (See Chaldean Philosophy and Magi.) All the writings which have been ascribed to the Chaldean Zoroaster are unquestionably forgeries. The Persian Zoroaster was probably of Persian extraction, and born in Media. Although much of what has been related concerning this Zoroaster or Zerdusht, the instruction which he received from the Jews, is fabulous; nevertheless it is not improbable that he might have learned some things from the inhabitants of the region in which he lived, of what nature we can here make no certain report, but which might enable him to correct the doctrine of the Perian magi; but it is not easy to specify particulars. Several miracles are ascribed to Zoroaster, but they are of such a kind as an impostor would not find it very difficult to perform. (See Magi.) To Zerdusht, or the Persian Zoroaster, many writings are ascribed; particularly the Zend. (See Zendavesta.) Fragments of a work, entitled "The Oracles of Zoroaster," are still extant. Several editions of them under the form of verses have been published, and pains have been taken to explain them. Stanley has subjoined to his "Lives of the Philosophers" a correct translation of them. The philosophers of the Alexandrian school highly venerate them as genuine remains of Chaldean wisdom; but they have so many evidences in their style and language of their origin in that school, as to render it probable that they were written by some Plato-like, about the beginning of the second century; a period in which copious writings were produced in order to support the linking credit of Gentile philosophy.

The learned Dr. Hyde, and after him Dr. Prideaux and several others, are of opinion, that Zoroaster was the same with the Zerdusht of the Persians, who was a great prophet of the Magi, and that he lived between the beginning of the reign of Cyrus, and the latter end of that of Darius Hytapas.

Dr. Warburton (Legation, vol. ii. part i. p. 8.) confuses Hyde and Prideaux for making an early Bactrian law-giver, to be a late Persian false prophet, and says this whole story of him is mere fable, contradicting all learned antiquity, and supported only by the romantic relations of later Persian writers under the caliphs.

Dr. Baumgarten likewise (Anc. Un. Hist. Suppl. vol. ii. p. 305, &c.) represents it as doubtful, whether the Persian Zoroaster ever existed, calls in question the credibility of the oriental writers who give his history, and makes the whole to be a forgery in later times by the fire-worshippers of Persia.

The learned Mr. Bryant (Anal. Anc. Mythol. vol. ii. p. 107.) observes, that there are more perions than one spoken of under the character of Zoroaster; though there was one principal to whom it more truly related. Of men, styled Zoroaster, he says, the first was a deluded personage, revered by some of his posterity, whose worship was called Magia, and the professors of it Magi. This worship was transmitted from the ancient Babylonians and Chaldeans to the Persians, who, succeeding to the sovereignty of Asia, renewed under their princes, and particularly under Darius, the fire of Hytapas, those rites which had been in a great degree effaced and forgotten. The Persians, says this learned writer, originally derived their name from the deity Peres, or Perez, the son; whom they also worshipped under the title of Zor-After. On occasion of the diptrels to which they were reduced upon the death of their last king Yefdegard, they retired into Gedrofia and India, where people of the same family had for ages refted, and carried with them those shattered memorials of their religion in writing, whence the Saddar, Shafler, Vedan, and Zendavesta, were compiled; and upon these the religion of the Brahmins and Perfees is founded. The person who is supposed to have first formed a code of institutions for this people is said to have been one of the Magi, named Zerdusht; the same, as Hyde and others suppose, both in character and name, with Zoroaster; but Mr. Bryant discovers no resemblance between them. There were, indeed, many persons of this name in different parts of the world, who were magi or priests, and denominated from the rites of Zoroaster, which they followed. We read of an Assyrian, Medo-Persian, Proconnesian, Bactrian, Pamphylian, Chinefe, &c. Zorosaster, supposed by Dr. Hyde to have been one and the same. But Mr. Bryant thinks that their respective histories furnish evidence sufficient of their being different persons; and besides, there seems to have been one person more ancient and celebrated than the rest. As for the Zoroaster or Zerdusht of Hyde, he lived in the reign of Darius, the father of Xerxes, about the time of the battle of Marathon, and consequently not a century before the birth of Eudosus, Xenophon, and Plato. This Zer-
many thousand years before Moses. Upon the whole it appears, that no memorial upon record is placed to high as the ancient writers have carried this personage; and though their accounts are for the most part exaggerated, yet they fully afferm the antiquity of this person.

The title Zoroaster, Mr. Bryant conceives, originally belonged to the fun, and was metaphorically bestowed on sacred and enlightened personages. Some have thought, that the first among men to whom this title was applied was Ham; others have taken him for Chus, for Mizraim, and for Nimrod, and Hucetus for Moses. But Mr. Bryant, after examining the primitive characters given of him by different writers, supposes, that they concur only in Noah, who was the first defiled mortal, and the prototype in the Magian worship. This writer supposes, that, as the object of the Peric and Chaldac worship was the sun, and most of their titles were derived there, Zoroaster denoted Sol Allerius; Zor being the fun, and Aller signifying sun.

The abbe Toucher, in a long series of memoirs, inferred in the 25th, 26th, 27th, 28th, 30th, and 31st vols. of the Histoire de l'Academie Royale des Inscriptions et Belles Lettres, &c. Paris, has given an ample account of the religion of the Persians. This learned author maintains, on the authority of Pliny, that the most celebrated Zoroaster was an ancient sage, who lived under Cuxaeres, king of the Medes, restored the worship of fire, was revered by the Persians as a celestial prophet, and whose euctacies, prodigies, and revelations, made a great noise in the world. See Zendavesta.

ZOROPASSUS, in Ancient Geography, a town of Asia, in Lesser Armenia, dependent on the precurse of Murianne. PIto.

ZORVI, in Geography, a town of Asia, in the province of Diarbekir; 22 miles E. of Anfa.

ZOSAWA, a river of Moravia, which runs into the Friawala, 6 miles W. of Hohenfeld.

ZOSIMA, in Botany, an umbelliferous genus, thus called by professor Hoffmann, in compliment to three brothers, Anathautios, Nicholas, and Zoa Zosima, distinguished for their editions of numerous works of the Greek classics. This botanical commemoration seems chiefly owing to the great propen- sity, (" magnus propeptus!") of the latter of these brothers, for natural history. We presume not to dispute the claim, because the author of this name is, doubtless, better able to judge of its propriety than we could possibly be.— Hoffm. Ubbell. v. i. 145; t. 1. B. f. 9.—Claes and order, Paeandria Digyna. Nat. Ord. Umbelliferae.

Gen. Ch. General and partial Umb of many unequil rays. General and partial involucrem of many, linear-lanceolate, acute, unequil, villous, permanent leaves. Perianth of five unequal, very short, permanent teeth. Cor. Universal nearly regular and uniform; flowers partly perfect and fertile; the central and lateral ones, in each umbel, male; partial of five, nearly equal, spreading, inverely heart-shaped, deflexed petals; rather concave, on each side, at the keel; tapering at the base; obliquely inrolled at the point, which is linear-lanceolate, acute, involute, channelled. Stam. Filaments five, spreading or deflexed, straight, longer than the involute corolla, dilated at the base; others very tabile, roundish, two-lobed. Pifh. in the perfect flowers, Gemen inferior, ovate, comprefled, villous; flowers two, thread-shaped, channelled; their timid base wav and crenate at the margin; at length reflexed and permanent; fibr nas simple, obtuse. Peric. Fruit roundish-obovate, comprefled, finely downy, bordered; the border externally tumid, and somewhat corrugated, internally flabriped; emarginate at the summit, crowned with the stigmas.

Vol. XXXIX.

on their short, nearly sessile, crisprefed bafe; thickened at the bottom; the disk elevated and flabriped. Stam. of a similar shape, convex in the middle, with three elevated, narrow, central ribs, and two marginal ones; their interflaces, in the upper half, occupied by four coloured stripes.

1. Z. orientalis. Oriental Zosima. Hoffm. n. 1. (Heracleum absinthifolium; Venten. Choix de Pl. 7. t. 7. March. a Biberf. Taur. Caucaul v. i. 224. Sphondylum orientale hulium, folis absinthii; Tourn. Cor. 22.)—Native of Persia, Georgia, and other countries about Caucasus, flowering in the early part of summer. The root is biennial, tap-shaped, milky. The whole herb when bruised smells like Smallage, Apium graveolens. Stem erect, near two feet high, cylindrical, furrowed, somewhat branched, and slightly leafy, about as thick as a man's quill, rough to the touch with short whitish hairs. Leaves opposite, stalked, thrice pinnate, hoary with short pubescence; leaflets small, wedge-shaped, lobed; entire at the edges. Umbels two or three inches in diameter, on long stalks, terminal: partial one of from twelve to fifteen flowers, which, according to Ventenat, are milk-white, but Hoffmann describes the petals of a yellowish-green. German down. If the flowers are really white, we should suspect this plant to be nearly related to Heracleum tomentosum, Sm. Prodri. Fl. Græc. Sibth. v. i. 192, which will be exhibited in t. 281, of the Fl. Græca; but the shape of the fruit of the latter is very unlike Hoffmann's figure, nor does it better agree with the representation in Ventenat's work. This leaf indeed is itself fo unlike Hoffmann's t. 1. B. f. 9. (be himself erroneously cites f. 7.) that we cannot but suspect some mistake. Nor are we, after all, persuaded that the plant under consideration ought to form a separate genus from Heracleum. In fo natural a family, the skill of a botanist is shown in combining, rather than dividing, which last is the most easy thing in the world, and the most pernicious to science. We do not, however, pretend to decide in the present case; because the generic distinctions of Umbellate plants are still judicious.

ZOSIMUS, in Biography, a Greek historian, who held various civil offices under the younger Theodorus, about the commencement of the fifth century, and left a history of Roman affairs in six books; the sixth of which furnishes a slight view of the emperors, from Augustus to Diocletian; and the others detail the public events that occurred to the second half of Rome by Alaric, and the pontificate and deposition of A Dd.
him to his communion. That of Pelagius was likewise approved. The African bishops, however, who were hostile to the Pelagian doctrine, interred the emperor Honorius in their favour; and obtained from the pope an anathema of the doctrine of Pelagius and Cælestius, with a sentence of excommunication if they refused to abjure their tenets. A council was assembled, in which other bishops, who concurred in the Pelagian creed, were degraded from their episcopal dignity. The fluctuations and inconsistencies of Zosimus's conduct depreciated the character of the pope, and furnished reason for questioning his infallibility. Other instances occurred, in which he was hardly able to maintain his authority. This pope died in December 418, leaving the character of an able man of business, but hasty, tenacious, and imperious. His thirteen epistles, that are extant, are written with spirit and elegance. He was canonized, as Bower says, by a mistake of cardinal Baroni, who supposed him to be a St. Zosimus in the martyrology of Bede. Dupin, Bower.

ZOSITERPUM, in Ancient Geography, a town of Thrace, in the province of Rhodope. Procopius.

ZOSSEN, in Geography, a town of Brandenburg, in the Middle Mark; 13 miles S.E. of Potsdam. N. lat. 52° 10'.

E. long. 13° 17'.

ZOSTER, in Ancient Geography, a borough of Attica, upon the sea-coast, with a promontory of the same name, extended into the Saronic gulf; but it is not known to what tribe it belonged. Minerva, Apollo, Diana, and Latona, were honoured here. As Zoster bore some resemblance to zone, or cincture, the inhabitants pretended that the borough bore this name, because Latona, finding herself in this place, and feeling that her time was approaching, unloosed her cincture. Faust. in Attic. c. 31.

Zoster, a word used by fome to express that kind of herbes, called by others nona and singilla, and by us usually known under the name of the single.

Gen. Ch. Cal. Spadix linear, flat, sheathed by the base of a leaf, bearing an indeterminate number of flowers on one side. Perianth none. Cer. none. Stam. Filament none; another fellese, erect, closely pressed to the spadix, simple, cylindrical, a little wavy, tapering at each end. Pist. Germen solitary, parallel to the anther, and of nearly a similar shape; style one, obliquely curved, shorter than the germen; stigmas two, linear, acute, spreading. Peric. Capsule pendulous, elliptical, membranous, of one cell, not furled. Seed solitary, oblong, frisated.

Obf. The above is the view of the genus in question, first given by Garttner, and confirmed from actual observation in the English Botany and Fl. Brit. Vahl adopts the same idea as ours of the place of this genus in the artificial system. The seed has a large, oval, half divided cotyledon, as we would call it; Garttner terms it a vitellus. (See the article York of the Seed.) From this genus is to be separated Z. oceanica of Linnaeus, which belongs to Cailinia Of De Candolle and Gervais; Paffodio of König in Ann. of Bot. v. 2. 95 t. 61. Kennera of Willd. Sp. Pl. v. 4. 947; but which is different from Cailinia of Willdenow; see that article.

b. Fucus marinus, feu Alga marina graminea mine; Rai Syn. 52. (Algoidez; Mich. I. Ind. t. 60. f. 2.)

g. Fucus, five Alga marina graminea angulifolia femini-

fera ramifier; Rai Syn. 52. (Algoidez; Mich. I. Ind. t. 59.)

3. Potamogiton marinus in urticulis epiphylluspermon minus; Rai Syn. 53.

1. Alga angulifolia vitrariorum; Rai Syn. 53.

Leaves entire, obscurely three-ruffled. Stem slightly compressed. Native of the sea-shore, or salt muddy ditches and creeks throughout Europe, possibly of New Holland and North America also, flowering towards autumn. The root is perennial, fibrous. Stems roundish, smooth, decumbent at the base, and trailing to a great extent, throwing out tufts of fibres here and there; their branches floating and leafy, simple, a little compressed. Leaves alternate, tapering at the base into a kind of sheathing footstalk, linear, a foot, or much more, in length, flat, smooth, blunting, quite entire, splitting longitudinally a little above the base, on the upper side, and putting forth from that a linear, obtuse, flat receptacle or flabell, two inches long, covered in front with a series of naked flowers. Each of these flowers consists of a green anther, and a pilus of the same hue, par-

allel to it; but in such an alternate order, that the anther of each flower is contrary to that of its neighbour, and stands above the pilla of the latter. The whole herb is flaccid and tender; yet Linnaeus says it is used in some parts of Sweden to make a thatch, which is very durable, and likewise to float up chinks in wooden buildings. It serves also for ma-

rure, as well as the various kinds of sea-weed.

Whether the varieties above indicated may or of them prove distinct species, must be left for future inquiry. The B is a small slender plant, differing in nothing but its leffer dimensions from the common kind. It is well represented in one of Micheli's unpublished plates. 7 is larger, more compact, and branched; we can scarcely doubt its being Micheli's t. 59. Of the others we know no more than can be gathered from Ray's Synopsi.

Z. oceanica of Linnaeus is quite different from any of these suppos'd varieties, constituting a distinct genus, called Paff-fo-dio Calvini, by Mr. König, in Ann. of Bot. v. 2. 95 t. 6; and well described by don Philip Cavolini of Naples, in a dissertation on these plants. De Candolle has named it Cailinia, but it is not Willdenow's. In Micheli's unpublished figures above cited, t. 58, is a good figure of this. We never met with any authority for its being a native of the British coast; but Mr. Horner, in a paper published by the Geological Society, in their Transactins, v. 4, mentions the submarine remains of a forest, on the Suffolk coast, in the brown vegetable earth, accompanying which are found fragments of a plant, whose leaves were thought by Mr. De Candolle to resemble Z. serri marina, except that, being much broader than usual, he supposed them to belong to Z. oceanica above-mentioned. If these leaves were sufficiently perfect to exhibit the three ribs, that question might perhaps be determined. As to the breadth, or size, of the leaves in
in this whole tribe, nothing is more variable. We have Z. ciliata of Vahl; to which he attributes leaves an inch or more in breadth: whose leaves, in our different specimens, are but one-third or one-fourth of an inch wide, and from three inches to eight inches long. Z. marina differs with us from one-eighth to one-fourth of an inch in width, and if the above synonyms be all right, its variations are still greater.

ZOLOXISIA, in Botany, was so named by the late professor Wildenow, in honour of the late Charles de Zois, a dig- 

nified ecclesiastic, reared in Carniola, who has long nur- 

sed with ardour the investigation of the botanical trea- 

tures of that country, and who is celebrated by Hoff, Wulffen, 

Jacquin, and other eminent writers, for the assistance which 

he has at various times afforded them.—“Wild. in Nov. 

Holl. v. i. 208. (“Matrella; Perf. Syn. v. i. 73.”)— 

Chafs and order, Triandria Diggynia. Nat. Ord. Gramina, 

Linn. Juff.

Gen. Ch. Cal. Glume of one valve, single-flowered, 

ovate-oblong, comprefled, cartilaginous, smooth, rigid, 

keeled, incurved, gaping at the apex of one edge; convex 

on one side; flattish on the other. Cor. Glume of two 

thin, membranous valves, enclosed within the calyx, awn- 

less. Nectary none. Stam. Filaments three, capillary, 

the others hafted. Pijf. German superior, linear, 

minute; 23, 45, 57 miles, the length of the calyx; $\text{fligmas}$ promi- 

nent, feathery. Peric. none, except the permanent glumes. 

Seed solitary, linear, inwetted with the calyx and corolla.

Eff. Ch. Calyx of one valve, single-flowered, comprefled, 

cartilaginous. Corolla of two membranous valves, within 

the calyx. Stigmas feathery. Seed linear, inwetted with 

the glumes.

1. Z. pungens. Sharp-pointed Zosna. Wild. as above. 

Brown n. i. (Agralis Matrella; Linn. Mant. 185. Wild. 

73.”)—Gathered in sandy ground, on the coast of Malab- 

bar, by Koenig; and near Port Jackson, New South 

Wales, by Mr. Brown. This is a small perennial grafs, 

with a creeping root, enveloped in theeathing furrowed scales. 

Stems alternate, ascending, flender, thread-shaped, flinte, 

leafy, three or four inches high. Leaves two-ranked, 

spreading, involute, sharp-pointed, smooth, an inch or an 

inch and a half long, with pale, furrowed, clofe $\text{fociata}$, concealing 

the joints of the $\text{fem}$. $\text{Sipulf}$ of several spreading 

hairs. Clyfers terminal, solitary, quite flinte, of ten or 

twelve nearly fefile, alternate, erect flowers, remarkable for 

their smooth ivory-like glumes, about two lines in length, 

out of which, at the tip, project the feathery $\text{fligmas}$.

Linnaeus was inclined to make this a diffinct genus by the 

name of Matrella; derived from matrius, and alluding to an 

anatomical resemblance, too obfure to be very inftuctive, 

if it were liable to no other objection. Such allusions were 

allowable enough while botany remained the abftrufe study 
of philosophers and physicians; but in proportion as it be- 

comes general and popular, they are either ufelefs or cenfurable.

This grafs might be forced into Agralis as the definition of 

that genus fixed in Linnaeus, but has certainly no natural 

habit, nor any preclude character, in common therewith. 

Mr. Brown remarks, that the corolla, (his perianthibum,) is 

inverted, or contrary to the single-valved calyx; on which 

account, added to the nearly spiked infloréence, he ranges 

Zosna near Rotisalla. We cannot but think it rather more 

related to Panicum Dayilton of Linnaeus, Haller’s Digiaria; 

though in fact so diffinct in its nature, as not to associate 

well with any thing.

ZOZONISIUS, in Natural History, a name of one of 

the gems of the ancients, but of which our accounts are so 

short, that we can make no conjecture of what it was. Pliny 

only tells us, that it was found in the river Indus, and used 

by the magi.
ZRATSCHÉ, in Geography, a town of Bohemia, in the circle of Czsalou; 16 miles S.W. of Czsalou.
ZRIN, a town of Croatia, near the river Una; 40 miles E.S.E. of Carlistadt. N. lat. 45° 16'. E. long. 16° 53'.
ZSCHOPA. See Tschora.
ZSCHORLAU, a town of Saxony, in the circle of Erzgebirg; 10 miles S.S.E. of Zwickau.
ZSOKEN, a town of Saxony, in the circle of Erzgebirg; 8 miles N.W. of Grimnaya.
ZUQUIL, a town of New Mexico, in the province of Sonora; 8 miles S.S.E. of Pitquin.
ZUATA, a town of New Grenada; 45 miles N.N.E. of Tunja.
ZUBETH, a town of Peru, in the province of Chuñafan; 105 miles N.W. of Sufter.
ZUBIA, a town of Spain, in the province of Grenada; 4 miles S.E. of Grenada.
ZUBTZOY, a town of Russia, in the government of Tver, on the Volga; 68 miles S.W. of Tver. N. lat. 55° 46'. E. long. 54° 58'.
ZUCARELLO, a town of Genoa; 7 miles N.W. of Albenga.
ZUCCAGNIA, in Batany, fo named by the late abbé Cavanilles, in honour of Dr. Attilius Zuccagni, superintendent of the garden at Florence. —Cavan. l.c. v. 5. 2. Poor in Lamark Dict. v. 8. 875.—Clafs and order, Decandria Monogynia. Nat. Ord. Lomentaceæ, Linn. Leguminosæ, Juss.
Gen. Ch. Cal. Perianth inferior, of one leaf, colourèd; tube turbinate; limb in five deep, oblong, obtuse, permanent segments, the lower one a little the longest. Cor. Petals five, obovate, inserted into the calyx; the uppermost broadest, vaulted. Stam. Filaments ten, awl-shaped, ascending, hairy in their lower part, about as long as the corolla; anther roundish, of two lobes, divided by a furrow. Pillé. Germen superior, roundish, compressed; style capillary, of the length and portion of the filaments, smooth; stigma funnel-shaped. Peric. Legume ovate, oblique, compressed, hairy, of one cell and two valves. Seed solitary, ovate, compressed, attached by its stalk to the summit of the legume. Cavanillæ.
Eff. Ch. Calyx bell-shaped; its limb in five permanent segments. Petals five, obovate; the upper one broadest, vaulted. Legume of one cell and two valves. Seed solitary.

i. Z. puntata. Dotted Zuccagnia. Cavan. as above, t. 403. Poor in n. 1.—Native of hills in Chili, between Portillo and the springs commonly called Manantiales, bearing flowers, as well as feed, in January. It was communi-
cated to the author by Louis Néé, to whom differences in South America and New Holland his Bowes are so much indebted. The stem is shrubby, four or five feet high, with numerous, twilled, glutinous branches. Leaves alternate, abruptly pinnate, of numerous, alternate, false, elliptical, entire, glutinous leaves, each one-third of an inch long, marked on both sides with blackish retinuous dots. Clafiers terminal, solitary, simple, of several rather small flowers. Partial flæk one-third of an inch long, each with a little acute štírka at its base. Calyx smooth, reddish-brown, rather shorter than the corolla. Petals a line and a half long, færon-coloured, with darker veins. Anthers deep orange. Legume about three lines in length, clothed with long rusty hairs. Seed of a shining brown. This pretty shrub does not appear to have been raised in the gardens of Europe.

ZUCCARIO, or Zuccherio, Tadeo, in Biography, was a painter of considerable renown, born at S. Agnolo in Vado, in the duchy of Urbino, in 1529. His father Ot-
taviano Zuccaro was also a painter, but of moderate talents; and Tadeo was principally indebted to Pompeo de Fano for initiation in the art. Having, as he imagined, exhausted all store of information to be derived from his preceptor, animated by love of his art and a desire to free his father from further charge on his account, he, at the age of 14, went to Rome, unknowing and unknown. His relation Franceco d’Agnolo was then engaged painting, with Pierino del Vaga, the grotesques of the Vatican, and he had some hope of assistance from him; but his application was vain, and he was obliged to earn his daily bread by grinding colours in different shops, wherever he could find employ-
ment. He divided his time between this labour and copying from the works of Raphael, in the Palazzo Ghigi particularly, and was often compelled to sleep under the loggie of the palace, being unable to procure better accom-
modation. Weary at length of so much misery, he returned to his father, but soon left him to revist the great emporium of art. Fortune now began to smile upon him; he became known to an artist named Giacomone, and having improved much with him, and acquired some credit, his relation Franceco d’Agnolo noticed him, and for a time they worked together. Afterwards he was engaged by Daniele da Parme, a scholar of Correggio and Parmegiano, to assist him in painting a chapel of Santa Maria, in a church at Vitto, in Abruzzo. The work was in fresco, and Zu-
caro, according to Vafari, painted a large portion of the subjects required. When this was done, he returned to Rome, and was employed by G. Mattie to paint a façade of the Palazzo Mattei in fresco, where he executed, in chiaro oscuro, nine historical pieces relative to the history of Turco Camillo. He was then only 18, and the execution of them was a matter of surprise to all who saw them.

By this his first public work he gained so much reputation, that he soon acquired considerable employment. The duke d’Urbino, hearing of his fame, sent for him to Urbino, and gave him a commission to paint in fresco the chapel of the Duomo there, which was delayed by various canes, and he returned to Rome in the time of Julius III., who em-
ployed him, under Vafari, in the Vatican, to paint in a frieze the labours of Hercules, which were afterwards de-
stroyed by pope Paul IV. to make room for other works. Hitherto he had been principally employed upon ornamental subjects, but now a more one was entrusted to his pencil; and he painted in fresco, for the church of Santa Maria della Confolazione, several subjects of the passion of the Saviour, which are regarded as among his best productions. He was afterwards called upon to exert his skill, by the cardinal Farnefe, in the Palazzo Caprarola. This is his greatest work, and is that wherein his reputation most de-
pends. He was liberally paid by the cardinal. The whole ornamental part of the building was entrusted to his care, and he laboured with great earneftness to make it honour-
able to himself and pleasing to his employer. It has been engraved by Premer in a set of 45 plates. Tadeo Zuccaro died at Rome in 1566.

ZUCCARO, Federigo, was a younger brother of Tadeo just mentioned, and born in 1543. He received his instruc-
tion from his brother, with whom he was placed at Rome, when very young, and who paid him the most affectionate attention. He soon rendered himself useful to Tadeo in his great works, and engaged also in some labour for himself. Pope Pius IV. employed him, in conjunction with F. Bar-
ner, in the Palazzo Belvidere, where he gained great reputation. The brothers continued to work together without rivalry, and co-operated at the Vatican and the
Villa Farnese. He was invited to Florence by the grand duke to finish the cupola, left imperfect by Vafani, and succeeded in pleasing his employer.

Gregory XIII. engaged him to paint the vault of the Capella Paolina; but having some dispute with the officers of his holiness, he avenged himself by a satirical picture which he exhibited. By this the pope was offended, and Zuccaro was obliged to fly, and leave his great work unfinished. He took refuge in France, where he was some time employed by the cardinal of Lorraine; and from thence he went to Flanders, where he painted cartoons for tapestries.

In 1574 he visited England, and was received very favourably. Here he painted portraits. The queen fat to him, and many of the nobility. How long he remained here is not exactly known. When he returned to Italy, he went to reside at Venice, where the patriarch Grimani employed him in his chapel to finish the fresco ornaments begun by Battilina Franco, and he added some designs of his own to them. He also painted there a large picture of the Adoration of the Magi. In conjunction with the great masters then living in Venice, he was employed in the hall of the grand council of that city, and he obtained as his reward the honour of knighthood. He soon after returned to Rome, and the pope not only overlooked his indiscretion, but allowed him to complete the work he had begun in the Capella Paolina.

On the accession of Sixtus V. he was invited to Madrid by Philip II. to adorn the walls and ceilings of the Escorial; but though he painted with his usual skill, and covered immense quantities of space, he had not his usual success in affording pleasure to his patron. Philip was not gratified with his works, and Zuccaro was dismissed; not, however, without being sufficiently rewarded for his labours. The works he left behind him were afterwards covered over by others from the hand of Pellegrini Tibaldi. On his return to Rome he established the academy of St. Luke, for which he received letters patent from Gregory XIII., and to which, at his death, which happened in 1609, he bequeathed all his property.

The talents of the Zucchiros were more splendid than great. They designed and executed with facility; but aiming at grandeur, fell into manner; and the vice of mannerism touched also the colour and chiaro ocearo of their productions. Sometimes happy in all parts, but more frequently defective in the principal one of expression and feeling, their works please without gratifying; and though they attract, do not afford the spectator.

ZUCCHABARI, CHADARA, in Ancient Geography, a town of Mauritania Caffariensis, situated on the left bank of the river Chinalah, and towards the north-east of mount Zalacus. This is very probably the Succabar and Colonia Augnita of Pliny.

ZUCCHARA, ZUANGGAR, an ancient town of Africa, and the most northerly of those which lay between Zingithania and Bisaarum. Its magnificent ruins and its temple are the coverts of Arabs.

ZUCCHERElli, FRANCESCO, in Biography, a very pleasing landscape painter, was born at Psiigliano in Tuscany, in 1702. He for some time attempted history, but abandoned it, and adhered solely to landscapes, which he adorned with very agreeably composèd groups of figures. In 1752 he visited England, where he was much encouraged; but our greatest debt to him is due for his having persuaded Wilton to adopt landscape for his object, instead of portrait. For this liberal act what adequate thanks can be offered to his memory? At the foundation of the Royal Academy he was chosen an original member. After remaining here twenty years, he returned to Italy, and settled at Florence, where he had the misfortune to be reduced to indigence, by the suppfession of a monastery where he had lodged the money he had acquired. He again resumed the pencil to support himself, and died at Florence in 1738, aged 86.

ZUCCO, in Geography, a town of Italy, in the county of Friuli; 5 miles N.W. of Friuli.

ZUCCORA, a river of European Turkey, which runs into the Morava, near Nikia.

ZUCHABARUS, in Ancient Geography, a mountain of Africa Propria, in which the river Cyniphs and the fountain Acaba have their source. Herodotus called it "Chalitimons."

ZUCHIS, a lake of Africa Propria, which is, according to Strabo, 400 fadia in circuit; and on the bank of the lake is a town of the same name.

ZUCHOW, in Geography, a town of Poland, in Volhynia; 32 miles E. of Lucko.

ZUCKMANDEL, a town of Silezia, in the principality of Neiffa, the see of a bishop; 17 miles N.N.W. of Jagendorf. N. lat. 50° 8'. E. long. 17° 16'.

ZUCKTOK, a town of Mexico, in the province of Yucatán; 80 miles S. of Campeachy.

ZUDA, a town of Arabia, in the province of Yemen; 12 miles W. of Chamir.

ZUDISHTIRA, in Hindu Mythology, is one of the heroic sons of Pandu, whose wars and adventures occupy a considerable portion of the Mahabarata, an epic poem of great celebrity in the Sanscrit language. See Mahabarat and Shanscrit.

ZUEELA, ZULI, or Zaulia, a considerable town of Africa, in the kingdom of Fezzan, said to have been anciently the capital, containing many rich merchants, situated in a fertile country. The remains of ancient buildings in this town, the number and size of the cîlers, and the construction of the vaulted caves, intended perhaps as repositories for corn, exhibit such vestiges of ancient splendour, as will probably attract, and may highly reward, the attention of the future traveller; 60 miles E.N.E. of Mourzouk. N. lat. 27° 35'. E. long. 16° 45'.

ZUENGA, a town of Thibet; 176 miles W.S.W. of Laffa. N. lat. 28° 32'. E. long. 88° 10'.

ZYVENIGOROD, a town of Rußia, in the government of Moscov, on the Moskva; 28 miles W. of Moscov. N. lat. 53° 40'. E. long. 35° 34'.

ZUENZIGA, a desert district of Africa, in the country of Sahara, situated to the south of Taritèl.

ZVERINOGOLOVSKAIA, a fort of Rußia, on the Tobol; 52 miles S. of Okunevsk.

ZUEVA, a town of Rußia, in the government of Irkutsk, at the union of the Kotol and the Angara; 60 miles N.N.W. of Irkutsk.

ZUEF, a town of the country of Candahar; 50 miles N.W. of Candahar.

ZUFFERABAD, a town of Hindoostan, in the sublah of Moultan, near the Rauvee; 25 miles N.E. of Moultan.

ZUFFIRWAL, a town of Hindoostan, in Lahore; 16 miles N.N.E. of Selcot.

ZUFFOLLO, in the Italian Music, a little flute or flageolet, having a very shrill sound, like the whistling of small birds.

ZUFOONE, or Mers el Falon, in Geography, a seaport of Algiers; 36 miles W.N.W. of Boujiah.

ZUG, a canton of Switzerland, bounded on the north and
and east by Zuric, on the south by Schweitz, and on the well by Lucerne; only about ten miles long, and nearly as much in breadth. The pastures here are excellent, and it produces also a famous kind of wine, with plenty of fruit, and some vines. On one side of the Zug lake, the country is covered with chestnut-trees, which form a very profitable branch of trade, by the sale of the nuts to the neighbouring countries. This district, on the extinction of the counts of Lenzburg, devolved to those of Kyburg, which latter also failing, it came to the counts of Habenburg, and in them to the house of Austria, towards which it always manifested an inviolable attachment; but in the year 1551, the town of Zug being besieged by the Helvetic confederacy, and not only neglected by the archduke, but even recommended by him to surrender, it followed his advice, and was admitted into the confederacy, to which its territory had previously acceded. The generosity of the conquerors rivalled the courage of the vanquished; for, in consequence of their subjection, the canton of Zug was rescued from the yoke of a foreign master, obtained liberty and independence, and was admitted into the Helvetic confederacy upon equal terms. This canton is the seventh in rank, and among the lesser ones the fifth; besides which, it is in a particular manner connected with Lucerne, Uri, Schweitz, and Unterwalden, commonly called the five territorial confederates. The government of this little canton is exceedingly complicated; and the inhabitants of the town have somewhat more influence, and enjoy a greater share in the administration of affairs, than those of the capital burghs in the five other democratical cantons. The supreme power resides in the inhabitants of Zug, Bar, Egger, and Meutzingen, who assemble yearly to enact laws, and elect their magistrates. The landman, reciprocally elected from each of the four districts, continues three years in office when taken from Zug, and but two years when chosen from each of the three other districts. The general administration of affairs is entrusted to the council of regency, composed of forty members, of whom thirteen are supplied by the district of Zug, and twenty-seven elected equally from the three remaining communities. This council, as well as the landman, resides always in the capital. Zug was the only one of the small cantons which did not send its contingent to the army, but made a show of resistance to the imposition of the new constitution. On the 29th of April, Zug was invaded by French troops, surrendered on the 30th, and on the 1st of May accepted the new constitution. The people of this canton are reckoned the most refined of Switzerland; their general assemblies are often tempestuous, though seldom attended with bloodshed.

Zug, a town of Switzerland, and capital of the above described canton, is beautifully situated at the north-east extremity of a lake, in a fertile valley, abounding with corn, pastures, and wood. It contains two churches, a convent, a town-house, arsenal, corn-magazine, a college, hospital, &c. The titular saint of this place is Oswald, king of Northumberland in the seventh century, who was defeated and slain in 624 by Penda, king of the Mercians. In the church is his statue, with the inscription: "Sanctus Oswaldus Rex Anglorum. Hujus Ecclesiae." This king was much renowned for his chivalry, piety, and power of working miracles; 15 miles S. of Zurich. N. lat. 47° 6'. E. long. 8° 16'.

Zug, a lake of Switzerland, eight miles long, and two wide, abounding in fish. It receives its name from the town on its coast.

ZUGANA, in Ancient Geography, a town in the interior of Arabia Felix. Ptol.
with persons of learning, and of contributing to the education of candidates for the ministry. Whist he was at Glarus he expost several superfitions of the church of Rome; and at Einsidlen he gained additional reputation by preaching against vows, pilgrimages, and offerings. Here he employed his influence so effectually, that he ordered the inscription over the abbey-gate, "Here plenary remission of sins is obtained," to be effaced, and the relics to be buried; and, among other rules which he established in a convent of females under his direction, he introduced one for obliging the nuns to read lefions in the New Testament, instead of reciting their hours. He was also intolerant and zealous in propagating rational sentiments of religion, and with this view he availed himself of a public occasion, when a crowd was assembled, to deliver a sermon designed to shew that no superior sanctity resided in any place so as to confer peculiar merit on vows addressed from it, but that their acceptance depended upon the purity of the heart and life of the worshipper. Declarations of this kind, whilst they gained the approbation of some of his auditors, excited the indignation of others, and alarmed the monks of this and neighbouring convents. Although he was regarded with jealousy and terror by those whose interest led them to oppose reformation, he was so much respected, that his ecclesiastical superiors manifested no displeasure against him; and by his correspondence with Erasmus, Glaireanus, Hedio, Rheinanus, and other learned persons, he established a reputation which enabled him to encourage liberal studies. In 1518 he was invited to occupy the vacant poft of preacher in the cathedral of Zurich, and before he was installed he announced his proposed plan of preaching, which differed from that which had been before practised, and which gave him an opportunity of explaining the books of the New Testament in an uninterrupted series, without regard to texts that were marked for each Sunday and Saint's-day in the year. This plan was approved by the majority of the chapter, and drew together a crowded auditory, who expiated in high terms their admiration of the preacher. A circumstance occurred which afforded him a complete victory over an emissary of pope Leo X., who was employed in the sale of indulgences, inomuch that he was obliged to quit the city and retire into Italy. Some writers, especially among the Catholics, have referred the origin of the reformation, and of the opposition of both Zwingle and Luther to the papal authority, to the disputes about indulgences; but, although this quarrel might have contributed to the promotion of the reformation, the people were previously prepared for the event by the preaching and conduct of Zwingle, and by the judgment and prudence with which he had planned and pursued his measure for this purpose. Luther proceeded very slowly to that extirpation from the prejudices of education, which Zwingle, by the force of an adventurous genius, and an uncommon degree of knowledge and penetration, easily got rid of. And we learn from the most authentic records of history, that he had explained the Scriptures to the people, and called in question the authority and supremacy of the pope, before the name of Luther was known in Switzerland. In process of time, after Luther had taken up arms against Rome, Zwingle, being then minister of the chief church in Zurich, concurred with him in preaching openly against indulgences, then against the intercession of the saints, then against the mass, the hierarchy, the vows and celibacy of the clergy, abstention from flesh, and also many things which Luther was disposed to treat with toleration and indulgence; such as images, altars, wax-tapers, the form of exorcism, and private confession, &c. Zwingle, at an early period of his ministry, had declared his decided disapprobation of all wars, excepting those that were undertaken for the defence of the country; and such was the influence of his opinion, that the canton of Zurich refused to concur with the other cantons in a subsidiary treaty with the French king. The refult of his arguments and remonstrances to this effect was a law passed by the assembly of the canton in 1522, abolishing all alliances and subsidies for the term of 25 years. He laboured at the same time to enforce a regard to the rules of the gospel in preference to the respect that was generally manifested to those of ecclesiastical discipline. Accordingly he defended those persons who had been denounced to the magistrate for infringing on the "fast of Lent" without a dispensation; and published on this occasion his treatise "On the Observation of Lent," which contained some free opinions on the obligation of fasting and keeping particular days. When the bishop of Constance remonstrated against his proceeding, and endeavoured by his charge and letters to excite apprehensions among the people, and in the council and chapter of Zurich, that he would spread through Switzerland such a flame as Luther had kindled in Germany, Zwingle obtained permission to reply; and composed a tract to prove that the gospel alone is authority from which there is no appeal, and that the decisions of the church are binding only inasmuch as they are founded on Scripture. When the bishop of Constance proceeded to order the arrest of a pastor accused of preaching the "new doctrine," Zwingle, who had now adopted and openly avowed the principles of the reformation, addressed to the heads of the cantons, in his own name and that of his friend, a summary of his doctrine, annexing an intreaty that they would allow liberty for the preaching of the gospel. In a conference before the deputies of the bishop of Constance, in the presence of the great council of Zurich, held in 1523, Zwingle gave an account of his doctrine; and the colloquy terminated in the following declaration of the council: "That Zwingle, having been neither convicted of heresy, nor refuted, should continue to preach the gospel as he had already done; that the pastors of Zurich and its territory should rest their discontents on the words of Scripture alone; and that both parties should abstain from all personal reflections." Zwingle, having been thus supported by the magistrates, and having obtained a public sanction of the principles of the reformation in this canton, has been charged, both by Catholics and Protestants, with allowing to the secular power an undue degree of authority in ecclesiastical matters; however it has been urged in his defence, that he did not intend to transfer to government the absolute power over confessions claimed by the popes; but that, for the preservation of order and tranquillity, he thought that the depositories of lawful authority ought to have a share in the direction of ecclesiastical affairs. Zwingle, though thus supported, proceeded with caution in promoting alterations in the ceremonies and modes of public worship, and was principally anxious to lay a proper foundation of change by enlightening the understanding and convincing the judgment of the people. When some zealous reformists instigated a mob to pull down a crucifix that had been erected at the gate of the city, and the culprits were brought before the council to be tried and punished, Zwingle interposed; and whilst he vindicated the offenders from the charge of sacrilege, he gave it as his opinion, that they deserved some punishment for having pulled down the crucifix without the authority of the magistracy. This dispute led to a general colloquy, which was held in October 1523; and the refult was, that all the culprits, except Hottinger their ring-leader, and the person who had actually
but committed the offence, were set at liberty; but Hottinger was banished from the canton for two years; and he was afterwards put to death for heresy, in consequence of a sentence pronounced by the deputies of seven cantons at Lucerne, notwithstanding the intercession of Zurich. The question of the celibacy of the clergy was agitated in these colloquies, and though no decisive opinion was given by the council, several clergymen married, and among them was Zwingli himself, who had expressed his sentiments against the question, at the age of 40. In 1524, the council of Zurich proceeded to the reformation of public worship according to the plan proposed by Zwingli. They began with causing all pictures and statues to be removed by those whose ancestors had consecrated them; and of these several were destroyed. These measures occasioned alarm and complaint in the other cantons; and acts of hostility were meditated. Without entering into a detail of the various circumstances that occurred on one side and on the other, we shall content ourselves with observing, that fanaticism and bigotry were engaged in opposition to each other, and produced in Switzerland effects similar to those that have attended innovation and reformation in other countries. At Zurich, the total subversion of the Romish worship was accomplished, by prohibiting processions and other ceremonies, and by the abolition of the sacrifice of the Mass. The latter event took place by the activity of Zwingli in 1525; and on Easter Sunday the Lord's Supper was celebrated according to his idea of this rite, which was that of a merely commemorative and symbolic service. Our reformer displayed in another instance a disinterred spirit, which reflects great honour on his memory. Although he was one of the canons who composed the chapter of the cathedral, and this body was independent of the council, and possessed its own jurisdiction and property, he prevailed with the majority of his colleagues to consecrate the large revenues of the chapter to establishments for public instruction, and to transfer its temporal power to the government. In the conduct of this event he manifested no less wisdom and moderation than disinterestedness; for the chapter charged itself with the payment of as many poor as were necessary for the public worship of the city, to which service those canons who were capable of service were devoted. Those who were old and infirm were allowed to prefer their benefits for life; and their revenues, as they became vacant, were to be employed in founding professorships for lectures, to which admission was to be gratuitous. These liberal conditions were religiously observed, and the regulations thus framed are still continued at Zurich. The orders of mendicant, and other religious houses, were abolished; and their revenues were appropriated to the support of hospitals, and other charitable institutions, as the old members dropped off. Zwingli was afterwards commissioned to organize a system of public instruction, in which he displayed a cultivated and liberal mind.

The reputation which Zwingli had acquired, and the success which had crowned his plans and labours in the cause of reformation, were not sufficient to secure him against the prejudices of fanatics, and the hostile attacks of malignity. Attempts were made to associate him with Munzer, one of the leaders of the Anabaptists; but he happily avoided the snare that was laid for him, and instead of taking part in those violations which called forth the interposition of the civil power, and which terminated in the death of one of the persons concerned, he did all that lay in his power to prevent them; and though he could not prevent the life of one disturber of the public peace, he composed the tumult occasioned by the intertemperate zeal of others. Notwithstanding the singular prudence and moderation which influenced his whole conduct, his reputation excited envy, and a conspiracy was formed against his life. Under the protection of the magistracy of Zurich he was safe; but his enemies maliciously proposed a conference at Baden, in Argovia. His friends, however, were not unapprelied of his danger, and well knowing that the cantons were actuated by inveterate hostility against his person as well as his doctrines, they would not consent to his leaving Zurich. At the conference, which he prudently declined to attend, enmity was awed both against him and his adherents. Some of the cantons, however, withheld their concurrence; and this was particularly the case with respect to the canton of Berne. In this canton, the reformation had made considerable progress, so that in 1527 several of its municipalities addressed the senate for the abolition of the mafs, and the introduction of the form of worship established at Zurich. The reformers at Berne summoned a convocation, to which the clergy of the other Helvetic states, and the neighbouring bishops, were invited. Zwingli's attendance was also requested; and he thought it his duty to appear in that assembly, professedly convened for the advancement of the reformation. Haller was the leader of the party in this canton, and in connection with Zwingli and other coadjutors the canons to which they were devoted obtained a complete triumph; so that the grand council of that canton fully adopted the measures of that of Zurich. Upon this, five of the cantons which were attached to the old religion entered into a solemn engagement not to suffer the doctrines of Zwingli and Luther to be preached among them. At length the hostilities that subsisted between the Catholic and reformed cantons were amicably terminated by the treaty of Cappel in 1529. The animosity, however, between these cantons was not extinguished. It broke out again with greater violence than ever; and the senate of Zurich has been charged with the first aggression, by arbitrary acts in favour of the reformed preachers in the common bailiages. Its project of secularizing the abbey of St. Gall, which belonged to the Helvetic confederacy, was a greater grievance; and on the other hand, the five allied Catholic cantons refused to concur with the others in expelling the Spaniards from the Valétine, and peremptorily the reformed in their jurisdiction with the greatest severity. The sufferers sought the protection of Zurich, and the eloquence of Zwingli was employed in recommending their cause to the senate. The breach widened, and a majority of the Protestants agreed in flocking the transit of provisions to the five cantons, which depended upon foreign supplies. Zwingli in vain remonstrated against this cruel act; and the five cantons took up arms, and having published a manifesto, marched into the field in October 1531. A detachment was ordered to prevent the junction of the forces of Berne with those of Zurich, and the main body advanced towards Cappel. This intelligence alarmed the people of Zurich; and they could only spare 700 men for the relief of their countrymen at Cappel. Zwingli was appointed to accompany them. A battle ensued; and though the Zurichers, animated by their exhortations, defended themselves valiantly, they at length were compelled to yield to superiority of numbers, and were entirely routed. Some died at their posts; others fled; and Zwingli received a mortal wound at the commencement of the action, and fell senseless to the ground. As soon as he had recovered sufficiently to raise himself up, he crossed his arms on his breast, and lifted his luminous eyes to heaven. In this condition he was found by some Catholic soldiers, who, without knowing him, offered to bring a confessor; but
but as he made a sign of refusal, the soldiers exhorted him to recommend his soul to the holy virgin. On a second refusal, one of them furiously exclaimed, "Die then, obstinate heretic!" and pierced him through with a sword. His body was found on the next day, and the celebrity of his name drew together a great crowd of spectators. One of these, who had been his colleague at Zurich, after intently gazing on his face, thus expressed his feelings: "Whatever may have been thy thy, I am sure thou wast always sincere, and that thou lovedst thy country. May God take thy soul to his mercy!" Among the savage herd some voices exclaimed, "Let us burn his accursed remains!"

The proposal was applauded; a military tribunal ordered the execution, and the ashes of Zuingle were scattered to the wind. Thus, at the age of 47, he terminated a glorious career by an event deeply lamented by all the friends of the reformation, and occasioning triumph to the partisans of the Romish church.

"In the character of Zuingle," says one of his biographers, "there appears to have been united all that makes a man amiable in private society, with the firmness, ardour, and intrepidity that are indispensable in executing the great task of reformation. By nature mild, his earnestness was the result of his sense of the importance of the cause he engaged in to the benefit of mankind, not of a dogmatic or dictatorial spirit. His views were large and generous, and his opinions rose above the narrow scale of sect or party. It was no small proof of liberality in that age that he ventured to affect his labor of the final happiness of virtuous beholders, and of all good men who act up to the laws engraved on their consciences. His temper was cheerful and loquacious, somewhat busy, but incapable of harbouring resentment, or indulging envy and jealousy. As a reformer he was original; for he had proceeded far in emancipating himself from the superstitions of Rome by the strength of his own judgment, and had begun to communicate the light to others, whilst Luther still retained almost the whole of the Romish system, and long before Calvin was known in the world. He was more learned and more moderate than the first of the divines, and more humane and kind-hearted than the last. He wrote many works of utility in their day; and the reform, of which he was the author, still subsists unchanged among a people distinguished by their morals and mental cultivation." Life of Zuingle, by J. G. Hefs. Mosheim's Eccle. Hist. Cox's Travels in Switzerland, vol. i. See Zuinglean.

ZUNGLIANS, in Ecclesiastical History, a branch of ancient Reformers or Protestants; denominated from their author Ulric or Huldric Zuingleus. See Zuingle.

As to the eucharist interpreting hoc est corpus meum, by hoc significat corpus meum, he maintained, that the body and blood of Christ were not really present in the eucharist; and that the bread and wine were no more than external signs or symbols, designed to excite in the minds of Christians the remembrance of the sufferings and death of the divine Saviour, and of the benefits which arise from them. This opinion was embraced by all the friends of the reformation in Switzerland, and by a considerable number of their votaries in Germany. On the other hand, Luther held his doctrine, which was consubstantialism, with the utmost obstinacy; and hence arose, in 1524, a tedious and vehement controversy, which terminated, at length, in a fatal division between those who had embarked together in the sacred cause of religion and liberty. From this time, Zuingle propagated his doctrine concerning the eucharist in a public manner by his writings, after having entertained and taught it privately before that period. His "Commentary on true and false Religion," containing his sentiments on this subject, was published in 1525, and followed by a learned treatise of Eccolampadius on the same subject.

With a view of bringing this controversy, which reflected much discredit on the Protestant cause, to an amiable issue, Philip, landgrave of Hesse, invited, in 1529, to a conference at Marpurg, Luther and Zuingle, together with the other principal leaders of their respective parties; who disputed, during four days, in presence of the landgrave. Luther attacked Eccolampadius, and Melancthon disputed against Zuingle. Before they parted, the Swifs and German theologians signed their mutual assurance to 14 articles, containing the essential doctrines of Christianity, and expressed a hope that their difference with respect to the real presence would not interrupt their harmony. The landgrave required from the two leaders a declaration that they would regard one another as brothers. Zuingle readily confessed; but Luther would engage no farther than that, speaking of the Swifs, he would for the future moderate his expressions. In this conference Zuingle was accused of hereby, not only on account of his explication of the nature and design of the Lord's Supper, but also in consequence of the false notions he was supposed to have adopted relating to the divinity of Christ, the efficacy of the divine word, original sin, and some other parts of the Christian doctrine. But though he cleared himself to the satisfaction even of Luther from the greatest part of these accusations, their disaffections concerning the manner of Christ's presence in the eucharist still remained. Nor did it terminate with the death of Zuingle in 1531, nor with that of Luther in 1546. Melancthon and Calvin made several attempts towards promoting a reconciliation between the contending parties. With this view Calvin proposed a system, with respect to the eucharist, more conformable to the doctrine of the Lutheran church than that of Zuingle. He acknowledged a spiritual presence of Christ in this sacrament, and supposed that a certain divine virtue or efficacy was communicated by Christ with the bread and wine to those who approached this holy sacrament with a lively faith, and with upright hearts; and to render this notion still more satisfactory, he expressed it in almost the same terms which the Lutherans employed in inculcating their doctrine of Christ's real presence in the eucharist. But whilst the followers of Zuingle asserted, that all Christians, without distinction, whether regenerate or unregenerate, might be partakers of the body and blood of Christ, Calvin confined this privilege to the pious and regenerate believer alone. Besides, the sentiments of the Zuingleans, with regard to the divine decrees, differed very little from that of the Pelagians; nor did they hesitate in declaring, after the example of Zuingle himself, that the kingdom of Heaven was open to all who lived according to the dictates of right reason; whereas Calvin maintained, that the everlasting condition of mankind in a future world was determined from all eternity by the unchangeable order of the Deity, and that this absolute determination of his will and good pleasure was the only source of happiness or misery to every individual. Moreover, Zuingle and Calvin differed in their notions of ecclesiastical government. The former ascribed an absolute and unbounded power, in religious matters, to the civil magistrate; allowing at the same time a certain subordination among the ministers of the church, and placing at their head a perpetual president, called the superintendent, with a certain degree of inspection and authority over the whole body; but Calvin, on the contrary, reduced the power of the magistrate, in religious matters, within narrow bounds; declaring the church a separate and independent body, endowed with the power of legislation.
legislation for itself, and maintaining that it was to be governed, like the primitive church, only by prebyters and synods, i.e. by assemblies of elders, composed both of the clergy and laity, and leaving to the civil magistrate little else than the privilege of protecting and defending the church, and providing for what related to its external exigencies and concerns. These and other circumstances prevented the union of the Lutheran and reformed churches; though in process of time almost all the latter churches adopted the theological system of Calvin. Mofh. Eccl. Hist. Eng. ed. 8vo. vol. iii. and vol. iv.

ZULAUF, in Geography. See Sulau.

ZULE, a town of South America, in the new kingdom of Grenada; 5 miles S. of Pampelona.

ZULIANA, a town of the republic of Ragusa; 30 miles W.N.W. of Ragusa.

ZULICHAU, a town of the New Mark of Brandenburg, formerly in the duchy of Holstein. This town is the capital of a district, or circle, and the seat of an ecclesiastical inspeétion, situated in a low plain, half a German mile distant from the Oder, and about the same distance from the Ober. The town itself consists only of 250 houses, one parish-church, and a grammar-school; but it has four large suburbs: without the walls is a feast belonging to the king of Prussia, fortified with walls and moats, which serves for the residence of the king's receiver of the prefécture; in this part also stands the Calvinist church. Zulichau contains a good woollen manufacture; 39 miles S.E. of Frankfort-on the Oder. N. lat. 52° 8'. E. long. 15° 45'.

ZULPHA, or JUFFA, a town of Peria, in the province of Irak, on the S. side of the Zenderoud, about a mile and a half from Ipahan, to which it is considered as a kind of suburb; it was built by Abbas I. after he had destroyed Zulpha, in Armenia. In the year 1522 this town was taken by the Afghans, under Maghmad, who demanded of the inhabitants the sum of 70,000 tomans. This suburb has been reduced from 12,000 to 600 families, which is the café with respect to most of the others; and a perfon may ride for miles amidst the ruins of the immense capital, Ipahan, which nevertheless still boasts of 200,000 souls. In the suburb of Zuffa, there still remain nine churches, in which weekly service is performed.

ZULPHA, or JUFFA, a town of Persia, Armenia, on the Aras or Araxes, supposed to be the ancient Arriamene. This town was taken and destroyed by Abbas I., who removed the inhabitants to Ipahan, where they built a faubourg, called Zulpha, containing 4000 houses; some families, nevertheless, returned back to their native place, and took up their residence among the ruins; 60 miles N. of Tauris.

ZULPICH, or ZUHEL, a town of France. This town contains three churches, and several cloisters. In the year 406, Klodwig, king of the Franks, overcame the Alemanni near this place; 18 miles S.W. of Cologne. N. lat. 50° 43'. E. long. 6° 34'.

ZULTZ, or BIALA, a town of Silesia, in the principality of Oppeln, and capital of a circle; 20 miles S.S.W. of Oppeln.

ZULUCK, a small river of Russia, in the country of the Coflacks, which runs into the Kardis, near Baberezovskia.

ZUZ, a town of the Grifions, in Upper Engadine, on the Inn; 31 miles N.N.E. of Chiavenna.

ZUM BÖRS, a town of Germany, in the county of Bregentz, on the river Bregentz; 18 miles S.S.E. of Bregentz.

ZUM CLERELIS, a town of Germany, in the county of Plundonz, on the river Alvens; 9 miles E. of Plundonz.

ZUM HOFS, a town of Germany, in the county of Bregentz, on the river Bregentz; 15 miles S.S.E. of Bregentz.

ZUM STEIN, a town of the district of Berg; 3 miles N.E. of Blankenberg.

ZUM VEGELSANG, a town of France, in the department of the Roor; 3 miles S.E. of Juliers.

ZUM ZONTAGE, a town of Germany, in the county of Bregentz; 24 miles S.S.E. of Bregentz.

ZUMAIJA, or ZUMAIJA, a town of Spain, in the province of Guipuzcoa, near the coast of the bay of Bilcz; 14 miles W. of St. Sebastian. N. lat. 43° 17'. W. long. 1° 51'.

ZUMAMPA, a town of South America, in the government of Tucuman, in the Rio Dolce; 90 miles S. of St. Yago del Elero.

ZUMELLA, a town of Italy, in the Trevisan; 10 miles N.W. of Venice.

ZUMIC ACID, in Chemistry, a name given by Dr. Thom- fon to a peculiar acid principle lately obtained by M. Bracconot from rice, and which that gentleman had abfurdly called Nancec acid, from Nancy, the name of the city where he refided.

This acid was obtained by fermenting rice in water by the application of a gentle heat. An acid liquor was obtained, which on evaporation to dryness left a gummy mass, having a very four tafle. This was digested in alcohol, which on evaporation let fall crystals composed of the peculiar acid and lime. The lime was thrown down by barytes, and the barytes afterwards separated by fulphuric acid, and thus the acid obtained in a separate fæt.

Zumic acid is colourles, has a very acid taste, and does not crystalfylize. It precipitates none of the metals from their solutions, except zinc from very concentrated solutions of its fæt.

With potaf and foda it forms incrystallizable deliquescent fæt, soluble in alcohol. With ammonia it forms a crystalizable fæt.

The neutral zurnate of lime crystalizes confudely in a form somewhat refeembling a cauliflower. It is opaque, very white, has little tafle, and has the appearance of having efforced.

We do not think it necessary to detail the properties of the other compounds of this acid, which have been but little examined, and appear to be totally devoid of interest.

Dr. Thomson thinks the zumic acid is the fame with the laftic acid, the latter being probably difguifed as usually obtained, by the presence of some animal matter.

ZUMPANGO, in Geography, a town of Mexico; 90 miles S. of Mexico.

ZUMPANO, a town of Mexico; 20 miles N. of Mexico.

ZUNAC, a town of South America, in the audience of Quito; 35 miles N.W. of Macas.

ZUNAPA, a small iſland in the Adriatic. N. lat. 43° 7'. E. long. 17° 7'.

ZUNCOLLO, a town of Naples, in Principato Ultra; 17 miles S. of Conza.

ZUNDEL, a town of Silesia, in the principality of Neife; 5 miles S.S.E. of Grodkau.

ZUNGER, a town of Prussia, in Pomeralia, at the mouth of the Nogat; 8 miles W.N.W. of Elbing.

ZUNG-GAR, a town of Tunis, anciently called Zuchara. Here are the ruins of a temple, and an aqueduct erected for the purpose of conveying water to Carthage; 48 miles S.W. of Tunis.

ZVORNICK.
ZU RO N I C K. See Zornado.
ZU PU, a town of Cirella; 106 miles E. of Theodofa.
ZUR GUGEL, a town of Prussian Pomerelia; 20 miles S.S.E. of Marienburg.
Zur Osa, a town of the duchy of Bremen; 3 miles S.S.W. of Bremerhorde.
ZURA, a town of European Turkey, in Moldavia, on the Dneiler; 22 miles E. of Orhei.
ZURARA, a town of Portugal, in the province of Entre Duero e Minho, at the mouth of the Ave, opposite Villa de Conde.

ZURBARAN, Francisco, in Biography, was a Spanish painter, born at Triente da Cantos, near Seville, in 1595. He was a disciple of Pablo Rocala, under whose tuition he acquired very considerable talent, and soon enjoyed a good reputation as an artist. He adopted the style of M. A. Caravaggio, painting with great boldness, force, and truth. His first public work was painted for the convent of La Merced Calzada, from the history of S. Pedro Nolasco, by which he added much to his fame. There are many other works of his in the public edifices at Seville and Cordova, particularly in the Collegio di San Pablo. He was invited to Madrid about 1630, and was appointed principal painter to the king, and employed in the Buen Retiro, where he painted the Labours of Hercules. His productions may also be found in the Casa de Campo, and other royal palaces, as well as in private collections. Zurbaran died in 1662, aged 63.

ZUREITA, in Geography. See Zuweita.
ZURIC, or ZURICH, a canton of Switzerland, and the first in rank, bounded on the N. by Swabia and the canton of Schaffhausen, on the E. by the Thurgau and the county of Toggenburg, on the S. by the cantons of Schwyz and Zug, and on the W. by the county of Baden. This canton is not unaptly called an epitome of all Switzerland, as containing in it hills, valleys, plains, corn-lands, vineyards, lakes, rivers, vegetables of all kinds, and whatever else is necessary to the support of life. Grain is cultivated all over the country; but it ripens later in the mountainous parts, where the air is colder, than in the levels or sunny valleys. The hilly grounds in the E., W., and S. borders, afford a specimen of the fertile Alps, as abounding in cattle, milk, butter, and cheese; at first the wines have a tartness attending them, yet they improve by keeping; and, after lying some years in the casks, become smooth, pleasant, and wholesome. Fruits also are everywhere found in great plenty, and very good. The most remarkable minerals and fossilis are chalk, potters' earth of several forts and colours, sulphur, and pit-coal; some mineral springs are likewise found. The proportion of grain to the other productions of the earth will appear from the following calculation: there are 217,424 acres, of 36,000 square feet each, laid out in grain, 14,466 in vines, 94,553 in meadows, 42,549 in pasturage, and 103,772 in forests. As sufficient corn is not produced for the interior consumption, the deficiency is chiefly supplied from Swabia. In order to prevent a scarcity of this material article, a public granary is maintained, at the expense of government, for grain at the common price; but in seasons of scarcity, it is sold considerably cheaper than it can be purchased at the market. The wine is mostly consumed in the country, and little of it is exported for foreign commerce. The canton contained, in 1784, 174,572 souls, including 10,500 in the capital: this large population, in proportion to the size of the canton, is owing to the trade of Zuric; as at least two-thirds of the inhabitants derive their livelihood by spinning thread and silk, and making linen for the manufactures of the town. The foreign power refutes exclusively in the burgesses of the town, confining of about 10,000; but a contracted disposition prevails in most of the states of Switzerland, so that they seldom confer the burgership. In Zuric, if it is false, a new citizen has not been admitted for the last 150 years.

The burghers, beside the advantage of electing their magistrates, and of aspiring to the administration of affairs, enjoy the sole right of commerce; all strangers, and even subjects, being excluded from establishing manufactures in the city, or in any part of the canton.

The burghers of Zuric are divided into thirteen tribes; one of which is called Contrafell, or the tribe of nobles, although at present not absolutely confined to persons of that description: it enjoys the privilege of giving eighteen members to the Sovereign Council, and fix to the Senate, whereas each of the other tribes only supply twelve to the former, and fix to the latter.

The legislative authority is vested by the burghers in the Sovereign Council of two hundred; confining, however, of two hundred and twelve members drawn from the thirteen tribes, and comprizing the Senate, or Little Council. This Senate, composed of fifty members, including the two burgomasters, has jurisdiction in all causes civil and criminal: in civil cases, when the demand is of a certain importance, an appeal lies to the Council of two hundred; but in criminal affairs, their sentence is final, and, when once passed, there is no reversal or mitigation. It is to be regretted, that in this republic, as in most other states of Switzerland, there is no precise code of criminal law. The Caroline, or code of Charles V., is often of course followed; but on account of its obsolete usages and extreme severity, the sentence is ultimately left to the discretion of the magistrates.

The power of the Senate, confederated in a collective capacity, is very considerable: it judges finally in all criminal cases, has the care of the police, and supplies the principal magistrates.

As too great a power of individuals is dangerous in a republic, the members of this assembly are liable to be changed, and a revision or confirmation is annually made, in some infinities by the Sovereign Council, in others by the particular tribes to which the senators belong. This annual revision is a great check to mal-administration, and at the same time prevents the Senate from gaining to great an influence as to be detrimental to the liberties of the people. A burgher is qualified to vote at twenty; is eligible into the Sovereign Council at thirty; and into the Senate at thirty-five. The canton of Zuric is divided into districts or bailiages, which are governed by bailiffs nominated by the Sovereign Council, exercising an authority subject to certain restrictions. The reform was begun by Zuinglius, in the year 1517, in the town of Zuric; and in 1524, gained footing in the whole canton.

The militia of the canton amounted, in 1781, to 25,718 infantry, 1025 artillery, 886 dragons, and 406 chasseurs; in all 28,235 effective men. The arsenal is well supplied with cannon, arms, and ammunition; and contains a reserve of muskets for 30,000 men. This canton had formerly a regiment and some companies in the service of France, a regiment in that of Holland, and some companies in the service of the king of Saragossa.

In ecclesiastical affairs the Senate is supreme: the canton is divided into fourteen districts, each governed by a dean, who, like the fynod, from three candidates, proposed by the clergy of the dioceese. The fynod, composed of the whole clergy, and several allegros on the part of the Little Council, meets twice a year. The principal ministers and professors...
ZURIC.

In the town constitutes, in conjunction with several magistrates and other affiurers, deputed by the civil power, an ecclesiastical and academical council: to this committee the deans recur in all concerns, which seem to exceed their jurisdiction, and determine border affairs, and refers cases of importance to the Senate.

During the French revolution, the canton of Zürich, after a feeble assistance, surrendered to the arms of the invaders; and the national assembly, which had been convoked, acceded to the new organization of the Helvetian constitution.

Zürich, a city of Switzerland, and capital of a canton of the same name, situated on a large lake, where the river Limmat is discharged, which divides it into two parts; supposed to have been built on the site of the ancient Tigurum, which was destroyed by the Allemanni.

The environs are very delightful; an amphitheatre of hills gradually sloping to the borders of the water, enriched with pastures and vines; dotted with innumerable villages, cottages, and hamlets; and backed on the W. by the Uetliberg, a bold and gloomy ridge stretching towards the Alps, and that chain of mountains which rises gradually to the Alps. Of the two parts into which the town is divided, the old part is surrounded with the same ancient battlements and towers which existed in the thirteenth century, and the suburbs are strengthened by fortifications in the modern style, but too extensive. The ditches, instead of being filled with stagnant water, are mostly supplied with running streams. The public walk is pleasantly situated in a lawn, at the junction of the Limmat and the Sihl, an impetuous and turbulent torrent, which descends from the mountains of Emfildin: two rows of lime-trees planted by the side of the Limmat, and following its serpentine direction, afford an agreeable shade in the heat of summer. The inhabitants are very industrious; and carry on with success several manufactures: the principal are those of linens and cottons, muffins, and silk handkerchiefs. The manufacturers do not in general dwell within the walls; but the materials are mostly prepared, and the work is completed in the adjacent districts. For this reason, Zürich does not exhibit the activity and numbers of a great commercial city. The environs, on the contrary, are so extremely populous, that perhaps few districts in the neighbourhood of a town, whose population scarcely exceeds 10,000 inhabitants, contain within so small a compass so many souls. The streets are mostly narrow; the houses and public buildings accord more with plainness and convenience, than with the elegance and splendour of a capital. In 1780 the town contained 10,550 souls; but the population had decreased from the difficulty of obtaining the burgership; whereas luxury and opulence had very considerably increased. In general, however, the manners of the inhabitants are simple. Dinner is usually served at twelve: in the afternoon the gentlemen assemble in clubs, or small societies, in the town during winter, and at their respective villas in summer. They frequently smoke, and partake of wine, fruit, cakes, and other refreshments. The women, for the most part employed in their domestic occupations, or devoted to the improvement of their children, are not fond of visiting. This reserve, however, has much abated, and gives place to a more sociable intercourse. Such, however, is the prevalence of national habit, that a few families, which form a more agreeable mixture of company, are considered as differing from the established customs, and are still known by the name of the French Society. Sumptuary laws are well observed. Amongst these, the use of a carriage in the town is prohibited to all sorts of persons except strangers; and it is almost inconceivable, that in a place so commercial and wealthy, luxury should so little prevail.

Zürich was formerly an imperial city, and obtained from the emperor Frederick II. very considerable privileges; which were acknowledged and augmented by several of his successors. The civil war between the magistrates and the people in 1335 nearly reduced the city to ruins; but the former being banished, the citizens, in 1337, established a new form of government, which was confirmed by the emperor Louis of Bavaria. The exiles, after several fruitless attempts, were at length re-admitted; but engaging in a conspiracy against the citizens, were discovered and put to death. In consequence of this execution, the nobles in the neighbourhood took up arms; and Zürich, after having ineffectually applied for alliance to the emperor Charles IV., formed an alliance with Lucerne, Uri, Schwitz, and Unterwalden, and was admitted a member of their confederacy. This event happened in the year 1331. The four cantons yielded the pre-eminence to Zürich: a privilege it enjoys at present; being the first canton in rank, and the most considerable in extent, both of territory and power, next to Berne. In the same year, Zürich was afflicted by the four cantons against Albert, duke of Austria, who besieged the town, and was repulsed with great loss.

Zürich was the first town in Switzerland that separated from the church of Rome, being converted by the arguments of Zwingli.

The charitable estabishments at Zürich are, the orphanhouses, which are regulated with extreme attention and care; an alms-house for poor burghers; an hospital for incurables; and that for the sick of all nations, which usually contains between fix or seven hundred patients; and the Allmone-Amt, or foundation for the poor; this excellent institution puts out children as apprentices; and distributes money, clothes, and books of devotion to poor persons, as well in the town, as in different parts of the canton, at the recommendation of the respective ministers. Here is also a chirurgical seminary, formed by voluntary subscriptions, to the support of which, Dr. Rhan, an eminent physician, was a liberal contributor.

At Zürich public education is a concern of the state, and under the immediate protection of government. The office of a professor gives rank and estimation, and is often held by a member of the Senate and of the Great Council. The principal literary establishments for the instruction of youth are, the Caroline college for students in divinity; Collegium Humanitatis, or the college for polite literature; and the school of arts: the first has twelve professors, the second two, and the last seven. The learned languages, divinity, natural history, mathematics, and in short every species of polite learning, as well as abstruse science, is taught at a small expense in these respective seminaries.

In consequence of the peculiar attention paid by government, since the reformation, to the education of youth, Zürich has produced many persons, who have distinguished themselves in all departments of literature: amongst whom we may reckon Zwingli and Bullinger, Conrad Gellen, Hottinger, Simler, Spon, Scheutzer, Heidegger, Breitinger, Bodmer, Hirtzel, Solomon Gellen, and Lavater. For each of these distinguished persons, see our biographical articles.

Dr. Hirtzel was a learned physician, and deferentially styled the Swiss Plutarch: he distinguished himself, among various publications, by the Socratic Rapiune, and by the lives of Sulfitzer and Heidegger. Leonhard Meiler, professor of history and morality in the school of arts, deferves mention, on account of his numerous and valuable publications, in all which he has displayed great zeal for the promotion of literature,
literature, correctness of style, liberality of sentiment, and extensive historical and biographical knowledge. In his observations on fanaticism and intolerance, he has forcibly evinced their dreadful effects on government and civil society by historical facts, and approved himself an able writer in combating pernicious, and in repressing the prevalent spirit of fanaticism.

The public library at Zuric contains about 25,000 volumes, and a few curious MSS., of which latter are, the original MS. of Quintilian, the Psalms in the Greek tongue, written on parchment dyed of a violet colour, the letters being silver and golden, and the marginal reference red, somewhat similar to the "Codex Argenteus" of Upfal, and supposed to have once formed a part of the "Codex Vaticanus," and several MSS. of Zuingle. Zuric is a district 41 miles S.E. of Bâle, and 36 S.W. from Conflant. N. lat. 47° 18'. E. long. 8° 25'. Coxe's Travels in Switzerland, vol. i.

ZURICH, a town of Austrian Poland; 22 miles S. of Luckow.

ZURITA, a town of Spain, in New Catalonia, on the left bank of the Tagus; 48 miles N.E. of Toledo.

ZURITO, a town of Peru, in the diocese of Cufco; 12 miles N.W. of Cufco.

ZURLINDEN, a town of Prussia, in the palatinate of Culm; 18 miles E.N.E. of Thorn.

ZURNAPA, in Zoology. See Camelopardal.

ZURUPALCA, in Geography, a town of Peru; 44 miles S. of Pototo.

ZURZACH, a town of Switzerland, in the county of Baden, on the Rhine, chiefly celebrated for its fairs, at which great quantities of goods are sold by the merchants from Germany, France, and Italy; 25 miles E. of Bâle.

ZURZONZA, a town of Mexico, in the province of Mechoacan, situated on an island in a lake; 20 miles W. of Mechoacan.

ZURZURA, in Ancient Geography, a town of Asia, in the Greater Armenia. Ptol.

ZUSAM, in Geography, a river of Bavaria, which runs into the Danube, oppoite Donauwert.

ZUSCHEN, a town of Germany, in the county of Waldeck; 4 miles N.W. of Fritzlar.

ZUSEL, a river of France, which runs into the Roer, at Sulseren.

ZUSMERSHAUS, a town of Bavaria, in the territory of Augsburg; 13 miles N.W. of Augsburg.

ZUSNIN, a town of Lithuania; 11 miles N.E. of Posen.

ZUTFHEEN, a city of Holland, and capital of a county to which it gives name, situated on the river Berkel, which passes through the middle of it, fills its ditches, and immediately joins the Ijssel. It takes its name from the two Flemish words "Zuut Vunen," which signify Southern Meadows. The principal buildings are, the church of St. Walburge, the town-house, the college of the deputies of the comit, and an ancient building, which they call "eGraven-Hof," or Palace of the Comité. Otto I. of Nassau, acquired this country in the 11th century, by his marriage with the heiress of Gerlach, count of Zutfhen, since which it has ever been annexed to Guelderland; 7 miles S. of Deventer. N. lat. 52° 10'. E. long. 6° 51'.

ZUTFHEEN ISLANDS, a group of small islands, in the straits of Sunda. S. lat. 5° 50'. E. long. 105° 42'.

ZUTZ, a town of Switzerland, in the league of the Grifons, on the Inn. This town, though not the largest, is reckoned the principal place of Upper Engadine, because it contains the criminal court of justice. This court conflicts with the landman of Sotto, one of the two communities of Upper Engadine, who is president, and sixteen jurymen, called Troudars, taken equally from each district. Justice is said to be more equitably administered in this court than in any other throughout the Grifons, excepting at Coire. The vicinity of Zutz, and also of Scampf, is the finest part of the valley of Engadine; it there produces some rye and barley, and the mountains are clothed with verdure to their very summits.

ZUURRE-VELDT, a division of Graaf Reynet, which is an extensive plain country, stretching from the Sunday river, in Zwartkop's bay to the great Fifth river, and is the same kind of good arable or pasture land as the plains of the Autinequias division in Zwellemud; but it is now exclusively in the possession of the Kiffers, from whom it was originally taken by the Boors. The great plains towards the sea-coast, that are filled with thicketts, abound in elephants and buffaloes; and in the great Fifth river are, occasionally at least, found a few of the hippopotamus, or river-horse.

ZUWEITA, or ZURITA, a town of the Arabian Iрак; 35 miles S.E. of Helleh.

ZUYDER-ZEE, or ZUIDER-SEE, a great gulf or bay of the German ocean, which extends from south to north, in the United Provinces, between Friesland, Overfiefl, Guelderland, and Holland. It is so called from its situation towards the south, and is said formerly to have been a lake, and that the land is swelled up from that united North Holland with Friesland.

ZUZAN, a town of Persia, in that part of Khorassan which extends from N. lat. 52° 10' to 34° 40', and from 6° to 62° of E. long. It is the ancient "Susa," now an inconsiderable place, situated at the same distance from Pashing as the latter is from Herat.

ZUZON, a town of Spain, in Old Catalonia; 22 miles N.E. of Siguenza.

ZYGNYUM, in Botany. See Syzygium and Calyptranthes, to which latter genus belongs the original Syzygium of Browne.

ZWAMMERDAM, or ZWANENBURGERSHAM, in Geography, a town of Holland, on the Rhine, which was pillaged and burned by the French, in the year 1762; 6 miles N. of Gouda.

ZWÄRTZ-BERG, as well as Cango and Truda, are divisions of Zwelflanden, which are the Karroo plains, situated between the first and second chains of mountains, but being well watered by the mountain streams contain fertile patches of ground. Their great distance, however, from the Cape, and very bad roads, prevent an extensive tillage. In these plains are numerous dolrchie, and herds of quachas, zebras, and hartebeests. Behind the first chain of mountains, in these divisions, are two hot springs of chalybeate water.

ZWÄRTZ-BERG is also a division of Graaf Reynet, which
is a portion of the mountain of the same name, in the district of Zwelendam, to which it ought properly to belong. Sheep and horned cattle are the chief produce of the farmers.

Zwarte-kop's River is a fertile and extensive division of Graaf Reynet, lying to the southward of Zwarte-Ruggens, and capable of producing an abundant supply of grain, convenient to be delivered at a trifling expense at the bay. About 15 miles to the westward of the bay are large forests of timber-trees, near which is an appearance of a rich mine of lead. Near the bay is also a salt lake, which yields a plentiful supply of that article. Wax from the myrica cerifera and aloes might be furnished by this division as articles of commerce.

Zwarte-Ruggens, a division of Graaf Reynet, which is a flomy tract of country to the southward of Camdeboo, another division lying at the foot of the snowly mountains. It is very feantly supplied with water, and produces little except succulent plants, among which are two or three species of euphorbia. Few families are found in this division, but here and there in the neighbourhood of the Sunday river, which runs through it. The cattle and sheep are small, but generally in good condition.

Zwartkop's Bay. See Algoa Bay.

Zwartland, East, and Twenty-four Rivers, are two divisions of the district of Stellenboch and Drakenstein, consisting of widely-extended plains, stretching, in breadth, from the Berg river to the great chain of mountains, and to the Picquet Berg, in length, to the northward. These are considered as the granaries of the colony. The crops, however, in Zwartland, are as uncertain as the rains, on which their success almost entirely depends. In the Twenty-four rivers, the grounds may be irrigated by the innumerable streamlets that issue from the great chain of mountains, in their course to the Berg river. These form swamps, that have been productive of very fine rice. Wheat, barley, and pulse, are the principal articles that are cultivated in these two divisions; but they have also plenty of fruit, and make a little wine for family use.

Zwellendam, a tract of country in southern Africa, which lies upon the sea-coast between Breede river on the W., and Camtsoos river on the E., and extends northerly to the second chain of mountains, called the Zwarteburg or Black Mountains. The length is about 380 and breadth 60 miles, comprehending an area of 19,200 square miles, which is occupied by 480 families, so that each family has, on an average, 40 square miles of land. The population of Zwellendam, ascertained on oath in the year 1798, consisted of 3967 Chilians, and 2666 slaves and Hotentots, making a total of 6663. The flock and produce comprised 9049 horses, 52,375 horned cattle, 154,992 sheep, 2203 leggers of wine made, 16,720 muids of wheat reaped in 1797, and 10,554 muids of barley and rye.

Zwellendam, Drotsy, or village of, a division of Zwellendam, situated at the foot of the first chain of mountains that runs E. and W., or parallel to the sea-coast, and distant from Cape Town about 140 miles. It is composed of about 30 houses, scattered irregularly over a small but fertile valley, down the middle of which runs a plentiful stream of water. At the head of the valley stands the house of the landlord, to which is annexed a large garden well flocked with a variety of fruits, and a spacious vineyard; the whole enclosed and planted with oaks and other trees. In the middle of the village a large church has been lately erected, which is the only place of worship in the whole district.

The other divisions of Zwellendam are, the country between the drotsy and Gaaritz river, named according to the rivers that cross it, Cango, Zwarte-Berg, Trada, Mossel bay, Autinequas land, Pettenberg's bay, Olifants's river, Kamnaal, Lange-Kloof, and Sitkamma. Barrow's Southern Africa. vol. ii.

Zwenkau, a town of Saxony, in the principality of Merseburg, on the Eltzer. In the year 1429, this town was burned by the Hussites; 5 miles S. of Leipzig. N. lat. 51° 14'. E. long. 12° 18'.

Zwentedorf, a town of Austria; 6 miles W. of Puhln.

Zwenzechbachlein, a river of Wurtemberg, which runs into the Nagold, near the town of Nagold.

Zweritz, a town of the principality of Calmbach; 10 miles S.W. of Calmbach.

Zwerntltdorf, a town of Austria; 6 miles E. of Weikendorf.

Zwethan, a town of Saxony; 20 miles S.E. of Wittenberg.

Zwetl, a town of Austria, at the conflux of the Zwetl and the Kamp; 26 miles W.N.W. of Crems. N. lat. 48° 33'. E. long. 15° 7'.

Zwett, a river of Austria, which rises about four miles well from Weitra, and runs into the Kamp, at Zwetl.

Zwetzen, a town of Thuringia; 3 miles N. of Jennew.

Zwetzey, a town of Croatia, on the river Mreñtzia; 12 miles S. of Slun.

Zweybruck. See Deux-Ponts.

Zweydrittelstuck, or Piece of Two-thirds, in Commerce, a silver coin in Germany, worth two-thirds of a rix-dollar of account.

Zwiahel, in Geography, a town of Russian Poland; 90 miles E. of Luckow.

Zwickau, a town of Saxony, in Erzgebirge, on the Mulda. It has a citadel, three churches, and a Latin school, in which is a good library: here is a manufacture of cloth, and another of cards, for the use of wool-combers; with a considerable inland trade; 38 miles S.S.E. of Leipic. N. lat. 50° 39'. E. long. 12° 25'.—Alfo, a town of Bohemia, in the circle of Bolelia; 4 miles W. of Gabel.

Zwielauka, a town of Moravia, in the circle of Olmutz; 26 miles W. of Olmutz.

Zwifaltten, a princely abbey founded in the year 1089. In 1802, it was given among the indemnities to the duke of Wurttemberg; 58 miles W. of Augsburg. N. lat. 48° 17'. E. long. 8° 30'.

Zwingenberg, a town of Heife Darmstadt, situated on the Bergsitrafe. In 1653, the greater part of this town was destroyed by the French, since which it has been rebuilt in a better manner; 10 miles S. of Darmstadt.

Zwingendorff, a town of Austria; 2 miles S. of Laab.

Zwingera, in Botany, a genus taken from Anblet, dedicated under this name to the memory of several Swiss botanists of the family of Zwingier, who for three generations have cultivated this science at Basel, chiefly, indeed, with a reference to the medical qualities of plants. Theodore Zwingier, professor of anatomy and botany in that university, who died in 1724, aged 57, published in 1696 a folio German Herbal, of 995 pages, with wooden cuts, borrowed from Gefer and Cameriarius, which is little known out of his own country. Some botanical differtations also appeared under his presidency. His son Frederick gave an enlarged edition of the above Herbal in 1744; and has published in the Acta Helvetica, v. 1. 50, a plate and description of a very remarkable fungus, apparently belonging to Periplo

**ZWO**

Obi. The flowers are said to be occasionally only four-cleft and ochandrous. This genus is not much known, as Willdenow thought, to *Quassia*, but rather to *Chest.* (fee these articles;) differing from the latter in having one *fly* instead of five. How far their *fruits* correspond, we know not enough of the feed-veil of *Zwingeria* to determine.

1. *Zw. amara*. Bitter *Zwingeria*. Willd. n. 1. (Simaba guianensis; Aubl. Guian. 440. t. 153.) —Native of the woods of Orapu in Guiana, bearing flowers and fruit in June. A shrub, not more than seven or eight feet high, whose *stem* is three or four inches in diameter, with a white soft wood. *Branches* numerous, alternate. *Leaves* alternate, flaked, either ternate, or pinnate, of two or three pair, with an odd one, of elliptic-lanceolate, pointed, emarginate, entire, smooth *leaflets*, the largest of which are three and a half inches long, and an inch, or more, in breadth. *Flowers* five or six together, in little axillary clutters. *Petals* whitish, surrounding the green *disk*. Fruit yellow; the inner rind green and bitter. Nothing is recorded concerning the qualities or uses of this shrub.

