29. *A. nematina*. Leaf Anemone. De Cand. n. 28.—“Leaves..... Involucral ones stalked, deeply three-cleft; lobes ovate, pointed, serrated externally and at the extremity. Petals five, oval-oblong, obtuse.”—Native of the Alleghany mountains in Virginia; *Palisat de Beaucoup*. Remarkably tender and delicate, resembling *A. triloba*, but only one-third its size. Root long, flender, horizontal, fending out a few fibres. Radical leaves wanting in the speci- men. Stalk flender, round, smooth, a finger’s length. Leaflets of the involucre closely set; the lateral ones strongly furred at their outer margin, and from the middle to the end at both margins. *Partial flake* the length of the involucre, erect, downy, simple. *Flower* small, white. *Petals* smooth, four lines long, and two broad. *Siemen* half as long. *Germens* few, downy. *De Cand. n. 29. A. ranunculoides*. Yellow Wood Anemone. Linn. Sp. Pl. 762. De Cand. n. 29. Willd. n. 26. Fl. Brit. n. 4. Engl. Bot. t. 1484. Fl. Dan. t. 1452. Sav. Etirf. v. 2. 123. (A. n. 1153; Hall. Hist. v. 2. 64. A. nemorum lutea; Ger. Em. 238. Ranunculi quarta species lutea; Fuchh. Hist. 162. R. tertia species; Cord. Ann. 120, with Tragus’s figure of *A. nemorosa*, of which the larger part resembles that species, the smaller this. Ranunculus nemorosus luteus; Bauh. Pin. 178. Lob. Isc. 674. Morif. sect. 4. t. 28. f. 11.)—Leaves ternate or quinate; leaflets three-lobed, deeply notched; wedge-shaped at the base. Involucral ones similar, ternate or quinate, somewhat flaked. Flowers mostly in pairs. Petals five or six, elliptical.—Frequent in groves, thickets, and hilly pastures, throughout the north and middle of Europe, as well as Siberia and part of Caucausis, but rare in England. Mr. Hudfon found it in Kent and Harfordshire; and the late Mr. Geo. Anderdon brought us specimens from near Abbott’s Langley, flowering early in April. The root is flender, horizontal. *Herbage* not unlike *A. nemorosa*, but the
the leaflets are more elongated and cut, and the stalks of the involucre much shorter. The petals are broader, and of a full yellow. Flowers often two together, one of which, according to De Candolle, is sometimes deficient in petals. The partial flake appears to droop as the fruit ripens. The germens are nearly orbicular, compressed, downy, the style of each forming a strong incurved beak. There is said to be a violet-coloured variety found on the Pyrenees.

31. A. reflexa. Reflected Anemone. Stephen in Wild. n. 25. De Cand. n. 30.—"Leaves ternate; leaflets somewhat three-cleft, toothed at the extremity. involucral ones similar, flaked. Petals five or five, linear, obtuse, reflexed."—Native of Siberia. Stalk finely downy at the top, slender, a palm in height. Involucral leaves smooth, on downy stalks; their leaflets acute, tapering at each end. Partial flake solitary, shorter than the involucrum while in flower, erect, slightly hairy. Flower yellow, one-third the size of the leaf. Stamens very numerous, shorter than the petals. De Candolle, Wild.

*** Involucral leaves flaked. Root of ithe fibres.

32. A. falcifera, Snow-drop Anemone. Linn. Sp. Pl. 761. De Cand. n. 31. Wild. n. 15. Ait. n. 12. Curt. Mag. t. 54. Bull. Fr. t. 59. (A. falcifera prima; Chf. Hft. 144. A. tertia; Math. Valgr. v. i. 565. Loup. 1. 282. Cameroon. Epit. 368. Dickev. Hft. 815. A. Michelm.; Ger. Em. 277. A. n. 1159; Hall. Hft. v. 2. 63.)—Leaves ternate or quinate; leaflets lobed; deeply notched at the end. Involucral ones similar, flaked. Flower solitary. Petals six, elliptical. Fruit very woollen. Root fibrous.—Found in woods and hedges in various parts of France, Switzerland, the north of Italy, Germany, Siberia, &c. but not in England, though a very debile hardy perennial in our gardens, flowering in spring, and sometimes in autumn. The root consists of long, black, rather stout fibres, and creeps rather extensively. Leaves large, dark-green, veiny, nearly smooth, coarsely notched; their leaflets or lobes wedge-shaped at the base. Fower-leaf fifteen or eighteen inches high, erect, downy at the top, bearing about the middle three, rarely four, large, flaked involucral leaves, whole leaflets, five or more, are scarcely distinct at the base. Fower pure white, rarely purplish, or greenish, externally downy; its petals near an inch long, slightly coriaceous. Fruit ovate, the seedscohering for some time by their dense cottony wool, which, at length, by spreading itself, wafts them away. We have one Swifl's specimen with two partial flakes, one of which bears a partial involucrum, as in the next section.

33. A. alba. Cotton Anemone. "Juff. Ann. du Mus. v. 3. 248. t. 20. f. 1." De Cand. n. 32.—"Leaves ternate or quinate; leaflets deeply toothed at the end. Involucral ones similar, flaked. Flower solitary. Petals five, obovate. Fruit very woolly. Root fibrous."—Native of Dauria, and the Crimea. Very like the last, but rather smaller. Petals five, not six, shorter, rounder, and very obtuse. The seeds are woolly, that Demidow affirms they supply the place of cotton. De Candolle. We concur in opinion with our author, that this plant is probably a variety, we should say a very flight one, of the foregoing species. If distinct, the name of cozzipina would have been far preferable to alba. We would also suggest, that this last division of the fourth fection of the genus, rather belongs to the fifth, which is shown by its habit and by the eafual variation in the inflorescence of A. tyllelgis above noticed, of which we have seen more examples.

Seet. 5. Anemonepernos of De Candolle; not of former authors.

Seeds rather compressed, villous, hooked with the per-
ANEMONE.

Partial flanks long, straight and slender, single-flowered, rarely somewhat leafy. Petals three-quarters of an inch long, obtuse. Seeds compresse, pointed, sparingly downy. A variety, or perhaps a distinct species, found by Laxmann in Siberia, is mentioned by De Candolle, which approaches *A. narcissiflora* in the first appearance of its *inflorescence*, but is really more akin to *penovskyana*, differing, as it seems, chiefly in the situation of each small *partial involucrem*, near the bottom of their respective flanks. We have not seen any specimen.

—Frequent throughout Siberia. *Gmelin*. In wet woods, and natural meadows, of Canada, and the western parts of New York, flowering in May and June. *Puebl. Root finder*. Herb smaller than the preceding, and smoother, with only two leaves to the general *involucrum*, and the leaves or segments have larger, but much fewer, teeth or serratures. The *flower* moreover is smaller, tinged with red on the outside; and the *seeds* are smooth.

40. *A. vitisfolia*. Vine-leaved Anemone. Buch. MSS. De Cand. n. 39.—Leaves palmate, acutely seven-lobed, serrated; downy and hairy beneath. Involutures ones similar, three or five-lobed, flaked, heart-flavored, two or three together. Petals five, ovate. Germens smooth.—Gathered by Dr. Francis Buchanan, near Sembu (not Lamba), and Narainhettty, in Nepal, flowering in August and September. The *radical leaves*, in his own specimens, are from six to ten inches wide, smooth above, strongly and copiously veined, cut more than half way down, into three principal, pointed lobes, with two or three more shalowy, rounded, and imperfect ones at each side. *Foot-flakes* a foot long, angular, hairy. *Involuture leaflets* much smaller, and leaves lobed; their *flasks* of various proportions; three at the first subdivision of the tall downy *flower-flask*, two at the upper ones. *Flowers* the size of *A. fyiiflora*, white, externally silky, reddish, and strongly ribbed. *Seeds* numerous, covering a globular *receptacle*, interperfed with long, white, woolly down. This species is remarkable for the great size, and white downy backs, of its leaves, some of which rival those of *Rupbus edorus* in dimensions.

41. *A. rivularis*. Water Anemone. Buch. MSS. De Cand. n. 40.—Leaves ternate, hairy on both sides; leaflets wedge-shaped, three-cleft, notched, and harshly toothed; involucral ones spongy, deeply three-lobed, pinnatifid, cut. Petals five, ovate.—Native of the moat banks of rivulets in Upper Nepal; gathered by Dr. Buchanan, near Chittog, April 12, 1802. *Root* rather woody, as thick as the thumb. *Radical leaves* numerous, three inches broad, on hairy *flakes* from four to eight inches long. *General involucral ones* three, larger, more elongated and pinnatifid; *partial two*, with full *receptacle* lobes. *Flowers* half the size of the leaf, white; purplish and hairy beneath.

Seet. 6. Omalocarpus. De Candolle.

Seeds compresse flat, oval-obicular, very smooth, perfectly definite of point or tail. Flower-flasks numerous, singly-flowered, naked, forming an umbel in the involucrum; rarely solitary.

70. monantha. De Cand. (A. dubia; Bellard. App. ad Phil. Pedem. v. 26. t. 5. (not 252. t. 7.)

Radical leaves slightly hairy, in three or five, very deep, wedge-shaped segments, with unequal, linear-saccate lobes. Flowers umbellate.—Found in mountainous pastures, especially on a calcareous soil, almost throughout the northern hemisphere; in the Pyrenees and all the alpine countries, in Siberia, Caucasus, Cappadocia, as well as in Canada, and on the north-west coast of America; but not in Britain, Greece, nor the Archipelago, as far as we have any information. It flowers early in summer, and is of an elegant appearance, though seldom seen in gardens. The umbel of pure white flowers, with obvate petals, occasionally tinged, especially underneath, with purple, readily diffusions this species. The involucrum is spongy, divided like the leaves, and like them hairy on both sides, but not particularly so at the edges. The germens and broad seeds are quite smooth. Tournouer's plant, our Β, is a very slight variety, with a more dense umbel. We know Dr. Bellard's *A. dubia* merely from his figure, for he himself never saw more than one specimen; and we concur with professor De Candolle, who appears to have occasionally seen a two-flowered specimen, in making it a variety. Concerning the two Siberian plants, to which De Candolle alludes, as possible varieties of *narcissiflora*, we have not materials to form any opinion; nor were those with which he was furnished quite satisfactory.

43. A.
Vahl (A. lobes a but De "Bauh. Tourn. De Breyn. lobes parvtjlora, CahdoUe in 'V. footjlalks —have <an Jerfey. Cand. Root notched. v/cll to fays fmooth. Gmel. two more fegmcnts. from PI. hairs, De VI. f radical five, as been obferves, copied by three, who agree in fixe, and in cer- tain pale glands, between the segments of the leaves, pecu- liarly visible in thefe Siberian specimens, though not noticed by authors in any. We fuppect that these specimens may prove the identity of A. umbellata and norcflifora.

44. A. fabrica. Siberian Tawny Anemone. Linn. Sp. Pl. 763. De Cand. n. 43. Willd. n. 13. (A. n. 41; Gmel. Sib. v. 4. 199.)—Leaves deeply three-lobed; lobes wedge-shaped, in many deep, linear-oblong, bluntish, fringed segments. Involutural ones similar, on short flalzk, partly erupted. Flower foliary. Petals fix, orbicular. Germen smooth.—Native of Siberia, from the river Yenifey to the country beyond the lake Baikal. Gmelin. That author fays not a word more concerning the plant in question. One of his specimens is in the Linnean herbarium, and appears evidently allied, in the general nature of its foliage, as well as the smooth germen, to the two laft-described. The footflalks and the flower-flalks, which is only four inches high, bear many, long, scattered, spreading, tawny hairs. The flower is an inch and a quarter broad, with orbicular spreading petals, longer than the involucrem, and, as far as can be judged from a plant so long dried, they appear to have been yellow, or orange-coloured, refembling a Trollius. 
† Species not sufficiently known.

45. A. Walteri. Walterian Anemone. Purf n. 5. De Cand. n. 44. (Thalictrum carolinianum; Walt. Carol. 157.)—"Radical leaves palmate, on long flalks. Flower-flalk radical, erect, long, single-flowered. Petals five. Root tuberous and fibrous." Walter.—Native of Carolina. Mr. Purf never found this plant, nor could he meet with a specimen in Mr. Walter's herbarium; but he considered it as more probably belonging to Anemone than to Thalictrum. Professor De Candolle fuppects it may prove akin to A. parviflora, n. 18.

†† The following synonyms could not be reduced by De Candolle to any known species.
Anemone n. 1, 2, 4, 5, 6, and 9 of Matthiolius; fee the Valgarian edition, v. 1. 563—567, where are figures of the fift five, copied in Bauhin's edition of 1598, p. 460, 461; Dalech. Hilf. 442—444 and criticized in Bauh. Hilf. v. 3. 409. These are very obscure, and perhaps, as De Candolle observes, fictitious; some of the cuts repreffing species of Adonis, we fhou'd say Papaver, rather than any Anemone.

A. quinta; Camer. Epit. 390, copied in Bauh. Hilf. v. 3. 458, 459, by the name of A. ranunculi facie lutea. This seems a confusion of Eranthis (Helleborus) hylomali, and Ranunculus montanus.

Ranunculus nemorofus, Anemones flore minor; Bauh. Prod. 95.—Found at Montpellier; but not known to Magnol.

A. folio aconiti, radice rapunculi, flore ex purpurà albicante; Bauh. Hilf. v. 3. 427, 428. —Found on funny hills near Warfaw.

A. folio coriandri, radice olave, flore purpuro, Tabern; Bauh. Hilf. ibid. Probably, as De Candolle fuggifegs, A. coronaria.

A. folio multiplo bifurto, flore quadrifido, rubro, albo, ceruleo; Bauh. Hilf. ibid. —Native of Italy, Schonia, and the Morea.

A. Anguillare lutea quadrifolia, folii multisidis; Bauh. Hilf. v. 3. 428. —Native of Apulia.

A. lutea Rauwoldi; Bauh. Hilf. ibid. —Found about Aleppo.

P. orientalis tenuifimé divia et villofa, flore rubro; Tourn. Cor. 20.

A. flameniis; Scop. Ann. Hilf. Nat. 2. 54.—Native of mount Feude, in the Tyrol. This feems, by the author's defcription, to belong to A. alpina, as M. De Candolle fup- pects. We do not understand the reference of the latter to Fl. Auftr. 2. p. 43. There is nothing to the purpoze in that vol. and page of Jacq. Fl. Auftr. nor in Scopoli's own Flora Carniola.

—Found in Silefia.

To thefe may be added A. anomala, Rafinefque in Florida Ludoviciana 82.—Leaves ternate, fefille, cut. Petals five, unequal. Stem about a foot high.

For A. Hepatica, Linn. Sp. Pl. 758; fee Hepatica hereafter.

ANEURISM. Subsequently to the period when the article Aneurism was infefted in the early part of this Cyclopaedia, many new and valuable observations have been made upon the fubjeft; and the fucces of operations for the cure of the difeafe has been proved in a manner which has falificd the expectations of the moft fanguine. The firf grand improvement in this branch of operative furgery was unequivocally that of not opening the tumour itfelf, but cutting down to the vesif ial a certain distance from the difeafe, and there applying the ligature so as to impede the flow of blood into the aneurifmal fack. The removal of the filling was then left to the gentle and gradual action of the lymphatics; a process infinitely safer than the violent and painful proceeding of laying open the large tumour with a knife, extracting the coagulated blood, and leaving an ample cavity to fuppurate. But thofe were not the only objections to the old method of operating; for the fack was opened, and the artery tied in a futation where its coats were actually in a difeafeed flate. Hence the ligatures moftly faild in their effect; the vesif did not undergo favourably the
the adhesive inflammation by which it was to be closed; and the patient frequently either lost his life by hemorrhage, or was rescued by the performance of amputation under the worst and most disadvantageous circumstances. The genius of a Hunter was soon struck with the defects of the former plan of operating, and instead of meddling with the tumorous fistula itself, and tying the artery in a place where it was in a morbid condition, this dilated suture was perceived that it would be far better practice to tie the vessel where it was more likely to be found, viz., at the point some way from the diseased towards the heart. Thus in the popliteal aneurism, he avoided the painful operation of laying open the swelling in the ham, and more skillfully and scientifically took up the femoral artery itself in the middle of the thigh. From this important innovation, all the successors which has characterized this department of modern surgery has unquestionably been derived. By extending the same principles to other cases of aneurism, and putting due confidence in the competency of the collateral and anastomosing vessels to carry on the circulation, some of our present surgeons have deviated and practiced operations for the cure of such aneurisms, as a few years ago were looked on to be hopeless and inevitably fatal. Not only have the carotid, the external iliac, and the subclavian arteries been repeatedly tied with the most successful result, the internal iliac itself, whose situation seems to render it almost inaccessible to the incisions of the most skilful operator, has now had a ligature put round it in two memorable examples, one of which we have already noticed in the article Surgery. The other operation was performed by Mr. Atkinson, of York; the case being a gluteal aneurism, the same kind of disease for which Mr. Stevens operated at Santa Cruz. The patient, whose name was Thomas Coll, aged twenty-nine, presented himself at the York county hospital, April 29, 1817. He was a tall, strong, active bargeman, not corpulent, but very muscular. He was enduring great pain from a large, rent, pulsating tumour, situated under the gluteus of the right side, an obvious aneurism. It had existed about nine months, and was the consequence of a blow from a stone. In a consultation with Dr. Lantin and Dr. Wake, the necessity of the operation was determined upon, and it was performed on the 12th of May, without any material difficulty or interruption, except what depended on the aneurism-needle not being pliable enough, and what was the consequence of the division of, and bleeding from, the small muscular arteries. Having got command of the internal iliac artery within the pelvis, which, says Mr. Atkinson, required the complete length of the fingers to accomplish, the vessel was tied. Sufficient proof of its being the identical artery was repeatedly obtained, by the pressure upon it, which could not be closed. The patient was discharged, and the operation was successful, and the patient, as seen in the hospital, regularly walked forty miles in two or three days.

The operation was performed by Mr. Stevens, the record of it is highly interesting, as tending to dispel the doubts which have been entertained about the practicable nature of the proceeding. Even the aorta itself has now been tied in the human subject. Of course, the circumstances which justified such a bold proceeding were desperate in the extreme, nor could much hope of the patient’s life be indulged; yet, as it was the only thing from which a possibility of preservation could be derived, we think, notwithstanding its failure, much credit is due to the enterprising surgeon who performed it. We shall introduce a few particulars of the case in another place. See Aorta.

In the article Aneurism, in the early part of this Cyclopædia, will be found some observations tending to make the reader imagine, that this disease arises from such a kind of weakness as may be supposed to arise from the division of the outer coat or coats of an artery. We therefore take this opportunity of correcting the statement, since it has been fully proved by the experiments of Hunter, Home, Scarpe, &c., that aneurism never originates from this cause; and that even stripping off the external coat of the vessel will not give rise to such an effect.

With respect to tying the subclavian artery for the cure of axillary aneurisms, we ought to have remarked, that the operation, as performed by making an incision above the clavicle, has never had a successful result in this country; but, from a communication lately made to the Medical and Chirurgical Society of London, such an operation appears to have been recently executed with complete success by Dr. Poole, of New York. We believe this to be the only instance in which this mode of operating has cured the diseased, and saved the patient’s life. The artery, however, has been several times taken up in this way in London; once by the late Mr. Ramden, and again by Mr. Thomas Blizard; but their patients did not recover. The particulars of Dr. Poole’s case are inserted in the Medical-Chirurgical Trans. vol. ix. p. 185, &c.

ANGAR ISLAND, in Geography, an island of the Peruvian gulf, somewhat larger than Ormuz, and equally barren. It is now uninhabited, but prefects traces of former population in the ruins of a considerable town, and many refervoirs for water. It has two wells and a stream of good water, is covered with pits of salt and metallic ores, and also a soft rocky substance resembling lava: its hills, which are overgrown with shells of oysters and other fish, abound in wild goats, rabbits, and partridges. It forms an excellent harbour, which has been recommended for a settlement.

ANGELO AMERIGI, &c. (see 7. r. Domenichino; i. 17, after life, add.-The master-piece of all his works, viz. the Entombing of Christ, is now in the Louvre at Paris.}

This is one of those curious genera of ferns, which like DANEA, GELECHIATA, and MARATTIA, (see those articles,) bear their capsules on the back of the leaf, or frond, without either a ring or involucrum. In the present instance, indeed, these capsules are not of many cells, like those of DANEA and MARATTIA, but as perfectly simple as in OSMUNDA already described, or BOTRYCHUM hereafter to be
be mentioned. They are, however, not dispersed, or irregularly placed, but compose oval masses, of twelve or more carpelles, which masses are ranged side by side, in a dense uninterrupted line, near the margins of each leaflet of the frond, a vein from the mid-rib running along the base, or interfin, of each mafs, between its two rows of carpells. That these masses are determinate affembliches of carpelles of an appropriate figure, is evinced by their having at each end a solitary tranverse carpelle, completing their oval outline, which is not perfectly expressed in Dr. Swartz's figure. The genus is, doubtless, very distinct; and as its present name is not only faulty, but unmeaning, it would be well if Clementea, in honour of an able crypto-comic Spanish botanist, Don Simen de Roxas Clemente, had been retained. We should certainly now, without scruple, have restored it, were there not several other names of ferns, composed of pteris, which must stand or fall with Angiopteris.

1. A. euchla. Tall Angiopteris. Hoffm. Comm. Gatt. v. 12. 29. t. 5, excluding the synonyms, except Forrier's. Swartz Syn. Fil. 166. 395. Wildil. n. 1. (Polypodium euclectum; Forill. Prodr. 81. Clementea palmiformis; Cavan. Leccion. 554.)—Native of the Society islands, and of Maria's islands. We have an Otaheite specimen from Mr. Menzies. The main stem is said to be arborecent, five feet high, and a span in diameter. Fronds fix feet long, doubly pinnate; leaflets from two to four inches long, opposite, fiddle, linear-lanceolate, taper-pointed, smooth, as well as their common stalk; their margins finely crenate, the points forked. Capsules brown, smooth, very numerous, scarcely larger than grains of sea-feed.

ANGLE, Rectilinear, l. 2, for I. r. II. Angles at the Periphery, for I. r. II. ANGOY. See Goy and LOango. ANGRÁ. l. 1, r. Terceira. ANGUELLA. For MYTUS r. MYRUS.

ANGUILLARIA, in Botany, a genus dedicated by Mr. Brown, to the memory of LUIGI ANGUILLARI (see that article), apothecary, in the university of Padua, to the Venetian republic, who left an Italian work on the Materia Medica, which has been published at various times, and translated into Latin. Haller speaks of its author as deeply learned in this subject, and perhaps the best Italian botanist of the earlier part of the sixteenth century, having travelled much in Europe and the Levant, and studied critically the writings of those who had gone before him. Gertner has called a genus Anguillaria, from the singular appearance of its embryo, resembling aeel, Anguilla; but this is the ARBIA of all authors at present. (See that article.)—Brown Prodr. Nov. Holl. v. 1. 373.—Claps and order, Hexandra Trigynia. Nat. Ord. Tripetalidae, Limn. Junct, Juff. Melanthacece, Brown.

Gen. Ch. Cal. none, unless the corolla be so called. Cor. Petals fix, lanceolate, inferior, spreading, equal, deci- duous, each furnished with a claw. Stam. Filaments fix, inserted into the base of each petal, awl-shaped, shorter than the corolla; anthers oblong, peltate, revexed. Pfg. Ger- men superior, oblong, furrowed; hyles three, spreading, shorter than the stamina; stigma acute. Peric. Capsule ovate-oblong, naked, of three cells and three valves, the partitions from the middle of each valve. Seeds numerous, nearly globular.

Obf. Anguillaria is nearly akin to Ornithoglossmus. (See that article.)—It confits of herbs, exactly resembling the Cape species of Melanthium, especially in their leaves and roots. The flowers are sometimes dioecious, or polygamous. The claw of each petal is, in some instances, marked with a double gland. A. indica, in habit, of the flowers, the perfectly deciduous corolla, and perhaps the situation of the embryo, differs from the red; can it be a distinct genus? Brown.

2. A. biglandulosa. Glandular Anguillaria. Br. n. 2. Flowers united. Spikes few-flowered. Claws of the petals with two glaids at the upper part. —Sent from Port Jackson, by Dr. John White, where it was gathered by Mr. Brown. The filament is solitary, from four to six inches high, simple, round, bearing two distant, linear, smooth, recurved leaves; flowerings inflated, and broad at their base. Spike solitary, terminal, zigzag, of from three to five pale, perhaps yellowish, flowers, half an inch broad, each claw bearing a demi-lunar, glandular, prominent, dark-coloured glandular spot.

Rotal bulbous. Stem from fix to ten inches high, simple, erect, smooth and slender. Leaves two or three, linear, taller than the stem. Flowers terminal, usually two or three, one much earlier than the others, on angular stalks, with lanceolate blade various in size and number. Petals narrow, of a dark purple, as well as the styles, which are dilated and revolute. Capsule elliptical, crowned with the permanent styles.

ANGUIS, l. 9, dele which fee respectively, and add—See SERPENTES.

ANGULOA, in Botany, named in honour of Francis de Angulo, a Spanish naturalist, of whom or his works we have no information. —** Ruiz et Pavon Prodr. Pl. Peruv. et Chil. 118. t. 26.** Swartz Orchid. in Schrad. Neues Journ. v. 1. 89. —Claps and order, Cynandria Monogynia. Nat. Ord. Orchidaceae.

Gen. Ch. Cal. Perianther superior, revolved, of three ovato-lanceolate, concave, converging leaves. Cor. Petals two, resembling the calyx, but rather narrower. Nectary a lip shorter than the calyx, stalked, pithcher-shaped, somewhat bell-shaped, split longitudinally at the inner side, two-lobed; lobes rounded, reflexed at the margin; having in the notch in front a small, lanceolate, reflexed segment; in the pol- lenger part another, tongue-shaped, concave, erect appendage. Stam. Anther a vertical, large, hemispherical, incumbent lid, pointed in front, of two cells, deciduous; masses of pollen two, globular. Pfg. Germen inferior, cylindrical; style erect, gibbous, three-toothed at the top, the middle tooth with three points; stigma transverse, in front. Peric. Capsule with six angles, three of them larger than the rest, of one cell, and three valves. Seeds numerous.

ANHYDRITE. See Mineralogy, Addenda.

ANENGIO, l. alt. N. lat. 8° 39'. E. long. 76° 40'.

Gen. Ch. Cal. none, unless we take the corolla for fuch. Cor. of one petal, superior, tubular, externally clothed with compound hairs; tube curved, rather swelling upwards; limb in fix deep, irregular, lanceolate, acute, unequal segments, much shorter than the tube, directed upwards; the two lowermost largest and most spreading. Stam. Filaments fix, awl-shaped, inserted in the mouth of the tube, shorter than the limb, opposite to its segments, and having a similar direction; anthers linear-oblong, erect, bulrung lengthwise in front. Pjfl. Germen inferior, oval; filaments thread-shaped, ascending, on a level with the stamens, deciduous; stigma undivided, tumid. Peric. Capsule nearly spherical, of three valves and crowns, crowned with the permanent corolla, bursting at the summit. Seeds numerous, angular, inserted into the inner angle of each cell.

1. A. rufa. Reddish Anizoganthus. Labill. Voy. as above q. t. 22. Nov. Holl. v. 2. 119. Brown n. 1.—"Stem permanently downy. Anthers pointless."—Native of Lewin's land, in dry sandy defarts, where it flowers in December. The stem is two feet or more in height, round, much downy in the upper part; somewhat leafy below. Leaves linear, acute, narrow, entire, finely laciniate. Panicle corymbose, downy. Flowers externally covered, like the whole of the panicle, with reddish, branched and tufted hairs. Their partial flanks are short. Labillardiere's figure represents the anthers with a point, but not an incurved one. Nothing is recorded concerning the colour of the infide of the flower. The flowers appear to be dilated at the base.

2. A. flavida. Rufflet-green Anizoganthus. Br. n. 2. Ait. n. 1. Redout. Liliac. t. 175. Curt. Mag. t. 1151. (A. grandiflora; Salis. Parad. t. 97.)—"Stem and leaves very smooth. Down of the panicle deciduous. Anthers with a little reflexed point."—Observed by Mr. Brown on the south-west coast of New Holland. We rely on that gentleman for the above specific characters; otherwise we should, like Mr. Ker, have scarcely considered these two plants as distinct. The present is said to have been sent to Kew by Mr. Good, in 1803. It was raised from seed, in Mr. Vere's garden, by Mr. Anderfon, now of Chelsea, who found it required merely to be protected from frost, and flowered during most part of the summer. The leaves are sword-shaped, much broader than the foregoing. Flowers, according to Mr. Brown, smaller than in that species. They seem to be two inches long, externally green, with red, tufted, branched hairs, as well as their foottails; inside of the limb smooth, dull purple. Anthers red on one side, yellow on the other, not represented with so much of a point in the Botanical Magazine, as those of the first species in Labillardiere's figure. We have seen no specimens of either. M. Redouté has detected the same specific marks as Mr. Brown, and is the author of the above name. He had specimens of both from his friend Labillardiere, and on minute examination determined them to be most probably distinct. The flowers of A. flavida are smaller in his figure than in the Botanical Magazine.

ANIMAL FLOWER, l. alt. See Calendar.

Eff. Ch. Calyx tubular, five-cleft, with ten furrows. Upper lip of the corolla small, undivided; lower three-cleft, middle segment two-lobed. Stamens prominent, ascending. Anthers of the shorter ones with two adjoining cells; often the longer ones halved, or dissimilar. Seeds smooth.

Downy herbaceous plants, growing within the tropics. Leaves crescent. Flowers whorled, with minute bractees. Calyx glandular. Corolla purple. The genus is akin to Angya and Tercium, but sufficiently distinct from both one and the other. The upper lip of Angya is extremely short, and has a small central notch. Its anthers are observed by Mr. Brown to be uniform, kidney-shaped, of only one cell; and the seeds reticulated.

1. A. moschatas. Musky Anisomeles.—Leaves elliptical, downy and hoary like the stem. Flowers few in each whorl. Calyx greyish, with conspicuous glands.—Gathered by Mr. Brown, as well as the two following species, in the tropical part of New Holland.

2. A. inodora. Scentless Anisomeles.—Leaves elliptical, nearly smooth; dotted beneath. Whorls remote. Calyx green, with conspicuous glands.

4. A. ovata. Broad-leaved Anisomeles. Brown in Ait. n. 1. (Nepeta indica; Linn. Sp. Pl. 799, excluding the fynonyms. Wildl. Sp. Pl. v. 3. 57. Ballelia disticha; Linn. Mant. 83. Ait. ed. v. 2. 504. Willd. Sp. Pl. v. 3. 108. Marrubium odoratissimum, botanic foio; Burm. Zeyl. 153 t. 71 f. 1.)—Leaves ovate, or somewhat heart-shaped, strongly crenate or ferrated. Whorls many-flowered. Bracteae linear. Calyx hairy; with scarcely visible glands.—Native of the East Indies, from whence it is said to have been imported by the first earle of Bute, in 1783. The plant has hardly perhaps been preferred in the fows, being an annual, of no great beauty; however, interesting to the curious botanist. The whole herb has a velvet-like softness, owing to its fine, short, soft, depressed hairs; its habit and size very like our Ballelia nigra. The leaves sometimes very much resemble those of the common Urtica dioica, in size, shape, and ferratures, but are often rather crenate than ferrated. Whorls for the most part crowded into thick, partly leafe, spikes. Calyx very curiously reticulated with copious tranverse veines; its teeth large, broad, pungent. The upper leaf of the corolla did not escape Linnaeus, who found therein his specific character of this plant, as a Nepeta. His
herbarium proves Mr. Brown's suspicion to be correct, of
Ballota difficha being the same plant. The seeds well answer
to the generic character of Anisofagous, being beautifully polished,
polished, or a thinning black.
These plants, at least the three New Holland species, seem most allied to Teucerum Iva and falsifolium of Limnus,
now removed to Ajuga. The silky odor of the first species is
found in Ajuga Iva, whence a fugular variety of that
plant, with regular flowers, being taken by Forstall for
a new genus, received the name of Moscharia. (See that
article.) The elliptical form of the leaves in Anisofogous
mofchatus, rare in this natural order, agrees nearly with the
Limnus Teucerium Lasmann, which is likewise an Ajuga.
See Teucrium.
ANISOPOGON, from aniso, unequal, and pogon, a
beard, alluding to the inequality and diffmilarity of the
awns.—Brown Prod. Nov. Holl. v. 1. 176.—Cliffs and
Eff. Ch. Calyx of two linen, membranous, ribbed, equal
valves, single-flowered. Corolla filaked, of two valves;
outer cylindrically involute, three-awned at the top, the
middle awn twinned, the lateral ones bristle-shaped; inner
longer, unawned.
1. A. avenaceus. Ost-like Anisopogon.—Native of the
neighbourhood of Port Jackson, New South Wales. A
grafs three feet high, resembling an Avena. (See that
article.) Stems unbranched. Leaves involute, with a fringed
petiole. Panicule loose. Calyx-glumes large. The outer
valve of the corolla is silky, connected with its own by an
obedate joint. A small bristle, at the base of the inner valve,
indicates this genus to be more strictly allied to Danthonia,
(see that supplementarv article,) than to Aristida, which
latter the reader will find in its proper place.
ANNER. Add—An anker of brandy contains 10 gallons.
It is also a liquor measure not only at Amsterdam, but at
Copenhagen, Hamburg, and other places. (See Vat.)
At Copenhagen, a fuder of wine contains 2 pipes = 8 ox-
hofts = 6 ahms; the ahm or tierce being 4 ankers =
40 flushgens = 77½ kannes = 155 pots = 620 polec. A
fluckglas is 7½ ahms = 30 ankers = 32 pots hold the
weight of a Danish cubic foot of water, each being 6½
Danish inches high, 3½ ditto wide, and containing 64 cubic
inches: 55 Danish pots, or 27½ Danish kannes = 14 Eng-
lish gallons, and an ahm = 396 gallons nearly. The
ahm at Hamburg is the fith part of the fuder, and is 4
ankers = 5 emers = 20 viertels = 40 flushgens = 160
quarters = 320 eftelf. See Measure.
ANN, QUEEN, in Geography, a county of Marylvand,
containing 16,648 inhabitants, of whom 6381 are slaves.
ANNA, a money of account in India. See Rupee.
ANNAPOLIS Royal, l. 13, for item r. flera.
ANN-ARUNDEL, l. 4, r. 26,668; l. 5, r. 12,693.
ANONNA, in Botany, (see our former article,) is a
name of barbabarous origin, made into Latin by Linnaeus,
in allusion, as he tells us in Hort. Clff. 222, to the value
of the fruit, as yielding a grateful harvest or crop, annona, to
the people where it grows. Anona is generally supposed to have
been the original word, and is accordingly retained by
the French school. But by Bauhin's Pinax, Anona appears
to have full as authentic claims, on the score of priority, as
Anona. The latter is moreover a Portuguese corruption of the
original Amon, which Clufius taking from Oviedo, makes
Anon, Anon. Anona, a, is very incorrect. We trutt our
learned friends in France will not inful on such an inaccuracy,
any more than on their great countryman Plumer's
name, Guiananacs, which they have commendably rejected,
tough of older authority than Linnaeus or Joffieu.—Linn.
Vot. XXXIX.

(Guanabanus; Plum. Gen. 42. t. 10)—Cliffs and order,
Jutf. Anonaceae, De Cand.
Eff. Ch. Calyx in three, more or less deep, concave,
somewhat heart-shaped, frappinous lobes. Petals fix, thickish,
the three innermost smaller or wanting. Anthers numerous,
nearly free, covering the receptacle; angular and dilated
at the summit. Germans numerous, coalescing into a single
fleshy berry, whose coat is either tuberous, fcaly, or reticu-
lated, the internal substance pulpy, surronded with
numerous, fingle-seeded cells. De Candolle.
N.B. In our former article, line 12, read (or a compound
berry, as in Rubus).
The species are trees or shrubs, whose bark is often reti-
culated, glansdular, and aromatic. Leaves undivided, some-
times besprinkled with pellucid dots. Flowers-stalks either
axillary, or oppofite to the leaves, often folitary, bearing
one or more flowers, sometimes accompanied by small
bractees.
Obf. Very rarely the calyx has four lobes. The inner
petals are occasionally imperfect.
Twenty-seven species are defined by De Candolle, but of
these five are marked as imperfectly known. They
are difposed in five fections, by the shape and confidence
of their petals.
Sect. 1. Petals concave, thick, rather coarifous, either
heart-shaped or ovate. Eleven species, subdivided as follows.
* Outer petals acute; inner ones obtuse, and rather
** Outer petals obtuse. Sp. 5.
*** Petals all acute; inner ones rather the smallest. Sp.
6—11.
A concise view of the species will be sufficient, following
the numbers of De Candolle.
1. A. muricata. (See Anon. n. 1.) Linn. Sp. Pl. 756.
Jacq. Obf. fac. t. 10. t. 5. (Zuurvack; Merian Surin.
t. 14.)—Leaves ovato-lanceolate, smooth, sometavt
thing. Stalks folitary, fingle-flowered. Outer petals hear-
shaped, pointed; inner obtuse. Fruit armed with fleshy
pointed tubercles.—Native of South America and the West
Indies. The flowers are large, yellow. Fruit as big as a
large pear, green or yellow, much eltement.
2. A. purpurea. "Dural Monogr. 64. t. 2."—Leaves
nearly fleshy, lanceolate; rather rufty beneath. Flowers
axillary, amolf fleshy. Outer petals heart-shaped, acute;
infen roundish.—Found in Mexico. Fruit unknown. Outer
petals yellow-brown; inner purple.
3. A. Humboldtii. "Ibid. 64. t. 3."—Leaves oblong,
poufed, smooth, slightly dotted. Stalks axillary, folitary,
short, fingle-flowered. Outer petals ovate, somewhat hear-
shaped, acute; inner bluntish.—Found by Humboldt
and Bonpland, in the South American province of Cumania.
A fbrub. Flowers yellowish, dotted with purple
and red.
Carol. v. 2. t. 67.)—Leaves ovato-lanceolate, smooth.
Stalks folitary, fingle-flowered, drooping. Outer petals
heart-shaped, acute; inner rounder. Fruit smooth, obovate.
—Native of South America, and some parts of the West
Indies. Outer petals large, green; inner white. Fruit green,
shaped like an inverted pear.
65."—Leaves oblong-lanceolate, wavy, pointed, copiously
ribbed; the young ones downy. Stalks axillary, fingle-
flowered.
ANNONA.

15. A. Forshihii. De Cand. n. 15. (A. glabra; Forst. \AEgypt.-Arab. 102. 1c. t. 15. A. a
tatica; Vahl Symb. v. 3. 73. "var. \sigma; Du
c Monogr. 71. A. squamosa; Delile \AEgypt. 17.\"")—Leaves ellip
tic-oblong, smooth, dotted; glaucous beneath. Outer pe
tals oblong, somewhat converging.—Gathered by For
khal and by Coquebert in Egypt. Scarcely, in De Candol
e's opinion, distinct from A. squamosa, but the leaves are
tinner and less pointed, more distinctly dotted.

16. A. cinerea. "Dunal Monogr. 71. t. 8.\"—Leaves
eelliptic-oblong, almost lanceolate, dotted; downy b
dneath. Outer petals somewhat converging. Fruit ovate,
nearly globular, fleshy.—Gathered by Ledru in the is
land of St. Thomas, but perhaps not really wild. The young
branches, leaves, stalks, and flowers, are clothed with grey
tish pubescence. Flowers flushed, two or three together. Fruit not unlike A. squamosa.

v. 2. 124. (A. tripetala; Aubl. n. 2. See Anno
n a n. 2. Guanabanus Pericex folio, flore in
to albo, &c.; Feuill. Peruv. v. 3. 24. t. 17. Trew Ehret, 16. t. 49.\)—Leaves ovate-lan
colate, without dots; very finely downy and fleshy
beneath. Outer petals slightly converging; externally
downy. Fruit nearly globular, somewhat fleshy.—Na
tive of Peru, or rather perhaps of some warmer country; for
Feuilles speaks of this tree as cultivated there with great
care, for the sake of its fruit, which is very wholesome, and
much esteemed, though, he adds, one of our pears or plums
is certainly worth all the Cherimolas of Peru. The tree
is twenty to twenty-four feet high, with pendulous
branches. Flowers pale green, with a crimson circle in the
middle. Fruit heart-shaped, fleshy and rough, the size of a
small apple, being drawn too small in Ehret's figure. De
Candolle says there are three inner petals, though very minute.

757. Wild. n. 5; excluding the syn. of Rumphius
maram; Rheede Hort. Malab. v. 3. 23. t. 30. 31. Guanabanus
fructu purpureo; Plenn. Ic. 134. t. 143. f. 11; not 43. f. 2.\)
—Leaves oblong-lanceolate, acute, smooth, slightly dotted.
Outer petals oblong, rather converging. Fruit ovate, nearly
and dotted, fleshy. Outer petals oblong, rather con
cering. Petals green, nearly globular, fleshy. Petals three.
Petals brown underneath; yellowish-white above, dotted
with purple at the base. Fruit the size of a large orange,
but more ovate, of a shining yellowish or reddish brown,
ripe. Professor De Candolle suspects that several species
may be here confounded; and Dunal distinguishes the plant of
Jacquin, from that of Rheede, by the reticulations of the
fruit being somewhat pentagonal in the former, more
rounded in the latter. Plumier’s flesms still more different
from both, in having the intericles very convex, each armed
with a spine. Domby appears to have gathered and pre
served under this name, in Peru, a species distinguished by
broader leaves, not marked with pellucid dots, but with
more regular and prominent pinnate ribs. All these points
can be cleared up by the acquisition of authentic fpecimens
only, or by observations made on the spot. The history of
the whole genus is as yet but a sketch, nor have European
botanists materials to fill up the outline.

19. A. mucofa. (See Ann o n a n. 19.) Jacq. Obf
fac.
ANN f. 1. 16. Add. Guian. 618. (Manoa; Rumph. Amb. v. i. 136; t. 45.)—Leaves oblong-lanceolate, smooth. Outer petals spreading at the extremity. Fruit tesselated, with gibusous interstices.—Native of South America and some parts of the West Indies. Cultivated in the Molucca islands. This is said to differ from the last, in having the interstices of the fruit tumid, (what then becomes of Plummer’s t. 143. f. 11) its pulp more yummy, and not agreeably flavoured. The leaves also are somewhat narrower.

Sect. 4. Outer petals elliptic-oblong, obtuse; inner smaller, lanceolate, bluntish. Calyx large, coriaceous, three-leafed, somewhat bell-shaped. Fruit conical, smooth? Three species.

22. A. glabra. (See Annona n. 8.) Linn. Sp. Pl. 718. Willd. n. 10. ("A. maxima, folis latis, fructu maximo, luteo, conoide, cortice glabro; Cateb. Car. v. 2. t. 64.");—Leaves ovato-lanceolate, smooth. Stalks two-flowered, opposite to the leaves. Fruit conical, obtuse, even.—Native of Carolina, according to Cateb. Cultivated perhaps in the West Indies. A tree sixteen feet high, with smooth leaves, much resembling those of a lemon-tree. Calyx red-dish externally, of three broad, very short, often abrupt lobes. Petals fix, nearly obovate, twice the length of the calyx.

21. A. grandiflora. Lamarck Dict. t. 2. 126. Willd. n. 17. "Dul. Monogr. 75. t. 6 and 6 a."—Leaves ovato-lanceolate, smooth; shining above. Stalks axillary, solitary, fruit. Leaf ovate, smooth, somewhat dotted.—Native of the Mauritius, and Madagascar. Leaves rather glaucous beneath. Calyx, and backs of the petals, finely downy. The inner petals are an inch long, being nearly equal to the outer. Fruit of a muddling hue, slightly rugose.

22. A. amplifolius. Lamarck Dict. t. 2. 127. Willd. n. 18. "Dul. Monogr. 76. t. 7."—Leaves oblong-heart-shaped, clapping the stem, acute, smooth. Stalks axillary, solitary, fagine-flowered.—Found by Commodon in the ifes of the Mauritius and Madagascar. The leaves are fefile; coriaceous or purplish beneath, at leaf when dry. Three inner petals rather the same.

Sect. 5. Annona not sufficiently known. Five species.

23. A. affatica. (See Annona n. 9.)—Linn. Sp. Pl. 735. Willd. n. 12. "Leaves oblong, pointed, without dots; downy when young.—Native of Ceylon. Annona. A species under this name is found in his herbarium, but there is no evidence of its being what he intended in his Pl. Zeyl. nor even in the first edition of Sp. Pl. There are neither flowers nor fruits, nor can we satisfy ourselves of this species being the same species as the botanists of Tranquebar fend us for A. affatica, which latter agrees better with Symp. mos. n. 14.

24. A. fealerufa. "Perf. Ench. v. 2. 95. Dul. Monogr. 75."—Leaves broadly ovate, somewhat heart-shaped, coriaceous, smooth; glaucous beneath. Footstalks finely downy. Flower-stalks two or three together, lateral, between the leaves.—Native of Senegal and Guinea. Flowers small. Three outer petals ovate, obtuse, thick, thrice the length of the calyx.

25. A. frutifera. "Dul. Monogr. 76."—Leaves oblong, pointed, smooth; glaucous beneath. Flower-stalks downy, hoary, opposite to the leaves.—Native of Para, in Brazil. Young branches downy and hoary. Leaves nearly sericeous. Flowers opposite to the uppermost leaf on each branch, with one or two orbicular leafy bracts. Calyx in three large, deep, ovate, coriaceous segments, externally hoary. The unexpanded petals appear similar thereto. A beautiful species, but the genus is doubtfulness. De Cand.

26. A. exsulca. "Dul. Monogr. 77."—Leaves ovate-oblong, coriaceous, smooth, like the branches, on both sides; polished above. Flower-stalks simple or divided, nearly opposite to the leaves.—Gathered in the woods of Guiana, by Mr. Alexander Anderson, whose specimens were examined by professor De Candolle in Mr. Lambert’s herbarium. A handsome tree, with a small, entirely dry, fruit. Branches smooth from the first. Leaves two and a half to four inches long. Petals three-lobed! This surely may well be deemed a doubtful Annona.

27. A. africana. (See Annona n. 10.) Linn. Sp. Pl. 758. Willd. n. 14; excluding the synonyms. (A. folis lanceolatis pubescentibus; Linn. Hort. Clift. 222.)—"Leaves lanceolate, downy."—This is recorded in the Hortus Cliffortianus to have sprung up from African seeds. The "habitat in America" is therefore a grofs and palpable slip of the pen, in the second edition of Sp. Pl. (it is Asstipodia in the first,) which the editors of Linnaeus’s writings should have corrected; for such a contradiction of the specific name, might have induced some inquiry. Nothing appears for this species in the Linnaean herbarium. In Hort. Cliff. the branches are said to be rough with minute dots. Leaves ovate, but rather elongated; downy, and in a manner hoary, on both sides, by no means polished.

For other plants which have been referred to Annona, see Organicum, Asimina, and Monodora.

ANOMALY. col. t. 17, for 122,441 r. 1,222,441.

ANOMATHECA, in Botany, from nymus, out of rule, and bege, a cafe; because the capsule is distinguished by its papillary roughnesses, from all the rest of the plants of the fame natural order, that have hitherto been examined.—

Gen. Ch. Calb. Sheath inferior, of two very small, elliptical, concave, leafy, nearly equal valves. Cor. of one petal, superior, falver-shaped; tube many times longer than the sheath, straight, nearly cylindrical, a little dilated at the mouth; limb not quite regular, in fix, nearly equal, obovate, deep segments. Stam. Filaments three, inserted into the tube, thread-shaped, erect, much shorter than the limb; anthers vertical, oblong, converging. Pyf. German roundish; flye thread-shaped, about the length of the flaments;figmas three, deeply divided, with linear, spreading segments. Peric. Capsule roundish-ovate, of three cells and three valves, its surface covered with small, papillary tubeles. Seeds numerous, round.

1. A. junca. Cut-leaved Anomatheca. Ker n. 1. Ait. n. 1. (Lapeyrroufa junca; Curt. Mag. t. 66b. Gladolus junca; Linn. Suppl. 94. Thumb. Glad. n. 18. Cap. v. i. 201, excluding the synonym of Jacobin! Redoutt. Lilac. t. 141. G. polyfrachus; Andr. Repof. t. 66.)—Found by Thumberg, in Lange Kloof, at the Cape of Good Hope, flowering from October to December. It flowers in May in our green-houses, where it is not uncommon, being easily propagated by offsets and by seed. The bulb is ovate. Leaves radical, equitant, sword-shaped, acute, dark-green, many-rubbed, with a deep flopping notch at their outer edge, from the base about half way up. Stalk a foot high, being twice as tall as the leaves, round, rather slender, branched, smooth, bearing many solitary, unilateral, slightly zigzag, flices, of elegant, rose-coloured, sentient flowers; the irregularity of whose corolla is evinced by the three lower segments being each marked with a deep red spot, and the middle one being moreover

T 1 2

white
ANONACEÆ, the fourth natural order of the Dicotyledones, or Exogenæ, of De Candolle; separated from the Commelinæ by the Anona of Jussieu, being thus named after Anona, one of the chief genera. De Candolle thus defines the order.

Calyx of three lobes, very rarely of four. Petals fixed, in two rows, alternate with each other; the inner row sometimes wanting. Stamens indeterminate, unconnected. Gersmens indeterminate; very rarely foliary. Fruit compound, either separate or combined. Seed with internal processes, separating the portions of the albumen.

FRUCTIFICATION. Calyx inferior, short, permanent, more or less deeply three-angled, very rarely with four lobes. Petals fixed, inferior, in a double row, alternate with each other, more or less coriaceous, and somewhat reenabling an inner calyx, imbricated in the bud, though each row is valvular in that state; the inner one sometimes larger, sometimes smaller, rarely wanting. Stamens numerous, clove-prefixed, generally covering the hemispherical disk (or receptacle of the flower); filaments very short; anthers nearly fleshy, with glandular, quadrangular, occasionally excoriaceous points; their cells bursting longitudinally, externally, and downwards. Gersmens mostly numerous, crowded closely together, in some instances aggregate or combined, in others, though very rarely, and profusely from abortion, solitary. Styles one to each germer, short. Fruits as many as the gersmens, fleshy or fcelate, sometimes combined, either pulpy or capsular, with one or many seeds, which are ovate, or ovate-oblong, in one or two rows, inserted into the inner corner of each fruit. Their skin is brittle, membranous or crenaceae, having internal, sometimes plaited, processes, either flat or awl-shaped, infiltrating themselves into the chinks or perforations of the albumen. The latter is fleshy, hard, shaped like the feed, very often bordered with a depressed furrow, accompanied by transverse plats, or contiguous perforations. Embryo minute, situated in the umbilical region of the albumen. Cotyledons short. Radicle nearly cylindrical.

HABIT. Trees or shrubs, with round, often slightly tworanked, branches, whose bark is mostly either reticulated, or warty; the young ones generally downy. Leaves alternate, connected with the stem by a joint, either fcelate or with short footstalks, fimple, almost always entire, or scarcely toothed, with pinnate veins; folded, and often downy, when young. Stipules none. Flower-stalks mostly axillary, sometimes lateral, or opposite to the leaves, solitary, generally furnished with small bracteas; they are shorter than the leaves, bearing one or many flowers, and not uncommonly twirled into a hook, some of the flowers being abortive.

QUALITIES. The roots, bark, leaves, and fruits, especially such as are capsular, are acrid, pungent, aromatic, and stimulating, often used for feasting. Those fruits which are of a fleshy nature are eatable, and esteemed in tropical climates.

HISTORY. The Anonaceæ, as being all strangers to Europe, were unknown to the ancient botanists. Cæsar Buebin has scarcely indicated two species, Linnæanus thirteen, Wildenow thirty-six, Peroon forty-four; but Dunal in a most excellent treatise, almost literally followed by De Candolle, defines one hundred and five. Of these, five are natives of the temperate zone in America; forty-seven of the tropical regions of the same quarter of the globe; eight of equinoctial Africa; three of the Mauritian isles; twenty-six of India or its islands; six of China and Japan; two of New Holland; and there are six whole native country is uncertain.

AFFINITIES. This order agrees with the Magnoliaceæ of the same learned author, in having the parts of the flower disposed in a ternary order, anthers united to the filaments, numerous petals and fillets; but differs very essentially (according to him) in having no fillets, and differently shaped anthers as well as seeds. Some few climbing species make an advance towards the Menispermae; but the indefinable filaments, and the structure of the fruit, afford a distinction. The Anonaceæ differ from all other polypetalous orders, with a superior germer, in the ternary structure of their flowers, as well as in the very peculiar insertion of the internal processes of the seed into its albumen. Such a structure was indeed found by Mr. Brown, in his Euonati (hereafter to be described in its proper place); a genus otherwise very different from the order before us.

The genera enumerated by De Candolle are, Kadipura of Jussieu; Anona of Linnæus; Monodora of Dunal; Afina of Adanson; Porcelia of Ruiz and Pavon; Uvaria, Xylopia, and Anona of Linnæus; and Quatteria of Ruiz and Pavon.

ANOPLOTHERIUM, in Natural History, an animal of an extinct genus, whose remains are found in a fossil clate in the vicinity of Paris. It is so called by Cuvier, to denote that it was without weapons, having no canine teeth. In the natural syllem, this animal should be placed between the horbe on one side, and the hippopotamus, the pig, and the camel on the other. The remains of five species of the anoplotherium have been discovered. The largest was the size of a small horse; the smallest not larger than a small rabbit. See STRATA in the Vicinity of Paris.

ANOPHELIUS, in Botany, owes that appellation to Labillardiere, who meant to express the situation of the wing, at the upper part of the feed, the word being formed from ανου, upwards, and ανω, a wing.—Labill. Nov. Holl. v. 1. 85. Brown Prodr. Nov. Holl. v. 1. 457.—Clams and order, Hæxandria Monogynia. Nat. Ord. Gentiana, Jufi, or perhaps Erices, according to Mr. Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, in six deep, acute, equal, spreading segments, permanent. Cor. of one petal, bell-shaped; tube very short; limb in six deep, equal, concave, obtuse, imbricated segments, much longer than the calyx. Stam. Filaments fixed, awl-shaped, smooth, equal, inserted into the tube of the corolla, opposite to each segment, and about half as long; anthers incumbent, heart-shaped, obtuse, two-lobed. Fil. Germer superior, ovate; style short, cylindrical, erect; stigma in two acute lobes. Peric. Capsule elliptic-oblong, of one cell and two valves. Seeds numerous, inserted into the margin of each valve, pendulous, imbricated, each crowned with an obovate, obtuse, membranous wing, twice its own length.

cloven. Capsule of one cell and two valves. Seeds imbricated, pendulous, winged.

1. A. glandulofila. Glandular Anopterus. Labill. Nov. Holl. v. 1. 186. t. 112.—Native of Cape Van Diemen. An elegant slender tree, about thirty feet high, very smooth in every part. Leaves scattered, occasionally opposite, obovate-oblong, serrated, fiddle-shaped, coriaceous, about four inches long, rather bitter to the taste; tapering at the base; a black prominent gland on the inner edge of each fork. Clusters terminal, simple, half the length of the leaves, either solitary, or as many as four together. Corolla about the size and shape of Psyrota rotundifolia; of its colour nothing is recorded, Labillardiere’s descriptions having been drawn up from his dried specimens after his return to Europe. Mr. Brown remarks, that the embryo is minute, nearly globose, enclosed in a flabby albumen; the radicle superior.

Eff. Ch. Calyx in two deep segments; keeled at the back. Corolla none. Style divided. Stigmas two. Seed clothed with the compref pendulous, two-winged calyx, emarginate at the top and rounded at the base.

Climbing Anredera. (Fegopyrum scandens, feu Volubils nigra major, flore et fructu membranacei, subtomentis; Sloane Jan. v. 1. 138. t. 90. f. 1.)—Native of Jamaica, growing among trees near the ruins of a monastery by the town. Sloane. The stems are twining, round, red, succulent, climbing to the height of seven or eight feet. Leaves alternate, heart-shaped, or somewhat deltoid, succulent, smooth, entire, two inches and a quarter long; on footstalks half an inch in length. Clusters numerous, alternate, many-flowered, axillary and terminal. Flowers orbicular, compref pendulous, green, bordered with a thin white membrane formed of the keel of each calyx-leaf. As the seed ripens, they turn brown. Sloane compares them to parsiup-seed. Swartz feems not to have noticed this plant. Its habit is nearly that of Bafella.

ANTELOPE, col. 3, l. 7 from bottom, r. Buralis or Cervine Antelope.

ANTHERYLIUM, in Botany, so named, either by Vahl or Von Rohr, apparently from alpha, an antler, and ως, wood, or materials of any kind, in allusion to its numerous and conspicuous anthers.—Vahl in Mem. of the Nat. Hist. Soc. of Copenhagen, v. 2. 211. Willd. Sp. Pl. v. 2. 980.—Clais and order, Iceniardia Monogynia. Nat. Ord. Hooperiæ, Linn. Myrti, Juff.

Gen. Ch. Cal. Perianth of one leaf, inferior, in four deep, lanceolate, spreading, permanent segments. Cor. Petals four, inserted into the calyx between its segments, large, obovate, pointed and undulated, with short linear claws. Stam. Filaments numerous, from about thirteen to fifteen, capillary, inserted into the calyx, longer than the corolla, permanent; anthers incumbent, convoluted, furrowed. Pist. Gynem superior, globose; style thread-shaped, very long; stigma capitiate. Peric. Capsule globose, oblong, triangular, of one cell, and three, occasionally four, valves, burrifying at the top and deciduous. Recapit. globose, somewhat triangular, spongy, dotted with little hollows to receive the Seeds, which are numerous and minute.

1. A. Robur. Flowery Antherylium. Vahl as above, 212. t. 8. Symb. v. 3. 66. Willd. n. 1.—Native of the West Indian island of St. Thomas. Von Rohr, and Weigt. A tree, with round, grey, scattered, keeled branches; leafy, and somewhat quadrangular, in their upper part. Leaves nearly opposite, flaked, ovate, acute, entire, two inches long, thin, very smooth, with one rib, and many transverse veins. There is a pair of filipendulous prickles, at the base of each footstalk, which disappear from the older branches. Flower-flasks axillary from the internode of the last year’s leaves, from five to eight, fewer on one side of the branch than the other, hardly an inch long, simple, fingle-flowered, naked, thread-shaped. Capsule downy, the size of a currant. Nothing is recorded of the colour of the flowers, nor of the qualities or use of any part. The habit of the tree is compared by Vahl to the Lenticis of Swartz, to which genus he supposes this to be allied. He suspects also some affinity to Aublet’s Botrya. See that article.

ANTHEBOLUS, we preface from aor, a flower, and μαθις, or lamp, the flowers forming little dense tufts.

Female, Calyx of three deciduous leaves. Corolla none. Stigma sessile, three-lobed. Drupa with one seed. Embryo inverted, in the axis of the flichty albumen.

Akin to Exocarpus and Osyris. (See those articles.) The genus confines of smooth fubby shrubs, copiously branched, in habit resembling Ophrys, the principal as well as the ultimate branches jointed at their internation. Leaves scattered, fcelled, articulated with the branch, narrow, nearly thread-shaped, delilute of fipilalis. Flower-flasks axillary; the male ones bearing each an umbel of three or four flowers; the female from one to three, jointed in the middle when simple, at the division when branched, and furnished at the joint with two deciduous bracteas. Flowers small, yellowish.