**ZWISSEL,** in *Geography*, a town of Bavaria, on the Regen; 42 miles E. of Ratibdon.

**ZWITTAU,** or *Zwittawa*, a town of Moravia, in the circle of Olmutz; 30 miles N.W. of Olmutz. N. lat. 49° 43’. E. long. 16° 16’. *Zwittau*, a river of Moravia, which rises in the south-east part of Bohemia, and joins the Swarta, near Brunn.

**ZWOL,** or *Swol*, a town of Holland, in the department of Overiöffel, situated on the river Aa, between the Ijël and the Vecht, in the country of Zallant. It is a florid place, well fortified, and surrounded with a double ditch, filled with the waters of the Aa. Its situation is very advantageous, on an eminence which commands the country, and is the ordinary pas sage from Holland to the provinces of Friesland, Groningen, and Overiöffel. It was formerly a free and imperial city, and ranked among the Hanse towns. The magistracy is composed of eight echevins, and eight common-council. The celebrated Thomas a Kempis, otherwise called Hamerken, was a regular canon in a priory of Angulfines in this place, and died here in 1471, aged 91; 28 miles S.W. of Covorden. N. lat. 52° 32’. E. long. 6° 2’.

**ZWOLFAING,** a town of Austria; 8 miles S.E. of Vienna.

**ZWONIGRAD,** a town of Dalmatia, and capital of a district; 60 miles S.E. of Segna.

**ZWONITZ,** a town of Saxony, in the circle of Erzgebirge; 8 miles N.N.W. of Grubenhagen.

**ZWORNICK,** a town of Bohemia; 68 miles S.W. of Bdegrade. N. lat. 44° 37’. E. long. 18° 50’. *ZWOTA*, or *Zwoda*, a river of Bohemia, which runs into the Egra, near Falkenheim.

**ZYDACZOW,** a town of Austrian Poland, in Galicia; 30 miles W.N.W. of Halicz.

**ZYG.**, in *Ancient Geography*, an island in the northern part of the Arabic gulf. *Ptolemy.* *Zyg.* in *Ichthyology*, a species of *jupinus*, which fee; called by *Willughby* *balance-fish*. See also *Shark.*

**ZYGASTICUM,** *Zyg. exeplicum*, formed of *zyga*, a balance, among the *Ancents*, money paid for weighing things.

**ZYGER,** in *Geography*, a river of Hungary, which runs into the Kyros, 5 miles W. of Boros Jeno.

**ZYGES,** in *Ancient Geography*, a people of exterior Libya, towards the coast of the Mediterranean sea, W. of the Mareotide Name. *Ptolemy.*

**ZYG.,** a people of Africa, of the number of those who inhabited the Cimmerian Bosphorus, between the Athisi and Heniochi. *Strabo.*

**ZYGIA,** in *Botany*, *zyga* of *Theophrastus*, the second kind of his *77. *76. 16007*, or *Maple*, remarkable for its yellow and veiny wood, is spoken of as a mountain-tree, but botanists have not ascertained the specific species. Pliny’s account of this matter is extracted and abridged from the above Greek author, but is not made at all more clear. He however feems to have been acquainted with a beautiful wood, of the Maple kind, which he says was compared to a peacock’s tail, and grew chiefly in Illria and Rhetaia. Can this have been the *Acer Opulus* of modern authors? (See Willd. Sp. Pl. v. 4. 550.) Anguillara has long ago suspected that tree, which Linneaus and many other botanists have strangled overlooked, to have been the *zyga* of *Theophrastus*. Its native country, and veined yellow wood, sometimes very beautiful, are in favour of this opinion. De Thes, following Bodzau a Stapel, and other commentators on *Theophrastus*, who are led by the obvious derivation of the name from *zyga*, *a yoke*, take the tree in question for our *Carpinus*, whose hard and tough wood serves to make yokes for oxen. He ingeniously supports this opinion by the Celtic origin of *Carpinus*, from *car*, wood; and *pin*, yoke; and further by its English synonym, *Hornbeam*, oxen being yoked by their horns. The wood of the *Carpinus*, however, is neither yellow nor beautifully veined, and it is most probable *zyga* had some other origin, or allusion.

Robert Cuffantaine, cited by Bodzau a Stapel, seems to confound the *Acer Opulus* with *Viburnum Opulus*, which he terms *54. Opulus* of *Columella*, a French shrub, used for bowers.” This last has nothing in common with the history of the *zyga*.

Whatever may have been the ancient *Zygia*, Dr. Patrick Browne, finding this name unoccupied, has applied it to a Jamaica shrub, which appears to belong to *Aimina*; see Browne *J. 179*. t. 22. f. 3. Nor is this application fo unsuitable as may seem at first sight; for the author had evidently in his mind the yoked leaflets, to which he alludes in his specific definition. We do not find that Linneaus, except in manuscript, or any other author, has adopted this as a *Mimosa*. Jullien, in his *Gen. Pl. 506*, ranges Browne’s *Zygia*, with a few other genera, at the end of his *Leguminosa*, adding a reference to *Mimosa*; *Bourgain*, Aubl. Guian. t. 358, as a similar plant or genus. We do not see why it
was not placed near *Mimosa*, in the first section of that natural order. Swartz, Ind. Occ. 980, speaks of Browne's figure of the flower of *Zygia*, as exactly like his own *Mimosa comosa*, Prodr. 85; but he adds that the plants are nearly without any further elucidation of the former. There is no specimen of *Zygia*, amongst the plants in the Linnean herbarium, collected by Browne, and sent by Solander to Linnaeus. In a manuscript catalogue of Jamaicaplants, in Dr. Browne's own hand, given to the writer of this article by A. B. Lambert, *Mimosa Ozygia* stands between *fagi-\*\*\*\*\* *fussia* and *Unguis Catu*, with this remark, which is not in the author's History of Jamaica, "solia bijuga, fove fissucenta-\*\*\*\*\* *bipartitis, frugula daphyllus." This plant is there called Yoke-wood.

In the printed work it is denominated Horse-wood, or Hoop-wood, the wood being "pretty tough, and sometimes cut for hoops. The shrub is very common in St. Mary's, growing chiefly in low moist lands; but is sometimes found in the mountains, where it commonly rifes to the height of ten or twelve feet, or better." These are all the particulars we can gather relative to Browne's *Zygia*.

*Zygia*, in the Instrumental Music of the Ancients, a flute peculiar to weddings, according to Apuleius. (Metam. lib. iv.) The word *zygia* is a Greek adjective, which implies *nuptial*. The *zygia* was probably a double flute; for Julius Pollux (Onomast. lib. iv. c. 10.) says, "there was also a flute air for the wedding; executed on two flutes, one longer than the other."

*Zygia*, in Entomology, a genus of insects belonging to the order of coleoptera, the characters of which are, that the antennae are moniliform, the palpi unequal and filiform, the lip elongated and membranaceous, and the jaw undivided. There is one species, *vis*. OZOLONGA. Found in the East, oblong, red, with head and wing-feathers cyanous.

*Zygiana*, in Ancient Geography, a country of Asia Minor, in Bithynia. Ptolemy.

*Zygis*, in Botany, the specific name of a species of *Thymus*, (see that article, n. 9) supposed to be the *zygi* of Dioscorides. De Theis, who writes this word *zygi*, without any authority that we can find, derives it from *zygys*, *the bun of bees*, which is confirmed, apparently without his knowledge, by the modern Greek name of the same plant, *zygi*, *the delight of bees*. Such an appellation is peculiarly suitable to a plant well known to be highly grateful to those insects, and which is supposed to give its aromatic flavour to the famous honey of mount Hymettus, a spot where this *Thymus* abounds. Undoubtedly there are other species of the same genus, as well as of *Thymbra, Satureia*, &c., found in the same neighbourhood, which contribute to produce this flavour, in as powerful a degree perhaps as the above.

*Zygitae*, in the Roman Gardens, a term used to express those rows in the trieres, or three-rowed galleries, who sat on the second row, that is, above the thalamite, and below the thranite.

*Zygoma*, *zygoma*, in Anatomy, a bone of the head, otherwise called os jugale; or, it is the bony arch under which the temporal muscle passes.

The word is formed from *zygyni", I join; so that zygo-

ma, properly speaking, is the juncture of two bones. See CRANIUM.

*Zygomatic Process* of the temporal bone and os melae: the parts contributing to form the zygoma.

*Zygomaticum*, Os, the cheek-bone, so called because it contributes largely to the formation of the zygoma. See CRANIUM.

*Zygomaticus*, Major and Minor, muscles of the face, connected to the corner of the mouth. See DECOL-

TION.

*Zygomaticus* is also an epithet given to the future that binds the two processes of the zygoma together.

*Zygophylllum*, in Botany, so named by Linnaeus, from *zygi", a yoke, and *phyllos", a leaf, each leaf, of most of the species, being composed of a pair of leaflets, yoked, as it were, together, and somewhat resembling the foliage of the garden bean, *Vicia Fabae*; whence this genus ob-

tained, from *Dodonaeus* and Tournefort, the name of *Faba-

geo*. Hence also arose its English appellation of Bean-

Caper, given by Gerard. *Fabago* was properly deemed inadmissible, being compounded of another name, though of one no longer in use as generic. We may observe over-

Gen. Ch. Cal. Perianth inferior, of five ovate, obtuse, concave, erect leaves. Cor. Petals five, dilated upwards, obtuse, emarginate, rather longer than the calyx. Nectary of ten converging, pointed leaves, or scales, sometimes divi-

ded, embracing the germen, each of them attached to one of the filaments near its base. Stvma. Filaments ten, awl-shaped, attached to the outside of the nectary, shorter than the corolla; anthers oblong, incumbent. *Pil*. Genn superior, oblong, tapering at the base; *style* awl-

shaped, the length of the filaments; stigma simple. Peric. Capsule oblong, or roundish, with five angles and five intermediate furrows, five cells and five valves, the partitions linear, from the middle of each valve. *Seeds* several, roundish kidney-shaped, inferted alternately, in two rows, into the middle of the valves.

Obf. Linnaeus remarks, that the seed-vesel differs in shape in the different species, and that in some the flowers are, pointed leaves, or scales, sometimes divided, giving its aromatic flavour to the famous honey of mount Hymettus, a spot where this *Thymus* abounds. Undoubtedly there are other species of the same genus, as well as of *Thymbra, Satureia*, &c., found in the same neigh-

bourhood, which contribute to produce this flavour, in as powerful a degree perhaps as the above.

*Zygophyllæ*, in the Roman Gardens, a term used to express those rows in the trieres, or three-rowed galleries, who sat on the second row, that is, above the thalamite, and below the thranite.

*Zygoma*, *zygoma*, in Anatomy, a bone of the head, otherwise called os jugale; or, it is the bony arch under which the temporal muscle passes.

The word is formed from *zygyni", I join; so that zygo-

ma, properly speaking, is the juncture of two bones. See CRANIUM.

*Zygomatic Process* of the temporal bone and os melae: the parts contributing to form the zygoma.

*Zygomaticum*, Os, the cheek-bone, so called because it contributes largely to the formation of the zygoma. See CRANIUM.
the edges of whole infixed valves seem to constitute the partitions; yet the cells do burst at the outer margin, as well as at the inner. Willdenow defines fourteen species, which we shall find a necessity of extending to sixteen.

1. **Z. simpliceflora.** Cylindrical-leaved Bean-Caper. Linn. Mant. 68. Willd. n. 1. (Z. portulacoides; Forlk. *Aegypt.-Arab.* 88. t. 12. f. B.)—Leaves simple, sessile, cylindrical.—The most common of all plants in the driest parts of the deserts of Arabia, where it is known by the name of *Garmal,* and esteemed by the Arabs very good for removing specks in the eyes, for which purpose the bruised leaves are applied, mixed with water. For this we have the authority of Forkal, who sent seeds to Linnaeus. Theie vegetated at Upsal, but the plants did not live to produce flowers. The root is simple, tapering, apparently annual. Stem proturate, repeatedly forked, round, smooth. *Leaves* simple at each joint, spreading, an inch long, obtuse, somewhat dotted. *Flowers* yellow, quarter of an inch in diameter, almost felate. *Fruits* round, with long claws.

2. **Z. cordifolium.** Heart-leaved Bean-Caper. Linn. Suppl. 232. Willd. n. 2. Thunb. Prod. 80. Ait. n. 1.—Leaves simple, sessile, opposite, roundish, somewhat heart-shaped.—Gathered by Thunberg, at the Cape of Good Hope, from whence it was sent by Mr. Maffon to Kew garden, in 1774. This is a green-house *shrub,* flowering in October. We have seen no specimen.

3. **Z. Fabago.** Common Bean-Caper. Linn. Sp. Pl. 551. Willd. n. 3. Ait. n. 2. (Capparis Fabago; Dod. Pemp. 747). Ger. *Ern. 897. Bell. *Eyl. xafr. ord. 10. t. 1. f. 1. C. leguminosae; Lob. *C. v. 2. 58. Fabago Belgian.; Dalch. Hist. 456. *Telephium Diocordiae; Column. *Ecpl. 132. t. 131. Morgani; Rauw. *I. t. 113.)—Leaves conjuge, stalked; leaflets obovate. Calyx smooth. Petals entire. *Capsule* oblong. Stem herbaceous. —Native of Syria, Persia, Barbary, &c. A hardy, but not common, herbaceous perennial in our gardens, flowering in autumn, cultivated by Gerarde, in 1596, and since a few years afterwards, in the garden of cardinal Aldobrandini, at Rome, by Fabius Collana, who took this plant for the *Telephium Diocordiae,* and has left us a most faithful representation of it, too much neglected by Linnaeus and recent authors, who only refer to Dendobus. Whether Collana erred or not with respect to the name, the reader will judge by consulting the article *Telephium.* The root is tapering, flathy, producing from its crown several spreading, alternately branched, leafy, round, herbaceous, smooth *flora,* one and a half or two feet high. *Leaflets* an inch long, entire, smooth, green, unequal at the base, furnished with a principal rib, and one or two smaller ones. *Follicles* rather shorter than the leaflets, swelling upwards, smooth, channelled, crowned with a small, intermediate, awl-shaped point, like an abortive leaflet. *Stipulas* between the foliages, in pairs, membranous, ovate, pointed, obtuse. *Flowers* yellow, on a pubescent, axillary, opposite, distinctly upright stalks, hardly so long as the foliages. *Calyx-leaves* conic, base of an inch long, green, even, with a membranous edge. *Petals* rather longer, obtuse. *Seeds* transverse, alate, pellucide. Five of the *flora* deflexed, five ascending. *Capsule* above an inch in length. *Seeds* numerous.

4. **Z. fatidium.** Cecid Bean-Caper. Schrad. Ser. Han- nov. 17. t. 9. Willd. n. 4. Ait. n. 5. (Z. infrutescens; Curt. Man. 172.)—Leaves conjuge, stalked; leaflets oblong; *Calyx* downy. Petals jagged. *Capsule* rounded. Stem shrubby. —Native of the Cape of Good Hope, from whence it was introduced in 1750, by Mr. Maffon. This is a hardy green-house shrub, flowering all summer long, but rendered *VOL. XXXIX.*

5. **Z. masculum.** Spotted-flowered Bean-Caper. Ait. ed. 1. v. 2. 60. ed. 2. n. 4. Willd. n. 5.—"Leaves conjuge, stalked; leaflets linear-lanceolate."—Native of the Cape of Good Hope, from whence it was introduced, in 1782, by George Wynch, esq. A green-house shrub, flowering in October and November. The *petals* are yellow, with a red heart-shaped spot, at the base of each, above which, in the three upper ones only, is a transverse red line. *Alton.*

6. **Z. coccineum.** Scarlet-flowered Bean-Caper. Linn. Sp. Pl. 551. Willd. n. 6. (Z. defertorum; Forlk. *Aegypt.-Arab.* 87. t. 12. 11. Fabago arabica terefifila, flore coccineo; Shaw Afric. n. 231. f. 231.)—Leaves conjuge, on a flathy flalk; leaflets cylindric, smooth. *Capsule* oblong.—Plentiful in the arid valleys of the desert, between Cairo and Szuez. The Arabs call this plant *Rottejel.* All kinds of cattle, even the camel, refuse to eat it. *Foukall.* The *flora* is shrubby, ascending, much branched, often a foot and a half high. *Leaflets* half or three-quarters of an inch long, obtuse, thick and succulent, quite smooth, supported in pairs on a club-shaped *follicle,* somewhat more in length. *Petals* red, pointed. *Capsule* near an inch long. The flake of the *capsule* and *leaflets,* not to mention the colour of the *flowers,* distinguishes this species from the following.

7. **Z. allum.** White Bean-Caper. Linn. Sp. Pl. 551. Mant. 379. Willd. n. 7. Ait. n. 5. Linn. fil. Dec. 1. t. 11. f. 6. Sm. Fl. Græc. Sitib. t. 371, unpublished. (Z. proliferum; Forlk. *Aegypt.-Arab.* 87. t. 12. f. A.)—Leaves conjuge, on a flathy flalk; leaflets obvate, downy and hoary. *Capsule* roundish, five-lobed. —Native of Egypt, Cyprus, Barbary, &c. *Foukall* found it very abundantly about Alexandria; and Desfontaines nearTripoli, as mentioned by Shaw. Mr. Maffon met with it in the Canary islands, and sent plants or seeds to Kew, in 1779, where this species is said to be kept in the dry flake, but not yet to have flowered. The *flora* is woody, diffuse, much branched, and very hoary. *Leaflets* opposite, or aggregate, being accompanied by axillary tufts of smaller ones. The *leaflets,* as well as their *follicles,* are thick, round, and juicy, both hoary, like the young branches, with fine, short, dense pubescence: the former are obovate, or almost globular, seldom a quarter of an inch long; the *follicle* twice as much, and club-shaped. *Flowers* a third of an inch broad. *Calyx* reddish. *Petals* white, obtuse, crenate. *Germes* roundish, depressed, downy, with five rounded lobes. *Capsule* of the same flake; its coat, according to *Foukall,* pulpy, and there are only two *seeds* in each cell. The *flam* is represented, in Mr. Ferdinand Bauer’s drawing, rather slightly notched, not simple, as described by the younger Linnaeus; but still lefs can we discern the five acute *flama,* mentioned in the *Manilla.*

fruitceens,
frutecens, portulacæ folio, Morgani lyorum, ex brevi pediculo binis; Pluk. Amathl. 173. t. 429. f. 4.)—Leaves conjugate, nearly sessile; leaflets obovate, flat, smooth. Stem shrubby. Capsule roundish, twined, five-lobed.—Native of the Cape of Good Hope. A green-house shrub in England, flowering most part of the summer.

The branches are somewhat quadrangular, very smooth. Leaflets an inch long, succulent, but not twined; their common fructifera very short, or altogether wanting. Stipulas in pairs, lanceolate, pointed, reflexed. Flower-flats the length of the leaves, unilateral, in pairs, declining. Flowers large, yellow, turning white in decay; their petals obovate, entire, broken with purple at the base. Nettaries jagged or fringed, as in n. 3, 4, and perhaps some other species. Capsule, as represented by Burmann, an inch in diameter, globose, with five large, rounded, prominent lobes. We find the petals uniformly five, and entire; Linnaeus says four, rarely five, and somewhat emarginate. There is reason to believe he confounded more than one species under the present. He has applied a specific name, which properly belongs to Z. Fabago.

A green-house shrub, flowering in July and August, which appears to have been known in our gardens for above a century. Its size is inferior to the last, from which, according to Dillenius and Burmann, this species is essentially differentiated by the fruit. The capsula is either exactly globular, or, as Dillenius says, deprest like a Dutch cheese, its diameter not half an inch, nor is it furrowed, nor parted into large tubar lobes, like Z. Morganiana. The leaves too are smaller, and more perfectly sessile. Linnaeus defines them “rough-edged,” which we can find nothing to countenance, even in his own specimen. The flowers are drooping, orange-coloured, turning white as they fade; the petals crenate at the end, not much spreading. The nettaries are smaller, and much less conspicuously jagged than in the preceding.

—Native of the Cape of Good Hope. Linnaeus latterly considered this as a variety of the last, but we cannot discover on what his opinion was founded, there being nothing in his herbarium to represent Z. fulvum. There is indeed a specimen, referred by him at one time to Z. Morganiana, and at another to coccineum, on which, having no affinity to the latter, we are led to suppose he wrote coccineum by accident for fulvum. In this the leaves have something of a common footstalk, though very short. The nettaries are long and jagged, as in Morganiana. There is unluckily no fruit. Burmann’s figure of the capsula is so precise, that, considering the analogy of other species, so well distinguished by this plant, we can have no hesitation in re-establishing Z. fulvum, as essentially differing from Z. frutecens, whether our specimen be what Linnaeus intended or not. The capsula of the real plant is above an inch long, with five acute angles, and as many deep intermediate channels, and terminates in a point, being equally unlike Z. frutecens on one hand, and Z. Morganiana on the other.

11. Z. sphenium. Spinous Bean-Caper. Linn. Sp. Pl. 552. Willd. n. 11. (Fabago tenuifolia sphenium, fructu rotundo; Burm. Afr. 5. t. 2. f. 2.)—Leaves conjugate, sessile; leaflets linear, flitchy, smooth, flat above. Stem shrubby. Permanent stipulas hooked, spinous.—Native of the Cape of Good Hope. The stem is bushy, shrubby, about a foot high, branched from top to bottom; the branches acutely quadrangular. Leaves numerous, flitchy like those of a Sedum; the leaflets acute, scarcely an inch long, blunt, with a small point; their underside convex, or hemispherical. Stipulas in pairs, small, lanceolate, spreading, at length becoming hardened, hooked, and pungent, so as to form two, three, or four prickles at every joint. Flowers drooping, large, and handsome, on longish, solitary, lateral stalks. Calyx reddish. Petals yellow, fading to white, nearly or quite entire. Nettaries entire, not fringed. Capsule, according to Burmann, “round, smooth, compressed, terminating in the very acute style.”

12. Z. microphyllum. Small-leaved Bean-Caper. Linn. Suppl. 232. Willd. n. 9. Thunb. Prodr. 80.—Leaves conjugate, somewhat stalked; leaflets inerwise heart-shaped, smooth. Stem shaggy, with ascending branches. Capsule roundish, abrupt, of five compressed lobes. Style permanent.—Gathered by Thuillberg, at the Cape of Good Hope. This is one of those hard, rigid, small-leaved, much branched shrubs, so characteristic of the botany of its native country. The branches are round, knotty, spreading, slightly hairy, or glaucous. Leaflets from one to three lines long, thick, oblique, sometimes obovate, but more frequently ovo-e Kampfer, so as to become inerwise heart-shaped; they are supported on a stalk, though short, thick, footstalk. Stipulas minute. Flower-flats thread-shaped, solitary, longer than the leaves, from the same buds. Flowers drooping, rather small, yellow. Calyx reflexed. Capsule the diameter of a pea, consisting of five rounded, vertical, compressed lobes, crowned with the fimbrius style, their surface rather reticulated; each of them bursts at the inner, as well as outer, edge into two elastic, or carunculose, valves, coated with a thin skin.

13. Z. retrostratum. Recurved Bean-Caper. Thunb. Prodr. 80.—Leaves conjugate, stalked; leaflets obovate, smooth. Stem shrubby, with spreading recurved branches. Flower-flats shorter than the leaves.—Gathered at the Cape of Good Hope, by professor Thuillberg, from whom we have a specimen. His short specific character was Willdenow’s only guide, when the latter reduced this plant to Z. fuditum, to which it has no affinity, and very little resemblance. The present, though a very distinct species, is most allied to Z. microphyllum, but the long, spreading, deflexed branches afford a characteristic difference of habit. The leaflets too are smaller, and seem to be always obovate, not cordate. Flowers very small, their little thick flanks hardly so long as the calyx. Nettaries lanceolate, entire. Germen, after the other parts of the flower are fallen, elliptic-oblong, deeply five-lobed, acute, crowned with the style; but we have none in an advanced state, to enable us to judge whether the lobes ever extend into a rounded semi-oriabicular shape, like the latic, as may very probably be the case.

14. Z. squamosa. Surinam Bean-Caper. Linn. Sp. Pl. 552. Willd. n. 12.—Leaves conjugate, sessile; leaflets obovate, abrupt. Stem herbaeeus, diffuse. Stipulas five at each joint.—Gathered in Surinam by Rolander, who sent seeds to Linnaeus; but the plants raised from them died.
died without flowering. The fl\em{}s are a foot long, smooth, roundish, except a flatness on the upper side. Leaves opposite, without veins. *Stipula\* reflexed; two between each pair of leaves, at the uppermost side of the fl\em{}; one between the same pair, on the lower side; one between the leaflets of each leaf. *Linnaeus.* This last seems to answer to the little point, or rudiment of a leaflet, which occurs in several others of the broad-leaved species.

15. Z. ? lanatum. Woolly-jointed Bean-Caper. Willd. n. 13.—"Leaves ternate; leaflets papillary beneath. Styles five. Stem zigzag, woolly at the joints."—Native of Sierra Leone. A plant of a doubtful genus, seen by the above author in a dried state only. The fl\em{}m appears herbaceous, round and smooth, except the joints, which are remarkably woolly. Leaves opposite, small, on footstalks. Leaflets three, on very short partial footstalks, roundish, tapering at the base, pointed at the end; smooth on the upper side; befet underneath with prominent points. Flower-stalks axillary, solitary, single-flowered, erect; drooping after flowering. Calyx of five linear, obtuse leaves; downy on the inside, and at the edges. Corolla not pre"m; perhaps fallen. Filaments but little dilated at the base. German club-shaped. Styles five, long, and thread-shaped. Stigmas obtuse. Capsule ovate, with five angles, five cells, and five valves with keel-like edges, bursting at the base. Seeds solitary. Wildenow. The ternate leaves afford a strong presumption against this being a *Zygophyllum*, and the want, as it seems, of *nolariet*, with the five *fiyes", decide the question, in our judgment. Not having seen the plant, we leave it here for further inquiry.

16. Z. orbiculare. Tree Bean-Caper. Jacq. Amer. t. 82. Linn. Sp. Pl. 1673. Willd. n. 14.—Leaves abruptly pinnate. Stem arborescent.—Native of South America. Found by Jacquin, in uncultivated valleys about Carthagena, as well as in woods on the sandy sea-shore, flowering in July. A very handsome tree, forty feet high; the trunk being about six feet; the head dense, widely spreading, and extremely ornamental; the branches opposite, or forked. Leaves very numerous, opposite, four inches long, of about seven pair, without a terminal one, of alternate, sessile, elliptic-oblong, obtuse, entire, smooth, shining leaflets, an inch or more in length. Clusters axillary and terminal, shorter than the leaves, compound, lax, generally forked. Flowers large and handsome, without scent. Calyx yellowish-green, smooth. Petals orange-coloured, roundish, emarginate; their claws as long as the calyx. Nectary fringed; its scales gradually larger towards the upper side of the flower. Stamens erect, convinging. German tapering at the base, into a long, thick, five-"urrowed stalk. Capsule with five large membranous lobes. When this blossoms this tree affords a most magnificent spectacle, from the innumerable flowers, covering the bright green leafy head. Before the inflorescence appears, the leaves might incautiously be supposed doubly pinnate. The inhabitants give the name of *Gwy-"acon* to this tree, which is a general appellation for all kinds of hard wood that is useful for cabinet or other work. The trunk is reported to become changed into stone by lying in the earth, being inexcusable of consumption. Jacquin.

*Zygophyllum* in *Gardening*, comprises plants of the herbaceous and woody succulent exotic kind, among which the species are, the common bean-caper (*Z. Fabago*), the African bean-caper (*Z. fel"liolatum*), the purplish-leaved Ethiopian bean-caper (*Z. Morgana*), the thorny bean-caper (*Z. *pinolatum*), and the white Egyptian bean-caper (*Z. album*).

The first has a deep fl\em{}thy, and soft herbaceous stalks, which decay in the winter.

The second is of a shrubby growth, and there are varieties, with yellow-flowers, with sulphur-coloured flowers, with white flowers, with copper-coloured flowers, having mostly a reddish or brown spot near the base of each petal.

The third has also a shrubby fl\em{}m, and there is a variety with flame-yellow-coloured flowers.

And the fourth has an under shrubby growth. *Method of Culture.*—The first fort is raised from seeds, which should be sown in the spring in pots filled with light sandy mould, or on a hot-bed. When the plants have a few inches growth, they should be removed into separate pots, plunging them into a hot-bed, admitting air so as gradually to harden them to the open ground. They should be protected for a winter or two, and then be turned out into borders, or other places, where the situation is warm, and the foil dry and rubbishy, as they are of a succulent nature.

The other forts are capable of being increased by cuttings and seeds; the cuttings should be planted out in the spring or summer in pots filled with light sandy mould, and plunged in a hot-bed, being occasionally watered, when they quickly emit roots, and shoot at top; and when in the summer months, they may be planted in a shady place, or in pots placed in the shade, giving frequent waterings, when they will also take good root. In either method, they should be potted off separately, towards autumn, in order to be moved into the green-house or glass-case in the beginning of autumn.

The seed should be sown in the spring in pots of light earth, and be plunged in a hot-bed, where they soon come up: when a little advanced in growth, they should be pricked out in separate small pots, being watered and re-plunged into the hot-bed till well-rooted, when they should be gradually hardened to the full air, and in June let out to remain till the autumn, when they should be placed in the green-house, or some other place, where they may have protection for the winter.

The first fort affords variety in the borders, as well as among other potted plants; and the others in collections of the green-house kind. *Zygopolis* in *Ancient Geography*, a town of Asia, in the Colchide, near the town of *Trapezunte*.

*Zygostates*, among the *Ancients*, an officer who was the overseer of weights, and was to take care that the tradesmen used none but what were just.

*Zygiris*, in *Ancient Geography*, a town on the coast of the name of Libya; and *Zygiria* are the people who inhabit this name.

*Zymar*, a name given by some of the chemical writers to verdigris.

*Zyme*, a word used by many authors to express fermentation or leaven.
trine of fermentation, established on this basis. Symphon's
Zymol. Chym.
ZYMOSIMETER, formed from ζυμοσίμη, fermentation,
and μέτρον, measure, an instrument proposed by Swammer-
dam, in his book "De Respiratione," whereby to measure
the degree of fermentation occasioned by the mixture of
different matters; and the degree of heat which those
matters acquire in fermenting; as also the heat, or tem-
perament, of the blood of animals.
ZYMOSIS, a word used by some to express
fermentation, and by others for a flatulent tumour of the liver,
or other of the viscera.
ZYMUM, in Botany, apparently from ζύμος, a ferment,
a name which, De Theis says, is given to a plant of the
Mauritius, by Noröna, a Spanish botanist, but without any
explanation of its meaning, or application. This name is,
nevertheless, retained by Aubert du Petit-Thouars, in his
Plantes des Isles d'Afrique, t. 4.
ZYORY, in Geography. See SOMRAU.
ZYPE, a kind of island of North Holland, formed by
canals cut from the Zuyder Zee to the German ocean. It
was formerly a moorish, but is now converted into rich
meadow land. On this spot the duke of York was poished,
when he made terms with the French general Brune to
evacuate Holland; having it in his power, by taking up
the sluices, to inundate the country.
ZYRAS, in Ancient Geography, a river of Thrace, which
watered the town of Dionysopolis. Pliny.
ZYRMA, a town of Thrace, near which ran the river
Hebrus. Ptolemy.
ZYTHOGALA, formed of ζύθος, cerevisia, and μάκα, lac, beer posset, a drink recommended by Sydenham, as good
to be taken after a vomit, for allaying the acrimonious and
disagreeable taste it has occasioned, as well as to prevent
ZYTHUM, or Zythos, a fort of malt liquor, in use
among the ancient Germans.
Matthiolus represents the ancient zythum, and curmi, as
the same with our beer and ale.
ZYTOPIERS, in Geography, a town and fortrefs of
Russian Poland; 65 miles W. of Kiev. N. lat. 50° 16'.
E. long. 28° 54'.

A, B, C, DARIA, in Botany, a name given by Rumphius, Herb. Amboin. v. 6. 145. t. 65, to the Verbena Aemella of Linnaeus, see Spilanthes, n. 3. The above appellation is designed to express the use made of this plant by the black school-masters at Amboyna, who cause their young pupils to chew the flowers or the root, either alone or with Betle-nut, in order that they may more easily pronounce some of the difficult Arabic letters, such as Tseba and Zs, both which they commonly confound with S. The Malay name, Daun murit, School-boy's herb, given to this Spilanthes, as well as to Bidens pilosa of Linnaeus, has the same allusion. Such plants agree with Pollitory of Spain, Anthemis Pyrethrum, in a peculiar property of stimulating the mouth, accompanied by a fene of coolness, and a slight saline taste, all which together cause a great flow of saliva. Hence they are beneficial in tooth-ache arising from cold rhum, but the slight numbness and tingling of the nerves, which attend their use, should seem rather unfavourable to precise enunciation. The recent flowers of Spilanthes oleracea, slightly rubbed upon the gums, are perhaps the best of the whole tribe for producing the above effects.

ABDALLAH, Ebn-Zobeir, l. 4, Heg. 63.

ABDAS, in Biography, a Perian bishop of the fifth century, who deferves to be exhibited in the page of history as a cautionary example of the folly of supporting any cause by perpecution. Having destroyed a pagan temple belonging to the worshippers of fire, the king of Persia, intitated by the Magi, ordered him to rebuild it at his own charge; but as he refused to comply with this order, a dreadful perpecution was commenced against the Chriftians, which lasted 30 years; and in this perpecution Abdas loft his life. Bayle.

ABELICEA, in Botany, 'Aslanis in modern Greek, fee our ninth species of Ulmus.

ABERARON, in Geography, a small town and port of Cardiganshire, much frequented by small coasting-vessels, which convey the corn and other produce of the district to the
the English markets. The harbour has been lately much improved by the construction of a pier. A market has been lately established here.

ABERMOA, in Botany, altered by Aublet from the Caribbean appellation of the same plant, Aubl. Guian. 610. t. 245; see QUATTERIA, under that. ABERPORTF, in Geography, a little fishing-town of Cardiganshire, pleasantly situated at the entrance of the river which flows by Blenport. The craft belonging to this port are chiefly employed in bringing lime-flour from Pembroke-shire and other parts, which are burnt here, to supply the neighbourhood with manure, and for other purposes.

ABILDGARDIA, in Botany, a genus of Professor Vahl's, dedicated by him to the memory of the late Peter Christoffer Abildgaard, a native of Denmark, formerly professor of the veterinary art, who contributed much information to Professor Retzolli on the subject of Gracilis. Mr. Brown retains this genus, not without a hint of its too near affinity to Fimbriulx; see that article. We trust the barbarism of the double a may be dispensed with, and we have ventured to make that alteration.—Vahl Enum. v. 195. Brown Prod. Nov. Holl. v. 1. 229.—Clafs and order, Triandra Monogynia. Nat. Ord. Calamaries, Linn. Cyperoideae, Juss. Cyperaceas, Brown.

Gen. Ch. Cal. a single scale to each flower, ovate, pointed, concave, compressed, forming a spike, imperfectly two-ranked. Cor. none. Stam. Filaments three, rarely but one, inserted beneath the germin, gradually elongated by age, anthers linear, longer than the filaments. Pijl. Germin superior, acutely triangular, rather contracted at the summit; style bulbous and pyramidal at the base, the bulb triangular, broader than the germin, permanent, the upper part bristle-shaped, deciduous; stigmas three, shorter than the style. Peric. none. Seed one, snow-white, nearly pear-shaped, with three angles, contracted at the base, crowned at the summit with the pointed base of the style, convex at the sides, and rough, with minute dots, without any surrounding bristles. Rest. thread-shaped, gradually elongated, minutely cellular, dotted with brown, the edges of the cells membranous, from the permanent bases of the scales.

The flims of this genus are angular, slender, without joints; leafy at the bottom. Leaves narrow, channelled, sheathing. Spikes ovate-oblong, acute, compressed, often twisted; their scales closely imbricated, keeled, very smooth and polished, white, dotted with purple, the green keel of each elongated into a little point; the two lowermost narrower than the rest.—Vahl. Brown.

Mr. Brown remarks, that the style is certainly deciduous, and the spike, when in seed, by no means perfectly two-ranked; circumstancies which bring the present genus very near to Fimbriulx. The following are the only described species.

1. A. moniliflora. Single-spiked Abildgardia. Vahl n. 1. Br. n. 1. (Cyperus moniliflorus; Linn. Mant. 180. Wildl. Sp. Pl. v. 1. 271. Swartz Obs. 29. Retz. Bot. Gram. 18. t. 13. f. 3.) Gramen cyperoides minimum, epica simplici compaBata, radice tuberfus odorata; Sloane Jam. v. 1. 120. t. 79. f. 2.—Spike solitary. Scales uniform, nearly all fertile.—Gathered, by Konig, in shady situations in the East Indies; in the pastures, and sea marhes, of Jamaica and Hiphania, by Sloane and Swartz; and in the tropical part of New Holland, as well as at Port Jackson, by Mr. R. Brown. The root appears to be perennial, with many long simple fibres. Herb slender, smooth and glaucous, forming tufts, about a foot high, with linear, very narrow, leaves, which sometimes break off, as Vahl remarks, at a foot or shorn, below the middle of each. Stem simple, slender, angular, and striated, taller than the leaves. Spike half an inch long, two-ranked, subtended by a linear-rounded leaf, sometimes, in the Linnaean specimen, exceeding its own length. The glumes, or scales, have a green keel, accompanied by two white ribs, next to which is an affablage of purple dots, the rest being cream-coloured. Two or three of the lower glumes are small, and apparently barren. There is said to be but one flower to each flower. Sloane's synonym seems to us, doubtful.

2. A. fesuoides. Ruby Abildgardia. Br. n. 2. — "Spike solitary, naked. Outer scales shorter and barren; terminal ones narrower, with spreading points."—Gathered by Mr. Brown, in the tropical part of New Holland. We have seen no specimen of this or the next.

3. A. vaginata. Sheathing Abildgardia. Br. n. 3. — "Spikes about three together; the middle one sessile. Scales pointed. Stem bristle-shaped, angular, hairy; sheathed at the base."—Found by Mr. Brown, in the tropical part of New Holland.

4. A. trifidus. Three-spiked leafy Abildgardia. Vahl n. 2. (Cyperus triflorus; Linn. Mant. 180. Wildl. Sp. Pl. v. 1. 272. Schoenus cyperoides; Retz. Obs. f. 4.) —Spikes about three together; the middle one sessile. Stem semi-cylindrical; round, bulbous, and leafy, at the base. Native of the East Indies, in hard dry ground. König. The flims are from one to two feet high, rough and rigid, erect; according to Vahl, bulbous at the bottom, and wrapped with dry brown sheaths among the foliage. The leaves are smooth, channelled, not so tall as the stem. Spikes two, three, or four, twice the size of the first species, tumid, ovate, acute, twisted, of a dirty but polished white; three of them generally springing from one short leafy sheath, the two lateral ones elevated on long, flattened, striated, smooth stalks. Stamin three; Vahl. Stigmas long and downy.

ABINGTON, in Geography, a town of Massachusettts, in Plymouth county, containing 1704 inhabitants.—Also, a township of Pennsylvania, in Montgomery county, having 1256 inhabitants.—Also, a township of Pennsylvania, in Luzerne county, having 511 inhabitants.

ABUCCO. Subjoin, See Weight.
ABUSCHÆHR. See BUSHEER.

ABUTA, in Botany, a Brazilian name, first published by Darrere, adopted by Aublet, and recently by De Candolle, as well as Jussieu. It may remain for the present, till the characters of the genus are known. These are hitherto involved in great uncertainty, the flowers not having been observed by any botanist.—Barr. Hist. Nat. de la France Equinoxiale, t. Aubl. Guian. 618. Joff. 286. De Cand. Syll. v. t. 542.—Clas and order. Dioscia Dodecatandra? (Polyandria Polynychia, Aubl.) Nat. Ord. Menispernum, Joff.

Eff. Ch. Male, unknown.

Female, P.l. unknown. Berries two or three, ovate, somewhat compressed, dry, single-seeded.

Diamarck and Willdenow have considered this genus as not distinct from Menispernum, see that article; but Professor De Candolle reckons the large, dry, ovate, not kidney-shaped, berries, to be armed, because of the brittle shell of their seed, as affording a sufficient character, even without the flowers. He is more inclined to refer Abuta to his own genus of Coeculus, separated by him from Menispernum; but their habits are somewhat different. Two species of Abuta are defined by this writer, but A. amara of Aublet, Guian. 620. t. 251, is referred, on the authority of Richard, to Arjiblochia. These are large twining thorns, with ovate leaves, whose pinnate ribs spring nearly from one point at the base.

1. A. rupestris. Reddish Abuta, or Falce Pareira-brava. Aubl. Guian. 618. t. 252. De Cand. n. 1. (A. bancans, amplissimo folio cordiformi, futbas tomento.) Barr. Fr. Equin. 1. Menispernum Abuta ; Lamark Dict. v. 4. 100. Willd. Sp. Pl. v. 4. 828..—Leaves ovate, acute, entire; downy beneath.—Native of woods in Brazil, Cayenne, and Guiana. Aublet found it in almost every forest of the last-mentioned country, which he examined, bearing fruit in January. The Portuguese confound this plant with the true Cissampelos Pareira, and considers its root of equal efficacy in jaundice, disorders of the kidneys and bladder; as well as internal abscences, and menstrual suppurations.

The climbing stems, and downy branches, reach to the tops of trees, and bear large, alternate, thalched, coriaceous, veiny, entire leaves, from four inches to a foot long; smooth above; covered beneath with prominent, reticulated, downy veins, springing copiously from five principal ribs, which radiate from near the base of the leaf. The pods or capsules are about half the length of the leaves, round, finely and dexterously downy. Berries elliptical, downy, an inch long, three upon each receptacle, and forming large axillary branches. There is said to be a variety whose wood is hard, as well as the pabuescence of the foliage, is reddish. The Creoles make a decoction of the branches of the red and white varieties indifferently, to cure obstructions of the liver, to which they are very subject. Aublet.

2. A. candidans. Whitish-leaved Abuta. De Cand. n. 2. Richard MSS.—"Leaves ovate, pointed, somewhat crenate, or minutely lobed; smooth and whitish beneath."—Gathered in Cayenne by M. Richard, who unfortunately did not meet with the flowers. The branches are round and smooth. Pods four inches long, round and smooth likewise. Leaves five to seven inches long, three or four broad, nearly entire, or slightly crisped, or toothed, in the margin; even and smooth above; pale or nearly white underneath, but, as it dries, quite smooth; the ribs pinnate, the two lower lateral ones close together. The inhabitants of Cayenne call this plant Liene amera, Bitter Vine. De Candolle.

ABYSSINIAN MUSIC. See MUSIC.

ACACIA, in Botany, an ancient Greek name, derived from αεκς, to point or sharpen, in reference to its thorny habit. De Thesius deduces all words of this etymology from the Celtic, et, a point. The name of Dioscorides, book i. chap. 135, was a fort of Egyptian thorn, "of a diffuse and spreading mode of growth, with a white flower, and a pod resembling lupines." Its expressed juice, dried in the shade, was an astringent medicine much in use, and the shrub yielded also a clear white gum. This may very well have been a plant of the present genus. Willdenow, who established this genus, first separated it from the Linnean Mimosa (see that article), which has become inconveniently numerous in species, and unprofitably is capable of division by the characters of the fruit, of which Willdenow has very well taken advantage. He leaves in Mimosa such species as have a longatus, or legume separating into single-seeded joints. Of these he defines 32, having a five-toothed corolla, and only eight flaments; and to many of them, being sensitive, the name Mimosa is properly appropriated. For his other genera taken from hence, see Desmanthus, Inga, and Schrankia. We must observe however that the Acacia of Tournfort is not analogous to what is now before us.—Willd. Sp. Pl. v. 4. 1049. Ait. Hort. Kew. v. 5. 459. Pursh 305.

Obv. The flowers, sometimes four-cleft, have, in some instances, a corolla which separates into four or five distinct petals. We have not had an opportunity of examining a sufficient number of species to give a full generic character. Willdenow reckons up 102, in seven sections; to which Mr. Brown has made numerous additions from New Holland, partly described in Ait. Hort. Kew. above cited. We shall give some examples of each section.

Seft. 1. Leaves simple. Sixteen species in Willdenow, to which ten are here added, nine of them from Hort. Kew.—Of this singular tribe, first discovered by our British circumnavigators, all the species, as far as hitherto known, bear, in a feeding state, compound pinnate leaves, soon replaced by leafy or spiny single-footed thistles, which latter confute the only foliage of the adult plant. There are no proper thorns or prickles in these. Their leaf is thorny, or arborescent, as well as throughout the whole genus. We have slightly adverted to this section at the end of our article Mimosa.

A. verticillata. Whorl-leaved Acacia. Willd. n. 1. Ait. n. 1. (Mimosa verticillata; L'Herit. Sert. Angl. 30. Curt. Mag. t. 110. Venten. Malmaif. t. 63.)—Leaves whorled, linear-awl-shaped, rigid, spiny-pointed. Spikes solitary, cylindrical.—Gathered in Van Diemen's island, by the late Mr. David Nelso, who sent seeds to Sir Joseph Banks in 1780. Hence this singular shrub became known in the English green-houses, where it flowers in the spring, and ripens seed. The first two or three leaves of feeding plants are compound and pinnate, with elliptical obtuse entire leaflets: the leaf is accurately whorled, simple, pungent, flat-topped thorns rather than leaves, fix or eight in each whorl, about half an inch long, somewhat unequal, spreading horizontally. Flowers in dense, yellow, thick, obtuse simple, slender, axillary thistles, but there are sometimes two or more of these thistles together. Legume linear, compressed, corrugated, of one cell with several kidney-shaped seeds.

A. juniperina. Juniper-leaved Acacia. Willd. n. 2. Ait. n. 2. (Mimosa juniperina; Venten. Malmaif. t. 64. "M. ulicifolia;
ACACIA.

"M. ulicifolia; Wendl. Coll. 25. t. 6." Willd. — Leaves imperfectly whorled, linear-awl-shaped, rigid, spinous-pointed. Spikes solitary, globose.—Found near Port Jackson, New South Wales, from whence Mr Joseph Banks is said to have received seeds about the year 1790. We have specimens from Dr. White. This differs from the foregoing in having its spinous leaves more crowded, and less distinctly whorled, more hairy branches, and globular heads of flowers, each flower, according to Ventenat, accompanied by a little ovate, pointed, flaked bractea.

A. acicularis. Needle-leaved Acacia. Brown in Ait. n. 3.—"Leaves scattered, roundish-awl-shaped, pointed, rigid. Stipules deciduous. Young branches smooth. Spikes solitary, globose."—Said to have been found in New South Wales, by colonel William Paterson, from whence it was sent to Kew in 1796. It flowers at the same season as the two preceding, and requires the same treatment. If we understand this species aright, the leaves are full an inch long, being twice the length of the two foregoing, and more slender. We received specimens answering to this description before 1796, from Dr. White.

A. flava. Furrowed Needle Acacia. Brown in Ait. n. 4.—"Leaves thread-shaped, furrowed on all sides, with a hairless point. Heads of flowers usually in pairs. Bracteas ovate, concave, permanent, at the base of the flower-fallk. Legumes ovate.—Observed by Mr. Brown on the south-west coast of New Holland, from whence it was introduced, in 1803, by Mr. Peter Good. This is likewise a green-hoe shrub, flowering from May to August.

—Native of New South Wales. Cultivated, before 1790, by Mr. Thomas Hoy, in Sion gardens. A green-hoe shrub, flowering in the spring. The acute edges of the branches are bright red. The first leaves are conjugate, pinnate, with thick elliptical leaves, and a lanceolate common footstalk; the leaf alternate, narrow, coriaceous, four or five inches long, rather glaucous, smooth, thick-edged. Flowers simply racemose, yellowish-white, fragrant, their corolla deeply four-lobed. Stamens very numerous. Legume elliptical, an inch and a half or two inches long, and one inch broad, finely glaucous.

—Native of New South Wales, from whence for Joseph Banks is recorded to have received seeds in 1790. This requires the same treatment, and flowers at the same time, as the last, from which its capitate five-cleft flowers, and more dilated rounded-pointed leaves, at once distinguishes it. Dr. Sims, in Curtis's Magazine, under this species, has given but too just reasons for retaining the genus Mimosa entire for the present, which principally refer to our ignorance of their fruit in a number of instances. Our learned friend, however, has since conceived to the new arrangement; and we think, with Willdenow, that enough is known for us to venture on the division this author has proposed, which may generally be supported by analogy, if not by absolute demonstration.

A. melanoxylon. Black-wooded Acacia. Brown in Ait. n. 12. Curt. Mag. t. 1659.—Leaves elliptic-lanceolate, many-rribbed, slightly falcate. Spikes globose, in short clusters. Flower-stalks and young branches angular, powdery. "Umbilical cord and pollen, plant, nearly surrounding the seed."—Found by Mr. Brown in Van Diemen's island. From him we adopt the singular character of the umbilical cord. This is a considerable tree, raised by John Walker, eqq. of Arno's Grove, Southgate, who received the seeds under the name of Black-wood, about the year 1808. The young twigs are covered with rusty mealinefs. Leaves flaked, three inches long, and one broad, slightly glaucous, usually five-rribbed. Flowers pale-yellow, their globular spikes disposed in short axillary clusters, about twice the length of each footstalk. We have no account of the legume.

A. Sophore. Sophore-podded Acacia. Br. in Ait. n. 13. (Mimosa Sophore; Labill. Nov. Holl. v. 2. 87. t. 237.)—Leaves oblong-ovate, equilatorial, many-rribbed. Spikes cylindrical, axillary, in pairs. Petals four. Legumes linear, curved, pointed. Umbilical cord plain.—Found by Labillardiere, as well as by Mr. Brown, in Van Diemen's island. Its seeds were brought by the latter to Kew Garden, and raised there in 1805, but the plants have not yet bloomed. The young leaves are represented by Labillardiere as pinnate and trijugate; the rote oblate, two or three inches long. Spikes nearly sessile, hardly an inch long, and very slender. Flowers small. Legumes five or six inches in length, tupid, and twisted, a quarter of an inch broad. Each seed is subtended by a cup-like tunic, which we presume is the umbilical cord of Mr. Brown.

A. marginata. Marginate-leaved Acacia. Br. in Ait. n. 14.—"Leaves oblong-lanceolate, rather falcate, bordered, fingle-rribbed; their anterior edge somewhat narrowed, with a solitary gland. Heads about four-flowered, difposed in clusters."—Observed by Mr. Brown on the south-west coast of New Holland, from whence seeds were sent in 1803, by Mr. Peter Good. A green-hoe shrub, flowering from April to June. Aiton.

A. myrtifolia. Myrt-leaved Acacia. Wild. n. 15. Ait. n. 15. (Mimosa myrtilfolia; Sm. Tr. of Linn. Soc. v. 1. 253. Bot. of New Holl. 51. t. 15. Curt. Mag. t. 502.)—Leaves elliptic-lanceolate, oblique, thick-edged, fingle-rribbed, with a solitary gland at their anterior margin. Heads of flowers clustered, aggregate.—Native of New South Wales. Raised by Mr. Thomas Hoy, before the year 1789. A green-hoe shrub, flowering from February to May, or late in autumn. The stem is three or four feet high, with angular branches. First leaves conjugate, pinnate; the leaf about two inches long, broadly lanceolate, pointed, very rigid, somewhat glaucous, often wavy, smooth. Flowers pale yellow, fragrant, three or four in each round head, the heads disposed variously in somewhat compound axillary clusters, nearly equal in length to the leaves. Legume linear, curved, tupid, with very thick edges.

A. hirispicula. Little harfh Acacia. Wild. n. 16. Ait. n. 16. (Mimosa hirispicula; Sm. Bot. of New Holl. 53. t. 16.)—Leaves elliptical, acute, oblique, minutely toothed, rough on each fide and at the margin. Young branches harfh. Flowers four-cleft, in solitary axillary heads.—Native of New South Wales, from whence specimens were sent to us, with coloured drawings, in 1794, and seeds about the same time to Mr Joseph Banks. The roughness of the foliage and branches is very remarkable, caused by short, rigid, prominent hairs, or points. The leaves are sessile, an inch broad, acuminate, or obtuse, sometimes toothed, deep-green. Heads flaked, globose, many-flowered. Legume thick-edged, elliptic-oblong, sometimes with one or two contractions. Seeds few.

A. laflulata.
ACACIA.

A. hysalata. Little Halberd-leaved Acacia.—Leaves deltoid, spinous-pointed, roughish; their upper angle glandular. Stipulas bristle-shaped, permanent. Branches rough. Flowers in solitary axillary heads.—Gathered near King George's fort, on the south-west coast of New Holland, by Mr. Menzies, to whom we are obliged for a specimen. This remarkable new species is evidently allied to the two last-mentioned, though abundantly distinct from both. The shrubby flow bears numerous, erect, round, rough, wand-like branches, beft with innumerable, spreading, vertical leaves, about a quarter of an inch long, fingle-ribbed, unequally deltoid, with an elongated spinous point, thick-edged, rough with minute points; their lower angle either rounded or somewhat toothed; the upper more prominent, and tipped with a gland. Stipular fender, erect, in pairs at the base of each leaf. Flowers three or four in each of the little ftalked heads, which are very numerous all along the branches.

A. decipiens. Paradadoxical Acacia. Br. in Ait. n. 17. Curt. Mag. t. 1745. (Mimosa decipiens; König in Ann. of Bot. v. t. 366. t. 8. Adiantum truncaturn; Burm. Ind. 235. t. 66. f. 4. Linn. Syt. Veg. ed. 13. 790.)—Leaves triangular-wedge-shaped, spinous-pointed, smooth; their upper angle glandular. Stipulas bristle-shaped, deciduous. Branches smooth. Flowers in solitary axillary heads.—Gathered by Mr. Menzies on the south-west coast of New Holland, and not on the west side of North America, as mentioned in the Annals of Botany. Seeds were sent to Kew in 1803, by Mr. Good, and the plant is marked by Mr. Alton as a green-house shrub, flowering from March to June. Its history is certainly curious; for specimens without flowers having been taken by Prof. Burmann, who miled Linn. mature, for an Adiantum, which error was detected by the late Mr. Dryander, on perusing Mr. Menzies's specimens. Those of Burmann were reported to have come from Java, in which there may be a further mistake. At any rate this plant is nearly related to our last-described, and grows in the same country. The leaves differ in being larger, half an inch to an inch long, erect, and differently shaped, their inner, or upper, glandular angle being greatly extended, while the lower or rounded angle, seen in A. hysalata, is wanting. The flowers are more numerous, from feven to ten, in each round head.

A. biflora. Two-flowered Acacia. Br. in Ait. n. 18.—Leaves triangular; the outer angle spinous; inner glandular. Stipulas bristle-shaped and spinous, permanent. Young branches downy. Heads two-flowered.—Observed by Mr. Brown, on the fourt-coast of New Holland, from whence it was sent to Kew by Mr. Good, in 1803. A green-house shrub, flowering from March to June. We have seen no specimen.

A. alata. Wing-ftalked Acacia. Br. in Ait. n. 20.—Leaves oblong, winged. The winged parts are folded in a manner so as to cover the surface of the leaf, which is of a yellowish green color. Flowers yellow, numerous.

Sect. 2. Leaves conjugate, pinnate. Seven species in Willdenow, to which one of Mr. Brown's is to be added from Hort. Kew. The Prodromus of this able author, when completed, will probably furnish more New Holland species to this section.

A. xylocarpa. Wooden-fruited Acacia. Wild. n. 17. (Mimosa xylocarpa; Roxb. Corom. v. t. 68. t. 100.)—Leaves conjugate, pinnate; leaflets four pair, ovate-oblong, acute. Heads globose, many-flowered, lateral, ftalked, in pairs.—Native of the mountainous parts of the Circuns of Hindooflan, calling its leaves during the cold feafon, and flowering when the hot weather begins. This is one of the largest trees of this genus or any of its allies; the timber very hard, of a chocolate colour towards the centre, and much esteemed for purposes where hardness, toughness, and durability, are requifite, as in ploughs, the natives seldom using iron in that implement. The leaves are large, smooth, paller beneath, confiding of two divisions, or wings, and thole of four pair of leaflets each, except that the innermost leaflet on each fide, at the bottom, is wanting; the lower leaflets are about two inches long; the upper four or five. Heads of flowers whithit, the fize of a cherry, on fimple ftalks, two or three inches in length. Corolla bell-shaped, five-fleft. Stamina ten. Legume only one from each head, ovate, com- preffed, very large and woody, three or four inches long, the ftalk becoming neccessarily greatly thickened. Seeds about ten, oval, ranged near the lower edge, as large as kidney-beans.

A. paludella. Zigzag Spiny Acacia. Br. in Ait. n. 22.—Leaves conjugate, pinnate, with a ftalked gland between the wings, each of which has from five to seven pair of leaflets. Stipulas spinous, nearly equal to the leaves. Heads foliary. Branches zigzag.—Observed by Mr. Brown, on the fourt-coast of New Holland, from whence seeds were sent to Kew, in 1803, by Mr. Good. A green-house shrub, flowering from April to July.

Sect. 3. Leaves doubly pinnate. Stem without thorns. Spikes oblong. Eleven species in Willdenow, the laft of which, A. Houfionii, we shall remove to the following fcction.

A. muricata. Warty Acacia. Wild. n. 25. (A. lati- folia alopecuroides, flure albo; Plum. Ic. 6. t. 11. Mimosa muricata; Linn. Sp. Pl. 1504.)—Thorns none. Leaves doubly pinnate; firt division of five pair; fcon of many pair; leaflets abrupt. Spikes axillary, aggregate, nearly cylindrical. Branches warty.—Gathered in South America, or the West Indies, by Plumer, whole figure is the only authority for this fcpecies. The branches are round, and warty, as well as the lower part of the flower-flets, which leaf are evidently axillary, not, as Willdenow fays, terminal. They are longer than the large compound leaves, and bear four or five alternate dense fikes, on partial flets. Leaf- fets numerous, crowded, elliptical, veiny, emarginate, about a half or three-quarters of an inch long. Flowers numerous, very small. Legumes ferveral, spreading, four or five inches in length, linear, flat, veiny, wavy at the edges, with many oval flat feds.

A. pallida. Pale South-American Acacia. Wild. n. 26.—Thorns none. Leaves doubly pinnate; firt division of two pair; fcon of twelve pair; leaflets linear, obtufe, downy. Spikes thread-shaped, much longer than the leaves.—Gathered by Humboldt and Bonpland, in South America. Branches round, warty, divaricated. Leaflets obtuse at each end, sometimes but ten pair; clothed sparingly on the upper fide, more denser on the under, with line pubefcence; the edges fringed. There is a cup-shaped fefile gland between the fepart divisions of each leaf (indications of which appear likewife in Plumer's plate of the foregoing).
Footstalks hairy. Spikes axillary, solitary, three or four inches long, being thrice the length of the leaves. Flowers opposite, of five petals. *Wildenow.*

This seems much allied to the last, but the shape and downiness of the leaflets, and the solitary spikes, indicate a sufficient difference.

A. angustifolia. Sand Acacia. *Wildl.* n. 29.—Thorns none. Leaves doubly pinnate; first division of six pair; second of sixteen pair; leaflets linear, acute. Spikes thread-shaped, in pairs. —Found by Mr. Bredemeyer at the Cannebas, among the sandy banks of rivers. A shrub ten or twelve feet high, with angular downy branches. Leaflets fringed, from sixteen to twenty-four pair. Footstalks clothed with hoary down; the partial ones accompanied by an acute intermediate gland. Spike axillary, measuring three or four inches, generally rather longer than the leaves. Flowers opposite, white, fragrant. Calyxes with four or five teeth. Corolla in four or five deep segments. Stomens twice as many, and thrice as long. *Wildenow.*

A. guianensis. Guiana Acacia. *Wildl.* n. 32. *Ait.* n. 25. (Mimofa guianensis; *Aubl.* Guiana 128. t. 357.)—Thorns none. Leaves doubly pinnate, each division of about ten pair; leaflets elliptical, obtuse. Common footstalk with a convex gland. Spikes thread-shaped, axillary. —Observed by Aublet in Cayenne and Guiana, flowering in November, and bearing ripe seeds in January and February. This is a large tree, whole trunk, thirty or forty feet high, is a foot or more in diameter, with a smooth grey bark, and white brittle wood; the branches widely spreading. Leaflets elliptical, about half an inch long. The first divisions of the leaves are sometimes not more than seven or eight. Stipulas rounded, deciduous. Spike axillary, from two to five together, on square fimple stalks, the flowers small and densely crowded. Calyx with five teeth. Corolla of one petal, in five sharp lobes. Stamens ten, inserted in the calyx below the corolla, long, slender, with heart-shaped anthers, each of which bears a little leafy flaked appendage. Legumes linear-oblong, flattish, brown, smooth, three or four inches in length, with several seeds.

A. lophanta more properly belongs to this fection, though placed in the next.

Sect. 4. Leaves doubly pinnate. Stem without thorns. Spikes globose. Thirty-one species in Willdenow, to which we have three to add, besides *A. Houftoni.*

A. citrata. Ciliate-winged Acacia. *Br.* in *Ait.* n. 23.—"Without thorns, hairy. Leaves doubly pinnate; first division of two pair; second of two or three pair. Stipulas nearly fetaeous, deciduous. Heads solitary." —Gathered by Mr. Brown, on the south-west coast of New Holland; and sent to Kew, by Mr. Good, in 1803. A green-house shrub, flowering from March to June, of which we have not seen either specimen or figure.

A. nigricans. Unequally-winged Acacia. *Br.* in *Ait.* n. 24. (Mimofa nigricans; *Labill.* Nov. Holl. v. 2. 88. t. 238.)—Without thorns, smooth. Leaves doubly pinnate; first division of two pair; second of two or three pair in the lower, and from five to seven pair in the upper. Stipulas slender-awl-shaped. Heads solitary. —Native of the south-west coast of New Holland, from whence Mr. Good sent seeds to Kew, in 1803. A green-house shrub, flowering from May to July, said to be about six feet high in a wild state. The leaflets are uniform, elliptical, obtuse, one-third of an inch long. Heads axillary, flaked, one, two, or three together. Corolla deeply five-cleft. Stamens about 150. Legumes one or two from each head, linear-oblong, one inch and a half in length, and one-third of an inch in breadth. *Labillardiere.*

A. arborea. Rough Tree Acacia. *Wildl.* n. 38. *Ait.* n. 28. (A. non spinos a jamacifenis, foliis latà bâi in mete formam faltigtatis; *Pluk.* Almag. 6. t. 251. f. 2. A. arborea maxima non spinosa, pinnis majoribus, flore albo, foliis contractis cumere ventricosa elegantiissima; *Sloane* Jam. v. 2. 54. t. 182. f. 1, 2. Mimofa arborea; *Lim.* Sp. Pl. 1503. *Watt* Obz. 590. Browne Jam. 252. n. 3.)—Thorns none. Leaves doubly pinnate; first division of seven pair; second of seventeen pair; leaflets halved, acute. Heads axillary, flaked. Legume contorted, tumid. Seeds spherical. —Native of fields and islands in Jamaica, where it is called Wild Tamarind, and is one of the largest trees of that island. The wood, according to Sloane, is durable, though fott and white. Leaves of numerous, small, dark-green, smooth leaflets. Heads globular, of numerous sweet-scented flowers, whose corolla is reddish, the flamen whitish, very long. Legume as if beaded, four or five inches long, red; its valves of a blood-red on the inside. Seeds globular, of a shining black. This species was cultivated by Miller, but is now unknown in our gardens, nor are botanists in general well acquainted with it; Forkall and Thunberg having given the name of *Mimofa arborea* to two plants very different from this, as well as from each other.

A. Julibrissin. Smooth Tree Acacia. *Wildl.* n. 39. *Ait.* n. 29. (Mimofa Julibrissin; *Scop.* Infubr. v. 1. 18. t. 8. *Ait.* ed. 2. v. 3. 440. M. arborea; *Forb.* *Egypt.-Arab.* 177. *Gmel.* It. v. 3. 372. t. 40.)—Thorns none. Leaves doubly pinnate; first division of about ten pair; second of many pair; leaflets halved, obtuse with a point. Heads lax, aggregate, terminal. Legume flat, membranous, smooth. —Native of the Levant. Forkall saw it cultivated at Constantinople, where it was called *Djal ibraz,* by the Turks; which name, denoting a flaky flower, in allusion to the flamines, appears to be the origin of the specific appellation chosen by Scopoli. We have seen this species as large as a common apple-tree, covered with a profusion of blossoms, in the open ground at Turin, nor could any thing be more elegant or splendid. In England it is usually treated as a green-house plant, and flowers sparingly; though it succeeds well against a wall, with some protection in winter. The leaves are large and spreading, of numerous leaflets, half an inch long, very unequal in their two halves. Flowers lilac, with long monadelphous flamines, forming most beautiful tassels like white fik. Legume half a foot long, thin, pale brown, corrugated, unequal in breadth, with many small flattith seeds.

A. villosa. Downy Jamaica Acacia. *Wildl.* n. 46. (Mimofa villosa; *Swartz* Prod. 85. 1st. Occ. 592.)—Thorns none. Leaves doubly pinnate; first division of five or six pair; second of many pair; leaflets elliptical, oblique, down. Stalks and branches hairy. Heads rather oblong,
ACACIA.

oblance, panicked, terminal. Legume hairy, flat.—Found by Dr. Swartz, on mountains in the south of Jamaica. Browne seems by his herbarium to have confounded this with the real A. arbores, just described. The present is much smaller, being merely a shrub, six feet high, with hairy twirled branches. Leaflets downy on both sides, smaller and more obtuse than in the arbores; glaucous underneath; from ten to twelve pair in each subdivision. Clusters terminal, composed of many oblong and obtuse, rather than globular spikes, on very hairy stalks. Flowers small, white, with numerous capillary flamen, of a tawny hue, inserted into the lower part of the receptacle. Legume short, very different from that of arbores.

A. disfolor. Two-coloured-leaved Acacia. Willd. n. 47. Ait. n. 32. Curt. Mag. t. 1750. (Mimosa disfolor; Andr. Repof. t. 255. M. botrycephala; Venten. Hort. Cel. t. 1.)—Thorns none. Leaves doubly pinnate; first division of five pair; second of about ten pair; leaflets lanceolate, pale beneath. Heads in terminal and axillary clusters, much longer than the leaves.—Native of New South Wales, from whence seeds and specimens were among the first brought into this country, in the year 1788. It is now not an uncommon green-house plant in general collections, flowering at various seasons. The branches are angular and zigzag. Leaves rather stiff, their footstalks hairy like the young branches; leaflets not half an inch long, acute, smooth; dark green above; very pale beneath. Flowers yellow, in numerous globular heads, disposed in very conspicuous long clusters.

A. pubescens. Hairy-stem'd Acacia. Br. in Ait. n. 33. (Mimosa pubescens; Venten. Malmaif. t. 21. Curt. Mag. t. 1263.)—Thorns none. Branches hairy. Leaves doubly pinnate; first division of about eight pair; second of about fifteen pair; footstalks without glands; leaflets obtuse. Heads in axillary clusters, longer than the leaves.—Native of New South Wales, from whence its seeds are said to have been procured by Sir J. Banks, about the year 1790. This pretty delicate species has an arborecent stem, with drooping branches, and its copious fern-like foliage exhibits a most elegant appearance. Both sides of the leaflets are of a similar bright green. The whole compound leaf measures usually two inches; the numerous clusters of yellow capitate flowers, which smell like new bay, being about twice that length.

A. longiflora. Two-spiked New Holland Acacia. Willd. n. 53. Ait. n. 34. (Mimosa longiflora; Venten. Hort. Cel. t. 20. M. elegans; Andr. Repof. t. 563.)—Thorns none. Leaves doubly pinnate; first division of ten or twelve pair; second of about twenty pair; leaflets lanceolate; top and bottom of the common footstalk glabrous. Spike oblong, axillary, in pairs.—Oberved by Mr. Brown, on the south-west coast of New Holland, from whence seeds were sent to Kew, in 1803, by Mr. Good. A tall shrub, or perhaps a tree, with drooped warty branches. Leaves large, drooping, dark green, with innumerable narrow smooth leaflets. Spikes stalked, ovate or oblong, not globose, of numerous, crowded, sulphur-coloured flowers, having each about 200 monadelphous flamen. Legume oblong, flat, thick-edged, somewhat constricted here and there occasionally, where the seeds happen to be abortive.

A. brachyloba. Illinois Acacia. Willd. n. 54. Ait. n. 35. Pursh n. 1. (Mimosa illinoensis; Michaux Boreal-Amer. v. 2. 254.)—Herbaceous, without thorns. Leaves doubly pinnate; first division of five to eight pair; second of many pair, with a gland between the lowermost. Heads globose, axillary, solitary. Legumes lanceolate, flat.—In the extensive natural meadows of Illinois and Kentucky, flowering in June and July. Perennial. Flowers white, with only five flamen. Pursh. Stem smooth, furrowed. Leaflets from sixteen to twenty-four pair, linear, acute, slightly fringed at the base. Footstalks nearly smooth. Heads of flowers the size of a pea, stalked. Legume the length of the nail. Wildenson.

A. glandulosa. Glandalous Acacia. Willd. n. 55. Ait. n. 36. Pursh n. 2. (Mimosa glandulosa; Michaux Boreal-Amer. v. 2. 254. Venten. Choix. t. 27.)—Herbaceous, without thorns. Leaves doubly pinnate; first division of about twelve pair; second of many pair, with a gland between each. Heads globose, axillary, solitary. Legumes oblong, curved.—On the banks of the rivers Tennefée and Missipipii, flowering in July. Flowers white, pentandrous. Pursh. This appears to be very nearly related to the last. Both are herbaceous, with perennial roots, and have been introduced into the English gardens, but we have not had any account of their fucces. They require the shelter of a green-house.

A. decurrens. Decurrent Acacia. Willd. n. 56. Ait. n. 37. (Mimosa decurrens; Venten. Malmaif. t. 61.)—Thorns none. Leaves doubly pinnate; first division of about eleven pair; partial of innumerable linear leaflets, on a winged stalk, with a gland near the base, on the common stalk. Heads globose, in axillary clusters.—Native of New South Wales. Sir Joseph Banks is said to have introduced this plant at Kew, in 1790. It flowers in the early part of summer, and is a green-houf shrub, of an elegant fern-like aspect, with strongly angular zigzag branches. The leaves, though their common stalk is subtended by a projection from the branch, are not really decurrent. Flowers yellow, forming short clusters of little round heads.

A. grandiflora. Great Red Acacia. Willd. n. 61. Ait. n. 29. (Mimosa grandiflora; L'Herit. Sert. 30. Thornton Illufr. t. 4. Andr. Repof. t. 594.)—Thorns none. Leaves doubly pinnate; first division of about fifteen pair; second of very numerous, elliptic-lanceolate, flat leaflets. Heads about five-flowered, in a terminal cluster.—Native of the East Indies, from whence it is said to have been introduced into the English stoves, by Mrs. Norman, about the year 1769. No figure of this stately plant, (Plutenus's fynom, cited by Wildenson, being too uncertain.) had ever appeared, till Dr. Thornton published his magnificent plate. The stem is thorny, erect, slightly branched, downy, twelve feet or more in height, even in our gardens. Leaves large and spreading, with downy footstalks; their leaflets a quarter of an inch long, slightly fringed, bluntish, unequal at the base, but not curved or falcate. Clusters solitary, large, terminal, erect, of many alternate leaflets, solitary or in pairs, clothed with rusty down, each stalk bearing a head of from four to six flowers, whole corolla is but half an inch long, of a pale greenish-red; but the very numerous stamen, two inches in length, and of a fine shining crimson, like tafks of filk, render this one of the most beautiful of its tribe.

in 1729. These produced plants which flowered in the
stove at Chelsea. The present species is certainly next
akin to the last, however differently its inflorescence may
have been described or delineated by authors, in which
respect indeed Miller and Houftoun disagree. The plate
of the former however has all the appearance of fidelity, and
it is possible that the partial flower-flattis may vary in length, or,
more probably, be elongated as the flowers open. Having
seen no specimens, we must be guided by the materials
before us, from which we gather that the leaves of A.
Houtoni have not half so many pins, and that their leaflets
are narrower, longer, more acute, and more curved. The
petals are purple. Legume thick-edged, hairy, tapering at
the base. The leaf in Par. Lond. t. 64, cited in Hort.
Kew, appears to belong to this species, but the flowers,
and perhaps the legume, which is smooth, seem those of A.
grandisflora. If this be the case, the smooth legume, not tapering
at the base, would be an important addition to the specific
character of grandisflora.

Sect. 5. Leaves doubly pinnate. Stipulas becoming spines.
Spekes elongated. Ten species in Wildenow.
A. juliflora. Long-flowered Acacia. Wildd. n. 66. Ait.
1. n. 88. (Mimosa juliflora; Swartz Prodr. 85. Ind. Occ.
986, printed by mistake piliflora. M. diffusa, spica oblonga,
ulius longioribus compresse; Browne Jam. 252. n. 2.)—
Spines stipulare, in pairs. Leaves doubly pinnate; first
division of two pair, with intermediate glands; second of
about twenty pair of oblong leaflets. Leaflets axillary, or
three or together, cylindrical, pendulous. Native of very
dry fields in the south part of Jamaica, flowering in the
middle of summer. The stem varies from five to thirty feet
in height. Branches long and spreading. Spines strong,
five or five lines in length, prominent, curved upwards.
Leaves spreading, with narrow, obtuse, smooth, ribbed
leaflets. Spikes two or three inches long, lax, many-flowered.
Flowers crowded, fertile, very numerous, yellow, sweetened.
Corolla internally hairy. Stamen eight or ten, distinct.
Legume from three to five inches long, compressed,
smooth, often twisted, containing several oblong brown
seeds, separated by flaky partitions. There are numerous
flowers in each spike destitute of a pilil. Cattle feeding on
the leaves and young branches, unless gradually accustomed
to them, are poisoned, and the sweet legumes are reported
to be noxious. The inhabitants of Jamaica call this plant
Caffew. Browne erroneously gives it the name of Popanax,
which belongs to Mimosa (Acacia) tortuosa. Swartz. See
Sect. 6.
A. caffra. Hottentot Acacia. Wildd. n. 70. Ait. n. 42.
(Mimosa caffra; Thumb. Prodr. 92.)—Spines stipulare,
in pairs, curved. Leaves doubly pinnate; first division
of twelve pair; second of many pair; with a gland on the
footstalk. Spikes axillary, cylindrical.—Found by Thun-
berg in Southern Africa. Sent to Kew in 1804, by W.
Somerville, M. D. The branches are round and frayed.
First divisions of the leaves from ten to twelve, second
from twenty to thirty, pair; leaflets linear, obtuse, smooth.
Footstalks nearly smooth; the common one bearing a de-
pressed gland above its base. Spike stalked, two inches
long. Legume the same length, linear-lanceolate, flat.
Wildenow.
A. Catechu. Medicinal Acacia. Wildd. n. 73. Ait.
v. 44. (Mimosa Catechu; Linn. Suppl. 459. Wood.
Terra Japonica; Kerr in Med. Obf. and Inq. v. 5. 181.
1. t. 4.)—Spines stipulare, hooked, in pairs. Leaves hairy,
doubly pinnate; first division of ten or twelve pair; second
of many pair; with a gland at each extremity of the com-
mon footstalk. Spikes cylindrical, axillary, two or three
broader.—Native of the mountainous parts of Coromandel.
A large tree of which feeds have been sent by Dr. Rox-
burgh to Sir J. Banks. These have vegetated at Kew, but
the plants have not arrived at a flowering state. The branches
are round, downy when young; the older ones beset with
numerous pairs of small recurved thorns, originating in the
flipulas, as in all the plants of this section. Leaves slender
and delicate, finely hairy, pale green; their leaflets crowded,
hardly a quarter of an inch long, linear, rounded at each
end, unequal at the base. Spikes slender, three or four inches
long, hairy, stalked, pale yellow. Legume oblong, acute
at each end, flat, smooth, with three or four distant flat
seeds. "The wood," says Dr. Roxburgh, "is good, and
applied to various uses; but the natives have no idea of
extracting from it, or any other, the Catechu, or Terra Japa-
nica. Yet I believe there are many trees as fit to yield this
extract, as the present." Mr. Kerr, anfiant forger to the
Civil hospital at Bengal, has however described the mode of
preparing the Catechu, (fee that article,) by boiling the
interior coloured part of the wood of this species, till an
insipiant extract is obtained, which is the drug in question,
long supposed to be an earth produced in Japan. Another
fort of Catechu, or Guuta Gambir, made in Sumatra, Prince
of Wales's island, &c., has been shewn by Mr. Hunter,
secretary to the Asiatic Society, in Transactions of the
Linnean Society, v. 9. 218. to be the produce of a species
of Naucele. (See that article, spec. 7.) We presume
that Mr. Kerr and Mr. Hunter are equally correct, and
that the two different kinds of Terra Japonica, known to
drugists, are accounted for.

Spikes globosus. Sixteen species in Wildenow.
A. macarranensis. Long-ternned Acacia. Wildd. n. 76.
Spines stipulare, in pairs, lanceolate, compresse, nearly
as long as the leaves, which are doubly pinnate; first divi-
sion of twelve pair; second of many pair; with a depressed
gland at each extremity of the common footstalk. Spikes
stalked, globosus.—Gathered by Humboldt and Bonpland
in South America. The branches are frayed, and nearly
round. Leaflets about thirty pair in each division, linear,
obtuse, fringed. Footstalks downy. Spines two inches or
more in length, sharp-pointed, spreading at a right angle.
Heads of flowers the size of a pepper-corn, on long
stalks, in pairs, either axillary, or disposed in a fort of chilter
at the ends of the branches. Wildenow. This species appears
very remarkable, on account of the great size of its thorns.
A. eburnea. Ivory-ternned Acacia. Wildd. n. 78. (Mi-
mosa eburnea; Linn. Suppl. 437. M. leucanitha; Jacq.
Hort. Schoenbr. v. 3. 75. t. 593.)—Spines stipulare, in
pairs, cylindrical-spathulate, combined at the base, spreading.
Leaves doubly pinnate; first division of three or four
pair; second of six or more pair; leaflets inflected, elliptic-
oblung. Heads axillary, stalked, aggregate.—Sent by
Keniog from the East Indies. Jacquin by mistake makes it
a native of Africa. He cultivated it at Schoenbrunn, but
we have not met with this species in any English stove,
the following one having been mifcalled by the above name.
The true A. eburnea, of which the original Linnean speci-
men lies before us, is a twisted irregularly branched shrub,
whose twigs are round and zigzag, armed with tremendous
fragile spines, which are white, smooth and polished, almost
like ivory, but brown and very sharp at the end: the longest
measure nearly two inches; some are but a quarter that size:
they taper gradually from a thick conjunct base; leaves
about two inches long, with smooth leaflets, placed at the
distance of their own width from each other. "Common foot-
stalk
Pluk. Pluk. Pluk. Mimofa leaflets common when A. the second first; Burm. Jalks linear twilled, in pairs, angular, spreading, longer than the leaves; some much shorter and recurved. Leaves doubly pinnate; first division of two or three pair; second of many pair; leaflets crowded, on a hairy stalk. Heads axillary, flaked, aggregate.—Native of the East Indies, flowering in the cold season, sent by Dr. Roxburgh to Sir Joseph Banks in 1792. This is a small ill-looking tree, or large bushy shrub, whose branches spread in every direction, and are round, purplish, wavy, very rigid, armed with formidable thorns, of two inches long. Some of the latter are two inches long, white, spreading horizontally in opposite directions, scarcely combined at the base, much more slender and linear than in the A. eburnea, flat or channelled along their upper side; when young they are much smaller, needle-like, and hairy; others, on the same branch, and of the same age, with the large ones, are very short and hooked. The leaves are not half the size of the leaf species. Heads of flowers globose, with a purplish corolla, and yellow filaments. Legume linear, twisted, two inches long, smooth. The flowers are said by Dr. Roxburgh to be separated from each other, on their globule receptacle, by abrupt, fringed, corymbose, of which we can find no traces in our specimens.

A. tortuosa. Poponax Acacia. Willd. n. 82. (A. americana, filius teretibus ventricosis, floribus luteis; Sloane Jam. v. 2. 56. Mimosa tortuosa; Linn. Sp. Pl. 1505. Swartz Obs. 391. Browne Jam. 251. n. 1.)—Spines fluted, in pairs, awl-shaped, much shorter than the leaves, round, downy. Leaves doubly pinnate; first division of three or four pair; second of many pair; leaflets crowded, on a downy flake. Heads axillary, on downy flake, solitary or in pairs. Legume externally flaky.—Very common in the low sandy lands of Jamaica. The stem is shrubby, with spreading wavy branches, rendering the plant useful for hedges according to Dr. Swartz; but Browne speaks of it as of little service, the smell of every part being rank and disagreeable, that it cannot be used even for fire-wood. The taste is bitter, and the flowers have an oppressive smell. Both these authors mention the legumes as furnished with a glutinous juice under their skin, whose qualities are eminently bitter and astringent. Sloane appears to confound the A. farneifana and others with this species. The true tortuosa, of which we have Browne's own specimen, comes near to borrida in botanical characters, but the leaves and leaflets are much larger; thorns smaller, not angular, but more tapering; flowers-flakes downy, not smooth. There are no scales on the receptacle between the flowers, but the teeth of the long tubular calyx are very densely and finely fringed. Dr. Swartz says this is the tree really called Poponax in Jamaica, Browne erroneously attributing that name to A. juliflora. Both are frequently met with in the same situations.

A. farneifana. Sponge Acacia. Willd. n. 83. Ait. n. 47. (A. indica farneifana; Aldin. Hort. Farasel. 3. 1504. Mimosa farneifana; Linn. Sp. Pl. 1506.)—Spines fluted, in pairs, awl-shaped. Leaves doubly pinnate; first division of from five to eight pair; second of many pair; leaflets crowded. Heads flaked, axillary. Legume tumid, coriaceous.—Native of Hispaniola, from whence the seeds were brought to Italy, early in the 17th century. This shrub is occasionally seen in our gardens, being esteemed for the peculiarly delicious scent of its balls of yellow flowers, which are produced during summer. A coloured figure is much wanted. The dry tumid legume distinguishes it clearly, as a species, from the last. The whole plant is smooth, or have we ever observed the herbage to be faint.

A. arabica. East Indian Gum-Arabic Acacia. Willd. n. 86. (A. altera vera, &c.; Pluck. Almag. 3. t. 251. f. 1. Mimosa arabica; Lamarek Dict. v. 1. 19. Roxb. Coromand. v. 2. 26. t. 149. Nella Tooma of the Telingas.)—Spines fluted, awl-shaped, in pairs. Leaves doubly pinnate; first division of five pair; second of many pair. Heads axillary, about three together. Legume necklace-like, flat, densely downy.—Native of the East Indies, whether of Arabia also may be doubted. Dr. Roxburgh says it is abundant over every part of India, thriving best in a low, flat, uncultivated soil, and flowering most part of the year. Besides yielding a great quantity of Gum Arabic, this tree is one of the most useful in India for its tough and hard wood, serving many valuable purposes in ship-building, wheel-carriages, &c. The astringent bark serves for dyeing, and making ink. The branches are round. Spines distinctly, an inch, more or less, in length. Leaves like several of the foregoing, as are also the aggregate globular heads of yellow flowers. But the legume afford a most striking character, being flat, four or five inches long, covered with dense hoary pubescence, like fine velvet, and remarkably contrasted into numerous orbicular portions, in each of which is lodged a flattened seed. Cattle are very fond of the tender branches and young pods.