1. A. filosus. Slender-leaved Anthobulus. Leaves thread-shaped, lax, as well as the young branches.—Gathered by Mr. Brown, in the tropical part of New Holland.

Gen. Ch. Cal. Perianth inferior of one leaf, cut half way down into five equal, erect, acute segments, permanent. Cor. of one petal, wheel-shaped; tube bell-shaped, contracted at the base, twice as long as the calyx; limb about as long as the tube, in five, sometimes seven or eight, very deep, equal, linear-lanceolate, spreading segments. Stam. Filaments four, with the rudiment of a fifth, inserted into the bafe of the tube, and not above half so long, awl-shaped, simple, smooth; anthers roundish, incumbent. Pist. Gynem superior, oblong; style cylindrical, the length of the tube; stigma capitare, notched. Peric. Capitale ovate-oblong, of two cells and two valves, with infolded edges, meeting the parallel partition. Seeds numerous, small, roundish, reticulated.

two cells and two valves, with infixed edges, and a parallel partition.

The shrubby smooth genus, whose habit announces an affinity to the Salicae, but whose regular, deep-cut, radiating corolla, is altogether fringe in the Linnæan class Didynamia. The leaves are alternate, tapering at the base, or somewhat stalked, articulated with the branch, thick, sometimes dotted with glands. Flowers axillary, nearly solitary, their stalks minutely bracteated, and mostly separating early at the joint. Corolla white or yellow, handsome; its tube internally triated; limb in from five to eight segments.

—Discovered by Labillardière in Lewin's land; and observed in the same neighbourhood by Mr. Brown, and Mr. Good.

The latter sent feeds to Kew in 1803. This is a greenhouse plant, flowering during mott part of the summer. Mr. Aiton favoured us with a specimen in May 1811, when it first began to produce flowers. These are an inch in diameter, indoros, pale lemon-coloured; the radiant segments of the limb narrow, taper-pointed; the tube triated internally with deep violet. Leaves about an inch long, abrupt or margined; nearly entire in our specimens. Labillardière says they are sometimes toothed, or serrated.

2. A. villosa. Glutinous Anthocereus. Br. n. 2.—

"Leaves obovate, marked with glandular dots; roughish at the edges; when young finely downy, as well as the young branches. Capsule ovate, about the length of the calyx."—Native of the southern coast of New Holland. Brown.

We have seen no specimen of this species, but from the above account, furnished by Mr. Brown, we presume its flowers to be white, and their limb not longer than the tube.

ANTHODON, a name which seems to allude to the toothed calyx and petals, is applied in the Flora Peruviana, v. 1. 45. t. 74. f. b, to a plant referred by professor Vahl to his Tonsella; see that article, fp. 4th.

ANTHOLOMA. Labill. Voy. Engl. ed. v. 2. 245. t. 41. Nov. Holl. v. 2. 121, is certainly the same genus as Bassia. (See that article.) Whether Labillardière's plant may be the obovata of Forrer, or a new species, we have no certain means of knowing.

ANTHOTIUM, from abo, a flower, and thion, a little ear, expressive of the auricles accompanying the upper segments of the corolla.—Brown Prod. Nov. Holl. v. 1. 582.—Cliffs and order, Penentriada Monogynia. Nat. Ord. Campanaceae. Limn. Campanulaceae. Juff. Goodnow's, Brown. Gen. Ch. Cal. Perianth superior, in five deep equal segments, permanent. Cor. of one petal, longer than the calyx, irregular; tube flat at the back from top to bottom, and easily separable into five parts, with infixed edges; limb two-lipped; upper lip in two, lower in three, deep segments, those of the upper lip having an ear-like appendage at their inner margin. Stam. Filaments five, shorter than the tube; anthers closely united into a tubular form. Pjil. Germen inferior, oblong; style capillary, the length of the 1aneces; stigma large, obtuse, enveloped in a bivalve beardless cover, contrary to the lips of the corolla. Peric. Capsule of two cells. Seeds several.

There are two varieties, one almost twice the size of the other, the parts of the flower somewhat differing also in their relative proportion. Brown.

ANTHRACITE. See Mineralogy, Addenda.

ANTHARIIS, in Botany, altered by Lefchenault from the name of the famous Poison-tree of Java, Upas Antiar, which botanists calls Antiaris toxicaria, and which Mr. Brown considers as of the same genus with what we are about to describe from his excellent General Remarks, Geographical and Systematical, on the Botany of Terra Australis, p. 70; published at the end of the account of captain Flinders's Voyage, 1814.—Cliffs and order, Monocolea Tetrandria. Nat. Ord. Scabridae, Limn. Urteas, or Urteas, Juff. Brown.

Female. Cal. Involucrum single-flowered, ovate, small, smooth, many-cleft at the summit, with lanceolate, fringed, converging, deciduous segments, some of them scattered over the body of the involucrum: perianth none. Cor. none. Stam. none. Pjil. Germen in the body of the involucrum, oblong, single-feaded; style divided almost to the bottom, its segments thread-shaped, parallel, smooth, diuretic, divaricated at the upper part; stigma simple, acute. Peric. Drupa formed of the enlarged involucrum, oval, smooth, the size, of a small plum, dark purple, internally fleshy and yellowish, containing a white milk. Seed. Nut pendulous, ovate, with a smooth, brown, tenacious crust; kernel without a skin; albumen none: embryo white, of two large, ovate, fleshy, almond-like cotyledons, flat on the inside, rather convex externally; radicle superior, very short.

1. A. macrophylla. Brown as above, t. 5.—Found by Mr. Brown, in barren flowy places, on the shores of the Company's islands, adjacent to Arnhem's land, on the north coast of New Holland, in about 12° south latitude, bearing flowers and ripe fruit in February 1803. A shrub, or very small tree, about six feet high, much branched, smooth, milky. Branches round. Leaves alternate, stalked, elliptic-oblong with a sharp point, entire, coriaceous, five inches long and three wide; unequal and slightly heart-shaped at the base; dark-green and shining above; more verdant beneath; with one rib, and many transverse parallel veins. Footstalks roundish, grey, half an inch long. Stipulas intracrenate, lanceolate, pointed, folded, leafy. Flower-stalks axillary, solitary, racemose, scarcely longer than the footstalks, each bearing six or eight alternate flowers, of which one or two of the lowest are female, and earlier than the rest, which are all male.

We presume the A. toxicaria of Lefchenault, Annales du Mus. v. 16. 478. t. 22, is another species of the same genus; but
but we are not informed of the specific characters of either.  Of that celebrated Poitou-tree the first satisfactory account, according to Mr. Brown, is therein given, which differs from his description above, merely in some particulars relative to the male flowers.  He adds that Antirrhis should stand in the "Urticce," between Bromusum of Swarta; and Olmeda of the Flora Pervisiana, agreeing with the latter in the structure of its male flowers, and more nearly resembling the former in its female flowers and fruit.

ANTIMONY, in Chemistry.  Several important additions have been lately made to our knowledge respecting this metal and its compounds, which we shall briefly notice here.

In describing this metal, we stated that Haiuy had been unable to ascertain its primitive crystalline form.  This indefatigable observer has at length, however, determined that the primitive form of its crystal is an octahedron, and that its integrant particles have the figure of tetrahedrons.  The specific gravity of antimony, according to Hatchett, is 6.712.  It melts at a low red heat, and has only 810° of Fahrenheit; and after this, if the heat be raised, the metal evaporates.

The oxides of antimony have been lately investigated with great care by Thendard, Proult, Bucholz, and Berzelius.  According to Thendard, this metal forms no less than six oxides; according to Proult and Bucholz, it forms only two; while according to Berzelius, it forms four.  These differences arise from the great difficulty of the investigation.  The protoxyd of Berzelius is obtained by expelling antimony to the air, or to the action of a galvanic battery.  It is a grey powder.  When acted upon by muriatic acid, it is separated into the protoxyd of Proult and metallic antimony.  Hence Dr. Thomfion remarks it is only a mixture of the two.  The two oxides of Proult are easily obtained, and possess specific characters.  Berzelius has shewn that the second of them possesses the properties of an acid.  The protoxyd of Berzelius is also readily obtained, though it is difficult to free it from water.  This likewise possesses the properties of an acid.  Hence, says Dr. Thomfion, we know three oxides of antimony.  The grey protoxyd, the white antimonious acid, and the fluor-yellow antimonous acid.

The following is the composition of the protoxyd of antimony according to Proult, Berzelius, and Thomfion.

The above results of Berzelius and Thomfion are rather obtained by calculation than actual experiment, being founded on the supposed composition of sulphuret of antimony, which, according to Berzelius, is composed of 100 antimony and 37 sulphur, and according to Thomfion, of 100 antimony and only 35.572 sulphur.

While such discrepancies exist respecting the composition of the oxides of antimony, it is impossible to fix with certainty the weight of its atom.  Dr. Thomfion, however, it may be proper to state, considers it as 56.25.

The two oxides of antimony, denominated above the antimonious and antimonous acids, are capable, according to Berzelius, of combining with different bases and forming two}

The following is the method of preparing the antimonium tartaricum, or tartrate of antimony and potash, according to the last edition of the London Pharmacopoeia.  Take sulphuret of antimony, powdered, two ounces; nitrate of potash, one ounce; tartrate of potash, two ounces; sulphuric acid by weight, two ounces; distilled water, a pint and a half.  Mix the acid with half a pint of water in a proper glafs vessel, and place it in a sand-bath.  When moderately heated add by degrees the sulphuret and nitre previously well mixed together; and then apply heat till the whole of the water is driven off.  Wash the remainder with distilled water until it comes off tafflefs, and while the mass is yet moist mix it with the tartrate of potash.  To this mixture add a pint of distilled water.  Boil the mixture, and when filtered put it aside to crystallize.

ANTONIUS LIBERALIS, in Biography, a Greek writer of an uncertain age, known as the author of 

\[ \text{Eunomia,} \]

or a Collection of Metamorphoses, published at Bzfal, in 8vo., by Xylas, in 1570, at Leyden, in 12mo., by Berklblius, in 1674; by Munkkas, at Amsterdam, in 1676; and by Gale, at Paris, 1675, 8vo.  This writer is not the same with a Latin rhetorician, mentioned by Jerom. Fab. Bib. Græc.

ANYCHIA, in Botany, so called by Michaux, on account of its affinity to PARONYCHIA.  (See that article.)  This plant therefore has as little concern with the finger nail, as, the other has with a whitlow.—Michaux Boreal-Amer. v. 1. 112. Pursh 176. St. Hilaire Paron. 98. (Queria; Gartn. t. 128.)—Clas and order, Pentandria Monogynia. Nat. Ord. Holerae, Linn. Amarantli. Juff. Paronychie, Juff. Ann. du Mu. St. Hilaire.

Gen. Ch. Cal. Ferianth inferior, of one leaf, oblong, in five deep, oblong segments, slightly hooded at the extremity, with a posterior point.  Cor. none. Stam. Filaments five, sometimes fewer, shorter than the calyx, opposite to each segment and inserted into its base, bristle-shaped, erec, dilanti, without any intermediate processes; anthers nearly heart-shaped.  Peric. German superior, roundish; fylle one, very short; stigmas two, oblong, recurved. Peric. Capsule roundish, membranous, of one cell and one valve, covered by the calyx, with an orbicular depression at the summit, pointed, separating at length irregularly at the lower part, Seed one, nearly kidney-shaped, smooth, attached by a lateral thread to the base of the pericarp.

Eff. Ch. Calyx inferior, in five deep, converging segments, hooded at the summit. Stigmas two. Capsule membranous, of one valve. Seed foliary.

This is a genus of diminutive herbs, with opposite leaves, attended by fipulas. Flowers minute, in leafy tufts, each of them solitary, with bractes like the fipulas. Michaux.

1. A. dichotoma. Forked Anychia. Michaux n. 1. Pursh n. 1. (Queria canadensia; see that article, n. 2.) —Stem forked, much branched, spreading. Leaves elliptic-lanceolate, smooth, erec. Bractes about as long as the smooth calyx.—On dry lime-flone hills, from New York to Kentucky, flowering from June to August. Perennial. Flowers exceedingly small; very variable in the number of fipaments, generally from two to five. Pursh; who quotes Orthega's Dec. t. 15. f. 2, a work not in our possession. The root has all the appearance of being annual, as professor Schrader found it in the garden of Gottingen.

2. A. berniaria. Rupture-wort Anychia. Michaux n. 2. Pursh n. 2.—* Stem diffuse, densely branched, downy all over. Leaves elliptic-oblong, fringed, bristle-pointed. Segments of the calyx awl-shaped, with bristly spreading points,
AORTA, in Surgery. As professor Scarpa observes, the whole body may be regarded as an anastomosis of vessels,—a vacular circle,—and the remark is too true, that even an obliteration of the aorta itself may happen, immediately below its arch, without the general circulation of the blood in the body being flopped. Meckel met with two cafes in which the aorta was thickened and considerably contracted just below its arch; yet in both subjects there was every reason to believe, that the abdominal vicesa and lower extremities had been duly supplied with blood. This fluid, which would only pass from the heart with great difficulty, and in small quantities, had, by regurgitating, lacerated the femi-lunar valves. (Mém. de l'Acad. Royale de Berlin, 1756, obs. 17 and 18.) A like example is recorded by Stoerk. Ann. Med. vol. xi. p. 171.

We have a very interesting cafe of obstruéted aorta related by Monfieur Paris, formerly difcoffer for the Amphitheatre of the Hôtel-Dieu. He injected the body of a very lean old woman, about fifty years of age, whose arterial system was found to be singularly deranged, and the circle of the blood altogether changed by a complete contraction of the aorta a little beyond the arch. The attention of M. Paris was particularly excited to the condition of this affection by the unaccountable enlargement of the small arteries upon the forepart of the chief. The injection which was employed entered the mouth of the aorta fo readily, that, so far was he from fetting any obliteration of this vessel, he could have thrown in more injection than is usually required for filling an adult body. The subject was fo meager, that, without difcoffing, M. Paris felt the thoracic arteries running down the sides of the chest tortuous and remarkably enlarged. On difcoffion, he found the aorta immediately beyond its arch contracted to the size of a writing quill; the coats of the artery were of their usal thicknesses, and its cavity of course extremely small; the arch of the aorta above this contraction was but very slightly dilated; the part below had lost nothing of its natural size.

The carotids were in the natural state; thearteria inno- minata and the left subclavian were enlarged to twice their natural diameter; all their smaller branches were increased in the same proportion, and had assumed a curled and zigzag course. The internal mammary and phrenic arteries were greatly enlarged, and very tortuous. The transverse arteries of the neck were of twice their natural size; their posterior branches were tortuous, extending to a great distance over the back, with long inflations, which were met from below by the branches of the upper intercostal arteries, which were also remarkably enlarged. The thoracic and scapular arteries which run along the side of the chest were twice their natural size.

Below the constricted part of the aorta the lower intercostal arteries were much enlarged, even to three or four times their natural size. Each of them was dilated; but those were most affected which were given off nearest the contracted part; and the posterior branch of each, which penetrates to the muscles of the back, was more dilated than that which runs between the ribs. Indeed those posterior branches were so remarkably dilated with contortions so closely succeeding each other, that they resembled a necklace of beads; and their inflations with the branches of the transfemoral cervix were very remarkable. The lower phrenic artery was enlarged, forming considerable inflations with the superior phrenic. The epigastric artery was dilated to the size of the enlarged mammae, and was joined with it by very numerous and conspicous inflations. Default's Parian Chir. Journ. tom. ii. p. 107, &c.

In the body of a male subject, two reatomatous tumours were found by Stenzel, situated in the substance of the membranes of the aorta immediately below its arch. Notwithstanding these swellings rendered the vessel nearly impervious, the man had the appearance of strength, and of having been well nourished. "Hac corpora ferè cor magnitudine aquabunt ut omne propemodum exuncti & finiffiri cordia thalamo fanguinii fpatium praecedentur." Diff. de Stenoma- matibus Aortae.

Dr. Graham, of Glasgow, has very recently published a full and remarkable case, in which the circulation was carried on for a considerable time through the anastomoses, notwithstanding a complete obftruction of a part of the aorta. The patient was a lad fourteen years old, who, in consequence of exposure to cold, was affected at first with a dry cough, followed by copious expectoration, pain, and difficulty of respiration. The disease was supposed to be pneumonia in an advanced stage. Dyspepsia, palpitations, and pain of the left side, were also the most remarkable symptoms at a later period. The pulse became weak, but was always regular to the very last. The boy at length died, after remaining in the Glasgow Infirmary about five months. On dissection, together with other morbid changes, the walls of the left ventricle of the heart were found about an inch in thickness; but no other derangement in the structure of the heart, or its valves, was observed. The aorta was unusually expanded near its origin, so as to form a kind of pouch; but, after having given off the branches to the head and superior extremities, its diameter was preternaturally con- tracted. It continued of this diminished size till after its union with the canalis arteriosus, when it became completely impervious. The coats were not thickened, nor in any way diseased, except that about half an inch below the fricture there was a smooth elevation on the inner surface, less raised, but having nearly the diameter of a split-pea. In other respects, the appearance was exactly such as would result from tying a ligature round the artery.

The artery then received three trunks, about as large as crow-quills, and near them three smaller ones, when it resumed its natural size along the vertebræ. The three trunks were evidently the uppermost of the inferior intercostals, the coats of which were remarkably thick, like those of veins. A probe passed from the pulmonary artery along the canalis arterio- usus to the obstruèted portion of the aorta; but from the thickened appearance of that canal, and the florid counte- nance of the boy during life, probably there had been little communication allowed by means of it between the aorta and pulmonary artery. Dr. Graham, it appears, did not inject the subjette, so as to demonstrate all the exact channels by which the circulation had been carried on; but he tells us, that the arteria innominata, the left subclavian, the superior intercostals, and the mammary arteries, were much enlarged. The epigastric was reported to be of its natural size. These facts, and the aorta acquiring at least very nearly its natural size immediately below the fricture, shew that the blood did not pass to the inferior extremities in any material quantity, as might perhaps have been expected by the inflations of the
AORTA.

the mammary and epigastric arteries; but chiefly, by the communications of the superior intercostals and the mammary arteries with the three large branches entering the aorta below the diaphragm; and of the mammary and thoracic arteries with the diaphragmatic and other intercostals. See Medico-Chir. Trans. vol. v.

If the aorta were obliterated, or obstructed in the abdomen, the blood would find adequate channels for its transmission in the mammary and epigastric, the superior and inferior meenteric, and the lumbar arteries. Mr. A. Cooper informs us, that he has never met with any instance of the latter description in the human subject. (Surgical Essays, part i. p. 117.) But he has several times applied ligatures to the aorta in dogs, and found that the blood was readily carried by anastomosing vessels to the posterior extremities of the animal. (See Medico-Chir. Trans. vol. ii. p. 249, &c.) The incision was in each experiment made on the left side of the spine; the aorta was drawn to the surface of the skin by an aneurism needle, and being quite separated from other parts was tied. The animals were then kept for a few weeks, and then killed. They were afterwards injected and dissected, when it appeared that the lumbar arteries were considerably enlarged, so as to be the chief agents of the new circulation.

In those difeases causing obstruction of the thoracic aorta a little beyond its arch, to which we have referred the reader's attention, no doubt the change was the result of a very gradual process, and consequently, the altered course of the blood through the collateral channels would also be established, not all at once, but by degrees. The anastomosing arteries would only enlarge, in proportion as the obstruction in the great artery increased. But in the experiment of tying the aorta in animals things were very different; for the stoppage of the passage of the blood through the tied portion of that vessel was not only effected instantaneously, but also completely, so that the whole office of transmitting the blood to parts beyond the obstruction suddenly devolved altogether to the anastomosing, which had had no time for any gradual and preparatory dilatation. Yet notwithstanding this seeming disadvantage, we find that the blood did pass into the posterior extremities.

The aorta of the human subject, however, has now been tied in the human subject by Mr. A. Cooper, and the following are a few of the particulars of the case. The patient, who was thirty-eight years of age, had on the left side an inguinal aneurism, which had actually burst, and discharged a quantity of blood sufficient to reduce the man to a state of considerable weakness. Another hemorrhage would have carried him off. It was apprehended, that the tumour extended too high up to admit of a ligature being applied to the external iliac artery itself; yet in the hope of being able to dispense with such measures as would be necessary to tie the aorta near its bifurcation, Mr. A. Cooper resolved to try whether it was possible to tie the aneurismal artery itself. He made, therefore, a small incision into the aneurism, about two inches above Poupart's ligament; but he found only a chaos of broken coagula, and that the artery entered the face above and quitted it below without there being any intervening portion of vessel. The operation was consequently abandoned. "When I was about to withdraw my finger," says Mr. A. Cooper, "I directed two of the students to compress with their hands the aorta upon the spine, and they succeeded in flushing the pulsation in the artery of the right groin. As I withdrew my finger, I put a doffil of lint by its side, and closed the opening which I had made into the face." Surgical Essays, part i. p. 118.

The only other chance of preservation was what might result from tying the aorta itself; and it was determined to adopt the proceeding, bold and unprecedented as it was in respect to the human subject. A doubtful remedy is always better than none. This ancient maxim in surgery seems to gather strength in proportion to its duration, and is a short but an effectual answer to every attempt which has been made by the ignorant and malicious to throw blame on the distinguished surgeon, whose ardent desire to save the life of an individual was the main spring of his conduct. Mr. A. Cooper, after enjoining the prudence of emptying the bowels previously to any other similar operation, states, that he made an incision three inches long into the linea alba, giving it a slight curve to the left side to avoid the umbilicus. One inch and a half of the cut was above and the remainder below the navel. He then made a small aperture into the peritoneum, and introduced his finger into the abdomen. This opening was enlarged with a probe-pointed bistoury to nearly the same extent as that of the external wound. During the progress of the operation, only one small convolution of intestine projected beyond the wound. The operator next passed his finger between the intestines down to the spine, where he felt the aorta beating with excessive force. By means of his finger-nail, he scratched through the peritoneum on the left side of the aorta; and next gently and gradually pinching the finger between that vessel and the spine, again penetrated the peritoneum on the right side of the aorta. Guided by the same finger, he now conveyed a blunt aneurism needle, armed with a single ligature, behind the vessel. After the ligature had been placed, much care was requisite to exclude the intima from it in drawing it into a noose. The operation being finished, the wound was closed with a quill-string and adhesive plaster.

During the operation the face was pallid off involuntarily, and the pulse, both immediately and for an hour after the operation, was 144 in a minute. An opiate was given, and the involuntary discharge of faces soon ceased. When the right thigh was touched, the patient thought it was the foot, so that the sensibility of that extremity was very imperfect.

The operation had been performed about nine in the evening. At one o'clock the following morning, the lower extremities, which had become cold soon after the operation, were beginning to get warm again, but their sensibility continued yet insufficient. At eight o'clock, the right leg was warmer than the left, and the sensibility was returning. At noon, the temperature of the right limb was 94°; that of the left, or aneurismal limb, 87°. At five o'clock in the evening, the temperature of the right was 96°, that of the left 87°. At nine the evening, the pulse was 100 and feeble, with vomiting, red lips, and an involuntary discharge of faces. At eleven, the pulse was 100 and feeble, and the vomiting still continued. At eight the next morning, the aneurismal limb appeared livid and felt cold, more particularly around the aneurism; but the right leg remained warm. At eleven the pulse was 120, and the patient seemed to be finking. In fact, he died eighteen minutes after one in the afternoon, having survived the operation forty hours. On dissection, no appearance of peritoneal inflammation was found, except at the edges of the wound. The omentum and intestines were free from any unnatural colour. The ligature which had not included any portion of bowels was placed round the aorta about three-quarters of an inch above its bifurcation, and about an inch below the part where the duodenum lies across it. In the aorta a coagulum more than an inch in extent was found to have sealed the vessel above the ligature. Below the bifurcation, other similar coagula were found in the right and left iliac arteries. By the fall to which the patient had ascended the tumour,
tumour, the neck of the thigh-bone had been broken within
the capsule, and it was still in a disjunct state. Mr. A.
Cooper imputes the man's death not to inflammation, but to
the want of circulation in the aneurismatic limb, occasioned in
a great measure by the immense size of the tumour, and the
disturbed state of the osseous which it contained. He con-
ceives, therefore, that, in any future case of this kind, the
ligature should be applied before the swelling has become
very large. Surgical Essays, part 1.

One thing seems proved by this memorable case, viz., that
the circulation in the lower extremities may continue not-
withstanding a sudden ligature on the aorta. Here it did
so in the right leg, and probably would have done so in the
left, had it not been for the obstruction arising on that side
from the magnitude of the tumour.

AOTUS, in Botany, so named by the writer of this
article, from o, without, and otus, an ear; because it is
effectually distinguished from Pulexena, (see that article),
by the want of the two ear-like appendages to its calyx, not
to mention other marks hereafter indicated.—Sm. in Sims
Kew. v. 3. 14.—Cliffs and order, Desidria Monogyni.a.
Gen. Ch. Cal. Periandar inferior, of one leaf, bell-shaped,
two-lipped, without appendages; upper lip of two divari-
cated, acute segments; lower of three rather longer, more
direct ones. Cor. papilionaceous, of five petals; standard
inverted-heart-shaped, ascending, with a linear claw of its
own length; wings obvate-oblong, shorter than the stand-
ard, each with an abrupt angle at the upper edge where it
joins the claw; keel as long as the wings, obtuse, of two
obvate-oblong, ascending petals, each with a similar tooth.
Stam. Filaments ten, separate, awl-shaped, ascending, nearly
equal, smooth, deciduous; anthers oval, of two cells. Psil.
Germen roundish, with the rudiments of two seeds; style
thread-shaped, parallel to the stamens, but rather longer,
twisted after impregnation, stigma simple, bluntish. Peric.
Legume nearly orbicular, acute, of one cell and two concave
firm valves. Seeds two, elliptical, inserted into the middle
of the upper margin of each valve, without any crest or
appendage.

Eff. Ch. Calyx simple, five-cleft, two-lipped. Corolla
papilionaceous; wings shorter than the standard. Stamens
deciduous. Style thread-shaped. Stigma obtuse. Legume of
one cell, and two valves. Seeds two, without a crest.

Aotus is very nearly allied to Pulexena, and had previously
been confounded therewith; but besides the want of appendages
to the calyx, and of a styleodium, or crest, to the seeds,
which last difference was first noted by Mr. Brown, the style
is not awl-shaped, but almost capillary, variously twilled as
soon as the flower falls, rather swelling upwards, and the
stigma is obtuse. The habit of the plant is also very distinct,
having nothing like the chaffy aspect of a Pulexena; there
are neither bracteas nor lacinulas; the leaves are partly oppo-
site, and almost whorled. Mr. Brown, by giving a specific
character to this shrub in Hort. Kew, leads us to presume
that he has found other species of the same genus; for he
is not one of those botanists who make a distinction without
a difference. We are however acquainted with the following
only.

1. A. villufa. Hairy Aotus. Sm. n. 1. Tr. of Linn.
Soc. v. 9. 240. Ait. n. 1. Curt. Mag. t. 949. (A. fer-
ruginea; Labill. Nov. Holl. v. 1. 104. t. 132. Pulexena
villufa; Andr. Repof. t. 309, but not of Wildl. Sp. Pl.
v. 2. 507. P. eriocides; Venten. Malm. t. 35.)—Calyx
filky, with close hairs. Legume filkcd. Seeds rough

APH

Native of New Holland, and Van Diemen's island. Sent
by Mr. Banks, in 1792, to Kew garden, where it flowers
in the greenhouse, from April to June. The flern is three
feet high, with numerous, round, filky, leafy branches.
Leaves scattered, or imperfectly whorled, on short hairy
flanks, spreading, linear, revolute, entire, a half or three-
quartets of an inch long; channelled, and rough with minute
points, above; filky beneath. Flowers bright-yellow, axil-
ary, on short, filky, rufly flanks, two or three together,
numerously crowded about the tops of the branches, so as
to form leafy clusters. Legume very hairy, two lines long.
The standard of each flower is marked with radiating crim-
son lines, as in the Dillwynia.

1547. See Thrincia, at the end of which is given the
history of this genus.

APERTO, Ital., in Myfes, open, opposed to chiuso,
closed.

APHELANDRA, in Botany, a genus first proposed
by Mr. Brown, in a note to his Prodrorum, to be separated
from Justicia. (See that article.) The name he has given
it is composed of aperto, open, and mon, a male, expressing
the simple structure, or single cell, of the anthers, one of
the most distinguishing characters of this genus.—Brown

Gen. Ch. Cal. Periandar inferior, of one leaf, in five
deb, oblong, unequal, erect segments. Cor. of one petal,
ringent; tube much longer than the calyx, incurved, an-
gular, gradually swelling upwards; limb in two unequal
acute lips; the upper erect, cloven, lower revolute, undi-
vided. Stam. Filaments four, awl-shaped, simple, erect,
inferted into the tube of the corolla, and rather flunter than
its upper lip, parallel, slightly curved, two of them a little
the longest; anthers incumbent, attached by the back, ob-
long, acute at each end, hairy behind, of one cell. Puf.
Germen superior, ovate; style thread-shaped, the length of
the stamens; stigma simple. Peric. Capsule oblong, taper-
ning at the base, of two cells and two elastic compressed
valves, the partition contrary to, and fixed in the middle of
each. Seeds two in each cell, roundish, each subtended by
a fimbriate process.

Eff. Ch. Calyx in five deep unequal segments. Corolla
ringent; lower lip undivided. Anthers fingle-celled. Cap-
ule of two elastic valves and two cells; with contrary parti-
tions. Seed subtended by spinous.

1. A. cri1ata. Denfe-spiked Aphelandra. Brown in
Ait. n. 1. (Julicia cri1ata; Jacq. Hort. Schoenbr. v. 3.
38. t. 320. J. tetragona; Vahl Symb. v. 3. 5. Enum.
Repof. t. 505.)—Leaves elliptic-oblong, pointed, smooth
on both sides, with hairy veins beneath. Bracteas
ovate, entire. Corolla smooth.—Native of Cayenne and the
Caracas, flowering in the Iove throughout August and
September. It appears to have been first brought to Eng-
land by the late Earl of Seaford, and flowered at Mr. Lum-
born in Wiltshire. The flern is thrubby, three feet high,
or more, with opposite, round, smooth branches. Leave
opposite, tailed, broadly elliptical, acute at each end,
somewhat wavy, dark green, plant, five or six inches long,
and three broad; smooth above, with a reddish mid-rib, and
many fine veins; the rib and veins only, according to
Jacquin, downy beneath. Flowers scarlet, large, splendid,
and extremely numerous, forming dense quadrangular flakes,
about a fpan long, branched at the base, with clove, ovate,
green, or brownish, fringed, single-flowered bracteas. The
corolla

61
corolla is full two inches in length. This plant is so very
nearly allied in habit, foliage, colour of the flowers, and their
general appearance, to the magnificent *Juticia cocineum*, Sm.
Ic. Dict. t. 8, that one would think they must belong to one
and the same genus. But on examination, the three-lobed
lower lip, two-lobed anthers, and leafy bracteas of the latter,
indicate a technical, as well as natural, distinction.

2. *A. pulcherima*. Downy-leaved Aphelandra. (*Juf-
ticia pulcherima*; Jacq. Amer. 6. t. 2. f. 4. Coll. v. 3.
(not v. 5) 252. Ic. Raf. t. 204. Linn. Suppl. 84, 
&. f. 7. J. putata; Loeff. I. 244.)—Leaves elliptic-oblong,
pointed; smooth above; finely downy beneath. Bracteas
ovate, entire. Corolla smooth.—Native of South America,
flowering in February. *Lecthout*. Von Toum appears to
have lent feeds to Miller, who cultivated this species before
the year 1733. Mutis communicated a specimen to Lin-
neus, which we see no reason to distinguish from Jacquin’s
plant, notwithstanding what is recorded in the *Supplementum*,
of the *flames* being two only; for we find four in the flower
we have examined, bearing the proper simple anthers of an
*Apbelandra*. How far the complete hairy downiness of the
backs of the leaves, and the smaller *spikes*, with less copious
flowers, may prove the present species distinct from the fore-
gone, we greatly doubt. Mr. Brown in Hort. Kew. unites
them, without marking this as even a variety of *criflata*.

fabra*; Vahl Enum. v. i. 120.)—“Leaves elliptic-oblong,
aicate; rough on the upper side. Bracteas oblong, acute,
haired.”—Native of South America. Leaves three inches
long, acute at each end; rough above with prominent
points; veins somewhat downy beneath. Vahl speaks of
this as very nearly related to the last; but as Mr. Brown,
who had doubtless examined specimens, enumerates it in his
*Prodomus* as distinct, and does not subsequently unite more
than the two first together, we premise it must be different,
and that the *corolla* is not smooth, nor the *bracteas* entire,
both which characters he makes discriminative of the *criflata*,
and they certainly exist likewise in the *pulcherima*.

APHELIA, apparently so called from *aphelo*, simple, in
addition to the great simplicity of parts and structure in the
flower.—Brown Prodr. Nov. Holl. v. i. 324. Clarke and
order, *Monandria Monogynia*. Nat. Ord. Realflora,
Brown.

Gen. *Ch. Cat.* Calyx of several imbricated, two-
ranked, fingle-flowered, pointed, hispid scales; the lower
ones sometimes barren, and longer than the cor. Cor.
of one membranaceous valve, at the inner side of each flower.
*Stam.* Filament one, capillary; anther simple. *Pil.* Ger-
men superior, single-seeded; style one, thread-shaped;
 stigma solitary, undivided. *Perf.* Capsule membranous,
of one valve, and one cell, burrting longitudinally at one

*Eff. Ch.* Scales two-ranked, fingle-flowered. Corolla

*Obi.* This genus is closely allied to *Devaunia* of Mr.
Brown, which will be described in its proper place hereafter,
and from which *Apbelia* differs in having a simple *pilif*, two-
ranked *spikes*, and only one valve to the *corolla*, situated at
the inner side of the flower. The only known species is

1. *A. cyperoides*. Cyperus-spiked Aphelia.—Discovered
by Mr. Brown, in the southern part of New Holland. A
small, tufted, grassy herb, resembling some of the leffer
kinds of *Scirpus* and *Cyperus*. *Root* fibrous. Leaves radical,
thread-shaped, heathing at the base. *Stalks* leafless, thread-
shaped, undivided. *Spike* terminal, solitary.

APHRITE. See *Schaum* Earth.

APPARITION. Subjoin at the close of the article,
In the year 1805, Dr. Alderbon of Hull read to the
literary society of that place, and published in 1811, “An
Effay on Apparitions,” designed to prove, that the
immediate cause of these spectral visitations lies not in the perturbed
spirits of the departed, but in the diseased organization of the
living. In 1813 Dr. Ferrier of Manchester published,
on a more extended scale, “An Effay towards a Theory of
Apparitions,” similar in results to the anterior production of
Dr. Alderbon. Both admit the reality and universality of spectral
impressions, and both attribute them to partial affec-
tions of the brain, independent of any feeble and external
agency. Thse and other such writers, who consider the
appearances of ghosts, &c. as the immediate effect of certain
partial but morbid affections of the brain, confine themselves
to physical phenomena, professedly discarding the consider-
ation of any higher efficiency in the series of caufation, than
what appears to be the result of diseased organisation; so
that their discovery, though completely overthrowing the
common superition as to the return of the departed spirit,
or the invisible interference of angelic agency, is yet, says
Dr. Drake, in the learned volume of his “Shakpipe and
his Timings,” very reconcilable with the pneumatology of
bishop Horley, who conceives that the Deity often acts
immediately through his agents on the human fenfory, as
a part of the material universe, thereby producing diseafe and
morbid impressions. (See Horley’s Nine Sermons on the
Nature of the Evidence by which the Fact of our Lord’s
Resurrection is faftablished.) Our Lord, according to the
bishop, after his resurrection, was no longer in a state to be
naturally visible to any man. His body indeed was rifen,
but it was become that body which St. Paul describes in the
15th chapter of his 11 Epifole to the Corinthians; which,
having no sympathy with the grofs bodies of this earthly
sphere, nor any place among them, muft be indiscriminable
to human organs, till they shall have undergone the similar
refinrmennt. Accordingly it is alleged, that we are told by
St. John, that the body of our Saviour, after his resurrec-
tion, could only be seen through the operation of a miracle.
“Him God raised up the third day,” and “gave him to be
visible.” “Et dedit eum manifestum fieri.” Vulgate.

APPRECIATION, i. 2. from bottom, r. abbé Peyton
for Feyer.

APRILE GUSEPPRE, in Biography. See TENDUCCI.

AQUILEGIA, in Botany, (see our former article.)
The history of this elegant genus is greatly enriched by pro-
feffor De Candolle, who reckons up thirteen species.
The following references require to be added.—Willd. Sp. Pl.
v. 2. 247. Lamarck Dict. v. i. 149. Illustr. t. 488.

Eff. Ch. Calyx none. Petals five, deciduous. Necta-
tories five, gaping and two-lipped at the funnitt; outer lip
large and flat; inner minute; each extended downwards
into a hollow spur, callous at the point, projecting between
the petals. Stamens numerous, diptod in five or ten par-
cels, the inner ones abortive, their filaments dilated, mem-
branous, and oblong; delinate of anthers. Germens five.
Capsules as many, erect, many-seeded, beaked with the
styles. *De Candolle*.

We here, of course, alter the phraseology of our author,
with respect to the parts of the flower, as in *Aconitum*.

U n 2

These
There are perennial herbs, with fibrous roots. Radical, or lower stem-leaves, on long three-cleft footstalks, divided in a twice-ternate manner; their leaflets three-cleft, toothed, mostly obtuse; their leaves cut, or deeply divided, into linear lobes. Flowers terminal, blue, white, rosy-coloured, or purple, very rarely of a dirty yellow. To which we may add that the flowers are pendulous, fruit erect.

The herbage is slightly bitter, tonic or somewhat astringent, fearfully acid. Seeds acrid, recommended in eruptive disorders.

The various species inhabit mountainous thickets and pastures of the northern hemisphere; one is found in America, four in different parts of Europe, seven in Siberia.

Obs. The leaflets, originating in the dilatation of the innermost filaments, and the abortion of their antlers, often surround the germens like bracteas, after the flower is passed. They are delineated in several of Barrelier's plates. Mr. Brown has remarked something analogous in the petal-like leaflets of his Eupomatia; see that article hereafter. The flowers in Aquilegia become double in four different ways. 1. Thole termed corniculi have accessory nectaries, originating from changed filaments, all spurred and pointing downwards. 2. Inversi have their spurs turned upwards, in consequence of a twist in the claws of those parts. 3. Stellati have accessory nectaries proceeding from enlarged filaments deprived of antlers; such being all flat, and without spurs. 4. Degeneres have all their flammis, pistils, and nectaries obliterated, nothing remaining but multiplied petals (sepala of De Candolle) of a greenish hue.

We shall follow our author, in a comprehensive review of the species, with some necessary alterations. They are not separated into fections.

2. A. villosa. (See Aquilegia, n. 1.) Linn. Mant. 77. Willd. n. 11. Alt. n. 1. Gouan Illfr. 23. 1, 19. 1. De Cand. Fr. ed. 3. v. 912. t. 5. 640. (A. hisuta, flore vificofo; Magn. Monf. 26. Hort. 21. A. montana, flore parvo, thalici tri folio; Bauh. Pin. 144. Prodr. 75. Lachenal Att. Helvet. v. 8. 146. t. 5. Bauh. Illfr. v. 3. 484. Moris. feécr. 12. t. 1. f. 5, bad.) —Nectaries incurred. Capules hairy. Stem with very few flowers, almost naked, downy and viscid as well as the leaves and flowers. Styles not overtopping the flammis. —Native of Switzerland, the south of France, and all along the rocky hills of the Mediterranean. De Candolle concurs with Villars in opinion, that this plant is only a variety of the foregoing. We have never compared them in a living state, but the singular vis¬ousSculpture which covers the whole herb, especially the flowers, and is visible even in dried specimens, seems to indicate an essential difference. The flowers too are larger, while the plant is smaller, sometimes single-flowered, and the leaflets, with their segments, are more wedge-shaped. Linnaeus however declares, Syft. Veg. ed. 13. 420, that seeds of the veficola, from Gouan himself, produced the vulgaris.

3. A. speciosa. Handflome-flowered Columbine. De Cand. n. 3, excluding the synonyms. (A. vulgaris, daurica; Willd. n. 2. 5.)—Nectaries incurred; spurr the length of the border. Capules hairy. Stem leafy, many-flowered. Flower-flats, footstalks, and backs of the leaves, downy. Styles taller than the flammis. —Native. Seen in a cultivated flate by De Candolle, flowering in May and June. He doubts whether his plant were different from A. vulgaris, as it differed only in the spur and limb of each nectaries being of equal length, the former generally yellow at the extremity, and the styles rising above the flammis during the flowering. Fisher and Perlofo, it seems, have mentioned a variety, in which the spurs are of the same colour as the limb. Whatever their plant may be, we are satisfied that the synonyms of Aiton and Ehrhart belong to the following.

4. A. ficilica. Siberian Party-coloured Columbine. Lamark n. 4. De Cand. n. 4. (A. vulgaris, speciosa; Ait. n. 2. 3. Willd. n. 2. n. A. bicolor; Ehrh. Beitr. v. 7. 146. A. hybrida; Sims in Curt. Mag. t. 1221? De Cand. n. 11?) —Nectaries incurred. Germens and capules perfectly smooth. Styles taller than the flammis. —Native of Siberia. Linnaeus cultivated this plant, and found it did not alter. We received it in 1796, from the garden of Meiffs. Lee and Kennedy, at Hammermith, who had the seeds from that country. Specimens of the fame, in the Linnaean herbarium, are marked as having been gathered near Irkutsk. M. De Candolle justly defcribes "the radical leaves on long flatstalks, smooth, except perhaps some downies on the footstalks; their segments obtuse, broadly notched. Stem hardly a foot high, mosty flingle-flowered, and entirely naked; sometimes bearing two or three flowers, with one or two leafy bracteas. Sepala (petals) blue, oval, obtuse. Nectaries white, half as long, very blunt. Capules quite smooth, by which character this species is readily distinguished from all the foregoing, and perhaps from all the rest." De Candolle. Our wild specimens have three or four flowers on each stem, and the garden ones are still more luxuriant. The flowers in both are pur¬plish-blue, the lips of the nectaries cream-coloured, as expressed in Ehrhart's name, and Dr. Sims's figure. We should have no hesitation about his synonym, were it not for the flight downies which he attributes to the herbage. The proportion of his flowers is right, but he does not say at any thing of the germens. We cannot but suspect the gar¬deners mixed seeds of the Siberian species with the Canada one, or possibly that pollen of the latter might have had some effect on the flowers of the former, of which the rather less curved nectaries of the offspring seem an indica¬tion; the pale hue of their limb is exactly that of our sicilica. The downy leaves do not accord with either. If we are right, De Candolle's hybrida, n. 11, must be expunged. Respecting Gmelin's A. n. 16, Fl. Sib. v. 4. 185, we sup¬pose by its laft synonym, alluding to the party-coloured et nectaries,
natives, it must have been what we just described, taken by him for the Linnean alpina, though not without some doubt.

5. A. alpina. (See Aegilegia, n. 3.) Alpine Columbine. Lind. Sp. Pl. 752. Willd. n. 3. 

6. A. pyrenaica. Pyrenean Columbine. “De Cand. Fr. ed. 3. v. 5. 640.” (A. alpina; Lamark n. 3.)—

Aqua

ARA

Petals elliptic-oblong, shorter than the petals. Styles much longer. Petals elliptic-oblong, shorter than the petals. ——

Flowers downy, encompassed by membranous abortive flaments, after the perfect ones are gone.

9. A. daurica. Daurian Columbine. De Cand. n. 9. —Spurs straight, shorter than the limb of each petal, flaments scarcely prominent. Styles much longer. Petals acute, shorter than the petals. ——

The flowers are described as dark purple, or blue-violet; the limb of each petal greenish-blue; spur blue-violet.

10. A. atro-purpurea. Dark Violet Columbine. Willd. Enum. 577. De Cand. n. 10. (A. viridiflora; Willd. n. 5.) —Spurs straight, the length of the limb. Styles and flaments scarcely equal to the petals, which are the length of the limb of the petals.

—Veery frequent in woods about the river Lena. 

Gmelin. Herb entirely smooth, except the bristy germen. Stem a foot, or rather more, in height, bearing from two to seven flowers. Leaflets ovate-wedge-shaped, with three broad obtuse teeth at the end. 

—Veery frequent in woods about the river Lena. 

11. A. pumila. Small-flowered Columbine. De Cand. n. 12. (A. fylvanum humble; Gmel. Sib. v. 1. 186. n. 17. t. 72.)—Spurs straight, shorter nearly as long as the obtuse limb of each petal. Stamens and peltals recurved, the length of the petals. Stem smooth, as well as the leaves. —Veery frequent in woods about the river Lena. 

Gmelin. Herb entirely smooth, except the bristy germen. Stem a foot, or rather more, in height, bearing from two to seven flowers. Leaflets ovate-wedge-shaped, with three broad obtuse teeth at the end. 

—Veery frequent in woods about the river Lena. 

—Veery frequent in woods about the river Lena. 

Gmelin. Herb three inches high, smooth, resembling Anemone tricrenata. Leaves radical, divided in a three-ternate manner, with oblong segments, either entire, or two or three-lobed. 

Stalks fleshy, shorter than the leaves, accompanied by two linear-lanceolate bractes. Petals ovate, obtuse. 

—Veery frequent in woods about the river Lena. 

13. A. atro-purpurea. Dark Violet Columbine. Willd. Enum. 577. De Cand. n. 10. (A. viridiflora; Willd. n. 5.) —Spurs straight, the length of the limb. Styles and flaments scarcely equal to the petals, which are the length of the limb of the petals.

—Veery frequent in woods about the river Lena. 

Gmelin. Herb entirely smooth, except the bristy germen. Stem a foot, or rather more, in height, bearing from two to seven flowers. Leaflets ovate-wedge-shaped, with three broad obtuse teeth at the end. 

—Veery frequent in woods about the river Lena. 

11. A. pumila. Small-flowered Columbine. De Cand. n. 12. (A. fylvanum humble; Gmel. Sib. v. 1. 186. n. 17. t. 72.)—Spurs straight, shorter nearly as long as the obtuse limb of each petal. Stamens and peltals recurved, the length of the petals. Stem smooth, as well as the leaves. —Veery frequent in woods about the river Lena. 

—Veery frequent in woods about the river Lena. 

—Veery frequent in woods about the river Lena. 

Gmelin. Herb three inches high, smooth, resembling Anemone tricrenata. Leaves radical, divided in a three-ternate manner, with oblong segments, either entire, or two or three-lobed. 

Stalks fleshy, shorter than the leaves, accompanied by two linear-lanceolate bractes. Petals ovate, obtuse. 

—Veery frequent in woods about the river Lena.
ARA

flamens definite. Styles and stigmas several. Fruit pulpy, or rarely fleshy, of as many cells as there are styles, with a solitary seed in each. Stem either arboreous, or shrubby, or herbaceous. Leaves alternate, often compound, their footstalk theading in its lower part. Flowers umbellate, either with an involucrum, or, more rarely, naked.

The genera are, Gallonia of Commenr; Polyscias of Forster nearly related thereto; Aralia of all authors; Cauffania of Linnaeus in his Supplementum; and Panae. The Aralia are naturally allied to the Umbellate, but differ in having their seeds in a pericarp, instead of being naked. They are akin to Cornus and Hedera, but distinguished by having more than one style. Jaff.

Araquy, in Geography, a river of Georgia, next in importance to the Cyrus, or Kur, which, rising near the gates of Caucasian, flows to the south, and after dividing into two equal parts, the southern range of mount Caucasian, falls into the Kur, at the town of Tigette, 25 miles above Teits.

Arasch, a rapid river of Mingredia, which has its source near the village of Kennes, and unites, on the borders of the Iberian lordship of Sa Schilo, with the Hippus, which rises in the highest mountains of the Soani, not far from the source of the Phasis, flows through Letiguiani, divides Mingreha from Iberia, and enters the Phasis, near the Tedia.

Aratum, r. Aratrum.

Araucaria, in Botany, a barbarous name, given by Jullien to the Chili Pine, which Lamarck, Schreber, and Lambert, have called Dombeya. (See that article.) Willdenow has unfortunately retained the above name, because he had already ignorantly followed Cavanilles in calling a genus Dombeya, which is not generically distinct from Pentapetes. Hence Araucaria has found its way into Mr. Aiton's Hortus Kewensis, where Willdenow is taken as the leading authority, and Dombey's ill fortune still pursues him. (See our biographical account of that eminent man, which we trust will be our sufficient justification in always maintaining the genus which he introduced, and which properly belongs to him: nor have we any doubt that our learned countrymen will concur in supporting his well-earned fame, when they properly consider the subject.)

We have further to observe, that the Dombeya of Lamarck, or that of Cavanilles, has, neither of them, any preference as to date, both having, we believe, been first announced in Jullien's Gen. Pl. in 1789, a year before the date of publication of each of those authors' works. We are also ready to allow that our illustrious friend Jullien, in the choice he made, was far from concuring in the base periclosure of Dombey, originally raised by the Spaniards. He was however evidently aware that the Dombeya he adopted could hardly be maintained, or at least that it was not distinct from Pentapetes panicat: now received as Pentapetes. (See that article.) Araucaria is not, as has been reported, the denomination of the Chili Pine, in any part of the world, but a perversion of that of its native country, the Araucanian mountains, and to such generic names there are many objections.

Araujja, so named by professor Brotero, in honour of a Portuguese nobleman, Don Antonio de Araujo, an eminent patron of botanical science.—Erect. Tr. of Linn. Soc. v. 12. 62.—Clavs and order, Pentandria Digynia. Nat. Ord. Conoidea, Linn. Apetoneae. Jaff. Ajcilepides. Brown. Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, ovate, permanent segments. Cor. of one petal, bell-shaped; tube rather longer than the calyx, inflated at the base, with five protuberances; limb in five deep, ovate, acute segments, shorter than the tube, slightly spreading, their points somewhat recurved and twisted. Nectaries five cells in the base of the tube, opposite to the segments of the limb. Stam. Filaments five, inserted in the base of the tube, between the nectaries, short, thick, flattened; anthers arrow-shaped, each surmounted by a small auricle, converging towards the point; pollen of two obovate masses, projected upon five angles of the stigma. Pfl. Germens two, superior, ovate-oblong; styles two, very short; stigma common to both, large, thick, roundish-ovate, smooth, with two acute points at the top, and five glandular lateral tubercles to receive the pollen. Peric. Follicles two, divaricated, large, oblong-oval, coriaceous, smooth, abrupt, with a small point, one of them often abortive; partition longitudinal, unconnected when ripe, except at top and bottom; the disk covered on both sides with numerous, elevated, parallel, sharply toothed ridges. Seeds very numerous, inserted into the teeth of the receptacle, imbricated downwards, ovate, clothed with papilary pubescence, and each crowned with a tuft of long silky hairs.

1. A. frcicofera. Silky Araujo.—Native of Peru. Cultivated in the green-house at Libren, where it flowers in autumn, and ripens seed in spring. The whole plant abounds with acid milk, but every part is inodorous. The root is creeping. Stem shaggy, weak, twining, three or four feet high, round, smooth, branched, leafy: the young branches rather downy. Leaves opposite, filched, lanceolate, acute, entire, nearly smooth, an inch and a half to three inches long; heart-shaped at the base, and marked with two glands on the upper side, a little above the insertion of each footstalk. Flowers three or four, or more, together, in short, lateral, drooping, smooth, somewhat coriaceous slaty, about half the length of the leaves, and inserted between the bases of the footstalks. Corolla yellowish-white, marked with purple lines; downy about the mouth. Follicles three or four inches long.

Arbela, l. 13, after Arbelitis, add.—This place, once the capital of the province of Adiabene, has wholly declined from its former importance, and dwindled into a wretched mud town, with a population not exceeding 5000 souls. Part of this town is built on a hill of a conical form, on which probably stood the old castle, and the remainder of the town encircles the base of the hill. The country surrounding Erbile, its present name, lying in lat. 36° 11', and between that place and Moful, is fruitful but hilly, and very deficient in wood, there being hardly a tree or even shrub to be seen.

Arch. l. 23, fig. 43: 1. 23, fig. 43.

Arc of a Circle, l. 11, fig. 45.

Arch, in Geography, a township of Ohio, in the county of Jefferson, containing 60 inhabitants.

Archipelago, col. 2, l. 2, r. 2100.

Arctomys. in Zoology. See Marmot.

Arctotheca, in Botany, a name revived from Vaillant, and originally synonymous with Arctotis, (see that article,) from which the genus we are about to describe has recently been separated, chiefly by the want of a seed-crown; for in habit there is no distinction.—Wendland Hort. Herrenhuf. 8. Willd. Sp. Pl. v. 3. 2565. Brown in Alt. Hort. Kew. v. 5. 141.—Clavs and order, Syngenea Polygonia-fruticans. Nat. Ord. Compositae, Linn. Corymbifera. Jaff.

Gen.
ARC

Gen. Ch. Common Calyx roundish, imbricated; its scales elliptic-oblong, woolly; the innermost with a dilated, membranous termination. Cor. compound, radiated; florets of the disk numerous, funnel-shaped, five-cleft, equal, all perfect; those of the radius about twelve, ligulate, elliptic-lanceolate, longer than the diameter of the disk, with four ribs, and about three unequal teeth, neuter. Stam. in the florets of the disk only, filaments five, capillary, short; anthers united into a tube, nearly as long as the corolla. Pill. Germen in all the florets; oblong; style in the flores of the disk only, thread-shaped; stigma prominent, cylindrical, erect. Peric. none, except the permanent, dry, curled calyx. Seeds in the disk only, obovate, without wing or down. Recept. flat, thickish, cellular.

1. A. repens. Creeping Arctotheca. Willd. n. 1. Ait. n. 1. (Arctotis repens; Jacq. Hort. Soc. Soc. v. 3. 31. t. 506. A. fascipaga; Thomb. Prod. 165.)—This, the only known species, is a native of the Cape of Good Hope. Seeds were sent by the celebrated Scopoli to the writer of this article, and the plants raised from thence flowered in the open ground in Chelsea garden, in the summer of 1790, but it was found necessary to shelter them in winter. The roots are perennial, creeping extensively. Stems herbaceous, prostrate, branched, clothed like the hack of the lyrate pinnatifid leaves, with fine white cottony down. Flower-flake radical, several together, tufted, erect, naked, about six inches high, being rather longer than the leaves. Flowers solitary, an inch and a half broad, lemon-coloured, with purple ribs beneath.

Eff. Ch. Upper half of the head deciduous. Filaments composing a dense denudated net-work, refting on the cup-like receptacle.

1. A.? leucophala. White-headed Arctotheca. Perf. n. 1. Hoffin. Germ. v. 2. 1. 6. f. 1. Trichia cinerea; Tronet. in Roth Catal. v. 1. 227.)—Aggregate. Head funnel-shaped below, reddish-brown. Net-work globe, meanly, snowy-white.—Found on dead leaves or flocks in autumn. Allo on mosses, or fragments of leaves, in rainy weather, very copiously, in June and July, according to Albertini and Schwiemz, Fung. Nénéans 160, who, like Perfoon himself hesitate whether to refer this elegant little species to this genus or to Physarum. See that article.

2. A. fleva. Yellow Arctotheca. Perf. n. 2. Obf. Mycol. 1. 58. Dips. Meth. 10. Albert. and Schw. Nénéans 279. (Trichia nutans; Bulliard Fung. v. 1. 122. t. 502. f. 3. Sowerb. Fung. t. 260. Stemotinis amena; Tronet. in Roth Catal. v. 1. 222.)—Aggregate. Yellow. Net-work cylindrical, elongated, drooping.—Found on rotten wood in summer, confiding of little tufts, of a pale or ochraceous yellow, each plant on a short stalk; the receptacle hemispherical; the cylindrical, rather tapering, net-work from half an inch to an inch long, reclining, abundant in powdery

3. A. cmeera. Ash-coloured Arctotheca. Perf. n. 1. Albert. and Schw. Nénéans 280. (A. alba; Perf. Dips. Meth. 10. t. 1. f. 2. Trichia cinerea; Bulliard Fung. v. 1. 122. t. 477. f. 3. Stemotinis glaucas; Tronet. in Roth Catal. v. 1. 221.)—Aggregate, greyish-white. Net-work cylindric-ovate, erect. Receptacle crenate.—Found in summer, in woods, on dead branches, flocks, &c. Smaller and shorter, as well as more obfute, but with a longer falk, in proportion, than the laft, from which also it is ditinctly distinguished by its dirty-white colour. They are puzzled, as well as the learned authors of the Fungus Nénéans, by Perfoon's allusion of the resemblance of this species to the fifth, hereafter described.

5. A. paniculata. Scarlet Arctotheca. Perf. n. 5. Dips. Meth. 10. Albert. and Schw. 282. (Clathrus dentatus; Linn. Sp. Pl. 1649. Jacq. Mice. Atur. v. 1. 136. t. 6. Trichia cinnabarina; Bull. Fung. v. 1. 121. t. 502. f. 1. T. dentata; Sowerb. Fung. t. 49. T. 2164. Hall. Hill. v. 3. 115. t. 48. f. 6. as Jacquin has it, rather than 4. as cited by Haller himfelf. Stemotinis coccata; Tronet. in Roth Catal. v. 1. 220.)—Crowded, ovate, orange-coloured.—Frequent throughout Europe on rotten wood, in fummer and autumn. When young it is white and foft, but advancing in fize, it affumes a confipuous orange-colour, with the dry rather firm texture of its genus. This fne colour chiefly reftes in the copious feminal powder, for the net-work itfelf is brownifh. The edge of the remaining base of the receptacle is often irregularly torn, and various in breadth. Bolton's v. 3. t. 93. f. 2. if really taken from this species, is not a happy reprefentation.

ARDELAN, in Geography, a province of the Persian empire, forming the eaftern division of Kurdtian, is in length 200 miles, from the little river Sharook to the Turkish district of Zohab, and nearly 160 in breadth. It is separated from the plain of Hamadan by a small range of hills, and its western boundary is 100 miles beyond Senna, the capital, situated in N. lat. 35° 12', and E. long. 40°. The territories of Ardelen extend as far as Kella Shah Khanee, and are peopled by a tribe denominated Gheefkee, who are recorded by the Kurds as the moft expert and daring robbers of their nation; nor will torture induce them to betray their accomplices, being habituated to pain and severe chastifement from their earliest infancy. They are, however, liable to the moft abject fuperfition.

ARGOLASIA, in Botany, all a good name, contrired by Juffien, from opes, white, and oche, hairs, or foage, alluding to the white woolly clothing of the herb. But this name is superfeded by one of fimilar meaning, Lanaria, (fee that article,) given to the fame plant by Dr. Solander, and published in Ait. Hort. Kew. v. 1. 462, in 1789. This latter has been adopted by Schreber, and is now eftablifhed.

ARGUNNA, in Geography, a town of Armenia, in the pachalic of Diarbekir, distant 483 miles from Diarbekir; situated on the fide of a lofty mountain, from which torrents of water are discharged in courses through the streets fo as to render them impaffable. The town is populous, but wretchedly built, and is remarkable for the quantity of wine and brandy made in its vicinity.

ARJONA, in Botany, fo named by the late abbé Cavaller,
A R I

Niles, in honour of Mr. Francis Arjona, a celebrated lecturer on botany at Cadiz.—Cavan. 1. c. v. 4. 57.—Clafls and order, Pentandra Monogynia. Nat. Ord. Lythraceae, Julf. affine?

Gen. Ch. Cal. Perianth inferior, of two small, concave, permanent leaves, each with three terminal teeth. Cor. of one petal, funnel-shaped; tube thrice the length of the calyx, slightly dilated upward; limb in five deep, ovate, acute, equal segments. Stem. Filaments five, capillary, very short, inserted into the throat of the tube; anthers oblong, within the tube. Pijl. Genuen superior, ovate, crowned with five minute persistent scales; style simple, thread-shaped, the length of the tube; frigmas two, flat. Peric. Berry globose, crowned with the scales, of two cells. Seeds . . . .

Eff. Ch. Corolla funnel-shaped, equal. Berry superior, of two cells, crowned with five scales.

1. A. tuberosa. Tuberous Arjona. Cavan as above, t. 383. — Native of South America, in dry barren ground, near Port Defire, flowering in December. We have a specimen from the lamented author, gathered by Louis Née. The long fibres of the root are furnished, here and there, with oval knobs, well suited to its arid situation. Stem foliary, a span high, with numerous branches from the bottom; nearly simple above; leafy throughout. Leaves very numerous, imbricated, sheathing, awh-shaped, pinous-pointed, channelled, entire, rather spreading, clothed with soft woolly hairs. Flowers in a terminal, terminal, dense, corymbose head. Corolla about an inch long; externally yellowish and very downy; internally smooth, yellowish-white. Style reddish, with sometimes three frigmas. Berry small, smooth. Seeds not observed.

There is something in the characters and hue of this plant, that approaches the natural order of Verpecula, or Thymeleon, especially in the form and aspect of its corolla. Possibly the fruit may not really be of two cells. The two corydodes of a single drupa might, in an early state, mislead the author, who fays he did not see the seeds. The bark, however, does not appear to have those flaky fibres, which are the strong indication of the Daphne family.

ARISTEIA, (see our former article,) a name left unexplained by professor Martyn, is rightly derived by De Theis from arista, an awn, but does not apply as he fays to the point of the leaf. Solander, the author of this name, appears rather to have alluded to the corydolea-like fringe of the sheaths, so remarkable in the original species. — Ker in Ann of Bot. v. i. 236. Dryand in Ait. Hort. Kew. ed. 2. v. i. 108. Vahl Enum. v. 2. 123.

Eff. Ch. Corolla superior, in fix deep regular segments, spirally twisted together after flowering, permanent. Capsule of three cells, with many seeds.

Four species having been added to this genus by Mr. Ker, it is necessary to review the whole.

1. A. cynnea. Grafs-leaved Arjona. Ait. n. i. Andr. Repof. t. 10.—Flowers in terminal heads. Sheaths and bractes in many fine capillary marginal segments. — Native of the Cape of Good Hope, as well as in the following. See ARISTEIA, n. 1.

2. A. capitata. Tallerf Arjona. Ait. n. 2. Ker in Curt. Mag. t. 605. (A. major; Andr. Repof. t. 160. A. curvata; Vahl n. 3. Oloialis capitatus; Linn. Sp. Pl. 53. Morfea curvata; Thunb. Mor. n. 15. t. 2. f. 2. Prodr. i. 11. Fl. Cap. v. 1. 277. Willd. Sp. Pl. v. 1. 243.)—Tufts of flowers alternate, racemose. Sheaths ovate, entire.—Native of mountains in the road to Hautiniques and Lange Kloof, as well as of hills about Cape Town, flowering in October and November, or in the latter situation, two months earlier. This species is two feet high, with broadish word-shaped leaves, and large handsome flowers, of a fine blue, composing a long faciculated cluster.

4. A. melaleuca. Mourning Arjona. Ait. n. 4. Ker in Curt. Mag. t. 1277. (Morsea melaleuca; Thunb. Mor. n. i. t. 1. f. 3. Prodr. 10. Fl. Cap. v. 1. 264. Willd. Sp. Pl. v. i. 240. Vahl Enum. v. 2. 153. M. jugens; Linn. Suppl. 99.)—Flowers alternate, foliary or in pairs. Three segments of the corolla not half the size of the reft. Leaves linear.—Found in several sandy bulby places, at the Cape of Good Hope, flowering in September and October. The root is fibrous. Leaves numerous, two-ranked, four to fix inches long, and not a quarter of an inch broad. Flowers few, somewhat racemose, larger than the leaf, and very hand- fome, having three concave, almost orbicular, segments, of a sky-blue, an inch and a half long, with three alternate, obovate, black ones, about half as long, and much narrower.

ARISTOLOCHIE, is named from the leading genus, is the twenty-third natural order in Jullieu's system, being the only one in his fifth class. That class is defined as follows. Colyledons two. Petals none. Stamens inferted into the style. The Calyx is superior, of one leaf. Stamena none. German inferior; file either wanting, or single, or definitely multiplied; frigmas simple or divided. Fruit of one or many cells.

The order is thus characterized. Calyx superior, of one leaf, entire or divided. Stamens definite. German inferior; file one, or nearly wanting; frigmas divided. Fruit of many cells, with numerous seeds.

The only genera are, Ariftolochia, Ajarum, and Cyttisus. Linnaeus arranged them with his Sarmentaceae, but was subsequently inclined to refer them to his Rhoeadee. (See those articles.) We have already observed that they do not belong to the latter, nor have they any relationship to the Sarmentaceae, except something in the habit and foliage of Ariftolochia.

A R K A N S A S, in Geography, a river of Louisiana, which, next to the Missouri, is the most considerable tributary of the Missippii. Its length is nearly 2500 miles, and at proper season it is navigable nearly through the whole distance. In many places, however, its channel is broad and shallow, at least above the rapids, so as to render navigation almost impracticable. Until 800 or 900 miles from its mouth it receives no considerable streams, on account of the vicinity of
of the waters of the Missouli, of the Kanfas, &c. on the one side, and those of Red river on the other. The chief rivers which fall into it are, the Verdigris, the Negracka, Canadian river, Grand river, &c. Several are remarkable for being strongly impregnated with salt; the Arkansas itself, at certain seasons, is said to be brackish. The lands on this river for 600 or 800 miles upwards are described as very fine, and capable of affording settlements, though principally timbered. The Arkansas is a place situated 60 miles up the river, and contains 450 inhabitants. It has a few fires, and seems to be improving. There is a considerable trade with the Osages up the Arkansas, and with the Indians, who live in the White river country. This is also a French establishment, and has the fame proportion of Americans as the other towns. The territory of the Missouli contains about 874 Arkansas, whose settlements are principally in the neighbourhood of the Arkansas post, or extend up the river; and they are the least considerable of the territory. 

Brackenridge's Views of Louisiana.

ARAB, in Commerce, a weight in Portugal and Spain. At Oporto 1 arabo, or arrove, = 32 arrears, and 4 arrobas, or 128 lbs. = 1 quintal. The quintal at the India-house is 112 arrears. (See Quintal.) In Spain the arabo is also a liquid measure. A moyo of wine contains 16 arrobas, an arabo = 8 azumbres = 2 quartillos. The arabo of wine, or great arabo, is the fame all over Spain, regulated by the standard measure of Toledo, which contains 34 lbs. of river water (Cathilinian weight), and measures 1 237 1/2 Spanish or 981 English cubic inches; so that 4 such arrobas = 17 English wine gallons. The arabo of oil, or lesser arabo, regulated by the same standard measure, which weighs 25 lbs. of oil, or 26 lbs. 16 oz. of river water (Cathilinian weight), and measures 956 Spanish or 771 English cubic inches. Hence 3 such arrobas answer to 10 English gallons. The arabo is divided into 4 quartillos, or 100 quarterones or panillas. A Spanish bottle contains 30 arrobas of wine, or 33 3/4 of oil; a pipe is 27 arrobas of wine, or 34 1/4 of oil; so that the botta is 127 1/2 English gallons, and the pipe 114 3/4. Kelly's Cambist.

ARKSEEN, or AREKIN, a long measure in Russia. See Verschock.

VOL. III.

ARTICULATIONS. Diseas of. Arteries being composed of blood-vessels, nerves, and absorbents, are liable to the same morbid alterations, and endowed with the same powers of reparation, as soft parts in general; their coats inflame, and pass through the different stages of adhesion, suppuration, or gangrene, in the same manner as the skin, a gland, or a mucous membrane.

The internal coat of an artery, Mr. Hodgson observes, bears a striking analogy to serous membranes in its tendency to the adhesive inflammation; and this property is in the blood-vessels, as in all organs, the first agent of reparation in injuries from accident or disease. The inflammation which is excited by the wound or division of an artery produces an effusion of lymph, which fills the extremity of the vessel, and affecting also the external coat becomes the basis of adhesion and final obliteration. A punctured artery is united by the same adhesive processes which repairs wounds in general; and if irritation be excited in the coats of an artery by preasure, adhesive inflammation is the consequence, lymph is diffused into the cavity, and into the cellular substance, connecting the coats of the vessel; its sides coalesce; and it is rendered impervious. The same adhesive processes frequently prevents hemorrhage, where abscesses, or extensive ulcerations, exist in the neighbourhood of large vessels, the inflammation which precedes the suppuration having produced an effusion of lymph between the coats, and into the cavity of the arteries, whereby it is obliterated. But the most perfect demonstration of the effects of acute inflammation upon the internal coat of an artery, Mr. Hodgson thinks, is to be met with in the cases where the disease appears to have extended to the vessel from the contiguous parts. Thus, in a fatal instance of violent pneumonia, besides the usual appearances on dissection, the inflammation was found to have extended to the aorta, the internal coat of which was of a deep red colour, and a considerable effusion of lymph had taken place into its cavity. The effused lymph was very intimately connected with the internal coat of the vessel, and a plug of it had extended into the left subclavus artery, and nearly obliterated the cavity of that vessel. (Treatise on the Diseases of Arteries and Veins, p. 5.) Mr. Hodgson has observed a similar state of the great blood-vessels in a less degree from carditis, pneumonia, and bronchitis.
bronchitis. The granulations, or fungous growths, which are not frequently met with at the origin of the aorta upon the semi-lunar valves, or in the cavities of the heart, are said sometimes to originate in the lymph thus effused upon the internal membrane. Mr. Hodgson also affures us, that the inflammation excited in an artery of the extremities by the application of a ligature has been known to extend along the internal coat of the vessel to the heart itself, as we know is often the case with respect to the veins.

According to the same well-informed writer, chronic inflammation may generally be remarked in thickened and calcareous arteries, particularly in aneurismal subjucts. The internal coat of the vessel is soft, thickened, of a deep red colour, which is not uniform, but irregularly disposed in the vicinity of ulcerations, thickenings, or calcareous depositions. P. 9.

Ulceration of an artery may commence in the vessel itself, or extend to it from the surrounding parts. In the first circumstance, it is always found first in the internal coat, and is generally preceded by some other morbid change of the vessel. Thus, it is not unfrequently met with around the circumference of calcareous depositions, or upon the surface of atheromatous thickenings; and aneurism is, without doubt, occasionally a consequence of such ulceration, the coats of the vessels being completely destroyed by it, and the blood escaping into the surrounding cellular substance, which becomes gradually expanded into a fac. Hemorrhage is often caused by ulceration extending from surrounding parts to the coats of arteries, as in cancerous and phagedenic ulcers; and Mr. Hodgson even thinks that many passive hemorrhages are produced by ulceration beginning on the inner surface of these vessels.

Sphacelation of arteries in consequence of inflammation of their internal coat has not hitherto been observed. Arteries, however, are often included in extensive floughing of parts, in which case the blood generally coagulates in the vessels to a considerable extent above the line of sphacelation; an occurrence which seems defined to prevent hemorrhage on the separation of the flough. The coagulum is afterwards absorbed, and the vessel obliterated.

From considering the inflammation of arteries and its effects, our author proceeds to speak of various morbid appearances to which the coats of arteries are liable, in consequence of their peculiar structure and functions.

1. The internal coat of arteries is sometimes thickened and converted into a substance resembling cartilage, or the thickened peritoneum of an old hernial sac. This disease is confined to the internal coat, which having lost its elastic fometies cracks, and forms scales that hang into the cavity of the vessel. Calcareous deposits often accompany this alteration of structure, and the surrounding parts of the membrane generally exhibit signs of chronic inflammation. The semi-lunar valves of the aorta are not unfrequently changed into a dense fibrous structure, resembling ligament, or tendon; sometimes they are converted into cartilage, and are manifestly incompetent to their office as valves. In several infancies, Mr. Hodgson has found them ruptured, forming cartilaginous eminences on the sides of the vessel.

2. The internal surface of arteries exhibits frequently a thickened and pulpy structure, sometimes with the appearance of small flattened tubercles, and, in other examples, with an irregular and somewhat flabby appearance over the whole surface. This disease is confined to the internal coat, and is often found in aneurismal subjucts.

3. A deposition of atheromatous or purulent matter in the cellular membrane, which connects the internal and middle coats of the vessel. The diseased part is of an opaque yellow colour, sometimes extensive, and considerably elevated above the surrounding surface, and on other occasions circumscribed, and having a pustular or tuberculated appearance. If punctured, matter may be pressed from underneath the internal coat, varying in confluency from that of cheese to that of common pus. Mr. Hodgson has seen the emolient and femoral arteries in the same subjuct quite obstructed by the accumulation of this curdy matter.

4. Certain fungous or wart-like excrescences have been observed upon the semi-lunar valves of the aorta and pulmonary artery, and also upon the mitral and bicupid valves. They are of rare occurrence. Corvifart's opinion respecting the syphilitic nature of their cause is not intitled to any degree of credit; and Mr. Hodgson relates a case, where the absence of that disease throughout the whole of life made it impossible that they could have had such an origin. The femoral artery and commencement of the profunda were in this instance completely obstructed by a fungous growth, similar to what was found upon the semi-lunar valves of the aorta.

5. The next disease to be noticed is a deposition or calcareous matter in the coats of arteries. In old age this happens so frequently, that Bichat was induced to regard it as a natural phenomenon rather than a disease. The incrustation seems to commence in the substance of the internal coat, a delicate pellicle covering the calcareous matter, and separating it from the blood passing through the cavity of the vessel. Sometimes this pellicle is deficient, or hangs into the cavity of the vessel, and the blood is in contact with the incrustation itself. Sometimes all the coats of the vessel are involved in the disease, and are converted into a long cylinder, in which no remnants of the original structure can be traced. (Hodgson, p. 21.) The formation of these depositions bears no resemblance to that of bone; they are seldom, if ever, preceded by the existence of cartilage; and no regular arrangement is discernible in them, corresponding to the fibrous structure of bone. According to Mr. Brande's analysis of them, they contain 65.5 phosphat of lime, and 31.5 animal matter, without any carbonate of lime.

Calcareous matter is frequently deposited in the substance of the semi-lunar valves of the aorta, and produces mercerious consequences, than when it takes place in any other part of the arterial fyltem. The valves becoming rigid and fixed diminish the fires of the opening into the aorta. Whilst the pulse at the wrift is feebly, the heart is acting violently to compensate for the diminution in the quantity of blood which should pass through the aorta; and this comparative difference between the pulse at the wrift and that at the heart will, Mr. Hodgson conceives, in advanced cases, be sufficient to enable us to ascertain the existence of this incurable disease. A similar disproportion between the pulse at the heart and at the wrift exists also when the opening between the left auricle and ventricle is contracted; but a double pulsation of the heart has been observed in this case, and is said to distinguish it from contraction of the orifice of the aorta by ossification of its valves.

Mr. Hodgson has given some interesting cases of ossification of the coronary arteries. In one, the heart was unusually small; its paries soft and flaccid, and upon the ventricles not the eighth of an inch thick; whilst the coronary arteries and many of their ramifications were converted into
ART

into calcareous tubes, and some of them nearly rendered impervious. This morbid appearance does not exist in every case which is attended with the train of symptoms, to which we apply the term angina pectoris. Violent pain in the situation of the heart, extending down the anus, and terminating in a sensation of numbness, palpitation, and irregularity in its action, with frequent syncope and difficult respiration, accompany almost all the organic diseases of that organ. (Hodgson, p. 36.) The deposition of calcareous matter is seldom found in the upper extremities; and although so frequent in the aorta, it has rarely or never been met with in the pulmonary artery, or its valves. See Hodgson on the Diseases of Arteries and Veins, 8vo. London, 1815.

Aneurism, which constitutes the most important disease of arteries, has been treated of in a separate article, to which we have already annexed some additional particulars under the head of Surgery. A few other observations, relative to the same subject, will be found at the words Aneurism and Aorta in this Addenda.

In habit, the generality of the species which constitute this genus are akin to Sphæroma and Opegrapha. (See those articles.) But Acharius originally included herein the Lichen croesus, and L. fascatus of Linnæus, which are now separated on account of their totally different habit, and leafy fronds, by the name of Solorina, Lichenogr. Univ. 25. t. 1. f. 5; 6; so that Arthonia is rendered much more natural. In the Synopsis of this writer, his latest publication, twelve species are defined.

Among them are,

A. hydropica, n. 7. (Opegrapha hydropica; Ach. Meth. 25. Engl. Bot. t. 1847.)—Crested limited, membranous, smooth, greenish-white, somewhat shining. Receptacles deferrated, flat, angular, irregularly flabby, black.—Frequent on young trees. We cannot consider this otherwise than as an Opegrapha.

A. obscura, n. 8. Engl. Bot. t. 1752.—Crust membranous, olive-brown. Receptacles minute, flattish, thin, elliptical or kidney-shaped, fleshy, slightly uneven, black.—On the barks of trees, not common, nor very easily to be observed. The crust rises into irregular swellings, and the copious receptacles are very deep into its substance. The genus of this plant is indeed obscure, nor can we offer any better determination respecting it than that of Acharius. A. lycena, n. 11. (Lichen lycena; Engl. Bot. t. 869.)—Crust white, thin, even, somewhat tartaceous. Receptacles numerous but distinct, flat, rather fleshy, oblong, blunted, often curved, black, with a glaucous tinge.—Found by Mr. Sowerby, nearly covering the rugged barks of old oaks. The receptacles resemble a leopard’s or lynx’s skin, and are not crowded nor confluent, though curved and approaching each other in every direction, the margin of each black. We should rather refer this species to Opegrapha.

A. prunofusa, n. 12. (Lichen impolitus; Ehrh. Cr. ft Achar. Prodr. 56. Engl. Bot. t. 981.)—Crust whitish, thin, somewhat tartaceous, unequal, smooth. Receptacles flat, fleshy, roundish or angular, confluent, dull orange-brown, with a glaucous tinge. On the trunks of trees, especially oaks. We cannot but think the original specific name peculiarly happy, and for that reason, if no other, it ought not to have been changed, especially as prunofusa is equally suitable to the last species. The present looks of an uniform dirty white, till touched by some hardish body, when the brown receptacles, tinged with yellow, become strikingly apparent, and are contrasted with the unaltered crust. The figure in Engl. Bot. printed in red, is altogether erroneous.

Gen. Ch. Cal. none. Cor. of one petal, inferior, in six deep, regular, spreading, deciduous segments; the three innermost waved or fringed at the margin. Stam. Filaments his, tapering, densely bearded; anthers roundish, attached by the notch at their base. Pist. Germen superior, roundish, with three stigmas; style solitary, erect, cylindrical; stigma capitate, hairy. Peric. Capsule nearly globular, with three stigmas; three cells, and three valves; the partitions from the centre of each valve. Seeds few in each cell, somewhat angular, with a naked crest.

Eff. Ch. Corolla in six deep equal segments; three innermost waved or fringed at the margin. Filaments bearded. Capsule nearly globular.

This genus is allowed by its author to come very near Anthéricum, to which some of the species have been referred by other writers. Indeed we can discover no difference, (three of the filaments in Anthéricum, if not all of them, being bearded,) except the wavy or fringed inner segments of the corolla. Anthéricum being a very extensive genus, whose limits are not well defined, it is highly desirable to lessen the number of species, by establishing new genera from among them, by any certain, however apparently slight, criterion; and it must always be recollected that, in the natural order to which these plants belong, very natural genera are discriminated by apparently rather trivial marks.

Arthropodium is observed by Mr. Brown to consist of smooth herbaceous plants, with fasciculated roots, composed either of bulbs, occasionally flaked, or of thick fleshy fibres. Leaves linear, flaccid. Flower-flakes either aggregate or solitary, each with a joint in the middle. Flowers pendulous, either purpshire or white. Corolla closing after flowering, and long before the fruit ripens, falling off, leaving its permanent cup-like withered bale behind. The anthers are purple, or white. Thyssanotus of our learned friend, already described in our thirty-fifth volume, comes nearer to Arthropodium and Anthéricum than to the Alparicus tribe, to which it has been referred; the beautifully fringed inner segments of the corolla especially the present genus. But Thyssanotus has smooth filaments, unequal anthers, and a declining style, with a smaller stigma. The seeds moreover differ very essentially.

X 2 finely
finely crenate. Capule pendulous. Bulbs filiform. - Native of the neighbourhood of Port Jackson, New South Wales, from whence we received specimens, nearly thirty years ago, through the hands of Dr. White. Seeds were communicated by Mr. Geo. Caley to Sir J. Banks, for Kew garden, in 1800, and this elegant species is now to be seen in many green-houses, flowering in various summer months. The fruit is perennial. Stem erect, round, three or four feet high; slightly leafy in the lower part; much branched and panicle above. Leaves linear, pointed, channelled; sheathing at the base, a foot or more in length, chiefly radical. Branches of the panicle usually in pairs, spreading, racemose. Flowers drooping, three or four together, on undivided partial flasks. Corolla reflexed, half an inch in diameter, white variegated with lilac; three outer segments small, acute; three inner ovate, elegantly crisped at the margin. Beard of the stamens dense, yellow. Anthers and stigma purple.

2. A. triflum. Upright Arthropodium. Br. n. 2.—“Cluffter almost simple, many-flowered; flower-flasks solitary. Capsules erect.”—Gathered by Mr. Brown, in Van Diemen’s island, but after the flowers were full. 3. A. minus. Letter Arthropodium. Br. n. 3.—“Cluffter simple, with few flowers; flower-flasks solitary. Bulbs sessile.”—Found by Mr. Brown, near Port Jackson. 4. A. fimbriatum. Fringed Arthropodium. Br. n. 4.—“Cluffer simple; lower flower-flasks in pairs. Filaments naked in their lower part; tumid and smooth at the top. Anthers linear. Inner segments of the corolla fringed.”—Native of the neighbourhood of Port Jackson, where it was noticed by Mr. Brown, who observes that the structure of the stamens is so different from the reil, as to make him hesitate whether this species ought not to form a genus by itself. We are not sure whether we are possessed of any specimens.

ARISTOSTYLIS, from αριστος, a joint, and στυλ, the style, because of the articulation by which that part is joined to the germen.—Brown Prod. Nov. Holl. v. 1. 229. —Claws and order, Triandria Monogynia. Nat. Ord. Calamaria, Linn. Cyperaceae, Brown.

Eff. Ch. Spikelet single-flowered. Glumes chaffy, imbricated; the lower ones empty. No bristles around the germen. Styleawl-shaped, triangular, articulated with the germen, deciduous. Stigmas three. Nut triangular. 1. A. aphylla. Leaflets Aristrostylis. Br. n. 1.—Found by Sir Joseph Banks, in that part of New Holland which lies within the tropic. The stamens are slender, unbranched, without joints of the ovary; sheathed at the base; naked in the upper part. Head terminal, simple, turbinate, longer than its three or four-awned, awl-shaped involucrum. This genus differs from Abildgardia in its habitat, and single-flowered spikelet; from Rhynchospora in having a deciduous style, and no bristles surrounding the base of the germen; see thefe articles. Brown.

ARTUSI, l. 4. ferrut, he.

ARVE, for Rhine r. Rhone.

ARUNINARIA, in Botany, inadmissible as a generic name, being formed by an alteration of Aruna, already received, is applied by Michaux, Fl. Bore.-Am. v. 1. 133, to a genus now called Migeia, in Perf. Ench. v. 1. 102, according to Pursh. 59. This cannot, we presume, apply to Schreber’s Migeia, (see that article,) as the floras in Michaux’s plant are numerous; so that here is some confusion which we must leave the writers to question itself.

ASC, in Common, a small Dutch weight, used also at Hamburg, and in Sweden. At Amsterdam, 232 ares are = an ounce, and 8 ounces = a mark toy. (See MARK.)

In Sweden the smallest denomination of weight is the quarter, which is the same as the as of Amsterdam. The mark for weighing gold and silver, called “silver-mark,” is 48s. ares, or 3252 grains English troy weight. Hence 40 such marks are = 271 ounces toy. In apothecaries’ weight, the pound is 7416 ares, or 5400 grains toy; and hence 16 such pounds = 15 pounds English troy, or apothecaries’ weight.

As, l. 16. 23. 27, for Tullius r. Tullus.

ASAM, l. 2, after Bengal, infer—bordering on the country of the Grand Lama, or Botan—after Hindoostan, or separated from Decca, the N.E. quarter of Bengal, by a range of hills, intersected by the Garrows;—after Meckley, or Ava and Arracan.

L. 16, after journey, add.—It is understood to be about 200 miles in length, and its mean breadth above 70, though in some places, where the mountains recede, it greatly exceeds that proportion. Dr. Wadie thinks 6,000 square miles a very moderate calculation of its superficial extent, so that it considerably exceeds England and Wales. The whole country is a valley of great fertility, not only divided by the great stream of Burnhaumpooter, but every where intersected by numerous rivers.

ASAPIH, Sr. l. 12, for Shipley r. Bzgot.

ASCHRAFF. Add—This place is seated on the shore of a bay, which is the only good harbour on the southern side of the Caspian sea.

ASCOBOLUS, in Botany, from ασκος, a skin, or cafe, and βολος, a cafe, or throw, because the seeds are thrown out with elasticity, several together, in oblong cafes.—Peri. Syn. Fung. 676. Obs. Mycol. f. c. 33. —Claws and order, Cryptogamia Fungi. Nat. Ord. Fungi.

2. A. carnox. Flesh-coloured Ascolobus. —Smooth, flesh-coloured.—Found rarely on dung, in woods. All over of a very pale red.

4. A. immeus. Sunk Ascolobus. Ibid. 35. t. 4. f. 7, d. —Scattered, immerge, irregular, somewhat conical, rather fuscous externally.—In the same situations, almost entirely sunk in the dung, so that the seed-cafes only are prominent, containing black seeds, floating in an evident fluid. Persoon.

Eff. Ch. Thread-shaped, terminating in an empty, slightly inflated, head.

Tode in Schrift. der Berl. Gesellschaft. Naturf. Fr. v. 3. 247. 4. f. 4—6.)—Found in autumn, either at the extremities of the branches, or on the trunks, of trees, such as Willows, &c. It may be preserved a long time without decaying, or even shrinking. Tode describes the head as at first like a drop of water, but soon assuming an oval figure, shining like silver, and subsequently besprinkled with snow-white powder, probably the seeds. This betrays some affinity to Stilbium; see that article.

ASCIDIA, l. ul., dele which see respectively, and infert, See VERMES.

ASCIDIUS, I. l., r. Pedianus; l. 54, dele Quincifilium and. See ASHY, in Geography, a county of North Carolina, containing 6,904 inhabitants, 147 being slaves.

ASHARIANS. See ASHARIAINS.

ASHBY, l. 3, r. 1103.

ASHFIELD, l. 4, r. 1809.

ASHFORD, a township of America, &c. add.—The number of inhabitants by the census in 1810 is 2532.

ASHFORD, New, &c., for 460 r. 411.

ASHTABELU, a township of the county of Georgia, in the district of Ohio, having 221 inhabitants.

ASHTON, a township of Pennsylvania, in the county of Delaware, having 765 inhabitants.

ASIA, col. 24, l. 31, after height, infert—but by late discoveries and measurements, their altitude has been found to be much more considerable than geographers formerly apprehended and flatted. See MOUNTAINS.

ASITUS, I. 16, dele which see respectively.

ASIMINA, in Botany, a barbarous name, employed by Adamson, and, according to him, of Canadian origin. De Candolle, by his adoption, Syll. v. t. 478, might possibly render it classical, there being no objection on the score of euphony, nor any meaning contrary to reason or sense, as in many other cafes of a similar kind. As far as we know, the word is defective of all meaning whatever; in which respect Michaux’s synonym, Orchidctearnum, would be preferable, were the idea it conveys unexceptionable, and the word not compounded of another generic name. All things considered, we prefer Porcelainia (see that article hereafter) as entirely free from objection; for we cannot follow our distinguished friend, De Candolle, in perpetrating this last-named genus from his Afinina. Our preceding articles Orchido-earnum and Porcelainia are now superferfed, in conformance of more accurate information, chiefly furnished by De Candolle.

ASPARGUS, the 12th natural order in Jussieu’s system, the second of his third classes; for the full characters of which class, see PAPAIS.

Jussieu thus defines the Aparagus, which are nearly equivalent to the Linnæan Sarmintaeceae. See that article.

Calyx in six divisions, regular, usually deeply divided and inferior, rarely superior. Stamina six, inserted into the lower part, rarely into the middle, of the calyx. Germin simple, mostly superior; styles either three, with as many stigmas, or the style is simple, with a three- or three-cleft stigma. Fruit pulpy, rarely capsular, superior, rarely inferior, of three cells, with one, two, or not many more seeds in each. Corculum at the scar of the horned albumen.

The stem is frequently herbaceous, in some cafes shrubby. Leaves mostly alternate, seldom opposite or whorled, for the most part not sheathing, but merely clasping the stem. Flowers each with a separate flower; in some inflorescences, perhaps from abortion, dioecious. A third part of the fructification is sometimes, in a few inflorescences, suppressed, or a fourth is added.

Sec. 1. Flowers perfect. Germin superior. Dracena of Linnæus; Dionella of Lamarck; Rigoneum of Forster; Flagellaria and Aparagus of Linnæus; Callixene and Philonis of Commerson; Medeola, Trillium, Paris, and Convallaria of Linnæus and others, constitute this section.

Sec. 2. Flowers dioecious. Germin superior. Rhus, Smilas, and Diospyros.

Sec. 3. Flowers dioecious. Germin inferior. Tamus of Linnæus, which Jussieu, following Tournefort, calls Tamus, and Ramea.

Mr. Brown, Prodr. Nov. Holl. v. 1, has greatly curtailed this order, referring some of its genera to the Assphodei or Assphodeles, and establishing out of it a new order, termed Smilaces, composed of Trillium, Paris, Medeola, (except its Cape species,) Convallaria, and Strepogurus, with his own Dryophosta, Rigoneum of Forster, and Smilas. The same author has also founded on the genera of Diospyros and Ramea another order called Diospyrea; but surely Tamus, by his own account, connects this with the Smilaces.

ASP, for Berne r. Bear; and for Switzerland r. France.

ASPER, in Commerce. Subjoin—See Piastré.

ASPERGILLUS, in Botany, a name first applied by Michelian, Nov. Gen. 212. t. 91, to a tribe of minute Fungi, and expressive of their resemblance to the form of a sprinkling-brush, used for holy water in Catholic countries. This tribe is now become a section of Perforon’s Monilia. See that article.

ASPERIFOLIA, the forty-first of the natural orders of Linnæus, is one of the most natural of these aggregations. It was first pointed out by Celsalinus, but obtained the above name from Ray, in allusion to the roughness of the foliage. To this character one or two species of Cynogloja and of Pulmonaria alone afford exceptions; which indeed are but partial, for even in these some br.1tly roughness is alono always to be discovered, either on the surface or branch. This order is analogous to Jussieu’s Borragines, and is so well defined that Linnæus has, contrary to his usual prachie, given its characters at some length, as follows.

Root fibrous. Cotyledons two. Stem with alternate round branches. Leaves alternate, simple, for the most part nearly entire, rough with scattered bristly hairs, or callous warts; convolute before they expand. Stipula wanting, as well as all other appendages in general. Flowers unitaler; their common stalks, generally in pairs, revolute in a spiral manner, and gradually unrolled as the flowers are ready to open. Calyx in five more or less deep divisions. Corolla monopetalous, inferior, five-cleft, regular except in Ecbium; its mouth either closed with vaulted valves, or crowned with teeth, or naked and pervious. Stamina five, equal, except in Ecbium. Fruit superior. Germin four, except in some species of Cynoquilum, Tournefortia, and Nolana, to which Cernins should be added; but Nolana was properly removed by Linnæus afterwards to his Euritide, which are inserted into the receptacle by their base; hence the lower part of each cell becomes tapers, as if fifhished artificially. Pistil one; style not an elongation of the germens, but sunk between them in the centre, often divided into two equal parts. Seeds four, rarely combined into two.

The genera stand thus:

Sec. 1. Symphytum, Oenoma, Cerninthe, Borago, Aebium, Lycopsis,
Lycoctis, Asphodelus, Pullmonaria, Lithospermum, Cyanoglaucum, Anchusa, Myosotis, and Heliocereus.

Sec. 2. Tournfortia, Varronia, Ebrozia, Cordia, and Patagonia.

Sec. 3. Nolana, here placed by itself, is now removed.

In the Linnæan manuscript, Mufcerfchmidia is introducted between Echium and Lycoctis; Coldenia after Heliocereus; Hydrophyllum and Elflia after Tournfortia; and Ebrozia is removed to the end of all.

In the generic definitions of this order, the valves or teeth of the corolla, and the more or less deep divisions of the calyx, take the lead. Linnaeus has been thought by some to have multiplied the genera beyond necessity; yet it is hard to say how they could naturally be abridged. The plants love a dry hilly situation, and become smoother as they approach nearer to water.

The numerical anomaly in the fructification of the Asphodeli, of the four-cleft fruit, with a five-cleft flower, is one of their striking characters, in which they indeed agree with the Linnæan Pteridium, Julleu’s Labintz, but the irregular corolla, unequally-divided style, opposite leaves, and square stems, of the latter, and especially their four stamens, two longer and two shorter, clearly distinguish them. Their qualities also greatly differ, being aromatic, not mucilaginous and scented. Their flowers are generally red or purple; those of the Asphodeli of a beautiful blue, though most of as beautiful a red before expansion.

Asphodeli, the sixteenth natural order in Jullieu’s method, the sixth of his third clafs, thus denominated after Asphodelus, one of its well-known genera. Mr. Brown, who has greatly enriched this order with new genera, as well as with removals from the Asparagi (see that article), gives it the appellation of Asphodelae. Prodr. Nov. Holl. v. 1. 274.

The characters of Jullieu’s third clafs are detailed under Palmæ. He thus defines the Asphodeli.

Calx inferior, coloured, often in fix deep equal segments; rarely tubular, with fix less deep divisions. Stamens fix, inserted into the bottom or the middle of the calyx. German superior, simple; style simple; stigma either simple or three-cleft. Capsule of three cells and three valves, with many seeds.

The root in a great portion of these plants is bulbous, feeding up a leafless stalk, and producing capillary fibres from its base downwards; in the rest it is fibrous, bearing a stem, for the most part herbaceous. Leaves sheathing, alternate, all generally radical. Spike often simple, terminating the stalk; sometimes branched, with scaly sheaths under each branch. Flowers each accompanied by a sheath, or spathe, spikèd, (in Allium umbellata,) terminal, or rarely axillary.

Sec. 1. Flowers spikèd. Root fibrous. Calyx tubular. Atelis and Aloe compose this section.

Sec. 2. Flowers spikèd. Root fibrous. Calyx in fix deep segments, bearing the stamina at its base. Anthericum of Linnaeus, comprehended under Asphodelus by Tournefort; Phalangium of Tournefort, partly comprehended by Linnaeus under Anthericum (and very improperly named, as Phalangium is an embellished genus of insects); with Asphodelus, of Tournefort and Linnaeus, constitute this section.

Sec. 3. Flowers spikèd. Root bulbous. Calyx tubular at the base. Bajus of Jullieu, now univerally called Eucnemis; Hypacitus of Tournefort and Linnaeus, including Mufcari of the former; Phormium of Forster; and Muscaria of Thunberg. Lachenalia of Jacquin ought also, as Jullieu supposes, to be placed here, being very distinct from Phormium, though once confounded with it.

Sec. 4. Flowers spikèd. Root bulbous. Calyx in fix deep segments, bearing the stamina at its base. Cynella, Albica. Scilla, and Ornithogalum.

Sec. 5. Flowers umbellete. Root bulbous. Calyx in fix deep equal segments. Allium is here the only genus.

Mr. Brown declares, that he has in vain sought to establish a clear definition of this order, though a truly natural assemblage, whether confedered as an order by itself, or as a fection of the Liliaceae. (See Lilia.) He has not been able to detect any character common to all the plants, which is not found in several of their near allies, except the black, cruciferae, brittle skin of the seed, easily separable from its very thin proper membranous integument. Hence Mr. Brown has been led to place at the end of this family, Hypeoxis and Curculigo, as having a similar skin, though their germs is inferior; and for the same reason he removes Blundfordia from hence, not only on account of the hairy integument of its seed, but also because there is a difference in the burling of its capsule, to say nothing of other particulars. The same author notices a joint at the middle or summit of the flower-flanks, frequent in this family, and scarcely observable in the neighbouring orders, except in Sanseviera, and some of the Composita tribe. He is decided against separating the pulp-y fruited genera from the rest, either in this order, or the true Liliaceae. It is needless to point out, that what Jullieu and Brown term calyx in all these plants, is with Linnaeus and his school a corolla, and bears the latter appellation in Hort. Kew. The New Holland Asphodelae are thus arranged by Mr. Brown. Anthericum; Arthropodium, Br.; Chlorophyllum, Ker in Curt. Mag.; Cala, Tricoryne, and Styphandra, of Brown; Dionella, Lamarcè; Cordylina, Commerson; Alpharagis; Eurybaphus, Br.; Luxuriaga, Ruiz et Pavon Fl. Pern. Fl.; Thysanotus, Br.; Scouleria, Sm.; Lasmania, Br.; Borya, Labill. Nov. Holl.; Johnfania, Br.; and Xanthorrhiza, Sm. To which are subjoined genera intermediate between the Asphodelae and Amurralidæ; Hypeoxis; Curculigo; and Campynea, Labill. With Asfelia, intermediate between Asphodelae and Juneeae.

Aspidium, a genus of Filices (see that article), separated from the Linnæan Polypondium, on account of its being furnished with an involucrum, to each round dot, or mafs, of capsules, meaning a small shield, which is very descriptive of the shape of this involucrum. The propriety of subdividing the original Polypondium was doubtfully hinted by the writer of this article, in his Essay on the Genera of Doriforous Ferns, and Dr. Swartz adopted this measure. Mr. Brown has carried it ill further, by founding his genus Nephrodium; see that article and Polypondium. We need not here repeat our observations, already made in those places. We shall give a general view of Aspidium, according to our idea of this genus.—Swartz in Schrad. Journ. for 1800. v. 2. 29. Super Fil. 42. Sm. Fl. Brit. 1118. Wildl. Sp. Pl. v. 5. 211. Ait. Hort. Kew. v. 5. 507. Brown Prodr. Nov. Holl. v. 1. 147. Pursh 666. (Nephrodium; Michaux Boreal-Amér. v. 2. 266. Brown Prodr. Nov. Holl. v. 1. 148.)—Clafs and order, Cryptogamia Filices. Nat. Ord. Filices.

Gen. Ch. Capsules annulated, numerous, assembled in roundish masses, scattered over the back of the frond. Inflorescence roundish or kidney-shaped, with a lateral sinus, by which it is attached to the frond, at length becoming umbilicated, and more or less orbicular.
Frond simple. Two species in Swartz; three in Willdenow.

A. rodorum. Knotty Shield-fern. Wild. n. 1. (A. articulatum; Sprague Crypt. t. 27, copied from Pluk.)—Fronds simple, oblong, lanceolate, finely crenate and wavy, pointed. Dots scattered, solitary. Stalks jointed, scaly. Root creeping, chaffy and hairy. —Found by Plumier on trees in the forests of Martinico, no other botanist having, as far as we know, ever met with this species. Willdenow separates it from the fori being disposed in chain-like rows, and the frond having a thickened margin. Petiver's figure is copied from Plumier, as usual with the Feras of that author.

A. articulatum. Jointed Shield-fern. Swartz n. 1. Wild. n. 2. (Polypodium articulatum; Lamarrck Diet. v. 5. 514.)—Fronds simple, oblong-lanceolate, finely crenate and wavy, pointed. Dots scattered, solitary. Stalks jointed, scaly. Root creeping, chaffy and hairy. —Native of the Mauritius, on trunks of trees. We have one of Commeron's specimens. The fronds are a foot long, not thickened at the edges, but very unequally and minutely wavy, as if crenate; the fall of each not one inch in length, instead of two, or more, as in the foregoing. Sorus in a simple, slightly undulating row, on each side the mid-rib, not half way between it and the margin, rather small. Involucre perfect petalate, but more or less notched at one side, dark brown; pale and undulated at the circumference.

Frond terna. One species in Swartz; four in Willdenow.

A. trifoliatum. Three-leaved Variable Shield-fern. Sw. n. 3. Wild. n. 5. Ait. n. 1. (Schkuhr Crypt. t. 23.) (Polypodium trifoliatum; Linn. Sp. Pl. 1547. Jacq. Coll. v. 3. 185. 1c. Rar. t. 638. Petiv. Fil. n. 18. a. 7. f. 3. Hemionitis maxima trifolia; Plum. Amer. t. 32. Fil. 127. t. 148. Hemionitidis affinis filix major, trifida, auriculata, pinnis lactifinis finatis; Sloane Jam. v. 1. 85. t. 42.)

ß. Polypodium Pica; Linn. fil. Suppl. 446.

Frond smooth-edged; either simple, heart-shaped at the base, and three-lobed; or ternate, partly pinnatifid; the middle lobe or leaflet largest; lateral ones auricled at the base. —Native of groves and shady places in the West Indies. A rather large, very variable species, of a fine grada-green, thin and pliant; either simple, in three deep taper-pointed lobes, laterally lobed or auricled, in which state it is, as Swartz rightly judged, Polypodium Pica of the younger Linnaeus; or perfectly and simply ternate, like Plumer's figure, copied by Petiver, and Phuk. Phyt. t. 291. f. 33 or the leaflets three-lobed, finated, occasionally pinnatifid, as in the plates of Jacquin and Sloane. The fori are numerous and scattered. Involucrum perfectly petalate, separating equally all round, without any lins, or notch. The margins of the all the segments or leaflets are sometimes only undulated, but more frequently toothed, in a blunt irregular manner.

A. cicutarium. Hemlock Shield-fern. Swartz n. 46. Wild. n. 7. Pursh n. 1. (Polypodium cicutarium; Linn. Sp. Pl. 1549, excluding both the bynomyns of Pluknet, and inserting the following. Filix jamaicensis, five Polypondium Cicutarium latifoliae foetidiissime foliis quodammodi convenienet. &c.; Pluk. Almang. 153. f. 286. f. 4.)—Frond ternate: leaflets pinnatifid, pointed, with rounded, obtuse, entire segments; the lowermost segments greatly elongated and subdivided. —Native of mountains in Georgia and Virginia. The Linnaean specimens come from Dr. Patrick Browne, and answer well to Pluknet's t. 289. f. 4, whatever his t. 296. f. 2, cited by authors, may be. The fronds are a span high, thin, delicate and smooth, with fine interbranching angular veins. We have seen no fructification. Neither Willdenow nor Pursh appear to have examined any specimens.

Frond pinata. Forty-four species in Swartz; seventy-four in Willdenow.

A. punctatum. Sickle-leaved Japanese Shield-fern. Swartz n. 7. Wild. n. 13. (Polypodium falcatum; Thunb. Jap. 336. t. 36, not 35. Linn. Suppl. 446. Filix chevranse, laitoni lonchitis ferrato folio, avera parte ferniginis punctulis refertissimo; Pluk. Amalth. 93. t. 405. f. 1.)—Frond pinata: leaflets ovate, coriaceous, bluntly ferrated, pointed, curved upwards; oblique and unequal at the base; strongly veined beneath; the odd one somewhat three-lobed. Stalk falcate.—Gathered in large, elongated, and frequently three-lobed fronds, beneath which we have examined forty-four species. Twelve or fifteen inches high, rigid; rather glaucous beneath. Involucre perfectly petalate and orbicular, with a central boss. The upper side of each leaf is smooth and even; the under very curiously reticulated, with flout, prominent, chain-like veins, meeting, but not strictly interbranching with, each other.

A. punctulatum. Dotted-bordered Shield-fern. Swartz n. 21. Wild. n. 17. (Lingua cervina dentata, punctulis nigris notata; Plum. Fil. 98. t. 112.)—Frond pinata: leaflets uniform, linear-lanceolate, pointed, ferrated; with a marginal row of minute imprefions on the upper side; downy beneath.—Gathered by Plumer in Martinico. We have it from Jamaica. Willdenow moreover mentions Guiana, as the native country of this species. Each frond is five or six feet high. Common flatish round at the back, furrowed in front, light brown, not smooth, but clothed with fine, soft, narrow, rufly scales. Leaflets very numerous, alternate, four or five inches long and wide, one broad, slightly stalked, bright green, rather thin and pliant, rounded, and sometimes doubly, ferrated; finely downy at the back; broadly wedge-shaped, and occasionally slightly auricled at the base; their upper side smooth, each vein terminating near the margin in a blueish, withered, minute spot, the foot, as it appears, of the flowers; for a similar mark is found over every masse of capfuales; but these being situated in a simple row, at some distance from the margin, the spots which mark their infection are much further from the edge than the abortive spots. Plumer represents a row of such spots on the under side, at every ferrature. He is so supremely accurate, that we have sometimes doubted our plant being the fame as his, of which there is otherwise no appearance. Every thing which may lead to the discovery of the flowers of ferns is so interlingel, that we are here tempted to be more particular than usual. The masses of capfuales are large, prominent, of a bright tawny-brown, each with an almost perfectly circular and umbilicated involucrum. It seems to us a curious question, how the spots above-mentioned which are attended by fertile capfuales, in large convex feri, come to be arrested at a considerable distance from the edge of the leaf, while, without any difference in their size or appearance, the abortive ones are advanced almost to the base, or even the disk of each ferrature.

A. Lon.
ASPIDIUM.

A. Lonchitis. Rough Alpine Shield-fern. Swartz n. 5. Wildi. n. 25. Fl. Zeyl. n. 1. Engl. Bot. t. 797. (Polypodium Lonchitis; Linn. Sp. Pl. 1548. Fl. Dan. t. 497. Lonchitis alpea major; Ger. Em. 1140. Matth. Valgr. v. 2. 273. — Camer. Epit. 664.)—Frond pinnate, chaffy: leaflets sickle-shaped, declining, acute, with fringe-like ferratures; auricled at the upper angle of their base; wedge-like at the lower.—Native of the crevices of dry rocks in alpine or subalpine situations, throughout Europe. It has been found in Scotland and Wales, but scarcely we believe in England, though staved plants of *A. aculeatum* are occasionally taken for this species. The fronds are a span high, more or less, growing in tufts, erect, lanceolate, rather narrow, or linear. *Leaflets* numerous, crowded, dark green, about an inch long, the upper ones, about one-third of the whole, copiously fruтиfying; the rift barren; several of the lowermost gradually shortened, but not contracted in breadth. *Sori* in a simple row on each side of the rift, rather nearer to it than to the margin; pale; the *involutum* of each peltate and umbilicated, without any notch, completely on the margin.

A. acrophylleides. Crowded Shield-fern. Swartz n. 11. Wildi. n. 26. Purfii. n. 2. ("A. auriculatum; Schkuhr Crypt. 31. t. 30, excluding the synonyms." Wildi. Nephrodium acrophyllleides; Michaux Boreal.-Amer. v. 2. 267. Polypodium fronde pinnata lanceolata, foliosis humatitis, &c.; Gron. Vr. ed. 2. 167, excluding all the synonyms, except Clayton's.)—Frond pinnate, chaffy: leaflets sickle-shaped, acute, with fringe-like ferratures; auricled at the upper angle of their base: uppermost diminished, covered with confluent maffes of capules.—Native of rocks, in shady low places, from New England to Carolina, bearing capules in the summer. *Purfii.* This fern has long been cultivated in the more curious gardens of England, having been introduced, if we collect any, by Robert Barclay, et al. at Clapham. A taller plant than the last, and of a lighter green. The auricle of the uppermost *leaflets* sometimes becomes quite distinct and separate. The *sori* are found upon half, or one-third, of the upper leaflets, in a single or double row, at each side of the mid-rib, and are particularly crowded on the auricles. They become tumid as the *capules* ripen, and run into one mass, fladded, as it were, with the pale-brown *involution*, which are circular and peltate, though cloven at one side, the edges of the finus folding over each other. *Linnaeus* confounded this with *Asplenium ebenum*, as well as with his own *Polypodium auriculatum*, an East Indian species, hereafter described.

A. auriculatum. Auricled Shield-fern. Swartz n. 10. Wildi. n. 29. Aitn. n. 3? (Polypodium auriculatum; Linn. Sp. Pl. ed. 1. 1088. ed. 2. 1548. Felix zeylana, lonchitis facie; Burn. Zeyl. 98. t. 44. f. 2.)—Frond pinnate: leaflets lanceolate, falcate, ferrated, frilled; auricled at the upper angle of their base. *Maffes* of capules distinct, in simple rows.—Native of the rocky summits of mountains in Ceylon. *Keng. Brought to Kew garden, in 1793,* by admiral Bligh. *Aiton.* This species has no affinity or resemblance to the last, with which *Linnaeus*, and after him *Swartz*, confounded its synonyms and character. Even Willdenow, who corrected these errors, is mistaken in saying the *flask* is smooth. The *frond* is from fix to twelve inches high. *Stalk* flesy in front; roughish with minute points behind. *Leaflets* numerous, narrow, an inch and a quarter or an inch and a half long, tapering but not pointed, coriaceous, smooth, with fine, blunted, close, not fringed, ferratures; even above, frilled with transverse veins beneath; dilated at the base; the auricle broad, short, and bluntnish. *Sori* small, distinct, in an even row on each side the mid-rib of the *leaflet* and its auricle. We have not seen the *involution*. The ripe *capules* are inferted by fine capillary flasks into a convex knob. *Linnaeus* says in Fl. Zeyl. n. 383, where he originally defined his *Polypodium auriculatum*, that the plant is entirely smooth. The flaggins and flight rough arenches of the *flask* may therefore be variable. He there cites Plunetum, t. 30. f. 4: which is in no respect distinct from *Keng's* spects. Mr. M prezies gathered on the weft coat of North America a fern very like this, except that the ferratures are brilily, and the leaflets frilled. Its *flask* is very fea all the way up.

A. exaltatum. Lofty Shield-fern. Swartz n. 14. Wildi. n. 34: excluding the synonym of *Linnaeus*. Ait. n. 4. "Schkuhr Crypt. 33. t. 32, b." (Lonchitis glabra minor; Plun. Amer. 19. t. 28. Fil. 48. t. 63. *L. altifrons*, pinnis utrinque, feu ex utroque latere, auriculatis; Sloane Jam. v. 1. 77. t. 31.)—Frond pinnate: leaflets lanceolate, ferrated; with a row of minute white impressions on the upper side, towards the margin; unequally baltate at the base. Maffes of capules in a simple row, towards the margin. Stalk even, slightly fea.—Native of Jamaica, and other parts of the West Indies. Brought to the *flowers* at Kew, by admiral Bligh, in 1793. The *fronds* are usually three or four feet high, erect, straight, narrow, with a polished, pale-brown *flask* and mid-rib, occasionally somewhat fagggy. *Leaflets* numerous, parallel, close, nearly ftraight, two inches long at most, very smooth; rather rounded at the point, their shallow, blunt, unfringed ferratures most abundant in their upper half; the base dilated into two short broad *auricles*, defluifet of fruтиfication, of which the lower one is shorted, and most rounded. *Sori* numerous, disfrined, rather large. *Involution* not perfectly orbicular, nor finitely peltate, having a deep finus at the side towards the base of the leaflet, so as to resembfe a horfe-shoe. This fern is very frined from our *Davallia falcata*, though Dr. *Swartz* fupperfed the contrary. *Linnaeus* confounded its synonims with the following. The row of minute withermed specks, as far as we can see, only accompany the *sori*, there being, in our specimens, no barren ones as in *A. punctatum*.

A. blechnoides. Long-leaved Shield-fern. (Polypodium exaltatum; Linn. Syft. Nat. ed. 10. v. 2. 1326. Sp. Pl. ed. 2. 1549; excluding the synonyms, and substituting the following. Felix minor, in pinias tantum divisa, crebras non cennatas, inferiore laterae auriculata, et rotundis pulvulentis areolas avera parte notatas; Sloane Jam. v. 1. 86. t. 44. f. 1.)—Frond pinnate: leaflets linear-lanceolate, elongated, entire, with a rounded incured auricle at the base on the lower side, and a flight dilation on the upper. Maffes of capules in a double row.—Native of Jamaica, on the sides of hills. *Linnaeus* received his specimen in Browne's herbarium, with an erroneous reference to Sloane's t. 31, which belongs to our last-described. Hence there has always been a confusion respecting these two ferns, which even Dr. *Swartz* could not reconcile; see his Syn. Ficulum, 65, where he cites Sloane's t. 44, but ought to have added fig. 1; as fig. 2. is *Blechnum occidentalis*. The specific name of *Polypodium exaltatum*, being taken from Plumer's and Sloane's accounts of the foregoing, and that being universally received as *Aspidium exaltatum*, we have not changed its denomination. That name is not at all applicable to the species before us, which is more expressly called *blechnoides*. Its height is only eighteen or twenty inches. *Leaflets* from four to six inches long, taper-pointed; the lower auricle of each overlapping the main *flask*, and hooked.
hooked or curved in a curious manner, not well expressed in Sloane's plate. Sori in double rows close to the mid-rib at each side. *Involucrum* perfectly peltate, orbicular, and entire.

Sect. 4. erroneously marked 3 by Willdenow, as is often the case in other parts of his work. *Frand pinnae: leaves pinnatifid, *Involucrum* rounded, or kidney-shaped. Thirty-four species in Willdenow. Swartz does not separate this fection from the following.

A. Hippocrepis. Horse-shoe Shield-fern, *Swartz* n. 45. Willd. n. 46. (Polypodium Hippocrepis; Jacc. Col. v. 3. 186.) Ic. Rar. t. 64t. Hemionitis lacinis crispa incita; Plum. Fil. 119. t. 150. Petiv. Fil. t. 7. f. 7.)—Frand pinnae: leaves oblong, sinuated; the upper ones confluent and decurrent; lowermost flatked, pinnatifid; segments obtuse, somewhat crenate; veins downy. *Involucrum* crezenet-shaped. Native of South America, and of Hiftaniacs, from whence our specimen was brought by M. Thierry de Menonville. Jacquin had living plants of this rare fern from Venezuela, and cultivated it at Vienna. The fronds are eight inches or two feet high, tufted, of a fine green, more or less downy, especially about the ribs and veins: their *leaffits* sinuated in the manner of some species of oak; the segments also sinuated, wavy, or crenate. Sori chiefly ranged on each side of the mid-rib of the segments, but not being uniformly perfected, they appear irregularly scattered. *Involucrum* like a horse-shoe, to which the specific name applies.

A. unium. United Shield-fern, *Swartz* n. 47. Willd. n. 57. Ait. n. 5. Schkuhr Crypt. 34. t. 33. b. (Polypodium unitium; Linn. Sp. Pl. 15.48; omitting the synonyms of Sloane and Pluckenet. Felix pyramidalis madraptana elegans, pinnalis ferratis; Pet. Muf. 10. n. 55. t. 1. F. zeylanica denticulata, non ramosa; Burm. Zeyl. 98. t. 44. f. 1.)—Frand pinnae: leaffets linear, pinnatifid; their very numerous segments ovate, acute, combined, hairy beneath. Stalk downy in the leafy part. *Involucrum* nearly circular, with a deep notch. Native of Transkeab and Ceylon. Frond two feet, or more, in height: Smooth and nearly naked in its lower half, except a few dimift small leaffets: finely downy and rufly in the upper half, and crowded with feftile, narrow, acute, linear leaffets from three to five inches long. These are composed of immeasurable little convex Segments, a quarter of an inch in length; smooth and veiny above; ribbed and downy beneath; appearing as if deeply separted, but their edges are firmly united for one-half or three-quarters of their length. Near the margins of these segments are simple rows of smooth horse-shoe like *involucrum*, covering numerous capsifidis with glittering brown rings.

A. obfutum. Blunted Shield-fern, *Swartz* n. 30. defcr. 248. Willd. n. 58. (Pteris interrupta; Willd. Phyto(tr. 13. t. 10. f. 1.)—Frand pinnae: leaffets linear, pointed, slightly pinnatifid; segments obtuse, downy beneath. Stalk smooth. *Fructification* near the margin. Native of the East Indies. Very like the last, but the leaffets are more pointed, rather crenate than pinnatifid, and the rows of *fori* so near the margin that Willdenow actually took the plant for a *Pteris*.

Vol. XXXIX.

with refrinous glands beneath. *Fructification* near the margin, confluent. — Mountainous heathy ground, and dry woods, in various parts of Europe, from Denmark to Italy, produce this fern, bearing capsules in July. Our British botanists long overlooked it, as a variety of the common Felix mas, whilst others mislooked it for *Thelypterus*. The refrinous dots at the back of the frond exhale a fragrant fmmell, more or less perceptible at different times; which induces a suspicion that this species may have been taken by Mr. Hudson for *Polypodium fragans* of Linnaeus, never found in our island. In fize the present species vies with *A. Felix mas*, hereafter to be described, but the whole *frond* is rather narrower. The segments of the leaffets usually quite entire, are occasionally somewhat crenate about their rounded obtuse points. Sori crowded, in a simple row near the margin, at length confluent, forming a beaded line. *Involucrum* fmall and thin, umbilicated, with a deep lateral fissus, and soon vanishing. *Root* large, scaly, tufted, not creeping.

A. Thelypteris. Marhi Shield-fern. *Swartz* n. 35. Willd. n. 74. Fl. Brit. n. 10. Engl. Bot. t. 1618. Pursh n. 4. "Schkuhr Crypt. 51. t. 52." (Polypodium Thelypteris; Linn. Mant. 505. Fl. Dan. t. 765. Aeroch- nium Thelypteris; Linn. Sp. Pl. 1528. Bolt. Fil. 76. t. 43. 44. Thelypteris non ramosa; Schmidel 15. t. 11. Felix tenuefimul et profundis denticulata Montbelgardica; Bauh. Hift. v. 3. 731. good. F. palnttis repens,摈inus non dentatis; Morif. flct. 14. t. 4. f. 17. 1.)—Frand pinnae: leaffets lanceolate, pinnatifid, somewhat crenate; dif tinét, but crofuing each other, at the base. *Fructification* scattered, confluent. *Root* thread-shaped, creeping. Native of rotten bogs, and turfy marshes on a fandy foil, in various parts of the north of Europe, as well as in North America. Mr. Pursh fays the *fructification* is very rare in the latter country; with us it is but sparingly produced, the plant increasing moll by the roots, which are long, fleaner, and creeping. The fronds are not half the fize of the leaf, and much more delicate; their height about a foot, their colour bright grafs-green. *Leaffets* generally smooth; almes a little hairy; the lower fode of each extended, as to fold over the oppofite one. *Fructification*, if prefent, abundant, confluent, blackifh.