A. vera. Egyptian Gum-Arabic Acacia. Willd. n. 87. Ait. n. 48. Veiling Egypt. 6. t. 8. Bauh. Hill. v. 1. p. 2. 429. (Mimosa melitica; Linn. Sp. Pl. 1506. Hafelq. Travels, Eng. ed. 250. Woodv. Med. Bot. 187. t. 67.)—Spines fluted, in pairs, linear-awl-shaped. Leaves doubly pinnate; first division of five or six pair; second of many pair; common flake glandular. Heads axillary, about three together. Legume necklace-like, nearly flat, smooth.—Native of the sandy deserts of upper and lower Egypt, from whence Hasselquist sent specimens to Linnaeus, who seems to have described the same plant under the name of Mimosa semen. This original Gum Arabic tree was known to our earher botanists, and Gerard appears to have cultivated it in his garden, whence it has obtained a place in Mr. Aiton's valuable work; but few persons at present are acquainted with living, or even dried, specimens, especially of the legume. These clearly distinguish the species, being more strictly contracted into orbicular portions than the leaf, with an obliquity well expressed in the wooden cut of Vellings. Their surface is brown, nearly or quite smooth, pale at the edges; the disk of each lobe rather tumid; from the swelling of the seeds. In the leaves or flowers of these two species, we cannot, from the dried specimens, detect any great difference; but the spine of A. vera are almost as remarkable for their length and whitensse as those of borrida. For the most valuable produce of this tree, see Arabie, Gum.

flacks prickly. Leaves doubly pinnate; first division of seven pair; second of fourteen pair; leaflets oblong-oval; a gland on the main footstalk. Spikes globose, in terminal panicked clusters. —Native of the East Indies, from whence it was procured for Kew garden, by Sir J. Banks, in 1773, but appears not yet to have flowered. We have seen no authentic specimen of this species.

A. pentata. Fine-leaved Acacia. Wildl. n. 98. Ait. n. 52. (A. aculeata multiflora, foliis pennas avium referentibus; Burn. Zeyl. 2. t. 1. A. zeylanica, florebus globosis lateribus, foliis pinнатis tenuissimis incisībus, pinīs minoribus; Burn. Zeyl. 3. Mimofa pennata; Linn. Sp. Pl. 1507.) —Branches prickly. Leaves doubly pinnate, some pair of general divisions, and very numerous linear leaflets; a gland on the common flalk. Panicle terminal, spreading; heads flalked, aggregate; general flower-flalks, like the bale of the common footstalks, prickly. Legume flat, smooth, wavy at the edges. —Native of Ceylon, and other parts of the East Indies. Sent to Kew, in 1773, by Sir J. Banks. We have specimens from Dr. Roxburgh. The very delicate slender leaflets, which, in the dried plant at leaf, fold together, give a feathery appearance, well expressed in Burmann's plate. The panicle is very large and compound, with downy rufy flalks; its main branches only armed with small hooked prickle. The legumes, not hitherto described, but very important in discriminating this multifarious tribe, are about three inches long, tapering, though rather blunt, at each end, flat, thick-edged, wavy or finous at both margins. Seeds about four.

A. Ceratonia. Round-leaved Acacia. Wildl. n. 101. Ait. n. 52. (A. repens aculeata, flore albo, foliis Silicis; Plum. Ic. 4. t. 8. Mimofa Ceratonia; Linn. Sp. Pl. 1508.) —Branches, and all the flalks, prickly. Leaves doubly pinnate; leaflets three pair, roundish-obovate, oblique, three-ribbed. Panicle terminal. Heads globose. Legume flat, prickly at the edges. —Native of the West Indies, from whence the pretent duke of Marlborough is said to have introduced it into his rich collection, before the year 1800. The remarkable roundness of the leaflets, which have authorized the name of rotundifolia, and their greater size, distinguishes the present species from all we have hitherto noticed. Every part is extremely prickly, but devoid of pubescence. The heads of flowers are rather small, and, according to Plumer, white. He delineates the legume of a flat, oblong, obtuse figure, two or three inches long and one broad, fringed with hooked prilded.

A. tamarindifolia. Tamarind-leaved Acacia. Wildl. n. 102. Ait. n. 53. (A. aculeata, flore albo, foliis Tamarindi; Plum. Ic. 4. t. 7. Mimofa tamarindifolia; Linn. Sp. Pl. 1509. Jacq. Hort. Schoenbr. v. 3. 77. t. 396.) —Branches prickly. Leaves doubly pinnate; first division of five or fix pair; second of about fifteen pair; a gland on the common flalk; leaflets oblong. Stipulas and bractees heart-shaped. Clusters terminal. Heads globose. Legume flat, smooth. —Native of South America and the West Indies. Said to have been cultivated by Kennedy and Lee, at Hamme'rsmith, in 1774. The name is very expressive of the aspect of the leaves. The very broad heart-shaped stipulas, and the smaller, more ovate, bractees, give a peculiar character to this species. Inflorescence rather racemosf than panicked, deltilute of hairiness or spines, though the branches of the item are armed with strong prominent prickles. Heads of a few white flowers, each on a long flalk, solitary or in pairs. Legume, according to Plumer's figure, linear-oblong, flat, straight, deltilute of prickles at the edges, acute, about three inches long and one broad. Seeds numerous, oval.

A. acanthobola. American Prickly-podded Acacia. Wildl. n. 95. —Branches prickly. Leaves doubly pinnate; first division of three pair; second of ten pair; leaflets linear, obtuse; downy beneath. Heads globose, nearly sefifile, racemofe. Legume prickly at the edges. —Gathered in South America, by the celebrated travellers Humboldt and Bonpland. Branches round. Leaflets ten or eleven pair, clothed beneath with clove-profled hairs. Foot-flalks downy. Prickles scattered, hooked, compressed. Heads small, almost sefifile, disposed in a terminal clufher. Legume an inch and a half in length, oblong, flat, membraneous, smooth, befet with prickles at the margin. Wildenowio. This author declares himself to have been possessed of fcceral fpecimens of the Mimofa tribe, which were too imperfect to be enumerated or defined. We are not only in this situation, but we have feveral in sufficiently good condition, which on account of the incomplete defcriptions of authors, especially concerning the fruit, we cannot aecertain to be defcribed or not.

ACADEMY. The Academy of Arts at Petersburg was eflablished by the emperoz Elizaobath in 1758, and annexed to the Academy of Sciences. At the fuggestion of count Shuvaloff, the late emperoz Catharine, in 1764, formed it, &c. Next clofl. after f. 54, add.

The academy of painting, sculpture, and architecture, at Vienna, was founded in the year 1705.

Under Academies of Nonconformift Ministers, instead of Manchester r. York, felc Exeter, and instead of Wrexham r. Llanfylling.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, permanent, with four teeth, each fometimes tipped with an upright brillly awn, barbed at the point, or the whole body of the calyx is fo armed. Cor. Petals four, roundifh, inferted into the border of the calyx, and shorter than its awns. Stam. Filaments two or four, thread-shaped, longer than the petals, inferted into the border of the calyx; anthers roundifh. Pij. German superior, oblong; 8yle thread-shaped; stigma many-cleft, tufted. Peric. none, except the permanent calyx. Seed solitary, ovate, coated with the thickened bafe of the calyx.

Eff. Ch. Calyx of one leaf, armed with barbed bristles. Petals four, inferted into the calyx. Stigma tufted. Seed solitary, coated with the calyx.

Obf. The petals are fometimes wanting. Flowers occasionally five-cleft, with five flaments. The item is herbaceous, or fometimes shrubifh. Leaves alternate, pinnate with an odd one, deeply ferrated or cut, often hairy or silky; their common foot-flalks flaking, bordered with a pair of membraneous
branched combined fipulas. Flowers small, greenish, in a globose head, or interrupted spike. Fruit reddish, dry.

2. A. elongata. Multiflora Acena. Linn. Mant. 200. Vahl n. 2. Wild. Sp. Pl. v. 1. 693.—Leaflets oblong, serrated; downy beneath; bearded at the tips of the quarters. Spikes elongated, compressed. Fruit all prickly. Stem nearly erect.—Found in Mexico, by the celebrated Mutis. Stem woody, perennial, with very long, ascending, somewhat compound branches, two feet in length. Leaves scattered; leaflets sessile, crowded; the lower ones very small, linear, acute, entire; from four to eight of the upper pair larger, oblong, serrated. Spike axillary, erect, rigid, a span long. Bractea solitary, close to the calyx, concave, ovate-oblong. Flowers alternate, nearly sessile. Mutis.

3. A. latebrofa. Hairy Acena. Vahl n. 3. Ait. n. 1. (Anciftrum latebrofum; Wild. Sp. Pl. v. 1. 155. A. decumbens; Thunb. Prodr. 6. Agrimonia decumbens; Linn. Suppl. 251.)—Leaflets oblong, cut, hairy. Stem creeping. Spikes elongated, flaked, many-flowered.—Native of the Cape of Good Hope. The germ is downy, beft with many barbed prickles, which, as the fruit ripens, project through the flalk of the calyx. See Gartner f. 2. and Lamarck f. 4.

4. A. pinntafida. Deep-cut Acena. Vahl n. 4. "Fl. Peruv. v. 1. 69. t. 104. f. k."—Leaflets oblong, deeply serrated, almost pinnatitdid; hairy beneath. Spikes cylindrical. Stem erect.—Found on dry exposed hills in Chili. Commerson gathered what appears to be the same, at Monte Video, not, as Vahl by mistake says, at the flaks of Magellan. The stem is quite simple, a span high, leafy, very hairy in the upper part. Leaves numerous at the root, and several on the stem, with eight or nine pair of leaflets, besides the one odd; the largest near an inch long, copiously and deeply cut, like Potentilla anodera. Spike obtuse, an inch or inch and half long, dense, many-flowered, dark purple. Germ beft with ftrong barbed thorns, not proceeding from its teeth.

6. A. ovatifolia. Oval-leaved Acena. Vahl n. 6. "Fl. Peruv. v. 1. 67. t. 103. f. c." Ait. n. 3. (Anciftrum repens; Venten. Jard. de Cels, t. 6.)—Leaflets elliptic-oblong; villous beneath. Spikes globose. Stem creeping. Calyx-teeth awned. Stigma unilateral.—Native of Peru, in moist shady places. Cultivated at Paris, by the late M. Cels, and at Kew by Mr. Aiton, where it is hardly flowering in May and June. We can discover no difference between this and the foregoing, the stigma being perhaps accidentally imperfect.

7. A. argentea. Silverly Acena. Vahl n. 7. Fl. Peruv. v. 1. 67. t. 103. f. b. (Proquin; Feuil. Voy. v. 3. 55. t. 41.)—Leaflets elliptic-lanceolate, acute, serrated; filly beneath. Spikes globose. Stem creeping.—Native of Chili, in moist ground. The Indians use it as a vulnery. The branches are two feet long. Leaves shining and smooth above; silvery beneath. Flowers in globular heads, on long flalks. Stamens two or four. Calyx with two, three, or four terminal awns.

8. A. lucida. Shining Deep-cut Acena. Vahl n. 8. Ait. n. 4. (Anciftrum lucidum; Wild. Sp. Pl. v. 1. 155. Lamarck Illistr. v. 1. 77. t. 22. f. 3.)—Leaflets in three or five deep oblong segments; hairy beneath. Spikes oblong. Stem almost buried.—Native of the Falkland Islands, from whence Dr. Fothergill procured it in 1777. Commerson gathered the same in the forests of Magellan. The flaks run just under the surface of the ground, sending up numerous leafy tufts. Leaves linear-oblong, of many pairs of small, elliptic-oblong, deeply divided leaflets. Spike partly interrupted. Fruit reddish, smooth, entirely unarmed, as well as the calyx, in our specimens. Vahl attributes four awns to the latter.

9. A. trifida. Three-cleft Acena. Vahl n. 9. Fl. Peruv. v. 1. 67. t. 104. f. c.—Downy and hoary. Leaflets wedge-shaped, in three or five segments. Spikes globose. Stem erect.—Native of pâturages, fields, and hills in Chili. Denfely villous. Stems several, unequal, the longest measuring about a foot. Leaflets seven or eight pair; the lowermost often undivided. Flower-flalks terminal, often bearing one or two little round heads, besides the principal one. Bractea linear. Calyx sometimes five-cleft. Stamens two to five. Fruit obovate, denfely villous, with four or five angles, and as many awns. Vahl.

10. A. magellanica. Magellanic Acena. Vahl n. 10. (Anciftrum magellanicum; Lamarck Illistr. v. 1. 76. t. 22. f. 2.)—Leaflets obovate, deeply serrated, three-cleft; hoary beneath. Spikes globose. Stem erect, smooth.—Gathered by Commerson, at the forests of Magellan. Stems rather shrubby, three or four inches high, branched, smooth; sometimes hoary at the summit. Leaves at the ends of the branches: leaflets five or six pair, scarcely half the length of the nail; the uppermost with seven or nine teeth, lower with about three, lowell of all entire. Flower-flalks axillary, at the top of each branch, erect, purplish, slightly villous at the upper part. Head twice the fize of a pea. Very nearly akin to the last, but the smoothness of the stem, branches clothed with imbricated bases of the foot-flalks, crowded leaves, and smooth bracteas, distinguiths this species. Vahl.

11. A. ascendens. Ascending Smoothith Acena. Vahl n. 11. (A. lavignata; Ait. n. 5; Anciftrum magellanicum 8; Lamarck Illistr. v. 1. 76.)—Leaflets oblong or obovate, serrated, nearly smooth. Spikes globose. Stem decumbent.—Gathered by Commerson at the forests of Magellan. We do not find any specimen from him in the Linnean collection; but Mr. Menzies has communicated some, by the name of Anciftrum alpinum, which appear to answer to Vahl's description, except being considerably hairy. These were gathered on the summits of the mountains near Cape Horn, along with Viola tridentata. (See Viola n. 76.) Vahl speaks of the stems as a span long, smooth. Leaflets from five to seven pair, opposite or alternate, bluntly serrated, veiny, somewhat hairy at the rib. Flower-flalks terminal, elongated. Head the fize of a cherry. Calyx
Calyx with four awns. The hairiness of the upper side of the leaves in our plant, and the smaller size of the heads of flowers, may be owing to a very lofty or exposed situation. We merely guess this to be *Mr. Aiton's lavicata* by the synonym of Lamark.

12. *A. cylindracea.* Cylindrical-spiked *Acacia.* Vahl n. 12. "Fl. Peru. v. 1. 68. t. 194. f. a."—Leaves oblong, ferrated; silky beneath. Spike cylindrical, on nearly radical stalks. Stems subterranean.†—Found on hills in Tarma, Peru. *Herb* clothed with silky pubescence. Leaves radical, numerous; leaves ten or eleven pair, obtuse, furrowed. *Flower-flalks* several, from three to nine inches high, bearing a few simple leaves. *Calyx* purplish, with four awns.

Stamen two.

**ACALZIKE.** After Tarney, add: the capital of *Akhia* (which see); a populous and commercial city, situated in an open valley, on the left bank of the Kur. The inhabitants are, Jews, Turks, Greeks, Armenians, and Georgians.

**ACANTHI,** in *Botany,* Jussieu's third natural order of his eighth clafs, or the thirty-sixth of his general clafs, named from the most celebrated and conspicuous genus which it contains. For the charactar of the clafs, see GENTIANAE. The *Acanthi* are thus defined.

*Calyx* divided, permanent, often bracteate. *Corolla* mostly irregular. *Stamina* either two; or four, two of which are shorter than the others. *Style* solitary; with a two-lobed, rarely simple, *stigma.* *Fruit* capsular, of two cells, often many seeded, with two elatic valves, and a partition contrary, or opposite, thereto, inferted into their middle, splitting from top to bottom into two uninterrupted *receptacles,* bearing seeds on each side, rendering the valves fimbriolar. *Stem* either herbaceous or shrubby. *Leaves* for the most part opposite, as well as the flowers.

**Seet. 1. Stamen four, in unequal pairs.** This contains *Acanthus* of all authors; *Dilovaria* of Jussieu, founded on *Acanthus ilicifolius* of Linnaeus; but purely on the slightest possible characters; *Blepharis* of Jussieu; *A. madasgaperi* of Linnaeus, as slightly distinguished; *Thymbra* of Linn. Suppl.; *Barleria*; and *Ruellia*.

**Seet. 2. Stamen only two.**

*J'utilia* and *Dianthera.*

Mr. Brown, who retains this order by the name of *Acantiaceae,* Prodr. Nov. Holl. v. 1. 472, has enriched it with many valuable remarks, and some new genera. He combines, like Professor Vahl, *Dianthera* with *J'utilia,* but extracts from the latter the *Hyposcites* of Solander; with *Erantheranum,* originally founded by Linnaeus; and establishes moreover two genera of his own by the names of *Hygrophila* and *Nelsonia.* (See those articles.) We perceive also that this intelligent writer retains Vahl's *Elytria.* He proposes also *Aphelandra,* consisting of *J'utilia pulcherrima* and its allies; *Acteinema,* founded on Forskall's *Ruellia imbricata,* and various undescribed Ealt Indian and African species, of which therefore we can give no account. *Lepidagathis* of Wildenow, Sp. Pl. v. 3. 400, of which we propose to speak hereafter, is admitted by Mr. Brown, as well as a new genus of Jussieu's named *Blechnum.* Some others are left distinctly indicated. We select from the work of our learned friend the following additional observations upon the *Acanthi,* or *Acanthaceae.*

The *anthers* are either of two cells, sometimes equal, sometimes unequal in their infusion, or of only one cell; and burst longitudinally. *Germs* surrounded at the base with a glandular disk. *Seeds* roundish, mostly subfurnished by *retinacula,* props, or awl-shaped ascending processes from the partition. *Skin* of the seed lax. *AlluMum* invariably none. *Embryo* either curved or straight. *Cotyledons* large, nearly orbicular. *Plumula* inconspicuous. These plants are chiefly tropical. Their pubescence, if any, is simple, occasionally capitate, very rarely flary. *Leaves* opposite, rarely four in a whorl, without *filipulas,* simple, undivided, either entire or ferrated; seldom serrated, or slightly lobed. *Inflorescence* terminal or axillary, spiked or racemose, fasciculated, panicled, or solitary. The order is certainly natural, though not easily to be defined. In some instances the props of the seeds are wanting. The rudiments of a fifth flamen frequently occur. The elactic mode of bursting in the *capsule* is nearly universal.

The following principles by which the genera are to be discriminated, are thus propounded by Mr. Brown in succession, according to their relative importance. 1. Seeds with or without props. 2. Partition combined with the valves or separate. 3. *Anthers* of two cells or of one. 4. Anther-bearing *flamines* two or four. 5. *Limb* of the irregular corolla with one lip or two. 6. *Calyx* equal or unequal. Cells of the capsule containing each two or more seeds. The following is the order of Mr. Brown's genera. *Hyposcites,* *J'utilia,* *Eranthera,* *Ruellia,* *Hygrophila,* *Acanthus* including *Dilovaria* of Jussieu, and *Nelsonia,* which may be found in their proper places.

**ACANTHONOTUS,** in *Ichthyology,* a genus of fish, whose characters are, that the body is elongated, without dorfl fins, and that it has several spines on the back and abdomen. There is one species, a native of the East Indies, described by Bloch under the name of *

**NASUS;** Snouted Acanthoanotus, which is grey, with the back transversely barred with brown. This fish is of considerable length, that described by Bloch being two feet and a half; the head is large, the teeth small, forming a row along each jaw, the eyes large, and the nostrils conspicuous; the body, moderately wide for about a third of its length, tapers towards the extremity; head and body are covered with scales, of a blueish tinge, silverly on the abdomen, the pectoral fins brown, of a moderate size, the ventral of like colour, and small; the lateral line straight, nearer to the back than to the abdomen; with ten spines, strong but short, along the narrow part of the back, and towards the abdomen from twelve to thirteen others, followed by the anal fin, which is shallow, and continued into the tail, which is very small. Shaw's Gen. Zool.

**ACANTHURUS,** a genus of fish, consisting of fresh species of the Linnaean genus *Chetodon* (which see) as, in contra-distinction to the principal character of that genus, have, in general, moderately broad and strong teeth, rather than slender and facetous ones; they are also furnished on each side of the tail with a strong spine. Their generic character is as follows: Teeth small, in most species lobated; tail acuulate on each side; habit and general appearance as in the chetodon. The species are:

**Unicornis.** Grey-brown, with a frontal horn *Aretching
ing forwards over the finout, and two spines on each side of the tail. See  **Chetodon Unicorns**.

**NASUS.** Grey, speckled with black, with a rounded frontals tubercle, and two spines on each side of the tail. A native of the Indian seas, and, according to Cepede, first described by Commeron.

**TEUTHIS.** Blue, with the middle of the body paler, and a spine on each side of the tail. See  **Teuthis Hippus**.

**CHIRORUS; Lancet  Acanthus.** Orange-yellow, with the body crotched on the hind part by transverse brown ripes, and a spine on each side of the tail. See  **Chetodon Chirurgus**.

**NIGRICANS.** Blackish, sub-argentinous beneath, with a spine on each side of the tail. See  **Chetodon Nigricans**.

**Militaris.** Brown, with rhombic-ovate body, and strong spine on each side of the tail. Native of the Indian and American seas.

**Triostegus; Triradiated Acanthus.** Greenish-brown, with four transverse dusky bands, and a spine on each side of the tail. Native of the Indian seas. See  **Chetodon Triostegus**.

**Harpurus; Guarded Acanthus;** Rhombic-ovate brown Acanthus, with extremely minute scales, and two spines on each side of the tail. Native of the Indian seas.

**Sohal; Dusty Acanthus, with longitudinal violet streaks, and two spines on each side of the tail imbedded in a red depression.** See  **Chetodon Sohal**.

**Nigro-fuscus; Dusty Acanthus, with ovate body, and spine on each side of the tail.** A variety of the preceding. See  **Chetodon Nigro-fuscus**.

**Achilles; Brown, ovate Acanthus, with a bare ovate red spot on the hind part, aculeated in the middle.**

**Lineatus; Ovate-brown Acanthus, with numerous longitudinal white ripes, and spine on each side of the tail.** See  **Chetodon Lineatus**.

**Umbratus; Brown-ovate Acanthus, with extremely minute scales, and a spine on each side of the tail.** Native of the Indian seas.

**Melagrins; Blackish-brown Acanthus, thickly marked with round white spots, and spine on each side of the tail.** Native of the Indian and American seas.

**Velifer; Broad-lined; Whitish Acanthus, with roundish-ovate body, marked by numerous brown transverse bands, and spine on each side of the tail.** Native of the American seas. Shaw's Zoöl.

**Acanthus, in Botany.** In addition to the observations of our predecessor, we would remark, what the writer of the present article has elsewhere hinted, (Confidizations respecting Cambridge, more particularly relating to its Botanical Professors, 37) that every mention of this plant in Virgil accords with the Common Holly,  *Ilex Aquifolium*, so far, at least, as the words of the poet indicate any thing in particular. The passages in question are,

---

"hucus femper frondentis acanthi." —Georg. 2. 119.

"aut flexu tacifemn ovina acanthi." —ib. 4. 123.

*Ilex comam multa jamb tum tendent acanthi." —ib. 4. 137.

*Et mollis circum eft anachs amplexus acanth." —Ecl. 3. 45.

*Mistaque ridentis colosphaca fundat acantho." —ib. 4. 20.

*circumtextum cresce volamen acantho." —Linn. 1. 653.

*— pitted cresce volamen acantho." —ib. 1. 715.

---

The flexible twigs, ever-green leaves, bright or gay saffron-coloured berries, (as the term *crescus* is used with confideable latitude by Latin writers,) the head of the plant being clipped by gardeners in the early spring, all sufficiently well apply to the Holly, which is a common wild, as well as garden shrub, throughout Italy, but of

Vol. XXXIX.

which we can find no mention whatever in all Virgil's writings, if these passages allude to any thing else. They are acknowledged to be inapplicable to the *acanthi* of Dioscorides, which is evidently the Linnaean *Acanthus*. They are no less so to the *acanthi* of Theophrastus, which is a tree bearing pods, or legumes. Thse Greek names, simply meaning a thorny or prickly plant, are variously applied, not only to different trees or shrubs, but to many kinds of thistles. The *Acanthus Dioforidis*, Linn. Sp. Pl. 891, a species adopted by Linnaeus from other writers, without seeing a specimen or figure, seems to be merely a narrow-leaved, or flared flat of *A. fimbrius*; of which *A. mollis* may, on the other hand, be a cultivated, or more bristly, variety. The latter was found by Dr. Sibthorp in Sicily, not in Greece; the former, apparently the natural state of this herb, as described by Dioscorides, occurs in moil stony places, as well as about the borders of fields, in the southern part of Greece, and the islands of the Archipelago, and is very common in Crete.

**Acarina, a name adopted from the Greeks, whose akos was, like this, some sort of thistle.** This name is now applied in Wildenow's Sp. Pl. v. 3. 1699, and from thence by Mr. Aiton, Hort. Kew. v. 4. 490, to a genus separated by thee writers from the Linnaean Atractylis (see that article) from which it differs in the width of a radius. The species referred to *Acarina* are, 1. *Atractylis purpurea* of Linn. Sp. Pl. 1161; 2. *A. macrocephala*, Desfont. Atlant. v. 2. 575; 3. *A. macrophylla*, ibid. 255. t. 256; 4. *A. castigata*, ibid. 254. t. 225; 5. *A. lancea*, Thurn. Jap. 306; 6. *A. ovata*, ibid. 306; and 7. *A. cancellata*, Linn. Sp. Pl. 1162. —We can by no means concur in this alteration. Nothing is less certain than such a generic distinction as the above, when unsupported by any natural character. Wildenow has also separated from *Atractylis* the *purpurea* and *mexicana* of Linnaeus, perhaps with more propriety, their receptacles being nearly naked, and their seed-down simple, to say nothing of a difference in the structure of the radiant florets of the former, which rather invalidates than confirms the new-delineated genus. See Onoseres.

**Accursius, r. Mariangela.**

**Acer, 1. 6. r. Tribblade Acer. Juif.**

**Acer, in Botany, the fifth natural order, of the 13th class in Jussieu's system; the 66th in his general series. See the characters of this class under the article Ganaka. The Acer is defined as follows.**

*Calyx of one leaf. Petals definite, very rarely wanting, inserted around the disk, which is under the germen. Stamina inserted into the middle of the same disk, definite, but often"
often unequal in number to the petals. *Genus* simple, standing on the before-mentioned disk; *fycle* one, or rarely two; *ligula* one or two.

*Fruit* of several cells, or several capsules, the cells or capsules three or two. *Seeds* in each solitary, or at the utmost three, attached to the inner angle, some of them frequently abortive. *Corolla* distinct of albumen, the radicle lying on the lobes. Stem arborescent, or furbby. *Leaves* opposite, without *fipulae*. *Flowers* racemose or corymbosse; sometimes by the abortion of one or other part becoming separated in fascic.

Sect. 1. *Fruit* of several cells, contains only *Aesculus*. Sect. 2. *Fruit* of several capsules, only *Acer*. Sect. 3. Conflits of genera alluded on the one hand to the *Acer*, on the other to *Malpigheae*; see that article.

These are *Hipppocrates* and *Thryallis*.

There is some doubt, even in the mind of Jullien himself, whether *Aesculus* properly belongs to this natural order; and he jully alludes to its great affinity to *his Sapindi*; (see that article,) with which its fruit undoubtedly very closely agrees.

Gen. Ch. *Cal*. Perianth superior, of three ovate, concave, equal, converging leaves. *Cor.* Petals two, linear-lanceolate, concealed by the calyx, and about the same length. *Neck* an oblong, flat, pendulous lip, much longer than the petals, with two pair of deep, linear, flat, dependent lobes, but no posterior spur. *Stam.* Filament none; anther erect, oblong, attached by its back, parallel to the style, of two cells, opening in front, the maffes of pollen club-shaped, each attaching itself, by a taper base, to two glands in a single pouch near the *ligula*. *Pfll.* Ger- men inferior, linear-oblong, twifled; *style* columnar, very flint; *ligula* below the anther, rather concave. *Peric.* Capsule oblong, with three blunt angles, twifled, of one cell and three valves, splitting by three lateral fiffures. *Seeds* numerous, minute, each with a chaffy tunic.

This genus was first established by Mr. Brown, who separates it from *Ophryss*, (see that article,) on account of the converging *calyx*, and especially the situatian of the two glands, which receive the *pollen*, being in one pouch, not in two distinct and distant ones. The latter character, though excellent in this instance, appears to us in others less satisfactory (see *Gymnadenia* hereafter); and even in the characters of *Aceras* and *Ophryss*, the flat lip of the former, controlled with the convex of the latter, seems a more obvious and natural distinction.

In affinity the present genus comes nearest to *Oriehus*, but wants the spur.

2. *A. anthropophorum*. Short-lipped Aceras. (*Ophryss anthropomorphia*; Willd. Sp. Pl. v. 4. 63.)—Lip but half the length of the germen.—Found on hills in Portugal, by professor Linck. About a span high, the *spike* an inch long. *Bractes* oblong, membranous, half the length of the germen, nor does the lip exceed that proportion. Willdenow thinks it can scarcely be a variety of the former. We have seen no specimen.

**ACERIC Acid**, in *Chemistry*, lately discovered by professor Scherer, of Vienna, in the lap of the *acer campestris*, or common maple. Its properties have been very imperfectly described. The acerate of lime is white, slightly translucent, has a weak acidulous taste, and is not altered by exposure to the atmosphere. 1000 parts of cold water dissolve 9 parts, and 1000 parts of boiling water 17 parts of this falt. Schweiger's *Journal*, iv. *Thomson's Chemistry*, iv. new edition.

**ACETATES, or *Aceti*,** a clasf of salts, the characters of which are, that they are all very soluble in water; that they are decomposed by the action of heat; and that they afford acetic acid when distilled with sulphuric acid. Accordingly we have acetates of barytes, of potash, of soda, of lime, of ammonia, of magnesia, &c. See *Acetic Acid*.

**ACETIC Acid.** It is now universally admitted by chemists, that the acetic acid differs in no respect from common vinegar, or what was formerly termed accetous acid, but in the degree of concentration only. This opinion, first advanced by Adet, has lately been fully confirmed by the experiments of Darraq and Proult. What has been said, therefore, on the subject of *acetous* acid and *vinegar* in the Cyclopaedia, is to be understood as applicable to dilute acetic acid; and the salts termed *acetites* are to be considered as acetates. The following facts are important, and deserve a place here.

The specific gravity of acetic acid does not enable us to determine its strength. The specific gravity is pointed out by Dr. Thomson to be a maximum when the liquid is a compound of one atom, and three atoms water. When the proportion of water is either increased or diminished, the specific gravity diminishes. Acid composed of one atom real acid and one atom water, and acid composed of one atom real acid and nine and a half of water, are filted by the fame chemist to have the same specific gravity.

The following table, drawn up chiefly from the experiments of Mollerat by Dr. T., exhibits the specific gravity of acetic acid of various strengths.

Acetic
Acetic acid of the fp. gr. 1.063 is the strongest that can be procured. It crystallizes at the temperature of $55^\circ$, and the crystals melt slowly when heated to $72^\circ$. This had been long ago observed by Courtenaux. Lowitz has proposed an ingenious method of obtaining it of the requisite degree of strength to crystallize. This consists in making distilled vinegar into a thick paste with well-burnt charcoal, and expelling the mixture to a temperature of $212^\circ$. The watery part is driven off, and the acid remains. The acid itself may be separated by a higher degree of heat, and thus obtained in a very concentrated state. It is commonly necessary, however, to repeat the process before it can be made to crystallize.

Mr. Chenevis, by distilling the acetates, obtained a peculiar motile substance different from acetic acid, and which he has denominated *pyro-acetic* spirit. The acetates of potash and soda gave a greater proportion of this principle than any of the metallic acetates; but when the acetate of barytes is distilled, the whole liquid product consists of this spirit without any mixture of acid whatever. No other genus of salts tried, such as the oxalates, tartrates, or citrates, yielded this spirit, nor was acetic acid converted into it by heat.

*Pyro-acetic* spirit is a white and limpid fluid. Its taste is at first hot and acid, but it becomes cooling and rather urinary. Its smell is peculiar, and is compared by Mr. Chenevis to that of a mixture of oil of peppermint and bitter almonds. Its specific gravity is 1.0764. It burns with a flame, white exteriorly, but of a fine blue within, and leaves no residue. It boils at a temperature of $165^\circ$. It mixes with water, alcohol, and volatile oils, in any proportion. With hot olive-oil it also mixes in any proportion; but with that oil cold it only mixes in certain proportions. When hot it diffuses wax and tallow. It diffuses also a little sulphur and phosphorus, and is an excellent solvent of camphor. It diffuses pothast, and becomes dark-coloured, but it may be obtained again unaltered by distillation. Strong sulphuric acid blackens and decomposes it. Nitric acid renders it yellow, and changes its properties. Muratic acid renders it brown. When distilled with this acid a combination takes place, and a substance is formed possessing very different properties from muriatic ether. These properties are sufficient to shew, that the pyro-acetic spirit is a distinct substance, and differs entirely from alcohol, ether, and volatile oils.

Of course, therefore, as Dr. Thomson observes, it deferves a distinct place among common combustibles.

Many attempts have been made to analyze the acetic acid. Thofe most worthy of notice are by Gay Lussac and Thenard, and Berzelius. The former burnt a mixture of acetate of barytes and chlorate of potash. The results were carbonic acid and water. Berzelius's analysis was made on the same principles, but the salt he employed was supposed to be quite free from water. The following are the results of these celebrated chemists:

\[
\begin{align*}
\text{Hydrogen} & : \text{Carbon} & : \text{Oxygen} & : \text{Acid} \\
\text{Gay Lussac} & : 5.629 & + & 50.244 & + & 44.147 & = & 100 \\
\text{Berzelius} & : 6.55 & + & 45.83 & + & 46.82 & = & 100 \\
\end{align*}
\]

If, with Dr. Thomson, we consider the results of Berzelius most entitled to credit, acetic acid consists of

3 atoms or proportions of hydrogen, weighing 0.375
4 atoms of carbon 3.000
3 atoms of oxygen 3.000

Or of ten atoms or proportions, and the weight of an integrant particle, will be 6.375; and this weight, as the same chemist has shown, accords very well with the composition of the acetates.

**ACHARIA, in Botany, a genus dedicated by Professor Thunberg, to the honour of his countryman Dr. Eric Acharius, knight of the order of Wafa, a member of various learned societies, and one of the most distinguished botanists of the present day, particularly with regard to the *Lichen* tribe, which he has profusely studied, and most learnedly illustrated.** (See *Lichenes.*) Dr. Acharius is now Regius Professor of Physic, at Vadstena, in Sweden.—Thum. Prodr. prof. n. 7. Willd. Sp. Pl. v. 4. 327. Lamarck Illustr. t. 755.—Chafa and order, *Monosoria Triandria,* or rather, perhaps, *Triandria Monogyna.* Nat. Ord. *Elaeagni.*

Gen. Ch. Cal. Perianth inferior, of two small, ovate, acute, permanent leaves. Cor. of one petal, tubular-bell-shaped, downy, in three deep, equal, elliptical segments, permanent. Stam. Filaments three, very short, inserted into the top of the tube of the corolla, opposite to its segments; anthers roundish, of two lobes. Pfi. Germin superior, roundish; style solitary, thread-shaped, half as long as the corolla; stigma three-leafed. Peric. Capele ovate, of one cell, and three valves. Seed solitary? globose, rough. The *flamines* are most perfect in the upper flowers, the *fij'sil* in the lower.

Eff. Ch. Calyx of two leaves. Corolla of one petal, three-leafed. Capele of one cell, and three valves. Seed solitary?

Obl. Nothing can be more imperfect or puzzling than the character and natural affinity of this genus, according to the materials furnished by Thunberg, especially what regards the *capule* and *seed*. He defines the fruit, "capule of one cell, with three *fij'sil*." Willdenow, who seems to have had no other authority than Thunberg's figure, says, "capule of one cell and three valves, with a solitary *fij'sil*," which last account both agrees with that figure. With respect to the natural order of *Acharia*, if we take for *bracteas* what Thunberg terms a *calyx*, the flower will indicate one of Jucass's *Elaeagni*, though the *capule* of three valves is very anomalous, and the lobed leaves no less so. By the specific name *tragodes*, or rather *tragodes*, and the place where the genus is introduced, Thunberg appears to have considered it akin to *Tragia*, (see that article,) which idea the aspect of the *leaves*, and the somewhat monoecious *flowers*, might probably suggest.

1. *A. tragodes*. Lobed Acharia. Thunb. Prodr. 14. t. 1. Fl. Cap. v. 1. 165. Willd. n. 1. — Gathered by Professor Thunberg, near Van Stade's river, and in other parts of the interior of Africa, above the Cape of Good Hope, flowering in December and January. *Root fibrous, annual*. *Stem solitary, herbaceous, erect?* from four to twelve inches high, branched from the bottom to the top, smooth; *branches alternate, angular, erect, somewhat zigzag, wand-like, subdivided. Leaves* alternate, on stalks about their own length, about an inch long, three-lobbed, finely downy; lobes obovate, variously cut. *Flowers* in effect monoecious, axillary, solitary, on short stalks, reflexed, small, the male about the upper part of the plant, female lower down. The *corolla* is about a quarter of an inch long, downy all over, as are likewise the *germen* and *fij'sil*. *Capule* obovate-oblong, acute, twice the length of the permanent corolla. *Seed* nearly the size of a pepper-corn, apparently black and rough.

ACHERON, 1. 1. r. *Theopria.*

ACHILLINI, 1. 25, for 40 r. 49.

ACHIMENES, in *Botany,* so named by Browne, possibly...
fibly from \( a \), and \( y \), to be country, or temperate, meaning that the plants in question are not calculated to endure rough weather. He tells us they thrive best in the cooler parts of Jamaica. When cultivated in Europe, they require great heat. This genus is founded on two species only, and those as generally different as two plants of the same natural order can well be. See Browne's Jamaica, 270. t. 30. f. 1, and Juff. Gen. 119. The latter writer, following Browne, did not distinguish these plants. One of them is Colomnea bifrons, the other our Ceyilla ; see that article.

ACHOR, last line. p. Porrício instead of Tinea Capsita.

ACHIROCOIDES. Add. See Serpentes.

ACHTIL, Achteling, or Martin, a common measure in Germany, which contains 4 firiners, 8 metters, 16 fechters, or 64 gefcheides. See MALTER.

ACIANTHUS, in Botany, from \( a \), a point, and \( a c h o s \), a flower, because of the brily tips of the calyx-leaves, unusual in this family.—Brown Prod. Nov. Holl. 1. 321.—Clafs and order, Gyandria Menandria. Nat. Ord. Orchidee.

Gen. Ch. Cal. Perianth three-leaved, somewhat ringent, coned; its two fide-leaves placed under the lip; upper one broadest, vaued, erect. Cor. Petals two, linear-lanceolate, much smaller than the calyx. Nectary a prominent undivided lip, shorter than the petals, with two swellings at the base, but no appendage to the disk. Stam. Antep terminal, permanent, of two cells close to each other; mass of pollen in each cell four, or two divided ones. Filj. Gernn inferior, oblong, angular; style erect, semi-cylindrical, without any auricles or wings at the summit; stigma in front. Peric. Capsule of one cell. Seeds numerous, minute.

Eff. Ch. Calyx somewhat ringent; its fide-leaves under the lip. Lip without a spur, shorter than the petals, undivided, with two prominences at the base. Anter terminal, without appendages, permanent. Pollen powdery. Column semi-cylindrical. This genus is next akin to Microtis of the same author (see that article); to whose effental character should be added, "Anter with two auricles. Column funnel-shaped."—Acianthus consists of little smooth herbs, with foliary, undivided, naked, downy, bullos, or tubercular, throwing out a few fibers, along with a downy fhoat, at whose extremity the young bulb is situated, on a partial stalk. Stem very short, its base enclosed in a short, tubular, pointed sheath. Leaf sfoliary, deeply heart-shaped, acute, with three ribs, and many reticulated veins; its under side red or purple. Flowers small, reddish, either clustered or solitary, their common flalk without bracteas, except beneath each flover.

1. A. fornicate. Vaulted Acianthus. Br. n. 1.—Flowers racemose. Awns four times shorter than the perianth. Petals nearly erect. Lip bearing longitudinal glands. Column concealed.—Native of the neighbourhood of Port Jackson, New South Wales, from whence we, long ago, received specimens in spirits, as well as dried, by favour of Dr. White, and where Mr. Brown has also gathered this curious little plant. The leaf is about as inch in diameter. Common flower-flalk from three to fix inches high, bearing from two to six flowers, about the size and aspect of the Corallorrhiza, each with an ovate bractea at its base. Lower leaves of the calyx linear-lanceolate, very narrow in comparison of the upper one. Petals linear-lanceolate, very delicate. Lip somewhat flake, having a longitudinal furrow, the ridges bearded horizontally with papillai glands. This is the only species we have seen.

3. A. taudus. Long-awned Acianthus. Br. n. 3.—"Stalk with one or two flowers. Awns very long. Leaf wavy at the margin."—Gathered by Mr. Ferdinand Bauer, in the neighbourhood of Port Jackson.

4. A. latis. Two-leaved doubtful Acianthus. Br. n. 4. (Epipactis reflexa ; Labill. Nov. Holl. v. 2. 60. t. 211. f. 1.)—"Stalk single-flowered. Leaves two, radical, hooded. Perianth without awns, its three leaves uniform; the lateral ones reflexed. Petals linear, narrow."—Gathered by Labillardiere, at Cape Van Diemen. Mr. Brown doubts whether this species, which he appears not to have examined, is most akin to Acianthus, or to another genus of his, hereafter to be noticed, named Chiloglottis. It agrees with the former in having four males of pollen, a column defluent of a point, and a lip without any appendage: with the latter in bearing two radical leaves, a perianth without awns, and very narrow petals. These leaves are represented in the plate, at fig. 2, as if situated on the outside of the calyx, which the description, and if we may take note of the other figures, liew to be an error of the draughtman or engraver.

ACICARPHA, so named by the celebrated Jussieu, from \( a \), a point, and \( a c i s \), a chaffy scale, because the scales of the receptacle, as he thought, become armed with a spinous point, when the seeds, which they separately envelop, approach towards maturity.—Juss. in Annal. du Mufl, d'Histo. Nat. v. 2. 347. Willd. Sp. Pl. v. 3. 2327.—Clafs and order, Synagenea Polyogamy-neceflaria? Nat. Ord. Composita capitata, or rather Aggregata, Linn. Comymhla, Feb. 5. Juss.

Gen. Ch. Common Calyx of one leaf, in five deep, linear, spreading segments, permanent. Cor. compound, bicordif. Florets all uniform, tubular, funnel-shaped; their limbs somewhat bell-shaped, five-leaved, obtuse; the central ones male, leaf-like numerous; those of the circumference more abundance, each furnished with flaves and pilifer, but not all fertile. Stam. Filaments five, very short; anthers oblong, united, shorter than the limb of the florec. Pijl. Gernn oblong; style thread-shaped, longer than the corolla; stigma club-shaped, notched. Peric. none, except the hardened scales of the receptacle. Seeds solitary; oblong, defluent of crown or wing, each enclosed in a greatly enlarged, hardened, concave, spinous-pointed scale of the lower part of the cylindrical chaffy receptacle.

1. A. tribuloides. Cultrip Acicarphe. Juss. as above, 548. t. 59. f. 1. Willd. n. 1.—Leaves oblong, deeply toothed.—Gathered by Commerson, on the leaflour, at Montre Video. Ross tapering, annual. Stems one or more, herbaceous, ascending or decumbent, a span long, somewhat branched, leafy, smooth. Leaves alternate, sessile, oblong, obtuse, flatish, smooth, an inch and a half to three inches long, deeply and coarsely toothed; tapering at the base. Flower-flalks terminal and lateral, opposite to the leaves, and about as long, simple, single-flowered, erect. Flowers white, hemispherical, one-third of an inch in diameter. Fruit a globular head, armed with unequal, rigid, sharp, palk, dividated, or recurved spines, and crowned with
with a tuft of withered male florets, like a tassel. The intermediate florets seem to be abortive, though furnished with the most conspicuous pistils.

2. A. fistulata. Spatulate Acicarpa. Brown Tr. of Linn. Soc. v. 12. 129.—Leaves spatulate, mostly entire.—Sent from Brazil by Mr. Sellow. A smooth, diffuse, apparently annual plant, with angular ascending branches. Leaves scattered, flaked, without stipules, spatulate, with a very short little point, rather thick, and perhaps glaucous, an inch and a half long; the lower ones sometimes toothed from above the middle. Footstalks linear, a little dilated at the base; the lowermost long, Heads of flowers yellow, solitary; either flaked and opposite to the leaves, or terminal and nearly serice. Involucre of five leaves in a simple row, longer than the flowers. Receptacle conical, fluted, with lanceolate pointed scales. Flores tabular, uniform, smooth. Those of the circumference in two or three rows, with perfect stamens as well as pistils. Tube of the corolla slender, cylindrical, closely united to the germen and base of the style; limb funnel-shaped, five-crested, segments parallel at the edges, half-lanceolate, flat, three-ribbed. Stamens five, inserted into the corolla, alternate with its segments, their filaments, as well as the lower half of the anthers, united into a tube. Gernmen combined, each crowned with a five-crested partial calyx, whose teeth, alternate with the segments of the corolla, becomes spinous, each germen containing one pendulous seed. Style thread-shaped, smooth. Stigma simple, obtuse, rather hairy. The numerous upper florets are rather smaller, with a membranous calyx, and imperfect germen. The ripe fruit, originating from the florets of the circumference, consists of close pericarps, combined together, not burling, each crowned with its own enlarged spinous calyx. Seed ovate, pendulous. Albumen fleshy, large, white. Embryo nearly cylindrical, central, about the length of the albumen, with two linear cotyledons. By this account it appears that Mr. Brown differs from M. de Julieu, in thinking the perfect genus belongs to the Linnaean order of Aggregate, and not to the Compositae. This last account of the fruit is evidently more natural than the above, and the character, if Mr. Brown, which we doubt not, be correct, must be altered to "Seeds crowned with the spinous partial calyx."

ACID. ACIDIFICATION, in Chemistry. When these articles were written for the Cyclopaedia, the theory of Lavoisier, that oxygen is the only principle of the acidification, was but imperfectly received. Since that period, however, a great revolution has taken place in chemistry, and the doctrine in question is now no longer admitted. This has indeed been noticed in subsequent parts of this work, more especially under oxygen and oxymuriatic acid; so that little more is necessary than to refer our readers to these articles. It may not be deemed superfluous, however, to mention here very briefly the discoveries that have led to these important changes.

The first circumstance which gave the death-blow to the doctrine of Lavoisier, was the demonstration by Gay Lussac and Thenard, and more especially by Davy, that oxymuriatic acid, or chlorine, as it is now termed, contains no oxygen, but is a simple elementary substance. Chemists indeed had never been able to demonstrate satisfactorily that oxygen actually existed in this substance; but by the plausibility of the Lavoisian doctrine, they had tacitly admitted its presence from analogy: and so strongly was this belief founded, that there are a few, we believe, who adhere to the old opinions even to the present time.

More recently, however, the old opinions have been rendered still further improbable, and the new ones corroborated by the discovery of iodine and cyanogen; the one an elementary, the other a compound substance, both which have been unequivocally demonstrated to form acids by combining with hydrogen. The analogy, also, of sulphur, and tellurium, and hydrogen, compounds free from oxygen, but possessing the properties of acids, have been like wise urged in proof of the new opinions, and as quite reconcileable with those of Lavoisier.

Our readers will find further information on this subject in the articles Chlorine, Cyanogen, Iodine, Muria-}

**ACINOCAFORME, Folium, in Botany, a Scimitar-shaped leaf, is scarcely used but for one species of Mesem bromanthemum, which bears this specific name. (See Leaf.)** It is of a succulent texture, compressed, one edge convex and thin, the other straighter and thick.

**ACINUS,** in Botany and Vegetable Physiology, a Grain, is technically used for each pulpy portion, containing a foilly united, of a compound. It has been called the fruit of the Raspberry, Bramble, &c., consists of several acini; and perhaps the same term may be applied to the separate portions of a Mulberry, though originating in the calyx of each flower become pulpy. In Paspalum the capsule is lined with very juicy acini, each lodging a single seed. Gærtner improperly extends the above term to the simple many-seeded berries of the Vine, Gooseberry, &c. The last-mentioned fruit, in an early state, rather resembles the Paspalum.

**Eff. Ch. Calyx none. Petals five; the uppermost vauclut. Nectaries two, flaked, recurved. Capsules three or five.**

M. De Candolle, following Jullie's view of the subject, gives the following characters, using the term sepala for calyx-leaves, and petals for nectaries.

Calyx of five petal-like, deciduous leaves; the upper one (hood) large, concave, helmet-shaped; two lateral ones, (wings,) orbicular; two lowermost oblong. Petals five, sometimes irregular in number; three very minute, claw-shaped, often converted into flamen; two uppermost with long claws, hooded, sheltered under the helmet-shaped leaf of the calyx, dilated at the top into a bag, whole bottom, the fummit, or pur, of the petal, is callous, incurved, its mouth extended into an oblong, emarginate limb, or lip. Stamens indefinite. Capsules three to five, with an indefinite number of seeds.

Perennial herbs, with tuberous roots, whose knobs in some instances bear fibres, in others are oblong, and mixed therewith. Stem leafy. Leaves flaked, deeply palmate, with from three to five segments, variously cut, cloven and toothed. Claviers terminal. Stalks single-flowered, from the bosoms of the bractea, each bearing two smaller bractea.

**Flowers**
ACONITUM.

Flowers large, irregular, sometimes sulphur-coloured, sometimes blue, or white.

All the species are poisonous; the Aconitum lefis dangerous; the *Aconitum* highly noxious. The root is always the most poisonous part, the herbage lefs acrid, and though in a fresh state injurious to animals, by drying, or by boiling in water, it becomes so mild, that some species, *A. foeniculum* for instance, are eatable! Dr. Storck, who found Aconite so useful in chronic rheumatism, confirmed gout, and venereal swellings of long duration, employed *A. poni
calum*; but other physicians have often, without sufficient attention, promiscuously given every kind with blue flowers.

The twenty-eight species at this time known inhabit rough buffalo or woody places, in the northern hemisphere; eleven are found in Europe, eleven in Siberia, one in Japan, one in North America, and one is common to Siberia and the western part of North America.

This is a most natural genus, but very difficult as to the determination of its species, nor has it been properly investi
gated. Clusius in his time was extremely well acquainted with the European kinds, and requires to be consulted in preference to all other writers.

Aconitum may be distributed by the habit, rather than by any characters, into five fections, or divisions, as follows.

Leaves in numerous deep linear segments. Species 1 and 2.

Leaves in numerous deep linear segments. Species 11—14.

5. *Anabates*. Flowers blue or white. Hood convex.

Stem climbing, somewhat twining. Species 21—25.

† Such as are not sufficiently described: 26—28.

++ Such as are doubtful, or uncertain: 29—35.

Sec. 1. *Aconitum*.

To the above characters are added—Hood acute at the apex. Root with two oblong knobs.

terum; Ger. Em. 966. A. vera, flore luteo; Barrel. Ic. t. 625.)

β. atrovirens; leaves and flanks smooth. (A. falis
terum elatus pyrenicicum, folio atris-virentibus, flore majori; Tourn. Infl. 425.)

γ. confertiflorum; cluster cylindrical, dense, downy. (A. tuberoforum; Patrin, unpublifh'd.)

Hood convex, terminating in a point; flurs spiral; lips inerfely heart-shaped. Leaves in numerous linear segments.

—Native of rough buffalo places, on the mountains of Europe; in Switzerland, on the Apennines, and in Siberia; β on the Pyrenees; γ on mount Caucasus.

Var. a has either a simple or branched flom, which, like the flower-flanks, is either smooth, or finely downy. β has smooth dark-green leaves, a taller and smooth flom, cvs convex hood, with a more abrupt and pointed back. γ is smaller, with a closer more cylindrical cluster, whose main flom, as well as the partial ones, are clothed with velvet-like down; it may be a distinct species. De Candolle.

We have not followed, here or elsewhere, our learned friend, in his elaborate assemblage of synonymy, nor in his chronological arrangement of them. To the latter we have obju&ion, and we wish to give our readers an idea of his powers of discrimination, and to profit by them ourselves.

2. *A. aconitum*. Prominent Wholefome Wolf's-bane. (A. pyrenicicum; Pallas Itin. v. 2. 315, by his hort. name.) —Hood convex; its back protruding forward, over the pointed beak; flurs spiral; lips inerfely heart-shaped. Leaves in numerous linear segments.—Gathered by Pallas in Siberia. This is fo like *A. aconitum*, that perhaps it may be esteemed a mere variety. It differs only in this respect, that the back, or ridge, of the hood is not merely convex, but ftreched forward over the point in front. This plant varies like the former as to the density of its cluster, and the smoothness or fine downiness of the flower-flanks. De Candolle. We must frankly concur in the opinion of its being a variety of the first species.

Sec. 2. *Lycocotonum*.

Flowers pale yellow, white, or blue; their hood conical, elongated, obtuse, or deeply pointed in front. Root tuberous, sending out fibres. Leaves with fome wedge-shaped lobes, deeply toothed, or jagged, at the extreme tip.

tas minute. Stem downy. Leaves in five deep divisions, with linear pointed lobes.—Native of the eafthern part of Siberia, about Irkoukii. Patrin. Intermediate between *Aconitum* and *Lycocotonum*, differing from the former in having a conical hood, from the latter in the linear lobes of its leaves; from both in the ftrange fflurs, or fummits of the floarics. (De Candolle's note.) Stem round, finely downy, not hip
dy. Leaves with long scattered hairs on the fflurs, and here and there on the under side; the upper appearing downy when magnified; their outline circular, divided nearly to the bafe into five fomewhat covering lobes, pinnatifid, with linear pointed fegments. Cluster erect, long and fow. Stalks erect, downy, shorter than the flowers, having under each a linear awl-shaped, scarcely downy; bracteae, fih fow; as well as a fmafer clofe tritate half way up. Flowers white, according to Patrin; pale yellow when dry; exter
dally downy; hood elongated; wings orbicular, with long hairs on their margin and inner surface. German downy.

4. *A. hispidum*. Rough-talked Wolf's-bane. De Cand. n. 4.—Hood conical, obtuse; flurs ftraight; lips obovate; wings flightly bearded. Bracteae awl-shaped, hairy. Stem hairy. Leaves in five deep divisions, with linear, rather acute, lobes.—Found by Pallas, in the eafthern part of Siberia. Lambers. Differs from the laft in its hipid, not downy; flom more deeply five-cleft leaves, whose lobes are not pointed, but rather obtuse, with a little calous apex; more hairy bracteae; and ftreched awl-shaped wings. The leaves are very like *Aconitum*, but with broader lobes; flowers like *Lycocotonum*, but with ftrange fflurs. Stem erect, round, simple; hipid chiefly at the bafe, with fow, rather defexed, hairs; the top almoft smooth. Lower leaves on long hairy fflurs, their outline orbicular; upper side scarcely downy; ribs of the under one hairy. Cluster simple, rarely with one small branch, cylindrical, erect. Stalks erect, shorter than the flowers, which are pale yellow, reembling the laft, but lefs bearded. Bracteae awl-shaped, faggy, two lines long; two smaller ones in the middle of each fflur. De Candolle.

as its place of growth.—Hood conical, obtuse; spurs spiral; lips inerterly heart-shaped. Cluster drooping at the summit before expansion. Leaves in five deep divisions; lobes pinnatifid, with spreading, recurved, acute segments. —Native of Siberia and Tartary; cultivated in the Upham garden. Very nearly allied to *Lycotonum*, but differing in the leaves being divided to the very base into many pinnatifid portions, whose elongated, acute, widely spreading segments are entire, not at all cut or ferrated. Cluster long, its upper part drooping while the flowers remain in bud. *Bracteae*, both general and partial, very small. Stalks shorter than the flowers, but much longer than their respective bracteas. The root as in *Lycotonum*. De Cand. To this original specimen is attached a different one from Siberia, which we concur with professor De Candolle in thinking no other than *Lycotonum*. Hence Linnaus has no authority for *A. pyreunicum*, which depends upon other authors, as follows. His herbarium indeed contains, if we mistake not, a specimen of this species, brought by baron Altroemer from Spain, but confounded by Linnaeus with *Lycotonum*. 

6. *A. pyreunicum*. Pyrenean Wolf's-bane. Lamarck Dict. v. 1. 33. Desfont. Tabl. 149. "De Cand. Franc. ed. 3. v. 4. 916. v. 5. 642." (A. pyreunicum, ampliorem folio tenumis incimato; Tourn. Dict. 144. A. n. 6; Camer. Epit. 831, with a figure.)—Hood conical, obtuse; lips spiral; lips obovate. Leaves palmate below the middle, with from five to nine three-cleft, deeply cut lobes, lying over each other. —Native of rugged meadows on the Pyrenees, among leesy thickets, flowering in July and August. Tournefort and De Candolle, Related to *Lycotonum*, but certainly distinct. A handsome plant, three or four feet high, downy, with large, long-flaked, almost circular leaves, whose main lobes are unequally divided, wedge-shaped at the base, separated upwards into acute, cut lobes, dilated a little as frequently to overlap each other. Cluster long, cylindrical, dense, more or less branched at the base. Stalks often shorter than the flowers. Lower bracteas in three or five lobes; upper linear, in the middle of each flake, spreading, from two to five lines long. Flowers pale yellow, externally covered with velvet-like down. German hairy. These characters are not very strong, but they are constant. Specimens gathered by De Candolle in the Pyrenees differed in no respect from those which have been cultivated at Paris, even since the time of Tournefort. De Candolle. We have had no opportunity of enquiring what bands for this species in the gardens of England, but Miller is most likely to have received the true plant from France. Our Linnaean Spanish specimen, mentioned under the last, correctly answers, in every point, to the above description.

7. *A. lycotonum*. Great Yellow Wolf's-bane. Linn. Sp. Pl. 750. Willd. n. 1. Ait. n. 1. Jacq. Auffr. t. 380. Balliard Fr. t. 63. Villars Dauph. v. 3. 703, from the author. (A. lycotonum vulgare, luteo flore; Cluf. Hist. v. 2. 94. A. luteum ponticum; Lob. Ic. 677. Ger. Em. 970. A. reticulatum; Lob. Ic. 599. 600. A. n. 2; Camer. Epit. 827. Matth. Valgr. v. 2. 431. A. caput animi; Lob. Ic. 877. Ravn. Penta. Irr. t. 129.)—Hood conical, obtuse; lips spiral; lips obovate. Leaves downy, divided more than half way, into from three to five lobes, which are three-cleft and jagged. Partial bracteas in the middle of each flower-flake. —Native of woods, thickets, and gravelly pastures, on the mountains of Switzerland, France, Germany, and Italy, flowering in summer. This is probably, as M. De Candolle indicates, the real *aconitum napellus* of Dioscorides, with whose imperfect account it sufficiently agrees. It is one of the most common of this genus, but not found in Britain. The *flam* is from two to four feet high, nearly simple, or very much branched, smooth or downy. Lobes of the leaves more or less deep, either close or spreading. Flowers crowded or distant. M. De Candolle hints that some of these diversities may afford specific distinctions, but we can scarcely suppose this. He observes that *A. lycotonum* differs from *bipinidum*, *aphrodeum*, and *abocheleum* in its spiral spurs; from *pyreunicum* in having from three to five, not seven to nine lobes in the leaves, and those not lying over each other, as well as in the *germen* being smooth, scarcely at all downy or hairy, and the *flanks* much longer than their flowers. From the following one, hitherto confounded herewith, it differs in having pale-yellow, not blue, flowers, and the partial bracteas fitted half way up the flower-flark, not near their base.

8. *A. septentrionale*. Blue Northern Wolf's-bane. "Kulte Acon.* 27. Wild. n. 7. De Cand. n. 8. Ait. n. 6. (A. lycotonum; Linn. Fl. Lapp. ed. 2. 185. Tour in Lapland, v. 1. 36. 47. 278. v. 2. 123. 372. Fl. Dan. t. 123. Calceolus Lapponicus; Scheff. Lapp. 360.)—Hood conical, obtuse; lips spiral; lips obovate. Leaves downy, divided more than half way, into from three to five divided sharply cut lobes. Partial bracteas at the lower part of each flower-flake. —Native of mountainous thickets and pastures on the sides of the Lapland Alps, and throughout Norway, as well as in some parts of Siberia, and on the Carpathian mountains. Linnaeus noticed it also about the bales of the larger hills in Medelplad and Angermanland; but though he has recorded in Fl. Lapp. that the flowers are of a greyish-blue; not yellow, as described in all the accounts of *A. lycotonum*; yet he still supposed him to be the same species. His own specimen retains evident traces of this blue or grey colour, and answers to the distinctive characters of the septentrionale, as given by De Candolle. The leaves, as that excellent writer remarks, are more acutely toothed. With respect to the situation of the partial bracteas, they are rather on the lower part, than at the base, of the flower-flakes. The flowers are less downy, and of a thinner texture, than in *lycotonum*. Perhaps if living specimens were compared, better characters might be discovered, for there is every reason to presume this a distinct species. Linnaeus in Fl. Lapp. speaks of the leaves being boiled and eaten with impunity; and in his Lapland Tour, v. 2. 123, records another infinace of the same fact. He was justly astonished, knowing the poisonous quality attributed by all writers to *A. lycotonum*. Perhaps this may strengthen our opinion of these plants being truly distinct, for we find no record of the true *lycotonum* being used as food, in any flate. Haller was one of the first botanists who suggested the propriety of separating these species; see his Hist. Stirp. Helvet. n. 1200. Yet there seems little reason for his wonder, there expressed, that this *aconitum* should be fatal to wolves. When recent its qualities are probably very different.

9. *A. echroleicum*. Pale Wolf's-bane. Willd. n. 4. De Cand. n. 9. Marfch. Taurico-Caucuf. v. 2. 14, excluding the synonymy of Tournefort.—Hood conical, elongated; lips curved; lips lancelolate. Leaves deeply palmate, five-lobed, scarcely downy beneath; lobes deeply three-cleft, acutely jagged and toothed.—Found in mountainous meadows of mount Caucasus; frequent about the mineral springs of Narzana; flowering in summer. Communicated to us by Dr. Fische. The habit entirely resembles *A. lycotonum*, but the surface of the herb is nearly smooth; the lobes of the leaves are more sharply toothed, and the *flurs* of the *nectaritis* are rather curved than spiral. Stem erect, round, pale green, three or four feet high, with straight branches. *Flowers* long, branched at the bottom.
ACONITUM.

**10. A. japonicum.** Japan Wolf's-bane. Thunb. Jap. 231. Willd. n. 2. De Cand. n. 10. (See Huso of the Japaneese.)—Hood conical, obtuse. Leaves palmate, three-lobed; lobes obtuse, cut; their segments rounded, with a point. Gathered in Japan by Thunberg, who describes this species as allied to *lycoctonum*. The stem is round and smooth. Leaves stalked; their lateral lobes in two segments; middle one in three; all obtuse, deeply toothed; their teeth rounded, with a point. Clufter short. Thunberg. Scut. 1. Naples.

Flowers blue or white, never buff-coloured; their hood convex, tapering into a point in front. Stem straight. Clufter cylindrical. Roots fibrous, from a rather tuberosous stock. Leaves lobed in a palmate manner, many-cleft; their segments linear.

All the species of this section having been confounded under *A. napellus*, De Candolle has thought right to lay aside that specific name entirely. But even he is doubtful whether they are not all one species!

**11. A. vulgaris.** Common Monk's-hood. De Cand. n. 11. (A. Napellus; Linn. Sp. Pl. 751. "Koelle Acon. 14, with a figure." Woodv. Med. Bot. t. 6. Sm. Prod. Fl. Græc. Sibth. v. 1. 372. A. lycoctonum 6. Napellus vulgaris; Chlf. Hift. v. 2. 96. Napellus; Matt. Valgr. v. 2. 448. N. verus carèx; Ger. Em. 792. N. flore minore; Rivin. Pentap. Irr. t. 130.)—Germens three, smooth. Wings hairy on the inside. Clufter cylindrical, elongated. Leaves in five divisions to the very base, with many linear acute segments, each with a longitudinal furrow on the upper side.—Native of mountainous meadows in most parts of Europe, from Switzerland, Germany, France, Spain, and Italy, to Greece, flowering in summer, and one of our most common garden plants ever since the days of Gerard. De Lech sent us specimens from Scotland; but there is reason to doubt the plant's being really wild in Britain. De Candolle distinguishes this from all its relations, though, as he says, with difficulty, by the simple, straight, upright stem, almost always terminating in a simple cylindrical close cladus, and not corymbose; leaves with linear segments, that are hardly at all dilated at the extremity, marked with a furrow, and not resembling any others, except perhaps those of *A. tauricum*, whose cladus is the only one more densely than the present; hood convex, rather acute at the summit, but not gibbous or elevated at the back, as in *tetricum*, *rugiatum*, and *variegatum*; wings hairy on the inside, which in *tetricum*, *paniculatum*, &c. are smooth; germens smooth, never more than three, not five, and hairy; cladus six lines long, and not an inch, as in *A. neubergense*. The present species however, being very common, is extremely variable; the whole surface is sometimes quite smooth, sometimes downy, especially about the flowers; the furrow on the segments of the leaves is more or less distinct; the flowers naturally blue, or (in the variety called by Schulz *biolor*) white at the base, blue at the summit, become in gardens white, rose-coloured, purple, or variegated. De Candolle. Their most usual and well-known colour is a deep and glossy blue; we have seen no other. Dr. Sibthorp's Greek plant must rest on his own authority, being only mentioned in his MSS., without any accompanying specimen; nor were the species of this genus so accurately noted in his time.

**12. A. friolidum.** Straight Monk's-hood. "Bebb. Monogr." De Cand. n. 12. Germens three, smooth. Wings hairy on the inside. Clufter cylindrical, elongated. Leaves in five divisions to the very base; their lobes wedge-shaped, jagged at the summit.—Native country unknown. Clofely related to the last, but differing in the three or five divisions of the leaves being wedge-shaped in their lower part, and cut at the extremity into oblong lobes, which are shorter, blunter, and twice as broad as in that; the cladus is shorter, with little short branches at its base. Perhaps this may not be sufficiently distinct from the following.

A. lycoctonum, vel neubergense; Chlf. Hift. v. 2. 96. Moris. sect. 12. t. 3. f. 11. A. purpureum neubergense; Ger. Em. 973. A. folorum lacinias linearibus, supræmel liatoribus, lineæ exaratis; Linn. Hort. Clift. 214. Morris in Stockh. Trans. for 1739. 43. t. 2. Napellus flore majore; Rivin. Pentap. Irr. t. 131.)—Germens three, smooth. Wings hairy on the inside. Clufter cylindrical, elongated, lax; stalks downy, rather spreading. Leaves in five deep, wedge-shaped, three-lobed, jagged segments.—Native of Alpine meadows in various parts of Germany, Hungary, Siberia, &c., flowering rather later than *A. vulgaris*, and no less common in gardens than that species, with which it is generally confounded. Cluisins having originally met with this plant in the greatest abundance on the mountain called Neuberg, in Styria, De Candolle has choosen the above specific name, which is indeed preferable to the mon- grol one of *neomontanum*, adopted by some writers. The species before us is said to differ from *vulgaris*, in having broader leaves, whose rather wedge-shaped divisions are more connected at the base; three-cleft and cut at the extremity, into acute segments, thice the breadth of *vulgaris*, and not marked with any furrow. The cladus also is more lax, its stalks always downy, more spreading, and longer than the flowers. The cladus, according to Wahlenberg, are three, above an inch long, spreading, those in the middle part of the clufter exceeding the length of their stalks.

**14. A. tauricum.** Taurian Monk's-hood. Wulf. in Jacq. Coll. v. 2. 112. Jacq. 1c. Rat. t. 402. De Cand. n. 14. (A. Napellus; Ball. Fr. v. 1. 492. De Cand. A. lycoctonum tauricum; Chlf. Hift. v. 2. 95. A. violaceum; Ger. Em. 973.)—Germens three, smooth. Wings smooth. Clufter cylindrical, elongated, very dense; stalks smooth, shorter than the bractees. Leaves in five divisions to the very base, somewhat pedate, with linear lobes.—Native of the Alpine heights of Tauria, Carinthia, &c. flowering in summer. Very like *vulgaris*, but the smooth wings and flower-stalks, the latter shorter than their bractees; the short dense cladus, whose main stalk is concealed; and the pedate, more wedge-shaped, linear-lobed, scarcely furrowed leaves, are thought by De Candolle to afford sufficient differences.

**Sect. 4. Cammarum.**

Flowers blue or white; hood very convex, or conical, ending, often abruptly, in a point in front. Clufter lax, somewhat corymbose. Stem straight. Leaves deeply divided, in a palmate manner, into wedge-shaped lobes. Roots navel-shaped, intermixed with small fibres.

For the same reason as concerns the last section, the specific name *Cammarum* is here laid aside, having been variously applied by different botanists. De Candolle sup- pepts all the species of the present section, or at least the first four, may be varieties of each other!  

**15. A.**
14. *A. intermedium*. Ambiguous Monk's-hood. De Cand. n. 15. (A. neomatonicum; Willd. n. 9, excluding the synonyms. "Hoppe Pl. Exiftc; De Cand. Thora italica, C. f. Napellus minor, flore careuleo; Barcel. Ic. t. 612.) — Germans three, smooth. Wings internally hairy. Clutter lax, corymbose; flacks smooth. Hood very convex, somewhat conical.—Found in mountainous woody parts of Germany and Flanders, flowering in July. In habit like the two following, but the hairy wings, (De Candolle by mistake fays lps.) distinguishes this species from all the rest of the section. We have seen no specimer.

Germans three, smooth. Wings internally smooth. Clutter lax, corymbose; flacks downy. Hood convex.—Found in various alpine parts of Europe, flowering towards autumn. The roots are roundish, tapering downwards, bearing many long fibres. Stem erect, smooth. Leaves somewhat pedate; their lobes wedge-shaped below, acutely pinnatifid upwards. Clutter usually erect, with long downy flacks; downy; the lower ones branched. Flowers large, of a brighter blue than vulgar, with a convex hood, whose point is more remarkable than in the 3d section. It may be important, if any person should repeat Storck's experiments, to be aware that this is the plant he used, and not our Common Monk's-hood, *A. vulgarae*.

17. *A. rostratum*. Beaked Monk's-hood. De Cand. n. 17. (A. Cammarum; Lamarck Dicr. v. i. 33. Willd. n. 14. A. lycoctonum nonum judgenbergense; Cluf. Hift. v. 2. 97. A. maximum judgenbergena; Ger. Em. 973. A. lycoctonum, flore maximo; Bauh. Hist. v. 3. 659.)—Germans three, smooth, or only fringed at the inner edge. Wings smooth. Clutter somewhat corymbose, of few flowers, with smooth flacks. Hood conical, elevated, abrupt in front, with a prominent beak.—Native of the Aufran and Swifs alps, flowering in summer. We have it in Mr. Davall's herbarium, but the plant seems unknown to cultivators. The roots are roundish, tapering downward. Stem a yard high, strait, round, smooth, purplish. Leaves somewhat pedate; with wedge-shaped, jagged, acute lobes. This species differs from the preceding, as well as from the following, in the very large and high hood, accompanied by a very considerable beak, being conspicuous for the greater size, and rather paler blue, of its flowers.

18. *A. hebegeum*. Downy-fruited Monk's-hood. De Cand. n. 18. (A. Cammarum; Linn. Sp. Pl. 751. Willd. n. 14.? Ait. n. 11? Jacq. Anfr. t. 424.)—Germans from three to five, all over finely downy. Wings nearly smooth. Clutter rather corymbose, of few flowers; flacks downy. Hood convex, beaked in front.—Native of rugged bushy places on the alps of Switzerland, from whence we have it; as well as of Austria and the receffes of the Carpathian mountains, flowering in summer. A large handfome species, with ample foliage, whole segments are acutely pinnatifid. Flowers dark-blue; their hood rounded, much less elevated than in the preceding. The Germans clothed with fine velvetlike down afford a clear specific character. There are no means of perfectly ascertaining the A. Cammarum of Linnaeus, he having left no specimer, and his synonyms pointing to different plants. His character of "floribus subpentagonibus" is all that indicates the present species, which is probably the plant of the gardens. De Candolle gives all the synonyms of his frill, or principal, variety of *paniculatum*, &c.; and it is as well serve for *hebegeum*; but surely Storck's figure cannot be mistaken for this. The plants themselves can never be confounded, provided the Germans be attended to; for which discovery we are indebted to professor De Candolle.

19. *A. variegatum*. Variegated Monk's-hood. Linn. Sp. Pl. 770. Willd. n. 13. Ait. n. 10. "Koele Acon. 18." (A. lycoctonum decimum, Thora italica; Cluf. Hift. v. 2. 98. A. lycoctonum careuleum parvum; Ger. Em. 971. Napellus flore mixto; Rivin. Penat. Irr. t. 133.)—Germans three, smooth as well as the petals. Clutter lax; flacks smooth; the lower ones many-flowered, twice the length of their many-cleft bracts; their lower partial bracts cut. Hood elevated, conical, obtuse, with a short beak in front.—Native of woody rather alpine situations in Carniola, Bohemia, and Italy, flowering in August. Roots, according to Clufius, tuberous, with ovate knobs, or rather perhaps buds. Whole herb smooth. Stem erect, with spreading branches. Lower leaves on long flacks, their outline orbicular, their upper side of a shining green, lower pale; their three or five deep principal divisions wedge-shaped at the base, dilated and many-cleft at the extremity, with oblong acute segments; upper leaves sessile; floral ones in three deep divisions, copiously, but not deeply, cut. Lower flacks of the lower flacks, each bearing three or four flowers. Partial bracts, which are under each flower, linear. Flowers large, perfectly smooth, blue (or blue and white); the hood very large, above an inch long, and extremely convex, not at all covering the wings, its back short; wings orbicular, six or seven lines long; stems smooth, flaccid. De Candolle. This description answers to the Linnian specime, and nearly to our garden plant, except that we have always seen the flowers principally white, with a portion of blue on the back and wings, and that the stem in ours is rather of the twining or wavy kind, as in the next section; by no means straight, though supporting itself. This character appears in the old wooden cuts, and may possibly have escaped M. De Candolle only because, as he himself mentions, he had seen no other than a dried specimen. The figure of Rivinus indeed is erect, and yet, notwithstanding the annexed representation of five capitules, we can scarcely doubt that this synonym.

20. *A. album*. White Monk's-hood. Ait. ed. i. v. 2. 246. ed. 2. n. 5. Willd. n. 6. De Cand. n. 20. (A. orientale; Mill. Dicr. ed. 8. n. 10. A. lycoctonum orientale, flore magno albo; Tourn. Cor. 30. Napellus flore albo; Rivin. Penat. Irr. t. 132.)—Germans four or five. Hood conical, with a long claw. Clutter lax, simple. Stalks erect. Leaves in three or five deep, ovate-wedge-shaped, three-cleft, toothed segments.—Found in the Levant by Tournefort, who sent seeds to the royal garden at Paris, and from thence, according to Miller, it came to England. Hence there can be no doubt respecting Tournefort's synnym; and yet his appellation of *lycoctonum*, and the place in his *Iift*, where he directs this species to be inserted, might favour the application of his synonym to *ochroleucum*, n. 9, as in the Flora Taurico-Caucasica. The plant of Aiton, and consequnently of De Candolle, is totally different from the *ochroleucum*, and very near *variegatum*. The stem is described by Miller fix feet high, or more. We have a specimen from Dr. Schrader, sent to be compared with *Napellus*, which appears to be this very species, and agrees well with the figure of Rivinus indicated above, except the flowers being blue; but that circumstance can...
be of no moment. The stem is round and smooth. Leaves smooth; their wedge-like lobes sharply pinnatifid. Clufter lax, with some axillary branches below. Stalks erect, smooth. Hood near an inch and a half long, obtuse, even, bent forward with a slightly recurved, notched, beak; its claw longer than the large round wings. Gernms five, smooth.

Scit. 5. [Anabates.]

We received a specimem in flower, in Sept. 1801, from the rich garden of the late Rev. Mr. Watts, of Affhill, Norfolk. The stem is round, slender, purplish, five feet high, varying in its degree of downiness. Leaves in size and figure not unlike Malva molichata. Clufter branched, lax. Flowers of a middle size, rather light blue, downy; hood convex, rounded, with a beak in front; stamens hooked, with an obtuse, inverely heart-shaped, lip. Gernms five or fix, elliptic-oblong, smooth. Stamens smooth. Our specimem rather answers to the more hairy variety of De Candolle, which he suspected might prove a distinct species; we have seen no other, and can therefore form no opinion.

23. A. tortuorum. Twisted Monk's-hood. Willd. Enum. 575. De Cand. n. 23. (A. n. 8; Matth. Valgr. v. 2. 437; A. comi ineflexa, folia latoriusa; Tourn. Init. 425?)—Stem twining, smooth, as well as the footstakles. Leaves in three deep, ovate, pointed, coarsely and deeply toothed lobes. Clufter lax. Gernms two or three, quite smooth, as well as the flaments.—Seen in a cultivated flat only, by Willdenow and De Candolle, who knew not whence it came. The stem rises to the height of fix or seven feet, branching, round, and smooth. Leaves smooth; their lobes wedge-shaped at the base; the lateral ones deeply cleft. Flower-stalks downy. Lower bracts three-cleft; partial ones oval-shaped, placed about half way up each stalk. Flowers smooth, pale blue; hood convex, gradually tapering into an acute beak. The figure of Matthiæus expresses the habit, but may probably belong to some other species. De Candolle. Indeed many of that author's figures are curved, evidently to accommodate them to the dimensions of the wooden block.

24. A. glabrum. Smooth Twining Monk's-hood. De Cand. n. 24.—Stem twining, smooth like the footstalks. Leaves in five deep, lanceolate, wedge-shaped, coarsely and deeply toothed lobes. Clufter lax. Hood flaked, elongated, conical, with a long, erect, cloven beak. —Native country unknown. Described from the herbarium of Prof. Forfell Desfontaines. The whole herb is smooth. The flowers are pale blue, and remarkable for the long linear lobes which terminate the beak, and flanding erect, are nearly on a level with the top of the hood, which appears to be the great peculiarity of this little-known species.

25. A. uncinatum. American Monk's-hood. Linn. Sp. Pl. 750. Willd. n. 15. Ait. n. 12. Pursh n. 1. Curt. Mag. i. 1119. De Cand. n. 25.—Stem somewhat twining, slightly downy. Footstalks smooth. Leaves abruptly at the base; lobes three or five, acute, with three teeth. Clufter lax. Hood flaked, elongated, convex. —In swamps, and by the sides of rivulets, on the high mountains of Virginia and Carolina, flowering in June and July. Flowers large, of a fine blue, and singular structure. Pursh. Stem round, somewhat branched, minutely downy. Footstamm smooth, round, with a longitudinal furrow. Leaves coriaceous, smooth, dark-green, lobed only about half down; lobes three-ribbed. Lower stamens of the clufter long and divided; upper simple and crowded; all downy in their upper part. Bracts two, oblong, not far from the flowers, which are large, of a rich violet purple; hood tapering into a sharp beak; wings orbicular, hairy rather than fringed. Gernms three to five, downy. Such is our Linnæan specimen, from J. Bartram.

M. De Candolle saw in the herbarium of Michaux, mixed with the above, specimens, whose hood was twice as long, almost conical, without any hook or beak. This he considers as the uncinatum of that author, Fl. Boreæ-amer. v. 1. 315, and possibly a distinct species.

Mr. Pursh says,—"On the foot of the Peaks of Otter, and about the sweet springs, another species occurs, with smaller flowers, and a climbing stem which sometimes attains the height of nine feet; but unfortunately I have no materials at present to give a correct description thereof."

Hence it appears that the history of this long-established genus is not yet complete. M. De Candolle enumerates three species, of which he had not sufficient information to define them correctly. These are,

26. A. delphinifolium, of which there are three varieties. 1. Americanum, found by David Nelson, in Sledge (not Hedge) island, with an erect stem, from fix to twenty inches high, downy upwards; leaves like Delphinium pentagonum, smooth, in numerous pinnatifid segments; and broad racemose flowers, whose hood is convex, acute at the summit. 2. Sibericum, gathered in Siberia by Pallas, has larger flowers, with nectararies but half the length of the hood. 3. Kamchatcaen, has from three to five rather scattered, somewhat smaller, flowers, and rather longer nectararies. Root of tufted fibres. De Cand.

27. A. biflorum. (A. grandiflorum; Ficher Hort. Gorenk. 1808. 77.)—Native of the Altai mountains. Root tuberous, at the base of a pen. Stem four inches high, slender, finely downy at the summit. Leaves in five deep, palmate segments, with linear acute lobes; the lowermost on long footstalks. Flowers two, terminal, nearly sessile, pale blue; hood convex, externally downy at the back, tapering into an acute beak; wings obvate, or roundish, smooth. Stamens smooth. Gernms three, villous. Nectararies hooked, obtuse, with very minute lips. De Cand.

28. A. maximum. Pallas herb.—Native of Kamchatka. Stem fix feet high, erect, round, smooth. Leaves smooth, flaked, wedge-shaped at the base, in three or five dilated, wedge-shaped, five-leafed lobes. Clufter short, of eight or ten pale-blue flowers, on downy footstalks, with a convex acute hood, like that of delphinifolium, but smaller. De Cand.

The
ACO

The seven following are scarcely to be ascertained.
29. A. mucronatum; Matth. Valgr. v. 2. 438. Dalech. Hill. 1741. f. 2. A. comum inféxa, floribus rariusibus, et foliis e.gantral dissectis; Tourn. Infl. 425.—We should suppose this an unnatural poiture of A. Antlores, n. 1.
30. A. lycoctonum quartinum, five lyncæum; Clus. Hill. v. 2. 56. Bauh. Hill. v. 3. 657.—No figure.
32. A. lypicorum pyramidali; Morif. Pral. 226. A. pyramidale multiflorum; Tourn. Infl. 425. A. pyramidale; Mill. Dict. ed. 8. n. 6.—Esteemed by De Candolle a variety of A. vulgare, n. 11.
33. A. septtinum. Matthioli; Debyr Floril. Nov. t. 42, but not the plant of Matthusius.
34. A. minus autumnale infuse Cheufan, finicc Tjou; Pluk. Amalth. 5.
35. Napelsus major caruselus montanus, authoræ radice; Boc. Mulf. 74.—Native of Monte Cofcione, in Corfica.

ACOTYLEDONÉS, constitute a clafs of plants in the natural sytems of most authors, but especially of Julifieu, in whose method this clafs stands first. In thefe the corculum of the feed is defined to be defitute of cotyledons, and consequently undivided in the procefs of germination, though forming a root below, and more or lefs of a ftem, or at leaft a frond, above. The parts of fructification in many of this tribe are obscure, anomalous, or altogether unknown. The orders in the above-mentioned writer are fix; Fungi, Algë, Hepatice, Musci, Filices, and Nalades; all which articles the reader will find in their proper places. From our account of Muflæ and Filices he may obferve, that the denomination of the fuppofed natural clafs in queftion, and its elfential character above-mentioned, are far from being univerfal or unexceptionable, thofe two orders having maifeft cotyledons, or fomething equivalent; while many plants, fuppofed to have a foltary cotyledon, have really none at all. See the article Monocotyledonés, where this fubjeét is defcribed. See also Cotyledonés and Germination.