A. criftatum. Leaffets Crested Shield-fern. *Swartz* n. 49. Willd. n. 79. Snc Compdenb. Fl. Brit. 10. Engl. Bot. t. 2125 not 1949. Pursh n. 5. "Schkuhr Crypt. 39. t. 37." (Polypodium criftatum; Linn. Sp. Pl. 1551. Aizel. in Stockh. Trans. for 1787. 248. t. 9. P. Calippiteris; Ehrh. Crypt. n. 53.)—Frand pinnae, nearly hipinnae; segments ovate, obtuse, crenate or pinnatifid, with sharp little terminal teeth. Stalk fcaly at the base. *Involucrum* nearly orbicular, with a deep notch. Native of Sweden, Germany, and England, as well as North America, in low boggy woods and thickets. Found by the Rev. R. B. Francis, on the heath between Holf and Hemp- fhead, Norfolk. The root is tufted, as in *A. Oreopecris*, not creeping like that of *Thelypteris*, and the whole habit and texture of the fern more resembles the frift of these two species. Fronds pale green, from one to two feet high; the fertile ones remarkably ereét; their barren leaffets shorter and rather more diftant, than thofe which bear *fructification*, the latter compofing the upper half of the frond; all are very deeply pinnatifid, fometines to the very rib; their segments, or partial leaffets, close, broad, obtufe, with sharp, fearley pinnus, teeth. Rhis fomewhat zigzag. Capsifidis blackifh when fresh, with a white circular *involucrum* to each aflamble, having a deep fissus at the lower side; but the Y y

Y y dried
dried foci are tawny. Common stalk of the frond chiefly scaly at the base. Mr. Pursh considers Willdenow's lanceafringe, n. 97, as a variety of this.

A. fragrans. Fragrant Shield-fern. Swartz n. 42. Willd. n. 80. (Polypodium fragrans; Linn. Sp. Pl. 1550. Dryopteris rubrum idizum spirans; Amman. Rath. 174. n. 251.)—Frond pinnate; leaflets lanceolate, crowded, deeply pinnatifid; segments elliptic-oblong, bluntly and deeply toothed; flasks and mid-ribs scaly. Fructification crowded. Involuture nearly orbicular, with a deep notch.—Native of hilly situations in Siberia, near the rivers Angara and Selenga. The inhabitants are said to boil this fern with their beer, in order to give that liquor the taste and smell of Raspberries, which is so powerful in the plant, that even in a dried state its odour fills the room where it is kept. The root is tufted, very scaly. Fronds several, a span high, lanceolate, tapering at each end, the lower leaflets being gradually more shortened. Small short, bearing large, rounded, lax scales; those on the leafy part, as well as on the mid-rib of each leaflet, being lanceolate and acute. The upper side of the leaflets is perfectly smooth; their lobes and indentations peculiarly elegant, without any terminal bristles. Sorus fo crowded about the lower half of each leaflet, that their expanded involucrum sometimes touch, or fold over each other, being moreover intermixed with rufy membranous scales.

Sec. 5, marked 4 by Willdenow. Frond doubly or triply pinnate. Involuture rounded or kidney-shaped. Forty species in Willdenow. The involucrum in this, as well as the preceding species, though, for the most part, laterally indented, is often nearly or completely orbicular, and it is even flicitly peltate in A. aculeatum and lebatum. Some of Prof. Willdenow’s species, adopted from Plummer’s plates only, appear to us fearely certain in genus,—such are A. nemorifum, Willd. n. 83, voluem, n. 84, and fynamaturn, n. 87.

A. aculeatum. Common Prickly Shield-fern. Swartz n. 53. Willd. n. 92. Brit. Fl. n. 5. Engl. Bot. t. 1562. Pursh n. 7. " Schkuhr Crypt. 41. t. 39." (Polypodium aculeatum; Linn. Sp. Pl. 1552. Willd. Illufr. t. 101. Bot. Fil. 48. t. 26.)—Frond doubly pinnate; leaflets ovate, somewhat falcate, flalked, with prickly ferratures; hairy beneath. Common flalks and ribs falky. Involuture peltate, entire.—Found in shady woods and hollows, throughout Europe, as well as in Africa, and North America, bearing feed in summer and autumn. The root is large and tufted, producing numerous dark-green fronds, usually two or three feet high, spreading in a circular manner, varying much in size; paler beneath; their general and partial flalks remarkably falky. Partial leaflets about a quarter of an inch long, rigid or coriaceous, each tapering down into a small fhort footstalk; their pinnas and ferratures each tipped with a little fpinous bristle; their upper edge at the base dilated, more or less, in a broadbif fhoulder. Sorus plentiful on the upper part of the frond, but in fingle rows, and dilatet, brown. Involutum pales brown, orbicular, peltate, at length deeply umbilicated, quite entire all round, as in A. Lonchitis, to which this species and the following are closely allied, though all three are very diffent.

The late Mr. Rob. Teasedale, (see Teesdalea,) found in many parts of England, a variety of this, which he suspected might prove a distinct species. It is fottet, and more delicate in texture, than the common kind, with smaller, more numerous, partial leaflets, which are more remarkably flalked, and their auricles are larger, broader, and different in aspect. This lay in Mr. Rofe’s herbarium for A. lebatum, which it certainly is not, the partial leaflets being even less decurrent than in our common aculeatum. It may probably be the variety B. of Fl. Brit. figured in Philenect, t. 180. f. 1, which figures represents well enough the general appearance of the frond, and shape of the leaflets; but their partial flalks are much more considerable and evident than they appear in that plate. A. aculeatum, if transplanted into a dry open situation, soon diminishes greatly in size, so as to resemble A. Lonchitis, for which we once received it; but these species are nevertheless essentially different, as any careful investigator will find.

A. lebatum. Clefe-leafed Prickly Shield-fern. Swartz n. 53. Willd. n. 95. Brit. Fl. n. 6. Engl. Bot. t. 1563. (Polypodium lebatum; Hudf. 450. Felix aculeata major, pinnaulis auriculatis cerebroribus, folis integris anguiiuribus; Raii Syn. 121. F. aculeata, Lonchitis fumula notfars; Pluk. Phyt. t. 180. f. 3.)—Frond doubly pinnate; leaflets elliptical, somewhat falcate, decurate, with prickly ferratures; hairy beneath; the forefoot of the lowest pair very large. Common flalks and ribs falky. Involuture peltate, entire.—Found in shady places, under hedges, in England; not unfrequent in the county of Eifex, where Fryr ffrif noticed this species, and from whence Mr. Edward Forster has fent us specimens. The Rev. Mr. Francis has met with it at Edgefield, near Holt, Norfolk. There is no record of this fern being found out of Britain. The fronds are always of a narrower, more linear, form than the last, and generally altogether smaller, as well as more rigid, of a paler more thining green. Leaflets rather elliptical than ovate, and Mr. Dawen Turner has well observed that they are decurrent, not flalked, which is perhaps one of the most certain means of distinguishing this species from A. aculeatum. The moft striking character, indicated by the specific name, conffits in the great size, and angular-lobed figure, of the lowest partial leaflet, on the upper side of each general leaflet or pinna, close to the main flalk, often extending beyond the pinna above it. The upper half of the frond, principally, is covered with fructification. The involucrum is perfectly peltate, entire; finally umbilicated.

A. marginale. Marginal-flowering Shield-fern. Swartz n. 41. Willd. n. 93. Ait. n. 11. Pursh n. 8. " Schkuhr Crypt. 195. t. 45. b." (Polypodium marginale; Linn. Sp. Pl. 1522. Nephrophorum marginale; Michelau Boreal.-Amer. v. 2. 267.)—Frond doubly pinnate; leaflets oblong, obtuse, decurrent, almost pinnatifid at the base. Maffes of capsules marginal. Involutum orbicular, with a lateral sinuos.—In rocky shady places, from Canada to Carolina, bearing capsules in July. This species has often been fuppofed a native of Britain, A. Oeopteris, whose fructification is likewise marginal, having been taken for it; but the American plant is very diffent, more resembing Felix mas than any other. The marginale however is a smaller plant, the upper half of whote frond only bears fructification, and the leaflets are bluntly crenate, instead of being sharply ferrated. They are moreover not uniform, as in Felix mas, but the lower ones of each pinna are larger and more or less pinnatifid. Involutum tumid, corrugated, forming a complete circle, though not peltate.

ASPIDIUM.

fleshy, sharply ferrated without prickles, uniform. Malees of capsules crowded towards the rib and base of each leaflet. Involucrum orbicular, with a lateral sinus.—Very common throughout Europe, as well as in the northern parts of Asia, Africa, and America, in shady situations, under dry banks, bearing feed about July and August. The root is tufted and scaly, often very large. Fronds numerous, bright green, about a yard high, and a foot wide, their leaflets and principal rib scaly; the rib of each leaflet is sometimes a little hairy, and slightly bordered, though the partial leaflets are scarcely decurrent, except the uppermost. The frutification is abundant over great part of the frond, of a rich tawny-brown, crowded, not confluent. Involucrum tumid, umbilicated, with a lateral notch, which is rather more open than in A. marginale, but not quite so deep. The root is a celebrated cure for internal worms, in Switzerland and other parts of the continent; and its nauseous taste may, as we understand, be detected in one or more of the popular quack medicines, which in this country obtain credit by piling advertisements, whose truth it is easier to believe than to examine. Happy if they are never composed of more dangerous materials than the root of the Male Fern!

A. spinuliferum. Letter Crested Shield-fern. Fl. Brit. n. 8. Engl. Bot. t. 1462. Swartz n. 58. Willd. n. 99. Pursh n. 117; "Schkuhr Crypt. 48. t. 48." (Polypodium spinuliferum; Retz. Prod. 250. Fl. Dan. t. 707. P. n. 841; Mull. Freid. 193. t. 2. f. 2.) Felix patula laxitatis altera; Pluk. Phyt. t. 179. f. 5. —Frond doubly pinnate: leaflets deciduous, elliptical, confluent, with deep-cut prickly ferratures. Mid-rib smoothen. Nerves zigzag. Involucrum orbicular, with a lateral sinus.—Native of boggy shady places, in various parts of Europe, as well as in North America, if Mr. Pursh be right; but he speaks of his plant as "a large species;" ours is certainly rather small, not above a foot high. The root is creeping. Frond broad, with a long stalk, which is scaly in the lower part only. Partial leaflets elliptic-oblong, of an elegant bright pellicul green, with wavy ribs; deciduous, so as to form a border to the partial stalk. Dots of capsules small, and rather distant. Involucrum small, soon pushed to one side. We fee nothing in it of a glanular nature, as mentioned by Willdenow.

A. dilatatum. Great Crested Shield-fern. Fl. Brit. n. 9. Engl. Bot. t. 1465. Willd. n. 100. Pursh n. 12. (Polypodium dilatatum; Hoffm. Germ. v. 2. 7. P. arifatium; Villars Dauph. v. 3. 844. Bellardi in Act. Taurin. v. 5. 255. P. cristaflata; Ehrh. Crypt. 81. Hud. 457. Bot. Fl. 42. t. 23. P. n. 845; Mull. Fl. Freid. 193. t. 2. f. 4.) Felix mas ramosa, pinnulis dentatis; Rallii Syn. 124. Pluk. Phyt. t. 181. f. 2. F. mas, pinnulis cristaatis; Morif. sect. 14. t. 3. f. 11.) —Frond doubly pinnate: leaflets deep pinnatifid, sharply cut, with prickly teeth and ferratures. Stalk and branches scaly. Involucrum kidney-shaped, foon orbicular, with a lateral sinus.—Native of shady watery places, sometimes on dry banks, in a sandy or gravelly soil, or in rocky moit woods, throughout Europe. Mr. Pursh met with this species in the sandy rocky woods of Pennsylvania and Virginia. The root is tuberous or tufted, fearemly creeping. Fronds generally two feet, or more, in height, though sometimes much smaller. Their broad, much compound, form and structure, and their bright-green colour, give them a very handsome aspect. They are often tripinately pinnate, or at leaft their ultimate subdivisions are so deeply sep-rated as to cause that appearance: these are pretty uniform, with deep, sharp, prickly-toothed ferratures and points. Stalks, ribs, and veins, a little downy, or glandular; none of them zigzag, or at most very lightly so. Shrillification copious all over the frond, rather crowded, not confluent, of a bright brown. Involucrum at first kidney-shaped, tumid, but soon becoming orbicular, the sinus closely closing, retaining only an umbilicated depression, and at length the membrane remains folded together vertically, in the centre of the mafs of capsules.

Sect. 5, marked 5 by Willdenow. Frond either doubly pinnate, or doubly or tripinately. Involucrum lateral. Twenty-six species in Willdenow: nineteen in Swartz. These are perhaps most entitled to constitute a distinct genus, but in several instances they too nearly approach the last section to admit of a clear generic definition.

A. fontanum. Smooth Rock Shield-fern. Swartz n. 74. Wildl. n. 122. Engl. Bot. t. 2024. (Polypodium fontanum; Linn. Sp. Pl. 1550; Fl. Brit. 1114. Hud. 456. Villars Dauph. v. 3. 849. P. n. 1706; Hall. Hift. v. 3. 15. Adiantum filicium duris cilium minimum; Barc. l. 175. f. 1.) Filicula faxatilis, omnium minima, elegantifima; Tourn. Init. 542. Pluk. Phyt. t. 89. f. 3. —Frond linear-lanceolate, smoothen, simply or doubly pinnate: leaflets alternate, rounded, their segments very sharply toothed. Stalks winged. Involucrum oblong.—Native of rocks in England, France, Switzerland, and other parts of Europe, but very rare in this country. Mr. Hudson, and the late Mr. Atton, to our certain knowledge, have gathered it on Amherst church, Buckinghamshire, where it is no longer, as we are told, to be met with. Limnæus confounded this fern with what is now named Woodia hyperboracea (see that article); nor has it been well understood by botanists in general, in being rare occurrence, obscure in its generic character, and very variable in luxuriance. This may be seen by comparing Plukett’s figure above cited, fig. 3, with his fig. 2, quoted by Willdenow, after Fl. Brit. With left is we believe the same plant, but not under its usual and most natural appearance. When once seen in perfection, this truly elegant little fern can be confounded with no other. The root is tufted. Fronds from two to six inches high, rigid, smoothen, rather glaucous, of a narrow lanceolate figure, composed of numerous, alternate, pinnate or pinna-tud leaflets, whole partial leaflets, or lobes, are wedge-shaped, somewhat italked, with deep, very sharp, in some degree fiumous, teeth, and all the flarks are winged. Malees of capsules at the mid-rib of each lobe, round, or nearly fo, with a delicate white involucrum originating from the rib, by a straight lateral infection, and separating inwards, that is, towards some other more principal rib, not towards the margin. Perhaps this plant is truly an Asplenium. Professor Willdenow has an A. Halleri, n. 125, which he confiders abundantly different from fontanum, but to which he refers some of our above-mentioned synonyms. We have Haller’s plant from Switzerland, and are perfectly certain of its being the same as our fontanum, though we have not the means of verifying all Willdenow’s synonyms.

This writer, whose labours respecting Ficites will ever do his memory great honour, notwithstanding errors unavoidable incident to fo difficult an enterprise, has, after the example of Swartz, associated with this tribe some species which we refer to Cyathia. (See that article, written by the late Rev. Mr. Wood.) These are, C. dentata, fragilis, and regius of Fl. Brit. and Engl. Bot. there being also several exotic species in the same predicament. Some of them come very near A. fontanum, just described, in the character of their involucrum, but they ill accord with the rest of this genus. A few species, now to be mentioned, perhaps connect them therewith. We shall select such as are most likely to elucidate the subject.
A. bulbiferum. Bulbiferous Shield-fern. Swartz n. 52. Wild. n. 326. Art. n. 10. Purfl n. 13. "Schkuhr Crypt. 55. t. 57." (Nephrodium bulbiferum; Michaux Boréal.-Amer. v. 2. 266. Filix baccafera; Cornut. Canad. v. 4. Barrel. l. c. t. 1120. Morif. fett. l. c. t. 3. f. 10.)—Fronc doubly pinenate: leaflets ovate, obtuse, pinnatifid or deeply ferrated; upper ones connate. Ribc bulbiferous.—Found in shady woods, among rocks, from Canada to Pennsylvania. Purfl. The frond is about eighteen inches high, narrow, bright-green, smooth, delicately cut; partial leaflets half an inch long at most, decurrent. Maffes of capfules mostly lacerated, small, round. The involucrum seems concave, almost hemispherical, turning to one side; but our specimens are not sufficient to ascertain its exact figure. Several of the secondary ribs bear fleesy bulbs, which fall off and become young plants, of which there are instances in Woodwardia, (see that article,) and some other ferns.

A. Filix foerina. Female Shield-fern. Swartz n. 83. Wild. n. 128. Fl. Brit. n. 7. Engl. Bot. t. 1459. "Schkuhr Crypt. 56. t. 58, 59." (Polypodium Filix forina; Linn. Sp. Pl. 1551.)—Bol. Fl. 46. t. 25, Filix mas non ramafa, pinnaufs angulis raris, profunde dentatis; Raff Syn. 81. 45, Pluk. Phyt. t. 180. f. 4. Morif. fett. l. c. f. 8.)—Fronc doubly pininate: leaflets pinnatifid, ferrated, pointed, oblong-lanceolate. Stalk smooth. Dots oblong. Involucrum somewhat kidney-shaped.—A common fern throughout Europe, in unhilly shady places, varying greatly in dimensions, but of a broadish-oblong figure, from one to two feet high, of a fine dark green, and very smooth. Stalk slender, pale, smooth, somewhat angular. Leaflets innumerable, tolerably uniform, delicately cut, bluntish, without any terminal bristles. Maffes of capfules covering the frond, one upon each segment of the leaflets, infected laterally into its minute mid-rib, oblong, the capfules dark brown. Involutum separating towards some larger adjoining rib, oblong, white, jagged or fringed, sometimes quite straight at the interference, sometimes kidney-shaped, but always finally assuming the latter form, as the capfules advance and cause it to turn back.

A. alpinum. Fine-cut Alpine Shield-fern. Swartz n. 89. Wild. n. 179. "Schkuhr Crypt. 60. t. 63, 6 b." (Polypodium alpinum; Jacq. Coll. v. 2. 171. Ic. Rar. t. 612. P. n. 1709; Hall. Hist. v. 3. 15. Filicula alpina cripta; Baut. Pin. 278. Segu. Veron. suppl. 55. t. 1. f. 3. Morif. fett. 14. t. 4. f. 27. Felle crepso tafatine; Pon. Bald. 224, with a figure.)—Fronc triply pinnate: leaflets linear-wedge-shaped, pinnatifid, connate; their segments linear, obtuse, emarginate.—Found on the alpine rocks of Carninha, Switzerland, France, and the north of Italy. A very slender delicate fern, from six to ten inches high, smooth, bright green, sometimes assuming a tawny hue. The frond is linear-lanceolate, the ultimate segments peculiarly narrow and linear, alternate, sharply cloven at the end, but otherwise entire; tapering down into the linear bordered stalk, quite smooth and naked, fiddle-ribbed. Every segment bears one small round mass composed of a very few capfules, rather large in proportion, each having a shining ring. The involucrum is very thin, white, and membranous, represented by Wulffen and Jacquin as perfectly peltate, without any notch, and attached by a fine central thread. This would make the plant a most indubitable Aspidium. But in our specimens, from Jacquin himself, the involucrum, turned aside by the ripe capfules, remains in the form of a thin concave or vauded scale, or scales, attached laterally beneath them, as in some of our British Cyrtens, without any peltate appearance. Unfortunately we have no fructification in a sufficiently early state to verify Wulffen's description or Jacquin's figure. We rely on Seguer and Haller for Pona's, and consequently Morifon's, synonym, though the figure suggests some idea of Cibetinches faucolona of Swartz and Willdenow, which Pona's account of the blackish or dark-coloured hue of the root, and upper part of the frond, rather conforms. Seguer's plant, though deficient of fructification, is sufficiently accurate, and cannot be disputed.

A. montanum. Chervil Shield-fern. Swartz n. 91. Wild. n. 147. "Schkuhr Crypt. 61. t. 63." (Polypodium montanum; Lamarc. Franc. v. 1. 23. Allion. Pedem. v. 2. 287. Hancke in Jacq. Coll. v. 2. 46. P. myrrhifolium; Villars Danp. v. 3. 811. t. 53, including Plukken's fynonym. P. n. 1710; Hall. Hist. v. 2. 16.)—Fronc ternate, pentagonal, triply pinnate: segments elliptic-oblong, obtuse, slightly toothed at the end, decurrent.—Native of the mountains of Aufriza, the Tyrol, Switzerland, Italy, and France. The name given by Villars is infinitely preferable to the unmeaning one which this elegant species has been suffered to retain. It differs from all we have hitherto described of this section, in the pentagonal outline of the frond. The colour is a light green. Ultimate leaflets, or segments, not linear, but rather elliptical, very small and delicate. Sori solitary on each segment or lobe, small, globose, of rather numerous brown capfules, entirely covered, while young, with a white, pellucid, hemipeltical involucrum, which turns gradually back, remaining attached, at one side, under the capfules, like half the cup of a true Cyrtens.

A. odoratum. Scented Shield-fern. Wild. n. 146.—"Fronc ternate, doubly pinnate: leaflets oblong, obtuse, hairy, deeply ferrated; ferratures blunt, with two teeth. Root chaffy."—Gathered by M. Bory de St. Vincent, on rocks in the isle of Mauritius. Root as thick as the thumb, springing from the fissues of rocks, denfely clothed with brown, oblong-lanceolate, very long-pointed, entire, brown, chaffy scales, half an inch in length. Stalk three or four inches long, smooth. Ribs hairy. Branches of the frond four or five inches long. Leaflets linear, oblong, obtuse, clothed on both sides with short hairs; their lower ferratures mostly with four teeth. Willdenow. The composition of the frond seems to agree with the last, as being ternate, a character we have not observed in any others. This frustre gives the whole a pentagonal shape, very different from the oblong or lanceolate figure of the greater part of this genus.

ASSIUT, in Geography. See STOUT.

ASTELIA, in Botany, a name originally given by Dr Joseph Banks and Dr. Solander, formed from a, against, and elia, a little pillar, because of the want of a style, which distinguishes this genus from several of its natural allies.
AST

Gen. Ch. Cat. none, unless the corolla be so called. Cor. of one petal, in fix deep, equal, ovate, half-membranous, permanent segments. Stam. Filaments fix., awl-shaped, along the length of each segment, and inferted into its base; anthers roundish, of two lobes. Pijü. Gernen superior, ovate, pointed; styles none; filigmas three, obtuse. Peric. Berry ovate, more or less perfectly three-celled. Seeds numerous, elliptic-oblong, somewhat triangular, polished. Receptacle three, attached longitudinally to the coat of the berry. Some flowers have imperfect flaments, and others, on a separate plant, an imperfect pistil.

The habit of the plants of this genus resembles *Tillandsia*, (see that article,) and they in like manner sometimes grow on the living or dead trunks of trees. The roots are fibrous. Radical leaves imbricated in three rows, either linear-lanceolate, or frowd-shaped, keeled, furnish, on one or both sides, with clofe, comprefsed, fagggy hairs; their base with fmyk wool. Stem very short or none, with few leaves. Flowers fmall, fmyk externally, racemose, or paniculured, rarely almost foltary; their partial fls without a joint, and having each a foltary bract at its base.

Mr. Brown finks *Aftelio* not nearly allied to any other genus, though somewhat approaching *Tillandsia*. The New Zealand plants, upon which Sir Joseph Banks and Dr. Solander founded this genus, differ from the foltary species which grows in Van Diemen’s ifland, in having a berry of three cells: two species moreover have a pitchet-shaped fix-cleft calyx, (corolla, as we term it,) which in another is pulpy. Should the genus therefore be divided? *Melan-thium pamum* (fee that article n. 9.) appears to be an *Aftelio*. Brown.

The learned author defines one species only.

A. *alpina*. Alpine *Aftelio*. Br. n. 1.—“Leaves flatth, fmyk on both fides. Clutter divided in the lower part; its branches bearing few flowers. Berries oval, fingle-celled. Flowers with fix deep segments.”—Gathered by Mr. Brown, on mountains in the ifland of Van Diemen.

To this we are enabled to add the following.

A. *Menzisifium*. Many-flowered *Aftelio*. —Leaves flatth; fmyk beneath. Stalk fagggy. Clutters panicled, many-flowered. Berry ovate, three-celled. Flowers in fix deep segments.—Gathered in the Sandwich iflands, by Mr. Menzies, to whom we are obliged for a fpecimen. The leaves are all nearly, or quite, radical, eighteen inches long, a half or three-quarters of an inch broad, taper-pointed, entire, frongly ribbed; smooth and green above; pale, and fmyk with fhinning clofe hairs, beneath. Stalk foltary, nearly as tall as the leaves, round, defeny fcloathed with pale, fagggy, fhinning wool; fmpie below; panicled at the top, with many hairy clutters, each two or three inches long. Segments of the corolla hairy at the back. Berries the fize of a currant, pointed, each containing feveral large, black, fhinning fets.

To these are to be added the New Zealand species, not yet published, which, by Mr. Brown’s remarks, appear to be at least three in number; and probably the above-mentioned *Melan-thium*.

Perennial, generally twining, plants, of southern Africa, with opposite leaves. Umbels lateral, between the footstalks. Flowers fmall.

This genus is founded on *Apocynum triflorum* and *lacera*, Linn. Suppl. 169, with two new species in the Bankian collection. *A. cordatum* and *lanceolatum*, Thumb. Prodr. 47, probably belong to it. The character is also modified so as to admit a very remarkable plant, found by Mr. Maffon in the fame country, whose *fem* is shrubby, with fpinefcent branches; leaves extremely minute, oppofite, diftant, and heart-shaped. *Corolla* rather urceolate than bell-shaped; the orifice of the tube furnishcd with defixed hairs. Maffes of pollen fixed by their tapering summits. *Stigma* blunt. *Pallides* nearly cylindrical, fmooh. The whole genus differs from *Microlofa* chiefly in the want of fcales within the tube. Mr. Brown finks they might be united, but this would lead to the junetion also of *Metafelmia*, which being of Weft India origin, he was unwilling to join it with Cape plants. We fhoild have thought the faff objection might have been overruled by fo near an agreement of character. See the two articles in question.

ASTERABAD, in Geography, a small province of the Perifian empire, sometimes included in Mazanderan, which it refembles in appearance, climate, and productions. It is the ancient Hyrcania; bounded on the W. by the Caffian fea; on the S. feparated by a lofty ridge of mountains from the diftricts of Damgan and Biftan; extending to the E. as far as longitude *58°*, and divided from Dafeftan by the river Afor. The capital of the fame name is fettled near the mouth of the river Afor, on a bay of the Caffian fea. E. of the capital, in which much treafure is faid to be defpoted, and 25 furlongs from Biftan, is the town of Jorjan, the ancient Hurkaun, from which the name Hyrcania may probably be derived. See ASTERABAD.

Gen. Ch. Cal. Perianth inferior, permanent, double; inner of five elliptic-lanceolate, acute, equal, erect leaves; outer of four or more, much shorter, concave, imbricated fcales. Cor. of one petal, tubular; tube twice the length of the calyx, infurted, furnished on the infide, near the base, with five tufts of soft hairs; limb in five deep, spreading, lanceolate, acute, hairy segments, shorter than the tube. Nectary a cup-shaped divided gland, surrounding the base of the germen. Stam. Filaments five, linear, inferted into the tube, and enclosed within it; anthers oblong, in the mouth of the tube. Pijü. Gernen superior, roundish, of five cells; style capillary, the length of the tube; fligma "globose, defeny downy." Cavan. Peric. Drupa glo- bular, slightly juicy. Sed. Nut of five cells, hard and folid, not burfting, with a pendulous oblong kernel in each cell.

Eff. Ch. Outer calyx of several imbricated leaves. Corolla tubular; tube swelling, twice as long as the calyx, with five internal tufts of hair at the base; tube shorter, spreading, bearded. Filaments linear, within the tube. Drupa almost dry, of five cells.

This
This genus is very closely related to *Stenanthera*, as well as to *Melichrus*. (See those articles.) We might perhaps safely unite them all to *Stryphila*. The opinion of Mr. Brown, however, who has examined the flowers in a fresh state, deferves all possible attention, and we have therefore followed his views of the subject. *Afroroma* consists of shrubs, of humble stature, for the most part decumbent. Leaves scattered, often ciliated. *Flowers* axillary, erect. Six species are mentioned by this author, under the following characters.

1. *A. humifusum.* Diffuse Afroroma. (Vintenatia humifusum; Cavan. T. v. 4. 28 t. 348.)—Stem prostrate, much branched. Leaves linear-lanceolate, fringed with minute bristles; slightly convex on the upper side.—Found in various parts of New Holland, on the south-west coast, as well as at Port Jackson, and in Van Diemen's island. We have not heard of this plant, nor any other of its genus, in the gardens of Europe. The *flema* are a foot, more or less, in length, round, spreading flat on the ground, and sending up numerous, crowded, erect, short, leafy branches. *Flowers* on the main stem and branches, axillary, solitary, sessile, an inch long, of a fine crimson, with a glaucous, somewhat rose-coloured, calyx. *Drupa* nearly the size of a pea, reddish, smooth, almost concealed in the permanent calyx. The abbé Cavanilles dedicated this plant, as a distinct genus, to the honour of M. Ventenat, though he made a mistake in its orthography. But there is another Ventenatia, of which the reader may find an account in its proper place. The remaining five species have all been found in the southern part of New Holland, by Mr. Brown, and apparently by no other botanist. We give their names and definitions from his work.

2. *A. prostratum.* Prostrate Afroroma.—Stem prostrate, much branched. Leaves linear-lanceolate, fringed; flat above; rather convex beneath.—Seen with unexpanded flowers only, by Mr. Brown.

3. *A. denticulatum.* Toothed Afroroma.—Stem procumbent, or somewhat erect. Leaves lanceolate, flat, fringed, with hairs dilated at the base.

5. *A. compadum.* Compact Afroroma.—Stem diffuse, with very short ascending young branches. Leaves obovate-lanceolate, fringed; rather concave on their upper side; tapering at the base into short footstalks.

6. *A. tectum.* Upright Afroroma.—Stem erect, somewhat branched. Leaves lanceolate-oblong, flat, imbricated; rough-edged; their teeth minute, very short, obtuse.

**ATHENS, in Geography, i. 4 r. 478.** Add.—Alfo, a township of Maine, in the county of Somerset, with 374 inhabitants.—Alfo, a township of Pennsylvania, in Lycoming county, having 759 inhabitants.—Alfo, a county of Ohio, containing 2790 inhabitants.—Alfo, a township of the said county, with 840 inhabitants.

**Gen. Ch. Cal.** Glume of two valves, two-flowered; floret neuter. *Car. Glume of two valves; in the perfect floret the outer valve has three awns, and the latter is crowded; in the neutral one the outer valve is membranous, cloven, awned below the point, the inner has two awns. *Stam.* in one floret only, filaments three; anthers scarlet. *Pilf.* in the same flower only, gamem oblong; *styles* two; *stigmas* feathered. *Seeds* solitary, oblong.

**Eff. Ch.** Calyx of two valves, two-flowered; one floret neuter. Corolla of two valves, the outermost with three awns; in the neutral floret both valves are awned.

1. *A. aphideoides.* Reflexed Atheropogon. Willd. n. 1. Pursh n. 1. — Gathered by the late Rev. Dr. Muhlenberg, on gravelly hills, in Pennsylvania, flowering in September. *Root* perennial. *Stem* twelve or eighteen inches high, round, smooth, jointed in the lower part. *Leaves* lanceolate, very long; hairy at the base; their *flema* downy, crowned with a *fipula*. *Clas* simple, erect, of about twenty alternate, distant, pendulous *flowers*, each on a short partial *flalk*. *Anthers* of a vermilion hue. Willdenow attributes but one *valve* to the *calyx*, Muhlenberg two. Their decriptions are meagre. There is no reason for referring this genus to *Polygamy*, even according to the most ample ideas of that clafs, for the presence of a neutral *floral* does not confluence its character, nor is perhaps any genus of gramine in the *Triandria Digynia* quite exempt from it.

**Gen. Ch. Male.** Cal. Perianth of one leaf, bell-shaped, with eight obtuse marginal segmens; the four alternate ones external and large; the inner ones coloured. *Cor.* none. *Stam.* Filaments numerous, erect, inserted into the base of the calyx, and much shorter than its limb, somewhat combined at the bottom, and accompanied by scales; anthers elliptical, attached by the back, erect, of two cells, each opening by a longitudinal valve from the base upwards.

Female, Cal. as in the male, with the addition of numerous, internal, acute, marginal scales. *Cor.* none. *Pilf.* Germs numerous, ovate, hairy; styles solitary, thread-shaped, hairy; *stigmas* simple. *Peric.* none, except the permanent, enlarged, hardened calyx. *Seeds* as many as the germs, small, oval, each crowned with its permanent feathery style.

1. *A. mofibata.* Nutmeg Atherosperma. Labill. as above, t. 224.—Native of Cape Van Diemen, from whence we have specimens from the author; with others from A. B. Lambert, &c.; gathered by general Grose. *A tree,* twenty-five feet or more in height; the young branches square, finely downy. *Leaves* opposite, on short thick stalks, without *fipulae*; elliptical-oblong, acute, either quite entire, or with a few sharp scattered teeth; smooth and bepressed with minute pubescent dots above; finely downy and hoary beneath, with a reddish mid-rib and slightly visible veins. *Flores* axillary, foliati, filiform, drooping, rather small. *Bract* two, (fructiculus of Labillardiere) close to each flower, ovate, acute, concave, downy, deciduous. *Calyx* finely hairy; that of the fruit much enlarged, half an inch broad, hemispherical, clothed with dense silky hairs, and filled like a bason with feathery-tailed *seeds*, whose downy remembrances of that of a syngeneous plant, and is not represented in the above figure. The dried *leaf,* like every other part, as far as we can examine, has a very strong flavour of nutmeg, to which, and not to any musky scent, the specific name alludes. We have chiefly followed our author in the above description, except a more important character, of the valvular *anthers,* borrowed from Mr. Brown, whose remarks in the following article will be found greatly to illuritate the present, and to render some future alterations necessary.
A T H E R O S P E R M E I, a new natural order, thus denominated from its leading genus. See the last article. Brown Bot. of Terra Auct. 21.

Flowers either separate or united. Calyx of one leaf; its margin divided into a generally double row of segments, the innermost, sometimes all of them, half petal-like (or internally coloured). There are also in the female, as well as in the united, flowers, small, internal scales, at the base of these segments. Corolla none. Stamens in the male flowers numerous, inserted into the bottom of the calyx, with accessory scales; in the united flowers they are fewer, and inserted into the throat; anthers attached by the back, of two cells, each cell opening by a longitudinal valve, separating from the base upwards. Gynerra one or more, generally an indefinite number, with a single erect germ; filaments solitary, occasionally lateral, or from the base; stigmas simple. Seeds, (termed seed-like pericarps by Mr. Brown,) swelled with the feathery filyles, and enclosed in the enlarged tube of the calyx; embryo erect, short, in the bottom part of a soft fleshy albumen. The several species are trees, with simple, opposite leaves, defulte of stigmas. Stalks axillary, single-flowered.

Jussieu it seems, Ann. du Mus. v. 14. 116, has established an order termed Monimiae, in which Atherosperma is included, along with Pavonia of Ruiz and Pavon, its near ally, and the Ambora, (see Mithridates,) Monimia, and Ruiza, which three last Mr. Brown considers as constituting the genuine order of Monimiae, and therefore he has proposed the above, of which a most eminent distinction is their having the valvaruli of the Lauri. (See that article.)

This separation is confirmed by two New Holland plants evidently of the same family, but which have united flowers, a structure not probable in Monimiae. The place of Atherosperma, in a natural series, is difficult to fix. Though so widely different, in most parts of their structure, from Lauri, (now called Laurina,) they agree in anthers, and very remarkably with some of them in sensible qualities. Pavonia above-mentioned cannot, by Mr. Brown’s account, be separated from Atherosperma, differing merely in the oblong form, and regular buriting, of its female calyx! Its qualities are the same.

ATMOSPHERIC AIR, Chemical Composition of. See Air.

ATOMIC Theory, in Chemistry. This important theory, which has added new lustre to chemistry by raising it to the rank of a mathematical science, was entirely unknown when the earlier volumes of the Cyclopædia were published. The history of its origin and progress has been amply detailed in subsequent parts of the work, particularly under the articles Proportions, Definite, Simple Bodies, and Theory, Atomic; so that we have little left to add here, except a brief summary of some recent modifications suggested by Dr. Prout, and subsequently adopted by Dr. Thomson. See an anonymous Essay on the relation between the Specific Gravities of Bodies in their gaseous State, and the Weights of their Atoms, vols. vi. and viii. of Thomson’s Annals of Philosophy.

The object of Dr. Prout in the above essay is to shew, it is, that the theory of volumes suggested by Gay Lussac, and adopted by Berzelius and some others, is absolutely identical with Dalton’s Theory of Atoms; and 2dly, that the specific gravities of bodies in their gaseous state are all multiples of the same unit, which unit is considered as hydrogen.

Dr. Prout’s essay is terminated very abruptly, and is evidently imperfect. The above views are not explicitly stated in the paper alluded to, though it is obvious they are what the author had in view; and as they have been recently adopted by Dr. Thomson, in the new edition of his Syllem of Chemistry, which may be viewed in the light of a national work, we consider it our duty to lay a brief account of them before our readers.

The first of the above points attempted to be established by Dr. Prout has been already discussed at some length in the articles Proportions, Definite, and Theory, Atomic. Indeed, we believe it is very generally admitted by all those chemists who have taken the pains to examine and think upon the subject. It is chiefly founded upon facts and reasonings, which few at present affect to doubt, and of which the following is a summary. 1. Bodies unite together in certain definite proportions by weight, that is, certain weights of some bodies always combine with certain weights of other bodies. This constitutes the basis of the atomic theory, or the theory of definite proportions, as some have chosen to term it. 2. Substances in a gaseous state have been demonstrated to combine with reference to their bulk or volume, that is to say, one volume of one gas always combines with one or more similar volumes of another, and not with any odd fractional parts. Moreover, the volume or bulk of the result of the combining, if it happens to be a gas, always bears a similar relation to the original volumes of its component gases. For these important laws we are indebted to Gay Lussac, and they constitute the basis of what has been denominated the theory of volumes. 3. It is universally admitted, that the same weights of the same result of the combining are formed when bodies unite in a gaseous state according to their volume, as when they unite in any other manner according to their weight; thus, for example, one volume (100 cubic inches) of muriatic acid gas will unite with one volume (100 cubic inches) of ammoniacal gas, and form the same weight of the same compound, (muriate of ammonia,) as if 39.183 grains (the absolute weight of 100 cubic inches) of muriatic acid, united with 18.003 grs. (the absolute weight of 100 cubic inches) of ammonia; the two numbers 39.183 and 18.003 being to one another as 1.278 : 5.920, or as 37 : 17, the specific gravities and the weights of the atoms of these two substances respectively. Such is a brief statement of the facts; and it is argued that if the above data are correct, it follows irresistibly from them that the weights of the atoms of bodies, are to one another as the specific gravities of the same bodies in a state of gas; and consequently that the theory of volumes and the theory of atoms is one and the same thing, different fets of numbers only being employed. Some apparent deviations from this law, which however cannot be by any means considered as exceptions, will be noticed hereafter.

With regard to the second point contended for by Dr. Prout; namely, that the specific gravities of all bodies in their gaseous state, or, in other words, the weight of their atoms are multiples of the same unit or hydrogen; it is partly founded upon experiment and reason, and partly (at present at least) upon hypothesis. The following is a summary of the grounds upon which the opinion has been formed.

1. The specific gravity of ammoniacal gas, according to Sir Humphry Davy, is .59016, common air being 1.000; according to Biot and Arrago, it is a fraction greater: hence
ATOMIC THEORY.

Dr. Prout has fixed upon .5902 as the specific gravity of this gas. The sp. gr. of azote he aflames as .9722, common air being 1.000, for reasons stated below. Now, as ammonia is known to be composed of one volume of azote, and three volumes hydrogen, condensed into two volumes, the specific gravity of hydrogen, according to these data, must be .0694.

2. Atmospheric air is admitted to be univerally composed of about 21 per cent. of oxygen, and 79 per cent. of azote, which so nearly corresponds with one volume of oxygen, and four volumes of azote, or 20 oxygen and 80 azote, that Dr. Prout has concluded that the above is its true composition, and consequently that it is a real chemical compound. (See Air, Atmospheric.) Now the weight of the atom of oxygen being supposed to be 16, and that of the atom of azote 17.5, (Dr. Wollaston makes it 17.55,) the specific gravity of oxygen gas, according to these data, will be 1.1111, and of azote .9722. But these numbers are multiples of .0694 for 1.1111 ÷ .0694 = 16, and .9722 ÷ .0694 = 14.

Such are two of the leading circumstances stated in the above essay, which appear to have induced our author to examine further into the subject. For this purpose, he seems to have selected a certain number of substances, and to have arranged a series of experiments on them, with the view of ascertaining the truth of the opinions which he had been led to adopt. These experiments are said to have been numerous; but their results are stated in a very summary way, and in a manner certainly not very likely to carry conviction. The whole is afterwards arranged in tables, and there contrasted with the acknowledged results of other experimentalists, with the view of shewing how nearly they coincide with each other. These tables will be found at the end of the present article, in an extended form, and comprehending all the new determinations of Dr. Thomson. The near approach to whole numbers of the weights of the atoms of all these substances, which have been most carefully examined, and are best known, is certainly very singular, and must strike every one who has paid attention to the subject. At the same time, no argument can be advanced against the opinion that certain relations exist among the combining weights or atoms of bodies; on the contrary, this opinion seems much more probable than that they have no connection and are entirely independent of one another.

With respect to the question, whether the above opinion will ever be verified by actual experiment? it is difficult to determine. The differences in general assumed by Dr. Prout are so small, that in the present state of chemical analysis they may be fairly said to be within the limits of possible error; until, therefore, more refined methods of experimental research be discovered, we can scarcely hope the matter will be decided in this manner.

We mentioned above, that there are a few substances whose specific gravity does not correspond with the weight of their atom; thus the specific gravity of oxygen, for example, is sixteen times that of hydrogen, while its combining weight is only half or eight times that of hydrogen. This at present cannot be explained; but it is remarkable, that the specific gravities are always some multiple of the weight of the atom. (See further on this subject under Theory, Atomic.) In the following tables will be found other examples of the curious circumstances under consideration.

We shall make no further observations at present, but adopt Dr. Prout's plan of throwing together in tables the great mass of evidence on the subject, and leaving the question to be decided by the impartial judgment of our readers.

In the first and second columns of the following tables are given the specific gravities and weights of the atoms of the different substances, supposing them to be in a gaseous state, hydrogen being 1; and if, says Dr. Prout, "we suppose the volume to be 47.2135 cubic inches, the numbers will at the same time represent the number of grains this quantity of each gas will actually weigh." We may remark here, that if these views should ever be established, they afford an excellent rational standard for weights, as compared with measures. Thus the cube of the pendulum, for example, vibrating seconds, might be the unit in volume of hydrogen, whose actual weight might be the unit in weight. Such a relation between weights and measures would be as general and immutable as the laws of nature themselves, and be worthy of the enlightened age in which we live. In the third column are the corrected numbers, the atom of oxygen being supposed, according to Dr. Wollaston, Dr. Thomson, &c., 16 or 17; and in the fourth, the same as obtained by experiment are stated to shew how nearly they coincide. The other columns will be sufficiently understood from inspection. The last column in the first table contains the numbers recently asigned by Mr. Brando to the elementary substances.

</table>

The subdivisions of the above Table include the different flates of oxydation of the different substances. A few only of the numbers of those felt known are introduced, as azote, &c., with the view, in the first place, of saving room; but more particularly because they are little or altogether unknown, or, if known, may be easily obtained from the data given in Table I.

ATRAGENE.
ATRAGENE, in Botany, (see our former article,) a name adopted from Theophrastus, whose Atraphaxis, according to De Candolle, is probably our Clematis Vitalba. This genus is much reduced by the learned writer just named, who refers A. japonica and alpina to Clematis, A. caprifolius and tenuifolia to Anemone. (See that article.) The only remaining species is A. seylanica, which De Candolle retains as a genus by itself, under the new name of Naravelia, taken from Narravel of Herm. Zeyl. 26, one of its synonyms. But this being a Linnaean Atragene, and the only one which remains, that name must, by every principle and right, remain with it, especially as it is distinguished from Clematis by the original generic character of Atragene. A figure of this plant is given in Roth. Coromand. v. 2, t. 188.

ATRIPLEDES, the twenty-ninth natural order in Jussieu's system, the sixth of his sixth classes, whose characters are given under LAURI. Mr. Brown, Prodr. Nov. Holl. v. 1. 425, adopts, from De Candolle, the appellation of Chenopoda for this order, for which we have discovered no reason, Atriplex being as well-known a genus, and as expressive a type of the order, as Chenopodium. The characters are as follows.

Calyx of one leaf, often deeply divided. Stamens definite, inserted into the bottom of the calyx. Gernion solitary, superior; style either single, or wanting, or for the most part manifold, of a determinate number; stigmas one, rarely two, to each style. Seeds solitary, (numerous in Phytolacca, two in Galeniis,) either naked, or covered by the calyx, which thus becomes, in a manner, superior; or inclosed in a pulpy, or a capular, pericarp. Corculum surrounding a firmaceous mass. Stem in numerous instances herbaceous, in some fleshy. Leaves mostly alternate, sometimes opposite.

Stamens occasionally in separate flowers from the pithil.

Sec. 1. Fruit pulpy.

Phytolacca, Rivina, Salvadoria, and Bofca; the last supposed to be more akin to the Rhamni.

Sec. 2. Fruit capular.

Petiveria; Polycnemon; Camphorofa; and Galenia: not without some doubts respecting the two last.

Sec. 3. Seed covered by the calyx. Stamens five.

Bafella; Ancredera, Julif. which is Fegopyrum scandens, &c., Sloane Jam. v. 1. 138. t. 90. f. 1; Anabasis; Coraxylum, Thunb.; Sal向东; Spinacia; Acida; Beta; Chenopodium; and Atriplex.

Sec. 4. Seed covered by the calyx. Stamens fewer than five.

Crucita; Axysis; Blitum; Ceratoecarpus; and Salicornia.

Sec. 5. Seed not covered by the calyx.

Cardipermon only.

This order is analogous to the Holocaceae of Linnaeus, though many extraneous things are referred to the latter. Mr. Brown affirms that the Atriplices, or Chenopodes are not distinguishable by any character from the Amaranthi, (see that article,) though different in habit, and differing from the Ipecacuan, (by which is meant Jussieu's third section of Amaranthi,) in the want of stipulas. The infection of the stamens into the calyx, according to this accurate observer, is not absolutely constant, nor are the Amaranthi all free from that infection. Yet on this mark the distinction is founded, not merely between these two neighbouring orders, but between the fifth and seventh classes of Jussieu, which thus run into each other. We do not mean, by pointing out these intricacies of Nature, which render it so difficult for us to submit her to human regulations, to throw needless difficulties in the way of those, who attempt this arduous task by other means than we ourselves pursue. We merely remind them of our common fallibility, and recom mend patient investigation, with mutual assistance, in the place of dogmatical assumption and invidious criticism.

ATTELABUS, col. 2, l. 1, for arc r. is; l. 23, dele which fee respectively, and add—One of the principal species is A. Coryli, a smallish insect found in hazel-trees, black with red wing-sheaths, usually measuring about a quarter of an inch in length. A much smaller species is the A. Betyale, altogether black, and remarkable for gnawing the leaves of that tree in the early part of spring; so that she appear notched on the edges. The A. Apiarius is an elegant species, deriving its name from the injury which its larva does in bee-hives by destroying the young. See APIARIUS.

AUFENREICH, See Use of Roses.

ATTLEBOROUGH. Add—It contains 2716 inhabitants.

ATTRACTION of Mountains, col. 2, l. 50, r. 4364; 1. 51, for 43° r. 42°.04.

AVA, l. 1, r. Aungawa.

AUBENAS, l. 3, for Coiron r. Privas.

AVERILL, in Geography, a township of America, in Vermont and county of Essex, having nine inhabitants.

AUGUST, a gold coin of Saxony, of which are double, single, and half August d'ors, reckoned at 10, 5, and 2.88 rix dollars: 35 single Augusts weigh a Cologne mark of gold 21 carats 8 grains fine.

AUGUSTA, in Geography, a town of the district of Maine, in the county of Kennebec, containing 1805 inhabitants.

Leaves thread-shaped, channelled.—Native of hills near the Cape of Good Hope. A frub one or two feet high, with round, red, leafy branches. Leaves numerous, scattered, simple, undivided, smooth, slender, spreading every way, two or three inches long. Flowers yellow; the male in several long clusters, forming a terminal leafy umbel; female in a dense solitary head.

Leaves linear-liliate, flat.—Native of hills at the Cape of Good Hope. A frub two or three feet high, with bright-green, bluntish, smooth leaves. Flowers yellowish, terminal; the male in shortish blunt clusters; female in a solitary whitish head, encompassed with long, narrow, yellow, radiating bracts.

Both these are green-house plants in England, flowering in the latter part of summer. The second is said to be the most hardy.
AVORA, a township of Ohio, in the county of Trumbull, containing 440 inhabitants.

AUTOGRAPHUM. See WRITING-MACHINE.

AUTOMALITE. See RUBY and MINERALOGY, Addenda.

Gen. Ch. Col. Peranthes superior, of three short, acute, unequal, deciduous leaves. Cor. of one petal, bell-shaped, var. small, its border in ten to twenty, short, rounded, equal segments. Stam. Filaments thinnest, capillary, the length of the corolla; anthers of two globular lobes. Pist. Germen inferior, ovate, furrowed; hylo thread-shaped, the length of the ilamens; stigma thickish. Peric. none. Seed solitary, ovate, furrowed, hairy.

AXY-PANA, a South American plant of the genus EUPATORIUM, (see that article,) of which an account is given in the Bulletin des Sciences, n. 67. 147. as peculiarly efficacious against the poison of serpents, on which account it is much cultivated in the island of Mauritius, and in Cayenne. The bruised leaves are said to cure the sting of a scorpion, and that of a poisonous fish, named lef. An infusion of the herb has proved useful in droppers, as well as in syphilitic disorders. This plant has been cultivated in the flowers at Paris, but we have heard nothing of it in England.

AYMOUTH. See EYMOUTH, dele.

Gen. Ch. Male, in pairs, enclosed in a single-leaved, membranaceous, close involucrum, (occasionally foliary under the female,) ovate, of two cells, their outer covering bursing tranversely; upper cell containing nine or six angular bodies, inserted around a tubular axis, which finally opens at the summit; lower cell spherical, closed by a double membrane, and filled with a fluid, which may perhaps change to a powder.

Female, axillary, on the same plant, foliary (sometimes accompanied underneath by a foliary male). Involucrum double, both closed, membranous; the outer like that of the male flowers; inner ovate, without valves, containing numerous capules, without valves, attached by capillary stalks to a common receptacle, originating from the base of the involucrum. Seeds from five to nine, angular, with exterior radicles.

Eff. Ch. Male, ovate, of two cells, separating transversely; the upper containing several angular, thallic bodies.

Female on the same plant, capules numerous, thallic, globose,
globose, of one cell and one valve, in an ovate, close involucrem. Seeds several, angular.

1. A. filiculoides. South-American Azolla. Lamarck n. t. 1863. (A. magellania; Willd. n. t. Mufcus squamosus aquaticus elegantissimum; Feuill. Voy. v. 3. 43—t. 35. Dill. Mufc. 335. t. 43. f. 72.)—Frond pinnate. Leaflets all papillary. Roots smooth. Found by Feuillée in Peru; by Mr. Menzies in Chili; in watery places; and at the tracts of Magellan by Commerson. This is a little floating mossy plant, resembling a Jungermannia, an inch or two long, alternately pinnate, with small, imbricated, ovate, scaly leaves, clothed externally with papillary hairs, and membranous at the edges. The roots are long, slender, smooth and naked, dark brown. No fructification has been discovered in this species.

2. A. pinnaeata. Triangular Pinnate Azolla. Br. n. t. Bot. of Terra Wint. 79. t. 10.—Frond pinnate, triangular. Upper leaflets papillary. Roots longitudinally feathered.—Gathered by Mr. Brown, in lakes and ponds, at Port Jackson, New South Wales. A little floating plant like the foregoing. Roots axillary, solitary, perpendicular, unbranched, pellucid, hooded at the point when young, at first light quite simple, but under a magnifier they appear feathered about the middle part. Frond half an inch long. Branches two-ranked, alternate, crowded. Leaves alternate, imbricated every way; those on the upper side of each branch ovate, somewhat angular, cellular, thick, often reddish, rough on the upper surface with papillary tubercles, those on the under side thinner, smooth, and lefs angular. Flowers on the under side of the frond, sessile, solitary at the base of each branch.

Mr. Brown seems to think the true pollen of this curious genus originates in the watery or turbid fluid, which he once found changed to powder, and which may be discharged through the tube above, whose angular appendages, once suspected to be anthers, (see his Prudr.) may by pressure facilitate its ejection, whether in a watery or powdery state.

3. A. rubra. Red Orbicular Azolla. Br. n. t.—Frond orbicular; lobes palmate; their subdivisions undivided or cloven. Upper leaves smooth. Roots feathery beyond the middle.—Gathered by Mr. Brown, at Port Jackson, as well as in Van Diemen's Island. The fructification has essentially the same structure of that of A. pinnaeata, except the angular bodies of the upper cell being only five, not nine. Brown.

4. A. caroliniana. Carolina Azolla. Willd. n. t. Purt. n. 1.—"Leaves imbricated, ovate-oblong, obtuse, spreading; red underneath."—Found by Richard, in Carolina; by Purt. floating on the waters of lake Ontario. We know nothing more of this species; and as those who have described it were unacquainted with the fructification, as well as with Mr. Brown's specific definitions, the above character requires revision.

AZOTE, in Chemistry. The specific gravity of azote, according to the most recent determinations, is 0.9722, and 100 cubic inches of it will weigh, at a mean temperature and pressure, 29.652 grains. Biot and Arrago make its specific gravity 0.9691, and Lavoisier 0.978. See Atomic Theory.

A new compound of chlorine and azote was discovered a few years ago, which, from its remarkable properties, deserves to be described here.

This compound seems to have been first noticed by M. Dulon in 1812; but this chemist, on account of two severe accidents which happened to him in the course of his experiments, did not complete the investigation of its properties, nor publish anything on the subject. Sir H. Davy was informed of the discovery of the substance soon after, but not by the method of preparing it. Chancing, however, to hear from Mr. Children, that Mr. Burton of Cambridge had procured an oily substance by passing a current of chlorine through a solution of nitrate of ammonia, he was enabled to prepare the compound in question, and investigate its properties.

Chloride of azote may be prepared by placing a jar of chlorine gas over a solution of nitrate or muriate of ammonia, heated to about 110°. The gas is slowly absorbed, and an oily-like matter collects at the bottom of the vessel, which is the substance in question. Care must be taken not to collect at one time more than a globule or two, as it explodes with prodigious violence from the slightest cause. Its colour closely resembles that of olive-oil. It is transparent: its smell is strong and peculiar, though it is not so disagreeable nor injurious to the lungs as chlorine. It is very volatile, and soon disappears when left in the open air. At 160° it may be diffused over without danger, but is partially decomposed. The temperature of 200° only occasions it to evaporate faster, but when heated to 212° it explodes with amazing force. In a vacuum it is converted into vapour, but again assumes the liquid form when the pressure of the air is restored. This vapour, if heated sufficiently, explodes with as much violence as the liquid itself. The fp. gr. of the chloride of azote is 1.953. It does not become solid on exposure to cold. When left in water it speedily disappears, and azotic gas escapes. In strong muriatic acid, chlorine escapes, and muriate of ammonia remains in solution. When brought in contact with phosphorus, oils, and many other substances, it explodes with very great violence. Metals, refining, sugar, and most of the gases, do not cause it to explode. The experiments of Sir H. Davy on the composition of this curious substance render it probable, in Dr. Thomson's opinion, that it is composed of one volume or atom of azote, and four volumes or atoms of chlorine.

Azote has likewise the property of forming an analogous compound with iodine. (See Iodine, and Simple Bodies.) The celebrated chemist Berzelius still, we believe, maintains the opinion, that azote is a compound of oxygen and an unknown substance, which he denominates nitricum; and a laborious series of experiments was some time ago published by Mr. Miers, to shew that this unknown substance is nothing but hydrogen. Chemists in general, however, do not at present acquiesce in either of these opinions, but consider azote as an elementary substance.

For the combinations of azote with oxygen, see Atomic Theory, Nitric Acid, &c. and Proportions, Definite.

AZUMBRE, a liquid measure in Spain. See ARROBA, Addenda.

Gen. Ch. Cal. Spatha inferior, large, of two valves; the inner valve deeply cleft with an intermediate pellucid membrane. Cor. of one petal, superior; tube funnel-shaped, longer than the fpatha; limb shorter than the tube, in fix deep, usually regular and nearly equal segments, sometimes very irregular. Stam. Filaments three, thread-shaped, inserted into the mouth of the tube, erect, much shorter than the limb; anthers oblong, incumbent. Pfj. Germe roundish; style thread-shaped, rather longer than the tube; flogmas three, spreading, obtuse, undivided. Petir. Capule roundish-ovate, coriaceous, unequally tumid, of three cells and three valves. Seeds numerous, globose, pulpy, tapering at the base, at length corrugated, and d-formed by mutual prefluence.

1. B. Tbunbergii. Many-spiked Babiana. Ker n. 2. Ait. n. 1. (Antholyza plicata; Thunb. Prodr. 7. Fl. Cap. v. 1. 169. Linn. Suppl. 96. Willd. Sp. Pl. v. 1. 223.)—Leaves many-ribbed, finely divided into the fathas and sheaths. Corolla ringent. —Native of sandy plains near the sea, below Verloren Valley, at the Cape of Good Hope, flowering in October. Tbunberg. Mr. Maffon fent this species, in 1774, to Kew, where it flowers in April. Bulb deep in the ground. Leaves radical, equitant, acute, with some principal, yellow, and many intermediate green ribs, minutely downy on both sides, with soft prominent hairs. Stalk radical, taller than the leaves, a foot high, zigzag, densely clothed with fine soft hair, and divided into about half a dozen alternate, spiked, many-flowered branches. Flowers crimson, two inches long, crowded, erect.

2. B. ringens. Gaping Babiana. Ker n. 1. Ait. n. 2. (Antholyza ringens; Linn. Sp. Pl. 54. Willd. Sp. Pl. v. 1. 223. Thunb. Prodr. 7. Fl. Cap. v. 1. 167. Gladiolo ethiopico similis; Comm. Hort. v. 1. 81. t. 41. Rudb. Ely. v. 2. 237.)—Leaves many-ribbed, smooth. Stalk downy. Corolla ringent. —Found in low sandy fields, often by the way side, in many places about the Cape of Good Hope, flowering from July to September. Not at present in the gardens, as far as we could ever learn; or at least we never heard of its flowering. Not so tall as the preceding, nor so much branched, but the flowers are larger and more handfome, remarkably widely ringent, with one faden far removed from the other two.

3. B. nervosa. Four-ribbed Babiana. (Antholyza nervosa; Thunb. Prodr. 7. Fl. Cap. v. 1. 164.)—Leaves smooth, with four prominent ribs. Stalk smooth. Spike oblong, two-ranked. Corolla ringent. —Native of the Cape of Good Hope. Leaves three or four, acute, smooth, with four yellow, elevated ribs, erect, about a foot high. Stalk as tall as the leaves. Flowers flesh-coloured, drooping, crowded into an ovate, rather abrupt, spike; their lower lip rather the shortfert, reflexed. There can freely be no doubt respecting the gender of this plant.

flender. Limb pale bluish purple, with elliptic-oblong, nearly equal segments, an inch long; three alternate ones bluish, with a point; three lowermost marked with white and violet.

7. B. sulphurea. Pale Babiana. Ker n. 5. Ait. n. 6. Ker in Curt. Mag. t. 1053. (Gladiolus sulphureus; Jacq. Ic. Iar. t. 239. Vahl Enum. v. 2. 99. G. plicatus; Andr. Repol. v. 2. 268.)—Leaves downy; shorter than the ascending downy flalk. Tube shorter than the spathe, and but one-third as long as the nearly uniform limb.—Native of the Cape, from whence it was procured by Meffrs. Lee and Kennedy, in 1795. The leaves are elliptic-oblong, strongly plaited, downy all over. Flowers large, with a short tube; limb cream-coloured, with some tints of blue.

8. B. plicata. Sweet-fowted Babiana. Ker n. 13. Ait. n. 7. Ker in Curt. Mag. t. 576. (Gladiolus plicatus; Thunb. Diff. n. 24. Fl. Cap. v. 1. 211, with many wrong synonyms. G. fragrans; Jacq. Hort. Schoenbr. v. 1. t. 14.)—Leaves elliptic-lanceolate, loofly plaited, very soft and downy. Segments of the limb nearly equal, the length of the tube; upper one hooded. —One of the most common species at the Cape, near the town, and in various other places, flowering from May to October. Thunberg says the Europeans call this plant Babiana. Has this, whatever it means, given occasion to Mr. Ker's generic name? Nearly akin to the last, but of a fower texture. Flowers fragrant, pale lilac, or bluish-white, marked with violet at the base of their three lower segments. Stament ascending.

9. B. fricta. Upright Babiana. Ker n. 6. Ait. n. 8. Ker in Curt. Mag. t. 621. 637. (Gladiolus frictus; Ait. ed. 1. v. 1. 63. G. plicatus; Linn. Sp. Pl. 53. Ixia; Mill. Ic. 103. t. 155. f. 1.)—Leaves elliptic-lanceolate, plaited, downy. Corolla funnel-shaped, nearly regular; segments about as long as the tube, all flat.—Native of the Cape; long known in our green-houses, though not very frequent. The flowers are smaller than most of the foregoing, with obovate, pointed, equal segments, either all blue, or pale grey, or alternately white and purplish, each hardly an inch long. Spathe small, linear-lanceolate, downy.

In the *Methodus* of Acharius, this genus is so characterized as to include all the *Lichenes pyxidatis*, as well as the *Gleditsia* of other authors. At present it is restricted to the first section of the original *Basmyces*, consisting of four species only. The characters and synonyms of these are correctly given by our learned friend, except that of *Lichen ericetorum* of Linnæus, which we remove from this genus, on the authority of original specimens.

—Found on mountainous heaths, in broad uninterrupted patches on the ground, of a greenish or glaucous grey when fresh and moist, conforming to all the inequalities of the foil; the surface finely granulated. Tubercles from one to two or three lines in diameter, of a bright and moft elegant rose colour, convex, more or less lobed, or irregularly tumid, each supported by a thick, round, folid fubftance, as high as the diameter of the head, white tinged with a buff-bred. This is by far the moft elegant, as well as the moft rare, of our British species. Dr. Acharius here cites Engl. Bot. t. 372, which is his *Lecidea Ismodaiphila*, Syn. 45, the true *Lichen ericetorum* of Linn. Sp. Pl. 1608. *Fl. Suec. 458. and Herb. Linn. Fl. Dan. t. 472. f. 4. Lichen Ismodaiphila; Linn. Suppl. 450. Ehrh. Phyt. n. 49. L. æruginofofa; Jacq. Auffr. t. 275.

2. *B. fungoides*. Pale Mushroom-Lichen. Ach. n. 2. ("B. helveloides; Bory Voy. 3." Lichen fungoides; Swartz Ind. Occ. 1886.)—Crufť white. Stalks thrie as tall as the diameter of the more fihn-coltured tubercules.

—Gathered by Dr. Swartz on the gravelly foil of high mountains, in the southern part of Jamaica. Bory de St. Vincent found the fame in the ifle of Bourbon. We have fpecimens from Dr. Acharius. The crufť is thin, hard, of a dirty white. Stalks white, thrie as tall as the foregoing; tumid at the bafe. Heads of a lighter fihn-coloured, with a white powdery effibrence.

4. *B. lignorum*. Achar. (B. rufetfis γ; Ach. Meth. 322.)

Cruft greenish-white. Stalks fhort, somewhat comprefled. Tubercles nearly globular, reddish-brown; fometimes aggregate.—Common on heathy ground, or on rocks, rarely on rotten wood; in which latl fuation the tubercles assume a darker brown. They are much smaller than in *B. rufus*, rounder and fefs lobed, though often cluftered together; their colour is a dirty brick-red.

The variety β of Engl. Bot. figured in Rail Syn. t. 1. f. 5, not f. 4.4 and in Dill. Mufc. t. 14. f. 5, is now effemed a fungus. See Oxygeva.

5. *B. placenthullus*. Broad-leaved Mufhroom-Mufhroom. "Wahlenb. Lapp. 449." Ach. n. 4. Meth. 323. t. 7. f. 4.—Cruft orbicular, rugged, somewhat lobed and imbricated, glaucous-white. Stalks elevated, comprefled. Tubercles convex, fimple, reddish-brown.—Found by Wahlenberg, on the flerie landy foil of Lower Lapland. We are obliged to Dr. Acharius for a specimen of this very curious species, whose cruft approaches that of the true Cup Lichens, its circumference almoft being lobed and almoft leafy, though of a thick fulidente. The tubercles are altogether thole of a *Basmyces*.

BAGDAD, col. 4, t. 1, after terraces. Bagdad is fill a plate of great trade, and the refort of merchants from almost every quarter of the East. It supplies all Asia Minor, Syria, and part of Europe, with Indian commodities, which are imported at Baffora, brought in boats up the Tigris, and then transported by caravans to Tocat, Conflantinople, Aleppo, Damascus, and the western parts of Peruia. The chief imports from India are, gold brocade, cloths, fugar, pepper, tin, fandalwood, iron, china-ware, fpice, cutlery, arms, and broad-cloth; in return for which they fend bullion, copper, gall-nuts, tamarick, leather, and otto of rofes. From Aleppo are imported European filk-flufs, broad-cloths, fteel, cochinile, gold, filver thread, and several other European articles, which are brought in Greek veftlces to Scanderbon. The imports from Peria are, fhauls, carpets, filk, cotton, white cloths, leather, and faffron; and thole from Conflantinope, are bullion, furs, gold and filver thread, jewels, broad-cloth, velvets, and otto of rofes. The principal manufacture at this place is that of red and yellow leather, which is much efteemed; but filk and cotton flufs are likewise made. The climate, notwithstanding its exceflive heat, is allowed to be very healthy. But the natives are fubjeft to a cutaneous diforder, for which no cure has yet been discovered: it appears in the form of a pimple, then degenerates into an ulcer, and at the end of eight or ten months dries up of itself, leaving a prominent mark. The inhabitants of Aleppo, and other towns in Syria, are fubjeft to this difeafe. The military government of Bagdad is, &c.

BAKERSFIELD. Add.—The bahar of Acheen, in Sumatra, contains 800 cattees, and is equal to 450 lbs. avoirdupois. The bahar of Belfteckee, in Arabia, containing 40 paracles, is 8154 lbs. avoirdupois. The bahar of Bencooone = 560 lbs. avoirdupois. The bahar of Junkeflyon of 8 capins = 485 lbs. 5 oz. 53 dr. The bahar of Malacca, of 3 peculs = 405 lbs. avoirdupois. The bahar of Mocha, of 15 franks = 445 lbs. avoirdupois.

BAIREN, N. lat. 28° 13'.

BAJOCCO. Add.—Rome exchanges with Amsterdam 42 bajocchi, more or less, for 1 florin banc; with Leghorn, 95 bajocchi, more or less, for 1 pessa of 8 real. Rome keeps accounts in fudi. See SCUDO.

BAIRDSOWN, L. 5, N. 221, 202 being fquares. See BAIRDS. Add.—See CLIPPER, Ablea.

BAKERSFIELD. Add.—It contains 812 inhabitants.

BAKU, Inferit, and BADUK. N. lat. 42° 22'. Add.—Baku is defended by a double wall and deep ditch, con- ftructed during the reign of Peter the Great. This was once a celebrated city of the ancient worhippers of fire, and before the conquest of the Saracens was annually visited by thousands of pilgrims.

BALDIVIA, L. 7, W. long. 74°.

BALDWIN, in Geography, a town of America, in the diftrift of Maine, and county of Cumberland, containing 546 inhabitants.
inhabitants.—Allo, a county of Georgia, which, together with its town Milledgeville, contains 6356 inhabitants; the
falves in the county being 2324, and in the town 226.—
Allo, a county in the territory of Mississippi, having 1427
inhabitants, including 717 falves.

BALFOURIA, in Botany, received its name from the pen of Mr. Brown, in honour of his illustrious countryman
for Andrew Balfour, knight, founder of the Botanic Garden,
as well as of the Public Museum, at Edinburgh. His friend,
for Robert Sibbald, has embalmed his memory in the Memo-
ria Balfouriana; nor could any one be more competent to
this tribut. These distinguished men first laid the founda-
tion of the study of natural history in Scotland.—Brown
467.—Clas. and order, Pentodnia Monogynia. Nat. Ord.

Eff. Ch. Corolla funnel-shaped; throat crowned with a
small cranate tube; segments of the limb straight, equi-
lateral. Stamens inserted into the throat; anthers arrow-
shaped, pointed, cohering with the stigmas about the middle.
Germen of two cells; hy stigmat with thread-shaped, dilated
at the top; stigmas angular. Scales ten at the base of the
calyx, on the outside of the corolla; none under the germen.

Follicles......

1. B. falina. Willow-leaved Balfouria. Br. n. 1.—
Difcover'd by Mr. Brown; in the tropical part of New
Holland. A tree, about twenty feet high, smooth. Leaves
opposite, linear-lanceolate, falcate, with little teeth between
the incision of their foottails. Gyms lateral as well as ter-
minal, three-cref.

BALK. Infert—or Bulkh. Col. 1, l. 3, after Buc-
triana, infert.—It was formerly included in Khorafian, and is
hounded on the C. E. by the Oxus, E. by Khoondeel,
W. by Khorafian, and S. W. by the mountains of Huzara,
and the independent state of Mymuna. Col. 2, l. 17, after
Perfians, add.—The Tanjets, or the race of people who in-
habit this country, besides the Afghans and Ulbeeks, are
corrupt and dissolute, and addicted to the most unnatural
vices. The Ulbeeks are simple, honest, and humane.
Col. 2, l. 60, after Hindosta, add.—It is laid to be as large
as Delhi; but most of the houses are uninhabited; and
the population is said to be reduced to between 6 and 7000
men, subject to the king of Cabul. The vicinity of the
town is well cultivated, and corn and provisions are abundant.

column.

BALLISTIC PENDULUM, a pendulum used in acfer-
taining the velocity, &c. of balls, the strength of gunpowder,
&c. &c. See GUNNERY, PENDULUM, and PENDULUM.

BALKISTAN, l. 10, r. Mekran. At the clofe,
add.—Ballogiftan, or, as it is otherwise called, Balouchiftan,
the country of the Balouches, is confidered by some as
a province diftinét from Mekran or Mervr; and as fuch
properly commences at Kohineen (the hilly road) 25 miles N.E.
of Bayla, or in N. lat. 26° 33', from which it extends to
Noolkhy, 79 miles N.W. of Kelat, or in N. lat. 30°. It
is faid to be a confused mass of tremendous mountains,
through which the road generally leads in water-courfes.
Flocks of sheep and herds of cattle are numerous in every
part of this country, and it also produces great quantities of
wheat. The territories of Mahomed Khan, chief of Ba-
loochiftan, comprehend all the countries lying between
26° 30' and 30° N. lat., and from 65° to 69° E. long. It
is divided into two montaneous provinces of Ihalawan
and Sarawan, the low county of Cutch Gandava to the E.,
and the provinces of Zufirce and Amund Dajal; to which
may be added the small districts of Shat and Muftung, lying
N. of Kelat. See SARAWAN and MECRAN.

BALLOUGHISTAN. See BALLOGISTAN.

BALSAMITA, in Botany, an old name, used by Dodon-
eus and others, alluding to the balsamic odour of the
flowers and herbage, and their reputed stimulating health-
ful qualities. It is revived by Persoon Desfontaines, who,
after the example of Vaillant, has recently parted the
several species of this genus from Cotula, Chrysanthenum,
and Tanacetum, into which they had been forced, though de-
situte of radiant, or female, florets, as well as of a crown to

Clafs and order, Symenewa Polygamia-equalis. Nat. Ord.
Compoite didecoides, Linn. Corymbifera, Juff.

Gen. Ch. Common Calyx flattyflied, imbricate; fcales nu-
erous, linear, convex, acute, the inner ones with a mem-
branous margin. Cor. compound, uniform, tubular, longer
than the calyx. Florets all perfect, numerous, funnelf-shaped,
equal; their limb in five regular, acute, spreading segments.
Stam. in each floclet, Filaments five, capillary; anthers
united into a five-toothed tube, hardly longer than the tube
of the corolla. Pist. Germin rounded, ftyle thread-shaped,
longer than the corolla; ffigmas two, revolute. Peris. none,
except the permanent calyf. Seeds ftylist to each floret,
small, oblong, fhrunk, sometimes bordered with a narrow
longitudinal membrane at one fide, but abrupt at the fummit,
without any crown or wing. Recept. fightly convex, naked.

Eff. Ch. Recapitb late. Seed-down none. Calyx
imbricate.

(Cotula grandis; Linn. Sp. Pl. 1257.)—Stem heraceous,
hairy, fimple and single-flowered. Leaves ferrated; radical
ones obovate; thef of the flume lanceolate; dilated and
deeply toothed at their base. Found by Desfontaines
in corn-fields at Alger, flowering in May. Limnus had it
from thence. A handfome biennial plant, conpofitious for
its large, yellow, effhine-like flores, about two inches broad,
compofed of immemorable crowded flores. The flum is two
or three feet high, unbranched, lefly, and hairy. Leaves
numerous, smooth; the radical ones flanked, two or three
inches long.

2. B. virgata. Wand-branched Colurnbary. Desf. as
above, 2. Willd. n. 2. Ait. n. 1. (Cotula grandis;
Jacq. Obf. fufe. 4. 4. t. 81. Chrysanthenum discoideum;
Allion. Pedem. v. 1. 190. t. 11. f. 1.)—Stem heraceous,
smooth; branched at the base; branches single-flowered.
Leaves linear-lanceolate, ferrated, nearly fefile; upper ones
linear, entire.—Native of Italy. This is the plant men-
tioned under his Cotula grandis by Limnus; as having been
fent by Allion. It is however, as he fuppofed, very diftinét
from that plant; being much smaller in every part; the
flum smooth and branched; leaves none of them fpatulate,
nor dilated and deeply cut at the base. Flowers similar, but
scarce and half fo large, especially thofe of the lateral branches.

3. B. ageratifolia. Sharp-toothed Colurnbary. Desf. as
above, 2. Willd. n. 3. Ait. n. 2. (Chrysanthenum flo-
culiorem; Linn. Sp. Pl. 1255. Bellis spinofa; Alpin. 
Exot. 327. t. 326. B. major spinofa. petalis carenis;
Morif. feet. 6. t. 9. f. 16.)—Stem shrubby, branched at the
base. Leaves obovate, sharply ferrated, crowded. Flowers
corymbose.—Native of Crete.—an old green-house plant in
3 A

England.
England, but not popular at present. The branches are rather loosely spreading, smooth, covered with smooth leaves, an inch and a half long, whose numerous teeth are sharp, and even spiny. Several deep-yellow convex flowers compose a corymbous cluster at the extremity of the stem or branch.

Baltimore, 1. 12, after contains, add—by the census of 1810, 29,255; and for 1877 r. 6697.

Baltimore, col. 1. l. 9 from the bottom, add—By the census of 1810, the number of inhabitants in the city of Baltimore was 35,583, including 3713 slaves; in the eastern precincts 4050, comprising 262 slaves; and in the western precincts 6522, including 6073 slaves.

Baltimore, a town of Vermont, in the county of Windfor, having 207 inhabitants.

Bamberg, col. 1. l. 19, add—Before it was secularized in 1813, it contained a surface of 65 German miles, with a population of 120,000 souls, and a revenue of 556,000 dollars. Col. 1. l. 24, after populous, add—containing about 2030 houses, and 16,500 inhabitants.

Bamff, col. 2. l. 31, insert—The burgh and parish contained, in 1811, 3603 persons; 1540 males, and 2063 females.

Bamffshire, col. 2. l. 4. r. in 1811, was 36,668 persons; 10,456 males, and 20,203 females; 3815 families being employed in agriculture, and 2105 in trade, manufactures, and handicraft.

Bampton, l. 19. r. 1061 houses, and 5864 inhabitants.

Banbury, l. ult. r. and the borough and parish, by the returns of 1811, contained 582 houses, and 2841 persons; 1331 males, and 1510 females.

Band, a weight used on the Gold Coast for weighing gold dust, and equal to two ounces troy.

Band-fifth. See Cepola.

Bandér-arassi, r. Gambronn.

Bangor, col. 2. l. 37, r. the city and parish, in 1811, contained 456 houses, and 2383 inhabitants, viz. 1094 males, and 1289 females.

Bangor, in America, add—It contains 850 inhabitants.

Bank, Million. Add to dittoisation—1796.

Banksia, in Botany, one of the most magnificent and peculiar genera among the native plants of New Holland, was with great propriety dedicated to the honour of the illustrious discoverer of this genus, by the younger Linnæus. (See our former article Banksia, which requires correction, as embracing several species not now included herein, but already described in the present work under the articles Conchium and Xylomelum.) On the other hand, a much greater number of genuine Banksia, first made known by Mr. Brown, since the publication of that original article, require to be added. We are at a loss to account for the report concerning the species with solitary flowers, at the end of that article. It may have had some foundation which has escaped the memory of the writer of this. The only Salisburia ever published belongs to a totally different family, and may be found in its proper place. Thirty-one species of Banksia are defined by Mr. Brown, of which four only were known to Linnaeus, from specimens and engravings communicated by Sir Joseph Banks.—Linn. Suppl. 15. Schrèb. Gen. 79. Murra in Linn. Syst. Veg. ed. 14. 161. Wild. Sp. Pl. v. l. 335. Mart. Mill. Dict. v. 1. Att. Hort. Kew. v. 1. 213. Brown Tr. of Linn. Soc. v. 10. 202. Pros. Nov. Holl. v. 1. 451. Juff. 79. Lamarell Illusr. t. 54. f. 1. 2. Gært. t. 48.—Chas. and order, Tetrandria Menzogynia. Nat. Ord. Aggregate, Linn. Proteacee, Juff. Brown.

Gen. Ch. Cal. Catkin cylindrical, dense, many-flowered; flowers in pairs, with three permanent scales to each pair, two of which are interior, and smallest. Cor. of one petal, in deep four linear segments, at length separating entirely, somewhat dilated and concave at the summit, their points long cohering, till forced aunder by the growing style. Nectary four scales at the base of the germen. Stam. Filaments four, very short, inserted into the base of the cavity of each petal; anthers oblong. Fil. Germen superior, of two single-seeded cells, very small; style cylindrical or angular, furred, gradually curved, firmly held for a long time, by the combined tips of the corolla; stigma undivided. Peric. Follicle woody, firmly fixed in the receptacle, obovate, of two shallow cells; the partition unconnected, rigid, elastic, cloven by a deep transverse fissure at the top. Seeds solitary, compressed, quite flat at the inner side, wedge-shaped, and extended into a rounded, membranous, terminal wing.

Eff. Ch. Corolla of one petal, four-leaflet, bearing the flowers in the hollows of its segments. Nectary four scales at the base of the germen. Follicle woody, of two single-seeded cells, with a cloven moveable partition. Catkin with three scales to each pair of flowers.

Ob. The greater part of the very numerous flowers are necessarily abortive, or there would not be room for the follicles to ripen.

The various species, all natives of New Holland, are either shrubs, or trees of no lofty stature. The branches are umbellate; or in Linnaean language the term is "determinately branched," as in Erica and other Bicorne. Leaves scattered, rarely whorled, simple, undivided, either entire, serrated, toothed, or cut in a pinnatifid manner; in a young plant they are often variously cut, or toothed, though undivided and entire on the frond when full grown. (Brown.) Catkin solitary, terminal, rarely lateral, cylindrical, in some cates very short. Bractes several at the base of each catkin, short and narrow. Catkin when in fruit hard and heavy, its enlarged common receptacle firmly united with the bases of the follicles, the surface briefly with remains of the flowers, and especially with the unipinnated styles of the greater part, intermixed with the large, hard, usually downy or hairy, follicles. Seeds black, with a brown, shining, oblique wings, the convex side of each filling a depression in the corresponding side of the thin wooden partition.

Sec. 1. Style longer than the corolla, projecting laterally, in a curved position, between its segments, the stigma being held fast, for some time longer, between their points. Catkin, when in flower, cylindrical; when in fruit, laden with numerous transverse follicles. Thefe Mr. Brown considers as true Banksia. Indeed this section embraces the whole genus, except one species. We follow Mr. Brown’s names and numbers.

1. B. pulchella. Small-flowered Bankiia. Art. n. 1.—Leaves accrofe, entire, pointles. Tube of the corolla woolly;
woolly; limb smooth. Stigma capitate, depreffed.—Native of dry heaths, near the fea-shore in Lewin's land, on the southern coast of New Holland, where it was found by Mr. Brown, and sent to Kew in 1805, but had not yet flowered there in 1810. The leaves are not longer than the finger-nail.

3. B. nutans. Nodding-flowered Bankia. Ait. n. 3. —Leaves acerofe, entire, pointed. Catkins drooping. Follicles silky. Follicles dilated at the summit, depreffed.—On dry heaths near the shore of Lewin's land, where, like the two former, it was gathered by Mr. Brown.

4. B. rieifolia. Heath-leaved Bankia. Linn. Suppl. 127. Willd. n. 7. Ait. n. 4. Banks Lc. Ined. spad Bibl. Linn. t. 4. Andr. Repof. t. 156. Curt. Mag. t. 738. Cavan. Ic. v. 6. 27. t. 538. (Bankia; White's Voy. 225. t. 22. t. 1.)—Leaves acerofe, emarginate, with two teeth; entire at the edges. Catkins elongated. Corolla silky. Stigma capitate.—Native of the eastern coast of New Holland, on rocky heaths near Port Jackson, from whence it was fent by Dr. White, among the first botanical communications from that country, and is now in several green-houfes, flowering at various times of the year. This species was however firft discovered by Sir Joseph Banks and Dr. Solander, in their celebrated voyage. The flen is three or four feet high. Leaves very numerous, the length of the nail, evergreen, smooth, revolute. Flowers bright yellow. Catina five or flx inches long. Follicles abrupt, rough with rusty, deciduous hairs.

7. B. occidentalis. West-cofl Bankia. Ait. n. 6.—Leaves linear, with fparcaneous teeth beyond the middle; veinfet beneath. Scales of the catkin smooth at the extremity. Corolla withering; bearded internally at the bafe. Follicles tumid, downy; rather compressed and naked at the summit. Stem shrubby. Young branches smooth.—Found by Mr. Brown, in heathy ground, at Lewin's land.

8. B. littoralis. Sea-fide Bankia. Ait. n. 7.—Leaves linear, elongated, with fparcaneous teeth; veinfet beneath; tapering at the bafe. Corolla deciduous. Follicles compressed, downy at the summit, as well as the scales of the catkin. Stem arborescent. Young branches downy.—Found by Mr. Brown on the sandy shores of creeks in Lewin's land. The flowers were pale.

10. B. microlepsa. Cavan. Ic. v. 6. 28. t. 541. excluding the reference to B. dentata of Linkius!
Mr. Brown, but not in fruit, by the sea-side at Keppel Bay, on the east coast of New Holland. He signifies it to be a variety of the last.

17. B. coccinea. Scarlet-flowered Bankia. Ait. n. 11. — Leaves alternate, wedge-shaped-obovate or oblong, toothed, abrupt, ribbed, reticulated with veins; transverse at the base. Scales of the catkin awl-shaped. Corolla woolly. Stigma pyramidal.—Found by Mr. Brown in Lewin's land, in fields near the coast. It was sent to Kew, by Mr. Good, in 1803.

18. B. paludosa. Marsh Bankia. Ait. n. 12. — Leaves imperfectly whorled, wedge-shaped-oblong, somewhat abrupt; tapering at the base; slightly revolute; coarsely serrated beyond the middle; ribbed and reticulated with veins beneath. Footstalks and young branches smooth. Corolla silky. Stem shrubby.—Gathered by Mr. Brown, in marshy ground, near Port Jackson. It is said to flower in the green-house at Kew, from January to March.

19. B. oblongifolia. Oblong-leaved Bankia. Cavan. Ic. v. 6. 28. t. 342. Ait. n. 13. (B. fallax; Cavan. Ic. v. 6. 31.) — Leaves scattered, narrow-oblong, abruptly, narrowly serrated; rather acute at the base; ribbed, and reticulated with veins beneath. Footstalks and young branches reticulated. Larger scales of the catkin pointed. Corolla silky. Stem shrubby.—Observed by Mr. Brown on heaths near Port Jackson. The leaves, according to his observations, are sometimes entire, or nearly so, (as we judge in this case from the word integra,) and therefore may answer to the falsifolia of Cavanilles, of which it is difficult to judge precisely, for want of a figure.

20. B. latifolia. Broad-leaved Bankia. Br. n. 20. Ait. n. 14. (B. robur; Cavan. Ic. v. 6. 29. t. 343.) — Leaves obovate-oblong, with pinacious furrows; acute at the base; ribbed, reticulated, downy and grey beneath. Tube of the corolla silky; limb smooth. Stem shrubby.—Observed by Mr. Brown in boggy situations near Port Jackson; plentiful about the town of Sydney, where it rarely ripens seed. That accurate botanist informs us the stem is usually three or four feet high, scarcely ever five feet. Louis Née, from whom Cavanilles had his information, appears to have accidentally confounded his specimens of this species, with his memoranda relating to B. ferrata, and hence it is described of the fize of an Oak, to which the name robur alluding, was necessarily obliged to be changed.

21. B. marcescens. Short-leaved Bankia. Br. n. 21. Ait. n. 15. (B. prorsorsa; Andr. Repof. t. 258.) — Leaves wedge-shaped, flat, scattered, abrupt, narrowly serrated more than half way down; rather acute at the base. Branches downy. Corolla permanent, smooth as well as the follicles. — Native of the southerly coast of New Holland; at Lewin's land, near the shore. Mr. Andrews says this species was first raised from seed at Kew, in 1788. Mr. Brown and Mr. Aiton, on the contrary, mark it as introduced in 1794, by its first discoverer Mr. Menzies. The stem is six or seven feet high in the green-house. Leaves so abrupt, that we could almost have allowed the name prorsorsa to remain. Flowers purple, in large handomie catkins; infide of the corolla white.

22. B. attenuata. Smooth-flowered Bankia. Ait. n. 16. — Leaves elongated and nearly linear, abrupt; tapering at the base; serrated more than half way down; ribbed and reticulated, with downy interlaces, beneath. Scales of the catkin hairy at the summit. Corolla smooth. Follicles downy.—This also was discovered by Mr. Menzies, on the southern coast of New Holland; and seen by Mr. Brown in Lewin's land, near the sea-coast. It was raised at Kew, in 1794, but appears not yet to have flowered; nor have we heard of the plant elsewhere.

—Discovered by Mr. Brown, on the east coast of New Holland, by the sea-fide, at Sandy Cape.

24. B. ferrata. Great Serrated Bankia. Linn. Suppl. 126. Wild. n. 1. Ait. n. 17. Banks Ic. Ind. t. 2. White's Voy. 222. t. 18, 19, 20. Andr. Repof. t. 82. Cavan. Ic. v. 6. 27. t. 540. (B. conchifera; Garret. t. 48.) — Leaves linear-oblong, abrupt, rather bluntly serrated; reticulated and nearly smooth beneath; tapering at the base. Lower part of the style downy and powdery. Stigma cylindrical, furrowed; obliquely swelling at the base. Stem arborescent.—Native of the east coast of New Holland, at Port Jackson, in fields near the sea, from whence specimens were brought by Sir Joseph Banks; but the plant was first raised in England, by Melfla. Lee and Kennedy, in 1786. This is described as the most flatly of its genus, rising to the height of thirty feet, with a hard reddish wood. The leaves are near a span long, almost perfectly smooth on both sides, not so deeply serrated as in the figures of Andrews or Cavanilles, or in White's t. 20, but rather bordered with a series of rectangular bluntish notches. Catkins large, thick and heavy, of innumerable downy flowers, whole corolla purplish, and style crimson. Cone ten inches long, very heavy. Follicles downy, an inch in diameter. Gartner's figure is from a poor diminutive cone.

25. B. amala. Large-fruited Bankia. Br. n. 25. — Leaves linear-oblong, abrupt, deeply and sharply serrated; reticulated and nearly smooth beneath. Corolla silky. Stigma capitate, poliished, pyramidal, not furrowed, twice as thick as the Style. Stem shrubby.—Native of heaths, and sandy fields, near Port Jackson, from whence we have long ago received specimens, with full-grown fruit, by the kindness of Dr. White. We have been used to call this species B. macrocarpa, a name well expressing its singularly large follicles, which are twice the dimensions of the preceding, though the whole cone is usually much shorter. It is impossible to mistake Mr. Brown's faithful specific definition, especially the character of the short pyramidal stigma. The leaves are much smaller than those of B. ferrata, though their ramifications are much deeper and sharper. Hence Mr. Brown was led to apply t. 20 of White's Voyage to the present species, with which the leaves in that figure pretty nearly agree; but the cone certainly, to our knowledge, belongs to the ferrata, which it well expresses, except being too small. The ferratas in Mr. Andrews's plate of ferrata most nearly approach our present plant. The shape and proportion of the calyx moreover bell agrees herewith.

—Discovered by Sir Joseph Banks and Dr. Solander, near Endeavour river, in the tropical part of New Holland. Mr. Brown also met with this noble species, which as yet is a Stranger
stranger to our gardens, at Arnhem's land, on the northern coast. Of the height or size of the plant we are not informed. The branches are rusty and somewhat downy. Leaves alternate, from a span to a foot long, on short stalks; their margins remarkably undulated, and bordered with broad, shallow, spine-pointed teeth. *Caxina* fixes inches long, more slender than usual; their scales downy, the larger one to each pair of flowers spinous-pointed.

27. B. querulenta. Oak-leaved Bankia. *Ait.* n. 18.—Leaves oblong-wedge-shaped, rather abrupt, smooth, deeply serrated, pointed. Segments of the corolla awned. Flowers nearly smooth.—Found by Mr. Brown, in fields near the fiery land. The awns of the corolla are indicated by him as a very remarkable character.

28. B. speciosa. Long-leaved Bankia. *Ait.* n. 19.—Leaves linear, pinnatifid; lobes triangular-halfovate, pointed, snow-white and lightly ribbed beneath. Limb of the corolla woolly. Style rather hairy. Follicles downy.—Native of the rocky sea-shore of Lewin's land, where it was found by Mr. Brown, and sent to Kew, with the leaf, in 1805.

29. B. grandis. Great Winged Bankia. *Willd.* n. 2. *Br.* n. 29. *Ait.* n. 20.—Leaves deeply pinnatifid; lobes triangular-ovate, acute, flat; many-ribbed, and nearly smooth, beneath. Corolla and follicles smooth.—Gathered by Mr. Menzies, at King George's found, on the west coast of New Holland. Mr. Brown met with the fame on rocky hills in Lewin's land. Seeds were sent to Kew in 1794, where this magnificent shrub thrives well, in the green-house, but has not yet flowered. Willdenow's specific name aludes, we presume, to the foliage, and not to the flowers, with which he was not acquainted. The leaves are twelve or fourteen inches long, pinnatifid to the very rib; abrupt at the extremity; lobes numerous, more or less alternate, crowded, transverse, coriaceous, entire, rather spinous-pointed; roughish to the touch on the upper side; paler underneath, furnished with five principal ribs, and many intermediate vein reticulations; they diminish gradually towards the top, and especially towards the base, of the leaf. We have seen no flowers nor fruit.

30. B. repens. Creeping Bankia. *Labill.* *Voy.* v. 1. 412. t. 23. *Br.* n. 30. *Ait.* n. 21.—Leaves pinnatifid; leaves fruticose or toothed. Stem prostrate.—Found by Labillardiere, on calcareous rocks on the south-west coast of New Holland, where also Mr. Brown met with this species. It flowers there in December. The creeping *hem* is clothed with rusty down. Leaves a span long, falked, erect, deeply pinnatifid, but not quite to the rib, which is winged nearly all its length: they are downy when young, but finally very smooth. *Caxina* ovate, nearly fiddle, erect, dense, many-flowered, about three inches long. *Corolla* and *german* hairy.

Sec. 2. Points of the corolla more freely separating; the narrow part of their segments coloring longitudinally, and as long as the style. *Caxina* short and level-topped, perfecting fearemly more than one vertical follicle.

31. B. ilexifolia. Holly-leaved Bankia. *Br.* n. 31.—Leaves wedge-shaped, deeply serrated; nearly smooth beneath. *Caxina* very short.—Gathered by Mr. Brown, in fields and hilly ground near the seas-coast, in Lewin's land. This species is so singular, that its learned discoverer appears to have been inclined to make it a distinct genus, by the name of *Ixiylolis*. He remarks that it forms a connecting link between *Bankia* and *Dynandra*; see the latter hereafter.

BANNUM, in *Ancient Geography*, a Roman station, called Gaer, or Caer Bannau, situated about three miles above the town of Brecon, in South Wales, near the confluence of the rivers Yakin and Ufs. The camp is a parallelogram, 624 feet by 456, having its longest parallels in a direction nearly S. and N. The foundation of the wall that encompassed this area remains still entire, and may be traced through the underwood that has overgrown and concealed it. In this situation there is a caledum, supposed to have been a branch of the great Roman caledum leading from Caerleon, in Monmouthshire, through the vale of Usk, and the eastern part of Brecknockshire to Ariconium, which is the 12th Iter in Antonine's Itinerary.
flouring in July. The whole plant is very smooth, fearlessly glaucous, two or three feet high, distingued by its perfoliate, almost orbicular leaves, about two inches broad, accompanied by lemon-coloured flowers, on short simple stalks. *Leuca* nearly globular.

2. B. *australis*. Downy Single-flowered Wild Indigo. (Podalyria uniflora; Michaux Boreal.-Am. v. 1. 263. Pursh n. 2. Sophora lanceolata; Walt. Carol. 135.)—Leaves ternate, feville, downy; leaflets lanceolate, obtuse. Stipulas bristle-shaped, minute. Flowers axillary, solitary. —Observed by Michaux in Carolina and Georgia. The whole herbage is downy, as well as the *calyx*. Flowers yellow. *Michaux*.

5. B. *alba*. White-flowered Wild Indigo. Ait. n. 4. (Podalyria alba; Wildl. Sp. Pl. v. 2. 503. Mich. ibid. 264. Pursh n. 5. Curt. Mag. t. 1177. Sophora alba; Linn. Syll. Veg. ed. 13. 325. Crotalaria alba; Linn. Sp. Pl. 1806. Anonis caroliniana perennis; non linnaeus, &c. Mart. Cent. t. 44.)—Leaves ternate, flanked, smooth; leaflets elliptic-oblong. *Stipulas* awl-shaped, shorter than the *footstalk*, deciduous. *Germes* smooth. —In the western parts of Virginia and Carolina, on the banks of rivers, flowering in June and July. *Pursh*. Hardy in our gardens, but not of frequent occurrence. Cateby first introduced it in 1724. The habit of this species, its smoothness, and rather glaucous hue, agree with the leaf, to which it is certainly most nearly allied; but the leaflets are elliptical, the flowers white, more oblong, in confinement of the greater length of the wings and keel, the *sepals* smaller and deciduous. *Podalyria* is here and there spotted with brown, and is reported to be sometimes blue. Some of the *flowers*, in both these species, are often whorled, and give the *cluster* an interrupted form, like that of a Lupine, the aspect of which genus is otherwise visible in these plants.

7. B. *tintoria*. Common Wild Indigo. Ait. n. 3. (Podalyria tintoria; Wildl. Sp. Pl. v. 2. 503. Mich. ibid. 265. Pursh n. 7. Lamarck f. 1. Curt. Mag. t. 1099. Sophora tinctoria; Linn. Sp. Pl. 524. Cytisus procumbens americana, flore luteo, ramofofolium, qui Anil luppeditat apud Barbadianum colonos; Pluk. Phyf. t. 86. f. 2.)—Leaves ternate, somewhat flanked, smooth; leaflets roundish-ovate. Stipulas petaceous, obfolete. Flowers racemose.—In woods on dry hills, from Canada to Carolina, flowering in July and August. Called Wild Indigo. *Pursh*. A low, partly procumbent, smooth plant, whole numerous branches are each terminated by a simple cluster of yellow flowers, about half the size of *B. auffratis*. The pods are ovate, on flanks much longer than the permanent *calyx*. This species is said to have been cultivated for Indigo, in the North American settlements, and even in Barbadoes, before the true *Indigofera* was introduced. It is tolerably hardy with us, in a dry soil and sheltered situation, but has nothing to recommend it for general cultivation.

BAR, in *Heraldry*, r. *Plate III.*

BAR, *Trial at*. See JURY.

BARACKS, col. 2, add—See CASENS.

BARAQUICIMITO, del. lat. and long., and—See BARGESMETO.

BARBAREA, in Botany, a name used by Dodoens, because this plant had been called the Herb of St. Barbara by some preceding botanists. It has always been referred to *Podalyria* (see that article) till Mr. Brown raised it to the rank of a separate genus, under the abope appellation, in *Ait. Hort. Kew.* v. 3. 109.—Clafs and order, *Tetradaemia Silicius*. Nat. Ord. Silicrices, Linn. Cruifereae, Jull. Eff. Ch. Pod quadrangular, comprofet. Cytaldeons acumbent. Seeds in a single row. *Calyx* erect. Glands between the shorter flaments and the germen.

Two species only are described.

2. B. *praecoxyx*. See the same article, n. 3.

Mr. Brown thus defines Erysimum.

We have explained the terms *acumbent* and *incumbent*, as thus technically used, under the article *Tetradaemia*, where a more particular account is given of our ingenious friend'aarduous undertaking, of reforming the genera of the natural order in question.

BARBAREEN. See CALTURA.

BARBET, in *Fortification*. See BATTERY.

BARBOURSVILLE, in Geography, a town of Kentucky, in Knox county, containing 55 inhabitants, eight of whom are slaves.

BARBULA, in *Botany*, so called by Hedwig, in allusion to the beard-like fringes of the *capsules*. See Tortula.

BARDSTOWN. Add—See BARDSTOWN.

BARQUISIMETO, in Geography, a city of America, in the government of Caraccas, 40 leagues W.S.W. of Caraccas, 150 leagues N.N.E. of Santa Fé, and 15 leagues from Tocuyo. N. lat. 9° 45'. The exellent heat is rendered intolerable by the cooling breeze arising from its elevated situation. The adjacent plains are covered with excellent pasturage favourable for rearing every marketable animal. The sugar-cane and the bell wheat are also cultivated. The vales produce excellent cacao; and the sides of the hills are devoted to the culture of coffee. This city accommodates 11,300 persons; its houses are well built, and the streets are so laid out as to afford a free circulation of air. It has a parish-church and two officiating priests, a monastery of Franciscans, and a hospital badly attended.

BARRE', a township of America, l. 2, r. 1671; l. 11, add—having 1553 inhabitants.—Algo, a town of Vermont, in Orange county, having 1606 inhabitants.

BARREL. By 43 Geo. III. c. 69, every 36 gallons of beer or ale brewed by the common brewers in Great Britain, taken according to the standard of the ale quart, four thereof to the gallon, in the excise, shall be reckoned by the gauger or other officer of excise for a barrel of beer or ale.

Barrel, a weight by which corn is sold in Ireland. The barrel of wheat, peas, beans, and rye, is 20 flask; of barley, bere, and rape-seed, 16 flask; of oats 14, and in some places 12 flask; of malt, 12 flask; the flask being 14 lbs. avoid any poison weight. A barrel of good wheat anwers to about four Winchester butheus.

BARREN FLOWERS, in Botany and Vegetable Physiology, Florea aestivata in Linnean terminology, are such as are not provided with organs for the formation of fruit or seed, but only with flaments for its impregnation. See Fecundation of Plants.

BARRIER, in Fortification. Add—See Cheval de Frise, Herndon, Klinksets, and Turnstile.

BARRILE, or Barrill, a liquor measure in Italy.

BARRIN, in Geography, a county of the district of Kentucky, containing 11,642 inhabitants, of whom 1565 are slaves. The town, Glodgart, has 244 inhabitants, of whom 68 are slaves.

BARRINGTON, a township in Strafford county, &c. l. 3, for 2470 r. 3564. Id. l. 5, for 683 r. 604. Id. l. 2, for 1773 r. 1784.

BARRIQUE, a measure for wine and brandy in some parts of France, as at Bourdeaux, Rochelle, &c. At Bourdeaux, a tonneau of wine contains 4 barriques or hogsheads = 50 fleskins in Amsterdam, 250 flotten in Hamburg, or 243 English gallons; and weighs with the wood about 2000 lbs. of Bourdeaux. The barrique contains 110 pots, or 32 vels.

BARRY-BENDY, &c. Plate III. Heraldry, &c.

BART, in Lancaster county, add—It contains 1099 inhabitants.

BARTHELEY, a river of Louisiana, which rises near the Arkansas, and after a course generally from N. to S. of 110 miles, falls into Ouachita, 3 miles below the Derbain, on the contrary side.

BARTHOLINA, in Botany, a genus of the Orchis family established by Mr. Brown, and dedicated to him by the memory of the great Danish anatomist and phytopholist, Thomas Bartholin, whose life is already given in its proper place, and whose various writings relating to plants, in the old Copenhagen Transact, entitle us to add the history of our science with his truly illustrious name.—Brown in Ait. Hort. Kew. v. 5. 194.—Clasfs and order, Gynandria Monotypiina. Nat. Ord. Orchides.

Gen. Ch. Col. Perianth superior, of one leaf, tubular at the base, deeply divided above into three, elliptic-oblong, equal, ribbed, spreading segments, externally hairy. Cor. Petals two, linear-lanceolate, erect, smooth, taper-pointed, nearly twice the length of the calyx. Nectary a large spreading lip, united to the base of the petals, thrice the length of the calyx, in three deep principal lobes, the middle one broadest, all divided, more than half way down, into many linear, fringe-like segments, and terminating behind in a tumid, curved, bluntly-pointed spur, rather longer than the tube of the calyx. Stam. Anther pointed, of two obovate, rather dilatate, parallel cells, opening in front, attached to the two margins of the style; masses of pollen each supported on a long, membranous-bordered stalk, to which their cells are laterally attached, "their glands distinct, half covered by the exterior lobe." Pip. Germen inferior, elliptic-oblong, curved, very hairy; style flattened, much shorter than the calyx; stigma a cavity between the lobes of the author. Peric. Capsule... Enl. Ch. Calyx tubular at the base. Petals united to the base of the lip, whose spur is shorter than the germen. Stalks of the pollen elongated; their cells laterally fixed; glands distinct, half covered by the exterior lobe.

O. pedicata. Fringed Bartholina. Ait. n. 1. (Orchis Barlanamiann.) Linn. Sp. Pl. 1354. Am. Acad. v. 6. 108. "Swartz in Web. and Mohr Archiv. v. 1. 55. t. 3." O. pedicata; Thumb. Prod. 4. Fl. Cap. v. 14. 453. Willd. Sp. Pl. v. 4. 11. Arethusa ciliaris; Linn. Suppl. 405.—Gathered by Thunberg and Sparmann, on the hills of hills at the Cape of Good Hope, in Roode Sand, as well as near Cape Town, flowering from October to December. The root consists of two ovate hairy knobs, the size of a liofe-bean. Leaf solitary, radical, orbicular, clasping the flower-flask, an inch broad, horizontal, festu; smooth, and of a fine green, on the upper side; paler and veiny beneath; the margin reflexed, and very densely fringed. Flower-flask solitary, simple, single-flowered, five or six inches high, erect, hairy, with a solitary, tubular, fringed, hairy bracteal, half an inch long, near the top. Flower large, of a very flagellate aspect. Calyx green, converging, strongly ribbed, and externally hairy, near an inch long, its tube included. Petals white, with a blue mid-rib, and a thread of the same colour in their lower part. Lip two inches in length and breadth, spreading, finely cut; its segments white above, blue underneath, the throat dotted and minutely fringed with
We have seen no specimens, and have scarce sufficient materials for drawing up a full generic character.

Eight species are described in Engl. Bot. and Compend. Fl. Brit., and there are several of exotic growth.

**sect. 1. Fruit-flalks shorter than the flm.**

1. B. Hallertana. Lateral Bartramia. Hedw. Crypt. v. 2. 111. t. 40. Engl. Bot. t. 997. Hook. and Tayl. n. 5. t. 23. (Bryum laterale; Hedl. 483. Ehrh. Crypt. 33. B. n. 1802; Hall. Hist. v. 5. 45. t. 46. f. 5.)—Fruit-flalks curved, shorter than the linear-awl-shaped, fingle-ribbed, rough-edged leaves.—Native of moit rocky mountainous woods, in Switzerland, Germany, Scotland, Wales, and the north of England. The flavem are, as Mr. Hooker observes, perennial, and repeatedly profliferous, so that, although the flowers are, like every Bartramia, originally terminal, the fruit soon becomes lateral, and remaining two or three years, is found numerousy ranged along the main stem, among the denfe, flever leaves. When ripe it becomes strongly furrowed, though originally smooth or even.

2. B. arcuata. Curve-flalked Bartramia. Engl. Bot. t. 1257. Fl. Brit. n. 5. Hook. and Tayl. n. 6. t. 23. (Munium arcuatum; Dickf. Crypt. falc. 3. t. 7. f. 3. M. chrylocomum; Hedw. Sp. Mufc. 74. Hypnum palfiurem, comà luteà, bafi nigricante; Dill. Mufc. 362. t. 39. f. 36.)—Fruit-flalks recurved. Leaves lanceolate, fingle-ribbed, furrowed, finely ferrated. Branches frondently spreading.—Native of mountains in Great Britain and Ireland. According to Mr. Hooker, it is found, in the greatest abundance, on wet rocks, at Lowdore and Keswick, Cumberland, and is also very common in the mountainous districts of Ireland, though unknown on the continent of Europe. With all deference to our worthy friend however, the ripe capfule is as decidedly furrowed as in any other species. The more branched and tufted habit of this mof, and the broader, shorter, rigid, yellowish, more spreading leaves, at once diftinguifh it from the foregoing. The fruit-flalks soon become lateral, and are very rather than recurved, longer than in the preceding. Mouth of the capfule small, with a red outer fringe; whole teeth are lined, as it were, with the fixteen oppofite teeth of the inner one.

**sect. 2. Fruit-flalks rising above the flm.**

with blue. Spur greenish-white. Mufles of pollen, (which Linneaus in the Supplement has described as a pair of ftyles,) inferted into the bafe of the ftyle, yellowish, prominent, very conflpicious even in dried specimens.

**Bartlet,** a town of America, in Coos, &c. r. 436.

**Barton,** in Orleans county, &c. add—It contains 447 inhabitants.

**Barton-upon-Humber,** l. ult. for 412 r. 191—for 1709 r. 1129. The parish of Barton, St. Mary, has 209 houses and 976 ferefs; and the parish of St. Peter has 266 houses, and 1228 ferefs.

**Baronia,** in Botany, received that name from Dr. Sims, in 1812, in juft commoration of the scientific merits and zeal of Dr. Benjamin Smith Barton, at that time professor of botany and natural history, in the university of Pennsylvania, who after many exertions, and several publications, in the service of national science, died of hydrophobia, at Philadelphia, on the 19th of December 1815, in the fiftteenth year of his age. His nephew, Dr. William Barton, in an animated and interesting "Biographical Sketch" of his charafter and pursuits, has preferved some account of the plants which compofe this genus, written by the late professor, three or four days before his death, and accompanied by many particulars, relative to Mr. Pursh and Mr. Nuttall, through whose means it has come to the knowledge of European botanists; all which evince a love of science, that the molt painful bodily fufferings could not repreft.—Sims in Curt. Mag. 1487. Purh. 327. Ait. Epit. 364.—Clasfs and order, Iofandria Monogynia. Nat. Ord. Lofeae, Juff. Ann. du Muf. d'Hift. Nat. v. 5. 18. Sims.

Eff. Ch. Calyx superior, in five deep segments. Corolla of many petals, with claws. Stamens uniform. Capfule cylindrical, of one cell, with a lid of three or five valves, and as many parietal receptacles. Seeds numerous, flat, and numerous, in double rows.

1. B. ornata. Large-flowered Bartramia. Purh. n. 1. Ait. n. 1. (B. decapetala; Sims as above, t. 1487.)—Germem leafy. Seeds without a wing.—Found by governor Lewis, in 1804, on chalky foil on the borders of the Mifouri, flowering in July and August. Purfth. Professor Barton records that Mr. Nuttall firft made this fine plant known to him in 1811, having found it growing all the way from the river Platte to the Andes, on broken hills and in the clefts of rocks. Mr. Purth by miftake, as the professor thought, speaks of the foil as volcanic. Living plants were brought to England by Mr. Nuttall, who is unquestionably entitled to the honour of this discovery, as they were not known what might be concealed in the herbarium of any deceafed traveller. The figure in the Magazine, though taken from a dried specimen, is unexceptionable, as far as it goes. The herb is biennial, downy, glaucous, about three feet high. Leaves alternate, fefile, oblong, pinnatifid. Flowers terminal, enveloped in leaves, three inches broad, with about ten elliptical, acute, white petals, and numerous flamas, half as long, whose anthers are elliptical, yellowish. These flowers expand suddenly in an evening, diffusing a moft agreeable odour, and rivef the fome of one of the fine species of Caftus in elegance.

2. B. nuda. Small-flowered Bartramia. Purh. n. 2. Ait. n. 2.—Germem naked. Seeds winged.—Found by Mr. Nuttall, on gravelly hills near the Grand Detour of the Mififiippi, flowering in August. Root perennai. Petals more numerous. Barton. Mr. Purth obferves that this has smaller flowers than the foregoing, and leaff glutenous leaves.

The petals vary in number, from ten to fifteen.
BARTRAMIA.

from one to three inches in height, clothed and matted together below with copious brown fibres. Leaves bright green, slender, gradually tapering from their base; strongly ferrated towards the point; somewhat twisted and curbed by drying. Fruit-flasks near the tops of the stems, about an inch long, bright orange-red, thinly wavy. Capsule globose, green and smooth while young; more elliptical when ripe, often brown. In six funnies. Lid rather convex, bored. Fringe short, red. Vell conical, curved, split half way up on one side.

4. B. cripta. Frizzled Bartramia. Swartz Mefc. Suec. 73. Turn. in Ann. of Bot. v. 1. 527. Winch Guide v. 2. 16. "Bridel. Mufc. v. 2. 3. t. 1. f. 4. Schwagr. Suppl. t. 59." Sm. Compend. n. 3. Engl. Bot. t. 1526. (B. poniformis $; Turn. in Ann. of Bot. v. 1. 527. Hook. and Tayl. n. 1. B.)—Fruit-flasks erect. Leaves brittle-shaped; dilated at the base; incurved and curled when dry. Lid slightly conical. Native of mountainous situations in Britain, and other parts of Europe. Larger in its stems and foliage than the preceding, the leaves of a lighter brighter green, longer, and more slender, except at the very base, and when dry to strongly curled, twisted, and involute, as to give the plant a very different aspect. The intelligent authors of the Muscolgia Britannica therefore judge this to be but a variety of the poniformis, and they unite it with Mr. Turner's supposed variety of that species, which he distinguishes from cripta, and which he has thought to be figured for cripta, in Engl. Bot. t. 1526. We acknowledged that figure to be not a very happy one, except the lid, which seems to us always rather more conical than in poniformis.

5. B. ityphylla. Straight-leaved Bartramia. Bridel. Mufc. v. 4. 132. t. 1. f. 6. Sm. Compend. n. 4. Engl. Bot. t. 1710. Winch Guide v. 2. 17. Hook. and Tayl. n. 2. t. 23.—Fruit-flasks elongated, erect. Leaves capillary, nearly entire, single-ribbed half way up; dilated at the base; straight when dry.—Found on dry banks, in the mountainous parts of Germany, Sweden, England, and Wales. The long, very slender, light-green leaves are only ferrated at the very point, and are remarkable for remaining always straight when dry, which Mr. Hooker has well attributed to the whole sufflacence of the mid-rib being dilated and lost in the upper half of the leaf, to which it consequently gives firmness. The capsule is much curved; their flutes longer than in the foregoing. The dilated base of each leaf is singularly membranous and thinning.

6. B. gracilis. Tall Slender Bartramia. Flörke in Schrad. Journ. v. 2. 171. Fl. Brit. n. 3. Engl. Bot. t. 1826. Hook. and Tayl. n. 3. (B. Oederi; Schwagr. Suppl. t. 59, as also, according to Mr. Hooker, B. grandiflora, t. 58. Bryum Oederi; Retz. Prodr. 261. Fl. Dan. t. 478.)—Fruit-flasks from lateral branches, taller than the stems. Leaves lanceolate, ferrated towards the point; recurved and twirled when dry.—Native of the lofty Scotch mountains, as well as of the north of Europe. The stems are two or three inches high. Leaf broader than in any of the three preceding species, somewhat revolute at the margin, especially when dry, in which state they become recurved, and not curled inwards. Their colour is a darkish grafs-green. Capsule small, from short lateral floutes.

7. B. jiluvnna. Spreading-leaved Bartramia. Turn. in Ann. of Bot. v. 1. 528. t. 11. f. 2.—Fruit-flasks lateral, taller than the stems. Leaves awl-shaped, entire; single-ribbed at the base; spreading and straight when dry.—Received from Java by Mr. Dickfon. Gathered by Conmerton, at the straits of Magellan. The tufted leafy

fleins, shaggy with ruffy fibres, and scarcely branched, are two or three inches high. Leaves slender, yellowish-green, longer than any of the preceding, except perhaps B. Helvetiana, and always quite straight, probably from the same cause as in ityphylla, the rib being soon lost in the sufflacence of the leaf. Fruit-flasks straight, erect. Capsule curved, strongly furrowed. Lid convex, blunt.

8. B. Menziesi. Tall Forked Bartramia. Turn. ibid. 525. t. 11. f. 1.—Fruit-flaks slightly elevated above the tall forked stems. Leaves lanceolate, single-ribbed, taper-pointed, entire; close-preferred when dry. Capsule nearly globular, with shallow furrows.—Gathered on the north-west coast of America, by Mr. Menzies. The tall slender stems, covered with close-preferred, tawny, shining leaves, half the length of the leaf, clearly distinguishes this species. The capsules are scarcely curved, even when fully ripe, and their surface is wrinkled as well as finely furrowed.

9. B. fberocarpa. Globose Bartramia. Hedw. Crypt. v. 3. 93. t. 38 A. Turn. as above, 525. (Minium sphacarianon; Swartz Prodr. 139, from the author.)—Fruit-flaks taller than the slender clustered branches. Leaves lanceolate-awhitched, close-preferred, finely ferrated. Native of Jamaica. Swartz. The slender stems are determinately branched, as in the following, to which this species is very nearly allied; though smaller, with longer branches. In the leaves, though ufuallu narrower, we scarcely find a permanent difference. Hedwigs figure erroneously omits the furrows of the capsule.

10. B. marlhor. Narrow-leaved Bolg Bartramia. Web. and Mohr Ind. 5. Sm. Compend. n. 7. Engl. Bot. t. 2074. (B. fontana $; Hook. and Tayl. n. 4. Turn. Mufc. Hib. 107. t. 10. f. 1. Minium marlehor; Hedw. Crypt. v. 108. t. 39.)—Fruit-flaks elongated, much taller than the clustered branches. Leaves lanceolate, finely ferrated at the point, close-preferred. Native of wet situations in Germany, the Highlands of Scotland, and the mountains of Nepal, for Mr. Hooker affires us his B. fontana, Tr. of Linn. Soc. v. 9. 317, is this plant. He is also of opinion that B. marlhor is merely a lanceolate-leaved variety of the following.

11. B. fontana. Broad-leaved Fountain Bartramia. Fl. Brit. n. 4. Turn. Mufc. Hib. 107. Hook. and Tayl. n. 4. t. 23. (Minium fontanaum; Linn. Sp. Pl. 1574. Hedw. Sp. Mufc. 193. Bryum fontanaum; Engl. Bot. t. 390. B. palafcre, foacis terretivs flittis, capulis magnis subrotundis; Dill. Mufc. 340. t. 44. f. 2.)—Fruit-flaks elongated, much taller than the clustered branches. Leaves ovate, finely ferrated at the point, close-preferred. Native of pongo bios throughout Europe, and perhaps in other parts of the world. It is one of our handfomefl and largefl mosses, bearing capsules in fpring and summer. The barren flowers form terminal leafy flars, on a separate plant from the capsule, whose flarks are two or three inches long, rifing high above the tuft of leafy branches, which have overtopped the originally terminal fufflacence of their flowers. Capsule brown, with a minute sharp braek to the lid. Leaves ufuallu direct, broadly ovate, entire at the edges, the point only being ferrated. They appear at first light very different from the lanceolate narrow shape of the leaf, and still more from the curved taper-points of Mr. Hooker's B. falvata, Tr. of Linn. Soc. v. 9. 317. t. 27. f. 4, which he is difposed to reduce to the fontana, having found the latter in Switzerland with leaves as decidedly curved. We cannot diptute his accuracy of obervation and judgment in this point; nor are we much disposed to question his further opinion, that Hedwigs fberocarpa, our n. 9, as well as ffabrida
BAR

fabriu.s Mublusbegii, (of which we have specimens from its
finder,) and radicans of Schwgrichen’s Supplement, may
possibly be likewise varieties of B. fontana.