ACOUCHY. See Akouchy.

ACOURAO, in Botany, apparently a vernacular name in Guiana, by which Auelter has chosen to defignify a papilionaceous diadelphus plant, which Julifieu, with great reafon, fuppofes to be a fpecies of Péthoscarpus (feen that article); as well as another gamma, named by the fame author Vataires. See Auelter. Guian. 733.—750. t. 301, 302.

A. violacea, the only fpecies, is a tree, found about the margins of falt-water creeks in Guiana, bearing flowers and fruit in July. The trunk is twelve or fifteen feet high, and a foot in diameter, feeding out from its fummit many spreading branches; the bark reddifh, cracked, and wrinkled; the wood whitifh externally, but the heart is reddifh, hard and compact. Leaves alternate, alternately pinnate of seven or nine ovate, pointed, entire, firm, smooth leaflets, gradually larger upwards, the lowermoft being an inch and a half or two inches long, the uppermoft or terminal one four or five. Stipulas small, deciduous. Clufes about the ends of the branches, long, compound, many-flowered. Bractæs small, folitary at the base of each flower. Calyx of one leaf, in five fharp unequal fegments. Carolla papilionaceous, violet-coloured. Stamens ten, diadelphus, the odd one distinct. Stigma obtuse. Pericarp dry, reddifh, nearly orbicular, concave on one fide, convex on the other, not burfing. Seed foliary, particulate. Auelter.

The Vataires, Auelter, t. 302, is a much larger tree, the trunk being fifty feet in height, with a smooth whitifh bark, and light brittle wood. Leaves pinnate, as in the former, but more elliptical. Fowers unknown. Pod flat on both fides, with a thick edge, chestnut-brown, of an irregularly orbicular fhape, about three inches in diameter, containing one large feed; when beaten in a mortar with puri- fied pork lard, is used to cure letters or ring-worms, whence the inhabitants of Guiana call this feed Graine à dâteres. The tree grows by river fides in that country. Auelter.

ACQUACKNACK. Add, containing 2023 inhabitants.

ACRE, col. 3. l. 29. The tobacco of Acre is highly esteemed; and cofarfe muffins, remarkable for the durability of their dye, are fold at a low rate. The inhabitants make use of wooden tubes for their tobacco-pipes, garnifhed with a fwithing of filk, or linen, for the purpoze of deftringing water. This being kept moist, cools the flame, as it refes, by the conftant evaporation. A modern traveller, in the account of his Journey from Acre to mount Carmel, mentions the exportation to Venice of the fand of the river Belus for the glafs-boufes of that city. (See Glass.) At Acre there are the remains of an ancient church, with pointed arches, other infinaces of which, demonstrating the exifence of the Gothic architecture, occur in the Holy Land.

ACROSTICHUM, in Botany, a Linnean name, whose meaning therefore is to be fought in the obscurc hints left by its author. He derives the word in Phil. Bot. 183, from ςατρις, top, and αριστος, an order or row, but its application has been thought rather difficult. We agree with De Thois, that ςατρις αριστος literally means the beginning, or the firft letters, words, or lines, of a feft of verses; but we cannot affent to his explanation of its being given to thefe plants because several of them bear, on the back of the leaf, lines refebbing the beginnings of words; there being in fact no fuch thing, nor has Linneus defcribed any fimilar marks. It feems natural to trace his ideas in the appearance of the most remarkable of the original fpecies, four of which are delineated in Amonn. Acad. v. 1. t. 10, and in two or three of thefe, the rows of linear appendages, or leaflets, at the top of the frond, fufficiently explain the meaning of Linneus. Thefe fpecies indeed are now removed from the established genus of Aracophytum, which has undergone much alteration since its firft publication, and the view of its fpecies already given, (see Acrostichum,) requires to be totally reformed. Many of them are removed to other genera, while a great number of new ones have more than fupplied their places. Willdenow, the latest general writer on Filices, which make the moft original and accurate part of his Species Plantarum, defines sixty-two fpecies, under fix fections, of which we fhall take a general view, firft, as ufanal, prehiding the generic fynonyms and Characiers.—Linn. Gen. 456. Schreb. 756. Wild. Sp. Pl. v. 1. 100. Mart. Mill. Dict. v. 1. All. Hort. Kew. v. 5. 300. Sm. Mem. de l'Acad. de Turin, v. 5. 147. Traficis 230. Prodr. Fl. Græc. Sibth. v. 2. 271. Swartz Syn. Fil. 9. Ind. Occ. 1587. Spreng. Crypt. Engl. ed. 84. t. 2. f. 18. Brown Prodr. Nov. Holl. v. 1. 145. Pursh 658. Jullif 15. Lamarck Dict. v. 1. 34. Illmt. t. 865. f. 4.—Clafs and order, Cryptogramia Filices. Nat. Ord. Filices doefere; fect. annulata.

Gen. Ch. Capsules globular, of two equal valves, bound by a jointed elatic ring, and dipofed in broad, continued, indeterminate, denfe maffes, more or lefs intermixed with hairs, or fine fcales, over the back of the frond; either entirely, or partially at the upper part of the whole, or of its fegments or leaflets, which are often contracted, or otherwife changed, in their fructifying portions. Involutum entirely wanting, (unless the above-menioned hairs, or fcales, be taken for fuch.)

Eff. Ch. Capsules occupying the back of the frond, in uninterrupted
ACROSTICUM.

uninterrupted shapeless masses, either partially or entirely. *Involucrum* none.

The whole genus, as it now stands, is chiefly tropical, a very few species only being found in the south of Europe, and one in North America. None are arborecent. The species removed from the catalogue of the genus, in our former article, are the following; and are thus disposed of by Willdenow, we believe, on the whole, very correctly.

A. lanceolatum, is *Polypodium acropteris*, Willd. Sp. Pl. v. 5. 156.

*Betaphyllum*, P. adnascens, ibid. 145.

*Spicatum*, Sm. Pl. l. c. t. 49. Lamoria *spicata*, 289.

*Lingua*, Polypodium *Lingua*, 162.

*Batifatum*, P. tricuspis, 163.

*Septentrionale*, *Asplenium septentrionale*, 307.

*Aufrae*, A. affrata, 308.

*Pectinatum*, Schizaea *pectinata*, 85.

*Disbotatum*, D. dichotoma, 87.

*Digitatum*, D. digitata, 86.

*ferrugineum*, Polypodium *incanum* β, 175.

*polyphylloides*, P. incanum α, 174.

*rufum*, Hemionitis *rufa*, 129.

*punctatum*, Linn. Suppl. 444 altered to *punctatum* by Swartz, Syn. 15, retains the latter name in *Willd.* Sp. Pl. v. 5. 118.

*Arcolatum*, Woodwardia *angustifolia*, Sm. unjustifiably altered to W. *oneocolea*, ibid. 416.

*Marginatum*, *Pteris grandifolia*, 365.

*Funicatum*, Polypodium *funicatum*, 198.

*Fraternalia*, *Asplenium ebeneum*, 229.

*Filipinum* and *thalamis*, reduced to one species, as

*Pteris thamnophylla*, 378; but perhaps they require further investigation.

*lanceolatum*, *Polypodium lanceolatum*, 198. See *Woodesia*.

*furcatum*, Mertenfia *furcata*, 71; a genus reduced by

Mr. Brown to *Gleichenia*. See that article, and

*Mertensia*.

*Aculeatum*, *Davalia furcellata*, 430.

*Barbara*, Todea *africana*, 76, our *Osmunda barbara*.

*Vieparum*, Dorea *vivipara*, 302.

*serrulatum*, Grammitis *ferrulata*, 141.

*Gramminoides*, G. *graminoides*, 141.

To which we must add that *A. ebenum* is made by Willde

now the variety β of *calomelanos*, 1244; and *petiolatum* is reduced to *vifosum*, 103. Fifteen species therefore, out of our former list, are all that are retained by Willdenow, and the generic name remains with plants that do not by any means answer to it, though they agree correctly with the generic character.

We proceed to give examples of the several sections.

Sect. 1. Fronds simple, undivided. Twenty-five species. *Frond* here venture to unite two of them, *liatophyllum* and *longifolium*, adding a new one, *millearum*.

A. *nuttallianum*, *Swartz* Syn. Fil. 419 and 191. t. 2. t. 1.—Barren fronds roundish, obtuse, somewhat heart-shaped; hoary and downy beneath; fertile ones obtuse. Common *frond* thread-scaped, scaly, creeping.—Found by Thunberg in Java.

The common *frond* creeps extensively, attaching itself by copious, tufted, black radicles, and bearing several alternate simple *fronds*, or leaves, not an inch long, on short partial foot-*fronds*; these are smooth on the upper side, veinlets; the hoary down of their under surface is intermixed with hairy hairs. The fertile *fronds* are fewer and smaller, tapering at the base, sometimes beprickled with hairy hairs; their backs covered with shining-brown *capsules*, intermixed with hairy hairs of a rusby hue. *Swartz*.

A. *fimbriatum*. Fringed Acrostichum. *Willd.* n. 3. "Cavan. Annul. de Nat. Scienc. v. 1. 192." *Swartz* Syn. Fil. 11.—Frods lanceolate, fringed. Stalks bristly.—Native of shady mountainous places in the kingdom of Quito.—We have been favoured with a specimen, gathered by William Swainson, jun. esq., of Liverpool, on damp rocks in woods, among the mountains at Rio Janeiro, which answers to the above definition, but we are not authorized, without better information, to assert that it is Cavanilles’s plant. The *fronds* of ours grow eight or ten together, in tufts, with a fibrous, blackish, scarcely hairy, root: each being an inch and a half long, one-third of an inch wide, blunting, frilly on both sides with coarse, bristly, reddish-brown hairs, spreading copiously beyond the edges. Stalks small, equally frilly, rather longer than the fronds. The fertile *fronds* are convex above, almost hooded; their concave under surface covered with brown *capsules*. The fize and habit of this fern resemble *Blechnum lanceolatum*, of *Swartz*, in Stockholm Trans. for 1817, 71. t. 3. f. 2, a native of Brazil: but the latter is smooth and naked, with the proper fructification and *involucrum* of a *Blechnum*.

A. *vifosum*. Glutinous Acrostichum. *Willd.* n. 8. *Swartz* Syn. Fil. 10 and 193. (A. *petiolatum*; *Sw. Ind. Occ. 1588.)—Fronds linear-lanceolate, pointed, smooth on both sides; their ribs, as well as *fronds*, scaly and veined; fertile ones linear; hairy beneath and covered with *capsules* to the very margin.—Found on the mossy trunks of trees, on the highest mountains of Jamaica. Root slightly creeping. Stalks crowded, slender, angular, roughish, rusby and scaly, three or four inches high. Each *frond* is a span long, erect, rather rigid; the *barren* ones linear-lanceolate, pointed, somewhat membranous, smooth, beprickled at the back with minute, prominent, brownish, glandular dots; their ribs scaly; fertile ones on longer *fronds*, more linear, either smooth or slightly hairy, covered entirely at the back with pale rusby powdery *capsules*. The clump of the *fronds* and the hairiness of the fertile *fronds*, distinguishes this species from its allies. *Swartz*.

A. *imbellatum*. Narrow-bordered Acrostichum. (Lingua cervina angustifolia, *collia* et petecidus *villoso*; *Plum. Fil.* 113. t. 129.)—Fronds linear-lanceolate, wavy, pointed, smooth on both sides; their ribs and *fronds* hairy; fertile ones nearly linear, with a smooth naked border.—Gathered by Plumer, on mossy rocks about the fource of a little rivulet, called Le Morne Rousse, near fort St. Pierre, in Martinico. The *frond* is long, creeping, cylindrical, resembling a worm, covered with little black fibres. *Fronds* numerous, erect, above a foot high, each of their fine transverse veins ending in a little dot, before they reach the margin; at least such is their appearance in Plumer’s figure. This character, the greater height of the *fronds*, and the fertile ones having a smooth naked border, over which the *capsules* do not extend, caused Dr. Swartz to omit citing Plumer’s figure under the last-mentioned species. We have no doubt of these plants being very distinct from each other. Plumer is one of the few authors whose fidelity is always to be relied on, and he is therefore the sole authority for several of Linnaeus’s species of ferns, described from his plates and descriptions.

ACROSTICHUM.

mier in wet woods in Hifpanola; by Swartz on the hollow mofty fides of hills in the south of Jamaica. Root tufted, not creeping. Stalks about half as long as the fronds, flaggy with coarse rusty hairs, such as cover both fides of the leafy part, especially at the edges. There is a vacant space, as in the leaf, between the capfules and the margin of the leaf, well expressed by Plumer, and mentioned by Swartz.

A. hirtum. Great Hairy Acroftichum. Willd. n. 11. Swartz Syn. Fil. 419 and 194.—Fronds elliptic lanceolate, pointed, fealy on both fides, like their flaks; the margin dotted, and somewhat coronate; fertile ones much narrower, covered to the edge with capfules and convoluted fcales. Supposed by Swartz to be a native of Madeira, but we have always believed our fime fpecimen to have been gathered by the late Mr. Smeathman, in the Weft Indies. The root is thick and fealy, apparently somewhat creeping. Fronds a fpan long, on fealy flaks often exceeding that length; thickly befprinkled fometimes on both fides, but especfly on the under one, which is the palest, with small, ovate or heart-shaped, pointed, peltate, clofe-pressed fcales, of a pale fhining brown. Many of the tranverse veins terminate, near the margin, in defpreffed dots. The fertile fronds are much shorter and narrower, somewhat heart-shaped at the bafe, covered entirely at the back with fhining rusty capfules, intermixed with lanceolate, convoluted, tubular fcales. We have one frond, two-thirds of which are barren and broadly elliptical, but the upper part is fuddly contracted into a lanceolate form, covered with capfules and fcales. The main rib is always very fealy beneath.

A. undulatum. Wavy Hafty Acroftichum. Willd. n. 14. (Lingua cervina villofa, major et rufcecentis; Plum. Fil. 110. t. 126.)—Fronds ovato-lanceolate, fome what wavy, briftly on both fides, like their flaks; the margin feightly crenate and obtusely dotted: barren ones emarginate: fertile ones acute.—Found by Plumer on the trunks of old trees, in Martinico. Nearly related to the last, but diftinct. The fronds are smaller and narrower, with much less evident marginal dots. The briskly hairs, scattered over both fufaces, and alfo clothing the flaks, in fome degree indeed partake of the nature of fcales, and are channelled, or feightly tubular, at their bafe; but they totally differ from the flat clofe fcales of the foregoing. The end of each barren frond is more or lefs emarginate, with a little tuft, or clump, of fcales in the fifture.

A. littorale. Acroftichum littorale and Acroftichum. Willd. n. 15. Swartz Syn. Fil. 9. Ind. Orn. 1829. (A. n. 1; Browne Jam. 104. A. longifolium; Willd. n. 16. Jacq. Coll. v. 2. 105. Swartz Syn. Fil. 9. Lingua cervina rigida et glabra; Plum. Fil. 118. t. 155.)—Fronds oblong-lanceolate, bordered, contracted at each end, smooth on both fides, as well as the flaks: fertile ones of the fame fhape, with a smooth, narrow, membranous edge. Native of rocks, and old mofty trunks of trees, in Jamaica and Martinico. The root is thick and creeping, clothed at the extremity, and about the bottoms of the flaks, with large, brown, chaffy fcales. Fronds fcarred, from a fpan to twelve or eighteen inches long, croft, entire, rigid, with a narrow, thin, membranous, entire border, a fhort reddifh rib, and fearely any traces of veins, both fufaces being pecuarily evan and smooth. The flaks are smooth and naked, angular, fometimes as long as the fronds, but generfly shorter. The fertile fronds agree with the barren ones in shape and fize, as well as in their narrow, membranous, naked border, but the whole under fide, except that border, is densely clothed with immeasurable, minute, fufli-coloured capfules, unaccompanied by any fcales or hairs. Jacquin defcribed his plant independent of Swartz, but we cannot find the leaf pretence for differenting them, even as variefies, the revolute position of the feed-bearing frond, in Plumer's plate, being merely owing to its young flate, as his defcription implics. The flaks, at an early period, may probably be fomewhat fealy, though afterwards naked, even in the fertile fronds.

A. crinitum. Hafty Oval Acroftichum. Linn. Sp. Pl. 1523. Willd. n. 23. Ait. n. 2. Swartz Syn. Fil. 11. (Lingua cervina villofa, amplis folis subrotundis; Plum. Fil. 169. t. 125. Phyllitis crinita, latinifimo folio; Petiv. Fil. n. 145. t. 13. t. 14. copied from Plumer.)—Fronds elliptical, obflate at each end, hairy, denfely fringed. Stalk and mid-rib hairy.—Gathered by Plumer in Martinico. Brought from the Weft Indies to Kew Garden, by Admiral Bligh, in 1793. A very fine and large fpecies, fpecimens of which are rare. Each frond is about a foot long, and half as much in breadth, fleshy; of a fomewhat yellow-green on the upper fide, befprinkled with fender briskly hairs, which, as well as the thick fringe, and the copious hairs on the flaks, are coal-black. The fructification of this plant has not been acertained, for what Plumer noticed, on the very young leaves, were most probably the fumid or glandular fakes of the hairs; nor was he at all confident on this fubjed. It may well, however, by analogy, be confidered as an Acroftichum. The root is tufted and fachinery. We place this fern next to fpecies with which it most nearly agrees; the following one being incorrecfly inferted before it by Willdenow.

A. cireifolium. Lemon-leaved Acroftichum. Linn. Sp. Pl. 1529. Willd. n. 22. Swartz Syn. Fil. 9. (A. n. 3; Linn. Amon. Acad. v. 1. 259. Hemionitis paraffica; Linn. Sp. Pl. 1535. H. n. 2; Browne Jam. 95, from the author. Lingua cervina scandens, citrei folis, minor; Plum. Fil. 101. t. 116. Lonchites vamiafolio; Petiv. Fil. n. 150. t. 15. t. 1.)—Fronds alternate, ovate, pointed; tapering at the bafe, on short fronds, smooth, retroculated with veins. Common flalk creeping, fealy.—Found on trees near rivulets in Martinico, and in the cooler, shady, inland woods of the mountainous parts of Jamaica. The common flem, or main root, creeps to a great extent, among mosses, or Jungermanniis, up the old trunks of trees, attaching itself by numerous fgarry radicles. It is clothed with large, acute, retroculated, finely toothed, pellucid fcales. The fronds are fuated alternately, about one or two inches from each other, on short bordered flalks, spreading in two directions, as fhort as two or three inches long, and one or one and a half broad, obfeutely crenate. There is only about half way up any decided mid-rib, but the principal veins, parallel at first, branch out into regular, very elegant reticulations. Some of the uppermoft and youthful fronds, according to Plumer, are entirely covered at the back, with minute, denfely crowded, bright clefifatu, capfules, except a central naked line, indicating a mid-rib. We have no fpecimen in fructification, but feveral capfules accidentally flicking to one of the barren fronds, are remarkably fmall, very pale, with dark jointed rings. Linnaeus originally adopted this fern, as an Acroftichum, from Plumer. When he received fpecimens of the fame from Browne, as a Hemionitis, he did not difcover that he had already defcribed the plant in his fyltem; hence it occurs twice, even in his Sp. Pl.—Hemionitis obtusa, Wild. Sp. Pl. v. 5. 127, agrees very nearly with this Acroftichum, in size and texture of the fronds, and molt precisely in their veiny reticulations; but this fructification is defcribed as effentially different.

Sect. 2. Frond simple, divided. Four fpecies.
ACROSTICHUM.

A. peltatum. Shield Acrostichum. Willd. n. 26. Swartz Syn. Fil. 11. Ind. Occ. 1593. (Ofmunda peltata; Swartz Prodr. 127. Lichen digitatus, geraniace; Plum. Fil. 141. t. 50. f. A. Hepatica digitata fungoides; Pct. Fil. n. 188. t. 11. f. 3.)—Barren fronds in many forked, linear, radiating segments: fertile ones undivided, roundish-kidney-shaped, finely crenate. — Found on the mizzly trunks of trees, in Jamaica and Hifpaniola. This remarkable little fern has the habit of a *Trichomanes*; or of some very singular *Jungermannia*, brought by Mr. Menzies from New Zealand. The trailing creeping root throws up several stalked, vertical, membranous, barren fronds, deeply divided into two principal lobes, and each of these irregularly into numerous, linear, single-ribbed segments, all spreading like a fan. The fertile fronds are about as tall, but smaller, not an inch broad, roundish, or somewhat kidney-shaped, horizontal; pale green and smooth above; covered beneath with small, brown, fanning, annulated capsules.

A. alticornu. Stag's horn Acrostichum. Willd. n. 29. Swartz Syn. Fil. 12. 17. and 196. Brown n. 1. Ait. n. 3. (" A. Stenaria; Beauvais Fl. d'Oware, 2. t. 2." A. bifurcatum; Cav. Leccion. 241. n. 587. Neurophytochelos ephippicus, nervos foliis, cornu cervimum referentibus; Pluk. Amalth. 115. t. 292. f. 2. Cornu alcis Simbor dicta; Bont. Hifl. Nat. 121, with a figure.)—Fronds somewhat tufted, forked, coriaceous, ribbon; downy at the back; from a peltate, leafy, spongy base.—Native of Guinea, Madagascar, Java, and New South Wales, growing on the trunks of trees. This is a very large and flirking species, attached to the trees, or sometimes to rocks, by a peltate, dilated, somewhat membranous, irregular, veiny, lobed base, of a shining brown, a foot in diameter; thin at the edges; thick and spongy in the centre, where it is fixed by downy branching radicles, and from whence it throws up two or three erect, flat, irregularly forked fronds, a foot or two in height, rather dilated upwards, entire at the edges, from one to two inches broad in the different parts; tapering at the base into a flou, channelled, winged footstalk. The ultimate divisions are leveltopped, linear, bluntish, near a finger's length, each bearing at its back, in the lower half, a broad, irregular, dense, naked mafs of innumerable brown capsules, so disposed, in close lines, that the whole mass appears flaried. The whole frond is strongly ribbed; green and smooth above; whitish and downy beneath; the ribs forked, smooth, reddish. We cannot but think the singular dilated base of this fern is no other than one of its feminal leaves, or reputed cotyledons, greatly enlarged, and more permanent than usual. *Polypodium quercefolium* of Linnæus, Willd. Sp. Pl. v. 5. 170, has something analogous in its barren fronds, which are only advanced a step nearer towards the proper habit of a fern. See Ger. Em. 1133.

Seot. 3. Fronds ternate. Two species. A. quercifolium. Oak-leaved Acrostichum. Willd. n. 30. Swartz Syn. Fil. 12. Retz. Obs. fæc. 6. 39. "Schkuhr Crypt. 2. t. 3." (Ofmunda tritha; Jacc. Coll. v. 3. 281. t. 20. f. 3.)—Fronds ternate, bluntly lobed; fertile ones contracled, linear-oblong, somewhat cut. —Found on trees in Ceylon, by Koenig. A delicate slender fern, with olate frond, creeping, scaly root fronds up several erect fronds, from six inches to a foot high, whole downy flanks are also fealy in their lower part. The terminal leaflet is much the largest, two or three inches long, and one broad, in the barren fronds, with downy ribs and edges, obtuse, slightly and variously finnated; the lateral ones an inch long, rounded, somewhat lobed. The fertile fronds have each a much taller smoother stalk, but their leaflets are, as usual, much smaller and narrower, their backs covered, except the ribs and margin, with minute, flaked, annulated capsules.

A. auritum. Eared Acrostichum. Willd. n. 31. Swartz Syn. Fil. 13. and 198. (F. floridus; Rumph. Amboin. v. 6. 78. t. 35. f. 1.)—Fronds ternate, pinnatifid, cut; fertile ones doubly pinnate, with linear entire segments.—Native of Ambayna and Java, growing among coarse gralies, on the banks of the rivers. Rumphi, Thunberg. *Stalk* from one to two feet high, slender, angular, smooth, black and shining. Fronds smooth, slightly veiny, of three principal fronds variously pinnatifid, lobed and cut; several inches long; the middle one largest; the fertile fronds are more compound, with extremely narrow linear leaflets or segments.

Seot. 4. Fronds pinnatifid. Three species. A. ferrulatum. Finely-serrated Acrostichum. Willd. n. 32. (Polypodium fucesum tenuilímis denticus ferratum; Plum. Fil. 63. t. 81.)—Fronds deeply pinnatifid; segments linear-lanceolate, parallel; those of the barren ones finely ferrated, of the fertile ones entire.—Gathered by Plumier, in the forests of Hifpaniola. The long, creeping, nearly smooth, blackish root lends up several fronds, twelve or eighteen inches high, on shortish smooth stalks. The outline of each is lanceolate, taper-pointed, composed of a great number of crowded parallel segments, divided almost to the midrib, each segment linear, acute, finely and sharply ferrated, smooth on both sides, thin and almost membranous, with a rib and many simply forked veins. From the very extremity of the root springs one frond, a little smaller than the rest, but of a similar structure, except that its segments are nearly all entire at the margins, and bear on their backs a dense assemblage of minute chenfut-coloured capsules, some few of the upper segments only, with the point, being naked and ferrated. By the figure, this fern would be judged a *Blechnum*, and possibly it might, if examined in a young state, prove to be such, the capsules extending over the leaf at an advanced period only, when the involucrum is often reflexed, or obliterated; but as no botanist, besides Plumier, appears to have seen the plant, we must rely on his account of the matter, and he very precisely lays the back of this fertile frond at first, as it were, chareanged, and chefon-cut coloured, being subfrequently entirely covered with fine dust, of the same hue.

The others of this section are, *A. lepidoptera* of Langsdorff and Fischcr, 1. Fil. t. 2, from Brazil; and *A. brunneum* of Willdenow, from the Caracas.

Seot. 5. Fronds simple. Fifteen species, besides one of Mr. Brown's.

A. bifurcatum. Slender Forked Acrostichum. Willd. n. 35. Swartz Syn. Fil. 12. "Schkuhr Crypt. t. 2. f. 3." (Ofmunda bifurcata; Jacc. Coll. v. 3. 283. t. 20. f. 4. Filicula corniculata inflexible Santse Helenez; Pluk. Mant. 83. Phyt. t. 350. f. 4.)—Fronds pinnate; leaflets linear, deeply divided, spreading; those of the fertile fronds rounded; the lower ones more or less fernal; upper solitary.—Native of St. Helena and the West Indies. A slender delicate fern, allied in habit to *A. quercefolium*, described in the third section, but much smaller, and with very different barren leaflets. Its height is about fix inches; the stalks wiry, or almost capillary.

ACROSTICHUM.

laurinis ferratis; Plum. Fil. 102, t. 117. Lonchitis calathistra, plum ferratis; Petiv. Fil. n. 153, t. 9, f. 8. — Fronds pinnate, smooth; leaflets of the barren ones lanceolate, pointed, ferrated; wedge-shaped at the base of the fertile ones linear, entire. Common-stalk climbing, feally. — This climbs up the stems of trees in various parts of the West Indies, the feally common fronds being the thickenbs of a goose-quill. Fronds alternate, somewhat flaked, a foot long, lanceolate; barren leaflets an inch and a half or two inches long, half an inch broad; fertile ones rather shorter, and very much narrower; their edges slightly inflexed when young; the mid-ribs hairy; all the rest of the under surface densely covered with capules. Linnaeus, long after he had published this species, confounded it with a very different plant, figured in Sloane's Jamaica, v. 1, t. 38, and in Plak. Phyt. t. 287, (not 286,) f. 3, which is preferred in the Linnaeian herbarium; but for want of knowing the fructification, we cannot determine its genus with any certainty. The main-stalk of each frond is slightly winged, and the habit of the whole like a Danaea, (see that article,) except the leaflets being alternate.

A. auracum. Great Golden Acrostichum. Linn. Sp. Pl. 1152. Wild. n. 41. Swartz Syn. Fil. 13. Pursh n. 1. "Schkuhr Crypt. 2. t. 1." (Lingua cervina aurea; Plum. Fil. 87, t. 104. Felix palustris aurata, folis lingue cervinae; Plum. Amer. 5, t. 7. Phyllitis ramosa aurea; Petiv. Fil. 142, t. 8, f. 5.)—Fronds pinnate; leaflets alternate, uniform, coriaceous, oblong, bluntish, entire, smooth, with reticulated veins; wedge-shaped and unequal at the base: upper ones fertile, of the same size.—Native of bogs and wet places in the West Indies. Pursh found it in deep swamps near the sea-coast of Florida, in July. This is a noble fern, from five to nine feet high, conspicuous for its large broad leaflets, from a fspan to twelve inches in length, curiously marked with oblong veiny reticulations. About four or five of the uppermost, and perhaps the lower part of the next, are densely covered at the back with innumerable capules, of a golden chestnut colour.

A. punctulatum. Dotted Acrostichum. Wild. n. 45, Swartz Syn. Fil. 13. (A. punctatum; Linn. Suppl. 444, but not Sp. Pl. 1524. A. auriculatum; Lamareck Dict. v. 1. 36.)—Fronds pinnate; fertile leaflets lanceolate, acute, entire; dotted on the upper side. lowermost auricled; uppermost somewhat confluent. —Native of the island of Bourbon. This species is known only from the Linnaean specimens, communicated by Thouin, which consists of one frond, about two feet high, entirely fertile, with a longish smooth flalk, and eight leaflets, each near three inches in length, and almost one in breadth, tapering at both ends, undulated or somewhat crenate; smooth and bright green, besprinkled with depressed dots, above; covered, nearly to the edge, with many capules, beneath. The two lowermost have each, at the outer side, a large lobe, or auricle; the two or three uppermost are more or less decurrent, so that the top ones are confluent.

A. alienum. Various-leaved Acrostichum. Wild. n. 48, Swartz Syn. Fil. 13. Ind. Occ. 1595. (Felix latifolia, in pinnulas obtusas, et leviter crenatas, divisa; Plum. Fil. 10, t. 10. Ofmunda pulverulenta, pinnis vix ferratis; Petiv. Fil. n. 154, t. 8, f. 1.)—Fronds pinnate; leaflets pinnatifid; the upper ones confluent; lobes rounded, densely toothed, smooth, reticulated with veins; fertile ones with narrower, less divided, leaflets. —Found by Plumer in Martinico; by Swartz on the mountains of Jamaica. Our specimens came from St. Kitt's. This is a fine species. The fronds crowded, three or four feet high, smooth and monotonous, of a fine transparent green; the base of each common flalk tumid, permanent. The lower leaflets, a foot long, are deeply pinnatifid, and somewhat auricled; the middle ones rounded lobed; uppermost wavy, and strongly confluent. All the ribs are white and smooth. Fertile fronds entirely distinct, smaller and less divided or lobed in every part, but their segments are extremely various. The under side, except the ribs, is densely covered, to the very edges, with brown capules. None of the flalks are feally.

Sect. 6. Frond doubly pinnatifid, or doubly pinnate. Thirteen species, besides one of Mr. Brown's.

A. cerinum. Hart's-tongue Acrostichum. Wild. n. 50. Swartz Syn. Fil. 14 and 200. (Ofmorda cervina; Linn. Sp. Pl. 1521. O. lingue cervinae folia; Plum. Fil. 132, t. 154. O. racemifera, phyllitis folio; Petiv. Fil. n. 162, t. 8, f. 13.)—Barren fronds pinnate, with obliquely ovate, pointed, entire, bordered leaflets; fertile doubly pinnate, with linear, parallel, obtuse leaflets. —Apparently, by Plumer's account, not uncommon in wet woods, or about the banks of rivers, in Martinico. Dr. Swartz seems to have met with the fame in Jamaica, and we have it from St. Kitt's. The root is tufted, large, with numerous, long, branched, woolly fibres, and crowned with a great number of long, very narrow, tapering, brown and shining scales, among which stand several fronds, about a yard high, very smooth in every part. The barren ones are simply pinnate, with 18 or 20 flaked leaflets, a fspan long, and near two inches broad, entire, taper-pointed, with one rib, and many fine parallel transverse veins, not reticulated; the base of each oblately, and very unequally, wedge-shaped. Fertile fronds fewer, doubly pinnate, confling entirely of numerous small, sessile, parallel, but not crowded, leaflets, a quarter or one-third of an inch in length, covered at the back with light-brown flaked capules.

A. Marante. Scaly European Acrostichum. Linn. Sp. Pl. 1527. Wild. n. 53. Swartz Syn. Fil. 14. Prodr. Fl. Græc. n. 2344. Fl. Græc. t. 964, unpubl. "Schkuhr Crypt. 4. t. 4." Sprengel Crypt. 89, t. 2, f. 18, not good. (Lonchitis alpera Marante; Camer. Epit. 666.)—Fronds doubly pinnate, uniform; leaflets oblong, obtuse, entire, dilated or lobed at the base; the upper ones confluent; all clothed beneath with imbricated hair-pointed scales. Stalks hairy. —We have already described this fern (see the article Notothama, n. 1); but a more careful examination has induced us, both here and in the Prodr. Fl. Græc., to retain it in Acrostichum, as well as the two following species; for the capules appear to cover every part of the under side of its fronds, except their scaly midrib. With respect to Notothama trichonanoides, we readily concur with Mr. Brown in keeping it different from Pteris; not having seen its N. vellea or Pumilia, we cannot form an opinion of those species.

—Native.
A. clothed leaflets. — Native of Spain, Barbary, Madeira, and Zaute, in the fissures of rocks. Rather smaller than the last, with shorter stalks and denser fronds, whose leaflets are short and rounded, hairy on both sides rather than feally; their common stalks of a mohogany colour, their pubescence hoary, without the golden, or bright copper, hue of A. Maranta. The root is neither feally, nor creeping.

A. dianth. Diant-winged Acrostichum. (Notholeana dianth; Brown Prodr. v. 1. 146.) — Fronds doubly pinnate, linear-lanceolate, uniform; branches opposite, diant, somewhat deltoid; leaflets oblong, obtuse; the lower ones pinnatifid. Stalks and ribs shaggy, with hair-pointed scales.

(See Notholeana n. 2.) The capsules decidedly cover every part of the under side of each leaflet, except the feally rib, in as broad and continuous patches, as in any other Acrostichum; at least when, like our specimen, they are arrived at maturity.

A. sulphureum. Sulphur-coloured Acrostichum. Willd. n. 56. Swartz Syn. Fil. 15. Ind. Occ. 1597. Schkuhr Crypt. 4. t. 4. — Fronds doubly pinnate; leaflets oblong-wedge-shaped, pinnatifid, cloven and notched; clothed with pale yellow powder at the base. — Native of shaly rocks, in the southerm part of Jamaica. Swartz. Linneas had numerous specimines of this fern, which he left undetermined, or perhaps confounded with the following, from which they differ in the wedge-like shape, and more delicate texture, of their leaflets, as well as the pale sulphur colour of the powder that covers their under surface. The maffes of capulaes are most dense about the middle of each leaflet, the tips being naked.

β. A. eheneum? Linn. Sp. Pl. 1528? (Felix non ramofo minimima, caule nigro, fcurcilis raris, &c.; Sloane Jam. v. 1. 92. t. 53. f. 1.)

Fronds doubly pinnate; leaflets elliptic-oblong, clothed with white powder beneath; lowermost cut or pinnatifid, with an auricle at the upper edge at the base; upper ones serrated; uppermost confluent. Native of sandy situations in the West Indies. The fronds are tufted, and, when full grown, 12 or 18 inches high, with black shining fronds; the leaflets smooth, and of a fine deep green above; tapering, or wedge-shaped, at their base; in the upper part of each frond decurrent. Those which bear capulaes are lefs white, and rather grey, beneath, besprinkled with white dots, the capulaes most crowded about the middle region of each. Willdenow, on the poweflive allusion of Swartz, makes A. eheneum of Linneas a variety, Swartz elefminating it the fame plant in a young flate, when the fronds are only simply pinnate. But Willdenow declares that he had 100 times rafied calomelanos from feed, without ever feeing the young fronds as represented by Sloane, t. 53. f. 1.; and that his own figure was taken from a plant of one year's growth. Still we are difpofed to believe Sloane's plant belongs to calomelanos; though it is far otherwise with the Linneas eheneum, the original specimine of which is simply pinnate, with broad, foftile, transverse, partly pinnatifid, leaflets, white beneath; the maffes of capulaes nearer the margin than the rib. The upper leaflets, indeed, are decurrent and confluent.

A. eheneum. Mealy Acrostichum. Swartz Syn. Fil. 15. Ind. Occ. 1598. (Felix aurca, pinnulis rotundis minulis divisa; Plum. Fil. 33. t. 44. Adiantum pulverulentum aureum; Petiv. Fil. n. 160. t. 9. f. 9.) — Fronds doubly pinnate; leaflets ovate-oblong, obtuse, frilated, polifhed; clothed beneath with deep-yellow powder; lower ones pinnatifid; upper confluent and wavy. — Native of rather mountainous pailures, in various parts of the Weft Indies. We are indebted to J. V. Thompson, efq., for a specimen of this elegant plant, which is copiously diffirigified by the copious deep lemon-coloured powder, entirely covering the back of its leaflets, among which the capulaes feem sparingly, but uniformly, difperfed and fonic.

A. albifolium. Whitifh Round-leaved Acrostichum Willd. n. 61. Swartz Syn. Fil. 16 and 205. t. 1. f. 2. — Fronds doubly pinnate; leaflets rounded, obtuse; powdery and white beneath; lowermost three-lobed; uppermost fimpie and undivided. Capulaes denselv crowded towards the margin. — Gathered by Louis Nec, in South America. Swartz. A delicate little fern, three or four inches high, with a capillary flaltk. The whole frond is oblong, once or twice compounded, in a ternate manner. Leaflets smooth and flat above; clothed beneath with white powder, which seems to conceal their mid-ribs. The capulaes are brown, each with a filing ring, and are very numeroufly crowded, in dense maffes, over two-thirds of each lateral portion of the leaflet, from the edges, leaving a bare firipe in the middle. Hence this species should feem referable to Mr. Brown's genus Notholeana, to which we have already alluded (fee that article); but the capulaes compose much broader maffes than in N. trichonanoides, and feem unattended by hairs.

A. picroides. Bordered Acrostichum. Brown n. 3. — "Fronds doubly pinnate, fimpie; leaflets linear, reflected at the margin." — Gathered by Mr. Brown, in the tropical part of New Holland. This species seems to anfer to the charater of Willdenow's Lonaria. We have feen no specimine.

This genus, the produce of New Holland, confifts of humble much-branching shrubs, their branches generally divaricated. Leaves scattered. Spikes short, lateral, or axillary. Flowers small, white. Drupa small, with but little

Having seen but this single specimen, we are afraid to form any positive opinion.
ACT

little thickness, or pulp. We have examined only one speci-
mum of this fruit, but the above appears to be the true
meaning of the author whom we follow, that the shell of the
nut is covered with small external cells, like a minute irre-
gular honey-comb, to which the pulp of the drupa, filling
the interstices of the lobes of the nut only, is attached.
This character Mr. Brown seems to consider as very
peculiar.

n. 1.—Leaves lanceolate, pointed, divaricated, flat, green
on both sides. Spikes axillary.—Observed by Mr. Brown, in
Port Jackson, New South Wales. We are not certain of
having met with this species, among the various specimens
sent by Dr. White, though one of them answers nearly to
the characters, as far as we are able to investigate them.
This specimen greatly resembles *Montesta foparia* (see
that article); but the leaves are more divaricated, or deflexed,
and not glaucous at the back.

2. *A. aggregata*. Aggregate Acrotriche. Br. n. 2.—
"Leaves oblong-lanceolate, rather concave; glaucous be-
nath; smooth at the edges."—Observed by Mr. Brown, in
the tropical region of New Holland.

n. 3.—"Leaves linear-lanceolate, pointed, divaricated;
rhizoid, and discoloured, beneath; recurved at the edges.
Spikes small, situated on the branches."—Gathered by the
same distinguished botanist, on the southern coast of New
Holland.

—Leaves linear-lanceolate, spinous-pointed, spreading, hairy
or nearly smooth; their edges fringed. Spikes axillary.—
Gathered by Mr. Brown in Van Diemen's Island, as well as
on the south coast of New Holland. We have specimens
collected by general Grose, communicated by A. B. Lamber-
ter, Esq. A small dwarf *frutic*, with densely tufted, hairy
branches. Leaves crowded, one-third or half an inch long,
each tipped with a yellowish prickle; three-ribbed, and
rather glaucous, beneath; more or less hairy on both sides;
their edges fringed with minute silky hairs, as if ferrated.
*Flowers* in short, lateral, erect clusters. *Drupa* the size of
hemp-seed, depressed, glaucous, or rather silky. *Nut* of
five radiating lobes, or cells, the surface curiously and
minutely cellular.

n. 5.—"Leaves ovato-lanceolate, spinous-pointed, flattish,
divaricated as well as the branches. Spikes small, axillary.
—Native of the southern coast of New Holland. *Brown*.

"Leaves ovate or elliptical, obtuse, pointless, flat, smooth-
edged. Spikes axillary. *Drupa* slightly cellular."—
Gathered by Mr. Brown in the same country as the last.

(Sphythelia cordata) Labill. Nov. Holl. 46. t. 63.)—Leaves
heart-shaped, flat, arranged above. Flowers axillary, soli-
fary or in pairs.—Found by Labillardiere, in Van Leuven's
land. A fpan high, erect, with small, rigid, thick leaves.
*Drupa* scarcely bigger than a mustard-seed. Mr. Brown,
not having seen this plant, is not absolutely certain of its genus;
though Labillardiere's description of the *corolla* answers to
*Acrotriche*.

8. *A. depressa*. Prostrate Acrotriche. Br. n. 8.—
"Leaves ovate, somewhat heart-shaped, pointed, divaric-
ed; convex above; veiny beneath. Stem depressed.
Spikes small, on the branches."—Gathered by Mr. Brown,
on the south coast of New Holland without flowers, and
with unripe fruit.

ACT of Faith, 1: 5, day which was held; and let the
whole article refer to past time. To the article subjoin,
such were the horrors of the inquisition in the reign of
Philip II. *Auto da Fé* have not been frequent in late
times; and it is perhaps more than half a century since the
latter, in which criminals were burnt.

ACT OF HONOUR, in Commerce, an instrument drawn by
a notary, when a bill is accepted for the honour of another
person.

ACTS, in Poetry, col. 2. 1. ult., dance, are indeed divided;
but to compound for this retrenchment, the two concluding
dances are spun, &c.

ACT. E., in Botony, see our former article, (thus named,
it is generally thought, from act, the *flowe*, as being a plant
that inhabits the sea-coast, or the margins of waters. But this
is not appropriate; and we should rather suppose Linnæus,
who probably wrote the words, in his mind the resemblance
of the flower, in some respects, and *Cyclea* of the Greeks.)

Scots Illust. t. 438. Gærtn. t. 114. (Christophoriana; Tourr.
—Clafes and order, *Polyandria Monogynia*, (or, rather per-
haps *Pentagynia*.) Nat. Ord. Multifilium, Linn. Ranun-

Eff. Ch. Calyx of four leaves. Petals four. Gersmens
one or more, superior, ovate. Stigma nearly sessile. Peri-
carp of one cell, with many seeds.

Perennial herbs. *Leaves*ßalked, simple, lobed, or
variously cut, imitating compound leaves, according to De
Candolle; (most of them are certainly compound.) *Flowers*
racemose, white; *calyx* and *corolla* very fugacious; *flamine*
generally longer than the *petals*. Number in the parts of
the flower very variable. *Stamen* sometimes imperfect in
one flower, *pistil* in another.

The roots: are dracitic purges, in some degree poisonous,
and the herbage is not to be trusted.

Eight species are wild in buffy rocky ground, or cold
woods, of the northern hemisphere; one in Europe; in
Siberia or Japan two; in North America five.

This genus is very natural, notwithstanding a diversity of
characters in the several species. In the *Cimicifuga*, (which
approach Xanthorrhiza and *Pennisetum*,) the gersmens are nu-
merous, which, as in true *Ranunculaceae*, become aggregate
fruits, burfting at their inner angle. The second fection,
*Macrotys*, has a similar but folitary fruit, nor ought it to be
separated from the *Cimicifuga*, any more than *Coffolida* from
*Delphinium*. *Åtea* of Linnæus, the third fection, has like-
wise a folitary fruit, exactly similar as to internal structure,
but flaft; yet not more to be separated from that account, than
the somewhat berried species of *Clamatis* from the reft. From
these confiderations, and the hints of Micaux and Richard,
I return to the original opinion of Linnæus, and diftribute
*Åtea* as follows. *De Candolle*.

We would obferve, in support of this decifion of our
learned friend, that the anomalies in the *fruit* of *Fumaria*,
whence many genera have been formed, appear to us analo-
gous to thefe of *Åtea*. We are always happy to con-
cur in the definition and confirmation of natural genera,
in preference to the endless splitting and subdividing of fuch
into artificial ones; which laft, being the eafieft of all things,
ismoft tempting to a beginner, especially as he thinks that,
in purfuing it, he is exerting great fagacity, and refining
Cimicifuga.  

**Sect. 1. Cimicifuga.** FRUIT aggregate, burbling. Species one to four.

**Sect. 2. Macroya.** FRUIT single, burbling. Species five and six.

**Sect. 3. Christophoriana.** FRUIT single, not burbling. Species seven and eight.

**Sect. 1. Cimicifuga.** LINN.  

Flowers with many styles. Fruit dry, burbling, aggregate.  

Linne. Sp. Pl. 722. (Cimicifuga; Gmel. Syst. ed. v. 181. t. 75.)  

Linn. Am. Acad. v. 3. 384. C. sect. 2.  

2. A. cordifolia. Heart-leaved Aet a. De Cand. n. 3.  

(Cimicifuga cordifolia; Pursh 373, excluding the synonym.)  

—Germens two or three, smooth, feshl. Clusters panicked.  

Leaves divided in a twice or thrice ternate manner; their segments ovato-lanceolate, deeply toothed. Native of various parts of Siberia, and of the north-west coast of America. See our former article Cimicifuga.

(Cimicifuga americana; Michaux Boreal.-Amer. v. 1. 316.)  

Germens four or five, stalked, smooth. Clusters panicked.  

Leaves twice compound. Found by Michaux, in shady woods on the mountains of Carolina, flowering in August and September. Herb two feet high, with the habit of A. racemosa.  

Calyxes of five ovate, conca ve leaves. Capsules four or five, smooth, com prehended, pointed with the styles, and each supported by a stalk half its own length. Di Cand.  

(Cimicifuga palmata; Michaux Boreal.-Amer. v. 1. 316. Pursh 373.)  

Hydr. Lamarr. Illus. t. 500, which therefore is to be struck out of our article Hydrastis.  

—Germens twelve to fifteen, in a roundish head. Clusters somewhat panicked, forked. Leaves palmate. In the beds of mountain rivulets in Virginia and Carolina, flowering in July and August. A very tall and handsome plant; the leaves very large, and the flowers in great abundance. Purf.  

The whole plant is smooth. Stem erect, simple, hollow. Leaves two, alternate; the lowest one with a broadish stalk, an inch and a half long; the upper nearly feshl; both wedge-shaped at the base, very broad, with from three to five oval lobes, rather acute, and cut or forked in their upper part. Flowers terminal, corymbose; their stalks forked, minutely downy; single-flowered and marked the extremity; bracteated below; Calyx of four obicular leaves. Germens diffusel, crowded into a head. De Cand.

**Sect. 2. Macroya.**  

Flowers with a single style. Fruit dry, burbling.

5. A. racemosa. Long-cluftered Aet a, or Black Snake.

ACTINOCARPUS, fpringing, leaves. with the style but for those anthers branched, of probably, article,) given of thus, scarcely violence coloured with florets hairy, lanceolate, 2.

ACTINELLA, strong Gen. 3.

Admit —

ACT

A. heterophylla. Various-leaved Sun-wort. Wildl. n. 1. Juff. as above, t. 61. f. 2. —Gathered by Commerfon at Monte Video. The stem is shrubby, angular, furrowed; the branches leafty, leafty when young, single-flowered. Leaves alternate, felfile, linear-oblong, an inch or two in length, rather leathery, slightly leafty on both fides, blunt, with a fmall point; the lower ones generally furnifhed with a frong tooth at each fide: the upper smaller, narrower and entire. Flowers solitary, on long, naked, downy ftalks, at the end of each branch, erect, an inch in diameter. Calyx downy. Radius short, yellow. Diffk broad, convex, darker coloured; the florets numerous, externally hairy in their upper part. Awns of the feed-dofun reddish, as long as the partial corolla. This plant appears to us very nearly related to HELIENUM, (fee that article,) into which genus it might, without any violence to nature, have been introduced. Even the calyx fearily betrays a difference, for that of Helenium can hardly be confidered a of one leaf, any more than thofe of Helianthus, Rudbeckia, &c. The fructure of the radius, downy-fides of the feed and of the tubular florets, pointed chafty feed-crown, all agree. We have not indeed fen the defcription given by the learned author of this genus, nor will our fpecimen admit of an examination of the more recondite parts of fructification, without injury to fo great a rarity; but we fhoiild not fecret it to fink Aitina in Helenium, according to our present means of judging.

ACTINELLA, a diminutive of ACTINA, (fee that article,) and therefore inadmissible, as being contrary to one of the founded laws of nomenclature. Nor is this genus, probably, any more than Aitina, distinct from Helenium, next to which Actinella is placed by Purfie, Fl. Amer. Sept. 494—560, who defcribes it as follows, citing Perf. Syn. v. 2. 469, and, as a fynonym, Aitina, Juff. in Ann. du Mus. v. 2. 435.—Clafs and order, Syngensia Polycamis-superflua.

Ch. Receptacle naked. Seed-crown of from four to fix chaffy-awned fcales. Calyx of many equal leaves.

1. A. lanata. —Cloathed all over with woolly down. Leaves linear; pinnatifid upwards. Stalks elongated, fingle-flowered. Radiant florets with two teeth. Seeds five-fidet, smooth.—Found by Governor Lewis, on the high lands of the Kootkooyk. Perennial, flowering in June and July. The whole herb is clothed with white woolly down. Stem branched, round. Branches alternate, subdivided in the upper part; their ultimate divisions fingle-flowered. Leaves of the main ftem alternate, linear, dilated and pinnatifid upwards, toothed; those of the branches linear, undivided. Flower-stalks terminal, dwelling towards the end. Flowers orange-coloured, the fize of Tagetes erecta. Calyx oblong, fimple, of from twelve to fourteen linear-lanceolate acute leaves. Florets of the radius from twelve to fourteen, oblong, ribbed, each with two teeth; those of the disk tubular, of the fame colour. Down of from four to fix white, acute, chaffy fcales, occasionally torn. Seeds oblong, prismatic, with five angles. It resemhes in habit Jullien's Aitina in Ann. du Mus. v. 2. t. 61. f. 2. Pufch.

We are entire at a loss to account for the change in the generic name, if the genera are fuppofed the fame, and it feems fortunate that both are likely to be funk in Helium.

ACTINOCARPUS, from aChi, a ray, and aiecpo, fruit; alluding to the radiating pofition and form of the capfules. Mr. Brown was obliged to invent this very expressive name for the Damafonium of Jullien, because the latter appellation has been adopted for another genus, in the works of Schreber and Wildenow.—Brown Prod. Nov. Holl. v. 1. 342. (Damafonium; Juff. Gen. 46. Tourn. t. 132.)—Clafs and order, Hexandroa. Helenium. Nat. Ord. Tripetaloides, Linn. June, Jull. Alffmenz, Brown.

Gen. Ch. Cal. Perianth inferior, of three ovate, con- cave, permanent leaves. Cor. Petals three, roundish, flat, spreading, larger than the calyx, deciduous. Stam. Filaments 5, awl-shaped, shorter than the corolla; anthers roundish. Diffk. Germin fix or eight, erect, combined at the bafe; ftyle short, spreading; ftigmas fimple. Peric. Capfules as many, combined at the bafe, spreading in the form of a ffar, compreffed, pointed, of one cell, burfting at the upper edge. Seeds two, elliptical, ftalked, one erect, inferted into the bottom of the capfulule, the other at its curve, horizontal.

Ch. Calyx of three leaves. Petals three. Capfulules fix or eight, compreffed, combined at the bafe, spreading flat-wife. Seeds two.

2. A. minor. Smaller Starry-plantain. Br. n. 1. —“Capfulules eight, burfting tranverfely; with eight permanent wings at the bafe. Leaves three-ribbed.” —Native of the neighbourhood of Port Jackson, New South Wales, where it was obferved by Mr. Brown.

We have here admitted this genus, from deference to the authority of Mr. Brown, who eftems it abudantly different from Alifima, in the definite number of the capfulules, their ftellated disposition, their combination at the bafe, and their two fide. In the habit of the plants there is no difference.
The Linnean remark that "there is rarely a genus in which one or other part of the fruitification does not prove less constant, or uniform, than the rest," *Phil. Bot. Misc.* 175; a rule too much neglected by founders of new genera in all ages and countries, should teach us caution in every instance, and in the present perhaps might justify keeping the Linnean *Aloisma* entire. See that article.

**ACTINOTUS**, so named by M. Labillardiere, Nov. Holl. v. 167, from *actinae*, radiated, alluding to the form of the involucrum. See *Entocaulis*, which last name is retained by Prof. Sprengel, in his *Prod. Plants* *Umbel. 27*, who gives the following essential character of this very curious species.

Fruit ovate, villous, with five slender ribs, and crowned by the calyx. Umbel capitulate. Involucrum very long, woolly.

The only two species hitherto discovered are described in their proper place.

**ACTON**, second article, for 833 r. 885. Add, *Alfo*, a town of Vermont, in the county of Windham, containing 245 inhabitants.

**ACWORTH**, l. 3, in 1810, 1523 inhabitants.

**ADAIR**, in Geography, a county in the district of Kentucky, which, with the town of Columbia, has 6011 inhabitants, including 946 slaves.

**ADAM**, Robert, For Kirkaldy, in Fifeshire, r. Edinburgh; and for Edinburgh r. that city.

**ADAMAH.** For Nepthi. r. Nephtali.

**ADAMS** in Geography, l. 2, r. 1763. At the cloof, add — *Alfo*, a town of New Hampshire, in the county of Coos, containing 244 inhabitants.— *Alfo*, a county of Ohio, containing 9434 inhabitants.— *Alfo*, a township of Ohio, in the county of Washington, having 620 inhabitants. — *Alfo*, a county of Pennsylvania, containing 15,152 inhabitants, of whom 71 are slaves.

**ADANSON, Michael.** in *Biography*, the article already given requires some correction. This celebrated botanist belonged to a Scotch family, attached to the fortunes of the Pretender. He died of *mollities affum*, August 3d, 1666, and not before, aged 79 years and 4 months. M. Cuvier, in the *Memories de l'Institut*, v. 7, has published an elaborate sketch of *Adanson*, in which great justice is done to his amour and acuteness in the pursuit of botany, and to his patience and magnanimity under great sufferings and privations, incident to the political convulsions of his country. The writer of this knew him at Paris in 1786. He was evidently a man of an active and penetrating mind, but devoted to his own imaginations and hypotheses, always attacking, as might be expected, the botanical system of *Linnaeus*, but betraying a weakness unworthy of his own talents, in contemptuously reprobating the whole principles and performances of the illustrious Swede. Yet we are polemics of two letters from *Adanson* to *Linnaeus*, both amicable and complimentary in the highest degree. In the first, dated June 28, 1754, the writer offers to communicate his discoveries and remarks made at Senegal, speaks of *Gum Edelium* as the *Thos.* or *Frankincense*, of Europeans, used for fumigation in churches, and exhorts *Linnaeus* to continue to illustrate botanical science. The second, dated October 2, 1758, acknowledges the receipt of a most welcome letter from *Linnaeus*; laments the recent death of Anthony de Jussieu, and the illness of Bernard de Jussieu, which obliged *Adanson* to undertake the department of herborizing with the students. He subjoins an account of the African tree *Baobab*, which Bernard de Jussieu had named *Adansonia*, and gives its natural generic character at length, professedly in the *Linnean* manner, with several articles of information which *Linnaeus* afterwards introduced into his account of *Adansonia*. This letter moreover contains some matters relating to Zoology; mentions the great want of accuracy in the characters of almost all the exotic genera of plants, described by travellers, which the writer had examined at Senegal, and concludes with most respectfully thanking *Linnaeus* for his promise to make *Adanson* a member of the Upfal Academy of Sciences. This promise appears never to have been fulfilled. It might well be dispensed with when *Adanson*, in the following year, read before the *Academy des Sciences*, at Paris, that history of botany, which now makes a part of the preface of his work, entitled *Familles des Plantes*, published in 1753. In this the sycophant of *Tournefort* is exalted above the natural as well as artificial methods of *Linnaeus*, and the peron whose correspondence he had been courting, and to whose "favour and friendship" he had so lately recommended himself, is depreciated in the most contemptuous manner, in almost every thing he had done for the science of botany. This has been attributed to the correspondence of *Adanson* being flighted by *Linnaeus*; but there was hardly time for such a consequence. He rather appears to have found it expedient and popular to attack the fame of the great naturalist, to whose merit the French were then becoming sensible, and who threatened to eclipse the honours so long enjoyed by *Tournefort*. Notwithstanding *Tournefort*'s merits, *Adanson* tells us, p. 154, that "he has reason to think his own *Familles* will be adopted," as containing the sum of all the knowledge acquired in the science of botany.

An author seldom errs more than when he prophesies the success of his own works. Had *Adanson* foretold that his performances would never be refuted, he had been right, for they have slept in almost total neglect. We have given a sufficient account of his method and nomenclature, under the head of *Natural Orders*. We are aware that it is still popular at Paris to commend him, nor would we deprive him of any praise which he can enjoy, without injustice to his predecessors, or without his authority leading to scientific error, and historical mistake.

**ADISSON, Joseph.** l. 2, r. Abrobury. **ADISSON, County.** l. 5, contained, in 1810, 19,998 inhabitants, dispersed in 24 townships. **ADISSON, l. 4, for 401 r. 1190. Add— *Alfo*, a town of Washington county, in the district of Maine, containing 399 inhabitants.— *Alfo*, a township of Pennsylvania, in the county of Somerset, having 678 inhabitants.

**Gen. Ch.** *Cal. Involucrum single-flowered, of from four to eight short, imbricated leaves. Cor. of one petal, inferior, tubular, cut round near the base, and from above that part decussate; its limb in four deep, lanceolate, flat segments, turned to one side. Nectary four glands, united with the permanent base of the corolla at its inside. Stam. Filaments four, short, inserted into the disk of each segment of the corolla; anthers oblong, erect. Pet. Germen inferior, roundish; style thread-shaped, longer than the corolla; stigma vertical, awl-shaped, rather thicker than the style. Peric. Nut tumid, of one cell, with a single seed.*

**Eff. Ch.** *Involucrum imbricated, single-flowered. Corolla four-cleft, splitting circularly near the base. Nectary of four glands, attached to the bottom of the corolla.* Style longer.

A shrubby New Holland genus. Leaves scattered, various in the different species. Flowers axillary, solitary, reddish; rarely terminal, somewhat aggregate, and yellowish.

Brown.

1. A. obvata. Obovate-leaved Adenanthos. Labill. Nov. Holl. v. 1. 29. t. 37. Brown n. 1.—Leaves obovate, entire, smooth.—Observed by M. Labillardiere, as well as by Mr. Brown, on styony hills in Lewin’s land, on the south coast of New Holland. Branches round, thickly clothed with coriaceous leaves, near an inch long, broadly obovate, triple-ribbed, beprinkled with blackish glandular dots; their lateral ribs bending off veins towards the margin. Flowers axillary, solitary, twice as long as the leaves. Involucrum of fix or eight smooth scales. Points of the corolla scarcely hairy on the inner side. Style hairy, except at the top and bottom. Stigma rather swelling. Labill.

2. A. acuta. Wedge-leaved Adenanthos. Labill. Nov. Holl. v. 1. 28. t. 16. Brown n. 2.—Leaves wedge-shaped, fiddle; bluntly toothed at the extremity.—Gathered near the sea-coal at Lewin’s land, by Brown and Labillardiere. We have a specimen from the latter. This fub is about the height of a man. Leaves hardly an inch long, erect, flaked, fiddy and silvery on both sides, with three principal ribs, sometimes combined at the lower part; their abrupt extremity unequally and bluntly notched. Flowers towards the tops of the branches, axillary, flaked. Involucrum fringed, fiddy, as well as the outside of the corolla, whose fegments are densely bearded on the inside. Style fwellng and hairy in the middle.

3. A. ftricola. Silky-leaved Adenanthos. Labill. Nov. Holl. v. 1. 29. t. 58. Brown n. 3.—Leaves thread-shaped, twice-ternate, fiddy. Flowers axillary, solitary. Style smooth.—Native of the fandy sea-coal of Lewin’s land, where it was found by the authors cited. Our specimen was gathered by Mr. Menzies, at King George’s found, on the west coast of New Holland. The branches are round and fiddy, the younger ones most densely leafy. Leaves about an inch and a half long, twice or thrice deeply three-claw, in narrow blunt, thread-shaped fegments, clothed with fiddy fairs. Flowers towards the tops of the branches, densely hairy, rather longer than the leaves. Style smooth in every part, rather fwellng in the middle.

4. A. terminalis. Terminal-flowered Adenanthos. Brown n. 4.—Leaves thread-shaped, three-cleft; their lateral fegments clowen; middle one undivided. Flowers terminal, solitary or three together. Style faggery.—Gathered by Mr. Brown, at Flinder’s land, on the south coast of New Holland, in low ground near the sea-coal.

ADENODUS, so called by Loureiro, from αδένος, a gland, because of the glands of the flower, which remain to accompany the fruit.—Loureiro. Cochinch. 294.—Clafs and order, Dodecaandria Monogynia.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, reflexed, deciduous leaves. Cor. Petals five, ovate, nearly erect, more than half the calyx divided half way down into many thread-shaped fegments. Nectary five large, depressed, permanent, two-lobed glands. Stam. Filaments fifteen, short, spreading, inserted into the receptacle; anthers oblong, quadrangular, erect, split and reflexed at the summit. Pj. German superior, elongated; style awl-shaped, the length of the stamens; stigma acute. Peric. Drupa ovate-oblong, small, smooth, fingle-fed. Seed Nut oblong, ruged.

Eff. Ch. Calyx five-leaved; inferior. Petals five, fringed.

Neckariferous glands two-lobed, permanent. Drupa with a single seed.

De Theis, Gloffaire de Batanique, 6, has anticipated us in the remark, that this plant approaches the genus Elaeocarpus. (See that article.) Indeed we have a scarcely a doubt of its being one of that genus, though, having seen no specimen, we cannot absolutely affect this point. Still less can we determine whether Loureiro’s plant be any of the species already known.

1. A. coriacea. Blue Adenosma. Br. n. 1.—Gathered by sir Joseph Banks, and Dr. Solander, in the tropical region of New Holland. Seen by Mr. Brown in a dry flate only. An annual downy herb, beprinkled with glands, and smelling like mint, turning black in drying. The fike is leafy; or the flowers may be termed axillary. Calyx rough with jointed hairs, and accompanied by a pair of bracteas. Corolla blue. Brown.

This author remarks, that Ruellia uliginosa and balsamea constitute a genus nearly akin to the present, and that both are related to the order of Acanthi, or Acanthaceae, but especially Adenosma, on account of its beaked capsule.

ADENOSTEMMA, Forl. Gen. t. 45. See LAVENIA.

ADEODATUS, Pope, in Biography, denominated "Diu donou," God’s Gift, was by birth a Roman, and by profession a monk. He became pope in 672, and died in 676.

ADEPS. Subjoin, See CELLULAR SUBSTANCE.

ADERME, in Commerce. See QUINTAL.

ADIANTUM, in Botany, an ancient Latin name, which by Pliny’s account, book 22. chap. 21, appears to have belonged to the very species of fern, Adiantum Capillus-Veneris, to which it is still applied. But that account, like half his work, as we have it, is a manifold jumble of various ill-assorted materials. What he hints there, as well as in the beginning of the 17th chapter of his 21st book, relative to the permanency of the leaves, whether originally reported of the same plant, or of some other, is not contrary to truth, inasmuch as this fern is almost always verdant. His derivation of the name, from αδίαντος, or contrary to, and τον, to moisten, because water trickes off the leaves without wetting them, may satisfy us, for want of a better; but how much better would such an explanation fuit any glaucous herb, like the cabbage.—Linn. Gen. 560. Schreb. 757. Willd. Sp. Fl. v. 5. 427. Mart. Mill. Dict. v. 1. Swartz Syn. Fil. 120. Sm. Fl. Brit. 1138. Prodr. Fl. Grce. Sibth. v. 2. 278. Brown Prodr. Nov. Holl. v. 1. 155. Ait. Hort. Eff.
ADIANIUM.

Eff. Ch. Maffes of capules oblong, or roundish, inferte into each marginal, reflexed, limited involucrum.

Such is the character of the original Adiantum of all authors, a numerous genus, from which Dr. Swartz has first distinguished his Cheilanthes, to be treated of hereafter in its proper place, whose character is, that the maffes of capules are really placed on the margin of the leaf itself, each being covered only by its respective involucrum. The difference is nice, and escaped every previous observer, but we believe it to be a very found one, inasmuch as it is attended by a difference of habit, and the involucrum of Cheilanthes is not always necessarily interrupted, though the maffes of capules, seri, are distinct.

In our former article, (see Adiantum,) forty-six species are briefly enumerated, with a particular account of two, which need not here be repeated. As the genus now stands, Willdenow has fifty-four, (besides ninety of Cheilanthes,) disposed in sections, of which we shall give examples, with additions of new species.

Sect. 1. Frond simplex. Three species in Willdenow.
1. A. reniforme, Linn. Sp. Pl. 1556; 2. ajarofylhum of Willdenow, Lamarck f. 2; and 3. philophere, Linn. Sp. Pl. 1576. We have none to add. For A. sagittatum, see Lindseya.

Sect. 2. Frond ternate.

Sect. 3. Frond pinnate. Twelve species in Willdenow.
5. A. macrophyllum, Swartz Ind. Occ. 1707; 6. obliquum, Willd.; 7. lunulatum, Willd. Phytog. t. 9 f. 1; 8. arcuatum, Sw. f. 9. pumilum, Sw. Pluk. Phyt. t. 251. f. 4 1o. caudatum, Linn. Mant. 308; 11. bisulatum, Willd. from the island of Mauritius; 12. ribosphorum, Sw. Syn. 320. From the same country. We have two to add.
A. platylellum. Broad-leaved Maidenhair. Swartz in Stockh. Trans. for 1817. 74. t. 4. f. 6. Frond pinnate; leaflets stalked, ovate, taper-pointed, nearly entire; oblique, and dilated upwards, at the base; glaucous beneath. Dots oblong, contiguous along the whole margin. Native of shady woods in Brafil. Freyreis. A foot high, or more, consisting of from three to five alternate leaflets, two inches long and one broad, with numerous divaricating veins; the barren ones very inconspicuously ferrated. Common stalk, smooth, of a shining black. The infection of the capules is by no means well explained, either in the figure or description.

Sect. 4. Frond partly pinnate. Five species.

Sect. 5. Frond three-branched, digitate, or pedate; the branches pinnate. Seven species.
18. A. ternaum, Willd., found near Caripe, in South America, by Humboldt and Bonpland; 19. radatum, Linn. Sp. Pl. 1556; 20. pedatum, ibid. 1557, see our former article; 21. Lindlea, Cavan. Leccion. 271, gathered by Louis Nee, at Quito; 22. patens, Willd., found by Bredemeyer at the Caracasses; 23. pubescens, Willd., which is pedatum of Forth. Prodr. 83; 24. flabellatum, Willd. Sp. Pl. 1557. This last is unquestionably A. fuscum, Retz. Obs. f. 2. 28. t. 5, the figure of which precisely answers to the Linnæan specimen of flabellatum.

except that the upper sides of the branches in the latter are clothed with fine short rufty down, like velvet, which might escape the notice of professor Retzius. The common stalk, except at the very top, is quite smooth and naked, as described by him.

Sect. 6. Frond twice, thrice, or four times, pinnate. Thirty species.
25. A. Lancea, Linn. Sp. Pl. 1557; 26. flabium, Sw. Ind. Occ. 1717. Jacq. Ic. Tar. t. 626; 27. tetraphyllum, Willd., found by Humboldt and Bonpland near Caripe; 28. polium, Willd., found by the same at Cumana; 29. pyramidalis, Willd., which is Polybodium pyramidalis, Linn. Sp. Pl. 1554. This is Felix ramosa pyramidalis, pinsis parvis, Petiv. Phil. n. 40. t. 4. f. 12, not f. 2. Linnæus adopted this species entirely from Petiver’s figure, and was thus led to make it a Polybodium. But that figure is copied from Lonicith ramosa tenuis, pediculifer spinosus, Plum. Fil. 42. t. 54, where the characters and habit of an Adiantum are conspicuous; 32. melandecum, Willd., adopted by this author, without seeing a specimen, from Adiantum luillus abicanthucus fignatum, Plum. Fil. 79. t. 96; 31. erifatum, Linn. Sp. Pl. 1558; 32. nervosum, Swartz Syn. 123. (see hispidulum, Br. n. 2, at the end of this section); 33. hispidulum, Swartz Syn. 124 and 321, gathered by Mr. Brown to be the same as n. 32; 34. ellipticum, Linn. Sp. Pl. 1559. This, with the other, gathered at the Caracasses by Bredemeyer n. 35, serrato-dentatum, Willd., found by Humboldt and Bonpland near Caripe, and in Brafil; 37. crenatum, Willd., taken up entirely from Lonicith ramosa, rotundu crenata, Plum. Fil. 41. t. 533; 38. pulverulentum, Linn. Sp. Pl. 1559; 39. umbrosum, Willd., found by Bredemeyer, in shady situations at the Caracasses; 40. trapexiformis, Linn. Sp. Pl. 1559, a West Indian fern, usually supped to grow in Scotland, because Sibbald’s rude figure of a variety of Asphelix marinum was taken for it; see Sm. Fl. Brit. 1128; 41. pentadactylon, Langordorff and Fitcher, Ic. Fil. t. 25, found in Brafil; 42. affine, Willd., which is trapexiformis of Forst. Prodr. 84. "Schkuh. Crypt. t. 121 b;" 43. Capillius Veneris, Linn. Sp. Pl. 1558. Fl. Brit. 1128. Engl. Bot. t. 1564, see our former article; 44. emarginatum, Willd., found by Bred. de St. Vincent, on rocky margins of trunks in the isle of Bourbon; 45. cuneatum, Langordorff and Fitcher, Ic. Fil. t. 26, found in Brafil; 46. tenerum, Swartz Ind. Occ. 1719; 47. fragile, ibid. 1721: 48, concinnum, Willd., which is tenerum, Schkuh. Crypt. t. 121 b, (but not of other authors,) gathered by Humboldt and Bonpland in the Caracasses; 49. furmarioides, Willd., communicated by Fliggere, from the isle of Bourbon; 50. athibicum, Linn. Sp. Pl. 1560: 51, trigonum, Labill. Nov. Holl. v. 2. 99. t. 248 f. 2, confused by Mr. Brown as not different from the following; 52. affine, Swartz Syn. 125 and 322. t. 3. f. 4; 53. pallescens, Swartz Syn. 125 and 323, figured in Pluk. Phyt. t. 403. f. 2; 54. polyphylhum, Willd., found at the Caracasses by Bredemeyer. We subjoin the following.
A. hispidulum, Roughhild New Holland Maidenhair. Br. n. 2. Swartz Syn. 124? See n. 32, above. (A. nervosum; Swartz Syn. 123? See n. 32, above. A. pedatum; Forth. Prodr. 83, on the authority of his herbarium.)—Frond doubly pinnate; lowest branches divided; leaflets ovate-homboid, toothed in front, fariated, rather hairy, and rough. Involution nearly orbicular, hairy. Common stalk, smooth, bristles long.—Gathered by Dr. White, as well as by Mr. Brown, in New South Wales, and by the latter in the tropical part of New Holland. A foot high, or more, with a strong tufted root, whose crown is fically. Stalks purplish-black, harfs. Leaflets somewhat filaked,
ftalked, numerous on each long partial branch, crowded, oblique, jagged, half an inch in length, of a fine green. *Involucrum* crowded most about the inner, or upper, angle of the bafe, brownish, round or kidney-shaped, rough with fine brilfly hairs; their under side covered with little brown crowded 

Capsules, which are quite unconnected with the leaf.

*Adonox.* Elegant New Holland Maidenhair. Br. n. 3. "Frond repeatedly compound, deltoid; branches triply pinnate; leaflets rhomboid, obtuse, smooth; the lower ones cut. *Involucrum* kidney-shaped. Partial ribs downy. Common frond rough."—Discovered by Mr. Brown, near Port Jackson, New South Wales. We know not that we have ever seen a specimen.

A. *affinis.* Rounded New Holland Maidenhair. Br. n. 4. Swartz Syn. 115 and 322. t. 3. f. 4. (A. trigonom; Labill. Nov. Holl. v. 2. 99. t. 248. f. 23; fee n. 51 and 52 above.)—Frond repeatedly compound, very smooth; leaflets roundish-rhomboid, deeply notched in front; the notches contracted, each bearing a smooth kidney-shaped involucrum. Common frond and ribs perfectly smooth.—Gathered by Dr. White and Mr. Brown, in the neighbourhood of Port Jackson, and by the latter, as well as M. La billardiere, on the south coast of New Holland, and in Van Diemen's Island. From one to two feet high, composed of numerous little, fan-like, ftalked, ribbed, bright-green leaflets, between whose rounded marginal segments the smooth, light-brown *involucrums* are ftationed. These by age become reflexed, and turn up the numerous pale capsules which cover their under surface.

A. *saberdatum.* Heart-leaved Maidenhair. Swartz in Stockh. Tranf. for 1817. 75. "Frond triply pinnate; leaflets ftalked, somewhat heart-shaped, pointed, ftightly crenate, with radiating veins. *Involucrums* at each margin, roundish-crescent-shaped."—Gathered by Mr. Freyreis, in fhady woods in Brazil. Common frond round, dark purple, smooth and polished. *Frond* eighteen inches long, its outline ovate, or deltoid. Primary and secondary branches alternate, widely spreading, ftaight, round, smooth, the colour of the frond. Leaflets alternate, rather distant, fome regular, others oblique and dilated at the upper angle of the bafe, an inch in length, with a long point to each; smooth on both fides; fringed beneath with copious, forked, radiating veins, and ftightly glaucous; the margin obscurely ferrated. Common rib ftightly zigzag, polished. *Dots* at the upper and under edges, not at the bafe or apex, roundish, diftinct, covered by brown crescent-shaped *involucrums*. Swartz. This mode of expréffion muft not be taken literally, for then the plant would be a *Cheilanthes*.

The author adds, that this fpecies is very different in the shape of its leaflets; for fo only can we understand the "forma pinnarum," as meaning pinnatifid.

A. *intermedium.* Intermediate Maidenhair. Swartz in Stockh. Tranf. for 1817. 70. "Frond doubly pinnate; leaflets halved, wedge-shaped, oblong-rhomboid, obtuse, ribbed and ftirted; with a right angle at the upper side of the bafe; fterrated and ft Audrey at the front and apex. Stalk and ribs rough and downy."—Gathered by Mr. Freyreis in low woods, in the interior part of Brazil, in September. Root creeping. Common fronds a foot high, ftightly divisions opposite, linear-lanceolate, curved upwards, of three pair of leaflets, half an inch in length, besides an odd one rather longer, all ftalked, ftightly falcate, obtuse, crowded, smooth on both fides, of a brownish-green. *Dots* four or five, distinct, each with a femicircular, curved, brown *involucrum*. Intermediate, as it were, between *crisatum* of Linnæus, and *nervosum* of Swartz, n. 31 and 32, but differing from the former in having the common frond not rough with prominent points, nor the lower branches deeply divifed; from the latter in having wedge-shaped leaflets, somewhat falcate in front, and other particulars. It is perhaps too nearly related to *A. acuminatum* of Deveaux. *Swartz.*

**ADIDISING.** See *Bundela* and *Rewah.*

**ADIPOCIRE,** in *Chemistry,* is described at length in the *Cyclopedia,* but the curious fact that this substance forms a principal ingredient in some fpecies of *Biliary Calculi* has been omitted under both articles.

**ADJUSTMENT,** the settling of the averages or lobbies on policies of assurance. See *Average.*

**ADONIS,** in *Botany,* was so named in memory of the favourite of Venus, reported by the poets to have been changed, by that goddes, into a flower. But whether ours is the very plant, known by this name to the ancients, would be almost as difficult to prove as the original fact.

Gen. Ch. Cal. Perianth inferior, of five obtuse, con- 

cave, clofe-prefted, fomewhat coloured, deciduous leaves, 

fometimes with a fmall fpur at the bafe. Cor. Petals from 

five to fifteen, oblong, obtuse, polifhed, with fimple naked 

caws. Stam. Filaments numerous, very fhort, awl-shaped, 

inferted into the bafe of the receptacle; antthers oblong, 

inftexed. *Phyll.* Germinings numerous, ovate, inferted into the oblong-conical receptacle, crowded, above the flamens, each pointed with a very fhort, partly decurrent, ftyle; ftigmas acute, reflexed. *Peric.* noce. *Recept. oblong*, fpeked. *Seeds* numerous, irregular, angular; gibbous at the bafe; reflexed at the point, rather prominent, without awn or wing.

Eff. Ch. Calyx of five leaves. Petals from five to fif- 

Herbaceous plants, with leafl.*isms.* Leafs deeply cut, 

in a pinate manner, their lobes many-cleft, in very numerous, 

linear fegments. *Involucrum* none. *Flowers* foltary, at the 

summits of the lem, or branches, yellow, scarlet or crimson, 

never blue.

All the ten fpecies are found in Europe, or in the adjoining 

countries of northern Africa and Asia; fome of the 

first fection in cultivated plains; of the second in rugged 

mountainous spots.

The perennial kinds have acrid, bitterish, purgative roots, 

capable of supplying the place of Hellebore. The annual 

fpecies are almost inactive.

The genus is divisible into two fections, by the habit and 

duration, confirmed by differences in the *flowers* and *fruit,* 

as follows.

*Seft. i. Adonia.* *De Candolle.*

Adonis of C. Bauh. Pin. 178.

Petals from five to ten, concave or flat. *Stam.* eighteen 

or twenty. *Seeds* collected into an ovate or cylindrical spike, 

always smooth, each beaked with a ftaight conical style.

Roots fikel, annual, tapering, but little divided. All these 

annual fpecies are so nearly akin, that they have been taken by 

several
several authors, perhaps not improperly, for varieties of one species. The following synonyms therefore are equally applicable to all of them.

A. n. 1158. Hall. Hist. v. 2. 66.

The following plants may, in M. De Candolle's opinion, be esteemed, with equal propriety, either species or varieties. He therefore proposes them with hesitation, recommending them to the observation of practical botanists. Whatever difficulties may attend some of these, we are persuaded that they cannot all be united, even though the autunnalis and affinevis should prove the only two that are permanently distinct, and the foundations of all the rest.

Ger. Em. 385. Lob. t. 283. Adonis; Camer. Epit. 647. A. n. 1186. Flore minor arcutruben. Monif. fett. 6. 1. 8. f. 1. Earanthum flore rubro; Bell. Eyl. afliv. ord. 5. t. 1. f. 2.)—Calyx smooth. Petals concave, converging, scarcely larger than the calyx. Seeds somewhat recuticulate, collected into an ovate head. Stem branched.—Native of corn-fields in various parts of Europe, from Germany to Greece, flowering through the summer to the end of autumn; not frequent in England, except in gardens, where it is often cultivated amongst other hardy annuals, and as De Candolle observes, prefers itself unaltered from seed. The root is somewhat spindle-shaped. Stem branched, bushy, round, flat, occasionally downy. Leaves alternate, dark green, thrice compound, with innumerable, crowded, rather short segments. Calyx pale green; sometimes purplish. Corolla of that peculiar intense crimson, or blood-colour, which gave occasion to the name of Phesfant's-eye, and probably to the original application of the fable to this very plant, whose beauty well merits the compliment. Each petal has a violet-coloured base. Petals inverely heart-shaped, usually about eight. Fruit ovate-oblong, measuring hardly an inch. Calyx-leaves gibbous below their infection. M. De Candolle remarks, that there is occasionally, though rarely, a paler variety. This seems, by Dr. Withering's specimens, to be what he found on Salisbury plain, and took for affinevis. Its petals are rounded, and do not extend beyond the calyx.

A. sylvetris, flore luteo, folius longioribus; Mill. t. 1. 14. f. 2. De Cand.)—Calyx smooth, with short furs. Petals flat, oblong, twice the length of the calyx. Seeds nearly smooth, collected into an oblong head. Stem scarcely branched.—Common in corn-fields and vineyards in every part of France, and apparently in Germany also, flowering in June and July. The flum is almost always quite simple. Flowers yellow, or lemon-coloured, rarely pale orange. Calyx-leaves elongated and unattached at the base, almost as in Sedum and Myojarus. Petals flat, nearly linear. The flowers generally almost rival the size of A. vernalis, but there is a variety only half as large; they run into each other.

De Candolle.

3. A. minilifa. Small-flowered Adonis. De Cand,

n. 3.—Calyx smooth; not spurred at the base. Petals flat, oblong, rather longer than the calyx. Seeds somewhat reticulated, collected into an ovate head. Stem somewhat branched.—Found in the south of France, in fields about Coulounieix, Aigron, &c., flowering in May and June. A doubtful species. Flowers small, yellow, or flame-coloured. Germin few, from seven to ten, composing a very short head. Stem simple at the base, but often a little branched at the summit. De Candolle.

4. A. mirraeora. Small-fruiting Adonis. De Cand. n. 4. (A. annua, flore minimo, pica tenui longifima; Monif. fett. 6. 1. 9. f. 4.)—Calyx smooth. Petals flat, oblong, twice the length of the calyx. Seeds reticulated, collected into an oblong head. Stem nearly simple.—Native of corn-fields in Spain, near Tudela; Dufloure: in the ill of Iwca: Delaroche: in Tenerife; Brongniart. Perhaps not distinct from flavia, n. 2. It appears to differ in the flum not being so short as to, with more crowded foliage. The calyx is scarcely, or not at all, spurred at the base. Seeds about half the size of flavia, more numerous, and much more reticulated, in a head eight or nine lines long. The corolla is either of a lemon-yellow, or somewhat flame-coloured. De Candolle. We take the liberty of introducing Morison's synonym, which seems to answer best to this species, though applied by De Candolle to the seventh.

6. A. flammea. Flame-coloured Adonis. Jacq. Aultr. t. 355. De Cand. n. 6. Willd. n. 3. Ait. n. 9. Hoff. Syn. 308. Hoffm. Germ. v. 1. 251. (Eranthum flore flammeo; Bell. Eyl. afliv. ord. 5. t. 11. f. 3.)—Calyx hairy at the base. Petals flat, oblong, somewhat acute, longer than the calyx. Seeds collected into a cylindrical head. Stem branched. Flowers stalked.—Native of corn-fields in Aultria, flowering in summer; Jacobin. In Brunswick; Hoffmann. The flum is two feet or more in height, branched from the bottom all the way up, furrowed, smooth or hairy. Poofostalk hairy. Leaves light-green, with lanceolate segments. Flowers large, on long stalks. Calyx acute, jagged, reddish. Petals eight or nine lines in length, somewhat obovate, but more or less acute, and frequently toothed; their colour orange-fláretal.