BARYTES, in Chemistry, one of the earthy substances
termed alkalis. We stated that this earth was considered
by Bergman, Lavoisier, and other eminent chemists, as a
refractory metallic oxyd; and this supposition has been
since confirmed by the experiments of Berzelius and Pontin,
who, led by Sir H. Davy’s decomposition of potash and
foda by galvanism, subjected this earth to the same agent.
Their experiments were attended with complete success,
and have since verified by Sir H. Davy and other
chemists. To this metallic basis, Davy gave the name of
barium. More lately, Dr. Clarke of Cambridge thought
he had decomposed this earth by exposing it to an intense
heat, produced by the combustion of a stream of oxygen
and hydrogen gas, mixed together in the requisite propor-
tions to form water. To the metal thus obtained, he
proposed to give the name of platonium. Many chemists, how-
ever, think, that Dr. Clarke from some cause or other per-
mitted himself to be deceived in these experiments, and that
instead of a metal he only obtained a flag with a pseudo-
metallic surface.

Barium obtained by galvanic agency is a solid metal of
the colour of silver. It melts at a temperature below
redness, and is not volatilized by a heat capable of melting
plate-glass; but at that temperature it acts violently on
the glass, probably by decomposing the alkali of the glass,
and converting it into a protoxyd. When exposed to the
air, it rapidly tarnishes, absorbs oxygen, and is converted
into barytes. It sinks readily in water, and seems to be at
least four or five times heavier than that fluid. It decom-
poses water very rapidly. Hydrogen is emitted, and the
barium is converted into barytes. Barium seems to be
both ductile and malleable.

Barium, according to the experiments of Gay Lussac
and Thenard, combines with two proportions of oxygen.
The protoxyd is the earth called barytes. No direct
experiments have been made to ascertain the proportion of
oxygen it contains; but this may be determined by other
means. Thus, sulphate of barytes is composed of

| Sulphuric acid | - | - | 100 |
| Barytes | - | - | 194 |

and carbonate of barytes of

| Carbonic acid | - | - | 100 |
| Barytes | - | - | 354-54 |

Hence it may be easily ascertained by calculation, that
the equivalent number for barytes is 97-5; oxygen being 10;
and if we consider this earth as a protoxyd, the number
for barium will of course be 97-5 - 10 = 87-5. Hence
one hundred parts of barytes consist of

| Barium | - | - | 89-74 |
| Oxygen | - | - | 10-26 |

Gay Lussac and Thenard found, that when dry barium,
from nitrate of barytes, or from the carbonate of barytes
decomposed by charcoal, was heated in oxygen gas, it
absorbed that gas with great rapidity. The peroxoxyd
formed was grey. It gave out its excess of oxygen, when
put into water. When heated in hydrogen gas, the hydro-
gen was absorbed, and water was formed, which remained
united to the barytes.

The facts of barytes are described under SALTS. The
equivalent numbers of these, however, require a little cor-
rection; for which purpose, we refer our readers to the
article ATOMIC Theory, where the latest determinations
will be found.

The muriate of barytes (see SALTS) has been employed
as a medicine in febrile and cancerous cases. Although
it has been accounted highly poisonous, Dr.
Johnstone, in his “Effay on Poisons,” says, that he
has seen a female take 30 drops of a saturated solution
of muriate of barytes repeatedly in the course of a day,
without even nausea; and he concludes, that it would
require at least two or three drachms to do mischief.
Barytes is capable of making a very tenacious cement,
but it has been yet much used in the arts, except by
limeers, as a most excellent water-colour. Mr. Hume,
says Mr. Parkes (Chem. Catech.), many years ago dis-
covered the method of making a colour from this earth.
It is the only white for water-painting that never changes.
It has another peculiar advantage, that it may be mixed
with any other colour without injury. It is sold under
the name of “Hume’s permanent White.” See WHITE.

BARYTES, Carbonate of. See CARBONATE of Ba-
ytes.

BASALT, in Mineralogy and Geology, a compact dark-
coloured rock, clasped by geologists with trap-rocks. (See
TRAP.) It has received the name of whin-stone in the
north of England (see WHIN-STONE) and in Staffordshire,
Rowley-rag (see ROWLEY-RAG). In the arrangement
of rocks by the Wernerian geologists, basalt is considered
as a compact green-stone, which latter rock is composed
of felspar and hornblende; but green-stone being more crys-
talline, the constituent parts are distinctly separated. Green-
stone and basalt often pass into each other. (See GREEN-
Stone, Addenda.) Basalt has generally been clasped with
simple minerals; and a short account of its characters and
concurrent parts are given under the article BASALT
(which see). More correct analyses of this rock have since
been made, in which fosa is found to be a concurrent part.
We greatly doubt the propriety of calling basalt with
simple minerals; for it has been ascertained, that most ba-
ftaltic rocks are composed of two or more minerals inti-
mately mixed, but requiring the aid of a lens to distinguish
them. Of these, the mineral called augit is the one which
prevails, or forms the dark colour; it is intermixed with
felspar and olivine. It is thus ascertained that basalt ref-
embles in its constituent parts, as it does in other characters,
dark compaét lava. (See VOLCANIC Products.) Before
the observations of the French mineralogist Cordier, both
basalt and compact dark lava were supposed to be formed
of hornblende and felspar.

Before the blow-pipe, basalt melts easily, without addition,
into an opaque black-coloured glass. It melts at a com-
parative low degree of temperature from 38° to 45° of
Wedgwood. If it be cooled rapidly, the mass is vitrified;
if cooled slowly, it is fleshy, and presents a tendency to a
columnar arrangement. Some interesting experiments of
this kind are described under the article ROWLEY-RAG
(which see).

The constituent parts of basalt, as given by Klapproth
and Dr. Kennedy, are as follow:

Basalt
RASALT.

Bafalt exists abundantly in the northern parts of England and in Scotland. It occurs at the Clea Hills in Shropshire, and at Rowley in Staffordshire; but is not met with in the southern counties of England. Some rocks of the trap or basaltic formation occur in Gloucestershire and Somersetshire. Bafalt forms the well-known columnar ranges at the Giant's Caufeway in the county of Antrim, and at Staffa. See Giant's Caufeway and Staffa.

The origin of basaltic rocks has excited much attention among geologists. Their similarity to volcanic rocks in composition and structure, the remarkable positions in which they occur, and the changes they frequently produce on the rocks in their vicinity, have led most intelligent and unprejudiced observers to the conclusion, that a great number, if not all, basaltic rocks have been formed by igneous fusion. The mineral veins filled with bafalt, that intersect other rocks, frequently produce all the changes which a fluid mass of heated lava would have effected. (See Veins, Mineral, and Trap.) In the latter article, the arguments which have been offered against the igneous origin of basalt are also stated. For further remarks on the subject, see Systems of Geology. But the most striking phenomena, and which seem to decide the question, are presented in the districts called Velay and Viverais, in the south of France. These districts have all the appearance of having been once the seats of active volcanoes, the remains of which are distinctly visible: from some of these ancient volcanoes, the lava may be traced to the crater, and this lava is a compact columnar basalt. See Plate II. Mineralogy, Bafalt.

The mountain of Aifa, called La Coupe, or the Col d'Aifa, of which a view is given, is situated near the village Entraigue, in the Viverais. This village, according to St. Fond, is placed on a kind of platform of volcanic matter above the torrent of the Volant, which has here excavated a bed of great depth and width, bordered on the right and left by grand ranges of basaltic columns. In the midst of a prodigious rampart of these columns, at different levels, may be seen a current of lava descending from a neighbouring mountain, and joining the columns that border the river. Here we see, in the most unequivocal and convincing manner, that the lava under the form of hard and compact basalt, has flowed at several times from the mountain, and has formed the great caufeway at different heights, to which the lava is still united and adhering. We may follow the current of basalt up the declivity of the mountain, which has a conical form and a great elevation, and is entirely volcanic from the base to the summit. According to St. Fond, it is the most remarkable and best characterized crater in all the Viverais.

All the base of the conical mountain La Coupe is covered by porous and cellular lava in detached irregular masses, heaped on each other, so as to leave no doubt that they have been ejected in a liquid state by one or more formidable eruptions, and have taken their forms as they fell at the foot of the cone.

On reaching the summit or edge of the crater we may see the whole mountain, which forms a regular cone resembling that of Vesuvius. The edges of the crater are steep, and formed in the shape of a tunnel; the greatest diameter being from 140 to 150 toises, and the depth about 600 feet. The lavas are coloured, and converted into a kind of puzzolani, and mixed with great masses of black and sharp fumarites, which makes the defunct difficult. At the foot of this inverted cone is a magnificent plantation of chefmont-trees, which have flourished astonishingly in this ancient mouth of a volcano, having no other foil than the dry and friable puzziolani. It may be noticed, that the crater of Vesuvius was lined with lofty trees at the period of its eruption in 1631, having been in a state of repose for nearly four hundred years.

At the bottom of the crater in La Coupe, we may observe a breach or opening on the side facing the houles of the Collet d'Aifa; there is a general inclination to this opening, which has served to give a passage to the lava. When we are arrived at the opening, we may observe a flood of lava coming from the interior, and taking its course down the mountain, it descends in a waving direction amidst the porous lavas. This current is a true black basalt, compact and similar to that of the columns; in certain parts, its surface appears blistered, and in other places is become porous. Following the current of lava, after it has crossed the path, which is at the foot of the mountain, we may trace its course to the bed of a torrent not far from the high road. There may be seen, says St. Fond, a spectacle most gratifying to the geologist; for the lava, whilst still on the defunct, and before it had reached the level ground, has affected a prismatic form; and the lava at the bottom has formed a beautiful colonnade.

We cannot doubt, says St. Fond, after viewing this mountain, that the lava which flows from volcanic craters is not absolutely the same as basalt. The name of La Coupe is evidently derived from the crater, the Latin name for a cup.

There is another conical mountain in the Viverais with a distinct crater, called La Coupe de Jaugay. The general resemblance of the latter is so similar to that of La Collet d'Aifa, that it may well be conceived from the view given of the latter. (See Plate II. Mineralogy.) It is rather less lofty, but the crater is nearly twice as large. The river Vignon flows at the foot of Jaugay. On its banks are immense ranges of basaltic columns, the most elevated of any in the Viverais. They incline the borders of the river on each side for more than a league.

Some of the prisms rife in one shaft to the height of fifty feet; in other parts, the articulated columns form a kind of regular caufeway. In some places the columns are bent, and above we see immense rams of basalt, of more than 140 feet in height, in several ranges, spreading out like a fan, and diverging in every direction. On the left, the current of basalt covers several little hills of granite, and is moulded upon them. In some parts, the compact lava forms one solid mass; in other places, it is arranged in great beds. Nothing can be more grand and varied, says St. Fond, than the course of the river Vignon to Ardeche, where the great current of lava joins the streams that have flowed from the volcanoes of Theyuys and Neyrac. Faujas St. Fond fur les Volcans eteint du Viverais et du Velay.

Plate II. Mineralogy, Bafalt, which is taken for this work, will convey at once a satisfactory proof of the igneous origin of the basaltic columns in the Viverais; but one engraver

3 B 2

has
BASALTIC HORNBLende. See MINERALOGY, Addenda.

BASMAN, in Geography, an island of the Persian gulf, situated 11°12' leagues N.N.W. from Shorga, in N. lat. 25° 54'. It is an uninhabited island, about five miles long, and remarkable for a high round hill in its centre.

BASSORA, col. 1, l. 15 from the bottom, after 1688, add—subject to various revolutions. L. 11, after Porto, insert—The muscumel, or governor, has ever since the year 1787, when it was recovered from the Monte-lidge Arabs, by Solyma Pacha, been lent from Bagdad, and is generally an officer of high rank. Full liberty is allowed, &c. Col. 2, l. 12, after 56,000, add—or 60,000, consisting of persons of almost every nation in the East. L. 29, N. lat. 31° 30'. E. long. 48° 30'.

BAT. HORSE, in Artillery, are baggage-horses belonging to the officers when on actual duty; and bat-men were originally servants hired in time of war to take care of the horses belonging to the train of artillery, baggage, &c., and who, during their service, generally wear the king's livery. Those who are executed regimental duty, for the specific purpose of attending to the horses belonging to their officers, are called bat-men. Horses and men of the preceding description are sometimes called bow-horses and bow-men.

BATAARIA, in Botany, so named by Pursh, in honour of his learned predecessor in the study of the Fungus tribe, Antonio Battarra, professor of philosophy in the Lyceum at Rimini, author of Historia Fungorum Agri Romani, published at the neighbouring city of Faenza, in 1759, in 4to., with 40 plates. A preceding edition is indicated in the title-page, which Haller dates 1755. The author was a disciple of Janus Planus, or Giovanni Bianchi, the conchoologist, and died in 1789, according to Dryander in Bibl. Banki. He was, however, an original observer, and delineated the figures himself.—Perf. Syn. Fung. 139.—Clas and order, Cryptogamia Fungi. Nat. Ord. Fungi.

Eff. Ch. Stalk burling from a wrapper, and elevating the bell-shaped, downy, powdery head, capped with a portion thereof.

1. B. phalloides. Tall Brown Batarrea. Perf. n. n. 1. t. 3. f. 1. (Lycoperdon phalloides; Dickf. Crypt. falc. t. 24. Woodward in Phil. Trans. v. 74—423. t. 16. Sm. Spellic. 11. t. 12. Sowerb. Fung. t. 395.)—Found on sandy banks about Norwich, by Mr. William Humphrey, and about Bangay in Suffolk, by T. J. Woodward, esq. We have reason to think it may be met with in other parts of England, as Mr. Hudson, author of the Fl. Angl., told the writer of the present article, he had seen this singular production on heaths in Kent, but passed it by as a blighted or abortive Agaricus procusus. We have not heard of this very curious fungus in any other part of the world. The volva, or wrapper, is about the shape and size of a hen's egg, originally of three slightly coriaceous layers, hollow internally, where a spongey flalk is formed, which riles very suddenly (in a few hours) to its full height of about twelve inches. This flalk is hollow, soon becoming dry, and externally filamentous, and carries up, on its summit, full half the innermost layer of the volva, which is white and smooth within, covered externally with copious brown powdery cells, intermixed with fibres, as in a Lycoperdon. A smaller portion of the two outer layers, irregularly torn away, forms a double cap to this powdery surface.

BATAVIA, in Geography, a post-township of New York, the capital of Genesee county, 256 miles from Albany, on the great road to Buffalo; about 50 miles long from N. to S., and from 24 to 28 miles wide; bounded N. by lake Ontario, E. by Murray and Caledonia, S. by Warwick, Attica, and Sheldon, and W. by Niagara county. The whole population of this town, in 1810, was 3645, with 1046 feratary electors, and 464,216 dollars of taxable property.

BATH. Add—The city of Bath, by the return of 1811, contained 3933 inhabi tants, and 31,496 per sons; viz. 12,373 males, and 19,123 females.

BATH, a county of Virginia, &c. Add—The total number of inhabitants, in 1810, was 4877, including 382 slaves.

BATH, a township, &c. l. 2, for 949 r. 2491.

BATH, in Grafton county, &c. l. 2, for 493 r. 1316.

BATH, a post-township, the capital of Steuben county, 245 miles W. of Albany. The whole population, in 1810, was 1036, with 97 electors.

BATH, a township of the district of Ohio, in the county of Greene, having 913 inhabitants.

BATSCHIA, in Botany, so named by professor Gmelin, the compiler of the 13th edition of the whole Systema Nature of Linnaeus, in honour of professor Batsch of Jena, known particularly by his Elhenchus Fungorum, published at Halle in 1783 and 1784, in 4to., with coloured plates, and his Annals Fungorum, a work of a similar description, which appeared in 1790. Gmelin however adopted this genus, like many others, entirely from the Flore Caroliniana of Mr. Thomas Walter, who had modestly left such genera without names, because, though he supposed them to be new, he had not the advantage of books, or other helps, to confirm his opinion. In the present inference we apprehend his Anonymous, n. 78. Fl. Carol. 91, cannot be supported, but we shall give its character and synonymy.

Gen. Ch. Col. Perianth in five deep, linear, acute, erect segments. Cor. of one petal, falver-shaped; tube straight, longer than the calyx, surrounding at the base, internally, with a ring of hairs; throat pervious; limb orbicular, in five deep rounded segments. Stam. Filaments five, very short, inserted into the tube; anthers erect, ovate, concealed within the tube. Pfll. Germen superior, roundish, with four prominences; style capillary, the length of the filaments, stigma minute, slightly cloncy. Peric. none. Seeds four, ovate, hard, polished.

Eff. Ch. Corolla falver-shaped; throat naked; tube with a hairy internal ring at the base; segments of the limb rounded. Calyx in five deep segments.

Obs. It appears to us that this genus cannot be kept separate from Lithospermum. (See that article.) The only mark of distinction is the hairy ring in the bottom of the tube, which surely is not sufficient. The form of the corolla is as much funnel-shaped as in that genus, and the seeds are acknowledged to be precisely the same. Michaux adds, (perhaps on account of the yellow flowers,) 'whether L. orientale of Linnaeus be not a Batschia?" We find no traces there of the hairy ring, nor was any such character detected by Mr. Bauer, when he made the drawing for Dr. Sibthorp's Fl. Graeca, t. 160. This circumstance does away the presumption of a generic difference here indicated by colour. The following are the only reputed species of Batschia.

Walter.

2. B. canescens. True Puccoon. Mich. n. 2. t. 14. Pursh n. 2. (Anchusa hirta; Mich. n. 19. A. virginiana; Linn. Sp. Pl. 191. A. floribus fparis, caule glabro; Cron. Virg. ed. 2. 24. Lithospermum virginianum, flore luteo dupliciti; Morit. fct. x. t. 28. f. 4.)—Downy and hoary. Leaves all oblanceolate. Calyx very short. Segments of the corolla entire. On dry sunny hills on a family soil, in Virginia, Tennessee, &c. perennial, flowering in June and July. Flowers of a deep golden-yellow. The root is covered with a red fulness, which is the true Puccoon of the Indians, and paints a beautiful red. Purf. With this colour, it seems, the native Americans painted their bodies. The whole herb is clothed with soft hairs, nor is the stem, as Linnaeus says, smooth. He had no specimen of this plant, when he wrote either edition of Sp. Pl., but afterwards confounded herewith a totally different Siberian plant, which lies under this name in his herbarium, but without the requisite marks of authenticity. Morison's figure represents a double-flowered variety, which is very unusual in this natural order.

3. B. longiflora. Long-flowered Puccoon. Pursh n. 3. —“Downy and feto. Leaves linear. Calyx long and linear. Segments of the corolla notched; tube elongated.” —Found by Mr. Nuttall, on the banks of the Millouri. Perennial, flowering in July. Flowers yellow. Purf. We should premise that all these species belong rather to Lithospermum than to Anchusa, but we have only seen the second, communicate in a dried flake, from Pennsylvania, by the late Rev. Dr. Muhlenberg.

BATTAM, the Bahia of Strabo, in Geography, a town of Armenia, in the pachalic of Erzeroum, on the Euxine. This is a commercial place; and between it and Akifila are the towns of Ifchoetchelou, Gartziemie, Schwaghaewal, and Kuettajeac.

Vol. IV.

BATTING. See Cotton, and Manufacture of Cotton.

BATTLE, 1. ult. r. and in 1811 had 361 houses, and 2531 persons; 1232 being males, and 1299 females. BATTLE, 1. ult. r. and in 1811 had 361 houses, and 2531 persons; 1232 being males, and 1299 females. BATTLE, Order of, Col. 6. 1. 19, to 1. 41. detl. BATZ. Add.—The florer at Augsburg is divided into 15 batazes, (or batzen,) or 20 kayfergrochen. A thaler, or rix-dollar, is worth 13 florin, 22½ batazes, or 90 creutzers. At Baffl, the thaler, or rix-dollar, is worth 3 livres, 27 good batazes, or 30 Swiss batazes; the florin, 15 good batazes, or 16½ Swiss batazes; the livre, 9 good batazes, or 10 Swiss dito. A good bataze is 4 creutzers; a Swiss bataze, 2 fous, or 3½ creutzers. At Bern, accounts are kept in livres of 20 fous, the sou of 12 deniers; also in livres, or francs, of 10 batazes, or 40 creutzers; and in crowns of 25 batazes, or 100 creutzers. A rix-dollar, or ecu blanc, is worth 30 batazes; a crown, 25 batazes; a florin, 15 batazes; a livre, or franc, 10 batazes; a pfund, 7½ batazes, or 15 fous; a bataze, 2 fous, or 4 creutzers.

BAUER, in Botany, received its name, not from Sir Joseph Banks, as Mr. Andrews, by mistake, has recorded, but from the author of the present article; in due commemoration of those excellent botanical artists, and practical observers, Mr. Francis Bauer, so long employed as a draughtsman at Kew, and his brother Mr. Ferdinand Bauer, who after being engaged in the same occupation by Dr. Sibthorpe in Greece, accompanied Mr. Brown to New Holland, and is now returned to Germany, having left behind him in England unrivalled monuments of his abilities. —Andr. Repof. t. 198. Ait. Hort. Kew. v. 3. 317. Salib. in Ann. of Bot. v. 1. 514. t. 10. —Cliffs and order, Poly-andria Digitata. Nat. Ord. Saxifrage Juf. Salib. Cono-nieves, Brown, Bot. of Terra Aulfr. 16.

Gen. Ch. Cal. Perianth inferior, of one leaf, in eight deep, lanceolate, reflexed, permanent segments. Cor. Petals eight, obovate, equal, concave, alternate with the calyx, and nearly twice as long. Stam. Filaments numerous, thread-shaped, inserted into the receptacle, half as long as the petals; anthers erect, obovate, of two cells, bursting at the summit. Pist. German superior, somewhat pyramidal, obtuse; styles two, thread-shaped, longer than the filaments, recurved; stigmas simple, obtuse. Peric. Capula roundish, tumid, somewhat compressed, with two short, divericated, pointed lobes, of two cells and two valves, bursting at the top, between the points; partition contrary to the valves. Seeds numerous, oval, corrugated, inserted into the central column.

Eff. Ch. Calyx inferior, in eight permanent segments. Petals eight. Capula inflated, of two cells, with many seeds.

1. B. rubiesfola. Madder-leaved Bauera. Salib. as above. Ait. n. 1. (B. ruiboides; Andr. Repof. t. 198. Curt. Mag. t. 715. Venten. Malmaif. t. 96.) —Native of New South Wales. First discovered in that country by Sir Joseph Banks. We received specimens and seeds from Dr. White, among the first communications from the settlement there, and this beautiful shrub was raised by the late marchioness of Rockingham, at Hillingdon, in 1793. It requires the shelter of a green-house, or conservatory, and flowers during most part of the summer and autumn. The stem is five or six feet high, much branched, woody, but slender and weak; the branches opposite, round, leafy, somewhat hairy. Leaves opposite, or sometimes three together, ternate, nearly fiddle, evergreen, widely spreading; leaflets three-quarters of an inch long, lanceolate, daintily ferrated, their ribs a little hairy beneath; their upper surface convex, of a deep shining green; under paler. Flowers axillary, on simple hairy flanks, longer than the leaves, a little drooping, scarcely an inch broad, of a beautiful rich rofe-colour, with yellow anthers, inodorous. The parts of the flower vary occasionally in number, from seven to nine or ten. The bractlets, like the leaves, are sometimes three together, and when young, have, like them, a reddish tinge, which the permanent calyx, and old leaves, likewise assume. We do not very clearly perceive the resemblance to Madder in the leaves, and should have been glad if the specific name originally proposed, formosa, had been retained for a plant which so well deserves that appellation.

Another species is mentioned, by the name of B. humilis, in Ait. Epit. 364, as introduced at Kew, from New Holland in 1805, and flowering in June and July. But not a word is said respecting the specific differences between the two.

BAYAZID, in Geography, one of the Turkish pachalics of Armenia: the city of this name lies at the distance of two days’ journey from Erwan, nine from Erzeroum, and four from Khoi, and occupies the declivity of a mountain, the summit of which is strongly fortified. The city is surrounded with walls and ramparts: it has two churches and three mosques; and the monastery of Karu Killefca is famous for the beauty of its architecture, its antiquity, and its grandeur. The inhabitants are reported to amount to about
about 30,000, and are esteemed the most learned and war-like people in Armenia. The climate is mild, and the city, with the extensive territory attached to it, is under the government of a pacha of two tails, archbishop of Mardin. M. Kinner's Perfé.

BAYLA, the capital of Lus, a district of the Perlian empire, in the province of Mekran, and country of the ancient Orizat, is built on the N.E. bank of the river Poorsalee, and contains 1500 houses, and 6000 inhabitants, of whom 400 are Hindoos. The present chief can bring into the field 4000 irregular troops, and enjoys a revenue of 50,000 rupees per annum.

BAYOU, a term originally Spanish, signifies the diminutive of bay; but in Louisiana, where it frequently occurs, it is synonymous with the word creek, and consequently becomes the diminutive of river.

BEAN-Goose. See ANAS and DUCK.

BEATTIE, James, &c. l. 2, born Nov. 5, l. 12, latter, by the liberality of a mother, (his father having died when he was seven years of age,) by, &c. l. 18, dele at Allas; and l. 19, dele affinit to the; l. 24, for 1760 r. 1761; l. 41, infert—which was written about the year 1764, though not published till some time after. Col. 2. l. 35, dele following; l. 62, for not long afterwards r. in 1770 l. 65, for 1777 r. 1776, (in consequence of which he obtained the pension above-mentioned.) Col. 3. l. 23, infert.—In 1790 he published a summary of his lectures under the title of "Elements of Moral Science;" the first volume of which contains a very accurate enumeration and arrangement of the perceptive faculties and active powers of man. He has also given a curvy view of what is called natural theology. The second volume, published in 1793, comprehends much miscellaneous information on ethics, economics, politics, and logic, including rhetoric. Towards the latter part of his life, his time, &c.

BEAUCAIRE, l. 7, dele The part of the Rhine is well constructed.

BEAVER, in Geography, a county of Pennsylvania, containing 12,168 inhabitants, in which are several towns of the same name; such as North Beaver with 932, Big Beaver with 702, Little Beaver with 1379, Beaver Borough with 426, and South Beaver with 1351 inhabitants.—Also, a township of Pennsylvania, in Northumberland county, having 502 inhabitants.—Also, a township of Crawford county, with 236 inhabitants.—Also, a township of Cambria county, in the district of Ohio, having 433 inhabitants.—Also, a township of the same district, in Greene county, having 793 inhabitants.

BEAVER CREEK, a township of Pennsylvania, in Beaver county, with 774 inhabitants.

BEAVER KILL, a township of the district of Maine, in the county of Kennebec, containing 354 inhabitants.

BEAUFORT, in South Carolina, l. 4, r. 25,887, including 20,914 slaves.

BEAUFORT, (col. 2, after l. 14,) a county of North Carolina, containing 7204 inhabitants, of whom 2568, are slaves.

BEAUFORTIA, in Botany, a truly noble genus, consecrated, by Mr. Brown, to the memory of Mary duches of Beaufort, who died January 7th, 1714, in the 85th year of her age. Her grace cultivated a number of rare plants in the flowers and green-houses at Badminton, Gloucestershire, during the life-time of her husband, Henry, first duke of Beaufort, whose death happened in 1699. The plants introduced by her always therefore bear this date in Mr. Aiton's Hortus Kewensis. Numerous specimens from the Badminton garden were communicated to Sir Hans Sloane, and if we are not mistaken, a splendid herbarium in the British Museum, bound in several large folio volumes, bears the title of "The Duchess of Beaufort's Plants."—Brown in Ait. Hort. Kew. v. 4, 418.—Clas and order, Psalephodia Leofardia. Nat. Ord. Helpisides, Linn. Myrii, Jurf.

Gen. Ch. Col. Perianth half superior, of one leaf, turbinate; limb in five deep, awl-shaped, deciduous segments. Cor. Petals five, elliptical, sessile, inserted into the rim of the calyx, between its segments, and of equal length. Stam. Filaments very numerous, in five sets, inserted into the calyx, opposite to the petals, the claw of each set regular, hairy at the base internally, much longer than the petals, divided at the top into seven, eight, or more, capillary spreading segments about a quarter the length of the claw; anthers terminal, inserted by the base, of two divericated, conical, deciduous, single-celled lobes. Pet. Germen in the bottom of the calyx, small, roundish, hairy at the funnun; style thread-shaped, shorter than the stamens, variously bent upwards and downwards; stigma acute. Peric. Capsule coated with the base of the calyx, and firmly united to the branch, roundish, of three cells. Seeds solitary.

Eff. Ch. Calyx in five segments. Petals five. Stamens numerous, very long, in five sets, opposite to the petals; anthers of two deciduous lobes. Capsule clothed with the base of the calyx, three-celled, permanent. Seeds solitary.

Obst. Many of the flowers are said to want the style. We are not clear, from the account of the author of this genus, whether more than one seed is perfect in each fruit. The capitula remain in maffes surrounding the branches, long after the seeds are gone, perhaps for several years, being firmly united to the bark or wood; a character common to many of this natural order in New Holland, as Melaleuca, (see that article,) and others. The very peculiar anthers seem to afford the most essential character of Beaufortia, and distinguish it from its near ally Calothamnus. See that article hereafter.

1. B. decussata. Splendid Beaufortia. Br. in Ait. n. 1. Sims in Curt. Mag. t. 1733.—Leaves opposite, ovate, many-rubbed, crossing each other in pairs. Claws of the stamens very long, their filaments radiating.—Gathered by Mr. Brown, on the south-west coast of New Holland, and sent to Kew by Mr. Good, in 1803. A green-house shrub, flowering in the spring, and increased by cuttings. Branches are angular. Flowers small, crowded, half or three-quarters of an inch long, recurved, smooth, rigid, entire, full of pellucid dots; paler beneath. Flowers in dense tufts, surrounding the branches here and there, most conspicuous for their copious spreading tufts of flamma, an inch and a quarter or more in length, all over of a rich scarlet, the petals, as well as calyx, being green.

2. B. florib. Alternate-leaved Beaufortia. Br. in Ait. n. 2.—Leaves scattered, elliptical, many-rubbed.—Gathered in the same country, by Mr. Brown, from whence it was likewise sent to Kew, by Mr. Good, in 1803, but does not appear to have flowered in 1812, when the fourth volume of Hort. Kew. was printed.

We presume Mr. Brown's Prodromus, when completed, will make us acquainted with more species of this genus.

BEAUMARIS, col. 2, l. 9, for 1275 r. 125. Col. 3, l. 1, for 37 r. 57; l. 37, r. Lavan. Add.—The borough of Beaumaris contained in 1811, 295 houses, and 1810 persons; 809 being males, and 1001 females.

BECKET, in Geography, l. 2, for 751 r. 1028.

BEDDOES, THOMAS, M.D. in Biography, a distinguished physician and philosopher, was the son of an opulent tanner at Shaftall in Shropshire, and born in 1760. Indicating at an early age peculiar talents, and dispelled to cultivate them by diligent
diligent application, he was destined for a learned profession. With this view, after the requisite previous education, he was entered, in the year 1776, at Pembroke college, Oxford, and in the progress of his studies acquired the reputation of a classical scholar; connecting with his other pursuits the study of the French, Italian, and German languages, as well as of pneumatics, chemistry, mineralogy, and botany. After having taken his first degree of arts, he repaired to London, where he prosecuted the study of anatomy and physiology, and published translations of Spallanzani’s Dif
tertations, of Bergman’s Essay on Elective Attractions, and of Scheele’s Chemical Essays. At Edinburgh, where at this time he had commenced his studies, he obtained high reputation among his fellow-students. In 1786 he graduated M.D. at Oxford, and in the following year visited the continent. Upon his return, he was appointed to occupy the chemical chair at Oxford. At this period he formed an acquaintance with Dr. Darwin, which gradually ripened into the intimacy and confidence of friendship. In 1790 he pre
tented to the public an analytical account of the writings of Mayow, well known for his early discoveries in the depart
tment of pneumatic chemistry. (See his article in the Cyclo
depedia.) And he also communicated several papers to the Royal Society. As a chemical professor at Oxford, he was a popular lecturer; and he was much respected in the university on account of the rank he occupied in general literature and science: but interesting himself in the party politics of that period, and avowing his opposition to fylems which then prevailed with regard both to church and state, he found it expedient to resign his professorship in 1792. He was adverse, however, to that detestable spirit which blended itself in France with their struggles for liberty. Among other publications which issued from the press about this time, our limits will only allow the mention of his “Observ
tations on the Nature of Demonstrative Evidence, with Refle
ctions on Language,” intended to facilitate the study of geometry to youthful minds, by shewing, in opposition to the doctrine of the author of Hermes, that geometry is founded in experiment, and that its elements may be ren
dered palpable to the fentes. The most popular of his publica
tions was a small work, which appeared under the title of the “History of Isaac Jenkins,” a fictitious narrative, exhibiting the character of a labourer immersed in the evils of habitual drunkenness, but reformed to sobriety and in
dustry; of which his biographer (abi infra) says, that if the au
tor had left no other monument of his ingenuity and benevolence, he would not have lived in vain. Without adventing to his other writings, we shall proceed to mention his pneumatic establishment in the vicinity of the Britol hot-wells, undertaken and for some time liberally supported for the purpose of curing diseafes by the judicious applica
tion of different kinds of faticitious air. For the con
cvenience of superintending this institution he resided at Clifton, and in 1794 formed a matrimonial connection with a lady of the jufly celebrated Edgeworth family. From this time his medical publications became numerous, and as a physician his advice was in high estimation; and he was con
tulced by persons in distant parts, who are paid to have derived great benefit from his precriptions. Although his pneumatic infituation failed with respect to the degree of lucness which he might augur, and proved of temporary duration, it Served to bring into notice the preifent for Hum
phry Davy, one of the most eminent philosophers of our time, whose talents, restricted in their exercise to a remote town in Cornwall, caufed him to be engaged as its manager. In the year 1806, Dr. Beddoes was attacked with some affection of the liver, which, after subsiding for a time, returned with a difafe in the chelf in 1808, and rapidly in
creasing terminated in his death on the 24th of December, before he had completed his 40th year. Although his manner, says his biographer, was cold and repulsive, he poffefled kind and tender feelings; and in the relations of domelic and private life his conduct was unexceptionable. Stock’s Memoirs of the Life of Thomas Beddoes, M.D.
BEDFORD, col. 3, l. 4, r. In 1811, the borough con
tained 940 houfes, and 4625 perfon; 2057 being males, and 2568 females.

BEDFORD, in New York, l. 2, for 2470 r. 2374, with
241 electors, in 1810. Add—Near the centre of this town is the village of Bedford, where the courts for the county are held one half of the time, and the other half at White Plains. Here are, a court-house and prison, a Pref
byterian church, an academy, and a small number of houfes.
BEDFORD, a county of Pennsylvania, l. 4, for 13,124,
including 46 fables, r. 15,766; fubfifing after 1795—it con
ains 547 inhabitants.
BEDFORD, a township in the fame county, includes 1352
inhabitants.
BEDFORD, a county of Virginia, &c. l. 5 and 6, for
10,531 r. 16,149, and for 2754 r. 6147.
BEDFORDSHIRE, col. 2, l. 8 and 9, r. The county, in 1811, contained 13,286 houfes, and 70,213 perfon;
33,171 being males, and 37,042 females; 9431 families em
ployed in agriculture, and 4155 in trade and manufactures.
BEDLIS, or BERTLIS, a large town, situated at the opening of the ftrongeft of the paffes in the road from Diar
bekir to Van and Tabriz. The river of Bedlis (the Cen
trites of Xenophon) is conducted by Haji Kalifa through the plain to the southward of Sahert, Sard or Sared (the ancient Tigranocerta). Bélis is one of the moft ancient cities of that part of the kingdom called Kurdítan; the cattle is on the top of a high mountain, which bounds the plain to the west: the inhabitants of the town and neigh
bouring villages amount to about 26,000 Kurds, Turks, Armenians, and Syrians. The Armenians, who enjoy a confiderable portion of liberty, have four churches and four monaftries. The lands around Bélis are highly cultivated, and produce grain of several kinds, cotton, hemp, rice, olives, honey, truffles, and muftrooms. The neigh
bourhood abounds with game, and the mountains are infefed by lions, wolves, and bears. In the vicinity are quaries of red and white marble. See BERTLIS.
BEDMINSTER, a township of Bucks county, in Pennsylvamia, having 1190 inhabitants.
BEDR, a town of the Perijn empire, in the pachi
of Bagdad, 13 leagues from Mendel, and four from the foot of the mountains; is the frontier town, in this quarter, of the Turkif empire. It is surrounded with a number of fine gardens; but its districts are damp and marfhly, inter
pered with pools of water, the receptacles of the torrents, which, in the spring, are continually rushing from the mountains.
BEER, col. 2, l. 4, from the bottom, add—For the excife duty on beer, fee Ale.
BEERING”S STRAITS, l. 7, after Cook, infer—He
afterwards affered, that Cape Prince of Wales was the western extremity of the whole continent of America; and
another cape was obferved to the northward of this, lying
in lat. 69° 45', and long. 194° 51'. To this cape, captain Cook gave the name of Point Mulgrave.

BEES' BREAD. See PAIN DES ATELLES.

BEBA, a land measure in Bengal, equal to about the third part of an acre.

BEGARMEE, col. 2, l. 9, for matured r. weakened.

BEBHANAN, in Geography, the capital of the mountainous district of Khogloea, in the province of Fars, in the Persian empire, which district extends from the valley of Ram Hormuz to the vicinity of Kazeroon. The town is pleasantly situated in the middle of an extensive valley, three miles E. of the ruins of the ancient city of Aragian, which may be seen on the banks of the river Jerahi. It is the residence of a beglerbeg, who has a palace in the N.E. corner of the town. The walls are about three miles in circumference, and the population is said to amount to nearly 10,000 souls. The plain of Behbanan is of considerable extent, and highly cultivated. The rivers Tab and Jerahi flow through it. Behbanan is 153 miles from Shiraz, separated from it by a mountainous country, almost wholly uninhabited, and infested by banditti.

BELLEFONTE, a township of Centre county, in Pennsylvania, having 303 inhabitants.

1. B. montana. Mountain Bellenden.—The only species, found by Mr. Brown on the summits of mountains in the island of Van Diemen, but as yet unknown in our gardens. This is a perfectly smooth shrub. The leaves are scattered, flat; three-nerved at the extremity. Spike terminal, raceme. Flowers scattered, rarely in pairs. Corolla white, foar falling. Germen connected by a joint with its stalk. Seed-souffl in colour, furrowed along one edge. Brown. Theification of the flaments into the receptacle, and not into the petals, is an unique influence in this natural order.

BELLMINGHAM, in America, l. 2, for 735 r. 766.

BELMONT, in Geography, a county of the district of Ohio, containing 11,097 inhabitants.

BELPRE, a township of Ohio, in the county of Washington, having 494 inhabitants.

BERARDI, l. 8, for Orcani, &c. r. Arcani Muscula Dialogo, &c.

BERBERIDES, in Botany, the 78th natural order of Jussiff’s system; the 18th of his 15th class: for whose characters, see GERANIA. This order is defined as follows.

Calyx of a determinate number of leaves, or deep seg- ments. Petals definite also, agreeing in number with the divisions of the calyx, and often opposite to them; sometimes simple; sometimes charged at the base with an inner petal. Stamens definite, as many as the petals, and opposite to them; anthers fixed, burting by a valve from the base upwards. Germin simple; style solitary or wanting; stigma often simple. Berry or capsule of one cell, often with several seeds, inserted into its base. Corollum decid- ing, flat, surrounded by a fleshy albumen. Stem either thorny or herbaceous. Leaves generally alternate, with flipulas, or more frequently without, simple or compound.

The genera are, Berberis, Leontice, Epimedium; with Rinorea and Conoria, two shrubs in Aublet’s work, little known. To these are subjoined the following, as related to the order in question, viz. Riana of Aublet; Corynocarpus of Forster, and Linn. Suppl.; Paragisstreus of Aublet, which is Bazzera of Schrebier’s Gen. 179; Hamamete of Linnæus; Othera of Thunberg; and Rapania of Aublet. These genera, says Jussiff, are in some of their characters akin, in others foreign, to the Berberides.

BERGEN, a county of America, &c. l. 9, for 12,601 r. 16,603; and for 2401 r. 2180.

BERG. Subjoin—Their number is 2690, of whom 390 are flaves.

BERGMANITE. See MINERALOGY, Addeado.

BERKELEY, col. 5 l. 52, to him, infert—the lefion in the bircher-service, taken from 1 Cor. xv.; and he was com- menting upon it, &c. Col. 6, l. 43, generally, infert—but not truly.

BERKHEYA, in Botany, (Berkheya is an error,) a genus of compound flowers, suitly dedicated to the honour of Dr. John le France van Berkhey, whose inaugural dis- dertation, published at Leyden, in 1760, is an elaborate and ample illustration of this difficult tribe, accompanied by es-

Gen. Ch. corrected by Mr. Brown. Common *Calyx* of one leaf, clothed with many lanceolate, imbricated leaves, with spinous teeth, and spreading points; the lower ones short-tubular, compound, radiant. Florets of the disk numerous, perfect, tubular, funnel-shaped, deeply five-leafed, glandular below; of the radius fewer, ligulate, lanceolate, four-toothed; glandular below, imperfect. *Stam.* in the florets of the disk, bilocular, with filaments very short; anthers forming a tube with five teeth; in thofe of the radius the anthers are short and incomplete. *Pist.* in the florets of the disk, Gemen turbinate, short, hairy; style thread-shaped, longer than the stamens; stigmas two, revolute; in thofe of the radius, Gemen small, with hardly any style, and no stigmas. *Peric.* none, except the permanent calyx. Seeds of the disk foliarly, turbinate, hairy, crowned with from ten to fifteen chaffy, lanceolate, finely ferrated, or fringed, scales; of the radius none. *Recept.* flat, cellular, the cells membranous, jagged and toothed.

The species of this genus, twenty-two in Wildenow, are confined to the Cape of Good Hope and its neighbourhood. Four of them occur under this name in Hort. Kew. as green-house plants, flowering in summer; three others compose Mr. Brown's genus *Cullumia,* to be described hereafter. They are generally perennial, often shrubby. They embrace Thunberg's whole genus of *Rohria,* (see another genus of that name in its proper place,) and several of them have been referred by Linnaeus to *Gorteria, Atracytis,* or even *Xeranthemum.* None has yet appeared in any of our English periodical works. We select a few examples.

* B. obtusata.* Smooth Shrubby Berkheya. Wildl. n. 2. Ait. n. 2. (*Gorteria spinosa;* Linn. Suppl. 381. "Bat-teria aculeata;" Houit. Nat. Hift. v. 6. 158. t. 34. f. 2.) *Arr.*—Leaves alternate, wedge-shaped-lanceolate, spinous-toothed, smooth on both sides. *Calyx*-scales with spinous teeth.—Sent from the Cape to Kew Garden, by Mr. Maffon, in 1794. Akin to the last, but with narrower leaves, and the whole plant is smooth.

* B. cynaroides.* Artichoke Berkheya. Willd. n. 19. Ait. n. 1. (Rohria cynaroides; Thunn. Prodr. 140.) *Gorteria herbacea;* Linn. Suppl. 381.—Stem-leaves alternate, clafping, fringed with prickles; radical ones elongated, entire, unarmed; downy beneath. *Calyx*-scales ovate, frail, spinous, nearly entire.—Sent to Kew, from the Cape, in 1789, by Mr. Maffon. The *flam* are herbaceous, a foot or more in height, angular, nearly smooth. *Leaves* rigid, or drooping, but not entire; *calyx* ovate, smooth, fringed, or ferrated, three or four inches long, tapering at the base. *Calyx* ovate, smooth, fringed, or ferrated, three or four inches long, tapering at the base. *Calyx* ovate, smooth, fringed, or ferrated, three or four inches long, tapering at the base. *Calyx* ovate, smooth, fringed, or ferrated, three or four inches long, tapering at the base. *Calyx* ovate, smooth, fringed, or ferrated, three or four inches long, tapering at the base.

BERKLEY, in Virginia, l. 5, r. 11,497, of whom 1529 are flaves.

BERKLEY, in Massachusetts, r. 1,014.

BERKLEY, col. 3, l. 16, for township r. parish; for 90 r. 124; and for 659 r. 616, 296 being males, and 320 females. l. 18, infer after act, in 1811; for 3490 r. 3608; for 9148 r. 10,144; for 10,074 r. 11,248. Add—1711 families employed in agriculture, and 2215 in trade and manufactures; and for 19,242 in r. 21, 21,362.

BERKS, l. 9, r. 13,466, of whom four are flaves.

BERKSHIRE, in Massachusetts, l. 6, r. 35,907.

BERKSHIRE. After Vermont, add—containing 918 inhabitants.

BERKSHIRE, col. 2, l. 20, r. This county contains 22,104 houles, and 118,597 persons; 57,480 being males, and 60,917 females; 13,409 families employed in agriculture, and 7584 in trade and manufactures.

BERKSHIRE, a township of Delaware county, in the district of Ohio, containing 284 inhabitants.

BERLIN, in Vermont, for 134 r. 1997.—In Con-necticut, add—the number of inhabitants, in 1810, was 2798.—In Worcester county, for 512 r. 591.—In So-merfield county, infert—the number of inhabitants, in 1810, was 330.

BERNACCHI, l. 13, r. when he was past his meridian.

BERNARD, ST., a parish of the territory of Orleans, in the county of Orleans, containing 1020 inhabitants, of whom 382 are flaves.

BERNARDSTOWN, l. 2, r. 1879: l. 4, r. 811.

BERNE, a township of the district of Ohio, in the county of Fairfield, having 976 inhabitants.

BERNARDIA, in *Botany,* to name by professor Wildenow, in honour of Dr. John James Bernhardi, of Erfurt, a learned writer on Ferns, and in other respects an excellent cryptogamic botanist.—Willd. in Act. Acad. Erford. for 1802. 11. Sp. Pl. v. 5. 56. Pursh 655. (See *Psilotum,* under which name we have treated of this genus in due order.) We know not whether any other genus be already dedicated to Dr. Bernhardi, but it is to be pre-sumed that this act of justice will not long be delayed.

BERTLE, l. 5, r. 11,218; l. 6, r. 659.

Berville, l. 1, r. The burghe and parish contain 193 3 C. 421.
houses, and 927 persons; 415 being males, and 512 females.

BERWICK, North. Add—The burgh and parish contain 208 houses, and 1727 persons; 759 being males, and 968 females.

BERWICK, col. 3, l. 26, infert—in cruces. Add—The town and county of Berwick-upon-Tweed, by the parliamentary return of 1811, contained 934 houses, and 7746 persons; 3325 being males, and 4421 females.

BERWICK, a town of Adams county, in Pennsylvania, having 17990 inhabitants.

BERWICK, in Maine, l. 2, r. 1455 for 3894.

BESANCON, l. 2 and 3, r. capital of Franche Compte, now of the department, &c.

BESANT, l. nd. r. under Henry.

BESITTOON, a long range of barren mountains, in the province of Irak, in the Persian empire, bounding the plain of Kermanshaw to the N, and terminating abruptly on the E, by a high and perpendicular rock, in one place cut to a smooth surface, and projecting over the road, like a canopy. It receives its name from fittoon, signifying, in Persian, a pillar, and be, a negative proposition. Near its projection, on a high and inaccessible part of the rock, is a group of figures, in the form of a procession, of the same age and character with those of Persepolis. The ruins at this place resemble the magnificent ones of that famous city.

BESLICK, a small Turkish silver coin, equal to 5 paras, the para being 3 apers.

BESSARABIA, col. 2, l. 9, for south-east r. south-west.

BESTIAN, or BOSTANA, a cape of Laritfan, in Persia, which forms one of the most secure roadsteads in the gulf of Persia, at the town of Moguo. The extremity is about N. lat. 26° 30′, bearing from Polbor N.N.E. 3°, and W, from the S. end of Khima. Shinaaz and Botaana are small towns that lie between Lunga and Cape Boitaana.

BETHEL, in Geography, l. 3. Lowermost Bethel is a township of Northampton county, having 1392 inhabitants; and Uppermost Bethel, in the same county, has 1188 inhabitants.—After Dauphin county, add—having 2091 inhabitants; l. 4, r. 1041: at the close, add—a township of Maine, in the county of Oxford, having 975 inhabitants.—Alto, a township in Bedford county, containing 1093 inhabitants.—Alto, a township of Ohio, in the county of Miami, having 506 inhabitants.—Alto, a township of Champaign county, in Ohio, having 484 inhabitants.

BETHLEHEM, col. 4, l. 10, add—Alto, a town of New Hampshire, in Grafton county, having 422 inhabitants; l. 15, r. 1738; l. 15, add—having 1118 inhabitants; l. 26, add—but by the census of 1810, they are listed to be 1436.

BETHLEHEM, E. and W., two townships of Pennsylvania, in Washington county; the former has 1826, and the latter 1849 inhabitants.

BETLIS. Subjoin—See BEDLIS.

BEVERLEY, l. ult. In 1811, the borough and liberties of Beverley contained 1457 houses, and 6731 persons; 3024 being males, and 3707 females.

BEVERLEY, l. 5, r. 4608.

BEVERSTONE, l. 7, r. Edward.

BEWCASTLE. Add—The township contains 35 houses, and 198 persons; 103 being males, and 95 females.

BEWDLEY, l. ult. r. The borough contained, in 1811, 632 houses, and 3454 persons; 1583 being males, and 1871 females.

BEZOZZI, col. 2, l. 8, r. The eldest, &c.; l. 12, composition; l. 26, do.; l. 27, for the r. their, after delicacy, infert—there was; l. 40, infert—a labour exquisite in performance.

BIBIEN, FERDINANDO-GALLI, l. 12, r. Alexander; l. 14, r. generofi.

BIBLES, LATIN. See ITALIAN VERSION.

BICE. Add—See CAST.

BIDDEFORD, in America, l. 5, r. 1563.

BIDDEFORD, col. 3, l. 2, r. 634 houses, and 3244 persons; 1415 being males, and 1829 females.

BIGNELVIA, in Botany, a genus which we here dedicate to our highly intelligent and scientific correspondent, Jacob Bigelow, M.D. of Boston in New England, Rumford professor of Materia Medica and Botany in Harvard university, author of the Florula Bozianera, published in 1814; and of the American Medical Botany, with coloured plates, now publishing periodically; works which, we are confident, will be but the forerunners of more ample and valuable communications from the same quarter. We have selected for the commemoration of our friend an American genus, to which the name of Borya, (see that article hereafter,) has been erroneously applied, and which therefore requires a new appellation. We have chosen one as indistinct as the genus itself, whose synonyms are the following.—(Borya; Willd. Sp. Pl. v. 4. 711. Pursh 22. Ait. Hort. Kew. v. 5. 365. Adelia; Michaux Boreal.-Am. v. 2. 223. Browne Jan. 561, but not of Linnaeus.)—Clafs and order, Diactia Dianthera. Nat. Ord. Spermato, Linna. J. f. M. Cluff.

Female, on a separate plant. Col. Perianth in four deep, oblong, slightly spreading, deciduous segments; two opposite ones very minute, and sometimes wanting. Cor. none. Pilt. German superior, roundish-ovate, of two cells: style short, cylindrical, thickish; stigma capitate, depressed, obliquely crenate. Peric. Berry oval-oblong, of one cell, its internal surface cartilaginous and rugged. Seed almost always solitary, oblong, tapering at each end, furrowed and ribbed longitudinally, with a membranous skin; its embryo straight, in a horny albumen.

Eff. Ch. Male; Calyx deeply four-cleft. Corolla none. Stamens two or three.

Female. Calyx deeply four-cleft; two opposite segments smallest. Corolla none. Stigma capitate. Berry with one seed.

Ophi. The description of Michaux, and his hint of the affinity of this genus to Chionanthus, have helped us to form, we truth, a correct idea of its characters. Wildenow had seen specimens of Browne's Adelia, and he probably had the function of the able M. Richard for uniting it with that of Michaux, the latter having already so decided this question; nor do we see any reason for a different opinion.

The species are all shrubby, with opposite, undivided, mostly entire, smooth leaves, and minute, tufted, bracted, flowers. The fruit is probably not eatable.

1. B. caffinoides. Elliptical Bigelovia. (Borya caffinoides; Willd. n. 1. Adelia n. 1; Browne Jam. 361. t. 36. f. 3.)—Leaves flattened, oblongate, obtuse, coriaceous, revolute; reticulated with veins beneath.—Native of the W. Indies. Common on low gravelly hills, eastward of Kingston, in Jamaica. Sometimes eight or ten feet high, with
with slender leafy branches. Flowers in little axillary tufts, or clusters. Leaves about an inch and a half long, smooth, entire. Br.
2. B. porulosa. Pierced Bigelovia. (Borya porulosa; Willd. n. 2. Pursh n. 1. Ait. n. 1. Adelia porulosa; Mich. Bor.-Amer. v. 2. 224.)—Leaves flexible, oblong-lanceolate, obtuse, coriaceous, revolute; dotted beneath. —On the coasts of Georgia and Florida. The leaves are rusty, and as if pierced with little dots, beneath. Michaux.
3. B. liguliflora. Prick-leaved Bigelovia. (Borya liguliflora; Willd. n. 3. Pursh n. 2. Ait. n. 3. Adelia liguliflora; Mich. Bor.-Amer. v. 2. 224.)—Leaves oblong-lanceolate, somewhats membranous, entire, on short stalks. Berry roundish-ovate.—Native of thickets and woods along rivers, in the countries of the Illinois, Tennessee, &c. flowering in July and August. This has the habit and foliage of our Privet. Michaux.
4. B. acuminata. Pointed Bigelovia. (Borya acuminata; Willd. n. 4. Pursh n. 3. Ait. n. 3. Adelia acuminata; Mich. Bor.-Amer. v. 2. 225. t. 48.)—Leaves ovato-lanceolate, membranous, flaked, slightly serrated, acute at each end. Unripe berry oblong, taper-pointed.—On the banks of rivers in Carolina and Georgia. The taper lateral branches appear to form something like thorns. The leaves are an inch and a half long. Male flowers several together, in small flexible tufts, encompassed with several ovate bracteae; female ones flaked, very small. Berries pendulous, elliptic-oblong, near an inch in length.

The three latter species are recorded by Mr. Aiton, to have been brought into England by Mr. John Lyon; the porulosa in 1826, the two others in 1812. They are hardy shrubs, but do not appear to have yet flowered.

BIGNONIA, the 45th order in Jussieu's flora; the 12th of his 8th class, whose characters are given at Gentianae. The following is that author's definition of the order before us.

Calyx divided. Corolla mostly irregular, with four or five lobes. Stamens usually five, one of which is, for the most part, abortive, or imperfect. Style one; stigma either simple or two-lobed. Fruit of two cells; sometimes capular, with many seeds, and with two perfectly separable valves; the feed-bearing partition opposite or parallel to the valves, and separable therefrom: sometimes coriaceous or woody, bursling at the top only, with but few seeds, the feed-bearing partition a continuation of the valves, not separable, and often ending out a flight wing, dividing each cell into two. Coriaceous, two, often. Stem herbaceous, shrubby, or arboreous. Leaves opposite, rarely alternate.

Sec. 1. Fruit capular, bivalve. Stem herbaceous. Clove and Sassafras, with Jussieu's Incavella, Lamarck. Illusr. t. 527, compose this section.

Sec. 2. Fruit capular, bivalve. Stem arboreous or shrubby. Millingtonia of Linnaeus; Jucarand, Catalpa, and Tecom of Juff. with Bignonia of Linnaeus.

Sec. 3. Fruit coriaceous, almost woody, opening at the top. Stem herbaceous. Tourretia of Dombey and Juff. ; Martynia, Cramiaria, and Pedalium of Linnaeus.

Mr. Brown, Prodr. Nov. Holl. v. 1. 475, retains the second section only, under the name of Bignoniaceae, to which he adds the genus SPATHODEA. See that article.

BIGONICA, in Cronwisses, a liquid measure in Venice. See AMPHORA.

BILE, Chemical properties of. Bile has been lately denied by Berzelius to contain a refruous or adipocorous matter, as had been maintained by former chemists. The substance peculiar to bile, or, as it is denominated by him, the biliary principle, has an exceedingly bitter taste, followed by some sweetish. Its smell is peculiar, and the colour in most animals varies from green to greenish-yellow. It is soluble in water, and its solubility is not in the least promoted by the alkali of the bile, since when the alkali is neutralized by any acid, the peculiar matter does not separate. It likewise diffuses in alcohol in all proportions. Like the albuminous materials of the blood, of which this peculiar matter is composed, it will unite with acids producing two compounds of two degrees of saturation, and hence of solubility. The dilute acetic acid which gives the soluble compounds with the albumen of the blood, does the same with the peculiar matter of the bile; and hence this matter is not precipitated on adding this acid to bile, though it falls down on the addition of the sulphuric, nitric, or muriatic acids. It is this sparingly soluble compound of biliary matter with a mineral acid which has been mistaken by many chemists for a refins, since it poisons the external characters of a refins, melts when heated, diffuses in alcohol, and is again partly precipitated by water. The alcaliee, alcaline earths, and alcaline acetates, decompose and diffuse it; the former by depriving it of its combined acid, the latter by furnishing it with acetic acid, which renders it soluble in water.

The peculiar matter of bile will also combine with many of the metallic oxides. The degree of the solubility poissified by the compound of acid and biliary principle, varies according to the length of time that the bile has been kept, and also according to the species of the animal.

The biliary matter may be obtained in a state of purity by mixing fresh bile with sulphuric acid diluted with three or four times its weight of water. A yellow precipitate first appears, which is to be allowed to subside, and then removed: more acid is then to be added as long as any precipitate is formed; heat the mixture gently for six hours, and afterwards decant the fluid part, and thoroughly wash the green mass left. This green refrinous-like mass reddens litmus, and is partially and sparingly soluble in water. It may be deprived of its acid either by the carbonate of barytes, or by the carbonate of potash or lime, and thus obtained pure. It is now soluble in water, and forms a green solution, having all the properties of bile. It is insoluble in ether, which converts it into an adipocorous mass. When burnt it yields no ammonia, and consequently contains no azote.

The following are the results of Berzelius's analysis of bile:

The bile of other animals has been but imperfectly examined. It resembles in its general characters the human bile above-mentioned.

BILLARDIERA, in Botany, so named by the writer of this, in honour of his friend James Julian la Billardiere, (or, as it is now written, Labillardiere,) M.D. author of Icones Plantarum Syriae Rarioeum, the fruits of his journey to the Levant, in 1786; and since much better known by his valuable Novæ Hollandiae Plantarum Specimen, in two volumes folio, with many plates. An account of his voyage to New Holland, in search of the unfortunate Lapeyrouse, contains...
contains also much botanical matter, and has been published in English, at London, in 1802, with plates. M. Labillardiere has also distinguished himself as a classical botanist, of the Linnaean school, preferring the interests of science to those of system, and following no leader but what he conceives to be the truth.—Smith Bot. of New Holl. 1. Labill. Nov. Holl. v. t. 64. Willd. Sp. Pl. v. t. 1150. Ait. Hort. Kew. v. 2. 39.—Clafs and order, Pentandria Monogynia. Nat. Ord. uncertain. Akin to Pâteporum, and therefore to the Rhamni of Jussieu, as they stand at present. Salsify.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, coloured, equal, deciduous leaves. Cor. Petals five, inserted into the receptacle, alternate with the calyx, and twice as long, linear-lanceolate, erect; their claws more or less converging in the form of a tube; border spreading, acute, recurved. Nectary none. Stam. Filaments five, inserted into the receptacle, alternate with the petals, the length of the claws, awl-shaped; anthers ovate-oblong, attached by the back, of two cells, burling lengthwise, internally. Fil. Germen superior, elliptic-oblong; style awl-shaped, the length of the flamen; stigma obtuse. Pedio. Berry roundish-oblong, of two cells. Sèeds numerous, roundish, inserted into the central column.