This Adonis is one of the tallest, with a copiously-branching, furrowed stem; light-green leaves; and long-stalked flowers, which we cannot, with De Candolle, term small ones, being, as far as we have seen, of the full size of any annual species of its genus. The petals are usually numerous, of a most vivid scarlet. Fruit long, but not interrupted, except by accident. We cannot but consider our friend M. De Candolle as having cited Morison, on the present occasion, with less accuracy than usual, and we have made an alteration herein; see species 4th.

—Native of corn-fields and barren ground, in Egypt and Cyprus; as well as in Provence, between Digne and Colmars. The figm is angular and fluted, firm, branched. Flowers on short stalks. In the Egyptian species, the petals are oval, yellow, with blackish claws; seeds furnished at the base with tooth-like prickers, finely corrugated, left crested at the back, and disposed in a fluted spike. In the Provence variety, the petals are oblong, and flame-coloured; seeds left toothed or tuberculated at the base, more crowded, by far more, and each other with their crests, so as to form a continued spike an inch long. De Candolle.

Sect. 2. Conflugo. Matthioli, De Candolle. Petals from eight to fifteen, always oblong, flat. Stamen from 25 to 30. Seeds, collected into an ovate head, each ovate, beaked with its hooked recurved style. Roots perennal, thick at the crown, blackish, with clustered fibres.

β. Mentzeli; De Cand. excluding the syn. of Linnaeus. (Helleborus niger ferulaceus, canle genculato, flore magno, pulpe minoris inflato; Mentz. Pugil. t. 3; copied in Morif. sect. 6. t. 9. f. 2.)

Silvrica, Petria; De Cand. (A. n. 43; Gmel. Sib. v. 4. 200.)

Root somewhat tuberous. Stem branched from the bottom. Petals ten, fifteen, or more, elliptic-lanceolate. Calyx downy. * Seeds hairy.—Native of mountainous or alpine situations, or open hills, on the island of Oeland, Germany, the south of France, Switzerland, and Italy. Frequent with us in gardens, flowering in the early spring. The tuberous crown of the black perennial root, lends down many long, simple, rather stout fibres. The stems are herbaceous, a foot high, frizzled, leafy, more or less branched from the lower part, in an alternate order, rarely bejewelled with a few hoof scattered hairs. Leaves crowded, felicie, alternate, smooth, in many three-cleft, linear, acute, entire segments; channelled above. Flowers terminal, solitary, nearly sessile, large and handsome, an inch and a half or two inches broad, of a bright shining yellow. Calyx-leaves concave, ovate, downy, frizzled. Petals twice as long, sometimes above an inch, uniformly ten or twelve, but sometimes, even in a wild state, above twenty; purplish beneath; varying in breadth, but always somewhat elliptical, either obtuse or acute, a little erenate. Stamens numerous, capillary, short, with vertical quadrangular anthers. Germens numerous, ovate, compressed, more or less covered with short soft hairs, and hooked with the recurved styles, collected into a globular head, the flalk much elongated as the fruit ripens. We readily follow De Candolle in thinking the plant of Mentzelius, (see p. 5. a very inconsiderable variety, differing only in having short and simple stems, with larger flowers: but Linnaeus has surely committed a great error in referring this plant to his apennina. The γ of De Candolle is said to have likewise a large flower.

—Gathered by Mr. Steven, near the banks of the Wolga. Perennial. Intermediate between vernalis and pyrenaica, differing from the former in having a branched stem, more fleshy leaves, often wanting on the lower part of the branches, and much less downy stems. From the latter it is distinguished by having its lower leaves abortive, like scales, and the seeds, if at least half young, somewhat downy. From both it differs in the calyx being externally downy or finely hairy, not smooth. Mr. Steven met with A. vernalis likewise in Taurus. De Candolle. These remarks of our learned friend caue us no small perplexity. All our specimens of A. vernalis, from Switzerland and the south of France, as well as the authentic Linnaean specimens, and one from professor Jacquin, have a downy calyx, and most of them branched stems. The half-ripe seeds in Jacquin’s plant are sparingly downy all over; the germens of those from Switzerland scarcely downy at all.

12. A. pyrenaica. Pyrenean Adonis. De Cand. n. 10. "Fl. Franc. v. 5. 655." (A. apennina; Gounn Illufir. 33.) —"Radical leaves on long stalks, ternate; leaflets in many deep segments; upper leaves fleshy. Fruit smooth. Petals eight or ten, oblong-wedge-shaped, undivided." —Found by Gounn in the valley of Eynes, in the eastern Pyrenees, flowering in July. The other places of growth, mentioned by De Candolle, are all bent omitted. He directs us in his Addenda to strike out the reference to Pallas, as belonging to A. volgeris; and perhaps also that of Fischer, A. charophylla. To the latter alteration we heartily assent. Dr. Fischer’s own specimen, seen in our hands by De Candolle, •
Candolle, has nothing but scales in the place of radical leaves, and certainly agrees in every respect with Jacquin's specimen of vernalis above-mentioned. The calyx is in the same manner hairy at the base only, a circumstance, indeed, on which, the more we enquire into it, the less we find reason to rely. Our specimen will not admit of an examination of the vernalis. M. De Candolle speaks of his pyrenaica, (a species entirely unknown to us,) as 'akin to vernalis, but most certainly distinct. The stem is often above a foot high, and branched. Radical leaves on long three-cleft footstalks. Flower nearly fefulile, at its first expansion among the uppermost leaves. Head of seeds raised on a greatly elongated stalk. Petals eight to ten, smaller and more obtuse than in A. vernalis. Fruit, even before it is ripe, smooth.'

We do not presume to form any decisive opinion concerning the perennial species of Adonis, without the examination of sufficiently perfect specimens, in every state of growth; but it appears to us that they are by no means well determined at present, nor do we perceive that any characters hitherto suggested are sufficient for the purpose. The vernalis and pyrenaica are probably very distinct, for which we have the weighty opinion of De Candolle; but whether the latter may not be found in many other countries, and confounded by the generality of botanists with vernalis, is a point we cannot satisfactorily determine.

ADPRESSA FOLIA, Clove-preffed Leaves, are such as have the upper surface closely applied to the stem, or branch, on which they grow. This is so complete in some plants, such as Paeonia bifolia, that only the under surface of each leaf being exposed to the air and light, the latter part appears to perform the functions proper to the upper surface of most leaves, and, in the instance just mentioned, assumes the deep green hue, and polished cuticle, usual on the upper side of leaves in general. Such is likewise the case with Xeranthemum proliffrum and filamoide of Linnaeus, now referred to Elachyurus. See Leaf.

ADRASTEA, so named by professor De Candolle, from Adraste or Adrast, a daughter of the goddess Nemesis, who was a daughter of Oceanus; because the plant in question is a native of New Holland, which has been called by some persons Oceania. De Cand. Syll. v. 1. 424.—Clas and order, Decandria Dignata. Nat. Ord. Magnoliis, Jfuf. Dilleniaceae, De Cand.

1. A. falicifolia. Willow-leaved Adrassea.—Native of bogs in New South Wales. Described by De Candolle from a dried specimen in Mr. Lambert's collection. This is a small shrub, approaching Hypebertia, (see that article,) in general appearance. The branches are round, long and slender, reddish-brown; downy when very young, but caller their cuticle in long portions when old. Leaves linear, entire, except three or five callous teeth at the extremity, the point being callous; their base somewhat contracted; their upper surface smooth, without veins; the under hoary with short silky hairs; their length is an inch and a half; breadth three lines; and they resemble the leaves of Salix alba, or of the Olive. Flowers at the ends of the young branches, solitary or in pairs, sessile between three or four crowded leaves, which exceed them in length. Calyx-leaves keeled, covered with close silky hairs; their margin mem-

branous; their point tipped with a bristle. Stamens ten, half the length of the calyx. Germens smooth.

ADRIANOPLE, coll. 2, 1, 5, r. 1453.

ADVICE, in Commerce, denotes the information given by letter of a bill drawn by one merchant upon another.

ADVOCATE, 1. 24, r. paffed A.U. 549. Col. 2, 1, 8, r. revived.

AECIDIUM, in Botany, from avus, a wound or injury, because the parts of a plant to which this genus of parasitical fungi attaches itself, always, in consequence, become discoloured, discoloured, and either tined, or, as it were, blazed.—Perf. Obs. Mycol. falc. 1. 97. Syn. Fungi. 204.—Clas and order, Cryptogama Fungi. Nat. Ord. Fungi. Eff. Ch. Head conspicuous, fcelile, round, membranous, at length burrting, with a toothed orifice. Seeds mealy, naked.

This genus is always parasitical on the backs of the leaves, or on the stem, of certain plants. In addition to what is said of it already, we shall subjoin illustraties of a few species. Perone defines twenty, in two repetitions.

Ae. cornutum. Horned Aecidium. Pers. n. 1. Obs. Mycol. falc. 2. 22. t. 4. f. 2. 3. Sowerb. Fung. t. 319. (Lycoperdon corniflrum; Fl. Dan. t. 838. L. corniculatum; Ehrh. Crypt. 200.)—Base yellowish. Heads nearly cylindrical, very long, curved, greyish-olive. Found in autumn, on the leaves of the Mountain Ash. On the upper side of the leaf is seen an orange-coloured spot; on the under a swelling, out of which proceed five or six bristle-like beads, a line and a half in length; each rather tumid at the base; contracted at the point, where it burts irregularly.

Ae. cancellatum. Reticulated Aecidium. Pers. n. 2. Sowerb. Fung. t. 416. (Lycoperdon cancellatum; Jacq. Anfr. v. 1. 13. t. 17. Fl. Dan. t. 704.)—Base tawny. Heads oblong, splittong into fibrous mafles, cohenting at the summit.—Not rare on the leaves of garden pear-trees. We first saw it on a baking pear at Mr. Hume's, Wormleybury, many years ago, where it still frequently occurs, without injury to the tree or fruit. The beads are much thicker and shorter than the foregoing, and when ripe, discharge their powderly seeds between the tough, brownish, permanent fibres of the bead, which last as long as the leaf, and actually seem an extension of its woody fibres. We cannot but concede Mr. Sowerby's t. 409 to be a different plant, belonging to the genus Spharia (see that article;) or rather perhaps Nannomycota, to be hereafter described.

Ae. oxyacanthae. White-thorn Aecidium. Pers. n. 3. (Aec. laceratum; Sowerb. Fung. t. 318. Lycoperdon penicillum; Fl. Dan. t. 833? )—Base unequal, rusty. Heads ash-coloured, cylindrical, splitting nearly from top to bottom, into numerous, fibrous, spreading segments.—Found on the leaves, or young buds, of Common Hawthorn. Peron defribes his specimens as divided to the very base, and therefore preserves the plant of Fl. Dan., which appears not split half way down, may be another species; but Mr. Sowerby's seems intermediate between both, and we can scarcely doubt his being the same as Peron's.

sprinkled with the little larry whitish orifices of the heads, full of orange powder. _Lycoperdon epiphyllum_ of Hudson and Lightfoot are different from this, and perhaps from each other. _Uredo tyflaginis_ resembe plant in general aspect, but on near examination will be found less distinct in the form of an orange powder, intermixed with the cotton of the Colts-foot leaf, without distinct white larry heads.

_Ae. berberidis._ Barberry _Aecidium._ Perf. n. 11. Sowerb. Fung. t. 397. f. 5. ( _Lycoperdon puciliforme;_ Jacq. Coll. v. i. 132. t. 4. f. 1.)—Baie orbicular, scarcely convex. Heads cylindrical, somewhat elongated, yellow.—Found on leaves of the Barberry, in cold wet autumnal weather, sometimes in the spring, constituting of very conspicuous and prominent tawny spots, the heads projecting much. The orifice of each is neither dilated, nor conspicuously toothed or jagged. The whole turns brown, or black, in decay, and may be observed in that state on the fallen leaves during winter.

Scz. 2. _Simple._ Heads scattered, not combined by any distinct crux, or base. Six species.

_Ae. euphorbiae._ Spurge _Aecidium._ Perf. n. 15. "Hum. Friberg. 128." ( _Lycoperdon euphorbea;_ Schrak. Barvar. v. 2. 631.)—_Eufila degener;_ Rivin. Tetrup. Irr. t. 113. f. 2.—Simple, crowded. Heads pale, cylindrical, reflected at the margin. Powder orange-coloured.—Frequent in summer on the leaves of _Euphorbia Cyparissias_ in Germany, France, and Switzerland, causing the whole plant to assume a diseased appearance, and often to fail of producing flowers. We scarcely think Rivinus, as Perfoon hints, meant to consider this diseased _Euphorbia_ as a distinct species.

_Ae. fragophylae._ Goat’s-beard _Aecidium._ Perf. n. 15. b. Sowerb. Fung. t. 397. f. 2.—Scattered. Heads somewhat elliptical, with an irregularly torn margin. Powder yellow.—On the stem and leaves of _Tragopogon pratensis._ Conspicuous for its short white heads. _Perfoon._ That author certainly means to describe this as a distinct species from the last, though by an error, which ought to have been corrected in printing, he has given the same number to both. Hence he has really twenty species in all, though apparently but nineteen.

_Ae. anemone._ Wood- _Aemoneum_ _Aecidium._ Perf. n. 17. Uilt. Annal. v. 20. 135. ( _Lycoperdon anemone;_ Pulten. Tr. of Limn. Soc. v. 2. 311.)—Simple, scattered. Heads cylindrical, rather prominent, pale, moistly toothed, filled entirely with white powder.—Found in the spring on leaves of _Anemone_ _Aegialitis._—_Rendering the plant sickly, and often barren. Dr. Pulteney observed that this fungus originates under the cuticle, and may be seen in a young state, through that membrane. At length each individual assumes a nearly globular form, burbling with lacerated edges, the cavity being lined with white powdery _seeds,_ intermixed with minute fibres. In fading, each turns yellowish, then brown, and finally "each fungus is resolved into a farinose particle, resembling the fruiting body of a Polypody." _Pulteney._ The _Æ. jufum._ Relh. Cant. 546. Sowerb. Fung. t. 53. found on the leaves and petals of the same species of _Ae. anemone_ without injuring the plant, is the _Puccinia anemoneum._ _Perfoon._ Syn. Fung. 256, a genus described as deflinate of a head, or _peridium._ In this respect we find it difficult to draw a line between Mr. Sowerby’s figure, and his various representations of _Æcilia._ t. 398, though we doubt not the specific difference of the above two plants. Which of them is the "Conjurer of Chalrave’s Fern," _Dill._ in _Rait_ Syn. 124. t. 3. f. 1, may be doubted; but we rather suppose the _Puccinia._

_Ae. puncticulum._ Yellow- _Anemoneum_ _Aecidium._ Perf. n. 13. Uilt. Annal. v. 20. 135. ( _Ae. anemone;_ Hoffm. Germ. v. 2. t. 11. f. 1.)—"Simple, pointed. Heads partly funk, their border nearly closed. Powder compact, brownish."—Found rarely on the leaves of _Anemone ranunculoides_ which it marks with brown dots. The border of the orifice is but slightly, if at all, toothed. _Seeds_ chestnut-coloured. _Perfoon._ We have not heard of this species in Britain.

Mr. Sowerby has represented several more species of this genus in his _English Fungi_, t. 397, 398, such as _Æ. corni_, _confumans_, _rubri fragariis_, _mentha_, _falcis_, _cardus_, _rhei_; but we do not see clearly how the generic difference between _Æcilia_ and _Puccinia_ is, in most of them, to be determined.

_EÆc._ l. 4, m. G. Bebelin.

_Aegerita_, in _Botany_, so called from _aeger_ a _Aegerita_, or rather _Alder_ tree, because the first-discovered species of this minute genus grows on the wood of the Alder, and was thence called _Sclerotium Aegerita_, which last word, on the establishment of the present genus, was taken for its generic name.—Perfoon. Syn. Fung. 684.— _Clas_ and order, _Cryptogamia Fungi._ Nat. Ord. Fungi.

Eff. Ch. Sellese _granulations foliis_ filled with a somewhat mealy powder.

1. _Ae. candida._ White _Aegerita._ Perf. Diff. Fung. 40. ( _Sclerotium Aegerita;_ Hoffm. Germ. v. 2. t. 9. f. 1.)—Crowded, smooth, pure white.—Found not unfrequently in the dry rotten wood of Alder, in mossy situations. This fungus consists of numerous little crowded granulations, the base of miller-feed, globular or elliptical, as white as sugar-plums, solid but friable, the internal substance appearing, when highly magnified, full of feed-like bodies. _Hoffmann._

2. _Ae. pallida._ Pale _Aegerita._ Perf. ibid.—Scattered, pale, somewhat warty.—On the fallen branches of _Acker._ Diflinguished by the inequality of its surface. _Perfoon._

3. _Ae.? cefca._ Grey Doubtful _Aegerita._ Perf. n. 3.—Scattered, glaucous or whitish.—On the trunks of trees in winter. Refembles small pale dots, of a softish substance; disappearing when dried. _Perfoon._

_Aelialitis._ _Aegialitis._ _Aegialitis_ _Aegialitis_, an inhabitant of the coast, alluding to its place of growth.—Brown. Prod. Nov. Holl. v. 1. 426.—Clas and order, _Pentadria Pentagynia._ Nat. Ord. _Aggregate_. Linn. _Plumbagineae._ Jull. _Plumbagineae._

Eff. Ch. Calyx of one leaf, coriaceous, five-toothed, with folded angles. Petals five, their claws combined at the base, bearing the flowers. _Stigmas_ capitrate. Percicap prominent, angular, nearly cylindrical, coriaceous, without valves. Seed germinating, without albumen. _Plumula_ conspicuous.

1. _Ae. annulata._ Gathered by Mr. Brown, in the tropical part of New Holland, growing among _Rhizophora_, near the sea-shore. A perfectly smooth _frutum_, of humble growth, having round, brittle branches, marked with annular scars, where the leaves have been. _Leaves_ alternate, without _fusules_, flat, coriaceous, ovate, entire; their _footstalks_ bordered, dilated and sheathing at the base. _Spikes_ panicled. _Flowers_ white, alternate, somewhat imbricated, with three _bractes._ _Brown._

Akin to _Statiche._ See that article, and _Tanna-theä._

_Aegiceras._ So called from _ae_ a goat, and _cera_ a horn, in allusion to the horn-like shape of the curved feed._

_The following is to be substituted in the place of our original article._—_Gern._ v. 5. 276, 5. 46. _Schreb._ Gen. 157. _Wild._ Sp. Pl. v. 1. 1183.—_Mart._ _Mill._ _Diff._ v. 1. 712.—König
AEG}

Gen. Ch. reformed. Cal. Perianthus inferior, of five roundish-oblong, concave, coriaceous, permanent leaves, thickset at the base, obliquely imbricated at the margin. Cor. of one petal, valver-shaped, somewhat coriaceous; tube the length of the calyx, nearly cylindrical, thickish, rounded at the base; limb the length of the tube, in five deep, ovate, pointed, equal, reflexed segments. Stam. Filaments five, prominent, awl-shaped, twice the length of the tube, united at the bottom into a ring, attached to the base of the corolla; anthers arrof-shaped, incumbent, veratellae, of two lobes and two cells, birking longitudinally. Pijl. Germen superior, linear-oblong, compressed, dotted, with rudiments of several feeds; style erect, the length of the flamines, tapering, permanent; stigma simple. Peric. Follicle cylindrical, coriaceous, curved, pointed, of one cell. Seed solitary, oblong, nearly filling the pericarp, and germinating there, attached by a thin flat umbilical cord, of its own length, which is dilated into a hood-like, pointed, partial tunic, closely covering the minute cotyledons, and part of the radicle; albumen none; embryo erect; radicle very large.

1. Ac. fragrans. Fragrant Aegiceras. Konig as above. Br. n. 3. (Ac. majus; Gertr. as above. Willd. n. 1. Rhizophora coriiculata; Linn. Sp. Pl. 635. Burm. Ind. 108. Pou-Randel; Rheede Hort. Malab. v. 6. 65. t. 36. Mangium fruticans coriiculatum; Rumph. Ambon. v. 3. 117. t. 97.)—Native of the maritime woods and thickets of the East Indies, as well as of the tropical and eastern coasts of New Holland. The stome are rather shrubby than arborescent, several from the same root, ten to fourteen feet high, three or four inches in diameter, with numerous slender spreading branches. Leaves alternate. Stam. imperfectly opposite, flat-falked, obovate, or somewhat elliptical, marinate, entire, coriaceous, smooth, single-ribbed, from one to four inches long. They are reported to have a briny taste; and Mr. Browne noticed a faline efflorescence, or excretion, on their upper surface. Flowers white, fragrant, about half an inch broad before their corolla is reflexed, collected into umbels at the ends of the short lateral, as well as principal, branches. Seed-coff from an inch and a half long, pointed, curved, but not spiral, as the generic name would seem to imply.

This shrub, which Linnaeus confounded with his Rhizophora, is the only known species of a very distinct genus; the Ac. minor, Gertr. t. 46, having been shewn by Mr. Konig to be Conuus fantalblados of Vahl, Symb. v. 3. 87. Sentibolados, Linn. Zeyl. 192. n. 408, a totally different plant in genus and natural order, though Gertner has quoted for a synonym, Umbraculum maris, Rumph. Ambon. v. 3. 124. t. 82. This last, as well as Mangium floridum of the same writer, v. 3. 125. t. 83, appear very nearly related to our Aegiceras program: inof that, without specimens, no one can safely distinguish them from it, or from each other, for the difference of zinc in their respective flowers is of no avail in Rumphius's, always variously diminished, plates.

Gen. Ch. Cal. Perianth sheath-like, inferior, of one leaf, ovate, concave, inflated, coloured, permanent. Cor. of one petal, tubular, longer than the calyx; tube globular at the base, bent horizontally towards the middle, swelling upwards; limb spreading, in five short, rounded, equal segments. Stam. Filaments four, incurved, two shorter than the reit; anthers oblong, simple, converging in pairs, slightly bent. Pijl. Germens superior, ovate; style fimple, curved, the length and position of the flamines; Rigma capitae, large. Peric. Capsule ovate, pointed, of two valves; with many cells. Seeds numerous, minute. Receptacles several, convoluted, attached to the valves.

1. Ac. indica. Indian Aegicetia. Linn. Sp. Pl. v. 1. 632. Roxb. Coromand. v. 1. 63 t. 91. Willd. n. 1. (Orobanchae Aegicetia; Linn. Sp. Pl. ed. 2. 883. "Thiem-cumulata; Rheede Hort. Malab. v. 11. 97 t. 47").—Native of Malabar, in the hilly parts of the Circars, but rare. Roxburgh. Root of many simple fibres, probably parietical and annual. Stams several, purplish, a span high, fimple, fingle-flowered, and naked, except a lanceolate, brown, fheathing scale at the bottom of each. Calyx fuffly-coloured, an inch long, turning green as it fades. Corolla half as long again as the calyx, and more slender, of a violet purple; the tube pale; deciduous. Style permanent as the fruit ripens, curved, projecting laterally out of the calyx. Seeds and receptacle tawny.

The generic distinctions between this plant and Orobanchae are obvious enough; the single-leaved fpathaceous calyx, regular corolla, undivided stigma, and many-celled capsule, whose internal structure Dr. Roxburgh says he could never well determine, but the numerous convoluted partitions, or receptacles, which he describes, are sufficiently different from Orobanchae. As to habit, these genera nearly agree, both having a rufty pubescence, a purple hue, and, if we mistake not, paraitical roots; though the inflorifence, and the form of the calyx, differ in each. Aeginetia appears to want the nectariferous gland, found at the base of the germen, in front, in Orobanchae; it wants also the bractse, observable in every species of the last-named genus, except the unflora.

ÆGISISSUS. See ÆGYPTUS.

AEGLE, in Botany, the name of one of the Hesperides, (see that article,) chosen by Mr. Correa de Serra for this genus, as Linnaeus had already dedicated one to her sister Archytha.—Correa Tr. of Linn. Soc. v. 5. 222. Ait. Hort. Kew. v. 3. 284.—Clafs and order, Polyandria Monogynia. Nat. Ord. Auranthi, Jaff.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, with five shallow lobes, at length deciduous. Cor. Petals five, ovate, acute, spreading, many times longer than the calyx. Stam. Filaments numerous, short, awl-shaped, inserted into the external part of the elevated receptacle of the flower; anthers oblong, erect, heart-shaped at the base. Pijl. Germen superior, ovate; style short, thick, Rigma oval, obilue furrowed. Peric. Berry coated, globular, smooth, almost woody when ripe, not burrting, of ten or twelve cells obliterated as the pulp arrives at maturity. Seeds ovate, compressed, numerous in each cell, in a simple row, each inferted by a short partial stalk from the central column; albumen none.

Eff.
AEG

1. Ac. Marmelos. Thorny Aegle, or Bengal Quince. 
Correa as above, 223. Willd. n. 1. Roxb. Coromand. v. 223. t. 143. (Cratoxylon Marmelos; Linn. Sp. Pl. 647. Willd. Sp. Pl. v. 2. 853. Cydonia exotica; Bauh. Pin. 432. Cucurbitifera trifolia indica, fruitulus pulpa Cydonia acum.); Rall Hift. v. 2. 1665. Pluk. Phyt. t. 170 f. 5. Bilicus; Rumph. Amboin. v. 1. 197. t. 81. Covalam; Rhee and Hort. Mal. v. 1. 37. t. 37. Morocco of the Tenduglas.—Native of the mountainous parts of the coast of Malabar, fometimes of the low lands, flowering during the hot fason. This is a rather large tree, whose trunk is nearly erect, clothed with all-colored bark. Branches scattered. Spines filipulary, in pairs, awl-shaped, pungent, strong, an inch in length, sometimes want. Leaves irregularly flattened, on downy flake, tereate; inflexed elliptic-oblong, with a blunt point, serrated, single-ribbed, veiny, smooth; tapering at the base; unequal in size; the odd one largest, about three inches long. Flowers of a dirty white, in short, aggregate, terminal and axillary, clusters. Fruit the size of a large orange, with a hard smooth greyish shell, from which the Dutch in Ceylon are fad to prepare a perfume. Dr. Roxburgh speaks of this fruit as delicious to the taste, and exquisitely fragrant, of a laxative quality, which renders it particularly serviceable in habitual colicines. A clear tenacious gum, enveloping the seeds, makes a good cement. The wood of the tree is hard and durable, of a light chocolate colour, variegated with dark veins, and serves for many purposes. Mr. Correa mentions another, likewise arboreal, species of Aegle, found in the Eaf Indies, and preferred in fr. 1. Banks’s herbarium, but of this he has unfortunately neglected to give either a name or description, nor have we seen any specimens. See Feronia for a genus next akin to the above.

Eff. Ch. Calyx of two valves, filigree-flowered; the valnes cleft, with an intermediate awn. Corolla of two valves; the outer with three awns; inner with two. Seed foliary, unconnected with the glumes. One or two lateral male flowers.

1. Ac. crenbroides. Spreading Aegopogon. Willd. n. 1. Palis de Beauv. as above, f. 3. Kunth n. 1. t. 42. —Clutter lax. Flowers all equally filate.—Gathered by Humboldt and Bonpland, on the exposed summit of mount Avila, near the town of Caracas; also in Quito; flowering from January to April. Root perennial. Stemus numerous, branched at the base, forming a tuft; thofe which do not flower, about as long as the finger; the r&th a fpan in height, naked above, densely leafy below. Leaves linear; the lowermost an inch, or an inch and a half long; the upper ones shorter. Sheaths irated, smooth, flightly membranous at the edges. Sipula divided. Clutter simple, rather turned to one fide, but spreading loosely. This graf has the aspect of Cenchrus ciliaris, or of Lappago racemosa. Willdenow. We know it only from this author’s description, and the figures cited. From M. de Beauvois our knowledge of the following species is entirely derived.

2. Ac. pellistrates. Small Aegopogon. Palis de Beauv. as above, f. 4. —Clutter denfe, turned one way. Perfect flower felle. —Native country not recorded. The perfect flowers of this species, whose clatter is represented about half the fize of the foregoing, are filate, their calyx apparently of two equal, awl-shaped, undivided glumes. The two lateral, or male, flowers are elevated on equal, slender, parallel flanks, twice their own length, though but half as long as the intermediate perfect flower. The inner valve of their calyx feems entire, though awned. Their corolla consists of two entire, not cloven, valnes, one of which only is awned. We do not pretend, without the investigation of specimens, to reconcile the contradictions of the generic character, nor to judge how far M. de Beauvois is right in uniting with this genus Mr. Brown’s Amphipogon, hereafter to be noticed in its proper place.

3. Ac. geminifolias. Twin-flowered Aegopogon. Kunth as above n. 2. t. 43. —Male flower foliary. —Gathered by Humboldt and Bonpland, on the banks of the river Orinoco, between Cerro Duida and Rio Tamatama, near Efmeraldan, flowering in May. Habit much like the firit species, but the spilets are considerably smaller, while the central awn of one valne of the perfect flower is remarkably long, rufus, and rough. Each flower is supported by a short partial stalk, and there are only two to each spilet, not three as in the two foregoing species.

AELUS, in Mechania, subjoin, see VENTILATOR.

AEON, l. 4. add.—Homer ii. v. 455. Pindar Olym. A. v. 18. Hence by an early figure it is used to denote the customs and manners of life. Ep. ii. 2.

AERIDES, in Botany, from aeg. air; because one of the principal plants of this genus has long been celebrated, under the name of Flus aera, for living entirely, as was supposed, upon air. This plant, and several others agreeing with it in habit, though not all perhaps in generic character, have been sent from the Eaf Indies to Europe, in baskets, without earth or any other apparent source of nutriment, and have not only survived, but bloomed during their voyage, as well as after their arrival. Their fluf fibrous roots, always more than half nacked as they run over the branches of trees, having entwinned themselves among the flisks of the bakfet, might perhaps imbibie fuufenance from the air in poke circumstances, as readily as in thofe natural situations; just as a pea will germinate and grow in moist cotton.—Loueri. Cochinch. 525. Swartz in Schrad. Journ. v. 2. 233. t. 2. f. 4. Eijf. Neues Journ. v. 1. 88. Kon. Trafts 195. t. 8 f. Y. Willd. Sp. Pl. v. 4. 130. Ait. Hort. Kew. v. 1. 247. —Clas and order, Gynandra Monogynia. Nat. Ord. Orchideæ.

Gen. Ch. reformed. Cal. Perianth of three equal, spreading, colored leaves, gradually dilated upwards, somewhat wavy, rather obtufe. Cor. Petals two, much like the calyx-leaves in colour, fize, and figure. Nectary a lip without a pur, shorter than the petal, inferted into the base of the fyle, gibbous underneath like a bag, often reverfed over the column. Stam. Anther a vertical, hemifpherical, movable, deciduous lid, of two or four cells; nafes of pollen globular, filate, in pairs. PI. Germin inferior, oblong; fyle erect, semi-cylindrical, concave in front; stigma in front, near the anther. Peric. Capsule obovate-oblong, with three large and three intermediate angles, of one cell and three valnes, separating between the angles. Seeds numerous, minute, each involved with a fuffy tuft.

AERIDES.

The species of this rare oriental genus are not at all distinctly known. Willdenow enumerates seven, to which we have some additions.

1. A. retutum. Blunt-leaved Air-blossom. Swartz n. 1. Wildl. n. 1. (Epidendrum retutum; Linn. Sp. Pl. 1551.) Limodorum retutum; Swartz Nov. Act. Upf. v. 6. 80. Anfili Maravara; Rheede Hort. Malab. v. 12. 1. 1. Raif Hift. v. 3. 588. Orchis abortiva aizoides malabaricensis, flore odoratissimo variegato, intus avicularium repræsentante; Rudb. Elyf. v. 2. 220. f. 5.) — Leaves nearly radical, linear, with two equal terminal notches. Cluster many-flowered, twice the length of the leaves. Capsules obovate. Native of trees in the East Indies, flowering at the beginning and end of the rainy season, that is, in April and October, and lasting long. The plant is three feet high, attached to the bark by thick fleshy downy-coated fibrous roots of a pulpy smell. Leaves spreading in two ranks, linear, stout, rigid, channelled, smooth, abrupt as if bitten off at the end, which feems characteristic of the genus; in this species the two notches are represented in the figure, which is all our authority, as equal and uniform. The flowers are very numerous, about forty, in several falked, terminal clusters, all expanded at once, whitish beprinkled with red, blue and dusky spots. The lip is said to be pure white on both fides, with a tongue-like appendage, brilliant with blue and red. Each flower is less than an inch in diameter.

2. A. prenorum. Jagged-leaved Air-blossom. Wildl. n. 2. ("Bitum Maram Maravara; Rheede Hort. Malab. v. 12. 5. 1. 2." Raif Hift. v. 3. 589. Orchis abortiva aizoides malabaricensis altera, flore odoratissimo variegato, intus avicularium purpureum referente; Rudb. Elyf. v. 2. 221. f. 6.) — Leaves radical, linear, variously and unequally notched at the end. Cluster many-flowered, twice the length of the leaves. Capsules cylindrical. Found on trees and Malabar. Nearly akin to the preceding, the flowers being in like manner spotted with red and blue, and moreover with yellow and green. The column is purple. Rheede says, this species acquires a poisonous property by growing on the Cantrjira, a shrub or tree akin to Daphne; which, if correct, is very remarkable. Perhaps fragments of the bark of that tree, which may well be supposed highly virulent, may have been gathered with the roots of the parasitical plant.

3. A. f3ploratum. Woolly-flowered Air-blossom. Wildl. n. 3. (Epidendrum Fllos aeriis ? Retz. Obf. fæc. 6. 64.) — Stem branched, creeping. Leaves ovate-oblong, each feated on a bulb. Calyx externally woolly, acute as well as the petals. — Found by König, on trees in the East Indies. There is nothing in König's description of the flower to convince us of this being an Aedides, while the account of its acute leaves, (not described as jagged or abrupt,) and their bulbous accompaniment, render it probable that Willdenow has here made a mistake. We retain this species and the next, merely as we find them in his work, for future enquiry.

4. A. matutinum. Morning Air-blossom. Wildl. n. 4. (Epidendrum Flos aeriis, vel Saaronicum; Retz. Obf. fæc. 6. 58.) — This having a spur to the nectary, according to König's description, cannot belong to the genus before us. We therefore decline attempting a specific character, or any necessary correction of Willdenow's.

5. A. odoratum. Fragrant Air-blossom. Wildl. n. 5. Ait. n. 1. (A. odorata; Loureir. n. 1.) — Stem ascending. Leaves linear, marginate, reflexed. Clusters axillary. Lip three-cleft; lateral segments obtuse. — Found on trees in China and Cochinchina, sometimes pendulous. Root of numerous thick fibres, entangled together. Stem nearly erect, a foot high. Leaves large and thick. Clusters simple, long, drooping. Flowers pale, rather flabby, sweet-scented. If this species be hung up in a houfe, it will continue to grow, and to flower for many successefull years; which Loureiro says he had long experienced. Sir Joseph Banks is recorded to have introduced this Aedides into the flowers at Kew, in 1800, but it has never flowered. The late duches of Portland received an air-plant, as it was called, from China or the East Indies, about twenty-five years ago, which we rather believe to have been the Epidendrum effulentum, Roxb. Corom. v. 1. 34. t. 42, Cymbidium n. 34. Wildl. Sp. Pl. v. 4. 102; or at least very near that species. It came in a baleft, without earth, in perfect health, and afterwards bloomed in the flower at Bulstrode; whether it received any different treatment there we have no recollection.

gure Catong; Kempf. Mem. Exot. 1868. t. 169. f. 1.) — Stem ascending. Leaves linear-lanceolate. Calyx-leaves and petals linear, revolute; dilated at the extremity. Lip cloven in front, with an internal cloven appendage. Native of Japan, growing parasitically on trees, and much admired for the pulpy scent of its large handfome flowers. The leaves are said to be narrow, thick, and soft. Flowers from seven to twelve together, in a loose simple cluster. Calyx-leaves and petals all nearly similar, each two inches long, linear; convex above; concave underneath; suddenly dilated at the end into a quadrangular form, all lemon-coloured, beautifully spotted with purple. Nectary much shorter than the petals, somewhat flaked, confining of a hollow abrupt lip, smooth, cloven deeply in front, ending below in a short point, from whose cavity springs an erect, fleshy, divided lobe or appendage. Such is the nectary of the plant figured by Dr. Swartz, of which two specimens are preserved in the Linnaean herbarium; but Kempfer's figure exhibits a very different appearance of the same part, like the injury leaves surrounding the column, in a manner we have never witnessed in any one of the Orchidae. We suspect two species may be confounded by authors.

7. A. coriaceum. Leathery-leaved Air-blossom. Swartz n. 4. tab. 2. f. 4. 5. f. Wildl. n. 7. — "Stem-leaves ovate, pointed, somewhat coriaceous, spiralled. Spikes panicked." — Found on trees in Madagascar. The flower as represented in Dr. Swartz's figure, which is all we know of this plant, is hardly an inch wide; the lip a deep pouch, bearing in front a small deflexed appendage. Column very short.

8. A. Boraffi. Fan-palm Air-blossom. Buchanan MSS. — Leaves radical, linear-oblong, obtuse, obliquely emarginate. Clusters leaflike, radical. Lip with a revolute undivided border. — Found by Dr. Buchanan growing on Borassus flahuliifer, in the Myore. The thick cracked or jointed fibres of the root have each a central tough thread. Stem none. Leaves equitant, about fix, a span long and an inch wide; their points rounded, but unequally, one fide extending further beyond the notch than the other. Clusters simple, scarcely flaked, twice the length of the foliage, deflexed, many-flowered, lax, with a few fheathing seales at the base. Flowers about an inch and a half in diameter. Calyx-leaves ovato-lanceolate, obtuse, somewhat revolute, near an inch long, pale buff with a purplish central stripe. Petals like them, but flat, and rather broader. Nectary half
AERIDES.

as long, red, ringent, its revolute border as long as the pouch.

9. A. maculatum. Spotted-flalked Air-blossom. Buch. MSS.—Stem creeping. Leaves elliptic-oblong, equally emarginate. Flatter lateral, flalked, corymbose. Lip the length of the petals; its border pointed, dilated at each side. Gathered by Dr. Buchanan, on trees in the Myfore country. The stems lend out very long curling fibrous roots. Branches short, leafy. Leaves obtuse, emarginate, hardly two inches long; fleathering at the base. Flower-flalk lateral, opposite to the lowest leaf on the branch, and protruding through its split base, a span long, erect, copiously spotted with dark purple, furnished with a few scattered bracteas, and terminating in a dense corymbose cluster of six or eight yellow unfotted flowers, with a similar cluster to each partial flalk. Calyx-leaves and petals obovate, about half an inch long, nearly uniform. Lip somewhat boat-shaped, with a deep keel, and prominent ascending point, accompanied at each side by a rounded dilatation of the margin. The back of the flower is tinged with greenish or purplish brown.

10. A. dafygon. Denfely-bearded Air-blossom. Stem ascending. Leaves ovate, with a jagged point. Umbels dense. Border of the lip kidney-shaped, dene bearded. Found by Dr. Buchanan, in Upper Nepal. Roots composed of long, white, entangled fibres, running over the molly branches of trees. Stems solitary, short, recurved, leafy. Leaves alternate, fleathering, broadly ovate, about three inches long, flaky; smooth above; minutely scaly beneath; somewhat revolute; with three crowded, unequal, sharp teeth at the point. Flower-flalks lateral, follicary, half the length of the leaves, each bearing a dense umbel of numerous, nearly sessile, very beautiful and fingular, reversed flowers, each hardly an inch in diameter. Calyx-leaves and petals similar, obovate concave; dark red on the upper side; green on the under. Lip keeled, but not very deep, globofe, yellowish, spotted with red; its border as long as the petals, dilated, kidney-shaped, white; dotted on the smooth disk with cirmion; fringed and thickly clothed towards each side with short, fibrous procecces, resembling velvet. Capfall three inches long.

11. A. calcicola. Slipper Air-blossom. Buch. MSS.—Stem creeping. Leaves linear-oblong, falcate, unequally jagged at the point. Umbels spreading. Border of the lip kidney-shaped, densely bearded.—Gathered by Dr. Buchanan on the molly branches of trees, in Upper Nepal. Stem creeping, by means of very long, fimple, fioot fibres, thrown out from within the sheaths of former leaves; its upper part ascending, leafy, three or four inches long. Leaves two-ranked, spreading, ascending, a span long, hardly an inch broad; jagged, with two sharp teeth, at one side of the point only. Umbels opposite to feveral of the lower leaves, foliary, flalked, Iax, each of about five flowers, which are rather smaller than thoje of the lat species, but the pouch of the lip is considerably larger in proportion, prominent, yellow variegated with red, as well as the disk of its border, which lat is dene bearded with white fibres like the foregoing. Calyx-leaves and petals uniform, obovate, incurved, yellow spotted with red.

12. A. rigidum. Rigid Air-blossom. Buch. MSS.—Stem creeping. Leaves oblong, obtuse, rounded, unequally at the point, four times as long as the corymbose clusters. Lip with an obovate smooth border, the fize and shape of the petals.—Found by Dr. Buchanan, running over rocks and large fones in Upper Nepal. The stems is woody, a yard long, and as thick as the finger, creeping among mosses, and sending out here and there, through the bafes of the leaves, very thick radicles. Leaves two-ranked, alternate, a foot long, extremely thick and coriaceous, three-ribbed, oblique at the termination, one side being greatly extended, in a round lobe, beyond the rib, the other flopening below it. The lower part of each leaf has a joint, where it finally separates, leaving the fleathering permanent bate, or foottalk, as in A. Boraffi, maculatum, and others of this genus and natural order. Flower-flalks opposite to the leaves, solitary, alternate, about three inches long, diffantly racemofe in the lower part, corymbose at the summit, each bearing from five to ten nearly or quite finside flowers, yellow spotted with red, about the size of the lat. Calyx-leaves and petals obovate, uniform, erect. Lip agreeing with them in colour and shape, except the small prominent pouch at its base, and the apex being a little reflexed.

13. A. undulatum. Wavy-flowered Air-blossom. (Epidendrum premorium; Roxb. Corom. v. 1. 34. t. 43. Cymbidium premorium; Swartz Nov. Ad. Upf. v. 6. 75. Schrad. Neues Journ. v. 1. 75. Willid. Sp. Pl. v. 4. 103. Thalia Maravara; Rhede Hort. Malab. v. 12. 6. t. 14. Raii Hilf. v. 5. 590. Orchis abortiva, floreus lutes minoribus, radiis rubris; Rudb. Elyf. v. 222. f. 8.)—Stem ascending. Leaves linear, channelled, acute, abruptly pointed, three as long as the corymbose cipples. Lip with an obovate flat border, the size and shape of the petals. Native of trunks and branches of trees, in the hilly parts of Malabar and Coromandel, flowering in October. The roots conifl of numerous long, fioot fibres. Stem ascending, leafy, four or five inches high. Leaves two-ranked, alternate, recurved, coriaceous, six inches long and one broad, concave, ending in a femicircular notch, whose two extremities are pointed, and nearly equ. Inflorescence like the laft. Flowers rather fmalier, fragrant. Calyx-leaves and petals obovate, equal, slightly wavy at the edges, yellow, marked with transverse, cirmion, undulating lines. Lip the size and shape of the petals, white dotted with red, its pouch but slightly indicated in parts of Dr. Roxburgh's figure, and probably of little obvious in nature, as to have efily escaped the artist's notice. Notwithstanding this apparent exception to the generic character, the present plant, improperly confounded by Linnaeus with his Epidendrum furvum, is so strikingly allied to the laft, and consequently to the two immediately preceding, that we must presume it to be an Aerides. If, on examination, it should prove to want the pouch, a fresh investigation must be instituted, reëxamining the distinguishing characters of this genus and Cymbidium.

The habit of Aerides is peculiar, though not perhaps exclusively fo, in the termination of its leaves, always more or less abrupt, unequal, or jagged. We have never seen a living specimen of any of the genus, but Dr. Buchanan's fine and scientific coloured figures, drawn from nature under his own inspection, are as precise and satisfactory as possible, and that excellent botanist has himself pointed out to us the characters and habit of Aerides, as a natural genus.

With regard to the name, it well expresses the quality of living upon air alone, for which several species have attracted notice. Linnaeus, who included the whole, with various other things, in his genus of Epidendrum, (see that article,) particularly applied the specific name of Flos aetis to our fifth species, citing with a query in Ab. Upf. the 2d chapter verfe 7th of the Wisdom of Solomon. This, in the English translation, is, "Let no flower of the spring pas by us." In a Latin version before us this text is rendered "ut pretereat nos juvendus aetis." Whence this ambiguity arose, or whether Linnaeus had any where read flos veris, which he confounded with flos aetis, we have not materials to determine. At any rate, the text in question has evidently
no reference to this, or to any other particular plant whatever.

AESTIVATIO, in Botany and Vegetable Physiology, a term used by Linnaeus for the mode in which the petals, or the segments of a corolla, are arranged with respect to each other, particularly before they expand. (See COROLLA.)

The word comes from æstus, summer, and æfurus, summer-quarters,summer being the usual flowering season, and the corolla the shelter or accompaniment of the organs of fecundation. So Vernaio expresses the arrangement of the leaves of plants in the bud, or, in other words, their vernal condition. Afflavitio imbricata, expresses the divisions of the corolla being imbricated, or folded over each other, either from left to right, that is, with the motion of the fun, as in Clitius; or the reverse, of which latter Linnaeus has in his manuscripts mentioned Pbytis as one example, and we would point out Hypericum as another. Afflavitio valvata is when the divisions of the corolla meet in the bud like valves, slide by slide, as in Protea and its allies. Of this Periploca is an instance, notwithstanding the obliquity observable in the segments of that flower after expansion. Linnaeus, in the MSS. above cited, speaks of Paenias as having, like its near relation Adenium, one petal exterior to all the rest, though the corolla is what would be termed regular in the first genus, and very irregular in the second. Such a diversity indeed is of small moment, for Mr. Correa has observed that every natural order, as far as he could examine, possesses irregular and regular flowers. In general the direction of the parts of a corolla, as to their activation (if we may use that word), are invariably alike in genera of the same natural order. But Hermannia, (fee that article,) affords a remarkable exception, every one of its species that we have seen bearing two flowers on the same stalk, has the petals of one of those flowers rolled to the right, while those of the other are disposed in a contrary position. Mr. Brown, in his learned Prodromus of New Holland plants, has paid more attention to the activation, in defining his natural orders, than any other botanist, and the term effractio valvata is, if we mistake not, his own invention.

ÆT, l. 4, infer after Brussels. It is the chief place of a canton, in the department of Jemmappe, and district of Tournay. The place contains 7634, and the canton 14,828 inhabitants. The territory includes 115 kilometres, and 11 communes. See Ath.

ÆThIONEMa, in Botany, so named by Mr. Brown, apparently in allusion to some tawny or fun-burnt tinge in the flaments, from æth, to burn, and μαξα, a flame. We perceive in our dried specimens an occasional purple hue in these parts. It may perhaps be more remarkable in the species we have not seen.—Brown in Ait. Hort. Kew. v. 4. 80.—Cliffs and order, Tetradynamia Siliculae. Nat. Ord. Silicul, Linn. Crucifere, Jaff.

Eff. Ch. Pouch with boat-like winged valves (sometimes much burfting.) Longer flaments either combined, or finely toothed towards the top. Infection of the calyx unequal.

Brown.

(Thalpi faxatila; Linn. Sp. Pl. 901. "Schluher Handb. v. 2. 223, l. 180." See Thalaspi, u. 6.)—Longer filaments distinct. Leaves oblong, tapering at the base.—Native of the South of Europe. Cultivated by Miller in 1759.

2. Ac. monspurum. One-seeded Aethionema. Ait. n. 2.—"Pouch single-seeded, without valves. Leaves oval or obovate."—Native of Spain. Cultivated in 1778, by Lee and Kennedy, at Hammerfmith. A hardy biennial, flowering in July and August. We have seen no specimen of this species. Our doubts respecting the genus may be found under Thalaspi.

ÆFER, DOMITIUS, col. 2, l. 11, for vanity r. variety.

AFFINITY, in Chemistry. The celebrated doctrine of Bergman is the last in order discussed under the article AFFINITY in the Cyclopaedia: since that time, however, very important changes in opinion have taken place, among chemists, respecting the nature and cause of chemical affinity. Some of these are mentioned in subsequent parts of the Cyclopaedia, especially in the articles Chemical Proportions, Simple Bodies, and Atomic Theory; but it may not be deemed superfluous to give a summary and connected view of the whole in this place.

Bergman's doctrine of elective affinity, so amply explained in the article above referred to, was universally admitted among chemists till 1803, when Berthollet published his Dissertation on Affinity in the Memoirs of the Institute, and about the same time his Chemical Statics. Berthollet considered affinity as an attraction existing between combining bodies. This attraction he appeared to consider as familiar in its nature to that which exists between the planets, or in short, the principle of gravitation. It consequently, in his opinion, increased with the mass of bodies. According to this doctrine, therefore, bodies which have an affinity or attraction for one another, have a tendency always to combine, in a greater or less degree, chiefly in proportion to their mafs. Thus, though barytes appears to possess a stronger affinity for sulphuric acid than potash, yet if we present a great quantity of potash to a small quantity of sulphate of barytes, the potash will separate a portion of the acid.

According to Berthollet, therefore, affinity is not cleis- tresse. A substance which has a stronger affinity is not capable of separating entirely those which have a weaker, unless some other cause than mere strength of affinity operates.

Instead of separating entirely the weaker body, it divides with it the base to which that body was united, each combining with a part of such base in the compound proportion of the strength of its affinity and of its quantity.

But no facts in chemistry are better established than those in which the addition of a third body frequently separates two substances previously united, the third body taking the place of one of the constituents, which is thereby separated altogether. Thus, if sulphuric acid be dropped into a solution of nitrate of barytes, or potash into a solution of nitrate of lime, the sulphate of barytes and the lime will precipitate, leaving, in the first instance, the nitric acid in a free state, and in the second, the potash combined with the nitric acid instead of the lime. These and many other well-known facts appearing, at first sight, contrary to Berthollet's doctrine, it was necessary for him to reconcile them to it. For this purpose, he called in the aid of the different modes of existence of bodies. According to him, therefore, whenever decomposition takes place, it is owing either to the insolubility or the clafficity of the ingredient which separates, Sulphate of barytes being insoluble in water, while nitrate of barytes and nitric acid are soluble in that liquid, it must happen,
AFFINITY.

 happen, when the substances are mixed, that the insoluble salt precipitates, on account of its insolubility. It is the insolubility of lime that causes it to precipitate when potash is dropped into nitrate of lime. Accordingly, when potash is dropped into nitrate of soda, no precipitation whatever takes place, because both the potash and the soda are very soluble in water; but if we concentrate the solution sufficiently by evaporation, crystals of nitrate of potash will be deposited, because that salt is much less soluble in water than nitrate of soda. So also, when nitric acid is poured upon carbonate of lime, the carbonic acid is disengaged, and flies off, because its elasticity induces it to separate from the soda, and to assume the gaseous state as soon as the nitric acid weakens the attraction, by means of which it was attached to the lime.

"Thus," says Dr. Thomson, to whom we have been particularly indebted in the compilation of the present article, "we have two doctrines respecting affinity opposite to each other. According to Bergman, affinity is élective. The body which has the stronger affinity displaces that which has a weaker, and the strength of affinity may be measured by decomposition. According to Berthollet, affinity is not élective. It never produces decompositions, but only combinations, and the decompositions which take place are owing to the agency of other causes. The strength of affinity is not an absolute quantity, but increases with the mafs of the attracting body. Bergman's doctrines lead to the opinion, that bodies are capable of uniting together indefinitely in any proportion whatever; Bergman's, that they unite only in determinate proportions, and that these proportions are independent of the relative quantities of the combining substances which are present." See Atomic Theory.

A most important fact respecting the combination of bodies was ascertained by Richter. This was illustrated in an elaborate work, published at different times between 1792 and 1802, which contains the result of his researches on the decompositions and combinations of chemical bodies. He observed, that when two neutral salts, which mutually decompose each other, are mixed together, the two newly formed salts still retain the same neutral state as the two original ones, from which they were formed. He likewise observed, that the same proportions of bases that saturate a given weight of one acid, saturate all the other acids; and the same proportion of acids that saturate one base, saturate all the other bases; which law enabled him to explain why two neutral salts form, as above-mentioned, two new salts, likewise neutral. These experiments and observations of Richter likewise enabled Fillcher to attach a set of numbers to the acids and bases, indicating the weight of each which will saturate the numbers attached to all the other acids and bases.

Mr. Dalton, without being aware of the law already discovered by Richter, turned his attention to the subject about two years afterwards, and was struck with the small number of proportions in which simple substances are capable of combing, and the confinity of these proportions. This led him to form the doctrine of definite proportions, or atoms, as it is usually termed, and which, as well as Gay Lussac's modification of it, our readers will find fully explained in the article Definite Proportions.

About the same period, that is, in the year 1803, the grand law respecting the agency of the galvanic battery in the decomposition of bodies was discovered by Berzelius and Hüngler. This law is, that oxygen and acids are accumulated round the positive pole; while hydrogen, alkales, carbonates, and metals, are accumulated round the negative pole. From this general law Berzelius deduced the confluence, that the decompositions in such instances were owing to the attractions existing between the bodies and the respective electivities. This opinion was afterwards extended by Davy, and the opinion in its extended form subsequently adopted by Berzelius himself. According to these celebrated chemists, chemical affinity is identical with electrical attraction, and bodies which unite chemically posses different kinds of electrical attractions. Every body, in their opinion, posses a permanent electivity state, either refrinous or vitreous. Two bodies in the same state of electricity have no affinity for each other. Those in opposite states have an affinity, and the strength of the affinity is proportional to the degree of intensity of the different electivities in the two bodies; and in order to make bodies separate from each other, we have only to bring them into the same electrical state, by making them both vitreous or both refrinous. See Electricity and Galvanism.

Such is a summary account of the revolutions in opinion which have taken place respecting the nature of chemical affinity, and the principal discoveries which have given origin to these changes since the time of Bergman. We shall conclude this article with a few general remarks upon the subject.

In the first place, the question whether the affinities of substances for one another be definite quantities capable of being represented by numbers, cannot, in the present state of chemical science, be satisfactorily determined. For though some substances always appear capable of separating others, as, for example, barytes, potash; yet the reason may be, that the salts of barytes are less soluble than the salts of potash. Again, iron, as is well known, separates oxygen from water in all temperatures; but, on the other hand, it has been equally well ascertained, that the oxied of iron is reduced when heated in hydrogen gas: "hence," says Dr. Thomson, "we have no data for determining whether iron or hydrogen have the greatest affinity for oxygen; each seeming capable of depriving the other of oxygen in the very same circumstances."

In certain cases, also, of double decompositions, it is often equally difficult to distinguish on which side the strongest affinities lie. Thus, as is well known, carbonate of barytes and sulphate of potash, when digested together, decompose each other, and are converted into sulphate of barytes and carbonate of potash; but on the other hand, it has been equally satisfactorily shewn by Mr. Philips, that carbonate of potash is capable of decomposing the sulphate of barytes.

Pfaff, however, has shewn, that the tartrate of lime and the oxalate of lead are completely decomposed by the addition of no more sulphuric acid than is necessary to form sulphate of lime and sulphate of lead; and hence he infers, that the affinity of sulphuric acid for lime and lead is actually superior to the affinities of tartaric and oxalic acids for the same bases respectively.

Berthollet has attempted to account for the first of the above experiments by the effect of mafs; and the experiments of Pfaff he endeavours to explain by the solubility of tartrate of lime and oxalate of lead, and the insolubility of the sulphate of lime and sulphate of lead in acids. And this brings us to the second place, to make a few remarks upon the supposed effects of mafs, and the modes of existence of bodies in modifying chemical decompositions. With respect to
to the effects of mafs, though at first sight there appear to be some circumstances favouring the opinions of Berthollet respecting its influence in chemical operations, yet we can by no means agree in supposing its influence so great as represented by that eminent chemist. No quantity of water, for example, would decompose sulphate of magnesia, though the affinity of sulphuric acid for water is very great, and though the infoluble nature of magnesia would, according to Berthollet’s views, favour the union of the water with the acid. Mafs here, therefore, either does not operate at all, or very feebly; and there are numerous analogous influences, well known to every chemist, to which the same remarks are equally applicable.

Again, it has been sufficiently established, that gases unite with reference to their volume, and cannot be made to unite in intermediate proportions, even although the reful of their union be likewise a gas. Thus, for example, one volume of chlorine gas and one volume of hydrogen gas unite together, and form, without any condensation, or other apparent physical change, two volumes of muriatic acid gas, nor can they be made to unite in any other proportions. Here then is an example of chemical union, in which the effects of mafs and mode of existence are quite out of the question.

From these, and particularly from many recently establiblished facts, we think it proved beyond a doubt, that the power which determines bodies to combine in certain proportions is a property inherent in the original cause of their union, and consequently is a power totally different from that exerted by mafs or other external circumstance, though it is not perhaps altogether independent of their influence. For further information, we refer our readers to sir Humphry Davy’s Elements of Chemical Philosophy, where, besides an excellent account of the subject in general, they will find a masterly refutation of Berthollet’s doctrines.

AFORELIA, l. 2, for fern r. item 1. 4, ditto.

AFZELIA, in Botany. (see that article,) is Gerardinia cappioides. Pursh 424. (G. Afzealia ; Michaux Boreal.-Am. v. 2. 20. Anomynous cappioides ; Walt. Carolin. 171.)

AFZELIA, Sm. Tr. of Linn. Soc. v. 4. 221, fo named in honour of its discoverer, Adam Afzelius, M.D. Director of Botany at Upsal, author of several disquisitions on Swedish Rofes, and of other learned botanical treatises, is a very noble genus, of which we have long expected from Dr. Afzelius himself an illustration of the species. They are all natives of Sierra Leone.—Clafs and order, Decandria Monogynia. Nat. Ord. Lomentatae, Linn. Leguminosae, Jaff.

Eff. Ch. Calyx tubular; limb in four deciduous segments. Petals four, with claws; the uppermost very large. Two upper flaments imperfect. Legume with many cells. Seeds with a tunic at the base.

This genus consists of trees with large, smooth, abruptly pinnate, alternate leaves. The flowers are racemose, crimson, with small bracteas. Legumes woody and ponderous, smooth, ovate, acute. Seeds near an inch long, parallel, ova, black, the lower half of each invested with a feathly tunic, of a brillant permanent scarlet, and a rather waxy appearance. The native Africans remove this tunic, and use the seeds for beads.

1. A. odorata. Fragrant Agastachya. Br. n. 1.—Found in the southern part of Van Diemen’s island, near Adventure bay, by Mr. David Nelson, and afterwards by Mr. George Caley. A shrub, perfectly smooth in every part. Leaves scattered, entire, flat. Spikes numerous, simple, terminal, as well as axillary from the upper leaves. Flowers alternate, effile, with a solitary, hooded, permanent bractea to each. Corolla yellowish, deciduous. Pijil shorter than the flaments. The fruit has not yet been examined. Brown.

AGATE, col. 2, l. 15. They are conveyed from Germany in blocks; and cut by means of diamond powder into leaves for making caps for the pivots of mariners’ needles, and other purposes.

AGATHARCHUS, in Biography, a painter of the isle of Samos, who is said to have been instructed by Alciphylus in the art of introducing perspective into the decorations of theatres, and to have been the first who wrote on this subject, and communicated the art to Democritus and Anaxagoras.

AGDESTIS, in Botany, a fanciful name, adopted by De Candolle, from the authors of an unpublished Mexican Flora, whom he cites as Moç, and Seifé. It is applied to a doubtful genus, related to Menisperum, and perhaps a sort of lulus natura, having flaments and pistils in the same flower, which is almost unexamined in this tribe. The above denomination is that of a fabulous monster, said to have been male as well as female, and produced by Jupiter from the flower Agdo. This genus therefore being not clearly understood, and as yet very little known, may hereafter be abolished as well as its name.—Clafs and order, Polyandria Monogynia. Nat. Ord. Sarmentace, Linn. Menisperma, Jaff. Menisperm., De Cand.

1. A. clartisea. Bowery Agdestis.—Native of New Spain. A smooth shrub, with a branched, twining, round, fratted item. Leaves alternate, dilatant, dilated, exactly heart-shaped, entire, pointed; their lobes very obtuse. Flowers reddish, corybofe, axillary and terminal; their flanks three-cleft. Fruit unknown. This plant appears very nearly akin to Clematis.

AGGREGATE, the title of the 48th order in Linnaeus’ fragments of a natural syslem, placed between the Stellate and Compositae. (See Aggregate.) This is a very miscellaneous and ill-defined order, of which it is by no means easy to seize the idea, much less to give any definition, or distinctive charater. Vaillant first laid the foundation of this order, in the Memoires de l’Acad. des Sciences for 1722. “The natural order of Aggregate,” says Linnaeus, Proef. in Ord. Nat. 528, “was first investigated by Vaillant, in the Mem. de l’Acad. des Sciences. They agree with the Compositae in having generally a common calyx as well as receptacle, collecting together many effile florets, each of which has always an inferior germin. But there is a total difference with respect to the remaining parts of fructification, nor can these two orders be, by any means, united. The calyx, as above said, is common to many flowers,
flowers, or florets. The common receptacle is either naked, villous, hairy, or scaly. In the place of a partial calyx is the corolla, generally monopetalous, either regular or irregular, four- or five-cleft, rarely polypetalous. Stamens four, with separate anthers. Germin inferior (with respect to each floret). Fruit single-seeded. The flower is therefore complete in this tribe, except only Valeriana, whose calyx is fearfully apparent. The leaves are often opposite. Stem often fleshy.

The genera which compose this order at the end of Gen. Pl. are: Sect. 2. Statice only. 8. Hartogia, Brunia, Protea, Globaria, Leucadendron, Hebe, Cephalaria, Selago, Cephalanthus, Disfaca, Scabiosa, Knautia, Allionia. But in his own copy Linnaeus has drawn a line between Selago and Cephalanthus, removing the β to that place, and characterizing his section as "alternifolia inferne," the remainder of the whole order beginning with Cephalanthus, being "oppositifolia superius." 7. Valeriana, Morina, Boeravania, Circaea, to which Mirabilis is added in MSS. 8. Lonicera, Cinchona, Trifolium, Mitchellia, Linnaea, Morinda, Conopurus, Loranthus, Vitex, to which Lysanthus and Hillia are added, certainly with no propriety.

This order in fact is not one of our great botanist's most finished or happy performances. It comprehends Julliff's Disfaca, Proteaceae, Caprifoliaceae, with various foliate genera from different orders. Notice was always a drubbling block with Linnaeus, nor does it assimilate with any thing among the Aggregate, being itself, however natural a genus, and as we think improperly subdivided by Tournefort and others, composed of species whose inflorescence is essentially different among themselves.

In his manuscripts Linnaeus has extended his first section as far as Selago inclusive, erasing Hartogia, and giving the characters of alternate leaves, and a superior germon to this section. To the second section, which begins with Cephalanthus, he attributes opposite leaves, and an inferior germon. He thought Statice akin to Brunia, and Protea the same genus as Leucadendron. To his third section he more happily adds Mirabilis; but to the fourth he very unfortunately introduces Lysanthus and Hillia.

The intelligent botanist will without difficulty trace the numerous errors of the above arrangement to various causes. Several natural orders, now well defined, had not entered into the conception of Linnaeus, such as the very natural and distinct one of Proteaceae; and of the Caprifoliaceae, flighted in his fourth section, he had evidently an obtuse perception. Of the differences of the Proteaceae genera he had scarcely any knowledge. That he should not have formed a right idea of Hebe, Selago, and Leucadendron, whose affinities are still in some uncertainty, is not wonderful; but they are unquestionably much out of place here. See Disfaca for further observations respecting some of the Aggregate.

AGLABITES, 1, 53, add, and governor in Africa, Heg., 184, A.D. 800. This dynasty lasted till the year of the Hegira 296, A.D. 908, and possessed the country which extended from Egypt to Tunis.

Eff. Ch. Calyx inferior, five-toothed. Petals five, converging in the form of a globe. Berry with one seed.

1. A. odorata. Fragrant Aglais. City ngdu of the Cochinchinae. (Cannenium finefue; Rumph. Ambin. v. 5. 281. t. 13. f. 1.) — Native of Cochinchina and China. Commonly cultivated in the latter country, for the sake of its great beauty and agreeable scent. Rumphius says it was imported from thence to Amboyna, where it still retained the Chinese name of Tsjikang, and was continually in leaf and bloom; being easily propagated by cuttings of the larger branches, whose bark must be bruised slightly, and then covered for the space of a month with good earth and dung, till roots are thrown out, which are then to be cut off and transplanted. Loureir describes this plant, as a tree eight feet high, with a yellowish hard wood, thin brown bark, and spreading branches forming a very dense head. Leaves pinate with an odd one, consisting of three or five oval, entire, smooth, shining leaflets, tapering at the base, on short footstalks. Clusters axillary, oblong. Flowers yellow, very minute, globose, odoriferous. Berry small, red.

Rumphius describes the flowers orange-coloured, never producing fruit in Amboyna. We cannot find that this plant of Rumphius is taken up by any author, nor is his description sufficient to procure it a place in any systematic work. Loureir, however, has furnished us with sufficient characters to enable us to judge of its natural order, and to determine that it is not, as he suspected, the same genus with Thunberg's Bombula.

AGRIFFYLLUM, in Botany, so called by Juffiff, from οὐδεμία, the bally, and φόδον, a leaf; because its flattened prickly leaves resemble that shrub. Juff. Gen. 190. See Berchexia hereafter.

AGUARI, LUCETIA. See Flber in Son.

AGUILLAS, CAPE, Del Cape Needles.

AGUILAS BANK, a bank on the southern coast of Africa, stretching from Cape Point across the entrance of False Bay to the mouth of Rio Infanta, or Great Fish River, and to the 37th parallel of Southern latitude. Mr. Barrow conjectures that this bank at one time formed a part of the continent.

AHM, in Commerce. See Stuegen.

AHMEDABAD. For Agmed's r. Ahmed's; 1. 6, r. Sebermadd.

AHMEDNAGUR, l. 2, r. Dowlatbad.

AHOUAS. Add.—This was once a large and flourishing city, the capital of a province of the same name, and the winter residence of Artabanes, the laft of the Parthian kings; but it is now a wretched town, containing 600 or 700 inhabitants, and situated on the banks of the river Karoon; 48 miles S. of Shafter.

AIDAN, col. 2, 1. 18, for bishop r. king.

AIDERBEITZAN. At the close add.—It is separated from Armenia by the river Araxes, and from Irak by the Kizilozoin, or Golden stream. This province, including Erivan with the Karabag and Karadag, is divided into twelve districts, viz. Uremea, Ardebil, Tabrez, Maraga Khoe, Kulkham, Serab, Gamoon, Sa Bulagh, Karadag, Erivan, Nuckhivan, and Misken, yielding a revenue of 89,957 tonauns. The most picturesque, and at the same time most flourishing...
flourishing division of Aijerbeirjan, or Azerbijan, lies along the N. and W. borders of the lake Urumea from Tabrez to the confines of Armenia, in which direction are the towns of E. Shebultar, Tafoun (in ruins), Selmaft, Khoe, and Urumea.

AIDIA, in Botany, a genus of Loureiro's, unknown to us but from his description, whose name, from adia, eternal, alludes to the indestructible nature of the wood.—Loureiro. Cochinch. 142.—Clafs and order, Pentandria Monogynia. Nat. Ord. Caprifolia, Juff. Gen. Ch. Cal. Perianth superior, tubular, five-toothed, erect. Cor. of one petal, falver-shaped; mouth of the tube woolly; limb in five deep lanceolate segments. Stam. Filaments none; anthers five, linear, inserted into the corolla between its segments. Pfl. Germen ovate, inferior; style on a level with the anthers; stigma ovate-oblong. Peric. Berry ovate, "calycine," (meaning crowned by, and con- fluent with, the calyx), small, umbilicated, of one cell. Seed solitary, ovate.

1. A. cochinchinesis. Everlasting-wood. Cdt Thai of the Cochinchinese.—Native of Cochinchina. A large tree, with spreading branches. Leaves opposite, lanceolate, entire, smooth. Flowers white, in short, lax, axillary clusters. The wood is white, heavy, composed of thick fibres, and not handsome. Its chief use is for building the lower parts of houfes, and foundations of bridges, being extremely durable, other under ground or in water. Loureiro.

AIMONTE. Add. See AYEMONTE.

AINSWORTH, Robert, l. 2, for Woodyale r. Woodyate.

AIR, col. ii, l. 44, inferi elastic, and r. whatever elastic matter, &c.

AIR, Atmospheric, in Chemistry. The most recent experiments shew that atmospheric air is composed by bulk of about 21 per cent. of oxygen and 79 per cent. of azote; and this coincides so nearly with four volumes of azote and one of oxygen, that Dr. Prout has been induced to confide this proportion as the true composition of atmospheric air, and consequently that it is a real chemical compound composed of one atom oxygen and two of azote. Upon this supposition, and the supposition that the atom of oxygen be 10 and the atom of azote be 17.5, atmospheric air will be composed by weight of

Oxygen 22.22
Azote 77.77

And the specific gravity of oxygen gas will be 1.1111 and of azote 0.7222, atmospheric air being 1.000. See Atomic Theory, Addenda.

The reasons upon which the above opinion is chiefly founded are, in the first place, the impossibility of accounting on any other than chemical principles for the remarkable uniformity observed in the composition of atmospheric air all over the world. This faet is universally admitted, and no one can adduce even the slightest argument why this uniformity should be explained on principles different from those which govern other definite compounds, as, for example, water.

Secondly, experiment coincides extremely near with the above supposition, perhaps as nearly as it has ever done in any familiar example, even in those on which the doctrine of volumes itself was founded by M. Gay Lussac. Those verified in eudiometry, and who know the imperfections of all eudiometrical methods hitherto advanced, will feel little inclined to vouch for the perfect accuracy of their results, and to deny the possibility of an error of one per cent. Besides, when we reflect how liable the atmosphere is to contaminations of every kind, the chance of such an error is still further increased.

About the same time (November 1815) that the above opinion was advanced by Dr. Prout, a similar opinion was published by Dobereiner, in a paper inserted in Schweig- ger's Journal. Thomson's Annals of Philosophy, vol. vi. p. 321.

AIR, in Music, l. 5, for rhyme r. rhythm. AIR-Lamps, col. 2, l. 4, for driven r. drive it.

AIR-Pump, Laws of Rarefaction, &c., col. 4, l. 11 from the bottom, add—Some of the experiments above recited, as having been made in vacum, would only succed in a very imperfect state of exhaustion, as is evinced from other experiments detailed in the sequel of the article.

AIR, in Geography, a township of Pennsylvania, in the county of Bedford, containing 1179 inhabitants.

AIRY. See AERY.

AITZEMA, l. 2, r. Dookum.

AKISKA, in Geography, one of the Turkish pachalics of Armenia, which lies near the limits of the Turkish empire, and has the Black sea to the W., Immeritia to the N., Kars and Erzeroum to the S., and Georgia to the E. It extends a considerable way along the banks of the Kur, and contains much arable land, with many cities and villages, and minerals in its mountainous parts. Akalzike (new Castle) or Akiska, which gives name to the province, is the capital: it is a populous and commercial city, without walls or fortifications, and only defended by a ruined citadel, standing in an open valley on the left bank of the kur, and inhabited by Jews, Turks, Greeks, Armenians, and Georgians.

ALA, in Botany, l. 4, for upwards r. downwards.

Gen. Ch. Cal. Perianth superior, of one leaf, short, permanent, with from fix to ten small crenet teeth. Cor. Petals from six to ten, linear, undivided, much longer than the calyx into which they are inserted, spirall in the bud, afterwards recurved. Nectary cup-shaped. Stam. Filaments ten or twelve, inserted into the calyx, crenet, thread-shaped, hairy below, scarcely half the length of the petals; anthers terminal, vertical, linear, obtuse, rather broader and longer than the stamens, bculating at each side longitudinally. Pfl. Germen turbinate, inferior; style cylindrical, crenet, rather longer than the stamens; stigma capitate, lobed, very large. Peric. Berry globular, with a rather conicous coat, crowned with the calyx, internally fleshy, of one cell. Seeds from one to three, nearly lenticular.

Eff. Ch. Calyx superior, with from fix to ten teeth. Petals from six to ten. Berry coated, of one cell, with few seeds.

Obi. We do not scruple to remove this genus from the clafs Polyantria, where Willdenow has placed it, but with which the insertion of the stamens does not agree, to Isefantria, where it ranges with its natural allies. Lemnisca (fix
LAMARCK, n. 1. Wildl. n. 1. Vahl. Symb. v. 2. 61. (Grewia falvifolia; Linn. Suppl. 499. Angiolam; Rheede Hort. Malab. v. 4. 39. t. 17. Arbor indica baccifer, frutico umbilicato rotundo, cerafi magnifìdico; R. Hill. v. 2. 1497.)—Flowers with ten petals. Branches becoming fpinous.—Native of the East Indies. Kernig fent pcncimens to Linneus, and in the year 1779 he also communicated feeds from Ceylon to Kew garden; but their progeny has not yet flowered, if it be fully alive. Rheede describes this as a handfome tree, an hundred feet high, and twelve in circumference, with fpreading branches, white hard wood, and a bitterih, acid, aromatic bark. The root is fungous, reddish, fragrant and bitter, with a yellowih bark. The branches bear leaves and flowers together, and finally assume a sharp fpinous terminatìon. Leaves alternate, on short downy flacks, ovate-oblong, obtufe, entire, ribbed, veiny, four or five inches long, pliant, fragrant; smooth and fhining above; paler, reticulated, and roughifh, beneath. Flowers axillariy, either solitary, or two or three together, on fimple, short, downy flacks. Calyx downy. Petals rather filthy externally; white within. Anthers bright red. Fruit the fize of a large cherry; downy when young; purplifh when ripe, full of sweet fragrant pulp, which is efteemed very delicious, and contains one, two, or three black feds. The inhabitants of Malabar compare the fflowers to an imfperial diadem, and therefore confider this tree as an emblem of royalty. The efpreffed juice of the root is purgative, and used for expelling inteffinal worms. Its powder is thought an antidote for the bites of ferpents, and other venomous animals.

2. A. kugii. Broad-leaved Alangium. Lamarck n. 2. Wildl. n. 2. Vahl. Symb. v. 2. 62. (Kara Angiolam; Rheede Hort. Malab. v. 4. 55. t. 26. Arbor indica prunifera, frutico umbilicato corticofio perfici fimili; R. Hill. v. 2. 1453.)—Flowers with six petals. Branches not fpinous.—Native of the coast of Malabar, in fply, sandy, mountainous places, always in flower and leaf. Its trunk is of lofty fhape, but inferior to the former. Leaves broader, more ovoate, and pointed, smooth, bitter and acid, but not aromatic; paler beneath. Flowers smaller, whifh, nearly fefile, with only six petals. Fruct globosus, the fize of a small apple, having a thick, downy, purple coat, and vifcid acid pulp.

3. A. repens. Downy Alangium. Lamarck n. 3. a. Branches fcarce fpinous. Leaves oblong, blufhing; their ribs downy beneath, like the footflacks. b. Polypodium. Allied to the firit species in the form of its leaves, and to the fcond in the nature of its fruit. The flowers are unknown. The young flouts, flacks, calyx, and ribs of the leaves, are clothed with fhort cottony down. Lamarrk.

AL-RARAF, l. 5, for Alcoran r. Koran.

ALASAN, in Geography, the Annan of Strabo, a river of Georgia, which separates this province from Shivan, and taking its rise near that of the Arapi, not far from the gates of Caucasus, pursues a S.E. course, until it meets the Kur or Cyrus at Doublizil. About 30 miles above this place it is joined by the Kabri or Yari, which fertilizes the greateft part of the province of Kaket.

ALBA LONGA, l. 8, for furrowed r. farrowed.

ALBANIA, col. 2, l. 5, add—Mr. Hobhouse rates the population of Albania at about 1,200,000 souls.

ALBANS, St., a township of America, l. 3, for 256 r. 1660.

ALBANY. Add after Saratoga.—It is now reftricted to an area of 462 square miles, or 295,689 acres. By the census in 1810, its population confifed of 34,661 fouls, its fentinorial electors were 2971, and the number of fhares was 772.

ALBANY, i. 4. This city and suburbs in 1812 contained about 12,000 inhabitants, 1800 houses and flores, 10 hours for public worship, and feveral public buildings.

ALBEMARLE, a county of America, &c. contained, in 1810, 18,268 inhabitants, of whom 9226 were fhares.

ALBERT's or Current Dollar, with $ and ½ ditto, Dutch filver coins valued at 50, 25, and 12½ fivers, each about 1 per cent. agio. Albert's dollar is also ufed as a money of account at Riga. See DIX-DOLLAR.

ALBUMEN, in Chemicfry. Considerable additions have been made to our knowledge refpeéting this important animal principle fince the firft volume of the Cyclopaedia was publifhed. These we fhall briefly notice here.

The firft thing deferving to be mentioned is the diftinction between coagulation, gelatinization, and precipitation, terms which had been always confounded till Dr. Botfock defined their difference. By coagulation is now underftood the paffing of a fubfance from a fluid to a folid flate by the agency of heat only, or, in fome inftances, without the immediate co-operation of any external agent; as, for example, in the coagulation of the fibrin of the blood. Gelatinization is the property which a warm folution of jelly prifcles of becoming concrete as it cools. Precipitation is the eflect which different fubftances or re-agents produce by combining and forming folid compounds with the principles operated upon.

The next circumftances deferving of notice are the effects of galvanifm upon albumen, as aflerted by Mr. Brande.

Mr. Brande found, that when albumen was expoied to the action of a galvanic battery, an apparent coagulation took place at the negative pole, as well as at the positive. The effects of this agent, however, were different, according to its intensity. Thus, with a high power, the coagulation went on rapidly at the negative pole, and flowed at the positive; whereas, with a very low power, the coagulation was comparatively rapid at the positive pole, while at the negative pole no coagulation took place, the small proportion of albumen being retained in solution by the alkali attraeted thither. Dr. Murray, however, who faw these experiments repeated in a general manner by Mr. Ellis, thinks that Mr. Brande was deceived, and that the appearance of coagulation was produced only from the numerous aérial bubbles entangled in the vifcid albumen.

The opinion entertained by chemifts at prefent refpeéting the coagulation of albumen, does not differ much from that of Buccet, who confidered it as a fort of foam, the animal matter being retained in solution by the foda prefent. An opinion, closely refembling this, has been fuccesfively advanced by Dr. Thomson, Sir Humphry Davy, and Mr. Brande, who appear to confider this albumen as merely a folution of an animal matter in water and foda, and that all the agents known to coagulate or precipitate it, act by abftracting the foda and water.

The effects of acids and other re-agents upon albumen, although they have been mentioned in a general manner in the
the Cyclopædia, defer to be more fully detailed here, as much additional light has been thrown on the subject within the last few years, from the labours of Berzelius and others.

Acids, as is well known, precipitate albumen immediately; at least this is the case with all the mineral acids when concentrated. Dilute phosphoric acid, however, do not precipitate albumen. Coagulated albumen, according to Berzelius, is charred by concentrated sulphuric acid; but when diluted with six or seven times its weight of water, and digested with it, the acid assumes a reddish colour, but dissolves feebly any thing. The portion not dissolved he considers as a compound of albumen with excess of acid. On depriving it of this excess of acid, by washing it with pure water, a neutral combination is obtained, which is soluble in water. This solution reddens litmus paper, and yields a precipitate with acids as well as alkalies, the former being combinations of the albumen with the acid employed, and which may be again rendered soluble by washing in water, the latter being again soluble with a flight excess of alkali. Hence he considers sulphuric acid to be capable of combining with albumen in two proportions; one in which the acid is neutralized, and which is soluble in water; the other, in which the acid is in excess, and which is insoluble in water. In dilute muriatic acid feebly any of the albumen is dissolved, even by boiling, neither does the acid liquor afford any precipitate with ammonia, or prussiate of potash. Evaporated to dryness, a brownish residue is obtained, from which potash disengages a little ammonia. Concentrated muriatic acid decomposes albumen by boiling, and produces a red or violet-coloured solution. The albumen that has been digested in weak muriatic acid, by washing repeatedly with water, is converted into a gelatinous mass, which is perfectly soluble in tepid water: this is to be considered as a neutral combination of albumen with the acid, while the former one contains an excess. The solution has the same properties nearly as that of sulphuric acid above-mentioned. Nitric acid of sp. gr. 1.25, digested with albumen, renders it yellow, and diminishes its cohesion. The fluid becomes yellow, and a small quantity of fatty matter is formed. During this process, azotic gas is given out in abundance. After twenty-four hours, the albumen is converted into a pulvulent mass of a pale citron colour, which is deposited at the bottom. This matter being separated and well washed acquires a deep orange colour, which Berzelius considers as the acide jaune of Fourcroy and Vauquelin, which obtained it by digesting mucular flesh with nitric acid. This is soluble in alkaline leys, and imparts to them an orange colour; and it is also soluble in acetate of potash and foda. Thus, according to Berzelius, albumen is capable of existing with the nitric acid, as well as with the other acids, in two distinct states of combination, the one having an excess of acid, and of a pale yellow colour, and the other neutral, and of an orange hue. Berzelius seems to consider the different nature of the compounds formed with nitric acid to depend upon the formation of the malic acid, by the action of the nitric acid upon the albumen, which at the same time combines with it. Hence, in his opinion, they are triple compounds of albumen, nitric and malic acids. Mr. Hatchett found, that if albumen, after being steeped in diluted nitric acid, be washed, and then boiled in water, it is dissolved, and forms a pale yellow liquid, which gelatinizes when properly concentrated, and has all the properties of gelatine. Perhaps this boiling deprives it of the malic acid above-mentioned, or perhaps the malic acid was not formed by the dilute nitric acid; for Berzelius, who seems not to have been acquainted with this fact, found also, that when albumen was precipitated from its solution in acetic acid by the nitric acid, the yellow precipitate was rendered gelatinous by washing, and soluble in water, like the compounds of albumen with the other acids above-mentioned; all which compounds are probably similar to the above, and which was confirmed by Mr. Hatchett as gelatine. The acetic acid readily dissolves albumen by the allitance of heat, first converting it, if previously coagulated, into a tremulous jelly. The solution is colourless, and of a mawkish and slightly acid taste. When sufficiently evaporated, it again becomes gelatinous; and when completely exsiccated is a transparent mass which reddens litmus, but is insoluble both in hot and cold water, without a fresh addition of acetic acid. Ammonia and prussiate of potash produce from this solution in acetic acid a whitish precipitate. Alkalies also produce a precipitate which is again dissolved on their being added in flight excess. Sulphuric, muriatic, and nitric acids produce precipitates, which are compounds of the albumen with the acid employed, the acid being in excess; hence, if they are washed in water, as before observed, they become neutral, and capable of solution in water, like gelatine.