Eff. Ch. Calyx of five leaves, deciduous. Petals five, alternate with the calyx, converging into a tube. Stigma obtuse. Berry superior, of two cells, with many seeds.

The species are all slender, twining, branched fibrous, with scattered, simple, undivided, nearly entire, more or less downy, leaves, on short footstalks. Flowers and fruit pendulous, on terminal stalks.

1. B. scandens. Climbing Billardiera, or Apple-berry. Sm. Bot. of New Holl. t. 1. Wildl. Sp. Pl. v. t. 801. Calyx-lanceolate. Berry cyllindric, obtuse, downy. Native of Port Jackson, New South Wales, from whence we received specimens and coloured drawings, by the kindness of Dr. White. Sir Joseph Banks sent feeds, or plants, to Kew, in 1750, and we have since seen flowers and ripe fruit in many conservatories. A low fibrous, with various twisted and climbing branches. Leaves an inch and a half or two inches long, elliptic-oblong, of a dull but not dark green; paler and matt downy beneath; their edges somewhat wavy and reflexed, scarcely notched. Flowers on hairy stalks, pale lemon-coloured, an inch long, with a hairy yellowish calyx. Germen very hairy. Berry above an inch in length, cylindrical, equally obtuse at each end, yellow, downy all over, full of brown seeds, its pulp soft, sweet, but rather insipid in this country, though famed, in a wild state, to resemble a roasted apple. The figure in the Botany of New Holland was taken from a drawing made in that country. We readily concur with our friend Dr. Sims, in Curt. Mag. p. 1507, that it is impossible to find a name which will contral the only known species of a genus, with all that may hereafter be found, and it happens that all the Billardiera are chimers. The appellation above, therefore, serves to throw the present to have been the originally described species. There are several such instances in the history of Linnean genera, nor would it be allowable to alter the original specific name on this account.

2. B. multibr. Changeable-flowered Billardiera. Salsify. Parad. t. 48. Ait. n. 2. Curt. Mag. t. 1313. Leaves linear-lanceolate. Berry cyllindric, obtuse, smooth. Native of New South Wales, Easily cultivated in a greenhouse, and increased by cuttings or seeds. The leaves are narrower and smoother than in the foregoing species. The flowers, at first of a pale greenish-yellow, turn purple before they fall. The germen and fruit are said to be always smooth, the form of the latter agreeing with B. scandens. Flowerstalks smooth.

3. B. sulphurea. Spindle-shaped Billardiera. Labill. Nov. Holl. v. t. 65. t. 90.—Leaves oblong-lanceolate. Flowers aggregate. Petals spreading. Berry spindle-shaped, pointed, silky, dry.—Gathered by M. Labillardiere at the Cape of Van Diemen, in December. The flamen is generally climbing. Leaves somewhat hairy, larger than in the last. Flowers from two to fix at the end of each branch, forming more or less of a cluster, blue, the petals more ovate, and spreading from the base, than in other species. Anthers converging. Berry small and tapering, of a membranous texture, silky, delusive of pulp.

4. B. longiflora. Blue-berried Billardiera. Labill. Nov. Holl. v. t. 64. t. 89. Curt. Mag. t. 1507. Ait. Epit. 564. Leaves lanceolate. Petals converging. Berry nearly globular, lobed, smooth.—Native of the same country as the last. Raised here by Meffrs. Lodigis. The flowers are solitary, pale yellow, longer and more tubular than in any of the rest. Fruit remarkably different, being short and roundish, of a fine blue. Dr. Sims has well observed, that this part affords, in the present genus, the best specific distinctions.

BILLERICA, l. 2. r. 1289. BilLS, Exchequer. See Exchequer-Bill.

Bill of Health, an account of the health of a crew, given by the captain or master of a vessel.

Bills, India, bills drawn in India on the East India company in London, and payable at the India-house.

Bills, Virtutalising. See Navy and Virtuallising Bills.

BILLYMEAD, a town of Vermont, in the county of Caledonia, containing 433 inhabitants.

BILSTON, l. ult. for 1305 r. 1818; and for 6914 r. 9646.

BILSTON, l. ult. for 121 r. 110; and for 744 r. 762.

BIR. Add.—According to M. d'Anville this place represents the ancient Birtha. The caravans travelling from Aleppo to Orfa pass the Euphrates on a bridge of boats at this place, situated 144 miles from Aleppo, and 67 from Orfa, in N. lat. 36° 58'. A tax is paid at this town, which is in a dilapidated state; and all travellers and merchants cross the Euphrates, which is here deep and rapid, and about 130 yards broad.

BIRDS, Anatomy of. The references to the plates to be expunged. Col. 7, l. 33, after another, insert—a good instance of which is found in, &c. ending heron; l. 35, r. The bulbus in the orbiculus is a long narrow band lying on the front of the flomach. The structure, &c.; l. 53, dele like other, &c. to secretion. Col. 9, l. 34, for superficial view r. flight examination. Col. 11, l. 20, after intelle of dele to ventricle, l. 34; and infect.—If the cavity of the flomach in the heron be diffused with any transparent fluid and held up to the light, the zone of galenic glands will be plainly seen through its coats. If Spallanziani had employed this expedient, he could not have denied a distinct glandular structure to the heron. The inferior part of the flomach is chiefly composed of muscular fibres, spreading in a radiated manner from a lateral aponeurosis, which supplies the place of the great tendons of the digastric muscle. The second cavity or flomach in the heron is a small round bag, furnished only with circular muscular fibres; l. 35, for straight r. contracted. Col. 13, l. 14, dele to 5; l. 15, after respect dele to the end of the paragraph. Col. 14, l. 15, dele after adjoining to the end of the paragraph. BIRD, in Geography, a township of Adams county, in the district of Ohio, containing 1442 inhabitants.

BIRMINGHAM. Add—In 1811, the town of Birmingham contained 16,653 houses, and 85,755 persons; 46,518 being males, and 45,235 females. 589 families employed in agriculture, and 17,294 in trade and manufactures.

BIRMINGHAM, a township of Delaware county, in Pennsylvania, having 586 inhabitants.—Also, a township in Chester county, of the same state, having 200 inhabitants.

BISHOP'S CASTLE, l. ult. r. The borough, in 1811, contained 288 houses, and 1367 persons; 651 being males, and 716 females.

BISHOP'S STORTFORD, col. 2, l. 36, r. The parish contains 479 houses, and 2630 persons; 1255 being males, and 1375 females.

BISLEY, l. ult. for 922 r. 1022; and for 4227 r. 4752.

BISMUTH, in Chemistry. There seems to be but one oxyd of this metal. What was formerly termed the magisfery of bismuth, and confidered as a peroxys, has been demonstrated by Bucholz to be a compound of the oxyd of bismuth and nitric acid.

Dr. Thomson has determined 88.75 to be the combining weight or weight of the atom of bismuth. According to this determination, the oxyd of bismuth will confift of

Bismuth 100

Oxygen 1112672

per cent. of 189.87

of 16.13

From the above number, and from the known weights of the different acids, the composition of all the falls of bismuth can be accurately ascertained. See PROPORTIONS, Definite, and Atomic Theory, Addenda.

BISON, in Zoology. See Bos and Ursus.

Bissippi, infert.—See SUMNUM and SMARTUS.

BISTINEAU, in Geography, a lake of Louisiana, formed by the agency of Red river, which has raised a bank of earth and sand across the lower extremity of a valley that serves to confine the waters between the hills at all seasons, and to produce this lake. The land along its banks rises into hills from 100 to 200 feet of elevation, clothed with pine, oak, and various other trees, that afford agreeable prospects. The eastern range, more broken than the western, abounds more with petrifications; and along the margin of the water, are found the white-thorn, hawthorn, and other dwarf trees, which form an elegant natural border. Many small prairies, eight or ten acres in extent, spread themselves over the projecting banks, and diversify this wild, uncultivated, but romantic scene. This lake furnishes evidence of the continual change effected in these alluvial regions, by the flow but unceasing action of water. The average depth of the water is from fifteen to twenty feet; and in the deep part of the lake presents to view cypresses-trees of various sizes that are dead, and the remains of which, refiting the action of air and water, attest the ancient situation of the country. Darby's Louisiana.

BIT, in Commerce. Add—1 bit being worth 5½ flettling, as 10 bits and 5d. currency make a dollar.

BITTER PRINCIPLE, Natural and Artificial, in Chemistry. This name has been given by chemists, and especially by Dr. Thomson, to different principles, extracted from various vegetables, particularly from quassia, cocculus indicus, ficubis, and some others. Though the characteristic property of these substances be their bitter taste, yet this appears to be almost the only particular in which they all agree. The bitter principle of quassia, according to Dr. Thomson, is of a brownish-yellow colour, somewhat transparent, of an intensely bitter taste, soluble in water and alcohol, has no effect on vegetable blues, and is little affected by re-agents; the nitrate of silver, and acetate of lead, being the only ones that precipitate it from its solution. It may be obtained by digelling quassia for some time in water, and evaporating the solution formed to dryness.

The bitter principles extracted from colosyn, bronbia alba, and from wheat-flour, seem to possess properties analogous to the above. The bitter principle from cocculus indicus, which has been named Picrotoxin, is described under that article.

The bitter principle of ficubis is white and transparent. It is soluble in water and alcohol, and rapidly attracts moisture from the atmosphere. Its taste is intensely bitter; though it usually retains a little from marine matter with great oblivignty. It was obtained by Vogel by evaporating the juice to dryness, and heating it with alcohol; the tannin taken up by the alcohol was separated by the acetate of lead, and thus the bitter principle, obtained in the state above described, combined with a little sugar, from which it was found impossible to entirely free it. The bitter principle of coffee principally differs from the preceding by the property it possesses of striking a green colour with iron, and of precipitating that metal from concentrated solutions.

According to the experiments of Bouillon la Grange, a sub stance not much unlike the above exists in the flowers of the arnica montana, obfinthum vulgare, juniperus sabina, ruta graveolens, anthemia nobilis, and achillea millefolium.

The artificial bitter principle seems to have been first formed by Hauflinian from indigo, though he millock its nature. Wecker afterwards obtained it from blue, ascertained its properties, and gave it the name of yellow bitter principle. It was afterwards obtained by Bartholdi from the white willow. Mr. Hatchett formed it, during his experiments upon artificial tannin, by heating indigo with nitric acid; and about the same time Courcy and Vanquelin procured it by the same means, and examined its properties. M. Chevreul supposes it to be a compound of nitric acid and a vegetable sub stance, probably of an oily nature. Its colour is deep yellow, and its taste intensely bitter. It is soluble in water and alcohol. It crystallizes in elongated plates, and possesses many of the properties of an acid, combining with alkaline substances, and forming crystallizable salts possessing peculiar properties.

The artificial tannin itself is by some chemists considered as little better than a variety of the bitter principle. See TANNIN, Artificial.

BITTERN. See WAtEr.

BITUMINOUS Marble Slates. See MINERALOGY, Addenda.

BIVOUACK, Bhouac, or Bigvac, Fr. formed from the German um-wach, a double watch or guard, denotes a night-guard, or a detachment of the whole army, which, during a siege, or in the presence of an enemy, marches out every night in squadrons or battalions, to line the circumvallations, or to take post in front of the camp, for

and anthers nor inferted

George duke of Marlborough, at that time marquis of Blandford, an honorary member of the Linnaean Society, and one of the mott ardent botanists and cultivators that this country ever policed in any rank of life. A genus belonging to what Linnaeus terms the Patrician order, was judged peculiarly eligible for this purpose; nor can any be more distinct, few more beautiful.—Sm. Exot. Bot. v. 1. 5.

Gen. Ch. Cal. none. Cor. of one petal, inferior, tubular, straight, with fix marginal lobes, regular, withering. Stem. Filaments fix, thread-shaped, inserted into the middle of the tube, decorator, shorter than the limb; anthers ovate, two-lobed, incumbent, attached by a hood at the base. Pfl. German superior, falked, oblong, with three angles, and three intermediate furrows; style vertical, awl-shaped; stigma simple. Peric. Capsule falked, prismatic, of three cells, burfting at their inner angles. Seeds numerous, oval, fent along the margins of each cell, imbricated, clothed with dense ftraily hairs.

B. grandiflora. Large-flowered Blandfordia. Br. n. 2. (Altesia punicea; Labill. Nov. Holl. v. 1. 85. t. 111.)—Brae teas nearly as long as the partial falks while in flower; the inner but one-third as large as the outer.—Observed at Port Jackson by Mr. Brown, who is not quite certain of Labillardiere's plant, found at Cape Van Diemen. We have seen neither, but we should fearly have thought the latter could be diftinguished even from B. nobilis.

Blandfordia cordata, Andr. Repof. t. 343. See Galax.

BLATTA, col. 2, l. 29, after gigantea, add—called in the Wilt Indies drummer, from the noise it makes, like a fmart knocking with the knockle upon the wainscot; l. 36, dele which fce repectively.

BLAYNEY, Benjamin, D.D. in Biography, an eminent Hebrew fcholar and critic, was educated at Oxford, and graduated M.A. in 1753, at Worecefter college, and becoming afterwards fellow of Hertford college, took the degree of B.D. in 1768, and of D.D. in 1787, in which year he was appointed regius proffor of Hebrew. As a Scripture commentator and translator, he acquired very con- siderable reputation. The publications by which he was diftinguished were, "A Difertation on Daniel's Prophecy of Seventy Weeks," &c. 1775. 4to.; "A New Translation of
BLEACHING, col. 10, l. 19, r. For an account of the progress of discoveries in the new method of bleaching by the oxygenated mariaic acid, see Oxysmurtic Acid Gas.

BLEACHINGLEY, col. 2, l. 11, r. By the returns in 1811, the borough and parish contained 184 houses, and 1116 persons; 575 being males, and 541 females.

These characters exclude Jussieu's B. anisophyllum, which, with Ruellia imbricata of Forckloll, and several East Indian as well as tropical African species, compose Mr. Brown's new genus of Aistolema, as yet, we believe, merely indicated in his Prose. Nov. Holl. v. 1, 478. The following are the only species of Blechnum there mentioned.

BLETIA, so named by the authors of the Flora Peruviana, after Louis Blet, a Spanish apothecary, whose botanical merits ought to be very great, to entitle him to so fine, if really distinct, a genus. — "Ruiz et Pavon Prodr. 119." Brown in Ait. Hort. Kew. v. 5. 265. (Phaius; Loureir. Cochinch. 529.)—Clais and order, Gynandra Monandra. Nat. Ord. Orchidceae.

Eff. Ch. Calyx and petals distinct. Lip fimbriate, hooded. Style unconnected. Anther a terminal deciduous lid. Males of pollen eight or four, two-lobed.

2. B. versicula. Tall Bletia. Ait. n. 2. (Cymbidium versiculum; Willd. Sp. Pl. v. 4. 105. Limodorum altum; Jacq. l. Rar. t. 602. Curt. Mag. t. 930.)—Petals converging. Lip without a spur; the ribs of its disk brichted; middle lobe broader than long; lateral ones contracted upwards. Stalk more or less branched.—Native of the West Indies, long known in our foues. Stalk three feet high, with spreading branches. Flowers crimson, an inch broad. Petals forming a hood over the styles. Furrows of the lip yellow.

3. B. floridu. Purple Bletia. Ait. n. 2. (Cymbidium floridum; Salib. Prodr. 9. Limodorum purpureum; Redout. Liliac. t. 83.)—Petals spreading. Lip without a spur; the ribs of its disk simple; middle lobe somewhat wedge-shaped; lateral ones dilated at the summit. Stalk somewhat branched.—Native of the warmest parts of the West Indies. Twelve or eighteen inches high. Flowers larger than the leaf, with more oblong, and more uniform, petals and calyx-leaves. Disk of the lip yellow.

5. B. capitata. Capitate Bletia. Ait. n. 5. — "Lip without a spur; callos internally near the base. Stem leafy. Flowers capitate."—Native of the West Indies, from whence it was procured by Dr Joseph Banks, in 1795. In flowers in the rose in June and July. We have seen no specimen nor figure.

Besides these garden species, and the original Peruvian ones, whatever they may be, there are doubtless several remaining latent in every good herbarium. We have some Nepaul Orchidceae from Dr. Buchanan, which may probably be referable to this genus.

BLETERIERE, l. 21, after Guyon, add.—He also edited Macler's Hebrew Grammar, vindicating his method in his "Vindicia Methodi Maclerianus," annexed to his edition of the Grammar in 1731.

BLIGHTIA, in Botany, so named in honour of admiral William Bligh, whose services rendered to botanical science, in the transportation of rare plants from remote countries, have procured him this compliment, in common with the great Captain Cook. — König in Ann. of Bot. v. 2. 369. Ait. Hort. Kew. v. 2. 350.—Clais and order, Olidnandra Monogynia. Nat. Ord. Trisholate, Linn. Sapindi, Juss.

1. B. sapida. Akee-tree. Ait. n. 1. König as above, 571. t. 16, 17. (Akee; Broughton Hort. Ealt. 1792. 10. "Akeia africana; Tussac Antill. 66. t. 3").—Native of Africa, between the tropics, from whence it was transported to the West Indies in 1788. The fleshy tunic, or support, of the seed is said to be a delicate article of cookery, resembling the white flesh of a chicken or frog, like which it serves to make fricassées for West Indian epicsion. The tree
tree is large, of handsome growth, with abruptly pinnate, ample, smooth, entire leaves, and copious, small, white flowers, in compound, axillary panicles. Some flowers have imperfect flaments, others an abortive germen. Nebthya a glandular notched ring, surrounding the base of the germen or its rudiment. Cappule elliptic-oblong, three-lobed, fleshy, variegated with red and yellow, about the size of a goose egg. Seeds globular, as big as cherries, dark brown, polished, each half funk in a white, turbinate, lobed and corru-gated tunica, of the substance of firm fruit, larger than the feed, and attached laterally to the central partition of each valve.

BLIGHT, l. 25, add—See Aphids.

BLISTERS, Fluid of, in Chemistry. See Fluids, Animal. 

BLOOD, Chemical Properties of. The chemical properties of the blood have been lately investigated with considerable success by Drs. Marcet and Berzelius, Brande, Berzelius, and others; with a summary view of whole experiments we shall here present our readers.

Of the serum.—The specific gravity of the serum of blood has been stated to lie between 1.028 and 1.029.5. The opinion of De Haen that it contains gelatine, was first given as erroneous by Dr. Boitock in this country, and about the same time by Berzelius in Sweden. The principle formerly termed gelatine has been variously represented and named by different chemists. Thus Dr. Boitock endeavoured to prove that it was a species of mucus, Mr. Brande that it was merely an alkaline solution of albumen; Dr. Marcet terms it mucous-extractive matter, Dr. Pearson an animal oxid; the French chemists ozma, ozmae, &c.; but it is to Berzelius that we owe the knowledge of its real nature. We infer, nearly in his own words, the following account of his analysis of the serum of the blood, as an excellent model for the analysis of all albuminous fluids.

One thousand parts of serum were evaporated to dryness till it could be easily reduced to powder. In this state the residuum weighed 95 parts, and confided of a yellowish yellowish gelatinous mass, resembling amber. Of this mass, says he, "I digested 10 grammes in cold water. The albuminous portion became softened and gelatinous. I separated by the filter the liquid from the insoluble part, and washed the latter repeatedly in boiling water. The undissolved albumen dried on the filter weighed 6.47 grammes, and did not give up its earthy phosphate by subsequent digestion in muriatic acid.

"The solution which passed the filter was evaporated to dryness, during which thick membranes formed at the surface of the solution, and the solution gelatinized before it was perfectly dry. I digested this residue in alcohol whilst it was still gelatinous; the spirit assumed a yellow colour, and on evaporation left an alkaline deliquescent mass, weighing .92 grammes. This confided of fda holding albumen in solution, of muriate of fda and muriate of potash, of lactate of fda, and of an animal matter which always accompanies the lactate. This animal matter has a brownish-yellow colour, is easily soluble both in water and alcohol, and is precipitated by tannin and submuriate of lead. It is constantly formed, as has been stated, in conjunction with the lactic acid only; and its presence may be taken as a sure indication of the presence of that acid."

"The portion not dissolved by alcohol, when digested with water, left a fresh residue of albumen, weighing 1.95 grammes. The watery solution could not be made to gelatinize, and did not contain the smallest quantity of gelatine. Besides the alkali, it contained an animal matter, easily precipitated by tannin and by oxy-muriate of mercury, and which appeared to me to be extracted from the albumen by boiling the water, and to be analogous to the subfiance obtained by boiling fibrin in water." See Fibrin.

Berzelius found only a slight trace of the phosphoric acid, and none of the sulphuric in the serum of ox blood; 1000 parts of which, according to him, consist of

</table>

According to Berzelius, "A more perfect agreement cannot be expected in the analysis of substances so liable to incidental differences, particularly in the quantity of water, which in the blood depends so much on the proportion of liquid taken into the stomach. It is clear that Dr. Marcet's extractive matter is impure lactate of fda; and I must also observe, that the sulphate of potash and earthy phosphates found by him in the ahas of serum are probably, for the reasons above-mentioned, formed by the processes of coagulation." See Albumen.

Of the colouring matter or red particles of the blood.—An opinion long prevailed among chemists, that blood owed its red colour to iron. Badia appears to have been the first who pointed out the existence of this metal in blood; but its presence was more satisfactorily demonstrated by Menghim, whose experiments were repeated and verified by subsequent
frequent chemists. Parmentier and Deyeux supposed, that the red colour depended upon the union of iron with the oxygen contained in the blood; Fourcroy and Vaquotin, who succeeded, denied this, and asserted that it depended upon the phosphophate of that metal. Dr. Wells, however, so long ago as the year 1797, called this opinion in question, and asserted that the most delicate tells of iron did not indicate the presence of that metal in the blood; that other red substances do not all contain iron; and that, on the other hand, other facts indicated that some iron were not red. Hence he supposed, that the red part of the blood was an organized animal substance. This opinion has been lately revived by an eminent modern chemist, Mr. Brando; who affirms, contrary to almost every other chemist, that the colouring matter of the blood yields no more iron when burnt than any other constituent of the blood, and that consequently it cannot owe its colour to that principle. Berzelius, however, though he denies the opinion of Fourcroy and Vaquotin, that the red colour depends upon a salt of iron, agrees with most preceding chemists, that its ashes contain much more of this metal than those of either of its other constituents, that is to say, that they contain go per cent. of oxygen of iron, while the ashes of albumen are fibrin do not yield a trace of that metal. Hence he concludes, that iron, somehow or other, and in a manner unknown to us at present, probably conduces to the colour of the blood. The opinion of Berzelius, and most modern chemists, respecting this principle is, that it closely resembles albumen and fibrin in its properties. According to Berzelius, the mineral acids act upon it nearly in the same manner as upon albumen. It is soluble also in dilute acetic acid, and precipitated by the prussiate of potash, like that principle; and hence Berzelius is inclined to consider it as a modification of albumen. Vaquotin has lately given a method by which he thinks the colouring principle may be separated from the other principles of the blood, which is a very difficult task; we do not think, however, that he has been successful.

Mr. Brando tried to form a lake, by precipitating its acid solution by means of different earthy and metallic salts. Neither alumina nor oxv of tin answered the purpose well. Corrosive sublimate or nitrate of mercury succeeded best. These gradually precipitated the colouring matter, and formed with it powders of a good red colour, not altered by exposure to the air. Mr. B. likewise made some attempts to employ it as a principle in dyeing, but they were not attended with much success.

Some interesting observations have lately been made on the size of the colouring particles of the blood by Dr. Young. According to this gentleman, they bear no proportion to the size of the animal. Thus,

\[
\begin{array}{ccc}
\text{The particles of bull's blood from} & \text{in inch} \\
\text{beef measured} & \frac{1}{4}^\text{\textsuperscript{4}} & \frac{1}{4}^\text{\textsuperscript{4}} \\
\text{Ditto of a mule} & \frac{1}{4} & \frac{1}{4} \\

\end{array}
\]

Of the Fibrin.—The experiments of Berzelius shew that this substance closely resembles albumen in its chemical properties. We do not think it necessary therefore to add any thing on the subject here, but refer our readers to the article Albumen. The physical properties of fibrin have been already deferred under Blood in the Cyclopaedia. Ac-Vol. XXXIX.

according to the experiments of Gay Lussac and Thenard, fibrin is composed of

The bloody coat of blood is fibrin.

Of the Secretary.—This term has been generally applied to the salt and animal matters existing in the forum of the blood, with the albuminous principle. See the description of forum in the present article.

With respect to the blood as a whole, little has been added to our knowledge. M. Vogel has attempted to shew, that when placed in the vacuum of an air-pump, it gives out a considerable quantity of carbonic acid; and Dr. Gordon has shewn, that during its spontaneous coagulation heat is emitted; but this has been denied by other observers, and especially by Dr. J. Davy.

The blood of other animals, and the blood of perfous labouring under different diseases, have been but little examined; indeed this extensive and important field of chemical investigation is almost entirely unexplored.

BLOOM, in Geography, a township of Pennsylvania, in Northumberland county, having 1285 inhabitants. Also, a township of the county of Fairfield, in the district of Ohio, having 829 inhabitants.

BLOOMFIELD. Add—Allo, a township of Pennsylvania, in Crawford county, having 114 inhabitants.

BLOUNT, J. 1, infra—Cain Tenneslee. Add—containing 8839 inhabitants, of whom 85 are slaves. Also, a county of the same state, having 3259 inhabitants, including 206 slaves.

BLOW-PIPE. We think it proper to notice here the important modification of this useful instrument, lately contrived by Mr. Brooke, and which, by the intensity of the heat it excites, has produced such interesting results in the hands of different experimentalists, and more especially of Dr. Clarke of Cambridge.

Mr. Brooke's blow-pipe consists merely of a strong copper or iron air-tight box, to which are adapted a condensing fyringe and jet-pipe, furnished with a fitchock. When used, the box is to be filled with condened air by means of the fyringe; the fitchock is then to be turned, and the condened air permitted to escape through the jet. From the smallness of the aperture of the jet, a conflant and uniform blast is thus kept up for a considerable time, and by the occasional use of the fyringe, may be continued for any length of time whatever) simply by means of the elasticity of the air itself.

A great advantage attending the use of this blow-pipe is, that the box can be readily filled with any gas, or mixture of gases, we choose. Accordingly advantage was soon taken of this property, and a mixture of oxygen and hydrogen gases, when inflamed as they issued from the jet, was found to yield a more intense heat than any other. From the liability, however, of this mixture to explode, great caution was required in using it, and this led to the necessity of some contrivance for obviating this dangerous circumstance. Various means were soon suggested, most of which were founded on the principle recently discovered by Sir H. Davy, that the inflammation of gases will not pass through minute apertures (see Wire-gauze); and, at length, we believe
BÖE

the instrument has been rendered quite safe; and, in this
state, may be obtained of any of the philosophical instru-
ment makers.

The public attention was particularly excited towards this
instrument by the experiments of Dr. Clarke, who supposed
that by its means, and the employment of the gaseous com-
ound above-mentioned, he had succeeded in reducing some
of the most refractory metals; and thus the accuracy of many of Dr. C.'s results has indeed been once
called in question; but they nevertheles demonstrate the
extraordinary powers and valuable properties of this modi-
cation of the blow-pipe.

BLUEHILL, l. 4, r. 658.

BLUE-WATER RIVER, a river of America, which
rises among the southern branches of Dock river, and em-
ties into the Tennessee.

BLUFF, a term ufed in N.W. America to denote a
particular tract of land. The alluvion of the rivers W. of
the Alleghanies is considerably lower than the surro-
unding country, and is of a breadth corresponding to the magnitude of the rivers; that of the Missouri is from 2 to 6 or 8 miles
in breadth, and is for the most part from 150 to 300 feet
below the general level of the country. The affluent from this
valley into the country is precipitous, and is called
"the bluff" and may conflict of rock or clay. Be-
twixt these bluffs, the river runs in a very crooked chro-
nel, and is perpetually changing its bed, and the permanent
beds are called the bluffs.

BOA, col. 3, l. 57, for CONSTRUCTOR r. SERPENTS.

BOARD of Agriculture. See Society.

BOARDMAN, in Geography, a township of Ohio, in
the county of Trumbull, containing 343 inhabitants.

BOCCA, a term ufed both in the Levant and on the
N. coast of South America, on the Spanish Main, for a
mouth or channel into any port or harbour; or the entrance
into a found which has a passage out by a contrary way.

BOCKFIELD, a town of the district of Maine, in
the county of Oxford, containing 1251 inhabitants.

BODMIN, l. ult. r. In 1811, the parish and borough
contained 315 houses, and 2383 persons; 158 in the parish
and 1008 in the borough being males, and in the former
175 and in the latter 1042 females.

BÖBERA, in Botany, formerly ufed by Willd., now, in
compliment to a Russian botanist, of the equitorial order.

——Willd. Sp. Pl. v. 3, 5126. Pursh 159.—Clafs and order,
_Symphoea Polygania-superflua._ Nat. Ord. Composit._ Linn.

Corymbifera, Jaff.

Calyx double; the inner of eight leaves, outer of many.

Pursh n. 1. (Tagetes papposa; Michaux Boreal.-Amr.
v. 2. 132. Vent. Hort. Celf. t. 36. _Dysoobia glandulosa_;
Cavan. Leccion. 602.)—Native of the overflowed banks of the
Missouri and Mississippi, annual, flowering in August
and September. _Pursh._ A branched herb, twelve or eighteen
inches high, with the habit of an Autumn, bebrinkled
with glandular pellucid dots, full of a fettid bitter fluid.
_Flowers_ of a golden yellow, with eight small rays. _Leaves_
pinnate, toothed, narrow. _Cavanilles_ says this plant grows
in every part of America, but especially in the kingdom of
South Fe., where it is commonly called _Rúyá_, on account
of its offensive smell. _Cavanilles_ speaks of it as a verminfuge,
and as affording a tolerably durable yellow dye.

BOERO, _del._

BŒUS, Rivière aus, or Os River, in Geography, is
the left and largest branch of Ouachita. It rises in the
angle formed between the Missouri and Arkansas, and pur-
cures a course to the S.W. for some distance, then turning
southward for 70 or 80 miles, enters the state of Louisiana,
and afterwards, at a short distance, crosses the N.E. line of
Baltimore's grant, pursues a S.W. course, and then refines
its direction to the southward, and after running about 65
miles enters Ouachita, above the well point of the island
of Sicily. The Basin, from its source in the Arkansas
lake to the boundary of the state of Louisiana, is about
120 miles, and from thence to its mouth nearly the same
distance, producing a length of 240 miles, independently
of its windings. It is navigable as far as Prairie Mar Rouge.
A strong brace of cane skirts the Basin nearly along its
whole course, through the state of Louisiana. Much land
near its banks might be cultivated, but is mostly subject
to casual inundation.

BOGAERT, l. 3, r. the Netherlands.

BOILING, col. 4, l. 10, after procefs, add—Under
the ordinary pressure of the atmosphere, with due allowance
for its variable density, water does not boil till it is heated
for 212° Fahrenheit. However far George Shuckburgh
found, that when the barometer was at 26 inches, water
boiled at less than 205°; but when it was at 31 inches it
required before it would boil a heat of nearly 214°. Under
the common pressure of the atmosphere, ether boils at 98°;
alcohol at 176°; water at 212°; nitric acid at 248°; ful-
phoric acid at 546°; phosphorus at 554°; and mercury
and linseed-oil at 600°. From the experiments of Dr. Black
upon several liquids in vacuum, it appears that, in general,
they all boiled with about 140 degrees of heat less than
when sublimating the weight of the atmosphere. Vitriolic
ether, if the pressure of the atmosphere be removed, will
boil when 52 degrees below the cold sufficient for freezing
water.

BOISSEAU, a meafeur for corn, according to the old
system in France, which varies much in different parts of
the country.

BOLAX, in Botany, a name of Commerson's adopted
by Jussieu. _Bolax_ means a clod, or lump of earth, which this
dwarf umbelliferous genus does not ill-resemble.—Juss. Gen.
(See Chamitis.)—The species, though not numerous, are
far from being, as yet, accurately determined, either with
refect to their permanent differences, or their synonyms.

BOLINGBROKE, l. ult. for 72 r. 741; and for 283 r.
361.

BOLINGBROKE, Lord. See ST. JOHN.

BOLIN-GREEN, in Geography, a town of Kentucky,
in Warren county, containing 154 inhabitants, of whom
51 are females.

BOLL, a corn meafeur in Scotland, containing 4 firlots,
each firlot being = 4 pecks; and 16 bolls = 1 chaler.

BOLOGNINO, a copper coin at Bologna and its neigh-
bourhood.

BOLSOVER, l. ult. for 435 r. 224; and for 1091 r.
1043.

BOLTON, in America, l. 3, r. 249; l. 6, add—contain-
ing 700 inhabitants; l. 8, for 861 r. 1037.

BOLTON-le-MOORS, l. 30, add—In 1811, the township
of Great Bolton contained 3120 houses, and 17,070 persons;
7988 being males, and 9082 females. Little Bolton town-
ship had 1286 houses, and 7079 inhabitants; 3366 being
males, and 3713 females.

BONAVENTURA, l. 2, r. Popayan.

BONDS, INDIA, bonds issued by the East India com-
pany of 50l. and 100l. each, bearing interell of 5 per cent. per
Bor per annum, which interest is paid at the India-house in London.

Bond, Post-Ohio, a bond payable after the death of the person whose name is therein specified.

Bones, Analysis of, in Chemistry. The analysis of bones was omitted under Bone, and will be found under Teeth, contralisted with the analysis of the teeth.

Vol. V.

Boone, in Geography, a county of Kentucky, containing 3668 inhabitants, of whom 666 are slaves.

Boonsborough, l. 2, r. Madison; and at the clofe add.—It contains 68 inhabitants, 15 being slaves.

Booroojird, a flourishing city of Persia, in the province of Irak, the capital of a wealthy district, subject to the prince, Mahomed Tukker Mirza, and containing a population of 12,000 souls. The district attached to its government is peopled by the tribe of Lock, who do not wander far from the spot to which they are partial, but settle in villages, and employ themselves in the improvement of their estates.

Borax, in Chemistry. See Boron, infra.

Bord, or Burn, in Commerce, a copper coin in Egypt, 8 bori being = 6 fori = 3 aspers = a medino, and 40 medini = a piastra current.

Borelli, col. 2, l. 6, r. 1670.

Boron, or Boracium, in Chemistry, the peculiar elementary basis of boracic acid. Sir H. Davy, in 1807, first decomposed boracic acid, and obtained this principle by the agency of galvanism. Soon afterwards another method of obtaining it was pointed out by Gay Lussac and Thénard, by means of potash, which was first seen by Davy and others. One part of pure boracic acid, previously melted and reduced to powder, is to be mixed with two parts of potash, and the mixture put into a copper or iron tube and gradually heated till it is slightly red, and kept in that state for some minutes. At the temperature of 500° the decomposition begins, and the mixture becomes intensely red hot, as may be perceived by making the experiment in a glass tube. When the tube is cold, the matter in it is to be washed out with water; the potash formed is to be neutralized with muriatic acid, and the whole thrown upon a filter. It may be washed and dried at a moderate heat.

Boron thus obtained is a powder of an olive-brown colour, without either taint or smell. In close vessels, it may be exposed to the most violent heat without being altered, or undergoing any other change than an increase of density. Its specific gravity, before being heated, is less than 1.84, but afterwards greater. It is insoluble in water, alcohol, ether, and oils, whether cold or hot. It does not decompose water even when heated in that fluid. It is a non-conductor of electricity. It undergoes no change when exposed to common air or oxygen at low temperatures; but when heated to about 600° it takes fire, and burns with great splendour; and at the same time absorbs oxygen, and is partly converted into boracic acid. The combustion, however, is soon stopped, from the coating of the boracic acid formed, which prevents the contact of the oxygen. Hence this requires to be frequently removed, by washing, before the whole of the boron can be burnt. The nitric acid also readily converts boron into boracic acid. Boron, heated with mord of the neutral salts, deprives their acids of the oxygen which they contain; thus, when heated in close vessels with sulphate or sulphite of soda, borate of soda and sulphur are formed. When heated with nitre or oxymuriate of potash, much deflagration ensues, and borate of potash is produced; so also the carbonate of soda is converted into borate of soda and charcoal.

There is considerable difficulty in fixing the proportion of oxygen with which boron combines to form boracic acid, as the results of Gay Lussac, Davy, and others, differ very much. Dr. Thomson, guided partly by these experiments, but chiefly by the analysis of borate of ammonia by Berzelius, fixes the weight of the atom of boron at 6.6, and supposes it combines with two atoms of oxygen to form boracic acid. Upon this supposition, 100 parts of boron will combine with 300 of oxygen.

Boron, when heated in chlorine, takes fire, and burns with a brilliant white flame. A white substance coats the vessel in which the experiment is made, and the boron is also covered with a white substance, which by washing is converted into boracic acid. It is probable that this white substance is a chloride of boron, but it has not been much examined.

Boron combines with fluorine, (see Fluorine,) and forms with it a powerful acid, which has been named fluoboric acid. (See Fluoboracic Acid.) It also appears, according to the experiments of Gmelin, to combine with hydrogen. Defocils has likewise shown that it combines with iron, and Davy with potash; but, as far as it is known, it combines with no other metal. With respect to the nature of this singular substance it may be proper to mention, that some consider the boron described above to be an oxyd of a metallic bafis, to which the name of boracium has been given.

Boronia, in Botany. (See Rutaceæ.) Mr. Brown, who could not but be aware of the ill-defined limits of this order, as originally constituted by Jussieu, has, in his General Remarks on the Botany of Terra Australis, 15, proposed to remove the 1st division, under the appellation of Zygophylleæ, naming the remainder Disfmes, the genus Ruta not being a good type of the order, so limited. This learned Australian botanist informs us that near 75 species have been observed, the greater part of them referable to our Boronia, Correa, Erioselemon, and Zieria, (as also we presume to Crowea,) and to Phebalium of Ventenat. "Of these genera Boronia is both the most extensive and the most widely diffused, existing within the tropic, and extending to the south end of Van Diemen's island. Like the others, however, its maximum is in the principal parallel, at both extremities of which it is equally abundant."

Borough, col. 3, l. 19 from the bottom, after London, r. by a writ bearing date the 12th of December, 1264, in the 40th year of the reign of Henry III.

Borough-Bridge, l. 23, r. The borough and township of Borough-bridge contain 131 houses, and 747 inhabitants; 373 being males, and 374 females.

Borragineæ, in Botany, the 42d order in Jussieu's system, the 9th of his 5th class; for whose characters, see Gentianæ.

This order, equivalent to the Linnaean Asperifolium, (see that article,) is thus characterized.

Calyx in five deep segments, permanent. Corolla mostly regular. Stamina generally five. Germin either simple or four-lobed; style one; stigma either cloven, or furrowed, or simple. Seeds generally four; sometimes enclosed in a capular or pulpy test-vefsel; sometimes naked, obliquely attached to the bottom of the style, and for the most part surrounded by the permanent calyx. Corollum without albumen. Stem in the greater number herbaceous; in a few
BOR

few shrubby or arborescent. Leaves alternate, often harsh or rough.

Seet. 1. Fruit pulpy. Stem shrubby or arborescent.

Patagonula, Cordia, Ebreia, Menai, Varronia, and Teu-nsfoxia.

Seet. 2. Fruit of one or two capsules.

Hydrophyllum, Phacelia of Jullieu, Elisia, Dichondra, 
Müllerhermitia, and Cerinoe. Dichondra (see that article) 
is erroneously placed here.

Seet. 3. Fruit of four naked seeds. Throat of the corolla 
naked. Plants mostly herbaceous and rough.

Cordonia, Lichonestum, Echinum, Lipobernum, Pulmonaria, 
and Chymoxina.

Seet. 4. Fruit of four naked seeds. Throat of the corolla 
furrowed with five scales, hollow like flukes, slightly projecting 
out of the corolla, at the base of its segments, gaping above. 

Germs generally with rough leaves.

Spermatium, Lycopsis, Myosotis, Anchoia, Borago, Alse-
rugo, and Gymnoglossum.

Seet. 5. Genera allied to the Borragineae.

Nolana, Sphenanthes, and Falkia.

Borrera, is dedicated by professor Acharias, 
to the honour of Mr. William Borrer, F.L.S., one of the 
most eminent British cryptogamists, whose studies 
have been particularly directed to the Lichen tribe, and who 
is also critically verfed, as well as singularly accurate, 
in every department of British botany.—Achar. Lich- 
Græc. Siith. v. 2. 313.—Clafs and order, Cryptogamia 

Eff. Ch. Shelves fchoked, coloured, with an elevated, 
infixed border, of the substance of the leafy, cartilaginous, 
elevated, linear froid.

This genus is very natural in habit, comprising the well-
known Lichen ciliatus of Linneus and its allies. Acharias 
defines seventeen species, among which several are very 
elegant, such as B. Trulla from Peru, figured in Ach. 
Meth. t. 4. f. 6; leconaoma, (see Engl. Bot. t. 254;) and 
ebsphylathyrum, t. 1088.

We have ventured in Prod. Fl. Græc. to remove hither 
the Evernia prunifolia, Ach. Syn. 245; Lichen prunifoli of 
Linneus; and feel much inclined to allocate the whole of 
that genus with Borrera, there being only two species 
besides, which are Lichen divaricatus and vulpinus of Linneus.

We re ally cannot perceive any diffusive character to keep 
Evernia separato.

Borrowstonness. —Add.—The parish contains 
352 houses, and 2704 inhabitants; 1102 being males, and 
1602 females.

Bory, in Botany, a New Holland genus, thus named 
by M. Labillardière, in honour of the distinguished bot-
anical traveller, M. Bory de St. Vincent. This genius was 
first made public by its author in 1804. A year or two 
afterwards, professor Willdenow published a different 
Borya, in his Sp. Pl. v. 4. 711. The former is adopted, 
in his Prodromus, by Mr. Brown, who, nevertheless, has 
admitted the latter into Ait. Hort. Kew. v. 5. 365. This 
can only have arisen from the professed plan of the Hort. 
Kew. being in general to copy Willdenow, and we trust 
Mr. Brown no more intended to give his function to this 
error, than to the adoption of Araucaria, to the pre-
judice of the rightful Domenea. (See those articles.) 
However that may be, we feel it incumbent on us to 
administer the original Borya, against which no valid objection 
can be raised, having already endeavoured to find a suitable 
name (see Bigelowia) for the other.—Labill. Nov. Holl. 

and order, Alexandria Monogyna. Nat. Ord. Alphadaceæ, 
Brown.

Eff. Ch. Spatha of two unequal, sheathing, permanent 
valves. Corolla of one petal, funnel-shaped, withering; 
limb in five deep equal segments. Stamens inserted into 
it contracted throat. Style thread-shaped. Stigma ob-
late. Capsule superior, of three cells, and three valves, 
with central partitions. Seeds several.

Mr. Brown conceives the present genus to be not very 
-nearly related to any, except perhaps Xanthorrhoea, 
(see that article,) and the genus Johnsonia. In habit it 
approaches some of the Junceæ, but differs in the black 
coarsely integument of the seed, and in the soft, fleshy, 
white or yellow, albumen.

It consists of perennial herbs, of a harsh dry texture. 

Grass composed of long, tough, somewhat fibrous fibres. 

Stem either simple, or divided and creeping, clothed with 
very crowded, acerose, pointed leaves; dilated and half-

sheathing at their base. 

Flower-flaks solitary, terminal, simple. 

Head nearly globular, encompassed with a few short leafy bracteae. 

Calys smooth, membranous, the outer one sheathing the inner, which is narrower, 

and embraces the tube of the corolla.

81. t. 107. Br. n. 1.—Stem much branched, taking root 
below, with simple piliferous fibres. Flower-flacks shorter 
than the ascending branches. Head ovate.—Gathered 
by both the differentialed botanists above cited, on the south 
coasts of New Holland, and the adjacent islands, in sandy 
ground. The plant is about a foot high, and, except the 
want of downy radicles, seems calculated to confine the 
blowing sands of its dreary country, like our Carex ace-
vario, Elymus arenarius, &c.

"—Stem simple, nearly erect, shorter than the flower-

flaks. 

Head globose."—Gathered by Mr. Brown, in 
the fame neighbourhood.

Bos, in Zoology, l. 13. after ferus, inferf.—See 
Urus.

Boscawen, l. 4. r. 1829.

Bos Rilla, in Botany, a fine papilionaceæ genus, con-
secrated by Ventenat, to the memory of his countryman 
M. Boillieu-Lamartinière, who accompanied La Pérouse 
in his voyage round the world, of which which, published 
at Paris, attests the merit of this unfortunate botanist, 
v. 4. 266.—Clafs and order, Diadaphia Decandria. Nat. 
Eff. Ch. Calyx two-lipped; upper lip largest, cleft, obtuse. Stamens all connected. Legume flaked, compressed, thickened at each edge, with many seeds.

1. B. flocculenta. Yellow Flat Boffizia, or Plank-plant. Sm. as above n. 2. Sims in Curt. Mag. t. 1255. (B. Scolopendrum; Ait. n. 1. Platylobium scolopendrum; Andr. Repof. t. 191. P. scolopendrum; Ven. Malmaif. t. 59.)—Branches compressed, winged, toothed, leaflets; flowering at the teeth. Stem erect. Keel naked. Upper bracteas permanent, imbricated, equal to the footstalk. Calyx very smooth.—Native of New South Wales, from whence it was introduced, in 1792, by Lee and Kennedy. A green-house shrub, flowering early in summer. The winged branches, in a manner prolific, and bearing handsome, red and yellow, flaked, solitary flowers, from their numerous alternate teeth, give this shrub a very singular aspect. The feeding plants only bear simple, alternate, flaked, ovate, entire leaves. The legume of this species, (and perhaps the following), is said by Dr. Sims to want that internal sponging, which, in those shrubs described by botanists, seemed to yield a good generic character. The texture of the legume, its thick edges, and the want of a dorfal membranous wing, are still abundantly sufficient to keep the genus distinct from Platylobium. (See that order referred to the species name, we must beg leave, like Ventenat and Sims, to consider it as an adjective, comparing this strangel plant’s branches to the infect called a Scodelium, or Centipede. It has no connection with the vegetable genus Scolopendria, and still less has it ever been so called.

3. B. heterophylla. Various leaved Boffizia. Venten. Jard. de Ceb. 7. Willd. n. 1. Sm. n. 1. Br. in Ait. n. 3. (B. lanceolata; Curt. Mag. t. 1444. Platylobium lanceolatum; Andr. Repof. t. 205. P. ovatum; ibid. t. 266, not 256) according to Mr. Brown.—Branches leafy, compressed. Leaves elliptical, obovate, or linear, flat. Legume of many cells, with spongy partitions. Native of New Holland. Imported by Lee and Kennedy in 1792. A branched bushy shrub, flowering most part of the summer. The branches, though nearly flat, are not dilated like the foregoing, nor are they either toothed, or denudated. The leaves are variable in figure, but on full grown plants usually linear, alternate, on short stalks. Flowers axillary, solitary, italked, large, yellow with a crimson keel, very ornamental.

4. B. longifolia. Narrow-leaved Boffizia. Br. in Ait. n. 4. —“Branches leafy, compressed. Leaves linear; recurved at the margin. Legume of one cell.”—Observed by Mr. Brown, on the south-west coast of New Holland. Sent by Mr. Good to Kew, in 1803, where it is said to flower from July to September.

5. B. profusa. Proornent Boffizia. Br. in Ait. n. 5. (B. ovata; Sm. n. 3, excluding the synonymy.)—Branches round, leafy, Stem procumbent. Leaves oval, smooth. Stipulas shorter than the footstalks. Legume of a single cell.—Sent from Port Jackson, by Dr. White, in 1793. Mr. Good is mentioned as having sent it to Kew, in 1803. The flowers are a span long. Leaves nearly uniform, a quarter of an inch long, their edges thickened, wavy, and somewhat crenate. We had mistaken this for the Platylobium ovatum of Andrews, t. 266, but Mr. Brown has convinced us of our error.

6. B. cineraria. Downy Sharp-leaved Boffizia. Br. in Ait. n. 6.—“Branches round, leafy. Stem erect, much branched. Leaves ovate-lanceolate; rough above; downy beneath; recurved at the margin.”—Found by Mr. Brown in Van Diemen’s Island, and sent in 1805 to Kew, where it flowers from May to July.

7. B. microphylla. Little-heart-leaved Boffizia. Sm. n. 5. Dr. in Ait. n. 7. (Platylobium microphyllum; Sims in Curt. Mag. t. 863.)—Branches round, leafy, spine-pointed. Leaves inerely-heartshaped, or wedge-shaped.—Native of New South Wales, from whence Dr. White sent us specimens in 1793. Mr. Caley sent seeds to Sir Joseph Banks in 1805. This species is said to have flowered at the present duke of Marlborough’s, at White Knights, in 1805. The flowers, though smaller than in some other species, are so numerous, and so prettily variegated with yellow, purple, and red, as to render this a very ornamental plant. The leaves are shorter than the flowers, veiny, smooth and entire, very abundant. The tips of the branches finally become spinous.

Mr. Brown is probably furnished with more species of this handsome genus, which have not yet made their appearance in the gardens.

BOSSINEY. Add. —The parish of Tintagel, in which this borough is situated, contained, in 1811, 141 houses, and 730 persons; 339 being males, and 391 females.

BOSTANA. See Bostian.

BOSTON. At the close, r. the parish of Bolton, in 1811, contained 1772 houses, and 8180 persons; 3805 being males, and 4375 females.

Bostoon, in Massachusett's, l. 17. after augmented, infert.—By the census of 1810, Bolton, Chelsea, and the islands within and without the jurisdiction of Bolton, included a population of 34,381 souls. The former islands are, Noodle's, Hog, Apple, Deer, Long, Spectacle, Governor's including Fort Warren, and Fort Independence: the latter are, Greene, Thompson's, Rainford's, George's, Great Brewter, Outer Brewter, Lighthouse, and Calfland. Bolton itself is stated as containing 33,250 inhabitants.

BOSTON, a town of the district of Ohio, in the county of Champaign, having 616 inhabitants.

1. B. glabra. Smooth Boswellia. Roxb. as above, t. 207. (Canarium odoriferum: Rumph. Amboin. v. 2. 156. t. 50. Guggulapootickthoo of the Telingas.)—Leaflets smooth, with shallow ferratures.—Native of the highest mountains on the coast of Coromandel, flowering in the cool seaon, and calling its leaves in October. This is one of the largest trees of that country; its wood hard, heavy, and durable. The wounded bark yields a fort of pitch. Leaves crowded at the ends of the branches, a span long, pinnate with an odd one; leaflets all uniform, opposite, ovate-oblong, an inch and a quarter in length. Flowers white, in aggregate, terminal, interrupted, spreading clusters, shorter than the leaves, and coming before them. In Nectary red. Anthers oblong, yellow. Capsule oval, about half an inch long.

2. B. kirtiata. Hairy Boswellia. (Canarium odoriferum)
B O T

terum bifurcatum; Rumph. Ambaun. v. 2. 157. t. 51, according to Dr. Roxburgh; but the leaflets are represented entire.}—Leaflets downy, deeply serrated. On the Ballagaut mountains. The flaves of this are inserted on the exterior margin of the petiole. Roxburgh.

BOTETOURT. Add.—By the census of 1810, it contained 13,301 inhabitants, of which 2,273 are laves.

Eff. Ch. Capsules nearly globose, naked, smooth, without a ring, united to the stalk of a compound spike, distinct, each of one cell, and two valves connected behind, burfling transversely in front.

We have already alluded to this genus under Osmunda, from which it was first separated by professor Swartz. Ten species are described in Wildenow, to which we have two to add.

B. Lunaria minor; Camer. Epit. 614. Frond finely pinnate; leaflets crenate-serrate. Native of dry hillocks, or open heaths, throughout the cooler parts of Europe, bearing capsules in June. Root perennial, with many fleshy fibres. Frond foliata, from a torn mem- branous sheath, erect, three to six inches high, smooth, pale green, confiting of a finely pinnate leaf, two inches long, with fix or few pair of oblique imbricated, fan-shaped, entire or notched, leaflets. From the base of the leaf springs a stout stalk, about the same length, bearing a twice or thrice compound, unilaterial, smooth spike of capsules, each about half the size of a mustard-seed; all firmly united, in two fejile rows, with the linear flat rib, or common receptacle.

2. B. rutaceum. Rue-leaved Moonwort. Sw. n. 2. Wild. n. 2. (O. Lunaria; Fl. Dan. t. 18. f. 3. Fl. Brit. 1875. Lunaria racemosa minor, matricaria folio; Breyn. Cent. 184. t. 93. Morif. fec. 14. t. 5. f. 5.)—Frond doubly pinnatifid; segments ovate, notched at the extremity. Fruitstalk from the base of the leaf.—Native of dry open situations, in several parts of Europe. We are not sure of having seen a British specimen; nor is it impossible that a jagged variety of B. Lunaria, such as is represented in Breyn. Cent. t. 193, and in Morison as above, f. 2, may have been confused herewith. B. rutaceum is certainly near akin to the Lu- naria, differing only in the compound division of its leaf, and sometimes of its spike.

3. B. maticariunum. Feverfew-leaved Moonwort. (B. maticarioides; Wild. n. 3. Lunaria racemosa, multifido folio; Bauh. Pin. 355. Breyn. Cent. t. 95. Fl. Dan. t. 18. f. 2, media. Morif. fec. 14. t. 5. f. 26.)—Frond doubly pinnatifid; segments oblong, obtuse, toothed. Fruitstalk from the base of the footstalk.—Native of shady situations in Pfriifen, Denmark, and Bavaria. Willdenow. Extremely abundant about Peterburgh, according to the Linnean herbarium, where are three specifions from thence. The more compound leaf, not always foliata, and especially the insertion of the fruitstalk near the root, not at the top of the leafstalk, surely mark this as a distinct species; which is confirmed by the plant not being of occasional occurrence, amongst the Lunaria, as might be expected of any variety, but plentiful in the countries where it grows at all. We have not heard of this species in Britain. The specific name in Willdenow is a barbarous compound of Greek and Latin, such as we with botanists, not altogether illiterate, would avoid.

4. B. fumarianum. Tumitory-leaved Moonwort. (B. fumaroides; Wild. n. 4. Ait. n. 1. Pursh n. 1. Lunaria; Sw. n. 5. „ Schkuhr Crypt. 158. t. 157.„ Botrypus lunariae; Mich. Bor.-Amer. v. 2. 274. O'fumba bitementa; Lamarc. Dict. v. 4. 650.)—Frond ternate; doubly pinnate; leaflets crenate-serrate, crenate. Fruitstalk radical.—In pastures and open woods, from New York to Carolina, bearing capsules in June. Pursh. Like the leaf, especially in the insertion of its fruitstalk, at or near the root, but the leaflets exactly resemble those of B. Lunaria, which, with professor Willdenow's leaf, are by no means uniformly entire.

5. B. obliquum. Oblique-leaved Moonwort. Wild. t. 5. Muhlenb. Cat. 98.—Frond nearly twice ternate; leaflets oblong-lanceolate, finely serrated, unequally heart-shaped at the base. Fruitstalk towards the base of the footstalk.—In open woods of Pennsylvania and Virginia, in June and July. Refemblles the preceding very much, and is probably only a variety. Pursh. This author describes the spikes as doubly pinate; those of the leaf only pinate.

6. B. asperula. Southern Moonwort. Brown n. 1.—Frond ternate; doubly pinnate; leaflets conjunct, cut. Fruitstalk from the base of the footstalk.—Sent by Dr. White, from Port Jackson, New South Wales; where, as well as in Van Diemen's island, it was gathered by Mr. Brown. Leaflets bluntly toothed. Fruitstalk pale, a sparn high, being thrice as tall as the leaf, into whose dark-coloured footstalk it is inserted, a little above the root. The spike is twice or thrice compound, spreading; the flaks pale. Capsules dark brown.

7. B. tennatum. Ternate Japan Moonwort. Sw. n. 6. Wild. n. 6. (Ofunda ternata; Thom. Jap. 329. t. 32.)—Fronds in pairs, tripinnate; leaflets notched and ferrated. Fruitstalk from the middle of the common footstalk. Spike pinate.—Gathered by Thunberg once only, near Nagasaki in Japan, in November. A foot high, with two large, opposite, spreading, ternate, then twice pinate, leaves, half the height of the fruitstalk.

8. B. dithecum. Cut-leaved Moonwort. Wild. n. 7. Muhlenb. Cat. 98. Ait. n. 3. Pursh n. 3. Sprengel Crypt. angl. ed. 187. „Schkuhr Crypt. 159. t. 158.„ (Lunaria botrytes rotata, geranioli molochati folis, floribus; Pluk. Amalthe. 324. t. 427. f. 5.)—Frond ternate, thrice pinate; leaflets decurrent, linear-wedge-shaped, sharply toothed at the end. Fruitstalk at the base of the leaf.—In pastures of open dry woods, from New York to Florida, in June. Pursh. We have Pennsylvania speci- mens from the late Dr. Muhlenberg, very much like Plu- kett's figure, but we can discover no essential difference between this plant and the following.

9. B. virginianum. Virginian Moonwort. Sw. n. 3. Wild. n. 8. Ait. n. 4. Pursh n. 4. „Schkuhr Crypt. 157. t. 156.„ (Ofunda virginiana; Linn. Sp. Pl. 1519, excluding Plumier's synonym. Lunaria americana, folis cicutariis modo eleganter divisis; Morif. fec. 14. t. 4. f. 7. L. multifido folio oblongo, &c.; Pluk. Mant. 120. t. 427. f. 8.)—Frond somewhat ternate, twice pinate; leaflets decurrent, obovate-wedge-shaped, sharply toothed. Fruitstalk at the base of the leaf.—In shady woods, on a rich vegetable soil, from Canada to Carolizina, in June and July.
July. *Pursh.* That author observes, "this is the largest of the species here described. It is known by the name of Rattle-snake Fern, probably from growing near the places where those venomous animals are generally found." Our specimens, one of which was gathered by Clayton, the other by Kalm, are scarcely so large as the last described, from which they differ chiefly in having rather less compound leaves. The inflorescence is somewhat hairy, as is that. Willdenow, negligently as it seems, changed the termination of the specific name to *virginicum*, which could only cause trouble, and we have therefore restored the original.

10. *B. gracile.* Slender Moonwort. *Pursh.* n. 5. Frond ternate, doubly pinnatifid, falcate; segments acute, spikes slender, pinnate, erect.—In shady fertile woods of Virginia, in June. This species approaches nearly, at first sight, to the preceding, but is much smaller and more slender, besides the other differences. *Pursh.* We have from Dr. Muhlenberg what answers to the above account, but should scarcely have thought it distinct. The inflorescence indeed is smooth, and simply pinnate, but this corresponds with the smallest size of every part.