Solutions of the different earths, and even some of their salts, as alum, sulphate of magnesia, and sificated potash, were found by Dr. Thomson to have no effect upon albumen when dissolved in water, in the proportion of one white of an egg to a pint of water. The cafe, however, was very different with the metallic salts and oxyds, most of which were found to have a powerful effect upon it, especially the sulphates, muriates, and nitrates of the metals, while the prussiates, and one or two others, had no effect. One of the most delicate tests of albumen, according to Dr. Boistock, is a solution of oxymuriate of mercury: a single drop of this, let fall into water, containing only a few parts of its weight of albumen, produces an evident milkiness, and a curdy precipitate falls. Heat renders the operation of this test more effectual. Perhaps the test of albumen least liable to ambiguity, is that recommended by Berzelius above-mentioned; namely, the addition of the prussiate of potash to a solution of albumen in acetic acid. Albumen is composed of hydrogen, carbon, oxygen, and nitrogen or azote, in the proportions, according to the experiments of Gay Lussac and Thenard, of:

Albumen never exists in an absolutely pure state in animal bodies, but is always combined with other animal matters, and various salts. See Blood and Animal Fluids.

ALBURGH, in Geography, a town of America, in Vermont, and county of Grand Isle, containing 1106 inhabitants.

ALBUS, in Commerce, a small coin and money of account at Caffel, Cologne, and other places in Germany. The whole principalcity of Hefel keeps accounts in rix-dollars of 32 albus, subdivided into 9 pfenings, or 12 helers current. 1 specie rix-dollar is worth 42½ Heffian albus. Coins in silver are pieces of 8, 5½, 4, 2½, and 1½ albus; and in copper, pieces of 1 and 2 albus. Cologne keeps accounts in rix-dollars specie of 8o albus,
or six-dollars current of 78 alufes; the alufus being reckoned at 12 hellers, and alufus are silver coins.

**ALCEDO** Capenis, l. 2, for short-tailed r. long-tailed. A. rufus, l. 3, r. long-tailed.

**ALCEDO.** Add—Dr. Shaw has described some other species, and referred some of those above-mentioned to other titles under Alcedo, and to Galbula. The A. giganta is the *fusa* above-mentioned: the *afra* is the *maxima*: the *amazonia* is glossy-green, white beneath; the lides of the neck white; the of the body variegated with green, and the wing and tail feathers spotted with white; the *amazonian* K. of Latham, about the size of the belted K., or *A. albeon*: a native of Cayenne. A. Malimbus, sea-green or beryl K. with the throat and belly white; the wing-coverts and streak across the eyes black: is much allied to the *A. capenis* in the form of its belt and distribution of its colours; numerous in Malimbus, about the sea-coasts, feeding on worms and shells. *A. javonica*, blue K., with sea-green back, yellowish-white head, neck, and body; the crown of the head streaked with black. (See A. leucophala.) *A. canerophaga*, greenish-blue K., yellowish beneath, with black wing-coverts and eye-stripe, and ferruginous bill; crabs-eating K. of Latham: native of Senegal, where it is called Crab-eater. (See A. Senegaofulsa.) *A. Coromandel*, pale-violaceous rose-coloured K., rufescent beneath, with the rump marked by a longitudinal blueish-white band, and for the throat: a native of Coromandel, an elegant species. *A. collaris*, blue-green K., white beneath, with white collar; Latham's variety of *A. fascia*: a native of the Philippine islands. *A. bicolor* of Cmellin, referred to A. inda. *A. c.-pilifera*, white-collared K. of Latham. (See *A. erula* above.) *A. albifrons* referred to Galbula. *A. cyanocphala*, described under *A. erula-cphala*. *A. tribrachys*, triseguated K. of Nat. Mifs., deep-blue K., ferruginous beneath, with blackish wings and three-toed feet; a native of New Holland: to this the azure K. of Latham is much allied.

**ALCINA,** in Botany, Cavan. Ist v. 10. t. 15, so named by that author, in memory of Francis Ignatius Alcina, a learned Spanish Jew, who resided long in the Philippine islands, and devoting his leisure hours to natural history, left a folio MS., of which Cavanilles speaks as likely to be published. This supposed genus, however, is now sunk in Writania; fee that article.

**ALCOHOL.** in Chemisty. A new analysis of alcohol has been lately published by M. de Sauffure. He employed for his analysis alcohol of the fp. gr. 0.802, at the temperature of 62.8, obtained by rectifying common spirits. This alcohol he considered as a compound of 13.8 water, and 86.2 of the Richter's absolute alcohol; and the water being subtracted from the products obtained, the residue gave the composition of the absolute alcohol of Richter. His method of analysis was to pass the vapour of alcohol through a red-hot porcelain tube, and along a glass tube surrounded by ice nearly fix feet in length. The products were carefully collected and weighed. There was a little charcoal deposited in the porcelain tube, and a very little oil in the glass tube. The water obtained amounted to \( \frac{144}{100} \) of the weak alcohol employed, which was 1256.7 grs., and it contained \( \frac{41}{100} \) of its weight of absolute alcohol. The combustible gas weighed 912.3 grs., and there was a loss of 55.82 grs. The gas was proved to possess the properties of olefiant gas. Hence it follows that alcohol may be considered as composed of olefiant gas and water; and the result of the analysis was, that the absolute alcohol of Richter is composed of

### TABLE ALCE

</tbody>
</table>

100.00

If, with Dr. Thomson, we suppose alcohol to be a compound of one volume of olefiant gas, and one volume of vapour of water, condensed into one volume, its specific gravity in a state of vapour will be just equal to that of these two elastic fluids added together. The specific gravity of these two bodies is,

- Olefiant gas: 61.63
- Vapour of water: 38.37

100.00

And M. Gay Lussac determined by experiment the specific gravity of the vapour of alcohol to be 1.613, which nearly coincides with the above. Hence there is every reason for presuming that the above is the true composition of alcohol, which, stated more correctly on this supposition, will be as follows:

- 3 atoms hydrogen
- 2 atoms carbon
- 1 atom oxygen

28.75

**Alcohol of Sulphur,** now generally termed sulphuret of carbon, is a curious compound of sulphur and carbon, first described by Lampadius. See Carbon, and particularly Sulphur, in the Cyclopedias; where the recent experiments of Berzelius and Dr.Marcet on this substance are detailed.

**ALDRICH,** col. 2, l. 5. r. ascribed to him, but, as some say, erroneously.

**ALE,** col. 2, l. 28. after parliament, add 'The grog duty on ale, or strong beer, is 10s. per barrel, with an allowance of 1d., so that the nett duty is 9s. 2d. For table-beer not worth more than 24s. the grog duty is 2s. per barrel, with an allowance of 2d., so that the nett duty is 1s. 1d.

By 48 Geo. III. c. 143. the several duties imposed upon ale-
ale-licences by former acts were repealed, and a new duty of 2l. 2s. imposed. All persons who shall sell ale or beer by retail, or shall sell cyder or perry, to be consumed in their houses or premises, shall first take out an excise-licence, within the limits of the chief office of excise in London, under the hands and seals of two or more of the commissioners of excise in England, or of such persons as they, or the major part of them, shall appoint for that purpose: and in other parts of England, the licences are to be granted under the hands and seals of the several collectors and supervisors of excise within their respective districts. The duration of such licences is limited to the 10th of October next ensuing the time of granting thereof. All licences granted at the general licensing day shall be made for one year only, to commence on the 29th day of September.

ALE-Houses, 1. 4, after houses, add—under penalty of 3l. 6s. 8d. 5 & 6 Ed. VI. c. 25. 26 Geo. II. c. 31. L. 9, after costs, add—But no person shall be liable to the said penalty, for felling ale or beer in cafes containing not less than five gallons, or in bottles, not less than two dozen quarts, not to be drank in his house, out-house, yard, garden, orchard, or other place. 38 Geo. III. c. 54. Penalties may be mitigated for the first offence; and all penalties shall be paid for and determined within six months after the offence committed.

L. 15, after only, add—The day and place for granting licences shall be appointed by two or more justices for the division, by warrant under their hands and seals, at least ten days before such meeting, directed to the high constables, requiring them to order their petty constables, or other peace officers, to give notice to the several inn-keepers and alehouse-keepers within their respective constabulary, of the day and place of such meeting: and all licences granted at any other time and place shall be void. And no licence shall be granted to any person not licenced the year preceding, (except in cities or towns corporate,) unless he produce a certificate under the hands of the minister and the major part of the churchwardens and overseers, or else of three or four respectable and substantial householders of the place, setting forth that such person is of good fame and of sober life and conversation; and it shall be mentioned in such licence that such certificate was produced, otherwise the licence shall be void. No justice of the peace, being a common brewer of ale or beer, inn-keeper, or distiller, or a feller of ale or spirituous liquors, or interloct in any of the said trades, or being a victualler or maltster, shall be capable or have any power to grant licences for selling ale or beer, or any other liquors, but the same shall be void. All mayors, town-clers, and other persons whom it may concern, shall make out ale-licences duly stamped before the recognizance be taken; on pain of 10l., half to the king, and half to the prosecutor, with costs. 6 Geo. c. 21. 1 Ann. Stat. 2. c. 22.

L. 18, after tipping, &c. add—1 Jac. c. 9. 1 Ch. c. 4. By 21 Jac. c. 7, innkeepers who suffer tipping are disfabled from keeping an ale-house for three years. By 35 Geo II. c. 24, if any person licenced to sell any sorts of liquors, or who shall sell or suffer the fame to be sold in his house, out-house, ground, or apartment thereto belonging, shall knowingly suffer any gaming with cards, dice, draughts, shuffle-boards, midshipman, or billiard-tables, flittles, nine-pins, or with any other implement of gaming in his house, out-house, ground, or apartment thereunto belonging, by any journeymen, labourers, servants, or apprentices, and shall be convicted thereof, or confession, or oath of one witnefs, before one justice, within fix days after the offence committed; he shall forfeit for the first offence 42s. and for every other offence 10s. by dint of warrant of such justice: three-fourths of which shall be to the churchwardens for the use of the poor, and one-fourth to the informer.

And if any journeyman, labourer, or apprentice, or servant, shall game in any house, out-house, ground, or apartment thereto belonging, wherein any liquors shall be sold, and complaint thereof shall be made on oath before one justice where the offence shall be committed, he shall issue his warrant to the constable or other peace-officer of the place wherein the offence is charged to have been committed, or where the offender shall reside, to apprehend and carry the offender before some justice of the peace where the offence shall be committed, or where the offender shall reside; and if such person shall be convicted thereof by the oath of one witness or confession, he shall forfeit not exceeding 20s. or less than 5s. as the justice shall order, every time he shall so offend, and be convicted as aforesaid, one-fourth to the informer, and three-fourths to the overseers for the use of the poor; and if he shall not forthwith pay down the same, such justice shall commit him to the house of correction, or to some other prison of the place where he shall be apprehended, to be kept to hard labour for any time not exceeding one month, or until he shall pay the forfeiture.

If any person (allowing for some excepted cafes under 1 J. c. 9,) shall continue drinking or tipping in any inn, victualling-house, or ale-house, he shall be convicted thereof before a mayor or justice of the peace on view, confession, or oath of one witnes, forfeit for every offence 3l. 4d., to be paid within one week next after the conviction to the churchwardens, who shall be accountable for the same to the use of the poor; and if he shall refuse or neglect to pay the same, it shall be levied by diftreffes. And if he be not able to pay the forfeiture, then the mayor, justice, or court where the conviction shall be, may punish the offender, by setting him in the flocks for every offence by the space of four hours. 1 J. c. 9. 4 J. c. 5. f. 4. 21 J. c. 7. f. 2. 1 C. c. 4.

If any alehouse-keeper shall be convicted of the said offence, he shall moreover for the space of three years be disfabled to keep any such ale-house. 7 J. c. 10. 21 J. c. 7. f. 4.

ALECTORIA, in Botany, seems to derive its name from auctor, una, unmar, because nothing has been made out respecting the male flowers. This is one of the tribe of filamentous Lichens, established as a genus by Acharius, (see Lichen,) and we shall endeavour to explain its characters.—Achar. Syn. 291. Lichenogr. t. 13. f. 1—4. Sm. Prodr. Fl. Græc. Sibth. v. 2. 523.—Clas and order, Cryptogamia Alge. Nat. Ord. Lichenes.

Eff. Ch. Frond cartilaginous, branched; spongy within. Shields fleshy, thick, rounded, flattened, of the substance of the frond; their disk slightly coloured.

Frond thread-shaped, smooth, very much branched, of a smoky.
a fmply-brown; branches capillary, compressed at their subfluvious. Shields fefile, blackish, with an entire mar-
gin; at length convex and hugged. Warts tumid, pow-
dery, white.—Found on the trunks and branches of old
trees, especially of the fir kind, throughout Europe, from
Lappland to the Bithynian Olympus. 8. On palei, rocks, and
stones. The shields are extremely rare. The older
specimens hang in long blackish tufts, like the mane of a
horse, from aged trees in mountain forests; the variety 8
grows proftrate and entangled. There is no central fibre,
the inside being hollow, or slightly spongy. White
powdery warts are frequent and conspicuous on the pendu-
ulous variety, but these are not now confidered by Acharias
as having any share in the fructification. The matter has
not been decided either way by sufficient experiments.
The learned author, whom we have juft named, reckons up
four more varieties, by the names of capillaris (which is
Lichen setiformis of Ehrhart); lanefris; cana (figured by
Wellfing above cited, at his t. 14. f. B.); and ftrata.
We have not examined the cana, which is hoary, with
black downy shields, appears to have some climes to
specific diftinction.
2. A. crinalis. Mane Alealtoria. Achar. n. 2. Lich-
enogr. 534.—"Frond flightly compressed, much branched,
greyfhit, very brittle; branches thread-shaped, rounded!
towards the upper part. Shields? convex, brown."—Found
often mixed with other f Samariflentens, on the trunks
and branches of trees. Acharius.
Achar. n. 3. (Parmelia ufeoides; Achar. Meth. 270.
Lichen Uhinea; Linn. Mant. 131. Swartz Ind. Occ.
1912. Uhinea ceratoidea candidas, glabra et odora-
ta; Dill. Mufc. 71. t. 12. f. 14 f and certainly t. 84.
f. 10.)—Frond compressed, flat, longitudinally ftruted, much
branched, pale and whiffit; the branches somewhat fibrous.
Shields flat, entire, of the fame colour.—On trees in warm
countries, in Afia, Africa, and America. Generally pen-
dulous, always spreading, from fix to eighteen inches long,
linear, flat, cream-coloured, very smooth to the touch;
fragrant and fmy when fresh; eafily fplitting when old and
dry, into two flat layers, exposing a pure white internal
powder. The fifkls are very fmall. By age the whole becomes
of a dirty-buff colour. The Arabian phyficins used this
moss as a cordial, and thought it alfo procured fleep. See
our n. 6.
(Parmelia farmentofa; Achar. Meth. 271. Lichen far-
mentolus; Achar. Prodr. 150. New Stockh. Tranf.
v. 16. 212. t. 8. f. 2. Schrad. Journ. v. 1. 83. t. 3. f. 4.
Engl. Bot. t. 2940. L. linumfium, ex cinere candido,
rufus et mollis, receptaculis florum rufefcensibus; Mi-h.
Gen. 77. t. 39. f. 2. Uhinea longis dichotomis, extre-
matibus tenutoibus; Dill. Mufc. 59. t. 11. f. 2. Ul.
dichotoma; Hoffm. Fl. Lich. t. 72.)—Frond roundish,
foemewhat angular and pitted, much branched, forked and
divariated, whitifh; ultimate branches capillary and lax.
Shields livid, rather concave, with a pale entire border.—
Native of mountainous tracts in various parts of Europe,
on trees or rocks. Mr. Borerre and Mr. Hooker met with
it on the mountains of Interveni-shire in 1808. The
fronds are of an ivory white, creeping, widely divariated,
sometimes powdery, hollow; their ultimate branches peculiarly
fine and numerous. Shields, communicated by Dr. Acha-
rius, fmall, with a greenifh fesh-coloured hollow difk,
finally becoming flattened and dilated.
5. A. trachyta. Brittle Alealtoria. Achar. n. 5. Liche-
enogr. 556.—"Frond round, somewhat compressed, branched,
Vol. XXXI. white; black at the base; branches unequal, zigzag,
minutely fibrous and somewhat tendril-like."—Native of
France and Switzerland. Acharius.
Lichenogr. 556. (Uhinea ceratoideas candidas, glabra et
odora; Dill. Mufc. 71. t. 13. f. 14.)—Frond round,
soemewhat compressed, branched, white; branches forked;
the ultimate points oneird and curved.—Native of the East
Indies, St. Helena, and Madagascar. Professor Acharius
adopts this from Dillenius without examining a fpecimen,
considering it a distinct fpecies from his ufeoides, n. 3, with
which other botanifs have confounded it. He rides alfo
on Dillenius for the present plant being the true Uhinea
of the Arabians. But as Dillenius confounded the two, and had
no authority for taking one more than the other for the Arabian
Uhinea, we cannot place any reliance on him in this repect.
Flow far the two plants, fo very similar in his figures, are
specifically distinct, can only be known by an examination
of the fpecimen of his t. 13. f. 14. at Oxford. The other
is sufficiently well known, and was drawn by him from the
herbarium of Mr. Charles Dan Boin.
(Uhinea dichotomas comprefsa, segmentis capillaceis tereti-
bus; Dill. Mufc. 72. t. 13. f. 15. Muifcus arbus arau-
ritances, flaminibus tenuifilis, ex infusus Fortunatius;
Pluk. Almag. 254. Phyt. t. 309. f. 1.)—Frond com-
pressed, branched, orange-coloured; branches simply or
triply forked; their ultimate segments round and capillary.
—Native of the Canary iflands. Acharius adopts this
fpecies entirely from Dillenius, who decribes it from a
fran to a foot in length, compressed, undivided in the lower
part, but in the upper copioufly and repeatedly branched;
the branches occasionally three together, and their fummits
very fine. The whole is neither very rigid, nor foft,
smooth, of a dull yellow inclining to red. It tinges
the falva with a redder orange colour, but has no particular
fmeil.
ALEMBERT, col. 4. l. 28, for Memoriae s. Membres.
ALEPYRUM, in Botany, a, without, &e, a bark, filel,
or covering, alluding to the want of corollaceous glumes,
by which this genus is distinguished from Devauiaxii
of the fame author, to be defcribed in its proper place hereafter.—
Brown Prodr. Nov. Holl. v. 1. 253.—Clufs and order,
Gen. Ch. Col. Sheath of two concave, keeled, permanent
valves, claffing each other at the base, containing one
or more flowers. Cor. none. Stam. Filament one, capil-
Iary, drooping, about as long as the calyx; another fimple,
cvall. PjL. Germans feveral, from fix to eighteen, ovate-
oblong, inferior, inferted into one side of a central oblong
receptacle, and all turned one way; ftyles as many, thread-
shaped, combined at the bottom, fprading or defixed at
the upper part; filaments linear, downy. Peri. Capfules
as many as the germane, membranous, ovall, of one valve
and one cell, burfting longitudinally at one fide. Seed
folitary, oborate, pendulous.
simple. Germans unilaterial. Capfules burfting longitu-
dinally at one fide. Seed foltary.
A genus of small herbaceous plants, nearly allied to the
more numerous one of Devauiaxii, and, in Mr. Brown's own
opinion, feerely to be feparated therefrom, the want of
petals in Alepyrum being the only difference. The three
fpecies defcribed by this author are all natives of the south
coast of New Holland, where he gathered them himfelf;
nor do they appear to have been met with by any other
botanif or collector. The roots are fibrous. Leaves radi-
N 7 a, cal,
A. uniflorum. - Sheath single-flowered; the outer valve with a leafy point. Germens from five to ten. Stalk twice or thrice the length of the leaves.

2. A. umbrosum. - Sheath single-flowered; the outer valve with a leafy point. Germens from six to nine. Stalk the length of the leaves.

3. A. cicutarium. - Pointed Alepyrum. - Sheath with a few flowers; the outer valve pointed.

ALEXANDER, in Geography, a township of Ohio, in the county of Athens, having 765 inhabitants.

ALEXANDRIA, col. 6, l. 24, for Allatifus r. Anatolius.

ALEXANDRIA, a town of New Ruffian, &c. add.-Alfo, the principal Ruffian settlement in the Fox islands, and the residence of the governor on the island of Kodiak. (See Kodiak and Fox Islands.) The harbour is excellent, and sheltered by several small islands lying to the S.W. It consists of about 700 houses built of logs, the rooms of which are caulked with mosses, and covered with grafs. This is the principal depot of the African company, where the furs are collected. This town is named St. Paul by captain LifIanfly. It has a church, a barracks for the Ruffian convicts, a school, and several floure-houses belonging to the N.W. Company. Campbell's Voyage round the World, p. 108.

ALEXANDRIA, in Grafton county, &c. for 298 r. 409.

ALEXANDRIA, in Hunterdon county, &c. for 1503 r. 2271; and for 40 r. 46.

ALLANITE. See MINERALOGY, Addenda.

ALLANTODIA, in Botany, from ala, ala; sfauoge, a laufage, alluding to the tumid oblong figure of the Sori, or lines of capsules, wrapped in their membranous coverings.

—Brown Prod. Nov. Holl. v. 1. 149. — Clads and order, Cryptogramia Filiata. Nat. Ord. Filicias. Eff. Ch. Fructification in scattered oblique lines, accompanying a vein. Involucrem vaulted, originating laterally from the vein, and inferted into it by both margins; at length separating into the inner one. The habitat of this genus, says Mr. Brown, is between Nephrodium and Diplazium. (See those articles.) Polypodium umbrosum, Hort. Kew. ed. 1, affords an example of it, and there are some unpublished species. The cylindrical involucrem prohibits its union with Alpidium or Athyrium of various authors, and that membrane, being inferted by both margins into the same vein, and truly bifurcating, differs from the involucrem of Alpneum, whose upper edge is not connected with the frond.

We select the examples indicated by the author, not being quite satisfied of the limits of this genus, which is reduced to Alpidium in the second edition of Hort. Kew. pothly not with Mr. Brown's concurrence, his moll indubitable genus of Woodsia (see that article) being likewise there rejected.

We are polluted of many, perhaps of all, the nondecript Allanodia of which he speaks. To these some other Alpidium of Hort. Kew. may be akin; but A. ensulanium, placed next to umbrosum, is not one of them, any more than a few of the neighbouring species, referred by the writer of this article to Cyathæa in Fl. Brit. whose involucrem solely does not answer to the above character, their fori being orbicular.

A. umbrosum. Madeira Wood Saffage-fern. (Polypodium umbrosum; Ait. Hort. Kew. ed. 1. v. 3. 466. Alpidium umbrosum; ed. 2. v. 5. 513. Wildl. Sp. Pl. v. 5. 283. A. axillarium; Schkuhr Crypt. t. 61.)—From triply pinnate; ultimate segments lanceolate, decurrent, deeply ferrated; the lower ferratures cloven. Lines contiguous; finally confluent.—Gathered in shady woods in Madeira, by the late Mr. Maffion, who sent roots to Kew, in 1779, and gave specimens to the younger Linnaeus. An elegant finely divided fern, about three feet high, with roughish stipes. Leaflets two or three inches long, and nearly one broad, pointed, pinnatisect almost to the mid-rib; the segments numerous, parallel, oblong, obtuse, decurrent, vein, smooth, of a fine green; most ferrated at their extremity and upper margin; one or two of the lower ferratures often cloven at the point. Lines moss copious about the lower part of each leaflet. Capsules brown. Involucres pale, variously torn and reflexed.

A. auriflora. Southern Saffage-fern. Br. n. 1.—Frond doubly pinnate, deltoid, membranous, fuscous. Leaflets pinnatifid, tapering at the point; lobes oblong, obtuse, deeply ferrated, many-flowered. Involucres oblong.—Native of Van Diemen's island.

A. tetra. Tender Saffage-fern. Br. n. 2.—Frond doubly pinnate, membranous, fuscous. Leaflets pinnatifid; lobes oblong, obtuse, ferrated, flowering at the base. Spots linear.—Gathered by Mr. Brown, in the neighbourhood of Port Jackson, New South Wales.

The Alpidium axillare, Wildl. Sp. Pl. v. 5. 278. Ait. ed. 2. v. 5. 512, should seem, if the specific character of Willdenow were right, to belong to the present genus. But we suspect that character to have been taken from something else. The fori are by no means rechis, or frigat; but remarkably recurved, much beyond kidney-shaped, finally affuming almost the peltate form of a real Alpidium. In an early state indeed they are frigate; but the inner margin is loofe, dilated, and fringed. In habit nothing can be more closely allied to Allantodia umbroso than this Alpidium axillare.

Gen. Ch. Cal. of one leaf, inferior; tube short, limb in 5,

Eff. Ch. Berry with numerous seeds. Germin between the five-cleft calyx, and corolla of four petals.

1. *A. popy.* Black-pudding tree. *Maringairingue* of the Africans. — Observed by Loureiro, at Mozambique, near the eastern coast of Africa. *A large tree,* with spreading branches, defiitute of thorns. *Leaves* opposite, digitate, of five oval, entire, hairy leaflets. *Stalks* many-flowered, nearly terminal. *Fruit* reddish-brown. A cataplaam of the leaves, applied to the back, below the kidneys, is said to promote delivery. Loureiro compares its plant, as to the leaves and fruit, with the *Jarcatica,* Pfl. Brac. 160. It is easy to trace the natural order of this *Alliofr,* and its relationship to *Carica.* Having feen no specimens, we cannot undertake to correct some apparent inaccuracies, nor to define the real character of the genus; neither is it necessary here to criticize, or to alter, the generic or specific name.

**ALLEGANY,** or *ALLEGHANY,* a county of New York, containing 12,421 inhabitants, of whom 21 are slaves.

**ALLEGHANY County,** 1. 5, for 10,309 r. 25,317, and for 159 r. 24.

**ALLEGANY,** in Maryland, l. 5, for 4809 r. 6909, and for 258, r. 620. Add.—Allo, a township of Pennsylvania, in Cambria county, having 610 inhabitants.—Allo, a township of Pennsylvania, in the county of Armstrong, containing 820 inhabitants.—Allo, a township of Pennsylvania, in Somerset county, having 271 inhabitants.—Allo, a township of Pennsylvania, in the county of Venango, having 299 inhabitants.—Allo, a township of Huntington county, in Pennsylvania, with 1159 inhabitants.

**ALLEN,** a township of Pennsylvania, in Cumberland county, having 1837 inhabitants.

**ALLENSTOWN,** l. 2. for 244 r. 346.

**ALEN-TOWN,** for 90 houses. r. 1291 inhabitants.

**ALLIGATOR,** after *Lacerta* insect, see *LIZARD.*

**ALLIUM,** in *Botany,* an ancient Latin name, of which many different etymologies have been propounded, but none has been thought perfectly satisfactory, is deduced by De Thes from the Celtic, *all,* signifying hot, pungent, or burning, than which nothing can be more suitable, whether we consider the various kinds of Garlic, Onions, &c. in common use, or the numerous wild ones. Several species require to be added to the fifty-five enumerated by our predecessor, the late Dr. Woodville, in the first volume of this work. (See *Allium.*) We shall indicate their respective places in each section, interpenetrating, in the same order, a few remarks concerning other species.

**Sect. 1. Stem leafy. Leaves flat. Umbel bearing capsules only.**

8. Smaller, with sweet-smelling bright crimson flowers.—This variety is a native of the Cape of Good Hope, being the *A. Ampeloprasium* of Thunb. Prodr. 65. It may not be confounded with the 8 of Curt. Mag. 1385, Wildl. and Kitaib. Hung. v. 1. 84. t. 82, which Mr. Ker now thinks a variety of *arenarium,* deprived of its flower-bulbs. The former botanist, to deeply skilful in the plants of this natural order and their allies, has expressed, like Linnaeus, an opinion of the real *Ampeloprasium* not being specifically different from the garden *Lewk.* *A. Porrum,* n. 2. It seems to us that the simply sheathed bisemial root of this latter is essentially different from the large, globulo-aggregate, perrenial bulbs of the other; and the keels of the petals in *Porrum* are certainly much less, if ever at all to, than those of *Ampeloprasium.* A good figure of *A. Porrum* is much wanted.

Such is all the information afforded by Dr. Sibthorps MSS., for he has left no specimen nor drawing of this interling plant, fapped by him to be the *Dioscorides.* He has not afforded us any materials for a specific character. Can his plant be the A. orientale latifolium, flore magnlo lateo? Tourn. Cor. 26? Of this a specimen may perhaps be found, in the collections at Paris or Oxford.

**Sect. 2. Stem leafy. Leaves flat. Umbel accompanied by buls.**

Here perhaps ought to have been inserted, on account of its near affinity to *rofiam,* our *ambiguum,* figured in Curt. Mag. t. 1978, and definned to appear in Fl. Græc. t. 327. See Sect. 4.

**Sect. 3. Stem leafy. Leaves nearly cylindrical. Umbel bearing capsules only.**

20. 21. *A. marginatum.* Pearly Garlic. Sm. Prodr. Fl. Græc. Sibth. n. 770. Fl. Græc. t. 315, unpubl.—Stem bearing round leaves and an umbel of capsules. *Leaves* channelled. *Stamens* three-pointed, prominent. *Petals* oblong, obtuse.—Gathered by Dr. Sibthorp, about Prufa in Bithynia, as well as on mount Athos, and in the islands of Naxos, Cyprus, and Cinolis. The *bulb* is about the size of a filber, coated with brown ribbed scales. *Stem* solitary, a foot high, erect, round, slender, leafy in its lower half. *Leaves* about four, spreading, tapering, as thick as a crown's quill, rather glaucous, smooth, fix inches long; channelled along the upper side; heating at the base; the two lowermost shorter and foon withering. *Umbel* erect, oval, obtufl, dense, attended at the bafe by severalf short, reflected, jagged, white involucral scales. *Flowers* on flender, ascended or upright, simple flakos, an inch long at most. *Petals* oblong, concave, not a quarter of an inch in length, concurring, tweaked with green, white at the edges, purple at the keel. *Stemns* white; three of them flimple, awl-shaped; three linear, with two long, lateral, spreading, narrow segments. *Germes* turbinate, with fix prominent angles.

26. 27. *A. caucasicum.* Crinum Caucasian Garlick. Ker in Curt. Mag. at the end of p. 1143. (A. paniculatum; ibid. t. 973, but not t. 1432. A. globosum; Redout. Lilic. t. 179, not t. 96!)—Stem bearing thread-shaped heating leaves, and an umbel of capsules. One valve of the shoot elongated and cylindrical. *Stamens* flimple. *Petals* ovate, acute. *Germes* globosum.—Native of mount Caucasus. Railed by Mr. Lodidges, from seeds imported from Russia. The cylindrical leaves, globoso umbel, shorter involucrum, ovate, not obovate petals, and round, even, not oblong and channelled, genus, as well as the rofe-coloured flowers, are sufficient marks of distinction between this plant and *A. paniculatum,* of which a imperfect figure, representing the leaves as cylindrical (contrary to nature and the description) is given in Curt. Mag. t. 1432. (A. carv.)
A. montanum. Crimson Olympian Garlick. Sm. Prodr. Fl. Græc. Sibth. n. 775. Fl. Græc. t. 319, unpubl. (A. montanum, radicis oblongā | Tourr. Inf. 324, according to Sibthorp) Stem bearing nearly cylindrical leaves, and an umbel of capsules. Sheath elongated, deflexed. Stamens simple. Flower-flanks uniform.—Found in the grassy pastures of the Bithynian Olympus, by Dr. Sibthorp. The bulb is ovate-oblong, red, with a ribbed angular coat, fibrous at the summit. Stem four or five inches high, smooth, round, bearing about two slender, smooth, gauze-green leaves, a little channelled on their upper side, one of them rising above the umbel, which is rather lax. Petals obovate, pale rose-coloured with a crimson mid-rib. German obovate-oblong, with six deep furrows.

A. flatiforme. Thrift-like Garlick. Sm. Prodr. Fl. Græc. Sibth. n. 775. Fl. Græc. t. 320, unpubl.—Stem bearing nearly cylindrical leaves, and an umbel of capsule. Stamens simple. German three-lobed. Umbel many-flowered, somewhat capitate.—Gathered by Dr. Sibthorp in the ile of Cimólis. The bulb is globular, about the size of a hazel nut, with several lateral offsets. Stem a spin high, reddish. Leaves about three, shorter than the stem, recurved, with flirated reddish sheaths. Umbel dense, of about an inch and a half in diameter, rose-coloured. Petals obovate. German, as well as the capsule, turbinate, abrupt, of three rounded lobes.

A. pilosum. Hairy-leaved Crimson Garlick. Sm. Prodr. Fl. Græc. Sibth. n. 777. Fl. Græc. t. 321, unpubl.—Stem bearing nearly cylindrical leaves, and an umbel of capsules. Stamens simple. Leaves and their sheaths very hairy.—Found by Dr. Sibthorp in the island of Cimólis, and we believe in the Peloponnaean also. Bulbs globular, small, purplish. Stem a spin high. Leaves about four, spreading, tapering, remarkably rough with spreading hairs, as are likewise their long, flirated, purplish sheaths. Umbel lax, hemispherical, many-flowered, smooth, the flowers and their flāks of a pale purplish crimson. Petals elliptic-ovate, obtuse. German three of hemispherical lobes, not turbinate.

A. junceum. Rush-leaved Purple Garlick. Sm. Prodr. Fl. Græc. Sibth. n. 778. Fl. Græc. t. 322, unpubl.—Stem bearing thread-shaped leaves, and an umbel of capsules. Three alternate stamens five-efvel. Umbel capitate.—Discovered in the island of Cyprus, by Dr. Sibthorp, who took it for A. Schoenopraun, from which, however like at first sight, it differs essentially. Our plant is more allied to A. aphyllum, but still distinct, and the stem is truly leafy. Bulbs aggregate, ovate, with dark-brown, flirated, elongated coats. Stem a foot high, slender, erect, leafy about one-third of its height. Leaves two, nearly as tall as the stem, very slender, tubular, quite round, smooth, a little glaucous, somewhat spreading at the top. Umbel globular, dense, its flāk of two broad, ovate, acute, concave, close leaves, shorter than the flowers. Flower-flanks green, but half the length of the petals, which are elliptic-oblong, acute, purplish, with a darker mid-rib. Stamens white; three of them simple, awl-shaped; the intermediate ones flat, dilated upwards, terminating in two taper vertical teeth, on each side of a similar one bearing the anther. German elliptical, with three flight furrows.

Sect. 4. Leaves radical. Common Flower-flanks naked.

35. A. inodorum. Carolina Garlick. Ait. Hort. Kew. ed. 1. v. 1. 427. ed. 2. n. 25. Willid. n. 33. Curt. Mag. t. 1120. (A. fritiun. Venten. Prodr. n. 3. t. 26. Redout. Liliac. t. 68. Purh. n. 2.)—“Stalk naked, oblong, trigonous, angular. Leaves linear, flat; keeled at the back. Umbel level-topped, capsule-bearing. Stamens simple.”—On the mountains of Virginia and Carolna, flowering in June, Perennial. Flowers white, with red veins. Purh. had seen it living. It is marked in Hort. Kew. as a hardy perennial flowering in March and April, and introduced by the late Duchess of Portland in 1776. We presume Dr. Solander to be the author of the above characters, given in Hort. Kew, and that the plant of the Botanical Magazine and that of Redouté are the same, though in the former work the petals are obovate, and remarkably elongated at the base; in the latter ovate, without any such elongation. One or other is a great, and very material, error, but not having seen the plant, we know not where the fault lies. There are errors also in the detail of its history. Redouté t. 6 for 68; Venten. Malwia. copied by Purh from the Magazine, for Venten. Hort. Celv., which proving that the work was not consulted by Purh, takes away our confidence in that author, as to synonyms. The name inodorum is acknowledged to express the want of the Garlick fator in the herbage, while that of fragrans alludes to the sweet scent of the flowers. We retain the original appellation. Mr. Ker, at the end of the history of t. 1293, in Curt. Mag. declares his conviction that A. gracile, our n. 55, is the same plant. We cannot afford the contrary, but we do not feel convinced, and there has been such a diversity of opinion on the subject, that till we can compare living specimens, we must leave the question in doubt. It is remarkable that Willdenow says A. inodorum “is like angulosum of Linneus, but twice as large, and differing in the specific character,” which chiefly amounts to the flāk of the latter being too-dged, and the leaves channelled. He had both plants living. But angulosum is most excellently represented in Curt. Mag. t. 1149, and surely few of the genus can bear less resemblance to t. 1129. It is fearfully more like Redouté's figures, named fragrans. We proceed to notice the species most akin to inodorum; for so at least it must be presumed to be.

35, 36. A. gracile. Jamaica Garlick. (See our n. 55.) Dryander in Ait. Hort. Kew. v. 1. 429. ed. 2. n. 38. Willid. n. 52. Andr. Repos. t. 107. Ker in Curt. Mag. at the end of p. 1293, var. 1. (A. fritiun; Redout. Liliac. t. 50. Curt. Mag. t. 1052? and t. 1524?)—“Stalk naked, round, very long. Leaves linear, channelled. Stamens awl-shaped, connected at the base.”—Native of Jamaica, from whence it was sent to Kew, by Hinton Eaff, efq., and flowered in the close, in February. Atton. Leaves a foot long, resembling those of a Narcissus. Stalk three feet high, slender. Petals erect, white, with claws, which are united with the flāk below, into a green tube. Perhaps this plant may form a distinct genus. Dryander as above. The writer of the present article happened to be with Mr. Dryander, when the original specimens of this Allium were brought from Kew, and on being asked for a name suggeted the above. He then obtained a specimen, which is now, along with others gathered at Kew in 1788, in his herbarium, as well as one more, undoubtedly the same species, procured from Mr. Vere's collection, in 1814, as a rare plant, by the name of A. fritiun. He can therefore speak to the whole barb being deficient of the Garlick odour, and to the want of scent in the flowers, by day at least, though they may very probably be, as reported, fragrant at night. He can also vouch for the fidelity of Mr. Andrews's figure; nor does he hesitate concerning t. 50 of Redouté; whatever kruples a deference to Mr. Ker may fugget, as to the two figures named fritiun in Curt. Mag. The first shows a good difference between this plant and Allium, arofe in Mr. Dryander's mind, from the combination of the fliaments, and was strengthened by the want of the garlick flavour.
flavour. The leaves are certainly not remarkably flirted at the back, as in the real *fritium*, of which we shall next speak.

**A. fritium.** Streaked-leaved Garlic. (See our n. 37.) Jacq. Coll. v. 5. 51. Ic. Rar. t. 366. Wild. v. 35. Ait. v. n. 27.—Stalk rigid, slightly triangular. Leaves linear, somewhat channelled; convex, with many furrows, but no keel, beneath. Umbel level-topped. Petals oblong-lanceolate. Stamens simple.—Native of the Cape of Good Hope, flowering in the gardens in September and October. Whole plant smooth, without much scent. **Bulb** the size of a hazel-nut, white, coated. **Leaves** about four, all radical, six inches or more in length, linear, blunted, or oblique, but little channelled; rather convex and flirted at the back, but not triangular. A transverse section, under a magnifier, shows a single row of perpendicular tubes, each running behind one of the furrows; but the **leaf** is not itself hollow, or tubular. **Stalk** radical, obscurely triangular, flender, erect, as tall as the leaves, or taller. **Umbel** of seven flowers, more or less, the partial flanks an inch and a half long. **Sheath** of two erect, ovate, pointed, membranous valves. **Petals** long-lanceolate, rather acute, spreading, white with a green longitudinal line in the middle. **Filaments** awl-shaped, equal, shorter than the petals. **Anthers** oblong, incumbent, yellow. 

**Jacquin.**

| A. pedemontanum. | Red Piedmonte Garlic. Wild. n. 37. (A. nigrum; Allion. Pedem. v. 2. 158. t. 25. f. 1. A. rofeum; Linn. Sp. Pl. ed. 2. 432, but not Sp. Pl. v. 1. 295.)—Stalk obscurely quadrangular. Bulb cylindrical. Leaves linear, obtuse, keeled at the back. Umbel rather dense, of few flowers. Petals elliptical.—Native of mountainous situations in Piedmont. Specimens from Allioni and Bellardi prove this species, as distinct from *nigrum* as from *rofeum*, to have been confounded by Linnaeus with the latter, which has a globe-like, very prolific **bulb**, a somewhat leafy **stem**, and far more numerous, brighter-coloured, **flowers**.

39. 40. **A. bellatun.** Muffoni Garlic. Ker in Curt. Mag. t. 1576. Ait. Epit. 363. (A. angulofum; Pursh n. 4, excluding the synonym.)—Stalks somewhat two-edged, recurved before flowering. **Bulb** ovate-oblong. Leaves linear, triangular, sharply keeled. Umbel many-flowered, lax, level-topped. Stamens combined at the base. Germin depressed, bluntly triangular.—Found on the banks of the Miffouri, by governor Lewis and Mr. Nuttall, flowering in July, and imported by Mr. Fraser, in whose nursery it bloomed in June 1813. Pursh by mistake says the flowers are white. In the Botanical Magazine they are represented of a deep pink, and the herbage somewhat glaucous. The **flats** are two or more. The **sheath** is of only one valve; but Mr. Ker doubts the permanency of that character.

**A. cernuum.** Bowed-umbelled Garlic. “Roth. Nov. Pl. Spec. in Roem. Archiv. n. 5. 40. Catal. Bot. falc. 2. 33. t. 29.” Sims and Kon. Ann. of Bot. v. 2. 27. Ker v. 3. Curt. Mag. t. 1324. Ait. Epit. 363.—Stalk angular, recurved at the summit. Leaves linear, slightly channelled, pointed. Umbel drooping, many-flowered. Stamens simple, twice as long as the corolla; turulid at the base. Germin turinate.—Native of Mount Caucafall, according to Mr. Aiton, who says it was introduced into England in 1801. The **bulb** are oblong, tapering, aggregate. **Stalk** eighteen inches high; roundish, compressed, and recurved, at the top. **Leaves** bright-green, narrow. **Flowers** white, with a delicate rosy-coloured ring. **Petals** ovate. **Stamens** unequal at first, but finally all about twice the length of the corolla. **Germin** three-horned. 

**A. rubellum.** Reddish Iberian Garlic. Marv. Taur.-Cauc. v. 1. 264.—Stalk nearly naked, round. Leaves semi-cylindrical, channelled. Sheath short. Umbel convex, many-flowered, half as broad as the **corolla**.—Gathered by Mr. Steven in Georgia. **Bulb** the size of a silver. **Stalk** with one or two leaves sheathing the bafe, on which account the author cited doubts whether this species and the following might not be referred to the third section; but there are many of the fourth whose foliage, when the bulb is deep, becomes in some degree cauline. **Leaves** linear broad, rather fl Malay. **Flower-stalks** flender, much longer than the **flowers**, which are hardly so big as those of *A. Ampeloprasum*, of a pale purple, with acute **petals**.

**A. faxatiile.** Stone Garlic. Marv. Taur.-Cauc. v. 1. 264. Sims and Kon. Ann. of Bot. v. 2. 436, excluding the synonym of Gmelin.—**Stalk** almost naked, round. Leaves semi-cylindrical. Sheath pointed, longer than the umbel. **Stamens** simple, longer than the **corolla**. —Frequent on the lime-stone rocks of Taurida, flowering in July and August. **Bulbs** aggregate, oblong, with dark brown coats. **Stalk** with a few sheathing leaves at the base, like the foregoing. **Petals** spreading. There is a variety with purplish **flowers**, on the eastern mountains of Caucafall. This species is very closely related to *A. bidulcanum*, Wild. n. 49, see our n. 51; but differs in having a long awl-shaped **sheath**. 

**A. bifidum.** Jonquil-leaved Garlic. Redouté. Lilac. t. 286. Curt. Mag. t. 1361. Ait. Epit. 363.—Bulb cylindrical. **Stalk** round. Leaves two-ranked, semi-cylindrical, channelled, acute. Umbel dense, convex. **Petals** oval. **Filaments** awl-shaped, the length of the corolla; three of them broader at the base.—Native country not known. The plant is said to be quite hardy, and of easy culture, flowering in June and July. Mr. Ker remarks its great resemblance to *fritifera*. (See n. 32) Curt. Mag. t. 115, next to which perhaps it ought to be placed, though akin also to our cl, from which the shortness of the **sheath** distinguishes the present plant. The narrow and thick **leaves** are very different from *fritifera*; and Redouté has observed that the inner ones are channelled on both sides; which may, as Mr. Ker thinks, be occasioned by pressure in an early state.

**A. triforum.** Three-flowered Garlic, or Mountain Leeks. Pursh n. 5.—**Stalk** naked, round, shorter than the leaves; which are lanceolate and ribbed. **Bulb** of few flowers.”—In shady woods, on the high mountains of Pennsylvania, flowering in May and June. Perennial. *Pursh.*

**41. A. triforum.** Milks-white Garlic. Sm. Prodr. Fl.
Bivona 5, the native of fields in Italy and Sicily, flowering in March. This is one of those plants, which, on account of their novelty, or rarity, Dr. Sibthorp admitted into his Flora Graeca, having gathered them in the course of his travels, though perhaps not in Greece itself. A. lacteum agrees with *triquetrum*, n. 44, next to which it should be placed, in having an acutely triangular stalk, but differs in the lanceolate leaves, and shorter, broader, more obtuse petals. The stigma moreover is simple, not three-lobed.

A. ambiguum. Bulbous Rohe Garlick. Sm. Prodr. Fl. Grac. Sibth. n. 783. Fl. Grac. t. 327, unpub'd. (A. rofeum β; Ker in Curt. Mag. t. 978. Bivona Sic. cent. 1. 18. Savi Etrufc. v. 2. 210.) A. carneum; Targioni Tozzetti fl. Bot. ed. 2. v. 2. 242. t. 6. Moly angustifolium canpanulatum, flore roséo, nodosum; Cupani Pamph. v. 2. t. 219; Moly serpentinum vocatum; Lob. i. c. 160. —Stalk naked. Leaves semi-cylindrical. Stamens simple, shorter than the corolla. Umbel bulbiferous.—Native of Italy and Sicily, flowering in May. Frequent about Pisa. Sicily. On the hills of St. Martino near Palermo. Bivona. This Allium, which, with respect to the Flora Graeca, stands in the same predicament as the lafia, is made by all authors a variety of rofeum; for the difference between the species with bulbiferous, and those with seed-bearing, umbels, is acknowledged to be, in many instances, not infallible. In the plant before us, however, there is a great disagreement, as to the character of rofeum, which is described with flat leaves and a leafy stem. But the dried specimens are very much alike, not discovering in either the semi-cylindrical and hollow structure of the leaves, shown by Dr. Sibthorp's figure. As to the stem being leafy or not, many species are in this respect ambiguous, and rofeum is perhaps improperly considered as of the former denomination. Their roots are precisely alike. The flowers of rofeum are far more numerous, and of a finer pink hue.

We cannot conclude our survey of Allium without remark that the whole genus requires to be reformed, with regard to the arrangement of the species, and the specific characters of many of them. We are also aware of several that might be added to the above list, but of which we want sufficient specimens or information clearly to dispose of, so as to elucidate rather than confound the subject.

ALLOCHROITE. See Mineralogy, Addenda.

ALLOY, in Chemistry, a combination of two or more metals. In addition to what has been said on this subject in the Cyclopaedia, we may add the following tabular view from Dr. Thomson, of the general properties of the different alloys, as far as they have been examined. The chemistry of alloys is at present but little understood, and, as Dr. Thomson justly remarks, these compounds in general appear to be much better known to artists and manufacturers than to chemists.

The first of the following tables comprehends the alloys of the malleable metals with each other; the second, the alloys of the brittle metals; and the third, the alloys of the malleable and brittle metals. In these tables, the letter M signifies malleable; B, brittle; S, submalleable, used when the alloy is malleable in certain proportions, but brittle in others. O is used when the metals do not unite. The sign + is used when the alloy occupies a greater bulk than the separate metals; the sign — when the alloy occupies a smaller bulk. The first indicates an expansion; the second, a condensation.

ALMANAC, col. 2, l. 15, add, see Stamp.

ALMUDÉ, in Commercio, a liquid measure in Portuguese, &c. (See Table XXII. of Measures.) At Lisbon, 982.763.45, and oil are sold by the pipe of these almudes; but the pipe of Lisbon wine sent to England contains about 31 almudes, and the standard gauge at the London Custom-house is 150 gallons; the Lisbon almude is therefore reckoned on 12 English gallons. At Oporto, the pipe is divided into 21 almudes, which almude and its subdivisions are 49% per cent. greater than those of Lisbon; so that the standard gauge of a pipe of port at the Custom-house of London is 138 gallons, so that the almude of Oporto is accordingly equal to fix English gallons and five pints nearly.

Nat. Ord. *Amacones.*, Linn. Juff. Gen. Ch. Male, *Cal. Catkin cylindrical, imbricated every way, lax, composed of wedge-shaped, three-flowered, abrupt, three-cleft scales. Cor.* compound, of three equal, tubular, four-cleft florets, sessile on the disk of each scale; their segments deep, equal, ovate, obtuse, spreading. *Stam.* Filaments four, minute, inserted into the base of each segment, and not quite so long as the segment; anthers of two round lobes. Female, on the same plant, *Cal. Catkin elliptical, imbricated, close, consisting of two-flowered, rounded, pointed, obliquely three-cleft, concave scales. Cor. none.* *Pil.* Germin two to each scale, ovate, minute, depreffed; styles two to each germen, tapering, rather longer than the scale; stigma simple. *Seed.* Nut naked, compressed, of two cells, with solitary kernels. Eff. Ch. Male, *Calyx the scale of a catkin, of one leaf, three-cleft, three-flowered. Corolla deeply four-cleft.* Female, *Calyx the scale of a catkin, of one leaf, obliquely three-cleft, two-flowered. Styles two. Nut compressed.* The presence of a *corolla in the male flowers, with a determinate number of *flamens* equal to that of its segments, are sufficient marks of generic distinction between this genus and *Betula*, which has no *corolla in either flower, and whose *flamens* are numerous, and indefinite. The fertile *catkin* more is elliptical in *Alnus* cylindical in *Betula*. Gartner finds differences in the *corolla*, which, if the germen be attended to, appear to us less decisive. By an occidental oversight, *Alnus* was neglected to be separated from *Betula*, in our Plants of Britain; see that article.

β, incises; leaves roundish, notched. *Wild.*

γ, lacinata; leaves oblong, pinnatifid, with acute segments. *Wild.* *Ait.* 2.

δ, aequicifolia; leaves oblong, fruited, with obtuse segments. *Wild.*

Leaves roundish-wedge-shaped, obtuse, wary, glutinos: down at the branching of the veins beneath. Native of swamps and the neighbourhood of rivers and pools, in low lands, as well as on mountains; throughout Europe, the north of Spain, and of Africa, as also in Canada and on the north-west coast of America. (*Pursh.*) flowering in March or April. In landscape this tree often supplies the want of the rich dark foliage of the Oak, where the latter will not thrive. The leaves are not fully expanded till the end of May, but they remain late in autumn. For the uses and further history of this tree, see *Betula*, n. 6. Our γ is the only variety cultivated for ornament, or rather curiosity, in England.

7, pinnata; leaves pinnate, hairy beneath; young branches hairy. *Wild.*

(Betula pinnata; "Lundmark in Stockh. Tranf. for 1792, 122, t. 5").—Leaves elliptic-oblong, acute; downy beneath; the branching of the veins naked. *Stipulas lanceolate.*—Native of marshes and the banks of rivers throughout Lapland. *Linnus.* It occurs also in alpine situations, in Germany, Switzerland, &c. The variety γ, of which we have specimens from Dr. Swartz, has been met with in one part of Sweden only, Waermund, and is increased by root only. The *leaves* are small, pinnate, and jagged. The usual appearance of *A. incana,* except its hoariness, and the glaucous hue of the back of its *leaves,* is not very unlike *A. glutinosa.* The *leaves* however are more acute, and their footstalks are reddish. This last character, as well as the glaucous hue just mentioned, is wanting in variety γ. The general pubescence of the under side of the *leaves renders it difficult to say how far the veins differ at their origin from those of the Common Alder, but though downy, they certainly want the glandular roughnesses to remarkable in that species. See *Betula*, n. 7, for a further account of this tree.

4. *A. viridula.* Curly-leaved Alder. *Wild.* n. 4. *Ait.* n. 4. (A. cripta; *Parth.* n. 2. *Betula cripta; Ait.* ed. 1. v. 3. 239. *Michaux Boreal.-Amer.* v. 2. 151.)—Leaves oblong, acute; rounded at the base; veins hairy beneath, like the footstalks, but naked at their origin. *Stipulas ovato-oblong.*—In Canada, and on the high mountains of Pennsylvania, in swamps overrun with Bog-mofs, flowering in April. *Pursh.* not above three or four feet high. *Leaves doubly serrated.* *Pursh.* See *Betula* n. 13. Willdenow seems to have unwarrantably changed the name of this species.

obovate, finely ferrated; veins and their origin hairy beneath. Stipulas elliptical, obtuse.—Native of North America. Common everywhere in swamps, and by river sides, flowering in March. A Sora, from six to ten feet high, growing in close thickets. Purp. See Betula n. 12. The leaves do not appear to be glutinous, or at least not so much as the Common Alder, from which also they differ in being regularly and finely ferrated, not notched, or jagged.

ALOEXYJJUM, a10eXJYJJus, Alcgo-wood, a name given to the tree which produces this precious wood, by Loureiro; Fl. Cochinch. 267. See Agallasolus.—He refers it to the Clafs and Order, Decandria Monogynia, and its Natural Order seems to be Lomentaceae, Linn. Leguminosae, Juff. Gen. Ch. Cal. Perianth inferior, of four acute, hairy, deciduous leaves; the lowermost falcate, incised, nearly twice as long as the refl. Cor. Petals five, unequal, longer than the calyx. Stam. Filaments ten; anthers .... Pijf. Germen superior, elongated, curved, compressed; fyle thread-shaped; stigma ...... Perig. Legume woody, smooth, falcate. Seed solitary, oblong, curved, tunicated. Eff. Ch. Calyx of four acute deciduous leaves; the lower one longest. Petals five, unequal. Legume curved. Seed solitary, tunicated.

1. A. Agallasolus. Fragrant Alcgo-wood.—Native of the lofty mountains of Cochinchina, near the great river which runs between that kingdom and Laofio. A large lofty tree, with erect branches. Bark fibrous, brown, smooth, not thick. Leaves alternate, fmalled, lanceolate, flat, entire, smooth, rather coriaceous, eight inches long. Flower-flalts terminal, many-flowered. Loureiro. This genus is manifestly different from Aquilaria. (See that article.) Loureiro describes the wood as white and inodorous, becoming fefuous and fragrant in confequence of some injury, till the tree dies. No part of this tree is milky, nor poifonous. He adds, that all the farts of genuine alcgo-wood are produced by this tree, even the mift precious, termed Calambac, which is found no where but on the mountains of Cham-pa, belonging to Cochinchina, frituated about the 13th degree of north latitude. The inferior fcpcies, or rather varieties, are obtained in various places, fometimes in pieces weighing thirty pounds or more. "There are," says Loureiro, 9 other valuable woods, called by ignorant peronas Agallasolus, and Lignum Alce, differing greatly from each other, and the produce of different plants." The common writing paper of Cochinchina is made of the bark of this tree. Yet the plant itself feems rare, Loureiro having long enquired in vain for the flowers, and having obtained them but once, in a bruised and mutilated condition.

Whether the Agallasolus, or Calambac, Rumph. Aboim. v. 2. 29, of which that author gives no figure, be the plant of Loureiro, we cannot poifitively determine, though it feems likely. The Agallasolus fecondaerum, or Gars, of the fame volume, 34. t. 10, is certainly the Aquilaria. We have received from Dr. Roxburgh fpecimens of the wood itself; as well as of the fruit, agreeing exactly with Rumphius's figure, and evidently the Gynnoos Walla of Garpert, v. 2. 276. t. 140. In Tr. of Linn. Soc. v. 11. 230, the writer of this has hinted at the probable affinity of Aquilaria to the Iuphorbie.

ALONSOA, a genus eftablifhed by Ruiz and Pavon, Fl. Peruv. Syfl. 150, and adopted in Ait. Hort. Kew. v. 4. 27, is founded on two fcpcies of Hemimeris, (fee that article,) nor can we discover the leaf pleife character to diftinguish them from the latter; which having been much confuted in its history by Linneus, was perhaps not under-food by the authors of the Flora Peruviana. These fcpcies are our H. utitifolia, (Alonoia inciJifolia; Fl. Peruv.) and H. linearis, (A. linearis of the fame work;) Professor Will-
denow, though he had never seen more than one Hemimeris, the montana, and that in a dried fate, could not overlook the identity of thefe genera, nor can we account for its having escapee the learned editors of the Hortus Kewensis. But it is evident from their generic character of Alonjot that they did not contral the two genera; for thefe are proved the fame by the character itself, which runs thus, and is equally fuitable to both.

Calyx in five deep fcgments. Corolla nearly wheel-shaped, revefed, five-clift; the upper fimple segment largest. Stamens declining; with smooth filaments; and converging uniform anthers. Capsule of two cells.

Hemimeris, being a long-eftablifhed Linncean name, of appropriate and without exceflional meaning, must, of course, be retained.

ALPINIA, the article already given requires reforma-
tion, in confequence of fubfequent discoveries, chiefly owing to Mr. Rofoee's investigations. (See Scitaminee and Rofoea.) Recurring to the original genus, founded by Plummer, and adopted by Linnceus, as the bafes of the whole, we do not, in quoting various authors, who have followed thefe, confider as Alpinia all that they have included herein.

Gen. Ch. Cal. Perianth superior, of one leaf, tubular, irregularly splitting into two or three teeth. Cor. of one petal, irregular, tubular at the base: limb double, unequal; the outermost two-dipped, in three deep segments, of which the upper one is usually broadest, and concave, the two lower equal and narrow; innermoft of a fingle lip, ftraight, as long or longer than the outer limb, dilated, lobed, or jagged, at the extremity, furnished at the base with a pair of awl-shaped teeth. Stam. Filament one, oppofite to the lip, fhort and flout, quite fimple; anther terminal, erect, thick, fimple, without any appendage, convex at the back, emarginate, divided in front into two parallel, clofe, oblong lobes, bursting longitudinally. Pijf. Germen inferior, elliptic-oblong, with three furrows; fyle thread-shaped, erect, smooth, the length of the flamen, embraced by the lobes of the anther; stigma peltate, umbilicated, hairy. Perig. Capsule fitefly, oval, abrupt, umbilicated, with three furrows, three valves, and three cells. Seeds numerous, tunicated, ovate, angular, abrupt, inferted into a pulpuy receptacle.

Dr. Roxburgh, who had opportunities of studying the various fcpcies of this, and many other Scitaminee genera, in their native fituations, speaks of Alpinia as a good natural genus, having, besides the proper characters in the ficification, certain peculiarly flirking ones in the habit. The roots are perennial, tuberous, ftrong, thick, crooked, running nearly horizontally, a little below the surface of the ground, O o and
and strongly marked with annual scars where former leaves have been; these fend down copious, long, thick, fibrous radicles. 

Stems either biennial or perennial, numerous, tufted, straight, erect, or more or less recurved at the summit, densely leafy, each terminating in a copious clusfer, or panicle, of large gaudy flowers, "except Cardamomium," says Dr. Roxburgh; but that plant, which has a radical panicule, is now excluded from Alpinia, and called by Dr. Maton Elettaria in Tr. of Linn. Soc. v. 10. 245 having sufficient marks of generic distinction in the flamen. We shall endeavour to collect under one view the numerous species of this fine genus, of which we can find any account, or have seen any figures or specimen.

—Native of rather mountainous shdy woods in the West Indies. Notwithstanding Dr. Swartz's doubts, we have no hcrapule respecting Plumer's synonymy. Root branching, feathery, with the flavour of Ginger; used in Jamaica as a poultice for cancers and other ills, according to Swayne, with good success. Stem herbaceous, two or three feet high, round, smooth, slender, simple, leafy. Leaves alternate, elliptic-lanceolate, entire, smooth, pointed, a foot long, with narrow feathery feathertils exceeding them in length. Clusfer terminal, solitary, flaked, unbranched, smooth, many-flowered. Outer bractees lanceolate, blood-red; the lowest an inch and a half long, the rest about an inch; inner bell-shaped, containing one or two flowers, shorter than the calyx, permanent. Calyx red, with broad and shallow teeth. Corolla white; tube slender, longer than the calyx; outer limb with three nearly equal, ovate, erect segments; inner somewhat heart-shaped, three-lobed, the middle lobe notched. Germin bluntly triangular, quite smooth, as well as the calyphe. Seeds thinning.

2. A. Galanga. Galangale Alpinia. Roxf. Tr. of Linn. Soc. v. 8. 345. Roxb. n. 1. Willd. n. 2. (Marantha Galanga; Linn. Sp. Pl. 3. Swartz Obs. 8. Amomum Galanga; Laouere. Cochinch. f. Galanga major; Rumph. Ambon, v. 142. t. 63. Dale Pharmac. 276. Ger. Em. 43.)—Clustcr compound, erect. Bractees all lanceolate, shorter than the flowers. Calyx bell-shaped, with three rather pointed equal segments. Germin slightly downy.—Native of various parts of the Malay Archipelago, communicated by the late Dr. Roxburgh, from the Calcutta garden, where this plant flowered during the hot season, and ripened seed, though very rare, in November. The root proved to be the real Galanga major of the shops. The stem is said to be seven or eight feet high. Leaves eighteen or twenty-four inches long, soft to the touch, though feebly conspicuously downy. Clusfer large, with very numerous, crowded, short, racemose branches, all downy. Bractees uniform, lanceolate, downy; thoae at the base of each principal branch very small. Flowers white. Calyx besprinkled with minute reflexus dots. Corolla elongated; lip externally downy, cloven at the extremity. "Capsule small, obvate, smooth, deep orange-red, not opening spontaneously. Seeds only two in each cell, even in the germin, bitter and nauseous, each three-fourths covered with a white tunic." Roxburgh. See Galangal.

3. A. occidentalis. Scaly-cluftered Alpinia. Swartz Ind. Oc. 9. Roxf. Tr. of Linn. Soc. v. 8. 345. Willd. n. 4. —Ait. n. 2. (Amomum minus, sespa vesito, floribus plicatis; Browne Jam. 112, excluding Swayne's synonymy. Sponserosa minor multicaulis; Plumb. MSS. cum icon.)—Clusfer compound, erect, on a fealy leafless stem. Partial bractees imbricated, sheathing, dilated, abrupt, hairy. Calyx turbinate, with three broad obtuse segments. Germin slightly downy.—Native of moist parts of the mountainous woods of Jamaica, flowering all the year, but especially in spring. Root knotty and fibby. Barren stems six feet high, erect, herbaceous, simple, leafy. Leaves elliptic-lanceolate, acute, very smooth, attached by a short contraction to their sheathing f Fixedals, as in the other species. Flowering stems as tall as the others, round, smooth, erect, not leafy, but clothed from top to bottom with flowering, oblong, obtuse secales, and terminating in a dent, erect, cylindrical, compound, many-flowered, chafier, with hairy stalks. Flowers all turned upwards, crowded, their partial stalks concealed by concave, sheathing, abrupt, partial bractees, while each common stalk, or branch of the clusfer, has at its base a very different, lanceolate, acute bractea, half its own length. Calyx coloured, hairy at the base; its segments smooth, rounded and obtuse. Corolla pale yellow; tube the length of the calyx; lip veiny, cloven at the end. "Capsule rather small, corraceous and fuffy, of three valves, red when ripe, pulpy within. Seeds yellow, two or three in each cell." Swartz. We are indebted to Mr. Lambert for a drawing of this plant, copied from Plumer's sketches at Oxford.

The habit of this species may, at first sight, seem to invalidate the character of a leafy flern, with terminal inflorescence, attributed to this genus in our introductory remarks. We think however that the difference between this and the others is more apparent than real. The scales may be considered as abortive leaves, not perfected on the flowering stems, while thoee stems which luxuriate in foliage, do not also bear fructification. Perhaps the more robust are more prolific than in other species.

4. A. Allughas. Ceylon Alpinia. Roxf. Tr. of Linn. Soc. v. 8. 346. Roxb. n. 2. Ait. n. 3. (Hellenia Allughas; Willd. Sp. Pl. v. 1. 4. Andr. Raph. t. 501. Heritiera Allughas; Retz. Obs. fasc. 6. t. 11.)—Clusfer paneled, erect. Calyx bell-shaped, two-lobed. Germin hairy. Lip two-lobed.—Native of the East Indies. Very common in Bengal, flowering throughout the rainy season, and ripening fruit in October and November. We received in 1786 a flower from Kennig's specimen of this plant, sent to professor David van Royen by the name of Grana Paradisi Zeylanica. It appears without doubt to be the Alughas of Hermann, mentioned, but not ascertained systhetically, in Linn. Zeyl. 207. n. 449, and it is said to be the Malo-infidezka, Rheede Hort. Mal. v. 11. t. 14. The illuflrious Mr William Jones has described it, by the Sanferit name of Zyraca, in the Atarific Researches, v. 4. 240. The stem is two feet high, simple, leafy. Leaves lanceolate, pointed, smooth, with long sheaths. Clusfer, or rather panicle, variously subdivided, lax, many-flowered, with denfely downy stalks. Bractees fnumco, for the most part very small, but those under the principal subdivisions of the inflorescence are sometimes elongated and lanceolate, and one or two of the lowermost occasionally become very large and leafy. Calyx downy, especially at the base, remarkable for having only two marginal acute segments. Segments of the outer limb of the corolla oblong, equal, coloured green by Mr. Andrews, crimson, like the lrp, in Retzius's plate, but the latter is probably accidental; the author having had no living specimen. The lip is shorter than those segments, and, like them, externally hairy; its two lobes appear to be sometimes cloven. Stem long, with a large wather, reddish as well as the lip. Fruit globose, purplish-
ALPINIA.

pulphid-black, with numerous tunicated seeds. This species was raised from seed by A. B. Lambert, esq. at Boyton, in Wilts, where it flowered very finely; but it is said to have been previously sent by Mr. Peter Good to Kew, in 1796.

5. A. alba. White Alpinia. Roxb. Tr. of Linn. Soc. v. 8. 346. (Helenium alba; Willd. Sp. Pl. v. 1. 5. Heritiera alba; Retz. Obs. falc. 6. 18. Linguas vulgaris; Koen. in Retz. Obs. falc. 3. 64.)—Clutter pa. n. 5. Calyx bell-shaped, three-toothed. Lip two-toothed. Leaves calyculate and fringed at the margin. Native of China; cultivated in the East Indies. Koenig terms this plant Galanga alba, and speaks of it as in much use among the Malays. The roots are white, thicker than the stem. Stems taller than a man, tuberous at the bottom, a little drooping at the top. Leaves about eighteen inches long, and hardly three broad, two-ranked, smooth on both sides; their edges calyculate, whitish, and rather rough with hairs. Five or six of the lower leaves are unaccompanied by leaves. Clutter oblong, with smooth flanks, except the partial ones, which are rather hairy. Bracteae lanceolate, acute, rufy-coloured, deciduous. Calyx with snow-white segments. Outer limb of the corolla greenish-white; lip inverely heart-shaped, deeply two-to-loged, jagged and crimpied at the margin, white, with fine rose-coloured veins. Calyptra scaber, membranous, rather rigid, fringed. Koenig's full and correct description of the flower, leaves no doubt as to the genus of this plant, though we have seen no specimens.

6. A. chinensis. Chinese Alpinia. Roxb. Tr. of Linn. Soc. v. 8. 346. (Helenium chinenses; Willd. Sp. Pl. v. 1. 5. Heritiera chinensis; Retz. Obs. falc. 6. 18. Linguas chinenses; Koen. in Retz. Obs. falc. 3. 67.)—Clutter p. n. 5. Calyx bell-shaped, three-toothed, obtuse. Lip emarginate, finely-toothed. Leaves recurved at the point; membranous, and fringed with scattered hairs, at the margin. Native of China? where at least it is cultivated, for medical use, in gardens. Root aromatic, with an acrid burning flavour, white, as thick as the middle finger. Stems two or three feet high, a little drooping at the summit. Leaves a spian long, and two inches or two inches and a half broad, with a white rib and margin. Clutter narrow, three or four inches long, its flanks more or less clothed with close-petted hairs. Calyx green, Corolla yellowish, the lip marked with a broad orange-coloured longitudinal stripe, and transverse waves of the same colour, accompanied by four broad-red veins. Fruit a capsule. Koenig.

7. A. aquatica. Water Alpinia. Roxb. Tr. of Linn. Soc. v. 8. 346. (Helenium aquatica; Willd. Sp. Pl. v. 1. 5. Heritiera aquatica; Retz. Obs. falc. 6. 18. Linguas aquaticum, l. fylvele; Koen. in Retz. Obs. falc. 3. 67.)—Panicle somewhat drooping at the top, with forked branches. Calyx bell-shaped, three-toothed. Lip four-toothed, erect; its lateral teeth with an oblong gland at the base, on each side. Found in marshy places, among bushes, by the sides of rivulets in the East Indies, but not very common. Roots numerous, thread-shaped, white, sending forth runners. Stem about four feet in height, leafy, as thick as the finger. Leaves oblong, acute, corniculatus, of a beautiful green; rather roughly fringed on the upper side; smooth at the back; the margin beset with minute calyculate teeth. Panicle slender, with two deciduous bracteae at the base; flower-flanks forked, two-flowered, divaricated, round, smooth, white, shorter than the flowers. Bracteae two or three, attached to the lower flower-flanks, linear-lanceolate, concave, membranous, whitish, deciduous. Calyx smooth, pure white, sometimes splot at the inner side. Corolla white. Lip small, brown on the inner side, rofe-coloured near its union with the filament. Anther reddish, crowned with a small, coloured, erect, semi-ornicular membrane. Berry oval, smooth, black. Seeds five or more, triangular. König. The membrane crowning the anther forms a small exception to the generic character, but can hardly invalidate it, or require the establishment of a separate genus; unless the fructification, when examined according to our present advanced knowledge, should afford other distinctive marks.

8. A. malaccensis. Malacca Alpinia. Roxb. Tr. of Linn. Soc. v. 8. 345. Roxb. n. 3. (Miranda) malaccensis; Willd. Sp. Pl. v. 1. 14. Burn. Ind. 2. Galanga malaccensis; Rumph. Amboin. v. 5. 176. t. 71. f. 1.)—Clutter simple, erect. Leaves villous beneath. Lip broader than long, toothed, concave, obscurely three-lobed; lateral lobes incurved. Native of Chittagong, from whence it was brought to the botanical garden at Calcutta, and flowers there in April and May. "This," says Dr. Roxburgh, "is the most flately and moft beautiful of our Scitamious plants. The flowers are particularly large; the bracteae, and exterior limb of the corolla, pure, smooth, lucid white; the large lip variegated with crimmon and yellow." Stem from twelve to fifteen feet high, villous. Leaves eighteen to twenty inches long, the breadth of five or six fingers, silky or downy beneath. Native of China; cultivated in the neighbourhood of Chittagong, and introduced into Calcutta, by Mr. Burman, and cultivated in the garden of Sir Joseph Banks, and flowering a few years after, excited the admiration of all beholders. The number of figures of this plant which have been published, prove it a general favourite. The tuberous odorous root is sometimes, as Dr. Roxburgh asserts, brought to England for Galanga major; see n. 2. Stem from five to eight feet high in India, but with us twelve to eighteen, perennial, erect, as thick as the finger, leafy. Leaves a foot long or more, with long sheaths, each sheath crowned with a fipula which is externally silky. The flower-tubes before they expand are of a shining white, tinged with rose-colour, and are enveloped in large, concave, toothed bracteae of the same porcelain-like splendid white, all together composing a dense pendulous cluyfer, like a bunch of oblong grapes. When the flowers open, they display the magnificent concave lip yellow at the margin, internally variegated and streaked with every shade of crimmon. The flames and its anther are short and thick. German hairy. Calyptra spherical, opening at the sides. Seeds aromatic, as is likewise the young germin. Linnaeus has greatly confounded the history of this plant, with which he had no acquaintance but from the work of Rumphius. Yet he subsequently cited the same synonym and figures under his Alpinia exilis, which is indeed an Alpinia, as we shall presently shew, but a widely different species.

O o 2
The real genus *Globea* is totally distinct from both; see the article.

10. *A. mutica*. Pointed Narrow-leaved Alpinia. Roxb. n. 5.—Cluster erect, compound. Leaves shortly stalked, linear-lanceolate, polished. Lip three-lobed; without a spur at the base. Capsule papilose. Seeds numerous, angular, with an evanescent tunic.—Found by Mr. W. Roxburgh, the son of our ever-lamented East Indian botanist, in the forests of Prince of Wales's Island, from whence being brought to the Calcutta garden, it flowered, more or less, during the whole year, but chiefly in the hot season, March, April, and May. This is also an elegant species, and holds a middle rank between *nutans* and *calcarea*. Roxburgh.

11. *A. calcarea*. Spurred Narrow-leaved Alpinia. Roxb. Tr. of Linn. Soc. v. 8. 347.—Clust. erect, somewhat compound. Leaves linear-lanceolate, polished. Lip ovate-oblong, cloven at the point. Segments of the outer limb linear-oblong.—Native of China, from whence it was introduced into the Calcutta garden in 1799, according to Dr. Roxburgh, who communicated the plant to Mr. Lambert. The numerous items are from three to five feet high. Leaves narrow, acute, smooth. Cluster three or four inches long, downy, rather denf, the stalks, though partly compound, some of them bearing two or three flowers, being so short that the whole cluster resembles a spike. Leaves twelve or fifteen inches long and one broad, pointed. *Braeuas* elliptical, concave, hardly equal to the calyx, which is tubular, white, split half way down at one side, and on the other very slightly and bluntly notched. Outer limb of the corolla pure white, the length of the tube, in three deep, equal, obtuse, flat, rather narrow segments. Lip nearly twice as long, concave, but not so fumid or inflated as in *A. nutans*; its upper fide crinum, beautifully streaked; the extremity flatfli, slightly cloven, more or less notched or curled. The base of the lip being furnished, as in *A. nutans* and some other species, with two small spurs, or awl-shaped appendages on the upper fide, which are wanting in the last, seems to have occasioned the specific name, which is more correctly calculated to mislead. Dr. Roxburgh had once an intention of changing it to *spicata*, which would not have been more correct, and the above being printed by Andrews, it was suffered to remain. *A. anguliflata* would have been preferable to other.

12. *A. acutiflora*. Spotted-leaved Alpinia. Roxb. Tr. of Linn. Soc. v. 8. 347.—"Leaves ovate, spotted."—Cultivated in the botanic garden at Liverpool. It is thus mentioned by Mr. Rofcoe, but with a mark of doubt, nor have we met with any future information respecting this species.

13. *A. spicata*. Small Spiked Alpinia. Roxb. n. 8.—"Spikes oblong, compactly imbricated, with narrow-lanceolate acute bracteas."—Native of Sumatra. Brought by Mr. William Roxburgh, from Bengooleen to the Calcutta garden, in 1803. At the close of the rains of 1808, it bloomed for the first time, and was then only about two feet high, being the smallest of the genus ever seen by Dr. Roxburgh. This is all the account he has left us of the present species.

14. *A. Reaalmia*. Surinam Alpinia. (Reaalmia exalata; Linn. Suppl. 79, excluding the synonym of Runphius, and the account of the stem and leaves taken from that author. Wildl. Sp. Pl. v. 1. 6. "New Bot. Ann. v. 3. 136." Myrmif n. 64; Linn. Pl. Surinam. in Amoen. Acad. v. 8. 251. n. 3, excluding the synonym of Merian, t. 54.)—Cluser lateral, compound. Calyx tubular, irregularly toothed.—Native of Surinam. The history of this plant is so confused, that we think it necessary to lay before the reader all the original materials. The generic description, Linn. Suppl. 7, and the specific one, p. 79 of the same work, beginning at the word *Racemos*, appear to have been made, with sufficient accuracy and fidelity, from specimens of a cluser of the flowers, and a quantity of the fruit, with a leaf, tint in bottles of spirits to LINNEUS. The former was taken out and dried by LINNEUS himself, for his herbarium, where it now lies, marked by him *Heliconia*, he having taken this specimen for Merian's t. 54, *Heliconia Bhula*, which it somewhat resembles in general aspect. The flowers, however, when examined, prove these plants totally different; but this mistake of LINNEUS accounts for his erroneous reference to Merian. "The spirits in the bottle of the fruit being gone, the latter is also dried; but enough remains to shew it has been a fleshy, very fibrous, oval, *capsula*, above an inch long, of three valves, strongly umbilicated, and containing numerous, roundish-ovate seeds, now of a shining brown. Their flavour is lol. A Dutch manuscript, sent from Surinam with the collection to which the above belonged, contains the following information. "No. 63 is a sort of reed, and has upon each flalk four fuch leaves as are here to be seen; two uppermost next to each other, and then the other two a span under the uppermost, and a span between these two, downwards to the fruit. The fruit is at firft red; black when ripe. The feed in the fruit tafes exactly like Cardamom. The flalk to which the fruit grows is two feet and a half long, beft with twenty-five to twenty-seven fruits." Such is as literal a translation as we could obtain. It seems indubitably to afeertain the situation of the *inflorescence* to be lateral, and in this point agrees with the following account given by Willdenow, we know not on whole authority. "A tree twenty feet high. Leaves five or six feet long, lanceolate, waved at the margin. The cluster originates from the trunk, above the root." New Bot. Ann. as above. If this laft description really belongs to the LINNEAN *Reaalmia*, our ideas of the plant are very incomplete. The lateral *inflorescence* would form a strong prepective argument againft its being an *Alpinia*; but we can allert, from a careful examination of one of the flowers, immersed in hot water, and compared with a living flower of *A. nutans*, that their structure agrees exactly, without the leaft mark of a generic deference, especially the essential part of the anther. This indeed appears from LINNEUS's remarks in the Supplementum, without which our history would be incomplete. We shall leave the reader to compare it with the defcriptions of other species, only observing beware that LINNEUS confiders the flower as reverfed, placing the *nefrary* uppermoft.

Nat. Ch. Cal. Perianth superior, tubular, of one leaf, burfting at the top into two or three irregular teeth. *Cor.* of one petal. Tube ftraight, cylindrical. Limb three-cleft: two upper (properly under) segments oblong, rounded, equal: lower segment faeady longer, channelled, oblong. *Nefrary* united with the tube, ascending under the upper segments, ftraight, the length of the corolla, oblong, with a tooth at the base on each side, and a hollow behind; dilated, and bluntly three-lobed, at the extremity. *Stam* Filament none. *Anther* folitary, inferted into the mouth of the tube, in the bofom of the lower (upper) segment of the corolla, oppofite to the *nefrary*, unconnected, ftraight, linear,
of the former; *Amomum reflexum* of Sonnerat and other authors. Willd. Sp. Pl. v. 1. 9; is now properly, we believe, removed from *Alpinia*, and proposed by Dr. Maton, Tr. of Linn. Soc. v. 10. 249, as a new genus, distinguished by two transverse proessæ at the top of the filament, and called by him *Elettaria*, under which name we propose hereafter to treat of this plant.

ALQUIER. Add—The fanega, which is the 15th part of the moyo, is 4 alquiers = 8 moyos = 16 quarters = 32 outavas = 64 mequinas. The alquier measures 675 French, or 817 English cubic inches; so that 21 alquiers are nearly = 1 English quarter; or, more correctly, 50 alquiers = 10 English bushels.

ALSOPHILA, in Botany, so named, we presume, from *αλσα*, a grove, or forest, and *φιλα*, to love; alluding to the favourite flaton of the beautiful tribe of Tree Feras, to which this belongs.—Brown Prodr. Nov. Holl. v. 1. 158.—This genus is founded on our *Cyathea afera*, *C. extensa* of Swartz, *Polyodium lunatum* of Forster, and some other allied species; but we fearlessly think the deeper segments of the burbling *involucrum*, or the situation of the fori at the divifion, instead of the side, of a vein, can authorize a separation of thele from *Cyathea*. See that article.

ALSESTE, in Geography, a town of America, in New Hampshire, and county of Cheshire, having 1694 inhabitants.

ALSTONIA, in Botany, received that name from Mr. Brown, in memory of Dr. Charles Alston, formerly Professor of Botany at Edinburgh. (See that article.) The genus originally dedicated to this gentleman, in the Supplement of Linnaeus, is now sunk in *Symphlocos*. (See that article, and *Alstonia*.)—Brown Tr. of the Werner Soc. v. 1. 75.—Clads and order, *Pentandria Monogynia*. Nat. Ord. Contorta, Linn. Apocine, Juff. Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, in five deep, rather blunt, segments, permanent. Cor. of one petal, falver-shaped; tube cylindrical, many times longer than the calyx, somewhat tuid near the top, pervious, deitute of scales in the throat or mouth; limb horizontal, in five deep segments, folding over each other at the base, mostly shorter than the tube. Nectary none. Stam. Filaments five, short, inserted into the tube, and not reaching to its summit; anthers lanceolate, not connected with the stigma, bursting longitudinally, excafed within the tube. Stig. Gernms two, simple; style solitary, central, thread-shaped, swelling at the top; stigma nearly conical. Peric. Follicles two, cylindrical, long, each of one cell and one valve. Seeds oblong, peltate, fringed, bearded with long hairs at each end.

Eff. Ch. Corolla falver-shaped, persistent; limb in five deep oblique segments, Nectarles none. Anthers lanceolate, within the tube, bursting lengthwise, unconnected with the stigma. Follicles two, cylindrical. Seeds fringed, bearded at each end.

This genus consists of trees, often of great height, with milky juice. Leaves either whorled or opposite, ribbed, smooth. Cor. terminal, panicled. Flowers for the most part white. Follicles generally very long. They grow in the East Indies, the Malay Archipelago, and the Society islands. *Alstonia* has little affinity to *Echites*, (see that article,) with which Linnaeus would probably not have confounded it, had he examined the fruit, or attended to the figure in the Hort. Malab., of which work indeed he had not a copy. *Brown*.

A. tuba. Americana. Pala; Rhode Hort. Malab. 81. t. 45, not 46. - Leaves several in each whorl, obovate-oblong, obtuse, ribbed, surrounded with a marginal vein. Cymes stalked. Limb of the corolla but partially bearded. Follicles very long and slender. - Native of Malabar and the Molucca islands, in sandy ground, flowering in January. A very tall and spreading tree, whose whole wood, Rumphius tells us, is used by school-boys in India, as flates with are us. The leaves are from five to seven in each whorl, flaked, with numerous, parallel, transverse veins, or ribs. Cymes many-flowered, compound, spreading, downy. Flowers small, about half an inch long, white, sweet-scented, but offensive to the head. Corolla downy on the inside and out, but not densely bearded, or faggery, except around the mouth. Follicles eighteen inches long, not so thick as a wheat straw. Seeds furnished at each end with a tuft of very long silky hairs.

2. A. spectabilis. Handsome Alstonia. Br. n. 2. - "Leaves four in a whorl, elliptic-oblong, ribbed, somewhat pointed, without any marginal vein. Cymes stalked, shorter than the leaves. Limb of the corolla bearded. Follicles very long." - Observed by Mr. Brown, in April 1803, in the island of Timor, near Coepang, bearing flowers and fruit. Very nearly akin to the foregoing, but distinct; not ill-represented by Rumphius's plate, t. 82, but his description agrees best with A. spectabilis. Brown. We would observe, that the number of the leaves in this figure agrees best with spectabilis, and that the omission of the marginal nerve, so little conspicuous in nature, is rather to be attributed to inaccuracy of the engraver, if not of the draughtsman.

3. A. venenata. Poisonous Alstonia. Br. n. 3. - Leaves four in a whorl, lanceolate, pointed; tapering at the base. Cymes forked. Tube of the corolla swelling upwards. Limb bearded, shorter than the tube. Follicles tapering at each end, scarcely so long as the leaves. - Native of the East Indies. Dr. Roxburgh. We received a specimen from the Rev. Dr. Rottler, gathered at Nundydroog, March 17, 1806. The leaves are crowded towards the ends of the branches, flaked, very smooth, three inches or more in length. Flowers like those of a Tabernanthea, their limb an inch broad, with oblong, oblique, rather blunt than acute segments; tube an inch and a half long, inflated in the upper part, very smooth, as well as the limb. The calyx is a little downy, or fringed. Flowers-flaxen quite smooth. We have not seen the follicles.

4. A. cotata. Ribbed Alstonia. Br. n. 4. - (Ethites cotata; Forlk. Prodr. 22, excluding the synonymy. Willd. Sp. Pl. v. 1. 1240.) - "Leaves opposite, elliptic-oblong, pointed, ribbed. Cymes loofe. Segments of the limb lanceolate, bearded, longer than the tube. Follicles very long." - Native of the Society isles. Forlker. Gathered by Sir Joseph Banks in Otaheite and Ulietane, between the summits of hills (called by the natives Attahi). Brown. We presume the plant, not the hills. A moderate-sized tree. The seeds are fringed, but, according to Mr. Brown, the silky hairs at each end are not remarkably elongated as in other species. Rsetiiti-Valii, Hort. Malab. v. 9. t. 14, is a climber, having short follicles, with winged naked seeds, and therefore cannot, as Forlker thought, be synonymous with this.

ALTAY MOUNTAINS. See ALT.

ALTERNANTHERA, in Botany, so called by Forlker, from the flanes being, as he thought, alternately furnished with anthers, and without them. - Forlk. Egypt. Arab. 28. Brown Prodr. Nov. Holl. v. 1. 416. - Clas

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, coloured, pointed, spreading, permanent, and finally hardened, segments. Cor. none. Stam. Filaments five, capillary, shorter than the calyx, inserted into a membranous ring, surrounding the base of the germen, with more or less remarkable intermediate teeth; anthers simple, oval, of one cell, generally wanting on two or three of the filaments alternately. Pet. Germen ovate, acute; style very short; stigma capitulate. Peric. Capsule membranous, involucrally kidney-shaped, compressed, of one valve and one cell, in fluted, not burfting, enclosed in the cartilaginous calyx. Seed solitary, roundish, pointed.

Obf. Mr. Brown properly retains the name of Illecebrum, (see that article,) for I. verticillatum and its allies, from which we can scarcely separate I. Paronychia, &c. He would divide the present genus, which agrees very nearly in habit with Illecebrum, into two sections. Thence we shall here adopt, according to his suggestion, for the distribution of the species.

Sec. 1. Two of the filaments deprived of anthers. Intermediate teeth very short, or obsolete.

1. A. feliflora. Selfiele-flowered Alternanthera. Fork. Egypt. - Arab. 28. (Illecebrum feliflora; Linn. Sp. Pl. 500. Mant. 345. Willd. Sp. Pl. v. 1. 1209. Ait. Hort. Kew. v. 2. 61. Vahl Symb. v. 2. 22.) Amaranthoides humble madaripatanum, capitulis candicantibus, folio mollii; Pluk. Phyt. t. 133. f. 1. Amaranthus humilis, folis oppositis, flofculis in alis conglomeratis; Bum. Zeyl. 17. t. 4. f. 2. - Calyx smooth; segments ovate, pointed, almmost twice the length of the capsule. Leaves elliptic-lanceolate, nearly entire, bearded at their inflorescence. Stem procumbent, hairy on two opposite sides. - Native of Arabia and the East Indies. A biennial, or perhaps annual herb, whose branching stems spread on the ground, in every direction, to the length of a foot or more, and are leafy, bluntly quadrangular; the opposite furrows densely hairy. Leaves opposite, flaked, spreading or reflexed, from one to two inches long, bluntish, nearly or quite entire, single-ribbed, smooth, bright green, rather fleshy. Flowers short, bearded, and connected by intermediate stipulate bristles. Heads of flowers sessile, axillary, solitary, obtuse, half an inch, more or less, in length, white and shining, like everlastings flowers. Calyx single-ribbed, strongly keeled, pellucid. Capsule broadly heart-shaped, finely reticulated. The leaves occasionally vary to an obovate, or spatulate figure.

2. A. dentiulata. Toothed Alternanthera. Br. n. 1. - Calyx smooth; segments ovate, pointed, almmost twice the length of the capsule. Leaves narrow-lanceolate, finely toothed, smooth; bearded at their inflorescence. Stem procumbent, smooth. - Gathered by Mr. Brown in the tropical part of New Holland, as well as in New South Wales, and Van Diemen's island. We have seen no specimen.

3. A. nodiflora. Knotty-flowered Alternanthera. Br. n. 2. - Calyx smooth; segments narrow-lanceolate, pointed, thrice the length of the capsule. Leaves linear-lanceolate, finely toothed, smooth; bearded at their inflorescence. Stem diffuse, square, smooth; its ultimate branches only downy on two opposite sides. - Discovered by Mr. Brown, in the tropical district of New Holland. These three species appear to be all nearly allied.

4. A.

5. A. nana. Dwarf Alternanthera. Br. n. 4.—Calyx smooth; segments ovate, slightly pointed, twice the length of the capsule. Leaves ovate-oblong, hairy; tapering at the base. Stem diffuse, hairy.—Found in the same country as the last, by Mr. Brown.

Sect. 2. Five of the Filaments with perfect anthers; five intermediate ones connective, without any.

6. A. Achyrantha. Creeping Alternanthera. (Illecebrum Achyrantha; Linn. Sp. Pl. 299. Willd. Sp. Pl. v. i. 1268. Ait. Hort. Kew. v. 2. 61. Achyrantha repens, folis bliti pallidi; Dill. Elth. 8. t. 7. f. 7.)—Stem creeping. Leaves ovate; densely downy when young. Calyx with somewhat spiny points.—Native of Buenos Ayres, from whence it was sent to Sherard, before the year 1732. We have specimens from the Paris garden. There is reason to doubt whether Linnaeus ever saw this species. The root is perennial. Stems prostrate, from one to two feet long, repeatedly forked, leafy, moss hairy at opposite sides, creeping by means of fibrous radicles from their lower joints. Leaves flaked, from one to two inches long, entire; nearly smooth, and of a bright green, when full-grown; the young ones covered on both sides with dense, itary, hairy hairs, such as compose the pubescence of the flmen, and especially of the younger branches. Heads small, from the forks of the stem, partly flaked, round, of few flowers. Calyx brownish-white; segments three-ribbed, unequal, strongly keeled, partly hairy, accompanied as it seems occasionally with smaller smoother scales.

7. A. polygonoides. Perficaria-leaved Alternanthera. (Illecebrum polygonoides; Linn. Sp. Pl. 300. Willd. Sp. Pl. v. i. 1208. Ait. Hort. Kew. v. i. 61. Hernia hirufata repens, ad nodos alternos florida; Browne Jam. 184. Amaranthoides humile curassavicum, folis polygoni; Horm. Pur. 17, with a figure. Sloane Jam. v. i. 141. t. 86. f. 2. A. marina hirufata, halimi folio; Plum. 1c. 12. t. 21. f. 2.)—Stem creeping, hairy. Leaves elliptic-lanceolate, tapering at the base, flaked, all smooth. Calyx ovate, single-ribbed, unarmed; hairy at the base.—Native of South America. A smaller plant than the preceding, except the flowers; with longer, much narrower, leaves smooth at every period of their growth, on long stalks. Calyx of a brilliant white; its segments ovate, pointed, but not spiny, the mid-rib less prominent than in the foregoing; the base only beft with conspicuous hairs. Plummer's plant fearely requires to be called a variety. The stem indeed is represented more hairy than it appears in our gardens, but it is always more or less so, and the hairs are always simple, not feffile like those of A. Achyrantha.

8. A. ficoides. Ribbed Alternanthera. (Illecebrum ficoidesum; Linn. Sp. Pl. 300. Willd. Sp. Pl. v. i. 1208. Comphrena ficoides; Linn. Sp. Pl. ed. i. 225. Jacq. Amer. 88. t. 60. f. 4.)—Stem creeping, smooth. Leaves ovato-lanceolate, tapering at the base, flaked. Calyx lanceolate, unarmed, three-ribbed, hairy at the back.—Native of South America. Cultivated by Linneas at Upsal. Jacquin's figure more resembles the last, closely matching with Browne's specimen, which indeed Dr. Solander, who first it to Linnaeus, marked Comphrena ficoides; but the latter found it to be his own Illecebrum polygonoides. The plant before us, from the Upsal garden, is a truly distinct species, with broader leaves, an inch and a half or two inches long, roughish with callos points; a smooth stem; and very different flowers. The segments of the calyx are much narrower, brown at the base, with three strong ribs, and clothed at the back, more than half way up, with prominent hairs; their points are tapering, but not spiny.

Mr. Brown speaks of some American nondefcript species, referable to this section. Whether the following be among them we know not, but they appear to be nondefcript.

9. A. villosa. Woolly-branched Alternanthera.—Stem decumbent, hairy; flaggy at the joints. Leaves ovate, flaked, nearly smooth. Calyx ovate, single-ribbed, smooth.—Sent to Linnaeus by Thouin, from the Paris garden, without any mention of its native country. Stems above a foot long, with ascending very hairy branches, bent at each joint. Leaves an inch or more in length, bluntish, dotted, rarely beaklined with a few long hairs. Footstalks accompanied, above their insertion, with very dense filipinous tufts, of long flaggy hairs, jointed, like all those on the stem and foliage. Of the flowers we have seen only one small axillary head, apparently not come to perfection, but its gluane are evidently unlike all the preceding, broadly ovate, even and smooth, acute but not spiny, with a simple mid-rib.

10. A. echinata. Prickly-headed Alternanthera.—Stem prostrate, hairy. Leaves roundish-ovate, smooth. Calyx spiny-pointed; outer segments lanceolate, elongated, partly three-ribbed, smooth; two inner shorter, gibbous, hairy at the back.—Gathered by Commerfon at Monte Video, and sent by Thouin to the younger Linnaeus. This remarkable species is among the largest we have seen. The leaves indeed are not above an inch long, but they are nearly as much in breadth, tapering at the base, their surface dotted with little points, not hairy. Heads ferial, axillary, somewhat aggregate, globose or oblong, pale brown, filiming, distinguished by the length and sharp thorns of their three outer calyx-segments, one of which is strongly three-ribbed, and by the tufted hairs of the two inner ones, projecting very conspicuously between them.

ALTMIKLIC, in Commerce, a Turkish silver coin = 60 paras.

ALTON, in America. Add.—The town contains 1279 inhabitants.

ALTUN-KUPRI, or the Golden Bridge, a town of Peria, in the pachalic of Bagdad, about the size of Kupri, (which see,) situated on a fine plain, on the northern bank of the Little Zab, 32 furlongs from Moful.

ALUMINA, in Chernifly, an earthy sublance, described as elementary, but which Sir Humphrey Davy has rendered probable to be a compound of a metallic basis with oxygen. See ALUMINUM infra.

We have little to add to the description of alunina, except the curious fact observed by Saufrure, that this sublance does not give out the peculiar earthy smell which has been considered as characteristic of it, except it is mixed with ozyd of iron.

ALUMINA, Salt of, the compounds formed by the different acids with alumina. By some accident, the description of most of the facts of alunina has been omitted. We shall therefore take the opportunity of introducing them here.

Nitrate of Alumina. See NITRATE OF ALUMINA. Carboneate of Alumina. The excellence of this salt has been usually admitted by chemists. Bergman, however, could not form it artificially, though he allows its existence, because when alun is mixed with an alkaline carbonate, most of the alunina remains in solution till the carbonic acid be driven off. Saufrure has more recently shown, that water saturated with carboonic acid is capable of dissolving alunina, but that this combination is destroyed by simple exposure to the air. Carbonate of alunina therefore, cannot exist in a dry
Dry Alum. What had formerly been considered as dry carbonate of alumina is a triple compound of alumina, carbonic acid, and the alkali employed in precipitating the alumina. This fact may be formed by saturating phosphoric acid with alumina. According to Fourcroy, who is the only chemist that has examined it, the phosphate of alumina is a tafteless powder, insoluble in water. When dissolved in excess of phosphoric acid, it yields a gritty powder and a gummy solution, which by heat is converted into a transparent glass.

Sulphate of Alumina. See Alum and Sulphate of Alumina. In addition to what has been said in previous articles, we may add the following analysis of alum by Vauquelin, Thenard and Roard, and Berzelius.

The analysis of Berzelius is probably most accurate, and is equivalent to

- Sulphate of alumina: 36.85
- Sulphate of potash: 18.15
- Water: 45.00

Total: 100.00

Which nearly coincides, according to Dr. Thomson, with three atoms of sulphate of alumina, one atom of sulphate of potash, and twenty-three atoms of water.

According to the experiments of Thenard and Roard, alum usually contains a little sulphate of iron, and the goodness of its qualities as a mordant in dyeing, according to these chemists, depends entirely upon the proportion of that salt present. The more free it is from it the better. The purest alum examined contained about 1% by weight of sulphate of iron; the impurest about 2%. When freed from sulphate of iron, every species of alum tries acts exactly in the same manner as a mordant.

Sulphate of Alumina. See Sulphite of Alumina.

Borate of Alumina. This salt may be formed by mixing together the solutions of borate of soda and sulphate of alumina. It is said to be scarcely soluble in water.

Arseniate of Alumina. See Arseniate of Alumina.

Tungstate of Alumina. A white powder, insoluble in water.

Acetate of Alumina. See Acetate of Alumina.

Benzoate of Alumina. This salt crystallizes, is soluble in water, and deliquesces on exposure to the air.

Succinate of Alumina. Wenzel flutes, that this salt crystallizes in prisms, and is easily decomposed by heat.

Carmelinitate of Alumina. This salt may be formed by heating together newly precipitated alumina and camphoric acid. It is a white powder, of an acid bitterish taste, and slightly astringent. Water dissolves about 1/4 th part of its weight of this salt; it is not soluble in boiling water, but separates as the water cools. Cold alcohol dissolves very little of it; but by the assistance of heat that fluid takes up a considerable quantity, which separates on the cooling of the alcohol. This salt undergoes but little change from the action of the air. Exposed to heat the acid volatilizes; and when this salt is thrown on burning coals it takes fire, and burns with a blue flame.
famous for its manufacture of leather; and it is also a
mart of commerce between Isphahan and Bagdad, and
between Bagdad and Tekroun. N. lat. 35° 51'. E. long. 48°.

AMADIA. Add.—This town does not contain above
600 houses; but the plain, at the foot of the hill, is covered
with dependent villages. It is nominally dependent upon
the pacha of Bagdad, but pays him no tribute.

AMANDA, a township of Ohio, in the county of Fair-
field, having 435 inhabitants.

AMANITA, in Botany, aurea, an old Greek name
for Fungi in general, is used by Haller, after Dillenius, for
the whole Lumnian genus of AGARICUS, (see that article,)
or nearly so. Perfoon adopts it for such species only as
are furnished with a velutus, which, on that account, he
considers generally distinct. —Perf. Syn. Fung. 245.—Clas and

Eff. Ch. Stalk with a wrapper at the base. Head fleshy.
Gills crowded, nearly undivided.

Obf. The head is generally warty, and the flake elongated,
either naked, or furnished with a ring. Perfoon describes
eighteen species, partly wrong numbered, all which, being
more or less remarkable, and some of them very much so,
we shall in order enumerate, with the addition of one.

Sect. 1. Stalk surrounded at the base with a distinct wrapper,
but distinct of a ring at the top.
(Agaricus plumbeus; Schaff. Fung. v. 4. 37. t. 85, 86.
Bulliard t. 512. f. M, according to Perfoon.)—Head
bofled, flattufh, fririated, livid lead-coloured. Gills white,
as well as the long flake.—Not uncommon in autumn, as
mutter, about the skirts of woods, and borders of fields.
The wrapper burfts irregularly. The flake is hollow, and
rather long in proportion, about twice the diameter of the
head, which is protuberant and brownish in the middle, grey-furfurated and fririated at the margin. Some individuals
are much thicker than others. Schaff. gives a good repre-
sentation of the various flakes and forms of this species.
The head is sometimes fluid with angular warts, at least
when young, as represented by Battarra, Leucomycetes gen-
neris, Batt. Fung. Arizm. 28. t. 6. f. 1. commented highly
in Withering; and by Micheli, t. 78. f. 2. These figures
exhibit a flake and habit of the plant, the reverse of what
is found in the Fl. Dan. and especially in Bulliard. This is
generally allowed to be a poisonous fungus. Some varieties
are indicated by Perfoon, one with yellowish gills, Schaff.
t. 244; and another with a browner head, and tapering flake,
found in dry woods, which feems to connect the prent
with the following species.

Meth. 66. (Aagaricus badius; Schaff. Fung. v. 4. 63.
t. 245. With. v. 4. 227. A. fulva; ib. t. 95. A. vagi-
natus; Bulliard t. 512. f. N.)—Head somewhat bell-shaped,
bofled, fririated, brittle, orange-brown. Gills white.

Stalk pale brown, fically.—Found in dry woods, about Auguf,
in various parts of England and Germany. Akin to the
foregoing, but much more delicate in texture. We should
fearfully think it more than a variety.

(Aagaricus incarnatus;巴斯. Elech. Fung. 51.) Fungus
magnum eculetum; e volv crumens, pleolo vollofo
albo, lamellis carneis, pediculo cylindrico glabro, pariter
albo; Mich. Gen. 182. t. 76. f. 11; not f. 2 as Perfoon has it.)
—Head hemipherical, white, hairy. Gills fleth-coloured.

Stalk white, cylindrical.—Found by Micheli, on old half-
decayed trees, in the woods of Viareggio near Florence, in
June. No other botanit feems to have met with this fungus;
at least not in the flate defcribed by Micheli. He reprofe-
fes it of very large dimensions, the head full fix inches broad,
while in its convex flate, and covered with fine hairs. Wraper
much divided and jagged, tumid. Stalk fix inches high,
smooth, thick, and very ftraight.

Albertini and Schweinfurth, in their very learned Conferent
fungorum, 142, fpoke of what they deemed a variety of this,
whole head is frotein, fearcely bearing any minute fibref or
fakes, by no means hairy or ftraggly. Every other part
agrees with Micheli's account. The undifplayed gills are
white, fonr affuming a very fliaggy-colour from the fernal
powder. Head never becoming quite flat; the border
neither furrowed nor fririated.

18 and 66. (Aagaricus volvaceus; Bulliard t. 262. Sowerby.
Fung. t. 11. With. v. 4. 286. Rell. Cant. 507. A. latus;
With. v. 4. 231?)—Aggregate. Head conical-bell-shaped,
foomewhat hairy, grey flecked with black. Gills reddifh-
cinnamon-coloured.—This occurs chiefly on the rotten tan
of hot-beds, in summer. The flake is often a foot high,
flander in proportion, of a dirty white, burfting from a
large pale-olive wrapper. Head about three inches broad,
fplitting into ferior unequal portions. Perfoon eftimates
Scheaffer's Aagaricus bonvinius, t. 98, as a mercen-
ary, var. of the above, with a yellowifh wrapper, and a
fliaggy-coated head. Dr. Withering diftingullihes between
the plants of Bulliard and Sowerby. The latter is certainly
Reshau's.

v. 2. 36. t. 4. f. 4. 5. (Aagaricus volvaceus minor; Bull.
t. 330. not 530.)—Head hemipherical, bofled, pellucid,
of a pearly white, somewhat cottony. Gills fleth-coloured.

Stalk white, rather longer than the breadth of the head.—
Native of gardens and woods in autumn, in a fomewhat
exposure. Bulliard. We have not heard of this pesics in
Britain. Its appearance is elegant and delicate. Head an
inch, or inch and a half, in diameter. Wrapper turbine,
much divided, permanent.

Sect. 2. Stalk proceeding from a lax wrapper, and fur-
riated at the upper part with a ring.

113. Perf. n. 6. (Aagaricus bulbofus vernus; Bulliard t.
188. Fungus totius candidus, pelloso amplus, glutine
limacino infcto, pediculo tenui cylindrico, annulo dirie-
tor minor; Mich. Gen. 173? at the speciation of La-
marck.)—Pure white in every part. Head at length con-
core, somewhat funnel-shaped. Ring pendulous. Stalk
elongated, folid, cylindrical.—Common in woods in France
during the fpring. Bulliard fays many persons have died
from eating this fungus by miftake for the white-gilled
variety of the Common Mushroom. It may be kept in the
mouth for eight or ten minutes, before its acrimony, refem-
bling pepper, becomes perceptible. If the wrapper at
the base be attended to, the plant can never be confounded
with any eatable Agaric.

7. A. parvula. Purple Egg-Agaric. Albert. and
Schweinfurth. Conip. 142. n. 401. t. 11. f. 1.—Head con-
vex, naked, smooth, of a livid parfth-brown. Ring nearly
of the fame colour. Gills and flake white.—Not rare in moif,
turfy, mossy spots, in fir woods more efpecially, over which
it is flattered in September and October. Habit of A.
viridis, n. 9, but only half the size. Stalk three or four
inches high, too dark-coloured in the figure. Head almoft
as much in breadth, never found with warts; very rarely
and slightly fririated at the margin.

Pp Albert.
AMANITA.

—Frequent from spring to the end of autumn, in rich soil, in woods, gardens, about hot-beds, &c. Its size is considerable. Bulliard speaks of his plant as having a very agreeable flavour, and therefore we presume it to be one of the eatable fungi. In the fourth of France it is known by the name of Aeger orange blancs; to distinguish it from the A. orange orai; see n. 11. The bulbous base of the nearly solid stalk is a characteristic mark. The ring is broad, loosely pendent, permanent. Head almost hemispherical, rarely with a slightly indicated bobs. Schaeffer's plate is too much coloured. The gills, if not absolutely white, are semi-pellucid, or watery, in their appearance.

—This is described as not frequent on the continent, in beech or oak woods, where the ground is sandy. Whether it be found in England, we are doubtful. Mr. Sowerby has exhibited in his t. 286, a pale yellow variety of Agaricus muscarius, see n. 13, for Schaeffer's cirrata; but this is not quite conclusive to us. Perfon cites Agaricus Mappa, Willd. Berol. 381. Batch. Elench. 57, as a variety of the present Amanita, distinguished by a darker colour of the head, and yellow gills: he speaks also of brownish warts on the head. Wildenow says the gills of his plant are whitish. Albertini and Schweins, accurate practical observers, say, "we find the warts upon the head not very rare. The ring, and frequently the stalk, is distinguished by a palef lemon-colour. The whole fungus is sometimes half a foot high, in which case the head is four inches broad, or more." Perfon notices apparently a still different variety, on rotten trunks of trees, distinguished by its elegant sulphur-colour, flattish head, and acid flavour.

10. A. viridis. Green Egg-Agaric. Perf. n. 9, not 8. Difp. Meth. 67. Albert. and Schwein. Consp. 143. (Agaricus viridus: Bulliard t. 2, and t. 577. Fungus phalloides annulatus, fordivévirecens et patulos; Vail. Parif. 74. t. 13. f. 5.)—Head convex, dull green, mottly naked. Stalk and gills white. Found in sandy moist shady woods, from August to October, in France and Germany. The wrapper is inflated, whitish. Head four or five inches broad, convex, not biffed, of a more or less bright green, variegated occasionally with brown, and turning olive-brown in decay, when, according to Bulliard, it exhalates an intolerable cadaverous smell, being a very dangerous species, though when young destitute of any bad scent or flavour. The head sometimes retains fragments of the wrapper, in the form of warts or broad patches, but this feems far from being universal or frequent.

—Native of Italy, France, Carniola, Bohemia, &c., but never observed in England. The wrapper is white, with a dilated entire border. Stalk hollow, nearly cylindrical, yellow-white, or pale yellow, from four to six inches high. Head from four to six inches wide, almost hemispherical when young, of a rich deep orange, smooth and naked, fiercely ever warty, striated near the edge, turning brownish or purplish in fading, as in Schaeffer's figure, where it is drawn somewhat biffed, which we have never seen. The gills are usally of a delicate lemon-colour, as well as the ring. Perfon rightly suspected his A. cefarea and aurantiaca not to be distinct species; they do not appear to us to be even varieties, Schaeffer's plant being only in a more forward state than Bulliard's. We retain the oldest specific name, which is that of Scopoli. It serves to commemorate an historical fact, that the emperor Claudius was murdered by poison given with this fungus, to which the Romans applied the name of Boltaus, and which Nero called "the food of the gods," because Claudius had eaten it, who was subsequentlly, like his faced companions, become a god! The Agaric before us is esteemed the most delicate and alluring of all fungi. The writer of this has examined and eaten it in Italy, where it is far from rare in summer, though so much in request, as to find a place chiefly at the tables of the great. Cluflus tells of his supposing some few, at a distinguished man's table in Hungary, made of this fungus, to have been coloured with saffron. Dr. Withering has confounded Schaeffer's plate with Agaricus sceramphilus of the same author, v. 4. 49. t. 214. Sowerb. Fung. t. 31. With. v. 4. 214. Hence he was led into the further mistake of supposing, as his A. sceramphilus, though eatable, is strong and disagreeable, that Agaricus delicatus was what Claudius feated upon. The latter is indeed a very favoury food, but defined to the vulgar in France and Italy, being by far more abundant than our Amanita cefarea. The oversight committed by Dr. Withering, respecting this famous fungus, and his own, as well as Schaeffer's, Agaricus sceramphilus, is the more remarkable, as the latter has neither a wrapper nor a ring. Such errors are rare in this excellent writer. Mr. Sowerby has avoided the same mistake, though he has not explained it. We decline citing Ervila Cerronius, Battar. Fung. Arimtn. 27. t. 4, C, because no ring is there expressed; but we do not doubt the identity of the plant.

Sect. 5. Stalk with an obliterated wrapper at the base, and a ring at the upper part. Warts on the head small, and generally equal. To this section Perfon gives the name of Myopera, because some of the species are used for killing flies. All of them perhaps are dangerous.

12. A. muscaria. Fly Egg-Agaric. Perf. n. 12, not 11. Albert. and Schwein. Consp. 143. (Agaricus muscaria; Linn. Sp. Pl. 1642. Hudf. 612. With. v. 4. 184. Schaff. Fung. v. 4. 13. t. 27, 28. Sowerb. Fung. t. 286. A. pseudo-aaurantiacus; Bulliard t. 122. Fungus bulbosus, c evolva crumempus, pileolo purpureo parte aureo, ad oras fibrato, inferno, et annulato pediculo, albis, radice bulbosa: Mich. Gen. 188. t. 78. f. 2. Fungi lethales: Ger. Em. 1851, fig. on the left, at the bottom.)—Head scarlet, shining, convex, at length flattish, variously bifiected with white warts. Gills, ring, and stalk pure white. Wrapper with scarcely any remaining border. —Common in woods in autumn, especially under fir-trees. A large species, conspicuous for the splendid orange-red hue of its fattin-like head, contrasted with the stalk and gills, and with the prominent angular white or cream-coloured warts, scattered, more or less abundantly, over its surface. These warts are formed from the wrapper, torn off close to the base of the stalk, which Bulliard well observed, as a specific mark between this and our last. It is highly important to discriminate them, A. muscaria being venemous in a great degree. When dry, it renders milk poisonous to flies and bugs, killing them very expeditiously; for
for which purpose it is preferred in some countries all the year round. Bulliard records, that he ate two ounces of this fungus raw, without any harm whatever, though he found it fatal when given to cats or dogs. Perfoon mentions a variety by the name of *A. formosa*, whose warts were loose and yellowish, the disk likewise being yellowish, very long, and loosely scaly. Also another, called *A. puella*, which is smaller, mostly naked, or only bordered with the warty substance; this is Schaffer’s t. 28. Dr. Withering reduces the two following, perhaps, to the same family; but so many authors have kept them separate, especially Albertini and Schweinicz, that we shall follow Perfoon in the same measure.

15. *A. umbrina*. Brown Warty Egg-Agaric. Perf. n. 13. not 12. Albert and Schw. Comp. t. 143. (Agaricus verrucosus; Hudf. 613. Curt. Lond. fac. 5. t. 72. A. maculatus; Scheff. Fung. v. 4. t. 96. Fungus muscaris, intericens fucus, maccul albis; Buxh. Halleni. 131.)—Head of a footy or tawny brown, flatish, varnishly fluided with white warts. Gills, ring, and stalk white. —More common than the preceding, but often accompanying it, in dry sandy woods, fields and pastures, especially under beech-trees, through the autumn. Withering, Curtis, and Lightfoot consider this as a mere variety of *A. muscaria*, differing in the brown colour of its head, often tinged with yellow, or faintly with red. The size of the whole plant is usually somewhat smaller. We have made no particular observations on this subject. Colour in this tribe often affords good specific characters, and we should, moreover, be careful in all the departments of natural history, not to be led away by any one very peculiar mark, like the warts in the present instance, to consider every thing, that has such a mark, as one species. Even Linnæus often fell into this error. We know not how the question is to be decided respecting these fungi, their artificial propagation by seed being attended with so much difficulty. It is sufficient that we here register their names and distinctions, under the correction of any person who may find good reasons for uniting them. The poisonous quality of *A. umbrina*, with respect to flies, is acknowledged in the above synonym of Buxbaum. Curtis however found the base of the stalk to be the favourite food of a non-descript species of *Tippula*, smaller than the *plumosum*, whose larvae soon devour that and every other part of the plant.

14. *A. rubescens*. Bluish-coloured Egg-Agaric. Perf. n. 14. not 13. Albert and Schwein. Comp. t. 144. (Agaricus pulchellus; scheff. Fung. v. 4. t. 91.)—Head convex, opaque, reddish. Warts crowded, white like the gills. Flesh turning red when broken. —Native of beech woods in Germany, in autumn. We know nothing of its occurrence in Britain, for Dr. Withering’s fifth variety of the *muscaria* may probably be different from what is before us. Albertini and Schweinicz affert that the head and stalk invariably turn red, sooner or later, after being broken, and that this is a pure specific trait. The head seems more convex than that of *A. umbrina*. Its hue, according to the authors just quoted, is occasionally reddish, livid, smoky, or inclining to a liver-colour. Stalk two inches high. *Taste* scarcely any. We conceive this to be distinct from both the foregoing, whatever may be the case between them with regard to each other; and its usual appearance is very elegant, owing to the delicate tawny heath-colour of the head, studded with copious white, or pale flesh-coloured, warts. Perfoon has a variety under the name of *cirrata*, for which he cites with doubt *Agricus myelles*, Scheff. Fung. v. 4. t. 261. This character given by Perfoon is, “Head hemispherical, somewhat umbilicated, reddish. Warts oblong, whitish, circularly disposed. Gills flatish, whitish. Stalk bulbous, scaly, the colour of the head.” He adds that the stalk is two inches long, solid, always perforated by worms (or insects) at the base. *Gills* obovate, sometimes decurrent in a tooth-like form. Substance reddish, under the cuticle. *Taste* not unpleasant. It occurs, but rarely, in woods during autumn. Schaffer’s figure exhibits a most elegant bluish-coloured fungus, internally red, when cut, to which we can have no hesitation in considering one species with Perfoon’s *cirrata* and *rubescens*.

15. *A. viscosens*. Greenish Egg-Agaric. Perf. n. 15, not 14.—“Head fibrous, flat, pale-green. Warts thick, whitish, with many angles. Stalk white, thick, with a bluish tinge.” —In woods, but extremely rare. *Stalk* three or four inches long, clothed with soft bluish scales. *Wrapper* nearly obliterated. Substance of the head pungent, from four to six lines in thicknefs, not unpleasant to the taste.

17. *A. aperta*. Rough-headed Egg-Agaric. Perf. n. 17, not 16. Obs. Mycol. v. 2. 38. ("Agricus apfer; Abbild der Schwämme, fac. 3. with a plate." A. verrucosus; Bulliart t. 316. A. myedes; Bolt. Fung. v. 4. t. 139; excluding both synonyms.)—Head hemispherical, fibrous, compact, darkly red, rough with crowded pointed warts. Gills white, rounded. *Stalk* rather bulbous. —Not rare in woods, about July, August, or September, growing diversified. It has been observed in Germany, France, and England. Perfoon says the scent is powerful; Bulliard, on the contrary, describes this species as inodorous, with a faint tinge, partaking but little of a mushroom flavour, and he prefigures it to be poisonous. This author judiciously adverts to the affinity of his plant to our *Amanita muscaria*, observing that it is white or reddish under the skin, never, like the *muscaria*, yellow. Perfoon in his excellent Obs. Mycol. gives the following account. "Head at first ovate, inclining to cylindrical; when expanded six inches broad, half an inch thick, compact in substance, strong in scent, often streaked with white at the margin, from cracks in the cuticle. Warts small, erect, pointed. *Gills*, as usual with this genus, thin, unconnected. *Stalk* from four to six inches high, solid, marked towards the base, with little scaly warts, like ridiments of the wrapper. *Ring* sometimes almoat obliterated, and hanging in fragments to the edge of the head."

The wrapper in all the species of this third section is, indeed, so closely united to the base of the stalk, as to constitute a kind of bulb, but there is a marginal dilatation, less visible in *A. aperta* than any other, which evinces the true nature of the part in question. This species, though generally so very convex, even hemispherical, appears by Bulliard’s plate, to assume a concave cup-shaped form in advancing towards decay.

AMARANTHUS, the 3th natural order in Jussieu’s system, being the first of his seventh classes. See NYCTAGINACEAE for the characters of this clafs. The following are the characters of the *Amaranthi*.

*Calyx* divided, more or less deeply, often surrounded by scales at the base. *Stamen* definite, sometimes distinct, sometimes monadelphous; in some genera there are scales alternate with the filaments; in others the combined fila-
ments form a tube or sheath. *Germ*en simple; style or stigma simple, or double, or triple. *Capsules* of one cell, with an unconnected receptacle, and either bursting at the summit, or splitting all round, containing one or many *seeds*. The *corolla* is curved round a farinaceous mass. *Flowers* capitate or spicate. *Leaves* generally undivided and pointed; in some alternate; in others opposite; in a few infestations accompanied by *filaments*. *Stem* for the most part herbaceous. *Stamens* and *filaments* sometimes in separate flowers.

Sec. 1. *Leaves alternate, without filaments.*

Under this division Jussieu enumerates *Amaranthus* and *Celosia* of Linnaeus; with *Auros* of Forkell, a genus formed of alternate-leaved species of *Illecebrum*; and *Digeria* of the same author, to which *Achyranthes maritima* of Linnaeus is supposed to belong.

Sec. 2. *Leaves opposite, without filaments.*

*Consists of* *tejina, Achyranthes, Gymnorea, and Illecebrum.*

Sec. 3. *Leaves opposite, with filaments.*

*Under this section are ranged Paronychia of Tournfort, separated from the Linnaean Illecebrum; and Herniaria of all authors.*

This order, as Jussieu candidly observes, is very nearly related to that of the Caryophyllaceae, which, on account of its having petals, he is obliged to place in a far distant part of his system. He remarks, on this subject, that the absence or presence of a corolla does not always afford an essential, or eminently natural, distinction; which is very true, but there is no character of natural orders without some exception, and hence Linnaeus was led to deny the possibility of defining really natural orders by words, or any essential characters.

Jussieu, in the Annales du Musum, v. 2, 151, has published some additions to the present order, which, according to a recent alteration, and perhaps an improvement, in the nomenclature of natural orders, he there terms *Amaranthaceae.*

A translation of his paper may be seen in Sims and Konig’s *Ann. of Bot.* v. 2. 274. The author here makes but two alterations of the order in question, one having named, the other filipared, leaves. To the first he adds a new genus by the barbarous name of *Papafis,* founded on the Linnaean *Achyranthes lappacea,* called in Rheede’s *Hortus Malabaricis,* v. 7, t. 43, *Papaf-Valli.* Of this we are surprised to find Jussieu had never seen the fruit, and we cannot but observe that its generic characters are rather weak, being chiefly taken from the infertility of the fruit and bracts.

To the section with filipared leaves, this eminent botanist adds three new genera. 1. *Ancyela* of Michaux, to which belongs *Queria canadensis* of Linnaeus. 2. *Lithophila* of Swartz. 3. *Polychna* of Loureiro. The last two are already described in their proper places. See also *Queria.*

Jussieu proceeds to remark, that *Cytisus* of Loureiro, a plant of this order, is really an *Achyranthes* with a many-clft stigma; but that *Pola* of the same author, (see that article and *Hageia,*) supposed to belong to the *Amaranthi,* is really one of the Caryophyllaceae.

**VOL. II.**

**Amboise, Ambaria, or Ambacia, in Geography, a town of France, in the department of the Indre and Loire, and chief place of a canton in the district of Tours, situated at the conflux of the Loire and Amasse. The place contains 5100, and the canton 14,415 inhabitants; the territory comprehends 3224 square kilometres, and 16 communes.**

**AMDOA,** in *Geography.* See *Thibet.*

**AMEDNAGUR, l, I., Subah, now called Downabad. Add—This city has generally been placed 50 miles to the S.E. of its true position.**

**AMELIA,** l. 3, including r. exclusive of; l. 6, r. 15,594 and 7160. Add—Nottaway contains 9278 inhabitants, of whom 3468 are slaves.

**AMENTACEAE, in Botany, of which term mention has already been made in its place, as designating a Linnean natural order, is also the appellation of the 95th order in Jussieu’s system, the fourth of his fifteen classes; corresponding for the most part, though not entirely, with that of Linnaeus, and so called from *Amentum,* a Catkin, in allusion to the nature of its fructification. See *Euphorbeae* for the characters of this fifteen classes of Jussieu, and remarks thereon. He thus defines his *Amentaceae.*

Flowers monoecious or dioecious, (rarely with flaments and filaments in the same,) all distinct of petals. The male, or barren, flowers dipped in a catkin, conflating either of scales, into which the flaments are inserted, or each of those scales has a calyx attached to it, which bears the flaments. The latter are either definite, or indefinite, with distinct flaments. (We would here observe that two or three species of *Salix* are remarkable for their combined, or monadophalous, filaments.)—The female, or fertile, flowers are either amentaceous, or falciculated, or solitary; sometimes furnished with a single-leaved calyx, sometimes with only a scale. The *germen* is superior, either simple, or in some rare instances more than one, of a certain determinate number. *Sepals* one or more. *Stigmas* generally several. *Seeds* either naked, or enclosed in superior *capsule,* which are either of a coriaceous or bony texture, as many in number as the germens, and for the most part of a single cell. *Corolla* definite of *alumina,* with a straight radicle. *Stem* arborescent, or shrubby, rarely of humble growth. *Leaves* alternate, accompanied by *filaments,* mostly simple.

Sec. 1. *Flowers with flaments and filaments.*

Here Jussieu ranges *Fothergilla, Ulmus,* and *Celtis,* of which the two latter are placed by Linnaeus among his *Segetal.* *Hamamelis,* which the last-named author has, in manuscript, referred to his *Amentaceae,* and which is rarely next akin to *Fothergilla,* is reckoned by Jussieu among his *Berberidae,* or at least among several genera supposed related to that rather miscellaneous order.

Sec. 2. *Flowers dioecious.*

This contains *Salix, Populus,* and *Myrica.*

Sec. 3. *Flowers monoecious.*

A larger assemblage of genera, if not of species, consisting of *Betula, Carpinus, Fagus, Quercus,* *Corylus, Liquidamber,* (under which last the genus now called *Comptonia,* see that article, is hinted at,) and *Platanus.* There is no appendix of doubtful genera, as in most other orders of Jussieu, but a suffusion is expressed respecting *Liquidambare,* and *Platanus.*

The *Amentaceae* of Linnaeus are, *Salix, Populus, Platanus, Stanaea,* with a just indication of doubt, *Fagus, Juglans, Quercus,* *Corylus, Carpinus, Betula, Myrica, Piptaden,* and *Cymnornis.* *Brachium* is, in the Linnaean manuscript, inserted immediately before *Fagus*; *Hamamelis* before *Betula,* after which *Brachium* is again written; an evident indication of great uncertainty in the mind of the writer, who knew this genus but imperfectly, and who had conceived no idea at all of the order *Proteaceae,* to which it clearly belongs, and which makes so striking a figure in the works of Jussieu; and especially of our countryman Mr. Brown. See *Prod. Nov. Holl.* v. 1, 363, and *Tr. of Linn. Soc.* v. 10.

**AMERCOTE, in Geography, a fortified place, which formerly belonged to the country of Scind, but is now in the possession of the rajah of Jundapore. Situated S.E. of Hydrabad, and about 25 miles from the eastern branch of the Indus.**

AMERICA,
AMERICA, North. See United States.

AMES, a township of Ohio, in the county of Athens, having 618 inhabitants.

AMESBURY, a town of the Massachusetts, in Essex county, having 1890 inhabitants.

AMHERST, (1) 3, r. 15,548; (2) 4, r. 5207. Add—Alfo, a town of Massachusetts, in the county of Hampshire, having 1496 inhabitants.

AMIA, in Ichthyology, a genus of the abdominal fishes, the characters of which are, that the head is bony, naked, rough, with conspicuous futures; teeth, both in the jaws and palate, close-fet and sharp; the two cirri near the nostrils; the gill-membrane twelve-rayed; and body scaly. There is one species, <i>Calva</i>; the Carolinian Amia, with a black spot at the base of the tail. This is a small fresh-water fish, inhabiting some parts of Carolina. Described by Linneus, from a specimen lent from Carolina by Dr. Garden.

AMITY, in Geography, a township of Pennsylvania, in the county of Berks, containing 1090 inhabitants.

AMMODYTES, in Ichthyology. Add—The ammodytes tobianus is the lance with the lower jaw longer than the upper. It conceals itself about a foot in the sand, with its body rolled into a spiral form; it is dug or drawn up, and used by the fishermen as a bait; it is also considered as a delicate article of food. The general length is from eight to ten inches. The lance lives on worms, water-insects, and small fishes, and even occasionally on those of its own species. It is itself preyed upon by the larger fishes, and particularly by the mackerel. It spawns in the month of May, depositing its eggs in the mud near the edges of the coast. The swimming bladder is wanting, so that the animal is fitted only for a littoral residence; and its scales are so small that they have been wholly overlooked, and their existence disputed by some ichthyologists. Shaw.

AMMONIA, in Chemistry. The following additions to our knowledge, respecting the volatile alkali, have been made since that subject was treated in the Cyclopaedia. Water, as has been already stated, by absorbing ammoniacal gas increases in bulk and becomes specifically lighter. The following table by Mr. Dalton exhibits the quantity of ammonia contained in ammoniacal solutions of different specific gravities.

</table>

When potassium or sodium is heated in ammoniacal gas, the metal becomes changed to an olive-green colour, and loses its metallic lustre; at the same time a portion of the gas is absorbed, and a quantity of hydrogen emitted, exactly equal to the quantity that would be evolved if the potassium or sodium were put into water. If the olive-green matter be heated, it gives out three-fifths of the ammonia absorbed, two-fifths in the state of ammoniacal gas, and one-fifth in the state of hydrogen gas and azote. Sir Humphrey Davy, having heated the olive-coloured matter strongly in a platinum tube, obtained nearly the whole of the ammonia absorbed, though about three-fifths of it were in the state of azotic and hydrogen gas. If the olive-coloured matter be placed in contact with a very little water, it is converted into potash, or soda and ammoniacal gas, and the gas is just equal to what the metal had absorbed. If it be placed in contact with a metal and heated, an alloy of the metal with potash or sodium is obtained.

For these curious facts we are indebted to Gay Lussac and Thenard, and Davy. Dr. Thomson thinks they shew that potassium and sodium have the property of decomposing ammonia, and combining with its azote, while the hydrogen of the ammonia is set at liberty; and the azote or the formed, he thinks, combines with a portion of the remaining undecomposed ammonia. He acknowledges, however, that there are some objections to this opinion; and the facts accord better with the opinion, that an unknown compound of azote and hydrogen unite with the alkaline metal, while the compound thus formed combines with a portion of undecomposed ammonia.

A curious experiment made by Berzelius and Pontin induced Berzelius to draw the conclusion that ammonia is composed of an unknown metallic basis, which he has called ammonium, united to oxygen. This experiment has been since confirmed by Sir H. Davy, Gay Lussac, and others, and is as follows:

When mercury is brought in contact with ammonia at the negative end of a galvanic battery, it gradually increases in volume, and is converted into a soft solid, having all the appearances of an amalgam. The experiment succeeds better if gal ammoniac lightly moistened be sublimated for liquid ammonia. This amalgam, at the temperature of 70° or 80°, is a soft solid, of the consistence of butter; at 92° it is a firm crystallized mass, having a specific gravity below 3. When exposed to the air, it soon becomes covered with a crust of carbonate of ammonia. When thrown into water, hydrogen is evolved equal to half its bulk, the mercury is revived, and the water becomes a weak solution of ammonia. When confined in a given portion of air, the air increases in bulk, and pure mercury appears. Ammoniacal gas, amounting to 1/2 or 1/4 of the volume of the amalgam, is evolved; and a quantity of oxygen equal to 1/3 or 1/4 of the ammonia disappears. When thrown into muriatic acid gas, it becomes coated with muriate of ammonia, and a little hydrogen is disengaged. In sulphuric acid it becomes coated with sulphate of ammonia and sulphur. All attempts to preserve this amalgam failed, from the impossibility of obtaining it free from water. When put into a glass tube, or when confined under naphtha or oil, the mercury separated, ammonia was formed, and a quantity of hydrogen evolved.

Gay Lussac and Thenard considered this amalgam as a simple compound of mercury and ammonia; but no analogous compound is known to chemists, as mercury when it unites to other substances, except metals, always loses its metallic lustre. There are reasons induced Berzelius to form the above opinion. Most chemists at present agree with Gay Lussac and Thenard; but if their opinion be well founded, we must alter the notions entertained respecting amalgams.

The
The opinion at present entertained respecting the composition of ammonia is, that it is composed of three volumes of hydrogen and one volume of azote condensed into two volumes. Hence its specific gravity compared with that of common air is .590; 100 cubic inches at a mean temperature and pressure weigh 18 grains, and the weight of its atom is 21.25; that of oxygen being considered as 16.

Ammonia, Salts of. These have been omitted in the usual place, namely, under Ammonia; but most of them will be found in a subfrequent part of the work, under Salts. Those deferred elsewhere will be referred to here, and those remaining to be described will be now noticed.

Sulphite of Ammonia. See Sulphite of Ammonia.

Chromate of Ammonia. This salt may be formed by saturating chronic acid by ammonia. It usually exists in the form of dendiratic crystals of a fine yellow colour. When slightly heated, it is decomposed, even when in solution, brown flocks of chronic oxyd precipitating.

Arseniate of Ammonia. See Arseniate of Ammonia.

Malodity of Ammonia. This salt diffuses readily in water. The solution does not crystallize. When heated, the ammonia is partly driven off, partly decomposed, and the acid is reduced to the state of an oxyd.

Tungstate of Ammonia. This salt may be formed by diffusing tungstic acid in carbonate of ammonia. It is soluble in water, and crystallizes. Its taste is metallic, and it is entirely decomposed by heat.

Beryllate of Ammonia. This salt crystallizes with difficulty. It deliquesces, and is very soluble in water. It has been recommended by Berzelius as an excellent re-agent for precipitating iron from its solution. It throws down this metal of an orange colour, and occasions no insoluble precipitates with any of the other bases, except tellurium and mercury, and perhaps copper, all of which are thrown down white.

Succinate of Ammonia. See Succinic Acid. This salt has also been much recommended for precipitating iron when in the state of peroxide.

Camphorate of Ammonia. This salt may be prepared by diffusing carbonate of ammonia in hot water, and adding camphoric acid slowly till the alkali is saturated. It crystallizes with difficulty; it is sparingly soluble in cold water, but much more soluble in hot. It is completely soluble in alcohol. Most of the calcareous salts form triple compounds with this salt.

Citrate of Ammonia. See Citrate of Ammonia. The remaining salts of ammonia are so totally devoid of interest, or so little known, that we do not think it necessary to enumerate them.

Ammyrsine, in Botany, a new genus of Mr. Pursh's, more happily circumstanced in its characters, perhaps, than in its name. The latter is formed from amuros, sand, and μυρίς, a dwarf myrtle; but Myrtilus, being an established generic name, cannot, with propriety, make a part of another. Linnean law, (see Phil. Bot. fei. 225,) and good sense, are both against it; and if some similar innovations have, from peculiar causes, crept in, they are not to be imitated, though for the present they may be tolerated. The genus in question is founded on Ledum bacciferum, (see Ledum, n. 3,) and stands in the Clasf and Order Pen- tandra Monogynia, in Mr. Pursh's Flora 280 and 301, agreeing, of course, in Natural Order with Ledum. The following are its characters.

Calyx in five deep segments. Petals five. Stamens prominent. Capsule of five cells, bursting at the funnicht. Marum is characterized.

Calyx minute, five-toothed. Corolla flat, in five deep segments. Capsule of five cells, bursting at the base.

Ammonias, Liquor of the, Chemical Properties of. The peculiar acid principle termed by Vauquelin and Buniva amniotic acid, does not appear to exist during all the periods of gestation in the liquor amnii of the cow. Dr. Prout examined this fluid taken from an animal which had been slaughtered in an early period of her gestation, but was not able to detect any of the acid in question. See Annals of Philosophy, vol. v. p. 416.

Amomum, in Botany, a name of the Greeks, most probably derived from its Arabic denomination hlaminda, as De Theis writes it, is the ancient name of a fort of aromatic grain, or fruit, included, according to all appearance, among the species of the present Amomum of botanists. (See our former article, where this genus comprehends a much more extensive range of species than are now understood to belong to it.) Linneus, and his immediate followers, included under Amomum almost every plant of the Scitamineae that they knew not how otherwise to dispose of; and Gartner, though he altered the name for the worse, to Zingiber, (fee that article,) threw no new light upon the characters or history of the genus, but rather, like every body else, added to their confusion. Mr. Roxfe first defined this genus, like the rest of the Scitamineae, as the reader will find under that head, by a clear distinctive character; and while he greatly reduced the number of species, rendered the whole perfectly clear and intelligible.

Gen. Ch. Cal. Perianth superior, of one leaf, tabular, flatting, membranous, coloured, splitting at one side about half way down. Cor. of one petal; tube shorter than the calyx, cylindrical, erect; outer limb in three nearly equal, oblong-lanceolate, concave, erect segments much longer than the calyx; inner of one large, undulated lip, with a short concave claw. Stam. Filament one, rather longer than the tube, clawed, flag, flowered, defreeved, somewhat incurved, with a lanceolate, acute, ascending lobe, about half its own length on each side, at the base, and a pair of similar, erect or transverse, lobes, forming a crest at the summit, with either an intermediate prominence, or a notch; anther of two distinct, elliptic-oblong, lobes, attached by the back, below the summit. Pijel. German inferior, small, roundish, somewhat furrowed; style thread-shaped, lying close to the filament, between the lobes of the anther; stigma funnel-shaped, fringed, erect, projecting a little beyond the filament. Peric. Capsule either ovate-oblong, or nearly globular, of three cells, and three coriaceous, somewhat furrowed valves; the partitions membranous. Seeds numerous, oblong, roundish, or slightly angular, each enveloped in a soft pulpy tunic, which becomes membranous, or evanescent, when dry.

One of the most natural genera that can exist, in any natural order, and the best defined in habit, as well as character.
character. The root is perennial, tuberous, jointed, and somewhat creeping, with long and deep fibres. Stems at least biennial, erect, simple, impressed with the sheaths of the two-ranked, simple, elliptic-oblong, flexed, vertical leaves. Spikes invariably radical, simple, rather lax, flexed, their filaments scaly. Bracteas large, concave, connate, more or less closely imbricated, single-flowered. Flowers large and handsome, white or reddish, remarkable for the broad, rounded, undulated, generally crenate lip, often yellowish at the base. Capsules large, with very numerous, in general powerfully aromatic, or very pungent, seeds. Every part of the plant is commonly aromatic. We have improved our knowledge of the fruit, and the nature of the tunic of the seeds, from Dr. Roxburgh’s observations in India. Garten speaks of the capule as not burbling, because he had chiefly examined specimens gathered before they were ripe, like all the Cardamoms of the druggists’ shops, some of which belong to the genus before us. The name able author has also mislaid the top for the bottom, in his figure called A. sylvestre.

We know not how it has happened that only one species of Amomum appears in Hort. Kew. A. Alphæi; and another, A. grandiflorum, (published long before) in the Addenda to that work. A. Granum-Paradisi, raised from seeds brought from Sierra Leone by Dr. Alphæus, has long been cultivated in England, though we have never heard of its flowering; and there are several more in the fame predication. They are flowes plants, requiring a considerable degree of heat. No collection perhaps is fo rich in this genus, or in the whole natural order, as that of the Botanic Garden at Liverpool, where the plants have every advantage of skilful cultivation, and where nothing that may occur, relative to their growth or history, can escape the eye of that illustrious witter and botanist, who first reduced them to order.

All the known species appear to be natives either of equinoctial Africa, Madagascar, or the East Indies; nor have we any from America, or the West Indies.

1. A. Cardamomum. Cluver Cardamom, or True Amomum. Linn. Sp. Pl. 2. Willd. n. 7. Loureir. Cochinch. 3. Retz. Obs. f. 3. 59. Rofc. n. 1. Roxb. n. 1. (A. n. 2; Linn. Math. Med. 1. A. verum; Ger. Em. 1548. f. 6. Amomum; Dale Pharmac. 277. Barrel. t. 1. c. 571. f. 1. Amomum legum decussati; Posa Baldo, 50. Cardamomum minus; Rumph. Amboin. v. 5. 152. t. 65. f. 1. Bent. Hist. Nat. 126, with a figure (the oblong capsule excepted, which belongs to Cardamomum medium of the shops). Zingiber minus; Gartn. t. 12. f. 6.)—Leaves lanceolate. Spikes lax, many-flowed. Bracteas lanceolate, acute. Lip three-lobed. Crest of three, nearly equal, erect lobes. Capsule globular. Native of the Malay islands, where the inhabitants use the seeds as a substitute for the Malabar, or Leffer, Cardamom. Dr. Charles Campbell sent plants from Sumatra to the Calcutta garden, where they blossomed in May, just before the rains begin. Roxburgh. Rumphius speaks of this species as cultivated plentifully, but not wild, in Amboyna and the neighbouring islands. It is certainly the true original Amomum of the shops, full to be met with at Venice and in other parts of the south of Europe, though generally supplanting the more valuable Leffer Cardamom, Amomum reginae of Sonnerat, which Linnaeus confounded herewith, and of which we propose to treat by the name of Elettaria hereafter. Nothing is more rare, with collectors of the Materia Medica, than the capsules of this A. verum in their native clusters or spikes. We were fortunate enough, after ranfacking the druggists’ shops at Marfellens and Venice, to meet with two or three such specimens, accompanied by bracteas, very important as determining the identity of this plant with the Linnean specimens of A. Cardamomum. By macerating the flowers of these last, we have also ascertained their structure, which agrees with Dr. Roxburgh’s account, the summit, or crest, of the filament being three-lobed. The lateral lobes are short and erect, not much elevated above the central one; neither are they tranverse, awl-shaped, and elongated, as in A. Alphæi, grandiflorum, and some others. The two lobes of the anther stand near the edges of the filament, remote from each other, but meet round the style. Dr. Roxburgh speaks of the flower-spikes as even with the earth. But however this may be, they are elevated above the root, each on a simple wavy spike, two inches long, clothed with sheathing, elliptical, ribbed, abrupt, barren scales. The spike is an inch or an inch and a half long, sometimes two inches when in feed, with many pale, smooth, imbricated, elliptic-lanceolate bracteas, near an inch in length, one to each flower. The perianth, calyx, and common receptacle, are hairy, or rather bristly. Capsule sessile, the size of a black currant, globular, somewhat depressed, obconically three-lobed, inflated, crowned with a blunt protuberant scar. Seeds roundish, angular, dotted, brown, aromatic and pungent, resembling in flavour the Elettaria, but less powerful, and rather less agreeable. The leaves of this species are rather narrower than in others of the genus, except perhaps the following; but our leading distinctions throughout must be taken from the bracteas, flowers, and fruit.

2. A. angustifolium. Greater Cardamom, or Madagascar Amomum. Sonneret. Ind. Or. v. 2. 242. t. 117. Willd. n. 6. Rofc. n. 2. Roxb. n. 2. (A. madagascariense; Lamark Dict. v. 1. 123. Cardamomum majus; Mattth. Valgr. 25. (but not Dale Pharmac. 276.) Camer. Epit. 11. f. 1. Barred. 1c. 1. 1. 3. 4. 12. the largest fruit. Grana Paradisi; Ger. Em. 1542, the figure, as being copied from Matthiolus, but not the description. (See also Bauh. Hist. v. 2. 204, and Lob. Inc. v. 2. 204, where the same error is committed, as well as in Chab. Strup. 128.)—Leaves lanceolate. Spikes capitate. Bracteas ovate. Lip obvate, undivided. Lateral lobes of the crest tapering, horizontal. Capsule ovate, pointed, inflated. Seeds globular, abrupt at the base.—Native of marshy ground in Madagascar, where it was first ascertained and figured by Sonnerat. It is cultivated in the Mauritius, and from thence was carried by captain Tenneur to the Calcutta garden, where it bloomed during the cool season. Dr. Roxburgh says, “the flowers poiffes a considerable share of spicif fragrance, and are showy, the upper bracteas, and exterior border of the corolla, being red, and the large lip yellow.” This writer terms the leaves broad-lanceolate, which does not answer to Sonnerat’s figure, name, or description, but perhaps this circumstance is variable. The flower-spikes rise above the ground, and are seven or eight inches high, clothed with tubular scales. Flowers in a short crowded spike, with a concave bractea to each, near an inch and a half long. The capsule and seeds we have already described, (see Mellettas,) where some other species are mentioned, which we shall here attempt to arrange systematically, but need not repeat the minute remarks there given.

3. A. macroperum. Large-seeded Gomes Amomum. (Zingiber Mellettas.) Gartn. t. 12. —Spikes capitate. Bracteas ovate, as long as the fruit. Capsule ovate, pointed, somewhat inflated. Seeds obovate, with a prominent, bordered, crenate scar.—Native of Sierra Leone, in the burying-ground of the settlement, from whence seeds were brought us by professor Alphæus; but having unfortunately...
unluckily not observed the plant or its flowers; nor gathered more than one capsule, he was unable to give us any further information than what these feeds afford. Their flavour is very slightly aromatic. Their lead-coloured hue is well noticed by Gärner, though his figure represents them scarcely half large enough. The bracteas appear twice the size of the leaf, to which unquestionably this specimen next akin. This is Amomum, n. 1. of professor Azelius’s MSS.
The natives call it Maboboos.

4. A. Clusii. Long-seeded Amomum. (Fruc tus 14: Clus. Exot. 37, 38, with a figure. Granas Paradisi, five Mellegetta affinis fructus; Banh. Pin. 413.)—Spikes capitata. Bracteas ovate, much shorter than the fruit. Capsule ovate, pointed, fruited. Seeds cylindrical, highly polished, with a bordered, crenate scar.—The native country of this species is unknown, Clusius’s specimen having been collected by an apothecary, who died in the course of his voyage, and left no memorandum respecting this point. (See Mellegetta for a description of a specimen, which we accidentally met with in a druggill’s shop, in a chell of Great Cardamoms, A. angustifolium, if we mistake not, and which therefore probably came from Madagascar.) The cylindrical, dark-brown, highly polished feeds, appearing as if varnished, clearly distinguish it from both the two last. The short bracteas in Clusius’s figure, unless the upper ones had been stripped off, afford a no less striking distinction. The seeds had only a flight pungency from the leaf. Those of our Great, as well as Chifter, Cardamoms, are as high flavoured as ever, though at least twenty five years old.

5. A. Grana-Paradisi. Grains of Paradise Amomum, or Mellegetta Pepper.—Spikes capitata. Bracteas ovate, rather shorter than the fruit; lower ones crowded. Capsule oblong, bluntly triangular, minutely hispid. Seeds ovate. Stipula entire, fringed. (See Mellegetta for the history and synonyms of this species.) The brown feeds, distinguished by a peculiar and very hot flavour, are very different from the following, and the bracteas have a short, thick, dorsal spine.

6. A. grandiflorum. Large-flowered Cardamom. Sm. Exot. Bot. v. 2. 103. t. 111. Ait. Epit. 363.—Spikes capitata. Bracteas elliptical, shorter than the fruit; lower ones dentate. Capsule oblong, bluntly triangular, minutely hispid. Seeds ovate. Intermediate lobe of the filament entire. Stipula cloven, smooth.—Native of Sierra Leone. Seeds, brought by professor Azelius, have produced flowering plants in England. The root is medicinal, woody, creeping. Leafy stems about three feet high, erect, round, smooth, very slender. Leaves several, elliptico-lanceolate, long-pointed, recurved, often tinged with red, very smooth: the long, narrow, polished sheaths each crowned with a somewhat cloven, rounded stipula, whole edges are quite smooth, not fringed with brilly hairs, as in A. Grana-Paradisi. Flower-flasks erect, two inches high, fruited, downy. Lower bracteas elliptical, concave, spreading, and so far distant that the flask is usually visible between them; upper much larger, though of a smaller proportion than those of our second or third species, and not above half so long as the flower or fruit, membranous, finely ribbed, fiercely spiny, somewhat coloured, permanent. Flowers in a short, dense, capitate cluster, large and handsome, whether fragrant or not we have no information, but when dried, and moistened again, they are highly aromatic. Calyx rose-coloured, above an inch long, with a blunt spreading point. Outer limbi of the corolla of the same hue, twice as long; lip of a broad rounded kidney-shape, waved, plaited, crenate, slightly notched, but not divided, nor deeply lobed, near two inches broad, white, with a yellow spot at the base. Stamens white, not half so long as the lip, furnished at the bottom with two awl-shaped divaricated lobes, and at the top with two nearly horizontal ones, of the same size and figure, having between them a central, short, rounded, quite entire lobe. The capsule is very like that of Grana-Paradisi, in size, shape, and pubescence. The feeds are also similar in size and shape to that species, but differ in being grey or lead-coloured, much less polished, and in having a totally different flavour resembling camphor, which they equal in warmth and pungency. As a stimulant, or cordial, these feeds appear equal to any Cardamom whatever. When the flowers of Grana-Paradisi become known, which is now one of our greatest botanical defiderata, there will probably be more distinctive characters discovered between that species and the present.

Ait. n. t. (A. exscapum; Sims in Ann. of Bot. v. 1. 548. t. 13.)—Spikes capitata, of few flowers. Bracteas shorter than the fruit. Capsule oblong, triangular. Stipula smooth? Intermediate lobe of the filament cloven.—For this also we are indebted to Dr. Azelius, who brought the seeds from Sierra Leone. From them Mr. Lodgeys at Hackney raised plants, which flowered in his roof in June 1804, and were described by Dr. Sims. The original name, exscapum, not being exactly correct, has been changed for one to which no lover of science or of personal worth can object. The leaves are as broad as the leaf, nor does the herbage of these plants in general afford many distinctive marks. We presume, from the figure, that the stipulas are smooth. The flower-flask, though not wanting, is much shorter than any of the former, and there seem to be no more than two external bracteas, besides some membranous ones close to the flowers, apparently left firm and durable than usual. The outer limb of the corolla is pale flesh-coloured. Lip rather more oblong, and plated lower down, than in the leaf, crease at the edges, white, with a yellow central spot. Stamens essentially different from A. grandiflorum, in having its middle lobe in two deep acute segments. What we have for the capsule of this species is ovate, pointed, triangular, nearly or quite smooth, rather larger than either of the two last. Seeds ovate, dark brown, highly polished, with a prominent-bordered scar, as in A. macroperum and Clusii, totally unlike the two foregoing. These seeds have scarcely any flavour, and are not at all aromatic. The flowers are fragrant only when dried, as in grandiflorum.

8. A. ferbatiflorum. Cone-bearing Amomum.—Spikes capitata. Outer bracteas numerous, elliptical, gradually larger upwards; floral ones scarcely longer, membranous, fruited, rough at the extremity. Stipula abrupt, nearly smooth.—Native of Sierra Leone, from whence we were favoured with a specimen by Dr. Azelius. This has very slender leafy stems. The leaves are elliptic-ovate, pointed, very smooth. Stipula rounded, scarcely cloven, very slightly, if at all, fringed. Flower-flasks several inches high, smooth, covered with numerous, imbriated, elliptical, very broad, concave, sheathing bracteas, gradually larger upwards, with broad dorsal points; the lowermost not quite an inch long, the upper two inches; all finely fruited, very smooth to the touch, of a bright chestnut colour when dry. Within the two uppermost are the proper bracteas, accompanying the head of flowers, much narrower, hardly at all longer, flatter, more membranous, hairy in the upper part, abrupt with a small point. Of the flowers we know nothing, nor are we certain of the fruit. The only unappropriated capsule of any Amomum, communicated from Sierra Leone.
by Francis Borone, (see the article RUTACEÆ) are those of A. n. 2. of Aizellus, called by the natives Moofi-aba, which are very likely to belong to the present plant, though we have no proof of it. These agree with the outer bracteas in colour and smoothness, and are ovate-oblong, nearly half the size of the leaf, with which their seeds very precisely accord, both in appearance and in want of flavour. Indeed they are so unlike, and such a coincidence between the seeds of different species of Amomum is so unusual, that we could almost presume the capsule above described for A. Azellii, might be a very large one of this n. 2. We do not however form any such conclusion, the seeds of A. Clerf, undoubtedly a distinct species from both these, having seeds precisely like them, only rather larger.

10. A. villosum. Rough-fruited Amomum. Loureir. Cochinch. 4. Wild. n. 8. Roxf. n. 5. (Globba crispa rubra; Rumph. Amboin. v. 6. 137. t. 61. f. 2.)—Spikes ovate, glabrous. Bracteas linear-lanceolate, elongated. Capsule globular, obscurely triangular, rough with scattered bristles. —Native of Java, Amboyna, and the Molucca islands, as well as of Cochinchina, in hilly situations. The seeds are exported in great quantities to China, for medical use, being, according to Loureiro, stimulant, warm and strengthening. The root is woody and creeping; its fibres aromatic. Leafy stems six feet (Rumphius says fourteen to sixteen feet) high, weak, erect, perennial. Leaves smooth. Flower-flalk four inches long, slender, reclining. Spike nearly ovate, with linear, imbricated bracteas. Flowers pale. Capsule nearly globular, half an inch in diameter, rather pulpy and sweet, reddish, clothed with numerous thick protuberances. Seeds angular, brown. The whole plant has an aromatic, but not powerful, odour. This description of Loureiro's is not suitable to the above synonym of Rumphius, to which he refers, except that the latter describes the roughness of the fruit as consisting of short flattened spines, or bristles.

11. A. nigrosum. Marth Amomum. Retz. Obs. fæce. 3. 56. Roxf. n. 6.—Cluter flaked. Bracteas ovate-oblong. Capsule globular, obscurely triangular, fagggy. Intermediate lobe of the filament in two rounded segments. —Found by Koenig at Raput-Nok, in Tranquebar, in shady wet situations, flowering about the middle of May. Leafy stems, a yard or more in height. Leaves smooth on both sides, with hairy flabellas. Flower-flalks somewhat curved, clothed with ovate-oblong, smooth, red feathers. Flowers white, variegated with red and yellow. Sixteen crowned with four lobes, the two lateral ones narrow and small, the two middle ones broad and rounded. Capdule clothed, before it is dried, with blood-coloured cirrhus, or threads. Koenig.

12. A. echinoïnum. Hedge-hog Amomum. Wild. n. 9. Roxf. n. 7. (Globba crispa viridis; Rumph. Amboin. v. 6. 137. t. 61. f. 1.)—Spikes capitate, nearly ffeilfe. Bracteas membranous. Capsule globose, all over spinous.—Native of Amboyna, the Molucca islands, &c. Rumph. Leafy stems, according to Rumphius, ten or twelve feet high. Leaves twenty inches long, of the breadth of four or five fingers. Fruit larger than that of A. villosum, always of a deep green, and armed with spines like a Thorn-apple, growing in dense feseilfe clusters or tufts at the root. We know nothing of this species but from Rumphius, for after much perplexity and consideration, we are decidedly of opinion that Amomum n. 2. of Koenig, Retz. Obs. fæce. 3. 56, cannot belong to it. See A. maxima hereafter.

13. Prickly Oval Amomum uterum. Roxb. n. 3.—Spikes obovate, on short flalks. Bracteas lanceolate. Crest of the filament abruptly three-lobed. Capsules oval, prickly. Leaves nearly feseilfe, lanceolate; heart-shaped at the base.—Native of the Malay Archipelago, from whence it was brought to the Calcutta garden, and flowers freely there in April and May, ripening feed in October. The capsule is perfectly destitute of grooves, and its coat of a soft flaky texture. Roxburgh.

14. A. maxima. Great Winged Amomum. Roxb. n. 4. (A. n. 2; Koenig in Retz. Obs. fæce. 3. 58.)—Spikes ovate, on short flalks. Bracteas lanceolate. Crest of one semi-lunar lobe. Capsules globose, with nine wings. Leaves flaked, lanceolate, villous beneath.—Native of the Malay Archipelago. Long cultivated in the Calcutta garden, where it blossoms in April and May, ripening feed in September and October. The flowers are nearly white, with a small tinge of yellow on the middle of the lip. The seeds have a warm pungent aromatic taste, not unlike the real Malabar Cardamom, (see L.B. A. Cardamom, but by no means so grateful. Roxburgh. The author appears to have confused himself between Globba crispa rubra of Rumphius, and t. 60, of that writer, but we readily agree with him, though not exactly for the reasons he gives, that neither of the synonyms belong to his A. maxima.

15. A. Rumphii. Angular-winged Amomum. (Globba longa; Rumph. Amboin. v. 6. 134. t. 60.)—Spikes ovate, on flalks three of their own length. Bracteas ovate. Capsule globose, with many angular-notched wings. Leaves flaked, smooth.—Native of valleys, and at the foot of mountains, in a cold, wet, clay, or fomy soil, throughout the Malay Archipelago, and all the eastern parts of India. The barren flaks are a yard high before they expand into leaves, after which they attain the height of twelve or fifteen feet. Leaves thin and smooth, two feet or two feet and a half in length, two palms broad. Flower-flalks a foot high, fealy, each bearing a dense, ovate, many-flowered spike, three or four inches long. Bracteas ovate, acute, reddish, spotted. Calys with a very long three-leafed tube. Corolla reddish externally, with a white lip, soon fading. Capsule nearly globular, with many unequal, yellowish, irregularly and sharply toothed wings. Seeds black, enveloped in a flivery pulp, of a gracefully acid flavour, very fragrant, but not acrid or aromatic to the taste. Rumphius.

We cannot reduce this plant to any of the species of Roxco, Roxburgh, or Koenig. We feel indeed great ceruples in referring the Amomum n. 2. of the latter to A. maxima, and shall therefore venture to propose it here as different, with that difference which must always attend the definition of a species taken up from description.

16. A. Kenngii. Single-fruited Amomum. (A. n. 2; Koenig in Retz. Obs. v. 3. 58.)—Spikes feseilfe. Bracteas ovate, membranous. Capsule solitary, globose, deeply furrowed, with intermediate wings, and somewhat tuberculated. Crest of three lobes; the middle one rounded, finely toothed. Leaves downy beneath.—Native of denfe woods in the East Indies. Leafy stems two feet high. Spikes or tufts of flowers feseilfe at the root, each perfecting but one capsule, the size of a large cherry, containing rarely more than nine seeds.

Although we have made out a far more ample list of species, of genuine Amomum, than has ever been attempted before, we are aware that several may yet exist, of which imperfect traces are to be found in various authors, so that it is more likely our number should be augmented than diminished by future enquiry. This genus ought perhaps to be divided into two families, the first with spikèd or racemose flowers, globose fruit, and angular feed; the second with capitulate flowers, ovate pointed fruit, and ovate or oblong, even feed. To the first belong A. Cardamomum and many
of our latter species; to the latter the Cardamom tribe, comprising the second and all after it to the eighth inclusive.

**AMPHIBOLE, or Hornblende.** See Mineralogy, Addenda.

**AMPHIGENE.** See Lecite.

**AMPHIPOGON,** in Botany, *147; and in 234, as having a beard, or awns, upon both valves of the corolla.—Brown Prod. Nov. Holl. v. 1. 175.—Clas and order, *Triandra Digynia.* Nat. Ord. Gramina.

**Eff. Ch.** Calyx of two nearly equal valves, single-flowered. Corolla of two valves; outer valve with three segments; inner with two; all the segments fleshy, awned, uniform.

A genus of grasses, growing in patches, with creeping roots, calciculated stems, and fleshy leaves. The flowers compose an equal spike, which sometimes assumes the form of a roundish head.

**Sec. 1. Spike capitatus.** Calyx smooth.

1. *A. Liguroides.* Hairless—tail Amphipogon.—Head globular. Calyx-glumes hirsute, with hairs dilated at the base; outer valve twice the length of its point.—Gathered by Mr. Brown, on the south coast of New Holland.

2. *A. turbinatus.* Turbinate Amphipogon.—Head obovate. Calyx-glumes clothed with hirsute hairs, simple at the base; outer valve feebly longer than its point.—From the same country.

**Sec. 2. Spike oblata.** Calyx smooth.

3. *A. Fritium.* Spiculiform Amphipogon.—Calyx-glumes linear, undivided, flunter than the smooth corolla. Awns and leaves fungous.—Found by Mr. Brown, near Port Jackson, New South Wales.

4. *A. dolichus.* Weak Amphipogon.—Calyx-glumes three-veined, flunter than the smooth corolla. Leaves fungous. Leaves rather ruffled.—Gathered by the same from the southern coast of New Holland.

5. *A. avenaceus.* Oat Amphipogon.—Calyx-glumes pointed, undivided, longer than the filik corolla. Awns spreading.—Native of the same country as the last.

We have seen no specimens, and therefore are indebted to Mr. Brown for all the above information. We would observe that this genus affords an exemplification of what specific characters ought to be, under the hand of a master, with nothing ambiguous or superfluous, but such a contrast of distinctions between all the species, as can leave no doubt in the mind of a student.

**AMPHORA.** Add—As a wine measure at Venice, contains 4 bigonias, and a bigoncia contains 4 quintals, 116 feet, or 256 lbs. peso grolo; but a bigoncia of brandy is only 14 feet, or 50 lbs.

**AMSTERDAM,** in Geography, an island in the Indian sea, lying in S. lat. 38° 42'. E. long. 76° 54'. This island is of volcanic origin, and fill in a state of inflammation. The great crater on the eastern side, now full of water, is by far the largest here, or, perhaps, elsewhere, and is of an astonishing size, considerably exceeding in diameter the confines of Etna or Vesuvius. Its length from N. to S. is upwards of four miles; its breadth from E. to W. about 24 miles; and its circumference 11 miles, comprehending a surface of about eight square miles, or 5120 acres, almost the whole of which is covered with a fertile soil. The island is inaccessible, except on the east side, where the great crater forms a harbour, the entrance into which is deepening annually, and might, by the aid of art, be made fit for the passage of large ships. The tides run in and out at the rate of three miles an hour, and rise perpendicularly eight or nine feet on the full and change of the moon. Their direction is S.E. by S., and N.E. by N. A northerly wind makes the highest side. The water is eight or ten fathoms deep almost close to the edge of the crater. The sea supplies this island with excellent fish, particularly a kind of cod, and eel-fish in abundance. Nevertheless, sharks and dog-fish, of uncommon size, were very numerous in the same place. The penguin, distinguished by the name of *Chrysoptera,* having large yellow feathers, forming two semi-circles over the eyes, like eyebrows, is found here in great abundance. Of the larger birds, here are also several species of the albatrosses, and also the large black petrel, or "procellaria equinocoli" of Linnaeus; the blue petrel, or "procellaria Forsteri," and the florny petrel. The small albatross, of the feathered tribe, inhabiting or visiting this island, was the silver kind, or "flæna lurindר," about the size of a large swallow or swallow, with a forked tail. The island St. Paul's, lying to the northward of Amsterdams, presented no very high land, or any rising in a conic form. In fr George Staunton's Embassy to China, we have a view and plan of the island of Amsterdam, and of the great crater on its eastern side.

**AMUL,** an ancient city of the Persian empire, in the province of Mazanderan, situated in an agreeable plain at the foot of a mountain, on the banks of a river, and celebrated for a handsome bridge of twelve arches, an old fortress, and a palace of Shah Abbas the Great.

**AMURATH (or MURAD) III.** In Biography, succeeded his father Sultan Beem 11. in 1573, coniiging his reign with casting his five brothers to be strangled in his presence. His reign was eventful in military transactions; and we shall be impartial in telling the story, if the Turkish historians. Amurath contributed to the election of Stephen Batteri, as king of Poland; and this circumstance favoured his own designs against Persia. The invasion of this empire by the Turks began in 1578, and, after much slaughter, terminated in Amurath's possession of Taurus, and three contiguous provinces of Persia. The Krim Tartars, who revolted from the Turkish dominion, were reduced. In 1590, Amurath being at peace with the other powers declared war against the emperor of Germany, which was the cause of much devastation and bloodshed; and the Turks triumphed in the capture of the important town of Raab, in Upper Hungary. During this war, Amurath died, in January 1596, at the age of 52. Christian authors represent him as of a mild disposition, a lover of justice, zealous in his religion, and a friend to temperance and order. Mod. Univ. Hist.

**AMURATH (or Murad) IV.,** surnamed Ghazi, or the Valiant, was son of Achem I., and succeeded his deposed uncle Mustapha in 1622, in his 13th year. He left Bagdad at the beginning of his reign; and after many unsuccessful attempts to retake it, he marched, in 1637, at the head of a numerous army, and after thirty days continual assault, and an immense loss of lives, formed the place. On this occasion he shewed the brutal ferocity of his temper, not only by driving on his men with a feytemor to the attack, but by slaughterings 30,000 Persians who had surrendered at discretion after the capture of the town. It is said, that the only peron who escaped was a famous herm- player, who requested the executioners to permit him to speak to the sultan before his death. When introduced to the sultan, and ordered to give a specimen of his powers, he touched his instrument so sweetly, accompanying the strains with pathetic lamentations on the tragedy of Bagdad, and artful praises of Amurath, that the tyrant was so
ANAGNORISIS. See Catastrophe.

ANALCIME. See ZEOLITE.

ANALYSIS, in Chemistry. The analysis of minerals, including earths, stones, and the ores of metals, and the analysis of organized bodies, or vegetable and animal substances, have been omitted; we shall, therefore, introduce a summary account of these subjects here, and at the same time endeavour to supply what has been omitted under other analogous heads.

Analyses of Minerals.—The particular methods of analysing different minerals and ores are given under their respective heads: our object here is to give a summary view of chemical analysis in general, a subject often referred to in the Cyclopaedia, but which has been unaccountably omitted.

"The progress," says Dr. Thomson, "which the art of analysing minerals has made within these last thirty years is truly astonishing. To separate five or six substances intimately combined together, to exhibit each of them separately, to ascertain the precise quantity of each, and even to detect the presence of the weight of substances which do not approach the five-hundredth part of the compound, would, at no very remote period, have been considered as a hopeless, if not an impossible task; yet this can now be done with considerable accuracy."

Margraff of Berlin was the first who undertook the analysis of minerals. He was followed by Bergman and Scheele, who very much improved this department of chemistry. The indefatigable and ingenious Klaproth succeeded, to whom the present improved state of the analysis of minerals is more indebted than to any other individual. To Vauquelin and Berzelius likewise we are much indebted, as well as to many other eminent living chemists.

Minerals of a saline nature, and soluble in water, may be analysed by the methods pointed out in the article WATER, Mineral Analyst of.

Hard flinty minerals are first to be reduced to a flake of powder. When they are extremely hard, they may be heated to redness, and then thrown into cold water, which will cause them to crack and fly to pieces; and this process may be repeated, if necessary. The mineral is then to be reduced to a coarse powder, in a steel or agate mortar (see Laboratory); and when thus reduced, a given weight of it, 100 grains for example, is to be reduced in a similar mortar (one of agate is preferable) to an impalpable powder. The powder, after this operation, will be generally found heavier than before, owing to the abrasion of the mortar; and this addition in weight is to be carefully noticed, and accounted for. If the mortar employed was agate, the addition in weight may be considered as fictitious.

Cruccibles of platinium and silver, evaporating dishes of glafs or porcelain, and other apparatus and requisites, will be necessary for the subsequent process, all which are described under the article Laboratory above referred to.

In the classes of minerals commonly denominated stones and earths, the ingredients usually met with are, silica, alumina, zirconia, glucina, lime, and magnesia; and the oxids of iron, manganese, nickel, chrome, and copper. Seldom more than four or five of these, however, enter the composition of a mineral at the same time; though, to avoid repetition, we shall suppose them all to exist at once.

When a mineral of the above description is to be analysed, 100 grains of it in fine powder are to be mixed with three times their weight of pure potash and a little water, and then introduced into a silver crucible, and exposed to a red heat for upwards of half an hour. Care must be taken to stir the mixture well till all the water be driven off, left, by the ebullition, any of the compound should be forced out of the crucible.

From the appearances presented during this step of the operation, some conjectures may be usually formed respecting the nature of the stone, so as to afford some assistance in the future steps of the analysis. If the matter melts completely, it may be concluded that the mineral is chiefly siliceous.
ANALYSIS.

Siliceous. If it remains thick and opaque, the other earths are more abundant. If it assumes the form of a pulverulent bulky white powder, the stone is mostly argillaceous. If the colour be full green or brownish, oxyd of iron is present. A bright green-grases indicates the presence of manganese, and yellowish-green chrome. When a stone is aluminous and very hard, potash acts very feebly upon it; and in this case, borax was used with great advantage by Mr. Chenevis.

The crucible being now removed from the fire, and cleaned externally, is to be placed in a porcelain capsule, and filled with water; and this is to be repeated till the whole of the matter is separated. A portion of the compound of potash, with the filex and alumina of the mineral, is taken up by the water, which would indeed dissolve the whole if added in sufficient quantity.

The detached matter is then to be dissolved in muriatic acid; at the commencement of the solution, an abundant precipitation takes place of a flocculent matter, which had been held in solution by the alkali, with which the acid combines. Then an effervescence takes place from the decomposition of the alkaline carbonate formed after and during the fusion, and at the same time the precipitate is redissolved. The portion of matter also not dissolved by the water, and which had remained at the bottom in the form of a powder, is dissolved; this not being attended with any effervescence, if it be alumina or filex; but if it contains lime, an effervescence takes place. If the muriatic solution be colourless, we may conclude that it contains very little or no metallic oxyd. If its colour be purplish-red, it is a further proof that manganese is present; orange-red indicates iron; and golden-yellow, chrome.

This solution is now to be evaporated to dryness upon a sand-bath, in a flat porcelain vessel loosely covered with paper. Towards the end of the operation, the fluid becomes gelatinous, and requires to be constantly flitted with a silver or porcelain rod, to facilitate the disengagement of the water and acid, and to render the exsiccation uniform throughout the whole. If this precaution be not observed, there is a risk of a portion of the alumina, from which the acid has been expelled, remaining with the filex; and with the alumina of a portion of filex being retained in solution; by the acid on account of its not being sufficiently diffipated.

When the matter is almost reduced to the form of a dry powder, a large quantity of distilled water is to be poured upon it; the whole is then to be gently heated, and thrown upon a filter. The powder remaining on the filter is to be washed with water, until the last portions added give no precipitate with solution of silver. This powder is filex. It is to be carefully dried between folds of blotting paper, exposed afterwards to a red heat, and weighed while warm. It ought to be a fine white powder, insoluble in acids. If it be coloured, the presence of a metallic oxyd is indicated, which is a proof that the heat towards the end of the evaporation had been raised too high. To remove this oxyd, the powder is to be boiled with an acid, and afterwards washed and dried, and the liquor must be added to the filtered fluid above-mentioned.

The solution is then to be evaporated till its quantity does not exceed an English pint. A solution of carbonate of potash is to be poured in, till no further precipitation takes place; and in order to render the precipitation more complete, the whole should be boiled for a few minutes. When all the precipitate has collected at the bottom, the supernatant liquor is to be decanted off; and water being substituted in its place, the precipitate and water are to be thrown upon a filter. When the water has passed through, the filter with the precipitate upon it is to be placed upon some folds of fabulous paper; and when the precipitate has attained a little confluence, it is to be carefully collected with an ivory knife, and mixed with a soltion of pure potash, and boiled in a porcelain crucible. If any alumina or glicina be present, they will be diffolved in the potash, while the other substanices remain untouched in the form of a powder.

The solution of alumina in the potash is to be super-saturated with an acid, that is, so much acid is to be added as is sufficient to redisolve any precipitate that may be formed. Carbone of ammonia is then to be added in excess, so as to be feible to the smell. This will precipitate completely the alumina, if any be present, while the glicina will remain in solition. The alumina is to be collected on a filter, washed with distilled water, and then dried at a red heat, and weighed. To determine if it be really alumina, diffuse it in sulphuric acid, and add a sufficient quantity of sulphate or acetate of potash; if it be alumina, the whole of it will be converted into crystals of alum. If glicina be present in the remaining liquor, it will fall down on boiling it for some time, so as to displace the excess of ammonia. After being washed and dried as before, it is to be accurately weighed.

The matter remaining undifolved by the solution of potash above-mentioned may conftit of lime, magnesia, yttria, and the metallic oxyds. If yttria be fufpected, add carbonate of ammonia, which will diffuse the yttria, and leave the other bodies. Then let the whole be dissolved in dilute sulphuric acid, and the soltion be afterwards evaporated to dryness, so as to displace any excess of acid. A little water is to be added to the solid refiduum, which will take up the metallic sulphates and the sulphate of magnesia, but leave the sulphate of lime, which is to be dried at a red heat, and weighed; and from its weight the quantity of lime present may be readily estimated. The substanices retained in solution by the sulphuric acid may be magnesia and the oxys of iron, manganese, chrome, and nickel. To separate thes, the soltion is to be diluted with a large quantity of water, a flight excess of acid added to it; and then a soltion of carbonate of potash faturated with carbonic acid is to be poured in. The oxys of iron, chrome, and nickel, will be precipitated, while the magnesia and manganene will remain in solution with the carbonic acid. To separate thes, hydro-sulphuret of potash well faturated with sulphured hydrogen is to be added to the soltion, which will precipitate the manganese in the flate of hydro-sulphurets, while the magnesia will still remain in solution. The magnesia may then be separated by a soltion of pure potash, and its weight estimated after it is washed and dried at a red heat. To obtain the weight of the oxyd of manganese, its precipitate must be calcined with the admission of air to expel the sulphured hydrogen.

There still remain to be separated the oxys of chrome, iron, and nickel. To do this, the precipitate is boiled in succeffive portions of nitric acid, to bring the oxyd of chrome to the flate of acid. It is then heated for a few seconds with potash, and after being heated the liquid is poured off. The undifolved matters are to be washed with water, which washings are to be added to the other liquid. The chrome acid remains in solution combined with the potash; muriatic acid is added to it, to ad be in excess; and is then evaporated until it affumes a green colour. If pure potash be then added, the oxyd will be precipitated, and it may thus be collected, and its quantity ascertained.

The undifolved matter of the preceding experiment may conftit of the oxys of iron and nickel. To separate them, they
they are dissolved in muriatic acid, and ammonia is added in excesses. The oxide of iron will be thus precipitated, and its weight may be ascertained. The excess of ammonia will remain the oxide of nickel in solution, which may be lastly obtained separately by driving off the ammonia by heat.

When the different constituent principles of a fossil have been thus obtained separately, their united weight ought of course to be equal to the original weight of the fossil itself. If they correspond, or differ only by .03 or .04 of a part, we may conclude that the analysis has been properly performed. But if the loss of weight be considerable, the analysis must be repeated; and if the result be still the same, it may be concluded that the stone has contained some principle either volatile or soluble in water, which must, therefore, be sought for. A proportion of the stone being broken to pieces, is first to be exposed to a strong heat in a retort of porcelain, to which a receiver is adapted. If it contains water, or any other volatile substance, this will be collected in the receiver, and its nature and quantity may be ascertained. But if it fail to have any loss by this operation, or a loss not equivalent to the loss indicated by the analysis, it is probable that it contains some substance soluble in water.

To ascertain the quantity of potash present in a mineral, Vauquelin (from whom the above account of the analysis of flinty bodies has been chiefly extracted) recommends that the stone reduced to an impalpable powder should be cautiously heated with sulphuric acid, and the mafs digested with water. The solution properly concentrated is set aside for some days. If crystals of alum make their appearance, the stone contains potash. If no crystals appear, the solution is to be evaporated to dryness, and the residue exposed to a moderate red heat. It is then to be digested in water, and the solution mixed with carbonate of ammonia, and filtered. It must be then again evaporated to dryness, the residue exposed to a heat of 750°, and redissolved. The solution by proper concentration will yield crystals, either of sulphate of soda or of potash, which may be readily distinguished.

The presence or absence of potash may be also ascertained by means of the muriate of platina.

The following method has been recommended by Rofe for detecting and distinguishing the fixed alkalies in minerals, and is easier than the above. He fused one part of the mineral with four parts of nitrate of barytes in a porcelain crucible. A pamozy mafs of a light blue colour, and completely soluble in muriatic acid, was obtained. The yellow-coloured solution formed was mixed with a sufficient quantity of sulphuric acid, not only to precipitate the barytes, but to expel the muriatic acid; and the liquid was evaporated to dryness. The mafs was digested in water, and thrown upon a filter. The sulphate of barytes and silica remained behind. The solution was now saturated with carbonate of ammonia, which precipitated all the earthy and metallic bodies, leaving in the solution only the sulphates of fixed alkali and ammonia, the latter of which was then expelled by heat. The fixed alkaline sulphate thus obtained was redissolved in water, and decomposed by means of the acetate of barytes. The sulphate of barytes formed was then separated by the filter, and the liquid evaporated to dryness. The other part was acetate of a fixed alkali, which was exposed to a red heat in a crucible, the charry residue diffused in water, filtered, and crystallized; and thus a fixed alkaline carbonate was obtained, easily distinguished by its properties.

Sir H. Davy adopted still a different method. He fused one part of the mineral with two parts of boracic acid, dissolved the fused mafs in diluted nitric acid, and concentrated the solution to separate the silica. The liquid was then mixed with carbonate of ammonia in excess, and boiled and filtered; by which means all the earthy and metallic ingredients were separated. The liquid was then mixed with a sufficient quantity of nitric acid, and evaporated till the whole of the boric acid separated. Nothing now remained but the nitric acid, combined with the alkaline constituents of the mineral, and with ammonia. The nitrate of ammonia was dissolved by heat, and the nature of the alkaline nitrate left was easily distinguished by its properties.

When the mineral contains fluoric acid, Klaproth ascertained its presence by heating the mineral with sulphuric acid in a glafs retort. The condensation of the retort, and the fleshy deposit in the water of the receiver, sufficiently demonstrate the presence of that principle. To determine its quantity, the mineral was fused with potash, and the fleshy deposit was filtered off. The remaining liquid was precipitated by means of the carbonate of potash; and the liquid being neutralized was mixed with lime-water. The precipitate of fluote of lime thus obtained was heated to redness, and from its weight the quantity of fluoric acid present in the mineral was estimated.

Those fossils in which earths are combined with acids, forming compounds not soluble in water, require different modes of analysis. The earthy carbonates are analysed by calcination by heat, with or without charcoal, or by solution in dilute nitric or muriatic acid; estimating the quantity of carbic acid disengaged, by collecting it, and discovering the barytes by the nature of the faint obtained by evaporation; or by precipitation by re-agents, and estimating by the same modes their quantities. Earthy sulphates may be decomposed by boiling with carbonate of potash for a considerable time: the sulphuret acid unites with the potash, and its quantity may be estimated by precipitating with barytes; the carbic acid is attracted by the earthy base, and the carbonate thus obtained may be decomposed in the same manner as a saline carbonate, or the quantity of earth which it contains may be estimated by its weight. Phosphate of lime, which is the only earthy phosphate that has been discovered, may be dissolved in diluted nitric acid by the assistance of heat; the lime may be then precipitated by sulphuric or oxalic acid; the phosphoric acid remaining in solution may be obtained concrete by evaporation; or its quantity may be estimated by combining it with lead, a solution of acetate of lead being added for the purpose.

Analysis of Ores.—Metallic minerals, in general, admit more easily of analysis in the humid way than the earthy fossils, from their being less hard. In the dry way also, their composition may be sometimes ascertained by expelling the mineralizing fubstance by heat, and reducing the metal to its metallic state.

Proper specimens of the ore, free from all foreign matters, should be chosen; and if the object be to ascertain the quantity of metal it may contain, different specimens taken from different parts of the metallic vein should be examined, as it often happens that different parts of the same vein vary much in richnesses. The ore being powdered, the general process, in the dry way, consists in calcining it at a low red heat in an earthen vessel loosely covered, to expel the sulphur or other volatile matter. Or this operation may be performed in an earthen retort and receiver, when the object is to ascertain the nature and quantity of the substance expelled. The residual matter in either case being weighed, to ascertain the loss of weight it has suffered, is mixed with three times its weight of black flux, and exposed in a crucible, to a heat sufficiency intense for its reduction and fusion. Sometimes boras, pounded glafs, or lime, are used
as fluxes. The metallic matter, when the operation is well conducted, is collected in a button at the bottom of the crucible, and its nature and composition may be ascertained in the humid way in the usual manner by means of the proper re-agents, &c.

In submitting an ore to analysis in the humid way, the general process is to digest it previously reduced to powder in different acids. Sulphur, if present, is precipitated, or is sometimes partially converted into sulphuric acid. If the quantity of sulphur be large, it is best previously separated as much as possible by roasting the ore as above. The residual matter is then submitted to the action of the different acids, these being often applied successively to different metals, if present, are separated by their proper solvents. The solutions afford by evaporation the metallic salts they contain, or each metal is detected in the solution by its proper test: it is also precipitated by the alkalies and other re-agents, and the precipitate is reduced to the metallic state, as before, by the aid of fluxes and heat; or sometimes it may be thrown down at once in the metallic state, by another metal having a stronger attraction for oxygen.

These are almost all the general rules that the analysts of ores will admit of, as the processes required for different ores differ extremely from one another, and are often very complicated. We refer our readers, therefore, for the analysis of particular earthy fillets and ores, to the different articles in the Cyclopaedia, where they are described.

Analyses of organic Bodies, including vegetable and animal Substances.—The older chemists attempted the analysis of organic compounds by distillation, and thus obtained a variety of refining substances equally or perhaps more complicated in their nature than the original substance to be analysed. When the theory of chemistry was changed by Lavoisier, that illustrious chemist began to consider the composition of organic substances in a proper point of view, and he endeavoured to discover the elements of these bodies, and to determine their proportions. He discovered the nature of their elements, though he was not so successful in determining their properties. Lavoisier's principle of analysis was to oxidize organic bodies till he converted them into binary oxides, the composition of which was known, and to perform the experiment in such a manner, that the quantity of these binary compounds with oxygen could be correctly determined. His mode of operating was to burn organic substances in oxygen gas; but this method, though in principle, did not enable him, to determine by the balance with much accuracy, either the quantity of water or of carbonic acid formed by the combustion; so that his results could be only considered as approximations.

Some chemists, after Lavoisier, endeavoured to determine the exact quantity of the products of dry distillation, and to calculate from them the composition of the body. Such was the attempt of Fourcroy and Vanquelin on the composition of urea, and of Dr. Higgins on the acetic acid. But the composition, and probably also the quantity of the products of distillation, being only imperfectly known, it is obvious that such experiments, however exact, can only afford data for calculations hereafter, when the products of the distillation come to be better examined and more accurately known. Theodore de Saussure has analysed alcohol and ether in Lavoisier's manner, and the results he obtained probably approach nearer the truth than any preceding analysis of a ternary compound. Thenard has also analysed different species of ether in the same manner.

The first grand step, however, towards proportion in the analysis of organic substances, was made by Gay Lussac and Thenard. These celebrated chemists, in an interesting memoir on the subject, after pointing out the difficulties and sources of inaccuracy of the methods then generally employed, gave a description of a new method of proceeding, by which they considered they were able to combine the hydrogen and carbon with the utmost quantity of oxygen with which they can unite; and thus, by proper data, to estimate the proportion of their constituent parts, and of oxygen existing in the compound analysed. The substance selected to furnish oxygen was the oxymuriate of potash, and the matter to be analysed was mixed with this salt, and flashed in an apparatus contrived for the purpose, consisting of a thick glass tube, A (Plate XXI. fig. 3. Chemistry,) let vertically in a fire, with a lateral tube, B, to conduct the gases produced to a mercurial apparatus; and a cock, C, above, the stopper of which was not perforated, but contained a depression, D, into which a portion of the material to be analysed was introduced; and by turning the cock downwards, this portion fell into the tube, and was there flashed. E is a vessel containing ice, to keep the upper part of the tube cool. The proportion of the oxymuriate requisite to burn completely the substance analysed was ascertained by previous trials in an open crucible; so much of the salt being required, that the residue after deflagration should be quite white, or at least not carbonaceous; and in the actual experiment a considerable excess of the oxymuriate was employed. The materials were then completely dried, by submitting them for a considerable time to a temperature of 212°, and afterwards accurately weighed and mixed in a mortar, with a little water, so as to form an adhesive mass, which was divided by being thrust into a brads mould, and the pieces shaped by the fingers into little balls, that they might drop clean from the stopper of the cock down into the deflagrating tube. These balls were dried again at the same temperature before they were thus burnt.

The oxymuriate of potash was itself analysed before it was used; and in order to insure uniformity in its composition, a considerable quantity of it was fused and pulverised, and kept for use. If the substance to be analysed was a vegetable acid, it was combined with lime or barytes before it was mixed with the salt; and this calcareous or barytic salt was separately analysed, and the carbonic acid remaining united with the earth after deflagration was properly estimated. The earth, or other incombustible matter belonging to the substance to be examined was also separately estimated, by calcining this substance by itself in a platinum vessel, and lixiviating the residue.

The authors, in their memoir, have given at length all the precautions required in the management of the apparatus, both in preparing for the deflagration, and in the estimation of the gases obtained; and after the operation the results of the analysis were made out in the following manner: "The proportion of combustible matter in the substance examined was previously found by calcination of another portion of the same; the actual quantity of oxygen employed in the deflagration was known by that of the oxymuriate used; the carbonic acid was absorbed by potash, and its carbon estimated; the excess of oxygen was found by subfrequent detonation with hydrogen; the hydrogen of the substance was presumed to form water with all the oxygen unaccounted for; and the azote exsolved in the residual azote gas."

Soon after the method of Gay Lussac and Thenard was published, Berzelius turned his attention to the same subject; and after bethowing, in his admirable effay, some just encomiums on the merits of his predecessors, proceeds to point out some defects in the apparatus and methods they employed, and proposes new ones of his own. The essential
tial principle of Berzelius's method is the same as that of Gay Lussac and Thenard, viz., the complete combustion of the substance to be analyzed with the oxymuriate of potash; but the apparatus he employed was very different, and certainly much better adapted for the purpose. It consisted of a glass tube, between one-half and five-eighths of an inch in diameter, and of a length sufficient to contain the mixture of the fuel and substance to be analyzed. This tube was hermetically sealed at one end, and at the other of the shape represented at A 1, (Plate XXI. fig. 4. Chemistry,) in order to facilitate the introduction of the mixture. When the mixture was introduced, this end was drawn into the shape A 2 in order to adapt its introduction into the small thin receiver B. C is a tube about twenty inches long, and a quarter of an inch in diameter, filled with dry muriate of lime in a flate of coarse powder; from one extremity of this, a bent tube D was connected with a small mercureal gasometer E; in this was introduced a small globular glass vessel, F, containing caustic potash, with the view of absorbing the carbonic acid. All the joinings in this apparatus were made by small caoutchouc tubes, prepared by cutting thin pieces of that substance into the requisite shape, and prefixing the newly cut edges together, which unite readily. The tube exposed to the fire was surrounded by a thin piece of tin plate, secured by wire to prevent its bursting. The apparatus was so managed, that by shifting the piece G the whole length of the tube could be heated in succession by the fire H, and thus the flow and uniform combustion of the whole substance be ensured. The other parts of the apparatus will be readily understood from inspection of the figures. At the end of the operation, the greater part of the water formed was found collected in the small receiver B; the remainder of water was found in the tube C, absorbed by the muriate of lime; and by substracting the known weights previously ascertained of these portions of the apparatus, from their weights after the experiment was concluded, the quantity of water was accurately determined. The greater portion of the carbonic acid was attached to the potash in the vessel F, and its quantity ascertained by weight. The minute portion adhering to the soda derived from the oxymuriate of soda was ascertained as nearly as possible by estimation. The substances analyzed were all carefully dried at 212° in a vacuum with sulphurous acid, and were generally combined with oxys of lead. The quantity burnt was from five to eight grains of the substance with thirty or forty grains of the oxymuriate of potash. For further particulars we refer our readers to Thomson's Annals of Philosophy, vol. iv. and v.

Berzelius was induced to adopt the use of the oxymuriate of potash from the recommendation of Gay Lussac and Thenard. Before that time he had employed the brown oxd of lead. In the analysis of animal substances, and all compounds into which azote enters, the use of the oxymuriate of potash is very troublesome, and liable to great objections from the uncertain state of oxidation of the azote. It becomes, therefore, an object of the first importance to possess a substanace that would oxidize hydrogen and carbon, but not azote; such a substance has been happily lately pointed out by Gay Lussac. This is the black oxd of copper, which at a low heat, scarcely amounting to redness, parts readily with its oxygen to hydrogen and carbon, but not to azote. Berard, Dr. Prout, and others, have taken advantage of this in their recent analyses of several animal substances, as will be mentioned under their proper heads. The apparatus employed by Dr. Prout closely resembles that of Berzelius described above, but is more simple.

Dr. Prout in general prefers making separate experiments for ascertaining the gaseous and aqueous products, for the former of which he uses a simple tube only; for the latter, a tube with a small ball, analogous to the receiver of Berzelius, connected with a tube filled with dry muriate of lime. See for further particulars Medicinal-Chirurgical Transactions, vol. vii.

Analysis of Mineral Waters. See Water.

ANAMENIA, in Botany, a name corrupted by Ven¬
ter, from laur. de Malem, t. 22. from the Arabian appella¬
tion of certain flowers of the family of Adonis and Anemone,
Anabahen, to which the present genus is related. See Knowl¬tonia.

ANARHICHAS, l. 6. The species of this genus enumerated by Gmelin are, Lupus, Minor, Pantherinus, and Strigias.

Lupus; shark, or wolf-fish. (See Lupus Marinus.)

This fish commonly frequents the deep parts of the sea, but in spring-time approaches the coasts, in order to deposit its spawn among the marine plants, &c. It is taken both in nets and by the line; and though the flesh is tolerable, its digestible appearance prevents its being much used as food, except by the fishermen. The Greenlanders, however, eat it, both fresh and dried, and make convenient patches of the skin, in which they keep various kinds of utensils.

Minor. Cinerous, black, with sharper cartilaginous teeth; found near Greenland.

Strigias, with transverse dusky bands, racemose and somewhat less regular than euful; tipped by Dr. Shaw to be merely a variety; found in the British ocean.

Pantherinus; Panther wolf-fish, marked over the whole body with round brown spots. This is allied to the first species, but differs much in colour, being of a deep yellow, variegated with numerous, round, deep-brown or blackish spots of different sizes; the largest being on the back, upper part of the sides, and dorsal fin; its length is about three feet or more. A native of the Northern seas.

Ed. Ch. Male, Petals six, nearly equal. Filaments distinct. Anthers didymous, cloven at each end.

The root is perennial. Stems compriwed, simple, sometimes branched in a proliferous manner; when simple they are without joints, and without sheaths, having, at the base vertical equitant, two-ranked leaves. Stiples terminal, compound, each branch subcorticated by a flattening deciduous bractea; sometimes they are simple, or the flowers are solitary. The capsule in some species form a kind of catkin, scarcely bursting. The structure of the flowers and fruit comes nearest to Elusia, but the want of sheaths upon the stem, and the equitant vertical leaves, make a wide difference. This genus agrees with Lyrinia, (see that article,) in having two anthers, but differs altogether in habit.

1. A. satura. Rough-edged Anarthria.—Stems perfectly simple, flat, rough-edged as well as the leaves. Petals of the male linear; of the female the three innermost are filamente.—Found by Mr. Brown on the south coast of New Holland.

2. A. livia. Smooth-edged Anarthria.—Stems perfectly simple, flatish, smooth-edged as well as the leaves. Petals of
of the male elliptic-lanceolate; of the female all nearly equal.—From the same country.

4. A. pauciflora. Slender-cluttered Anarthria.—Stems simple, thread-shaped, compressed, nearly refembling the solitary leaf, and likewise smooth. Cluster loose, of few flowers. Flower-fls in pairs, unequal, shorter than the sheathing bractea.—The male plant only was gathered by Mr. Brown, on the southern coast of New Holland.

5. A. prolifera. Proliferous Anarthria.—Stems branched in a proliferous manner, two-edged, leafy. Flowers either solitary or some what spiried.—Found in the same part of New Holland as all the preceding. Brown.

ANATOMY. For Anther. & Anna.

ANATOMY, Picturaque, col. 4, I. 15, for head r. face.

ANCHOR, in Archit., &c. I. 3, for Tufcan r. Doric.

ANDALUSITE. See MINERALOGY, Addenda.

ANDANTE, 1. 2, dele or grasiolo; I. 5, r. or rather grasiolo.

ANDERSONIA, in Botany, received that denomination from the pen of Mr. Brown, in honour of three different botanists of the name of Anderson. First, Mr. William Anderson, surgeon in the navy, the companion of captain Cook in two separate voyages, during the latter of which he died. Although most devoted to the study of man, and of the animal kingdom, in those new and remote regions which it was his lot to visit, he did not overlook the vegetable world. Several of his manuscript descriptions exist in the Bankian library, where characters of some new genera, since published under other names, are to be found. The genus in question also serves to commemorate Mr. Alexander Anderson, curator of the botanic garden at St. Vincent's, so important, in a national point of view, as a nursery for tropical plants, and for their interchange between our several colonies. Thirdly, this genus is well merited by a most affidious and observing cultivator and botanist, Mr. William Anderson, F. L. S., now superintendent of the Apothecaries' celebrated garden at Chelsea. Let the writer of this be allowed to subjoin to Mr. Brown's list of these botanical worthies, the name of his lamented friend Mr. George Anderson, F. L. S., whose early death, owing to a melancholy accident, January 10th, 1817, is a real loss to science. No one had paid more attention to the cultivation and distincion of the different kinds of British Snake, or the beautiful exotic tribe of Peonia; on which last subject a paper in the Linnean Society's Transf. v. 12. 283. published under the care of his able friend Mr. Sabine, will always evince Mr. George Anderson's just claim to botanical commeremation.—Brown Prodr. Nov. Holl. v. 1. 553. Dryand, in Ait. Hort. Kew. v. 1. 321.—Cliffs and order, Persiaria Monogynia. Nat. Ord. Erices. Jussi. Epacridae, Brown.

Gen. Ch. Col. Perianth inferior, of one leaf, charpy, coloured, in five deep, equal, lanceolate segments, erect after flowering, permanent, accompanied at the bafe by two, or more, imbricated scales. Cor. of one petal, wheel-shaped, in five very deep, linear-lanceolate, equal segments, nearly as long as the calyx, each of them bearded at the base. Nec- tary of five scales, below the germen, sometimes combined. Stam. Filaments five, infected into the receptacle, linear, hairy, shorter than the corolla; anthers vertical, oblong, distinct. Pith. Germen superior, roundish; style simple, cylindrical, about as long as the flaments; stigma obtuse, crenate. Petio. Capsule oblong, with five furrows, five valves, and five cells, the partitions longitudinal, from the centre of each valve. Seeds several, small, erect, inserted into the angles of the short central column.

Eff. Ch. Calyx in five deep segments, permanent, coloured, with two or more imbricated scales at the bafe. Corolla wheel-shaped, the length of the calyx; segments bearded at the bafe. Stamens inserted into the receptacle. Anthers unconnected. Nectary of five scales at the bafe of the germen. Capsule of five valves and five cells, the partitions from the middle of each valve.

This genus consists of small shrubs, with squirelle, half sheathing leaves, no annular fcares remaining on the denudated branches. Flowers terminal, either spiried or solitary, erect. Receptacles from the bottom of the capsule, short. Seed but few brought to maturity. Brown.

In habit, as well as in the general structure of the fructification, nothing can be more abolutely like our Sprengelia (see that article); inomuch that no perfon could, at first sight, form any idea of a difference between the two genera. (See also Ponceletia.) The preference of scales at the bafe of the calyx, so unlike it as to be more properly termed, with Mr. Brown, bracteas, but in that case not entitled to enter into the generic character; the five nectariferous scales, wanting in Sprengelia; and the bearded bafe of the segments of the corolla; these are the distinctive marks of Andersonia. Similar differences serve to subdivide the original genera of Epacris and Stylidium (see those articles); but, as it seems to us, the genera thence derived are better defined, and accompanied with some distinctions in habit. In the present inflance, with the greatfet deference to the acute and learned author of Andersonia, we fhould be inclined to reduce one genus, under one effential character, plants so strikingly alike, and fo different from all others. Genus dabit characterem. One thing is certain, that we are in no danger of being fpulected of wishing, by this means, to get rid of the name Andersonia, though Sprengelia, having been long previously efftablifhed, must be preferred to it. Its character indeed must be reformed, because we were originally acquainted with but one species, the only one, it seems, whose anthes are connected. Such is the cafe with some fpecies of Genlana, but not with all. The following are Mr. Brown's fix fpecies of Andersonia, ranged in two fections.

Sect. 1. Flowers with two scales, spiried.

1. A. sprengelid. Spreading-leaved Andersonia. Br. n. 1. Art. n. 1.—Leaves spreading; with a flat point. Flowers spired.—Found by Mr. Menzies, at King George's found, on the south-well coast of New Holland. Sent to Kew, by Mr. Good, in 1803. It is faid to flower more part of the year, being treated as a green-house plant. We received fpecimens from Meffrs. Lee and Kennedy's green-house in 1814, but this little shrub is far from being generally cultivated, nor has it yet been figured. The ftem is a foot or more in height, determinately branched, round, rigid, smooth, all the branches covered with numerous, rigid, glaucous, feffile, smooth, ovate, spinous-pointed, entire leaves; roughish at the edges; clafping the ifem at their bafe; each about a quarter of an inch long, permanent. Flowers pale rofe-coloured, fentalefs, in dem, fhort, lefty, terminal, upright fpires, not separately falked, or racemofe, as in Sprengelia incanata, but otherwife very nearly refembling, in size and colour, the elegant flowers of that plant. Stems. A. pauciflora. Small-leaved Andersonia. Br. n. 2.—"Leaves close-preffed; with a triangular point."—Dis- covered by Mr. Brown, on the southern coast of New Hol- land. We have not seen this fpecies. The spinous point of each
each leaf is somewhat triangular in the former, though with an obtuse keel.

Sec. 2. Flowers with many scales, solitary at the ends of small branches.

3. A. cerulea. Blue Anderonia. Br. n. 3. — "Leaves moderately spreading; the young ones, as well as the calyx, externally downy." — Found by Mr. Brown, in the same part of New Holland as the last.

4. A. squarrofa. Squarrofe Anderonia. Br. n. 4. — "Leaves prominent, divaricated and recurved, smooth; naked at the edges. Calyx and style smooth. Stem erect." — Native of the same country, where it was gathered by Mr. Brown. We have not seen this, nor either of the two preceding.

5. A. depresa. Procumbent Anderonia. Br. n. 5. — "Leaves prominent, divaricated, twisted and recurved, downy; fringed at the edges. Calyx smooth. Style hairy in the middle. Stem deprefed. — Gathered at King George's Sound, on the south-west coast of New Holland, by Mr. Archibald Menzies, to whom we are obliged for specimens. Mr. Brown also met with this species in the same country. The root is long and tapering. Stem hardly a span long, much branched, for the most part in an alternating manner, thickly covered with imbricated, spreading, rigid, minutely punctate, lanceolate, variously twisted and projecting leaves; smooth and somewhat glaucous on both sides; dilated at the lower part, where especially the edges are fringed. Flowers larger than in the hirt species, sessile at the ends of the little lateral leafy branches, solitary, apparently flesh-coloured. Corolla densely clothed internally with long white hairs. Style just perceptibly hairy in the middle.

6. A. micrantha. Small-flowered Anderonia. Br. n. 6. — "Leaves clove-preflu. Style downy below the middle." — Found in the same part of New Holland as the last, by Mr. Brown. We have seen no specimen.

ANDERSON, in Geography, a township of Ohio, in the county of Hamilton, having 1538 inhabitants. — Also, a township of East Tennesse, having 3599 inhabitants, of whom 260 are free.

ANDOVER, 2d article, l. 3, r. 3164; 3d article, l. 2, r. 1259; 4th article, l. 3, r. 957.

ANDOVER, East, a township of Maine, in the county of Oxford, having 264 inhabitants.

ANDREA, in Botany, a very curious and distinct genus of Moles, is thus named by Ehrhart, in honour of his friend John Gerhard Reinhard Andree. (See that article.) This genus was intended to have been inferred by its author into the Supplementum of Linneus, with the printing of which he was entrusted. (See Linneus, or Von Linné, Charles.) Such was the case with many others, belonging to the same natural order, and now well-established, though the younger Linneus then forbade their admission into his book. Ehrhart called it Andrea, but the above orthographic is justified by many similar examples among learned botanists. — Ehrh. Hanno. Mag. for 1778, 1601. Biebrage v. 1, 15 and 180. Hedw. Sp. Mucf. 47. Turn. Mucf. Hib. 13. Sm. Fl Brit. 1178. Compr. ed. 3. 153. Hooker Tr. of Linn. Soc. v. 10. 381. Mucf. Brit. t. 1. t. 1. — Cilia and order, Cryptogamia Mufci. Nat. Ord. Mufci. Gen. Ch. Male, terminal, bud-like. Amth. three to seven, nearly cylindrical, somewhat flaked, interfiled with numerous, jointed, succulent threads, swelling upwards, taller than themselves.

Female, terminal, filiform. Scales of several imbricated conical scales, shorter than the fruit-flask, which is cylindrical, scarcely longer than the capsule, tumid at its base. Pufc. Vol. XXXIX.

Capsule on a turbinate fleshy base, ovate or cylindrical, somewhat quadrangular, of four equal oblong valves, irregularly longitudinally, cohering at their points, under the permanent lid: column cylindrical, about as long as the valves: lid minute, conical, permanent, confining the points of the valves. Veil membraneous, pellucid, bell-shaped, torn irregularly from its base, and finally turned to one side, crowned with the slightly prominent style. Seeds minute, spherical, brown.

Eff. Ch. Capsule of four valves, cohering at the summit, crowned by the permanent lid. Veil irregularly torn. Ehrhart first removed this genus from Jugurmannia, with which it had been confounded, and properly referred it to the order of Mucfi. But he mistook, as he well might, the valves of the capsule for its fringe or teeth; an error first corrected by Mr. W. Hooker, who, in the Trans. of the Linn. Soc., has first given a just and clear view of the subject. In his Mycologia Britannica the same author remarks, that the supposed fruit-flask, as he himself had heretofore called it, is merely an elongated receptacle, bearing some abortive spores. This is certainly true, but we conceive it nevertheless to be analogous to the more extended fruit-flask of the generality of Mofles, truly wanting in Sphagnum. All the known species of Andreae are British, and amount to four.

2. A. rupefris. Dusky Rock Andreae. Hedw. Sp. Mucf. 47. t. 7. f. 2. Engli. Bot. t. 1277. Hook. Tr. of Linn. Soc. v. 10. 391. t. 31. f. 2. Mucf. Brit. n. 2. t. 8. (Jugurmannia rupefris Linn. Sp. Pl. 1601, excluding the synonym of Dilleniuss.)—Stems branched. Leaves ovate, taper-pointed, ribbed; upper ones falcate. — On rocky mountains throughout Great Britain. Hooker. Small- and greener than the former, with which it agrees in the want of a mid-rib; but differs from it in the tapering, more or less curved, leaves. All botanists confounded this species with the following, till Dr. Roth distinguished them chiefly by the presence of the mid-rib in that species.

is also found in Germany, and doubtless in other mountainous parts of Europe. Like both the foregoing, it bears cap-

fules in the spring and summer. The presence of a strong rib in the leaves clearly distinguishes it from those species, though the paler, blunter, and more oblong, scales of the sheath have no rib. The flaves, generally almost simple, are occasionally much branched, as in Engl. Bot.

This is by far the tallest Andraea known, being three inches high, or more, forming rather lax olive-brown tufts, tinged with a chocolate-colour, of which half thec are the capfules, whose subflance is strongly reticulated. The scales of the sheath being of the same lanceolate figure, furnished with a mid-rib, are as the leaves, clearly defines the species. Mr. Hooker has observed this moss on the granite rocks of the most elevated of the Swiss alps, retaining all the characters of the Scottish specimens.

ANDREW, Knights of, &c. l. 12, r. Favin; col. 2, l. 28, r. commissioner; l. 29, r. little for litter.

ANDROMACHA, l. 1, r. Zygena.

ANDRONICUS II., PALEOLOGUS, in Biography, son of Michael Paleologus, succeeded to the Greek empire in 1283. He is characterized as learned and virtuous, but feeble in his conduct, and abjectly superstitious. His old age was em-

bittered by blindness and neglect; and having assumed the name of Father Antony, he closed his unquiet life four years after his abdication, A.D. 1332, aged 74.

ANDRONICUS III., Paleologus, the younger, was the son of Michael, eldest son and colleague of the elder Andronicus. With his grandfather he was a favourite, on account of his wit and beauty; and he was thus led into habits of intemperance and debauchery, which involved him in difficulties and disgrace. Having compelled his grandfather to abdicate in 1328, he reigned alone, and contended against the Bulgarians and Turks, with the latter of whom he signed an ignominious treaty, relinquishing to them all the places which they had taken in Asia. At length, exhausted by his vices, he died in his 45th year, A.D. 1341. Gibbon.

ANDROPHYLAX, in Botany. See WENDLANDIA.

ANEILEMA, from ά, without, and άφηνεν, an invi-

tocurum, this genus being separated by Mr. Brown, Prod. Nov. Holl. v. 1. 270, from COMMELINA, (see that article,) on account of the want of the large folded infor-

curum, or rather bratsea, which in Commelina contains a considerable number of flowers; whereas in Ancilema the inflorcence is scattered, somewhat panicked. The differ-

ence between the two reffides therefore in this part of the plant, and not strictly in the fructification.

The kind species of Commelina referred by Mr. Brown to Ancilema are, vaginita, audifora, and fpiritata of Linneus, medica of Loure, Vahl Enum. v. 2. 175. n. 28; and gigantea of Vahl, n. 34, found by Mr. Brown, in the tropical part of New Holland. To thefe the author adds nine new species, found by himself, either in New South Wales, or the warmer parts of New Holland, one of them only being defcribed from the collection made in the latter country by erf Joseph Banks. Some have smooth filaments, others bearded ones. It is suspected that Pollia of Thumberg may not be generically different from these; but the fruit in our fpecimens is evidently a berry, according to Thumberg's de-
scription, and remarkable, even after having been dried more than thirty years, for its bright blue colour. (See Pollia.)

The habit and inflorescence are indeed, as Mr. Brown ob-

serves, familiar to his Ancilema. Whether Cartenon of this

author be distinct, we do not presume to judge, having seen no specimen. In the regularity of its flowers, and the equality of their flaves, it differs from Commelina and An-

cilæma, and agrees with Tradescantia, but differs from the latter in several particulars pointed out by Mr. Brown, besides its spiked inflorescence.

ANEMIA, a genus of ferns, separated from Os-
munda, (fee that article,) by Dr. Swartz, and thus named from ανεμία, naked, or not covered; because its capfules are deftitute of all covering or involurum whatever.—Swartz Syn. Fil. 155. Wildl. Sp. Pl. v. 5. 89. Ait. Hort. Kew. v. 3. 149.—Clads and order, Cryptogamia Filices. Nat. Ord. Filices, fig. 2, фopиe γυράε.

Eff. Ch. Capfules somewhat turbinate, concentrically fribated at the top, burfitting laterally, fefile on one fide of a compound linear receptacle. Involurum none.

The habit of this genus is different from Osmunda, and extremely remarkable, on account of its compound spikes, always perfectly distinct from the leafy part of the frond, and generally sitted in pairs, on long falks, on the common falk at the base of that leafy part. Such at leaft is the cafe with the whole of the firt fect; in the fcond, the fruit-bearing falks are radical and solitary. It is closely related to Botrychium, to be defcribed hereafter; but that has globular capfules of two diftinct valves, neither fribted nor annulated. Their receptacles, indeed, exactly agree; and the three are fo obtuse in Anemia, that we are much inclined to unite it with Botrychium.

Sect. 1. Panicvcs of fikes in pairs, flalked, at the base of the leaf.

1. A. phyllidif. Broad-leaved Anemia. Swartz n. 1. Wildl. n. 1. (Osmunda phyllidif; Linn. Sp. Pl. 1520. O. lanceolata et subfìlitìe frrata; Plum. Fil. 113. t. 156. O. racemifera, phyllidif folio vix crefuto; Petiv. Fil. n. 163. t. 8. f. 15.)—Frond pinnate; leaflets ovate-lanceo-

late, pointed, finely fribted, smooth as the common falk. — Native of South America and the West Indies. Brought from Brazil, by the late Sir George Leonard Staunton, in 1753. A very handsome fern, eighteen inches or two feet high, its tufted root producing fveral upright fronds. Each of these confifts of a smooth, rather flender, ftraight common falk, bearing at the top an upright fimplicy fribted leaf, of from four to eight pair of smooth, veiny, bluntly fribted, somewhat falked, leaflets, beftides an odd one; their length from two to four inches. Close to the base of this fribted leaf, on the upper fide, or front, are fationed a pair of equal, long-falked, triply fribted fikes, of minute, pale, very fribted, capfules, ranged in double rows along one fide of the linear compound falk, or recepta-

cle, the common falk of the whole being somewhat hairy. These compound fikes always rife a little above the point of the terminal leaflet.

2. A. hirta. Rough-leaved Anemia. Swartz n. 2. Wildl. n. 2. (Osmunda hirtif; Linn. Sp. Pl. 1520. O. hirifuta, longifidiis folio; Plum. Fil. 113. t. 157. O. fpcis geminis; Petiv. Fil. n. 164. t. 14. f. 5. Lonicif hirifuta floris; Plum. Amer. t. 18. t. 26.)—Frond pinnate; leaflets oblong-lanceolate, hairy, finely fribted, and somewhat cut; very unequal at the base. Stalks all hairy.—Native of the West Indies. Smaller in every part than the laft, being scarcely above a foot high; and dilinguifhed also by the great dilatation of the upper fide of each leaflet, at its base.

The upper ones run into a fort of pinnatifid elongated point.
point. Both sides of the leaflets are hairy in our specimen, as Plummer describes them; though Willdenow and Swartz call them smooth. The dense, thin, hairy, twice-compound spikèl usually rife a little above the leaf.

3. A. blebnoideas. Many-leaved Anemía. — Frond pinnate, longer than the spikes; leaflets numerous, parallel, oblong, obtuse, serrate, smooth; rectangular on their upper side at the base. — Brought from Brazil, by the late Sir George Leonard Staunton, from whom we received specimens in 1792. We cannot find any figure or description of this species, though a very remarkable one. The common flalk, in its naked part, is smooth. The leaflets are about forty pair, parallel and crowded; the lowermost an inch and a quarter long, and opposite; upper ones gradually smaller and alternate; all together forming a linear-oblong frond, eighteen inches in length, with a slightly hairy common rib, which, by a hairy bude at the summit, seems as if it would take root there. Spikes lax, twice compound, measuring with their slightly hairy flalks, about two-thirds of the length of the leafy part. Their subdivisions are extremely narrow.

4. A. oblongifolia. Oblong-leaved Anémia. Swartz n. 3. Willd. n. 3. (Ofmunda oblongifolia; Cav. Can. v. 6. 69. t. 592. f. 2.) — Frond pinnate; leaflets obovate, obtuse, dilated at the upper angle of their base, fringed. Stalks smooth. — Gathered by Louis Née at Panama. Several stalked fronds, hardly six inches high, spring from the hairy crown of the tufted root; some of them barren. The leaflets of each are about ten pair, rather alternate than opposite, half an inch long, rounded at their extremity, as well as at the dilated angle. Both spikès rife much higher than the leaf part, on slender flalks, and appear to be rather dense. We know this and the following from the work of Cava-nilés only.

5. A. humilis. Dwarf Hoary Anémia. Swartz n. 4. Willd. n. 4. (Ofmunda humilis; Cav. Can. v. 6. 69. t. 592. f. 3.) — Frond pinnate; leaflets obovate-wedge-shaped, abrupt; crease at the extremity; hairy beneath. Common flalk hairy.— Native of Tabago, an island on the Mexican coast, near Panama. Of more humble stature than the last, and further distinguished by the wedge-like shape of its leaflets, which are fewer, rather larger, crease, and not fringed. The spikes are much smaller than in the foregoing, raised high upon slender smooth flalks.

6. A. fitiformis. Slender Hoary Anémia. Swartz n. 5. Willd. n. 5. (Ofmunda fitiformis; Lamark Dict. v. 4. 652.) — Frond pinnate, downy and hoary; leaflets oblong-wedge-shaped, obtuse; jagged at the extremity. Common flalk hairy. — Gathered in South America by Mr. John Frazer, who is reported to have communicated a specimén to Lamark. We have never seen this plant. It is described as eight or nine inches high, besprinkled in every part with white or hoary hairs. Leaflets striated very copiously and conspicuously beneath. Spikes slender, compound, on capillarv flalks, rising high above the leaf. Savigm in Lamark.

8. A. bifurca. Hairy Anémia. Swartz n. 7. Willd. n. 7. Ait. n. 1. (Ofmunda bifurca; Linn. Sp. Pl. 1520. O. mollitèr bifurca, et profundè lacinìata; Plumb. Fil. 159. t. 152. O. fipèis gernìnus vilòfa; Petiv. Fil. n. 105. t. 8. 16. Lunaria elatìor, matrìcarìis folio, spicà dupliqui; Sloane Jam. v. 1. 71. t. 25. f. 6.) — Frond pinnate, hairy; leaflets deeply pinnatifid; segments tapering downwards; obtuse and jagged at the extremity. — Native of the West Indies, growing on rocks. About a foot high, hairy all over, except the spikès and their flalks. Several of the fronds are barren, which we presume is the case with most of the neighbouring species. Each leaflet is about an inch and a half long, with many narrow-wedge-shaped, deep, fringed segments, hairy on both sides, and sharply notched. Each spikèl, near three inches long, is doubly pinnate, with flat close segments, broader than in most of the genus, and the capiûla are represented by Plummer as marginal, and blackish, with much more intermediate space than usual on each segment. Willdenow adverted to this circumstance, and the hairiness of the common flalk, as indicating a specific difference between Plummer's plant and what he had examined. Specimens from the West Indies, and from Dr. Swartz, certainly agree with Sloane's plant, and like that, have a smooth common flalk; but having seen none answering to Plummer's, we decline attempting a specific definition, from his figure. He is, however, the original authority for Anemía, or Ofmunda, bifurca, and Petiver copies him; but Sloane's synonym must be referred to the new species, if such be established.

9. A. deltoides. Triangular Anémia. Swartz n. 8. Willd. n. 8. (Ofmunda deltoides; Cav. Can. v. 6. 69. t. 593. f. 1.) — Frond triangular, pinnate; leaflets deeply pinnatifid, with rounded, crease, crowded segments; glaucous above; hairy beneath. Common flalk hairy at the upper part.—Found on rocks in the plain of Buenos Ayres, by Louis Née. A few plants, with broader and rounder segments of the leaflets than any of the foregoing. The divisions of the common receptacle of the spikèl are broader, and more rounded, than usual, approaching to those in Plummer's plate of the last.

10. A. vilòfa. Shaggy Anémia. Willd. n. 9. — "Frond doubly pinnatifid, oblong, shaggy on both sides; segments roundish-ovate, obtuse, entire; the lower ones usually three-lobed. Common flalk flagggy." — Gathered by Humboldt and Bonpland in South America. Common flalk fix inches high, or more, roundish, clothed with short rusty wool. Fronds three or four inches long, covered with rusty hairs; the upper segments roundish-ovate, very brown, and entire; lower with two or three flight lobes; common rib densely flagggy. Spikes triply compound, dense, taller than the leaf, with hairy ribs and flalks. Apparently akin to the following, but the outline of the frond is oblong, not triangular, and the rib straight, not zigzag. Willdenow.

11. A. flexuosa. Zigzag Anémia. Swartz n. 9. Willd. n. 10. (Ofmunda flexuosa; Lamark Dict. v. 4. 652.) — "Frond doubly pinnatifid, triangular, downy; segments oblong, obtuse, nearly entire; common rib zigzag. Common flalk downy." — Supposed to be a native of Peru, but for this there is no direct authority. We have seen no specimens. Savigm in Lamark describes this species as related, in many respects, to A. bifurca, n. 8, but the principal leaflets are simply pinnatifid. The spikès are a foot high, semi-cylindrical, channelled, besprinkled with rather rigid, tawny hairs. Fronds from five to seven inches long, with narrow, deeply pinnatifid, leaflets; their segments oval, or somewhat oblong, nearly opposite, very blunt, depressed, ribbed, entire, or slightly notched; paler beneath.

R. 2. The
ANEMIA.

The summit of each frond is obtuse, and simply pinnatifid. Spike triply and minutely compound, with linear short segments; their leaflets bipinnate.

12. A. tomentosa. Downy Anemia. Swartz n. 10. Willd. n. 11. (Olmunda tomentosa; Lamarck Diet. v. 4. 572.)—Frond doubly pinnate, oblong, clothed with tawny down; leaflets crescent-shaped, entire; the lower ones bluntly pinnatifid.

Common fronds downy. Ofmunda. Another species, seven or eight inches high, exuding the smell of myrrh, and covered all over with fine, long, cottony, tawny down. The common flanks is rather stout, twice the length of the leafy part, which is about two inches broad. Spike compound, on slender decurrent flanks. Savigny.

13. A. fulva. Tawny Branching Anemia. Swartz n. 13. Willd. n. 12. (Olmunda fulva; Cav. 1c. v. 6. 70. t. 593. f. 2.)—Frond doubly pinnate, triangular, somewhat downy; leaflets elliptic-oblong, bluntly pinnatifid, or ferrated. Spikelets partly whorled. All the flanks hairy.

—Gathered by Louis Née, on the hill called Pan de Azúcar, or in the Sugar-loaf, thirty-two miles from Monte Video. Above a foot high, with very hairy flanks, and broad fronds, doubly pinnate throughout, except at the very top. Leaflets three-quarters of an inch long, and one-third as broad, uniform, somewhat decurrent. The flanks seem to be simply compound, their branchi, horizontal, linear, deeply notched, many of them in whorls of three or four together; their common flanks and ribs hairy, fissioning off one or three lateral branches, which we have seen in no other species.

B. Willd. (A. afplenifolia; Swartz n. 10. Ofmunda afplenifolia; Savigny in Lamarck Diet. v. 4. 572.)

Frond doubly or triply pinnate, triangular; leaflets oblong, sharply toothed at the end, partly notched, hairy, as well as their common rib. Common flanks nearly smooth. Spikelets digitate. Native of the West Indies, particularly of Hispafonia, in dry rocky or sandy places. Its large handfolme, thinning, frizzated fronds bears considerable resemblance to our common Asplenium Asiantum-nigrum, to which, and not to the real genus Adiantum, the specific name alludes. The naked flanks is often a foot high; the length of the leafy part almost as much. The copious leaflets measure about half an inch, and are strongly frizzated; convex above; paler, and rather more hairy, beneath; all their leaflets hairy. Spikes somewhat panicked; their ultimate divisons radiating, or finger-like, linear, flat. Capsules of a light shining brown.

Sir Joseph Banks has favoured us with several specimens of a variety of this fern, gathered at Camphey by Houtteau, which differs chiefly in being not above a span high, with a leaf compound fronds, and having sometimes, from the fame root, much narrower, almost linear, leaflets. These common flanks are also rather more hairy, and the spikes more compact. It is nevertheless an evident variety, and probably the £ of Willdenow, to the characters of which it answers.

3. Pinnicle of flanks, on which flanks.

The height of each frond, with its flske, is about two feet. A few rather more slender flskes, from the root, bear each a long interrupted, whorled flske, with six or eight drooping, obtuse, defcne, blackish branches, in every whorl, above an inch long, on capillary flsks, but how they are subdivided we have no information. Plummer compares them to little black caterpillars.

18. A. ficulifolia. Hemlock-leaved Radical Anemia. Swartz n. 17. Willd. n. 17. (Ofimunda ficulifolia; Linm. Sp. Pl. 1521. O. ficulifolius folio altera; Plum. Fl. 138. t. 161. O. ciutte folio; Petv. Fl. n. 170. t. 9. f. 3.)—Frond three-branched, pinnate, pinnatifid; segments wedge-shaped, decurrent, notched at the extremity. Spikes panicked, on radical flsks.—Found but rarely by Plummer, in the forests of Hispaniola. A specimen, without any indication from whence it came, is preserved in the Linnaean herbarium, and referred to Ofimunda (Anemia) bipinnata, (see n. 15.) Linnaeus appears to have had it when he wrote the first edition of Sp. Pl., but all he says of either of these species is entirely taken from Plummer, who is the primary authority for both. A. ficulifolia varies from five inches to above a foot in height. The barren fronds have flsker, roughish, rather long, flsks, and are nearly pental- gonal in their outline; having three principal branches, which are first pinnate, then more or less deeply pinnatifid and cut, always in a wedge-like manner; they are hairy on both sides. The common midrib is winged. From the fame tufted root grow one or more rather taller flsks, each bearing a triply-compound, slightly hairy, panicled, or com- pound flske, whole linear ultimate segments are linden, on one side, with rather large, and not very numerous, capulfales, each having a very distinct, brown, shining, radiated top, below which is a lateral flske. The engraving of Plummer gives no idea of the fize or nature of these capulfales, nor of their arrangement, so that we may suppose him equally incorrect with regard to our fiftenth or seventeenth species.

Dr. Swartz, Syn. Fl. 158, points out, as a probable species of this genus, Ficuliforum americainc minus, ficus ramad fiberfur, Ammann in Comment. Petrop. v. 10. 395. t. 19. This was found by Dr. Houftoun at Vera Cruz, and however unlike the figure may seem to Plummer’s t. 161, our fpecimen mentioned, and partly defcribed, under the falt fpecies, serves to prove them, at leat in our opinion, one and the fame plant; for it explains the inaccuracy of both figures, and is intermediate between the two in the ftructure of the barren frond. We cannot doubt its being one of Houftoun’s fpecimens. The panicked infefure agrees with Ammann’s figure, but the detail of that figure is no lefs incorrect than Plummer’s, fo that nothing precise can be gathered from either.

ANEMOMETER, col. 2, for IX. infert VIII. No. 3.

Gen. Ch. Cal. none, except a three-leaved, variously

uncinate, involucral. Cor. Petals from five to fifteen, ovate or oblong. Stam. Filaments numerous, capillary, not half the length of the corolla; anthers two-lobed, erect. Pfl. Ger- mens numerous, collected into a head, fingle-feeded; flyles tapering; fligmas blunt. Peric. none. Recep. globose or oblong, covered with fmall excavations. Seeds numerous, crowded, roundifh, pointed with the permanent flyle, which in fome is lengthened out into a feathery tail.

This genus confines of perennial herbs. Roots (or perhaps fubterraneous flents?) either tuberous, or horizontally creeping, or simply fibrous. Leaves radical, flalked, fimple (or compound), lobed or cut. Flower-flalx radical, bearing at the fimmit an involucrum of three, rarely but two, leaves, variously cut, but confolmable in general to the proper foliage. From this involucrum proceeds usually one or many fimple, naked, fingle-flowered flske; some apparently caulefcent fpecies have one fuch leaflefs flske, and, besides, a fort of branch, bearing another flower-flalx, accompanied by a two-leaved involucrum. The flowers are indoruous, very variable, and readily become double.

The recent plants are acrid, and raise blifters in the skin, if applied externally; internally they are poifonous in fome degree, though feveral have been prefcribed in chronic obfthalmia, and venereal caries of the bones.

The forty-five fpecies, with which we are at preient acquainted, inhabit faiures, hills, woods or thickets, of temperate climates, principally in the northern hemisphere; the Pulsatilla are found on rough exposed hilly fields; Prenanath on the loftift mountains; Pulsatillata at the Cape of Good Hope; Amonanthece in meadows, faiures, or woods; Amonanthes in North and South America and in Asia; Omalanthe in mountainous situations. There are two fpecies from the Cape of Good Hope, four from South America, eleven from North America, feventeen are natives of Europe, three of the Levant, five of Siberia, two of Nepal, and one of Japan. Four appear to be common to North America and Europe.

Anemone is a very natural genus, and De Candolle declares his opinion againit subdividing it; firt, because the fcction Prenanathus has the habit and flower of the Amonanthece, with the feathery-tailed fluit of Pulsatilla; fecondly, because the fruit being furnished with fuch an appendage, or deftrute of it, is not to be confidered essential in the preient cafe, the fame circumstance proving of no avail in the genus Clematitis, fo nearly related to the preient.

The following divifions, founded on the whole habit as well as the fruit, prove extremely natural.

3. Pulsatillata. Seeds very hairy. Petals fifteen to twenty. Involutal leaves two or three, fefile, cut at the summit. Species 9 and 10.

ANEMONE.

† Species not sufficiently known; 44 and 45.

We have corrected some accidental numerical errors, and we take the liberty of using the Linnaean terminology, as to calyx or corolla, here as in Aconitum, &c. Carpelis, a word used by our learned friend for partial fruits, several of which belong to one flower, as in Uovaria, Unona, &c., seems to us well expressed, in English at least, by the plural, fruits; the singular, fruit, being always used when the pericarp is simple, or solitary. Carpopis is used by Richard and De Candolle for the naked seed of Graines, as well as of Ranunculosae, of which we do not see the utility. A multiplication of terms, without absolute necessity, is burthenome to science, and we rather with the learned would labour to competitors, instead of extending; the terminology of natural history.

Seeds terminating in long bearded tails. Involutional leaves sessile, dilated at the base, divided upwards, in a palmate manner, into linear segments. Petals five or six. Glands, (abusive flaminos,) in several species, on short flanks, between the perfect flaminos and petals. The radical leaves are mostly divided in a pinnate manner, their segments many-cleft, with linear or wedge-shaped lobes. Flowers in general purple or crimson.

—Native of rocky pastures on the loftiest mountains of Switzerland, the Pyrenees, Germany, Sweden, and Norway, flowering among the melting snow in spring. The broad leaflets, with the beautifully silky involucrum and petals, distinguish this species. The flower-flank is three or four inches high, hairy, much elongated above the involucrum after flowering, as in all the Pulsatilla tribe. Flower white, variegated with purple, extremely elegant; we have some doubt whether the report of its being ever yellow be well founded, and whether the term "golden!" in Dalechamp, copied by J. Bauhin, may not apply to the brilliant yellow pubescence of the living as well as dried flowers, noticed by Haller.

3. A. sernas. Drooping Japane Confeder Anemone. Thumb. Jap. 238. De Cand. n. 5. Willd. n. 3. —Leaves pinnatifid, with notched oblong segments. Flower rather drooping. Petals fix, elliptic-oblong, spreading,—Native of Japan, about Jedo and Nagasaki, (Thunberg,) flowering in spring. All the flanks are very hairy, as are the leaves beneath, especially when young. The segments of the latter

are intermediate between vernalis and Pulsatilla. Staff six inches high. Flower dark purple, hairy externally, smaller than in A. Pulsatilla. De Candolle.

4. A. patens. Naked-flowering Anemone. Linn. Sp. Pl. 759. De Cand. n. 4. Willd. n. 2. Ait. n. 2. (Pulsatilla polyanthos violaces, anemones folio; Breyen. Cent. t. 61. "Helv. Pulsl. 52. t. 2. 3")—Leaves later than the flower; leaflets ternate, wedge-shaped, deeply and acutely pinnatifid and cut. Flower erect, spreading.—Native of Siberia, Poland, Silelia, &c.; recently found by Mr. Schliecher in Switzerland. The flowers are as large as any of this fiction, and more spreading, either pale yellow, white, or purple, than on a very short partial flank; the involucrum is very narrow, linear, hairy segments. The leaves expand after the flower is past, and are ternate, not pinnate, with radiating, very acute, variably notched, segments. The partial flank is greatly elongated, from six to nine inches, as the fruit ripens. De Cand.

6. A. proctens. Dark Meadow Anemone. Linn. Sp. Pl. 756. De Cand. n. 6. Willd. n. 7. Ait. n. 5. Fl. Dan. t. 611. Woodv. Med. Bot. t. 148. (Herba venti; Trag. Hift. 435. Pulsatilla; Cameer. Epit. 392. P. flore clauo; Lob. Ic. 283. P. flore minore; Ger. Em. 386. P. altera; Dalech. Hift. 850.)—Leaves doubly or triply pinate, with lanceolate, elongated segments. Flower pen-dulous. Petals fix, erect; reflexed at the summit.—Native of meadows, as well as of dry open fields, in Sweden, Denmark, Ruffia, Germany, France, and according to the abbe Belluci, near Corfum, France, with the same flowers. This species is distinguished from A. Pulsatilla, by the larger coarser segments of its leaves, and smaller, darker-coloured flower, whose petals are recurved at the top. Dr. Storck recommended an extract or infusion of the herb, in chronic diseases of the eyes, and even confirmed lues. Hence it has attracted the notice of physicians, who have been commendably anxious to procure the true plant, which is not found wild in Britain. Probably its virtues, whatever they may be, exist likewise in the A. Pulsatilla. Both are easily cultivated.

7. A. albo. Pale Caucasian Anemone. "Steven Mem. Soc. Nat. Mofc. v. 3." De Cand. n. 6.* addend. 545.—Leaves doubly pinate, with numerous oblong-linear segments. Flower drooping. Partial flank feebly longer than the involucrum. Petals fix, erect, slightly reflexed at the summit.—Gathered by Mr. Stevens, on the lofty mountains of the eastern part of Caucasus. Allied to A. proctens, but differing from in the lobes of the leaves, and their subdivisions being shorter as well as more obtuse, rather oblong than truly linear; secondly, in the partial flank, even throughout the whole duration of the flower, rising scarcely above

the
ANEMONE.

the involucrum, instead of being four times longer: thirdly, in the flower being whitish, or sulphur-coloured, not purple: fourthly, in the total want of glands, or abortive flaments, at least in the specimen seen by professor De Candolle; which are very abundant in the preceding species.

Sec. 2. Preonanthes. Ehrh. Phryg. 95. Seeds terminating in long bearded tails. Involucral leaves ternate, tallked, pinnate, with deeply ferrat, notched lobes. Petals five or six. No glands, or abortive flaments. Radical leaves ternate; their divisions pinnate, doubly compound, cut and ferratated. No flowers white or yellowish.

2. Flower white, as in s, but much smaller. (A. alpina; Jacq. Auftr. t. 85. Wildl. n. 8, a. A. fylvetris alta; Cluf. Hist. v. i. 245. Pulsatilla alba; Lob. Inc. 282. Dalech. Hist. 849. P. flore albo; Gen. Em. 386.)

1. Floral large, yellow. (A. api folia; Jacq. Muc. v. 2. 47. t. 4. Wildl. n. 9. A. sulphurea; Linn. Mant. 78. A. myrrhifolia; Villars Dauph. v. 3. 727, from the author. A. n. 1149, 8; Hall. Hist. v. 2. 63. Pulsatilla lutea; Camer. Epit. 393. P. tertia; Dalech. Hist. 851, bad.)

Leaves ternate, pinnate, with pinnatifid, decurrent, ferratated lobes. Involucral ones similar. Petals fix, spreading.

—Native of paitures and rocky declivities in most alpine parts of the middle of Europe, Switzerland, the Pyrenees, the south of France, Austria, Carinthia, &c.; flowering in summer. The conformity of structure between the involucrum and the radical foliages, clearly averts this species. We readily concur with Haller and De Candolle, that the dilate type of bole, between the yellow, lemon-coloured, or white flowers, or of fize between the large-white and the small, indicate more varieties. But we fearly fee any reason to mark the more or less hairy leaves as permanent varieties; the former being caufed by more dry and exposed situations of the fame plant. The petals are always more or less pale, purplish, and hairy, at the back. The flowering plant is from two to twelve inches high. When in leaf its dimensions are every way doubled. A fingular moniftrophy of variety 8, sent us by the late Mr. Davall, has one of its petals flipped down, if we may fo express it, into the involucrum, and greatly enlarged. This, as M. De Candolle juftly observes, proves an analogy between the petals, (his calys,) and the involucrum; but it will not prove them to have more affinity than the petals and actual leaves of a Tulip, which we have feveral times seen running into each other, or half and half of the perfect nature of each. See 3. Petals Pulsatilloides. De Candolle.

Seeds very hairy. Petals from feven to twenty, oblong. Involucrum of two or three leaves, somewhat flathing at their base; cut and toothed upwards. Leaves twice ternate, cut.

10. A. capensis. Broad-leaved Cape Anemone. Lamark Dict. v. 1. 164. De Cand. n. 9. (Atragene capensis; Linn. Sp. Pl. 764. Wildl. Sp. Pl. v. 2. 1286. Ait. Hort. Kew. v. 3. 342. Andr. Repof. t. 9. Curt. Mag. t. 716. Pul- satilla folis trifidis, dentatis, flore incarnata, pleno; Burm. Afric. 148. t. 52.) —Leaves twice-ternate, rigid, smooth; segments wedge-shaped, sharply toothed.—Native of flowy acclivities of mountains, at the Cape of Good Hope, flowering from October to March. It is said to have been first cultivated in England, by Meffrs. Lee and Kennedy, in 1792. This plant is somewhat caulecent, but the leaves are crowded about the lower part, almost close to the woody root. Their texture is extremely firm; their segments varying greatly in feize, breadth, and shape; the young ones villous. Flowers one or two from each involucrum, which resembles the leaves, but is smaller, with a dilated inflated flalk. The partial flower-flalks are long and downy. Petals thirteen to eighteen, linear-oblong, above an inch in length, pink, or pale blith-coloured, spreading, very handfome. German extremely hairy, ovate, each with a recurved style.

11. A. tenuifolia. Fine-leaved Cape Anemone. De Cand. n. 10. (Atragene tenuifolia; Linn. Suppl. 270. Wildl. Sp. Pl. v. 2. 1286. Thunb. Prodr. 94. A. tenus; Thunb. Jap. 239, note.) —Leaves three-ternate, rigid, smooth; leaflets pinnatifid, with linear-threaded, acute, entire lobes. —Found by Thunberg at the Cape of Good Hope. The leaves are more compound, and more finely divided than thofe of the preceding species; the plant is defcribed as more caulecent, and the flowers but half as large, with only from seven to nine petals. We have seen no authentic specimens, but are not without a fufpicion that Linnaeus confounded this with the lat. See 4. Anemonanthea. De Cand.

Seeds nearly ovate, hooked with the permanent style, either very hairy or haggry, or in fome inftances nearly smooth. Partial flower-flalks solitary in each involucrum, or very rarely two together, always single-flowered and naked. Petals from five to fifteen.

12. A. coronaria. Poppy Garden Anemone. Linn. Sp. Pl. 760. De Cand. n. 11. Wildl. n. 10. Ait. n. 7. Curt. Mag. t. 841. Sm. Fl. Grac. Sibth. t. 514, unpubl. Lamark f. 1. (Anemone; Camer. Epit. 386. A. hor- temis tenuifolia, fimplices flore, n. 2—20; Cluf. Hist. v. 1. 255—260; alfo pleno flore; ibid. 263. A. tuberofa radice, et coccineae multiplex; Lob. Inc. 277. Gen. Em. 374; fee alfo feveral in his fubfquent pages.) —Leaves twice ternate, pinnatifid; segments linear-wedge-shaped, smooth-edged, sharply cut. Involucrum fefille, many-cleft. Petals fix, oval, concave, converging.—Native of dry, as well as rather moist, paitures, in the south of France, Italy, and the Levant, flowering in the early spring. Very common on dry hillocks in Greece, according to Dr. Sibthorp, who concurred with former botanifs in thinking it the anemone 87 of Dioscorides; and the learned Sprengel takes the anemone 87 of Hippocrates to be the fame plant. This species, however, bears the fame name in modern Greek, ανημονια, as the Field Poppy, Papaver Rhaea; nor is the history of these two flowers, however different, free from ambiguity. A. coronaria has been the delight of florists ever since the time of Gerarde, and its numerous double varieties, difplaying every beauty and splendour of colour, are among the most rare and admired decorations of a parterre. We

confes
ANEMONE.

confers a predilection for the single kinds, equally beautiful and various in colour, which may be raised abundantly from seed in any airy and sunny spot, and require but little trouble in transplantation every fourth or fifth year. They flower mold in the winter or spring. The leaves vary in breadth. The natural colour of the flower, which is cup-shaped, and full two inches broad, is a light purplish-blue, as represented in Dr. Sibthorp's drawing, and as we have gathered it in the groves and gratinlates of the Roman villa. The feeds are covered with long, soft, tenacious down, concerning the effect of which an amusing story is told by Tournouet and Miller. A lawyer in the south of France fole these feeds from a covetous amateur, by ordering his page to drop, as if by accident, the silk train of his robe, when they passed over the bed of feeding Anemones, and thus obtained a plentiful supply.

13. A. pyllata. Dwarf Anemone. De Cand. n. 12.—Leaves thrice ternate, pinnatifid, many-cleft, with linear pointed segments. Involutum seifile; cut at the summit. Petals fix, oblong, distant.—Gathered in Cyprus by Labiliardiere. Nearly akin to the last, and perhaps a variety. Root tuberosous, the size of a filberd. Leaves smooth, stalked, with narrow linear segments. Flower-flalk a finger's length, slender, downy, erect. Involutum of three leaves acutely cut and toothed at the apex. Partial flalk either the length of the involucrum, or twice or thrice as long. Flower erect, pale purple. Petals fix, rarely but four or five, oblong, bluntish, distant and spreading, about four times the length of the flaments. Seeds woolly, collected into an oval-oblong head. De Cand.

14. A. pannonica. Peacock Garden Anemone. Lamarck Dict. v. 1. 166. De Cand. n. 13. "Fl. Franc. v. 5. 634." Brotn. Lufft. v. 2. 353, not 263. (A. Hortenisia latifolia, pleno flore, et flore coccineo; Clus. Hift. v. 1. 261, 262, with three figures. A. maxima chalcedonica polymathos; Ger. Em. 375. Lob. Ic. 278. A. flattata, gerani aut aconito folio, duplicato flore purpureo; Cupan. Panph. v. 1. t. 121. ed. 2. t. 22.) Leaves ternate or deeply three-lobed; leaflets or segments wedge-shaped, cut and toothed. Involutum seifile, its leaves oblong, entire or slightly cut. Petals ten or twelve, lanceolate, very acute.—Found in vineyards in Navarre, also in the south of France, and probably in the Levant. De Candolle. Diffees from A. coronaria in its leaves divided leaves, and especially thofe of the involucrum, which are five or fix, elliptic-lanceolate, rough-edged, most of them quite entire, one or two only partially notched. The narrow and acute petal are also peculiar. We feel convinced with Lamarck and De Candolle that this must be a distinct species, though confounded by Linneus and others with the more frequent A. coronaria. We have not sought out its varieties among the double Anemones, but there is a scarlet one not uncommon. The French know some of these varieties by the names of Oeil de paon, Candida, &c. If this be not distinct, it should seem to belong to the following rather than to any other.

15. A. hortenias. Starry Garden Anemone. Linn. Sp. Pl. 751. Willd. n. 11. Ait. n. 8. Curt. Mag. t. 123. Sm. Fl. Græc. Sibth. t. 515, unpubl. (A. Hortenisia latifolia, simplici flore, n. 3—18; Clus. Hift. v. 1. 249—254. A. prima; Dod. Pernst. 434. A. secunda; Camer. Epit. 487. A. tubera, bulbocastani radice; Lob. Ic. 279. Ger. Em. 375. f. 5. A. n. 1122; Hall. Hift. v. 2. 64. A. flattata; Lamarck Dict. v. 1. 166. Brotn. Lufft. v. 2. 353. Savi Ettruf. v. 2. 122. De Cand. n. 14. "Fl. Franc. v. 5. 634.")—Leaves ternate; leaflets wedge-shaped, rough-edge, three-cleft, cut. Involutum seifile; its leaves lanceolate, undivided or partly cut. Petals ten or twelve, elliptic-lanceolate, obtuse.—Found on banks, ruins, or bushy waste ground, in the south of Europe; very commonly in Italy and Greece, flowering in the early spring; lefts abundantly in the south of France, and Switzerland. Clulius observed this species near Mentz. It has been known in gardens for a century, and is peculiar in beauty and variety, has given place to that popular species. We cannot follow Lamarck in its specific appellation, becaufe there is no end of changing names for the better; unless all leading botanists would concur in a general reform; and even in that cafe, positively erroneous names only should be altered. This pretty species has an oblong tuberous root, producing many leaves and stems. The latter are ternate, on long stalks; their leaves coriaceous, strongly veined, either cut half way down into three broad lobes, or divided nearly to the base, into three subdivided narrow ones; their segments all acute; their edges remarkably rough, though both surfaces are usually, if not always, smooth and naked. Involutural leaves three, an inch long, silky, rough-edged; one of them in general slightly notched at the end. Partial flalk long, silky, especially near the top. Flower scarcely above an inch wide, of a delicate rose-colour, or full carnation; the petals bilky at the back, veiny, often emarginate. The rough-edged leaves and involucrum are characteristic of this species, but the involucrum of pannonica, (we have not examined its leaves,) has the same character, which coronaria has not. We are strongly perfuaded of pannonica being a variety of hortenias, and that the acutens or bluntets of the petals is variable.

16. A. palustris. Cyclamen-leaved Anemone. Linn. Sp. Pl. 758. De Cand. n. 15. Willd. n. 12. Ait. n. 9. Andr. Repof. t. 172. Vahl Symb. v. 3. 73. Desfont. Atlant. v. 1. 432. (A. hortenisia latifolia, simplici flavo flore; Clus. Hift. v. 1. 248. Morif. féc. 4. t. 25. f. 3. A. latifolia Clusii; Lob. Ic. 275. Ger. Em. 376. A. latifolia flava; Barrel. Ic. t. 792.)—Leaves simile, heart-shaped, rounded, with three or five blunt, sharply-toothed lobes. Involutum seifile; its leaves in three linear, acute, hairy lobes. Petals ten or twelve, oblong, obtuse.—Native of rather moist waste ground, in Portugal, Spain, the south of France, and the north of Barbary, flowering early in spring. Rarely cultivated with us, except in curious gardens, though the brilliant golden flowers are very handsome. The leaves, notwithstanding Mr. Andrews's doubts, are truly palmet, differing from the last in being simile, and, though more or less hairy, not rough at the edges as in that species. They are coriaceous, strongly veined; often purple beneath. The involucral ones are three, almost uniform, hairy or filky, an inch long, narrow, each divided about half way into three nearly equal, sometimes notched, linear lobes; the edges apparently fringed, but not rough. Stalk above the involucrum rather long, filky. Flowers an inch and a half or two inches bread. Petal linear-obovate; the five outer ones remarkably hairy externally, and so disfigured in Linneus's only specimen, that he took them for the same kind of close calyx as occurs in Hepatica, only with a double number of segments. Thus he was led to place A. palustris in his first edition, Hepatica, and this will solve Vahl's difficulty, recorded in his Symbola above cited. But it will not account for this author's extraordinary quotation of Linneus's words, which are "calyx fesparitus, integerrimus, villosus, coloratus, nec a flore remotus. Vahl cites this pallage, "calyx hexaphyllus, coloratus, a flore remotus." The lopped double variety of the present speci-
ANEMONE.

acies, Chlor. Hift. v. 1. 249. f. 1, and Ger. Em. 376. f. 7, which De Candolle marks with doubt, and has never seen, is represented with the many-knobbed root of a Ranunculus, to which genus we should not be surprised if it proved to belong.

17. A. decapetala. Little Three-leaved Anemone. Ar- 
duin. Spec. 2. 27. t. 12. Linn. Mant. 79. De Cand. n. 16. 
Wildl. n. 17. Lamarck Dicî. v. 1. 167. ('Ab trilobata; 
Juff. Ann. du Mus. v. 3. 247. t. 21. f. 15.')—Leaves ter- 
rate; leaflets rounded, unequally three-lobed and toothed. 
Involucral leaves felife, three-twin, with linear seg-
ments. Petals ten or twelve, elliptic-lanceolate, obtuse.

Sent by Father Panizzi to professor Ardutus, from Brasil, 
where Comerçon also met with this curious little plant; as 
did Dombey and Nez in Peru and Chili. The root is ovate 
and tawerous, about the size of a fingerb.’ Leaves smaller 
than the leaf, and perfectly tawert, obliquely dotted, be-
prinkled with short hairs, but not rough-edged; their 
teeth unequal, bluntish, often callous-pointed. Stalk 
two or three inches high, silky at the top, with an involucrum 
about the middle, totally unlike the leaves, being doubly, 
but imperfectly, three-cleft, with linear segments, callous 
at the tips. Flower scarcely half the size of A. hortensis, 
which it resembles in form. The petals appear to be white; 
filky and purplish at the back.

Michaux Borel. Amer. v. 1. 319. De Cand. n. 17. ("A. 
Pursh 386.")—Leaves ternate; leaflets wedge-shaped; 
abrupt and tawert at the extremity. Involucral leaves 
fellife, deeply three-cleft, somewhat notched. Petals six, 
ovo-oblong.—Native of banks of rivulets at Hudson’s bay, 
Labrador, and Newfoundland, flowering from March to 
May. Akin to the two last. Radical leaves smooth and 
naked; involucral ones with oblong segments. Stalk very 
long. Flowers, according to Pursh, white, the size of A. 
memorofa. Seeds woolly, pointed, forming a globular head. 
De Candolle.

Carol. 157. De Cand. n. 18. ("A. tenella; Pursh n. 4.
"—Leaves ternate; leaflets deeply three-cleft, cut, sharply 
toothed. Involucral leaves three-cleft, notched. Petals 
ten or twelve, linear."—Gathered in Carolina, by the late 
Mr. Walter; on the banks of the Millouri, by governor 
Lawson; flowering in May. Root small, mellow. Herbs 
tender and delicate. Leaflets borne with only toothed, and 
others with deeply three-cleft, jagged, and sharply toothed, 
lubes. Stalk single-flowered. Involucrum of three leaves, 
with jagged segments. Partial flabk long. Petals small, 
white, externally downy. Seeds pointed, woolly. The 
fourth Ranunculus, Pluk. Almag. 310, cited doubtfully by 
De Candolle, who has omitted the word processus in tra-
scription, seems to us at best very uncertain, and particularly 
on account of that very word.

Symb. v. 3. 34. t. 65. De Cand. n. 19. Wildl. n. 18. 
Lamarck f. 3. ("A. fumariaefolia; Juss. Ann. du Mus. 
v. 3. 247. t. 20. f. 2.")—Leaves thrice ternate; leaflets 
cut; segments lanceolate, acute. Involucral leaves in many 
fetaceous divisions. Petals ten or twelve, oblong, obtuse.

Fruit cylindrical. —Gathered by Comerçon at Monte 
Video. It is said to have been also found in Peru, by Leu-
baz; flowering in November. The root and flowers bear 
a great resemblance to A. decapetala; but the leaves are 
totally different, being cut into innumerable, fine, disarrivated seg-
ments, quite smooth, entire at the edges, and not at all 
toothed or serrated. The involucrum too is somewhat dif-
ferent, each of its three leaves being first divided half way 
down, into three parts, and those subdivided into many 
flesher, tapering segments. The seeds are numerous, taper-
ing, beaked, very hairy, closely imbricated in a cylindrical, 
however elliptical, head, an inch long.

Cand. n. 20.—Leaves ternate; leaflets deeply divided 
into linear, obtuse, partly cut, lobes. Involucral leaves felife, 
in many deep segments. Partial flower-stalks in pairs, one 
of them with a partial involucrum."—Gathered by Michaux 
in the Levant. Of this De Candolle describes two var-
ieties.

Curt. Lond. f. 1. 3. 35. (A. geranifolia; Banh. 
hortensia tenuifolia, simplex flore; Chlor. Hilt. v. 1. 
254. Ranunculus nemorosus, flore caruleo, duplex, apennini 
monis; Mentz. Pugl. t. 8.)—Leaves twice ternate, pin-
atifid, sharply notched. Involucral ones flaked, ternate, 
pinnatifid and cut. Petals twelve to fourteen, oblong, ob-
tue.—Native of groves and thickets in some parts of Eng-
land, but rare, as near as Wimbledon, Lutton-hoe, and Ber-
hamstead. Fl. Brit. In Italy it occupies the place of A. 
memorofa in the more northern parts of Europe, and is 
equally plentiful, flowering in March and April. Dr. 
Sibthorp noticed it in the Morea; Dr. Clarke on the banks of 
the Simum; and the maron Marschall von Bieberstein in the 
Iberian Caucasus. The root is smaller than a filderb, bear-
ing one or two leaves, each on a zigzag footstalk, very 
flesher at the base. The leaves much resemb I Geranium ro-
bertianum; those of the involucrum are similar, but less 
separated, with narrower segments. Stalk solitary, from four to 
nine inches high, fiaky above the involucrum. Flower of a fiaky 
blue, with pale flaveus and fflavis, very beautiful, said to be 
of occasion whilily white.

r. 22.—Leaves... Involucral ones on short flalks, trilab 
pinnate, cut and toothed. Petals four or five, oval."— 
Gathered by Mr. Patrin, near Zemof in Siberia, flowering 
in the early spring. The root and radical leaves are 
wanting in the specimens seen by De Candolle. This species 
agrees in description with the leaf, but the partial flalk is 
... much
much shorter than the involucrum, and the small blue flower has only four or five roundish, very obtuse petals, more like *A. nemorosa*, except in colour.

***Involucre leaves flaked.*** Root-stock cylindrical, flender, elongated.

24. *A. baldenia*. Strawberry-fruit Anemone. Linn. Mant. 87. De Cand. n. 23. Willd. n. 14. Allion. Pedem. v. 2. 172. f. 44. f. 3, and t. 67. f. 2. (A. fragifera; Jacq. Misc. v. 2. 55. L. Rar. t. 103. A. alpina; Scepp. Cam. v. 1. 384. f. 26. A. n. 1151; Hall. Hist. v. 2. 63.)—Involucres twice-ternate, many-cleft; segments linear or wedge-shaped, acute. Involucral ones similar, flaked, lefs compound. Petals eight to ten, elliptic-oblong. Fruit ovate, woolly.—Native of the alpine precipices of mount Baldus, as well as of Switzerland, Dauphiny, Savoy, Austria, the Tyrol, &c., first cultivated in England by Mr. Lodidge, in 1792. It flowers early in summer. The root is long and woody. Leaves firm and rather glaucous, smooth, like rue, but narrower; their footstalks hairy, an inch and a half long. Flower-stalk hairy, erect, three or four inches high, with a large three-leaved involucrum below the middle. Flower white, rather larger than *A. apenninna*, with fewer and broader petals. Fruit the size and shape of a small strawberry; with the reddish beaks of its styles hinging out of the copious dense mats of twanny silky wool. * receptole* perfectly cylindrical.

Leaves ternate; leaflets in three, or five, deep, three-lobed, notched, lanceolate, acute segments. Involucral ones similar, flaked, lefs compound. Petals six, elliptical.—Common in groves and thickets throughout Europe, where *A. apenninna* scarcely occurs, flowering in spring. About the size of that species, with some resemblance of foliage; but there is less difference between the leaflets of the radical leaves and those of the involucrum. The root also is long and flender, not ovate. The flowers are white, often tinged with purple externally, formed of six broad petals, totally unlike *apenninna*. The double variety is very elegant. That with five deep lobes in each leaflet, occurs occasionally in England as well as North America, and is evidently a most trifling variety, though Linnæus, led perhaps by Plukkenet’s bad figure, made it a species.

26. *A. triloba*. Wedge-leaved Anemone. “Juff. Ann. du Mus. v. 3. 240. f. 20. f. 3.” De Cand. n. 25.—“Leaves twice ternate; leaflets somewhat wedge-shaped, deeply three-toothed. Involucre leaves flaked, ternate; lateral segments divided. Petals five, oblong.”—Described by De Candolle, from Juffien’s herbarium, but the native country of the plant is unknown. It is said to be extremely similar to *A. nemorosa*. The root is horizontal. Radical leaves on long stalks, whose partial stalks bear each three nearly wedge-shaped, cut, or toothed, leaflets. The lateral leaflets of each involucre leaf being divided, give the appearance of five leaflets in each. *Flowers one or two to an involucrum. Petals oblong, narrow, elongated.* De Cand. n. 21. *A. lancifolia*. Lanceolate-leaved Anemone. Pursh n. 2. De Cand. n. 26.—Leaves all stalked, ternate; leaflets lanceolate, bluntly toothed. Petals five, ovate, acute. On high mountains in a foggy soil, in Pennsylvania and Virginia, flowering from May to July. Refers to *A. nemorosa*, but the flowers are larger, of a clear white. Pursh. De Candolle says the leaf of *A. triloba* from which we are led to suppose that Plukkenet’s t. 106. f. 3, cited by Linnæus and others for quinquifolia, with which it does not well accord, may belong to the species before us.

28. *A. triloba*. Three-leaved Anemone. Linn. Sp. Pl. 762. De Cand. n. 27. Willd. n. 21. Ait. n. 16. Dodd. Pemps. 436. Ger. En. 357. Morif. sect. 4. t. 25. f. 1. (A. trifolia, flora albo; Bauh. Hist. v. 3. 412. Alabastrites, five Dentaria alba; Lob. Isc. 281.)—Leaves and involucre flaked, ternate; leaflets of all ovate, acute, serrated. Petals five or six, elliptical, obtuse.—Native of rather mountainous groves and thickets, in France, Piedmont, Tufcany, Carolina, Cariithia, and Siberia, flowering in spring. Gerard shows to have cultivated this species, but we have never seen or heard of it in modern times. The root is oblong, horizontal, somewhhat toothed. Leaves two or three inches high, each of these leaflets about an inch long, with hairy ribs and edges. Stalk about a foot high, or more, angular, smooth, bearing an involucre of three uniform flaked leaves, like the radical ones, but rather larger; the lateral leaflets very unequal at their base; the central one tapering into the footstalk. *Partial flower-stalk* about the length of the stalks of the involucre, solitary, simple, flender, hairy. *Flower* scarcely an inch broad. *Petals* from five to seven, white; purplish underneath.