11. *B. circiatum.* Hemlock Moonwort. *Sw. n.* 4. Willd. n. 9. (Osmunda circiatia; Lam. Dict. v. 4. 650.) O. afpocladi radice; Plum. Fil. 156. t. 159. Petiv. Fil. n. 156. t. 9. f. 2.)—Frond triplicate; leaflets pinnatifid; terminal one pointed. Fruitstalk from near the base of the footstalk.—Gathered by Plumier in the forests of Hispaniola. The roots confistles of oblong tapering fleshy knobs. Frond much larger than either of the three half, and essentially different in the nearly radical inflorescence of the fruitstalk. The spike is twice pinnate. Plumier records, that the Indians give the name of Serpent-herb to this, and to the *Anemia decadentifolia*, thinking them useful applications for the bite of a serpent. This may account for the appellation of Rattle-snake Fern given to it.

12. *B. zeylanicum.* Great Ceylon Moonwort. *Sw. n.* 7. Willd. n. 10. (Osmunda zeylanica; Linn. Sp. Pl. 319. O. n. 373; Linn. Zeyl. 178. Ophioglossum lacinatum; Rumph. Amboin. v. 6. 153. t. 68. f. 3.)—Frond ternate; leaflets pinnate or somewhat pinnate, lanceolate, pointed, finely crenate. Spike cylindrical, dense; spikelets capitate. —Native of Ceylon and Amboyna, on the sides of hills, in the borders of woods and thickets. The root is long and creeping, very deep in the ground, with numerous long fibres. Fronds a foot and a half or two feet high, naked, except at the very top of the stalk, from whence proceed three slightly-flattled branches, each of two, three, or more, equal, uniform smooth leaflets, five or six inches long, and one broad, partly decurrent, light green, with many fine transverse veins. From the same point springs a fruitstalk, with a dense cylindrical compound spike, riling rather above the leaflets, the caryophylls about three together, capitate, at the end of each short branch partial.

BOTRYOLITE. See Mineralogy, Addenda.

2. *B. ramosa.* Croft-headed Cluster-mould. *Pursh.* n. 2. (B. ramosa cinerea, fæminus rotundus; Mich. n. 3. f. 2. 11.) B. alba. (B. non ramosa alba, fæminus rotundus; Mich. n. 2. f. 3.)—Ash-coloured, branching, with four-rayed spikes. Very common in all kinds of corrupting substances. *Micheli.* The minute stems are more or less branched and forked, each branch terminating in a composit of four dense ovate maffes of globulles, on short horizontal falks.

3. *B. simplex.* Simple Cluster-mould. *Pursh.* n. 3. (B. comata grisea, canile fimplici caffraio, fæminus rotundus; Mich. n. 1. f. 4.)—Grey, simple. Spikes radiating.—On half-rotten wood, or wheat-draw, in winter, not infrequent. *Micheli.* Each plait consists of a simple, rather firm, falk, a line or two in height, crowned with from three to six ovate maffes of globulles, on horizontal radiating falks.

5. *B. diffusa.* Great White Cluster-mould. Albert. and Schwein. Fung. Nat. 352.—White, with extensive diffuse branches, and terminal clusters, of about four globulles each.—Found once only on half-rotten stalks of potatoes in November, composing dense, white, cottony, fagaceous maffes, two inches or more in diameter. The globule discharge abundance of powdery seeds like smoke.

BOTTOMRY, col. 4, l. 23, for course r. courts.

BOUSSAKTA, in *Botany*, a name of barbarous origin, being formed by Dilleni from the German *Buch*.

Eff. Ch. Cafe smooth, femail, burting irregularly at the top; its white external coat (or wrapper?) at length separating in fragments. (Powder or feed brownish-purple.)

*Perforo.*

The author defines four species.

1. *B. nigrescens*, which is *Lycoperon globosum*, Bolt. Fung. t. 118. With. v. 4. 382, and *L. arrhizon* of *Batch*, t. 29.

2. *B. plumbea*, figured in Sowerby's Fungi, t. 331, as *L. Bovisia*, and judged by that author to be but a variety of the former.

3. *B. papilla, " Batch, t. 41. f. 228," akin to the five, but only three lines in diameter.

4. *B. furfuracea*, figured by *Micheli*, Nov. Gen. t. 97. f. 6, who says it is common on heaths, and fold with other fungi of this tribe, in the market, at Florence. *Perforo* is doubtful of the genus of this leaf, and we should suspect it to belong possibly to *Tuber*.

*Bovisia* differs from *Lycoperon* in not being elongated at the base into a sort of stalk; but hardly they might, without violence to nature, be united, especially as the species of the present genus are so few and so disputable.

BOURBON, in Kentucky, l. 2, r. 11,869; l. 3, r. 2507.

BOURN, col. 2, l. 21. In 1811, the parih of Bourn contained 308 houses, and 1551 persons; 779 being males, and 812 females.

BOURSIPPA, in Geography, a town of Babylonia, according to Strabo; to which Alexander retired when warned by the Chaldeans not to enter Babylon. This is supposed to be the present village of Bouris, two leagues to
to the S.E. of Hilleh, the cite, as it is conjectured, of 
ancient Babylon. On the road from hence to Meked Ali, 
or Ncjatt, is the tomb of the prophet Ezekiel, where they 
pretend to saw the fiery furnace of Shadrach, Meshach, 
and Abednego. It is a large clumsy building, without 
beauty or ornament; and, like the tomb of Ezra, on the 
banks of the Tigris, a short way above Korna, is much 
frequented by Jewish pilgrims.

BOUVARDIA, in Botany, so named by Mr. Salib- 
burry, in memory of Charles Bouvard, M.D., formerly 
superintendent of the garden at Paris.—Salib. Parad. 88.

AI. Hort. Kew. v. 1. 245.—Clafs and order, Tetrandria 

Eff. Ch. Calyx in four deep segments, with inter-
mediate teeth. Corolla tubular. Anthers within the tube. 
Caplile of two separable cells, with numerous bordered 
seeds.

Salib. Parad. t. 88. (Houttonia coccinea; Andr. Repof.
t. 106. Ixora americana; Jacq. Hort. Schoenbr. v. 3.
t. 357. I. ternifolia; Cav. Ic. v. 4. t. 265.)— 
Native of Mexico. Introduced by fr Joseph Banks 
1794, and now become common in the English gardens, 
where, if planted against the front of a green-house, it will 
stand our ordinary winters; flowering from Midsummer 
till the end of autumn. The stem is from one to two feet 
high, thunbry, branched, down when young. Leaves 
usually three in a whorl, ovato-lanceolate, varying in 
breadth, entire, rough-edged, nearly felfile. Flowers an 
inch long, bright scarlet, in dense, terminal, forked panicles, 
very abundant, and extremely showy, though ditinct of 
scents.

BOW, l. ubi., r. The parish contains 414 houses, and 727 
perons; 329 being males, and 398 females.

Bow, in America, 1. 4. r. 729.

BOWDOIN, l. ulti., for 638 r. 1649.

BOWDOINHAM, l. ulti., for 455 r. 1412.

BOWLESIA, in Botany, so named by the authors of the 
Flora Peruviana, in honour of Mr. William Bowles, a 
native of Ireland, who published at Madrid, in 1775, an 
Introduction to the Natural History of Spain, making a 460 
volume of 529 pages, in the Spanish language. This work 
has been translated into French and Italian. The author 
Umbell. 13.—Clafs and order, Perandria Digynia. Nat. 
Ord. Umbellifere.

Eff. Ch. Fruit ovate, quadrangular, briskly; concave 
at the back. Umbel fimple.

The author enumerates three certain species in his Pro-
 dronum.

1. B. palma, of Ruiz and Pavon, of which he gives 
no character or description.

2. B. lobata, of the fame, "Fl. Peruv. v. 3. t. 251, B." 
Spreng. Sp. Umb. 13.—Somewhat hairy. Leaves lobed, 
ribbed: abrupt at the base; lobes entire, pointed. Foot-
flakes elongated. Flower-flakes axillary, markedly folty. 
Tendrills none.—Native of the loftiest mountains of Peru. 
Herb tender, green, with some scattered hairiness. 
Leaves opposite, an inch broad, half an inch long, five-
ribbed, on fender zigzag footflakes about a finger's length. 
Stipulae membranous, linear, in pairs. Footflakes about 
two lines long, reflexed after flowering, the stipular serving 
as an involucrum. Petals live cream-coloured. Fruit in 
pairs, solid, ribbed at the back, clothed with hairy hairs.

3. B. incana, of the fame, "Fl. Peruv. v. 3. t. 268, A." 
Spreng. Spec. Umb. 13. t. 5. f. 10.—Hoary. Leaves 
kidney-shaped, lobed, notched; heart-shaped at the bafe.

Flower-flakes axillary, aggregate. Tendrils axillary. — 
Native of Peru and Brazil. Our specimen was gathered 
in the last-mentioned country, by Commeron, and is larger 
than Sprengel's figure, being a foot long, though incom-
plete. This species seems nearly allied to the last. We 
discover no tendrils in our specimen.

(Perecundum geniculatum; Forst. Prodr. 22. Willd. 
Sp. Pl. v. 1. 1408.)—Smooth. Leaves nearly orbicular, 
crenate; wedge-shaped and entire at the bafe. Umbels 
terminal, many-fowered.—Native of New Zealand. Stem 
prostrate, branched. Leaves not half an inch broad. 
Umbel compound. Fruit unknown. This seems to us a 
very doubtful Bouvardia, and is referred hither merely on 
account of some resemblance of habit.

BOWLING-Green, in Geography. Add—Alto, a town-
ship of Ohio, in the county of Licking, having 379 inhabi-
ants.

BOXBOROUGH, l. 2., for 412 r. 388.

BOXFORD, l. ubi., for 925 r. 885.

BOYLSTON, l. ubi., for 839 r. 802.

BOYSTON, Wft., a town of the fame flate and county, 
having 612 inhabitants.

BOZRAH. Add—It contains 950 inhabitants.

BRACClO, plur. Bracti, a measure for cloth in Italy.

BRACHIONIUS, Add—See VERMES and Wheel-
Animals.

BRACHYSEMA, in Botany, so named by Mr. Brown, 
from BCR
c, short, and ?wvq, a flanderd, alluding to 
a striking part of the generic character.—Brown in Ait. 
Hort. Kew. v. 3. t. 30.—Clafs and order, Decandria Mon-

Eff. Ch. Calyx nearly equally five-ceil; with a fwell-
ing tube. Corolla papilionaceous; flandard shorter than 
the compressed keel, which is equal to the wings. Stalk 
of the germen minutely fheathed. Style thread-shaped, 
elongated. Legume tumid, with many feds.

Curt. Mag. t. 2008.—"Leaves ovate, flat. Standard 
oblong-obovate."—Sent by Mr. Good, in 1803, from the 
flans of this coast of New Holland, where it was alfo 
gathered by Mr. Brown. A hardly green-house procemcnt 
or pendulous flurb, eafily propagated by cuttings, and 
flowering in the spring. Flowers fcarlet, very handfome, 
flandise, nearly felife, folty, fometimes two or three 
together, their small acute flandard yellow at the bafe; 
wing and fell full an inch fmall.

There appear to be other species, not yet introduced 
into the gardens.

BRACKEN, in Geography, a county of Kentucky, 
having 3451 inhabitants, of whom 295 are flavcs.

BRADFORD, col. 2, l. 11, r. In 1811, the houses in the 
hundred of Bradford were 1756, and the number of 
perons was 9435; 4260 being males, and 5166 females. 
The parish of Great Bradford contained 548 houses, and 
2989 perons.

BRADFORD, in Yorkshire, l. 12. The parish of Bradford 
contains 13 townships, and in 1811 the township of East 
and West Bradford contained 1574 houses, and 7767 perons. 
East Bradford having 725 houses, and 3559 perons; 
1603 being males, and 1865 females; and West Bradford 
having 849 houses, and 4208 perons; 1986 being males, 
and 2222 being females.

BRADFORD, East and West. Add—the former contained, 
in 1810, 1003, and the latter 1219 inhabitants.

BRADFORD, l. 4, r. 1369; l. 9, r. 1034; l. 12, r. 
1302.

BRADYPUS,
BRA

BRADYPUS, l. 16, for cloth r. bear; l. 20, after megatherium, add—(which see).

BRAIN, Chemical Analysis of. For ADIPOCIRE 1. ADI-
POIRE.

A new and elaborate analysis of the brain has been lately
made by Vauquelin; but it must be confessed that his results
throw no light whatever upon the manner in which its
costituents are combined, or to what its peculiar appear-
ance is owing. The following are the results: 100 parts
contain,

BRAINTREE, in Geography. In 1811, the parish of
Braintree contained 508 houses, and 2298 persons; 1082
being males, and 1216 females. The parish of Bucking
containing 573 houses, and 2544 persons; 1134 being males,
and 1410 females.

BRAINTREE, in America, l. 4, r. 870; l. 12, The in-
habitants, in 1810, were 1351.

BRAMPTON, l. 20, r. In 1811, the number of houses
was rated to be 265, and of inhabitants 2043; 920 being
males, and 1123 females: 52 families being employed in
agriculture, and 394 in trade and manufactures.

BRANDON, l. ult. r. In 1811, Brandon parish contained
206 houses, and 1360 persons; 646 being males, and 714
females.

BRANDON, in America, l. 2, r. 1355.

BRANDYWINE. Add—containing 1257 inhabitants.

ALTO, a hundred in the district of Delaware, and county
of New-Caflle, containing 2577 inhabitants.

BRANFORD. Add—It contains 1532 inhabitants.

BRANTRIM, a township of Luzerne county, in Penn-
sylvania, containing 904 inhabitants.

BRASAVOLA, in Botany, has received its name from
Mr. Brown, in memory of Antonius Mufa Brasavolus, or
Brafavolo, an Italian physician and botanist, born at Fer-
rara in 1500. Haller, who inaccurately spells his name
BraSavoluS, speaks of him as not unlearned in books or
languages, or in the plants of his own country. His works,
which have been often republished, relate chiefly to the
Materia Medica. Their author visited France in 1528, and
died in 1555.—Brown in Alt. Hort. Kew. v. 5. 216.—Cliffs

Eff. Ch. Calyx and petals diffusely spreading. Lip
dilated, undivided, nearly flat. Column simple. Anther
a movable lid. Malles of pollen two; divided behind;
attached by their middle to a common process of the
stigma.

1. B. maculata. Spotted-flowered Braflia.—Native of the
West Indies. Imported by sir Joseph Banks in 1806. A
large and very handsome plant, with broad sheathing cori-
aceous leaves, and a cluster of large flowers, whole calyx
and petals green, the broad lip white; all beautifully
and variously spotted with purple.

BREATTLEBOROUGH, l. 3, r. 1891.

BREADED BREAD. See Pain des Abîtres.

Breathe. See Wood.

BREAST, Inflammation of, in Surgery. The diagnosis of
this disorder is sufficiently obvious, from the preface of
such symptoms as are characteristic of inflammation in gen-
eral, and which are detailed in our account of this subject in
a former volume. Inflammation may be confined to the
skin and cellular substance of the breast; or it may affect
more particularly the glandular part of this organ. Accord-
ing to usually-received opinions, either of these cases may
originate from a suppurition or obtruction of the secretion
of milk, rough handling of the breast, external violence,
stoppage of the menes, impediment to the discharge of the
lochia, &c. When the inflammation is moderate, it gen-
ernally terminates in resolution; but when more severe, or
improperly treated, an abcess is the consequence. Though
considerable indurations are often produced in the breast by
attacks of common inflammation, it is but in a limited pro-
portion of cases that such hardness partsakes of the true
fibrous or cancerous nature.

The treatment of inflammation of the breast is to be re-
gulated in a great measure by the kind of caufe that has given
origin to the complaint; a subject which cannot be duly
understood without advertizing to what has been said in the
various medical and surgical articles of this work on the
different species of inflammation. Inflammation of the breast
is most frequent in women within the first three months
after delivery; and the best means of preventing the disorder
consists in having the milk drawn or sucked out of the
nipple some weeks previously to delivery. But when the
inflammation already exists, or threatens to begin, the same
plan of drawing or sucking the breast should be pursued;
and, together with general antiphlogistic remedies, the sur-
genian may have recourse to emollient applications, leeches,
foetomations, and when the acute stage of the inflammation
is over, to gentle friction with liniments, or to the employ-
ment.
ment of roselvent platters. Abbeesses are to be treated on the principles explained in the article Supputation.

BRECHIN, in Geography. In 1811, the burgh and parish of Brechin contained 769 houses, and 5559 persons; 2514 being males, and 3045 females.

BRECKENRIDGE, a county of Kentucky, containing 3450 inhabitants, of whom 505 are slaves.

BRECKNOCK, l. 1, for Laurellar r. Berks; and add—containing 725 inhabitants.

BRECKNOCK, col. 3, l. 4, after parishes, add — and in 1811 contained 718 houses, and 3196 inhabitants; 1433 being males, and 1763 females: 205 families employed in agriculture, and 375 in trade, manufactures, and handicraft.

BRECKNOCKSHIRE, l. 17, r. There, with the hamlets, were peopled in 1811 by 377,735 persons, and contained 7555 houses; 4667 families being employed in agriculture, and 2293 in trade and manufactures. — L. 35. The other rivers are, the Irvon, which falls into the Wye above the town of Buitb; the Tawe, which discharges its waters into the Bristol Channel at Swansea; the Taft; the Llŷn, which passes through Langorfe Mere or Llynfawdaddan, and runs into the Wye at Glabury; the Dulas or Islie, remarkable for its subterraneous passage in one part of its course; the Hapse, celebrated for its beautiful cascade; and the Honddy at Brecknock. The principal lake in this county is Llynfawdaddan; which see. — L. 41. The iron-works of this county are objects of great importance, in connection with its commerce and prosperity. The birth of thee is at Llangwyne, in the parish of Llangenua, now forming an appendage to the works at Sihrowy in Monmouthshire: the next works are those in the vale of Clydach, in the parish of Llanelly: there is another in the parish of Llangattock: others are situated near the source of the Rumney river, on the borders of Glamorganshire: and those of Hirwaun, in the parish of Penderg, at the southern extremity of the county.

BRENT, in Commerc., a liquid measure in some parts of Italy, as at Bergamo.

BRENTFORD. Add—Old Brentford forms a part of Ealing parish, which in 1811 contained 922 houses, and 5361 inhabitants; 2509 being males, and 2852 females. New Brentford is a distinct parish, and contained 279 houses, and 1793 inhabitants; 809 being males, and 924 females.

BRENTWOOD. In 1811, Brentwood contained 218 houses, and 1228 persons; 575 being males, and 663 females.

BRENTWOOD, in America, l. 2, r. 905.

BRETON, CAPE, l. 6, for 34 r. 84.

BREWER. Add—By 43 Geo. III. c. 69. every common brewer of strong beer shall take out a licence, for which he shall pay according to the quantity of beer brewed by him within the year, as specified in the act, ending 5th July every year: but every person who shall first become a brewer of strong beer, for every fuch licence l. 10s., and within ten days after the 4th of July, after taking out fuch licence, shall have a further additional sum as with the said l. 10s., and amount to the duty hereinbefore directed to be paid, according to the number of barrels of strong beer brewed within the preceding year. If he neglect to take out such licence, and to renew it annually, ten days at least before the end of the year, he shall forfeit 50l. 24 Geo. III. c. 41. And every common brewer of table beer, not being a common brewer of strong beer, shall take out a licence and pay for the same yearly l., to be renewed annually. By 42 Geo. III. c. 38, no person not being a common brewer shall be allowed to retail beer at any higher price than 3s. 4d. the quart without entering into a recognizance and obtaining a licence as an ale-house keeper, under pain of forfeiting for each offence 50l. over and above the penalty imposed upon selling beer without a licence. By 15 C. II. c. 11, notices of brewing beer or ale shall be given, and also of altering or altering any implements for this purpose, on pain of 20l. By 5 Geo. III. c. 43, the portion of any tun, cooler, copper, &c. shall not be altered without notice, under penalty of 20l. The officer of excise shall enter and examine suspected places; and if any person oppose him, he incurs a forfeiture of 20l. 7 & 8 W. c. 30. No common brewer shall use any pipes or other private conveyances from any copper in his brew-houfe, &c. on pain of 200l. 8 & 9 W. c. 19. 42 Geo. III. c. 38. Search shall be made by the officer, and the penalty of opposing him is 50l. No common brewer, innkeeper, victualler, or other retailer of beer or ale, shall keep any private florehouse or cellar for laying any beer or ale, or worts in cach, on pain of 50l. 15 C. II. c. 11. 1 W. l. i. c. 24. By 42 Geo. III. c. 38. every common brewer who shall lay off any beer, ale, or worts contrary to the 8 & 9 W. III. shall for every such offence forfeit 100l. Persons inhabiting a market-town, or town corporate, or parts adjoining to a city or town corporate, in which there is a common brew-houfe, who shall suffer liquors to be brewed in their houses, otherwife than for their own families or for purposes of charity or hospitality, and who shall lend out brewing vessels, shall forfeit 32 & 23 C. II. c. 5. Gaugers shall take an account, and obstructing them in the exercise of their office incurs a penalty of 10l. and forfeiture of double value for beer, ale, or other specified liquors that have been sold or delivered out, without payment of duty. If any brewer shall brine the gauger to make a false return he shall forfeit 10l., and the officer so bribed shall forfeit the same sum; 5 C. II. c. 11. By 42 Geo. III. c. 38. the penalty on mixing liquors to imitate beer, and to be mixed with or used as beer made from malt and hops, or felling such liquors, is 200l. and forfeiture of liquor and utensils; and the penalty on a brewer's receiving stale beer-grounds, and mixing any liquor with beer, except malt and hops, is 100l. Excise officers are authorized to take samples of suspected liquors, search suspected places, and seize forbidden liquors, ingredients, and utensils; and the perfon in whose custody they are found shall forfeit 100l. No common brewer shall carry about any ale or beer to his customers in any city or market-town, before notice given to an officer of excise, but between three in the morning and nine in the evening from March 25 to September 25; and between five in the morning and five in the evening from September 29 to March 25, on pain of 200l. a barrel; 15 C. II. c. 11.

And whereas it is expedient that the quantities to be returned as and for a barrel of beer or ale brewed by the common brewer and the allowances for wai te should be in all places the same, it is enacted that after the 5th day of July 1803 every 36 gallons of beer or ale brewed by the common brewers in Great Britain, whether within the weekly bills of mortality or without the same, taken according to the standard of the ale quart four thereof to the gallon in the excisegar, shall be reckoned and returned by the gauger or other officer of excise for a barrel of beer or ale; and the allowances to be made in Great Britain to the common brewer not felling beer, ale, or worts in any lefs quantity than a whole cask containing 4£ gallons, whether within or without the said limits, for wai te by fillings and leakage, or otherwise, out of the returns by the gaugers, or other officers, shall be three barrels upon every 36 barrels, both of strong beer or table beer and ale, and after that rate for any greater or les quantity; 43 Geo. III. c. 69. A common brewer who shall fell beer, ale, or worts in any lefs quantity than in a whole cask containing 4£ gallons, shall forfeit 50l. for every such
fuch offence. And if any perfon, not being a common brewer, shall retail beer at a higher price than after the rate of 14d. the quart, ale-house measure, without obtaining a licence as a common ale-house keeper, he shall forfeit 50l. over and above any other penalty for selling beer or ale without such licence; 42 Geo. III. c. 38. Entries shall be made by common brewers once a week, under penalty of 10l.; and by innkeepers once a month on pain of 5l.; and also ale-house keepers, victuallers, and other retailers, shall do the same on penalty of 20s. Beer and ale above 18s. per barrel shall be deemed strong, and at 18s. and under, table beer; 43 Geo. III. c. 81. The 42 Geo. III. c. 38. regulates the price, &c. of table beer, and repeals as to this beer 22 Geo. III. c. 68. The penalty for selling table beer at more than the barrel price, exclusive of duty, is 100l.

BREWERIA, in Botany, so named by Mr. Brown, in memory of Mr. Samuel Brewer, a Wilts botanist, the companion of Dillenius in a botanical visit to Wales, Anglesea, and the Isle of Man, in 1726, and subsequently one of his most valuable correspondents, especially for the Cryptogamic department. Mr. Brewer spent the latter part of his life at Bradford, under the patronage of Dr. Richardson, and, according to Dr. Pulteney, was living in 1742.

Eff. Ch. Calyx in five deep segments. Corolla funnel-shaped, plaited. Style deeply divided. Stigmas capitate. Capsule of two cells, valvarl, surrounded by the permanent calyx. Seeds two in each cell. These are diffuete hers, not milky; their leaves undivided; flowers axillary, narrowly solitary. The genus appears most akin to Porana, differing in habit, and in the unaltered calyx of the fruit.

2. B. media. Intermediate Breweria. Br. n. 2.—Slightly villous. Leaves lanceolate; obtuse and somewhat heart-shaped at the base. Style divided half way, into two unequal segments.—From the same country. Br.

We know not whether there be any more species in other parts of the globe.

BREWSTER, in Geography, a town of Barnstable county, in the Masachusetts, containing 1812 inhabitants.

BRIBIESCA, delc.

Eff. Ch. Calyx inferior, in five deep segments. Petals five, inserted into the calyx. Stamens with a tubular, columnar bafe. Styles two, divided. Berry with two seeds. Some flowers want the lamens, some others the germs.

The fruit distinguishes this genus from Cluytia. (See that article.) Three species only are described, all East Indian.

1. B. montana. Mountain Bridelia. Willd. n. 1. (Cluytia montana; Roxb. Corom. v. 2. 38. t. 171.)—Stem ereced, without thorns. Leaves obvate-elliptical, entire, smooth.—Native of Coromandel. On the interior mountains it grows to a tree, but on the lower lands is only found of a small size. The Teligas calls Panigya. Roxb. The wood is reddish, very hard. Stem short and thick. Branches slender, spreading. Leaves numerous, alternate, two-ranked, an inch and a half long, on short stalks. Flowers small, crowded, axillary. Berry purple, globular, succulent, the size of a pea.

2. B. scandens. Climbing Bridelia. Wild. n. 2. Ait. n. 1. (Cluytia scandens; Roxb. Corom. v. 2. 39. t. 173.)—Stem shrubby, climbing, without thorns. Leaves oblong-ovate, entire, acute; Downy beneath.—Common on the banks of rivers and water-courses, on the coast of Coromandel, flowering in November and December, and called by the Teligas Donkyboosa. Roxb. Stem climbing; its branches leafy, flowering at their pendulous extremities. Leaves three inches long; thole which accompany some of the flowers diminished almost to bracteas. Berry oval, of a rusdy black, the size of a horse-bean. This species was first to Kew in 1804, by colonel Hardwicke, F.L.S., so well known by his various communications, illustrative of the natural history of India.

3. B. spinosa. Thorny Bridelia. Wild. n. 3. (Cluytia spinosa; Roxb. Corom. v. 2. 38. t. 172.)—Stem arbores, erect, thorny. Leaves ovate, acute, entire, smooth.—A tree of considerable size found on the mountains along with the frict species, and called by the Teligas Coro-maun. The bark is a strong astringent; wood hard and durable, dark-coloured; leaves eaten greedily by cattle, and said to destroy worms in their bowels. Roxb. The leaves are three or four inches long. Flowers in terminal, or axillary, interrupted flukes. Berry black, the size of a pea.

BRIDGE, l. ult. r. The parish of Newcastle, higher and lower, contains 157 houses, the former having 49, and the latter 117, and 640 inhabitants, the former including 174, and the latter 469. In the higher, the males are 84, and females 87; in the lower, the males are 210, and females 259.

BRIDGE NORTH, col. 2, l. 9, add.—In 1811 the borough of Bridgenorth contained 978 houses, and 4386 persons; 2006 being males, and 2380 females; 81 families employed in agriculture, and 870 in trade and manufactures.

BRIDGEPORT, a township of Pennsylvania, in Fayette county, having 280 inhabitants.

BRIDGESTON, a town of the distriet of Maine, in the county of Kennebeck, containing 214 inhabitants.

BRIDGE-TOWN, l. 5, r. 882.

BRIDGEWATER, col. 2, l. 26, add.—In 1811 the borough of Bridgewater contained 857 houses, and 4911 persons; 2241 being males, and 2670 females; 87 families employed in agriculture, and 570 in trade and manufactures.

BRIDGEPORT, a township of Pennsylvania, in Fayette county, having 280 inhabitants.

BRIDGTON, l. ult. r. In 1811 Bridgton contained 849 houses, and 3741 inhabitants; 1706 being males, and 2035 females.

BRIDPORT, l. 39, add.—In 1811 the borough of Bridport contained 512 houses, and 3507 persons; 1532 being males, and 2035 females; 20 families employed in agriculture, and 620 in trade and manufactures.

BRIDPORT, in America, l. 3, r. 1520.

BRIGHTHELMSTON, l. ult. r. In 1811 Brighten contained 2577 houses, and 12,012 persons; 5069 being males, and 6043 females.
B R O

BRIGHTON, a town of Massachusetts, in Middlesex county, having 608 inhabitants.

BRIMFIELD, l. 3, r. 1325.

BRISTOL. Add—In 1811, this city, with Barton Regis hundred, contained 11,940 houses, and 76,433 persons; 32,842 being males, and 43,591 females.

Bristol, in America, l. 2, r. 2753; l. 8, r. 37,168; l. 13, r. 5072; l. 23, r. 2693; l. 29, add.—It contains 1428 inhabitants; l. 33, after houses, add.—The number of inhabitants, by the census of 1810, was 628; l. 36, after county—having 965 inhabitants; l. 59, r. 1179, add.—Allo, a township of Pennsylvania, in Berks county, having 1608 inhabitants.

—Allo, a township of Ohio, in the county of Trumbull, having 202 inhabitants.

BRITAIN, LITTLE, a township of Pennsylvania, in Lancaster county, containing 1708 inhabitants.

BRITAIN, London, a township of Luzerne county, having 404 inhabitants.

BROAD CREEK, a hundred of Delaware, in the county of Sussex, having 3789 inhabitants.

BROOKESBY, l. 10, after Ballytore, add.—(which see,) and dele the remaining part of the sentence.

BRODIEA, in Botany, so named by the writer of the present article, after James Brodie, esq., F.L.S., of Brodie in North Britain, an experienced and liberal British botanist, whose name often occurs in the English Botany, and to whom a genus of the patrician order is with great propriety inscribed.—Sm. Tr. of Linn. Soc. v. 10. l. 14. Phila. 223. (Hookera; Salif. Parad. 98.)—Cliffs and order, Triandria Monegynia. Nat. Ord. Spatanae, Linn. Narr. Juff.

Gen. Ch. Cal. none, unless the bracteas be fo called. Cor. of one petal, bull-shaped, cut half way down into fix nearly equal, oblong, rather spreading segments; throat crowned with three cedal scales, shorter than the limb, opposite to three alternate segments. Stam. Filaments three, inserted into the tube between the scales, and opposite to the other three segments, awl-shaped, cedal; anthers vertical, linear, shorter than the scales, cloven at each end. Pét. Germen superior, elliptic-oblong, triangular; style cylindrical, nearly the length of the itamens; stigma triangular, three-lobed. Peric. Capsule of three cells and three valves, with central partitions. Seeds numerous, elliptic-oblong, inserted into the inner margin of each partition in two rows.

Eff. Ch. Corolla inferior, tubular; limb regular, in fix deep segments; throat crowned with three scales, alternate with the itamens. Capsule of three cells, with numerous seeds.

1. B. grandiflora. Large-flowered Brodiaea, or Millouri Hyacinth. Sm. n. 1. Pursh n. 1. (Hookera coronaria; Salif. Parad. t. 98.)—Scales of the corolla undivided. Partial flaks longer than the flowers.—Discovered by Mr. Menzies in 1792, in New Georgia, on the west coast of North America. Governor Lewis is recorded to have gathered this plant on the plains of the Columbia and Millouri rivers, flowering in April and May. It is reported to have bloomed in Mr. Salibury's garden, but is not admitted into Hort. Kew. or the Addenda to that work. The root is bulbous, folioid. Leave two, radical, linear, channelled, near a foot long. Flower-spike solitary, bearing an unequal, bracteated umbel, of upright, handfonse, blue flowers, each near an inch long, with yellowish fekke, and yellow anthers.

2. B. engelii. Crowded Brodiaea. Sm. n. 2, t. 1.—Scales of the corolla close. Partial flaks much shorter than the flowers.—Brought by Mr. Menzies, with 2 coloured drawing, from New Georgia. The flowers are rather numerous, smaller than the foregoing, and form a dense head, subtended by pointed bracteas.

BROKENSTRAW, a township of Warren county, in Pennsylvania, having 379 inhabitants.

BROMELIÆ, in Botany, the 15th order in Jussieu's system, the 5th of his third clas. See Junce.

The Bromeliae are thus defined. Calyx (Corolla of Linneas) in fix, more or less deep, segments, either superior or inferior, equal, or moftly unequal, the three alternate divisions being large. Stam. fix, inserted into the bottom or middle of that part, or sometimes into calycine glands, lying over the gemens. Germen simple, superior or inferior; ftyle one; stigma threeleft. Fruit of three cells, either pulpy and not burfting, or capfular and of three valves; each cell containing one or many feeds. The leaves are fhewing, all for the most part radical. Flowers spiked, panicled, or more rarely corymbose, each accompanied by a foath.

Seef. 2. Germen inferior. Xerophyta, Bromelina, and Aovee. BRÖMSGROVE, in Geography. In 1811, the parish of Bromsgrove contained 1378 houses, and 6932 persons; 3349 being males, and 3583 females: 357 families employed in agriculture, and 1085 in trade and manufactures.

BRÖNTZE. See Mineralogy, Addenda.

BROOK, Honey, in Geography, a township of Pennsylvania, in Chester county, with 1073 inhabitants.

BROOKE, a county of Virginia, containing 5843 inhabitants, including 3212 slaves.

BROOKFIELD, l. 3, r. 370; l. 11, for 421 r. 1384; l. ult., add.—containing 1037 inhabitants.

BROOKLINE, a town of New Hampshire, in Hillsborough county, having 538 inhabitants.—Allo, a town of Vermont, in Windham county, having 43 habitants.—Allo, a town in Strafford county, in New Hampshire, with 677 inhabitants.—Allo, a township of Ohio, in the county of Trumbull, having 345 inhabitants.

BROOKLYN, l. 2, 704 inhabitants; l. ult. containing 1200 inhabitants.

BROOME, a county of New York, including 8130 inhabitants.

BROSELEY. In 1811 this parish contained 1025 houses, and 4850 persons; 2414 being males, and 2426 females: 48 families employed in agriculture, and 850 in trade and manufactures.

BROTERA, in Botany, a name applied to two very different plants, in due commemoration of the Rev. Father Felix Avellar Brotero, professor of botany at Coimbra in Portugal, author of the Flora Lusitana, and several other learned works. The Broker of the late professor Willdenow, Sp. Pl. v. 3. 2399, Carthamus corymbosus of Linneas, appears to us founded on a total misconception of the structure of the flower, in which we can find no character whatever different from Carthamus. This genus is, however, adopted in Ait. Hort. Kew. v. 5. 186, according to the general plan of that work, where the editors had no particular object of reformation or illustration in view. The other Broker is published by professor Sprengel, in Tr. of Linn. Soc. v. 6. 151. Its only species is B. perfica, brought by Olivier and Bruguere from Perou. We regret to observe that this is manifestly a Hypefs (see the article); and we lament that it was, from full confidence in its learned and distinguished author, too incursively admitted into the Linnean Tranfactions, for which
which the writer of this acknowledges himself cuttled to a fear of the blame.

BROTHERS' VALLEY, in Geography, a township of Pennsylvania, in Somerft county, having 3114 inhabitants.

BROUGH. In 1811 this township contained 131 houses, and 758 persons: 369 being males, and 389 females.

Eff. Ch. Calyx and petals spreading, Column unconnected, or attached at the base only to the stalked lip. Anther a moveable lid. Male of pollen four, parallel, divided by complete permanent partitions, and extending at the base into an ecalmic granulated thread. Obf. In some instances the base of the lip is elongated into a little tube, attached to the gemin.

1. B. fanguinea. Blood-red Broughtonia. Ait. n. 1. (Dendrobiun fanguiineum; Swartz Nov. Ait. Upf. v. 6. 82. Ind. Occ. 1529. Wild. Sp. Pl. v. 4. 132. Vicium radice bulbosa minus, delphinii flore rubro specioso; Sloane Jam. v. 1. 250. t. 121. f. 2.)—Leaves obovate, in pairs from the top of a bulb. Flower-stalk divided. This grows on trees and palisades in the woods of Jamaica, forming tufts of leaf-bearing bulbs, the leaves light green, two inches long. Stalks radical, a foot high, with a few handifome, corymbose, dark crimson flowers. This is the only species yet known in our fstones, nor have we an account of any other.

BOUSSONETIA, in Botany, (see PAPYRUS), where the history and description of this curious tree are given.

BROWN SPAR, or Bitter Spar. See Mineralogy, Alkendra.

BROWNFIELD, l. 2, for York r. Oxford; l. 3, r. 398.

BROWNINGTON, a town of Vermont, in Orleans county, having 236 inhabitants.

BROWNSVILLE. Add.—It contains 698 inhabitants.

BRUCHUS, l. 8, de keyree successively, and inftert—the infites of this genas are, in general, of a small kind. The B. granarius is found among leaves, vetches, and other feeds, the lohes of which it devours. It is about two lines long, of a black colour, and its wing-shells are freckled with white specks; the two fore-legs are reddish, and the thighs of the hind-legs armed with a tooth and forcepts. The B. humilis is rather smaller than the preceding, but like it, without the denticle of the hinder thighs. The exotic species are chiefly natives of America.

BRUNNERSTOWN, in Geography, a town of Kentucky, in Jefferson county, with 92 inhabitants, of whom four are fables.

BRUNONIA, in Botany, so named by the writer of this, after his highly-valued friend Mr. Robert Brown, F.R.S. librarian to the Linnean society, no lefs eminent for acutenes of observation, than for deep botanical science, whole discoveries in New Holland have to often been brought before our readers, and who met with this new and singular genus in that country. The memory of Dr. Patrick Brown, the natural-philosopher of Jamaica, being already preferred in the Brown, (see that article,) it has been found necessaary to adopt the above construction, authorized by prece-

Gen. Ch. Cal. Perianth double, both inferior; outer of four membranous, nearly equal, creft, concave, obtuse leaves; inner of one leaf, rather the longest, turbinate, permanent, with five fheath teeth. Cor. of one petal, funnel-shaped, longer than the calyx; limb in five deep, spreading, nearly equal segments, the two upper ones most deeply divided; tube separable into five narrow claws. Stam. Filaments five, capillary, weak, inserted into the receptacle; anthers linear, united into a cylinder, the length of the tube of the corolla. Pith. Germen inferior, roundish; ryle club-shaped, about twice the length of the lamens; fligma turbinate, obtuse, concealed by two vertical, equal, orbicular, concave, membranous, converging valves. Peric. none, except the inner perianth, fused with the membranous base of the corolla, both together enlarged and hardened, and crowned with the five fheath teeth elongated and diversificated, so as to form a crown-crown. Seed solitary, covered, ovate, destitute of albumen, with an erect embryo.

The generic distinction of Brunonia are abundantly cally; but to determine its natural order, or affinities, is very difficult, the latter being so many, and so remote from each other, that the plant resembles Horace's imaginary feathered monfter, with a horse's neck and human head. Mr. Brown, in the latest view he has taken of the subject, in a most invaluable paper on the natural order of Compo-fite, Tr. of Linn. Soc. v. 12. 132, has pointed out Brunonia as a connecting link between that family and the Goodnovia; nor are various other links between these very different tribes wanting. With great candour he nevertheless admits whatever favours our idea of its relationship to Dipsaceo and Glandularia, and moreover adverts to circumstances approximating it to the Styloideae, near allies of Goodnovia. Two species only have been detected.

1. B. auraitis. Australian Brunonia. Sm. as above. 367. t. 28. Br. n. 2.—Leaves clothed with spreading hairs. Segments of the calyx feathery all over.—Native of the fandy coasts of the south part of New Holland. Abondant in Van Diemen's island, and observed also on the opposite fhoat of New Holland, at Port Phillip, flowering in January 1804. Mr. Brown. Herb apparently annual, without a ftem, hairy all over, much rembending in habit, colour, and pubefcence, the Linnean Sefiabof cretica. Root fimpfe, tender. Leaves radical, numerous, ifpathulate, pointed, fingle-ribbed, entire, tapering at the base, two or three inches long, very hairy. Flower-stalks radical, soli- tary, fimple, hairy, efpecially the lower part, a foot high, each bearing a head of numerous blue flowers, not unlike the Sheep's Scabious, Jasione montana, but rather larger, and loofely hairy. The head is subtended by numerous, nearly equal, spreading, permanent, hairy bracteas, shorter than the flowers; the inner ones small, solitary under each flower.

2. B. ficosa. Silky Brunonia. Sm. as above, 367. t. 29. Br. n. 1.—Leaves fily with clofe-prefted hairs. Segments of the calyx with naked coloured tips.—Gathered by Mr. Brown, on the fandy fca-face at Pine Port, on the eft coast of New Holland, juft within the tropic, flowering in August 1802. The afpect and pubefcence of this species
species exactly answer to Scabiosa granifolia. It differs from the foregoing in having narrower, more numerous, silky leaves, and the flowers differ remarkably in the blust, coloured, naked points of their inner calyx.

BRUNSVIGIA, so named in 1753, by Heifl, in compliment to his patron Charles duke of BrunsvicL Luneburg. What were his ferene higness's claims to this honour, we know not, nor is Heifier any authority in such a cafe (see his biographical article); but we hope all Englishmen will ever have reafon to hail the name of BrunsvicL, wherever it appears, and the genus in question, long confounded with Amaryllis, being now restored, the name of Brunsvigia appears with peculiar propriety in the royal garden of England.—Heifl. Brunsv. 2. Ait. Hort. Kew. v. 2. 230. Ker in Curt. Mag. under p. 923*.—Clafs and order, Hexaentia Monogynia. Nat. Ord. Spathaceae. Linn. Nativ. Jull.

Gen. Ch. Cal. an oblong, obtuse, comprefTed, leafy sheath, of two valves, withering. Cor. superior, in fix deep, lanceolate, recurved, nearly equal segments. Stam. Filaments fix, awl-shaped, about the length of the corolla; anthers oblong, incumbent. Pjfr. Germen inferior, ovo- 

vate, with three furrows and as many rounded angles; fyle thread-shaped, the length and position of the flaments; stigma blunted. Peric. Capule turbinate, abrupt, with three rounded wings, membranous, somewhat transparent, of three cells and three valves. Seeds feral, ovate, acute; curved and comprefTed at the point.

Eff. Ch. Corolla superior, in fix deep segments. Cap- 

tule turbinate, membranous, with three wings. Seeds feral, pointed.

1. B. multiflora. Broad-leaved Brunsvigia. Ait. n. 1. (Brunsvigia; Heifl. as above, t. 1—3. Amaryllis orientalis; Linn. Sp. Pl. 422. Willd. Sp. Pl. v. 2. 58. Jacq. Hort. Schoenbr. v. 1. 38. t. 74. Narcissus indicus sphenicus; Morif. fct. 4. t. 10. f. 35. N. indicus, flore lilaceo, sphenicus; Ferrar. Fl. 125. t. 129. 131. 133.)—Leaves tongue-shaped, defempt, smooth. Flowers somewhat irregular, with ascending flaments and fyle. Native of the Cape of Good Hope. The bulb is not uncommon in our floves, but we never heard of its flowering. That defirable event however happened in the imperial garden at Schoenbrui, and has enabled the late professor Jacquin to adorn his Hort. Schoenbr. with one of the most splendid botanical figures extant. This is perhaps the moft flately of its flately tribe. The large fcaly bulb bears five or fix obvolute-oblong, dark green leaves, lying over each other in two ranks, and usually a foot long, near three inches broad. Flower-flalk earlier than the leaves, erect, round, a foot high, crowned with a broad fpuria, of two coloured valves, unequal in breadth, accompanying a very large umbel, of about thirty-five rays, fpuading in all directions, each fix inches long, bearing a solitary erect flower. All the flalls are more or lefs of a blood red. Corolla richly varied with cinfion and a kind of orange fcarlet; its segments an inch and a half long, acute, converging into a tubular form at the bafe, fpuading in the upper part, and reflexed. Capule two to four inches long, and one broad, pale brown, finning; tapering very much at the bafe.

3. B. Radula. Rapf-leaved Brunsvigia. Ait. n. 3. (Amaryllis Radula; Jacq. Hort. Schoenbr. v. 1. 35. t. 68. Willd. Sp. Pl. v. 2. 61.)—Leaves ellipiticl, defempt, rough with brillite tubercles. Flowers ringent, with declining flaments and fyle.—From the fame country, introuduced by Mr. Maffon, in 1790. Leaves two, leafine more, three inches long, rough-edged, covered on the upper side with brillite-pointed warts. Umbel three or four inches high, sometimes in pairs. Umbel of only four or five pink and white flowers, five of white fegments are directed upwards, the fifth defempt, along with the flaments and fyle.

4. B. friata. Striplon Brunsvigia. Ait. n. 4. (Amaryllis friata; Jacq. Hort. Schoenbr. v. 1. 36. t. 70. Willd. Sp. Pl. v. 2. 61.)—Leaves ellipitic-ovate, erect; densely fpuaded. Flowers nearly regular, with declining flaments and fyle. From the fame country as the ref, introduced by Mr. Maffon in 1795. Larger than the left, and diftinguifhed by its upright red-edged leaves. Umbel of many flowers, whose outside is rofe-coloured, inner paler, or whithe, the segments narrow, nearly or quite regular.

BRUNSWICK, in Virginia, l. 3. r. 15, 411 inhabitants, including 9368 females; l. 5. r. 4378; l. 6. r. 2254; l. 19. add—containing 143 inhabitants.

BRUNSWICK, North, contains 3980 inhabitants.

BRUNSWICK, South, contains 2332 inhabitants.

BRUNSWICK, in Maine, l. 5. r. 2682.

BRUNSWICK, a township in Brinks county, in Pennsylvania, having 1770 inhabitants.

BRUSH CREEK, a township of Ohio, in the county of Highland, containing 551 inhabitants.

BRUSSELS, Roger of; r. BRUGES, Roger of.

BRUTON, col. 2, l. 2, r. In 1811, the parish of Brunt contained 353 houses, and 1536 perfonns; 658 being males, and 878 females.

BRUTUS, l. 5. r. Cayuga. Subjoin—This is an excellent township of Cayuga county, about 10 miles long, N. and S., by 5 to 64 E. and W. The foil is rich and fertile, and well watered: it contains about 330 families, and 182 fenatorial electors. It was erected in 1802, from the N.E. part of Aurelius. In 1810 the population was 2030, and the taxable property amounted to 84,514 dollars.

BRYAN, l. 3. add—containing 2827 inhabitants, of whom 2264 are females.

BUBALIS, See Antelope.

BABASTUS, dele fee Didima.

BUCCO, col. 2, l. 1, after cinereus, dele which fee, and add—These are all inhabitants of Africa, and the warmer parts of Asia and America. Their head is very long, their bills strong and nearly straight, almost covered with brillite; tail-feathers generally ten. They are a folitary flupid race, living in fequeftered forests, and bifbiting principally on insects.

BUCEROS. Add—Several other species are mentioned by Dr. Shaw.

BUCANAN, l. 7, infer—l. 1520. Col. 3, l. 9, infer—in 1532; l. 10, r. Cellitus; l. 15, r. 1533; l. 18—this happened probably in the year 1537; l. 43, after said (but without sufficient evidence); l. uli. but one, infer after admired.—The next in merit is the 1537th, in elegiac verse. Col. 3, l. 19, after country, infer—In 1562, he officiated as classical tutor to the queen, who was then in the 20th year of her age, and who many afternoons perused with him a portion of Livy. Aboot the year 1566, &c.: l. 30, after York, infer—in 1568; l. 55, after VI, infer—
— in 1570, when the young prince was only four years of age; 1. 43, after reading, infert—when the countess of Mar, hearing him wailing, hurried and took him up in her arms, reproaching the tutor for having laid his hand upon the Lord’s anointed. Buchanan is said to have replied in terms that contained a very unceremonious antithesis relative to the part which had received the châtiment. Col. 4, l. 9, after motives, infert—and it likewise evinces his anxiety for forming a patriot king; l. 15; for 5th of December r. 26th of September; l. 23, after Edinburgh—in the cemetery of the Grey Friars. Col. 5, l. 10, after unequal, add—although he maintains the unfeudalistic notion that the earth does not revolve round the sun, he supports his opinion by arguments which must at least be allowed to be plausible; l. 9, from the bottom, after great man, infert—neglected by his ungrateful country, which never afforded him the grave of a monument of a public man. Subjoin—See Irvine’s Life of Buchanan.

BUCKENHAM. In 1811, the parish of New Buckenham contained 127 houses, and 656 inhabitants; 315 being males, and 341 females. The parish of Old Buckenham contained 200 houses, and 1024 persons; 491 being males, and 533 females.

BUCKINGHAM. In 1811, the borough of Buckingham contained 572 houses, and 2987 persons; 1313 being males, and 1674 females: 232 families employed in agriculture, and 466 in trade and manufactures.

BUCKINGHAM, a county of America, l. 3 and 4, for 1792 r. 1810; for 9779 r. 20,559; for 4168 r. 11,675. Also, a township of Bucks county, in Pennsylvania, having 1715 inhabitants. Also, a township in Wayne county, in the same state, having 1713 inhabitants.

BUCKINGHAMSHIRE, l. 19 and 20, r. In 1811, this county contained 21,929 houses, and 117,650 persons; 13,933 families employed in agriculture, and 8424 in trade and manufactures.

BUCKLAND, l. 2, for 718 r. 1097.

BUCKS, l. 5, for 25,401 r. 32,571; for 114 r. 11; l. 7, for 27 r. 29.

BUCKSTOWN, a township of Rofis county, in the district of Ohio, containing 781 inhabitants.

BUCKSTOWN, l. 3, for 316 r. 4403.

BUENA, in Botany, Cavan. l. c. v. 6. 49. t. 571, is a genus of the natural order of Rubiaceas, so named by that author, in honour of Dr. Cofno Bueno, an eminent writer on the natural history and topography of Peru. There is no certain proof of this genus being distinct from what Ruiz and Pavon had already called Gonzalagonia. We are equally unacquainted with both.

BUFFALOE. Add—East Buffaloe contains 2869, and West Buffaloe 2373 inhabitants. Also, a township of Pennsylvania, in Washington county, having 1416 inhabitants. Also, a township in Armstrong county, in the same state, having 1150 inhabitants. Also, a township of Butler county, having 375 inhabitants. Also, a township of Ohio, in the county of Guernsey, having 285 inhabitants. Also, a township in Ohio, in the county of Jefferson, having 696 inhabitants.

BUFFY Coat of the Blood. Chemical Properties of. See Blood, fibrin

BUILDING, col. 10, l. 47, for 42d r. 14th.

BUILDTH, or BULIT, derived from Bu, an ox, and all, an eminence, i.e. a wooded eminence, bearing reference to the adjacent country. Col. 2, l. 13, for two weekly r. one good market on Monday; for three r. five; after contains, r. by returns of 1811, 182 houses, and 815 inhabitants; 384 being males, and 431 females. The hundred of Bulth included 1686 houses, and 5788 persons; 2698 being males, and 3090 females: 833 employed in agriculture, and 284 in trade, manufactures, and handicraft.

BULLET, a county of Kentucky, having 4311 inhabitants, including 976 slaves.

BULLOCK, a county of Georgia, in America, containing 2305 inhabitants, 420 being slaves.

BULLSKIN. Add—containing 1439 inhabitants.

BUMCOMBE, a county of North Carolina, containing 9277 inhabitants, of whom 695 are slaves.

BUMEN. See RENAN.

BUMGALOW, a term used in Bengal for a kind of country-house erected by Europeans.

BUNIUM, col. 2, l. 20, for They r. Ray.

BUPHAGA, l. 6, for legs r. feet.

BUPRESTIS. At the close, dele which see respectively, and add—The B. gigantea is the largest of this genus hitherto discovered, being two and a half inches long; a native of India, China, and many other parts of Asia; and found also in South America. The European species of this genus fall short of the Indian or American species both in size and splendour.

BURCHARDIA, in Botany, is thus named by Mr. Brown, in commemoration of Dr. John Henry Burchard, author of a letter to Leibnitz, in 1702, in which he founded the principles of botany are developed; the exclusive importance of the parts of fruitification, in forming characters, are especially insisted on, and the classification of Linnaeus, by the flaminis and pittis, is anticipated. Heitler published this letter, for the first time, in 1750, probably to depreciate the honour of Linnaeus. But as the latter could have heard nothing of Burchard’s sentiments, he has all the merit of originality, and the attempt to deprive him of this credit, serves only to shew the high estimation in which his performance was held. Heitler has named a plant Burdardia, but this is Callicarpa of Linnaeus, so called many years before.—Brown Prodr. Nov. Holl. v. 1. 272.—Cliff and order, Hexandra Trigymia. Nat. Ord. Melanthesae, Br.

BURGH upon the Sands, l. 4, as he was preparing for an expedition against the Scots. Hume.

BURICH. For BUDERICH r. BADELICH.

BURKE, in Geography, l. 2, r. 11,607; l. 3, r. 1433; l. 5, r. 10,747, and 4691: l. 9, add—containing 460 inhabitants.

BURKESVILLE, a town of Kentucky, in Cumberland county, containing 106 inhabitants, of whom 20 are slaves.

BURLINGTON, l. 6 and 7, for 18,695 r. 24,979, and for 227 r. 93; add—It contains 12 townships; l. 13, r. 24,19, and 4 slaves.

BURLETON, a township of America, &c. l. 3, add—This township is well watered, and abounds with mill-heats; its situation is elevated, and the air salubrious: the population is 3196; the senatorial electors 294; and the taxable property,
property, in 1810, amounted to $78,783 dollars. It has two Baptist meeting-houses, one for Congregationalists, and one for Quakers. The inhabitants are principally farmers.

BURLINGTON, a town of Massachusetts, in Middlesex county, containing 471 inhabitants.—Alto, a town of Hartford county, in Connecticut, having 1457 inhabitants.—Alto, a township of Lycoming county, in Pennsylvania, having 661 inhabitants.

BURNTING, Extraordinary Cafe of. Col. 3, p. 111, for of the head r. and the head: l. 5, for 332 r. 1690.

BURNLEY, l. ult. after contains, add—by the return of 1811, 807 houses, and 4368 inhabitants; 2129 being males, and 2239 females.

BURLINGTON, a town of Rhode island, in the county of Providence, containing 1834 inhabitants.

Eff. Ch. Petals five, inserted into the receptacle. Capsule superior, compressed, of one cell, with four valves. Seeds two, winged.

1. B. Ipomoea. Thorny Burfaria. Cavan. Ic. v. 4. 30. t. 350. Ait. n. 1. (Itaca Ipomoea; Andr. Repof. t. 314.) —Native of New South Wales; first raised in 1793, by the late marchioness of Rockingham. This is a thorny, bushy, green-house shrub, flowering from August to December. The leaves are scattered, serrate, narrow-wedge-shaped, emarginate, smooth, entire. Flowers numerous, white, small, in copious, aggregate, terminal clusters, of considerable elegance.

BURTON, in Kendal, l. ult. after contains, add—by the return of 1811, 94 houses, and 574 persons; 274 being males, and 300 females. There is another township, named Holme, in the same parish, containing 43 houses, and 283 persons; 137 being males, and 146 females.

BURTON—upon-Trent, l. 4 from the close, add—by the return of 1811, contains 785 houses, and 3979 persons; 1844 being males, and 2135 females.

BURTON, l. 1, for Grafton r. Stafford; for 143 r. 194. Add—Alto, a township of Ohio, in the county of Geauga, having 517 inhabitants.

BURTON, in Botany, so named by Mr. Brown, in memory of the late Mr. David Burton, a celebrated collector of plants for the Kew garden, under the patronage of Sir Joseph Banks. He died after a short stay in New South Wales; but Mr. Aiton's work evinces the great diligence of this unfortunate traveller. Mr. Salibury's original Burtonia proved an Hibbertia. (See that article.)—Brown in Ait. Hort. Kew. v. 3. 12. —Clafs and order, Decandra Monogynia. Nat. Ord. Papilionaceae, Linn. Loguminosae, Juff.

1. B. fcabra. Rough-leaved Burtonia. Ait. n. 1. (Gompholobium scabrum; Sm. Tr. of Linn. Soc. v. 9. 250.)—Leaves ternate. Calyx smooth. Style bearded beyond the middle.—Found by Mr. Menzies, on the south-west coast of New Holland; and sent to Kew by Mr. Good, in 1803. A green-house shrub, flowering from May to July. The leaves are ternate, sessile, linear, revolute, rough to the touch. Flowers about the ends of the branches, axillary, dull purple when dried. There is no account of their natural colour. We do not perceive any important difference in character, and there is none in habit, between this plant and Gompholobium (see that article); but the unpublished species may be more distinct.

BURY, l. 10, after Peele, add—created a baronet in 1800, who, about the year 1773; l. 15, add—In the course of his prosperity he purchased a seat at Chamber-hall, in the neighbourhood, which he afterwards sold; l. 18, for Bolton in Yorkshire r. Bolton-le-Moors in Lancashire: l. 23, r. the wheel or fly-shuttle, invented about one hundred years ago by Mr. John Kay, who, on account of the perfection he suffered on this account, was obliged to remove to France, where he died; and the card-making machine, for making several cards at once, invented by Mr. Robert Kay, the son of the former, who died about the year 1804. This machine straightens, &c.; l. 29, after shaft, add—and touching neither the wire nor the leather. The woolen manufactures, confisting of flannels, blankets, and a variety of other articles, were established in this town long before the introduction of the cotton trade, and contributed in no small degree to its prosperity; l. 47, r. in 1811, the number of houses in this township was 1562, and the number of inhabitants was 8762; 4216 being males, and 4543 females. The parish of Bury includes six towns, viz. Bury, Elton, Heap, Higher and Lower Tottington, and Walmerley.

BURY ST. EDMUNDS, col. 3, l. 31, r. In 1811 this borough had 1474 houses, and 7986 inhabitants; 3559 being males, and 4447 females; 164 families employed in agriculture, and 966 in trade and manufactures.

BUSHHEL. Add—See Coal-Bushel and Weight.

Bute. The shire of Bute, by the parliamentary return in 1811, contains 2047 houses, and 12,033 persons; 5545 being males, and 6488 females; 1216 families employed in agriculture, and 530 in trade, manufactures, and handi craft.

BUTLER, r. BUTLER, WILLIAM.

BUTLER, in Geography, a county of Pennsylvania, containing 7346 inhabitants.—Alto, a township of this county, having 458 inhabitants.—Alto, a township of Ohio, in the county of Columbiana, having 316 inhabitants.—Alto, a county of Kentucky, containing 2181 inhabitants, of whom 274 are slaves.

BUTTER, Chemical Properties of. See Milk.

BUXTON. In 1811 the township contained 180 houses, and 934 inhabitants; 447 being males, and 487 females.

Buxton, a township of America, l. 5, r. 2324.

BYRAM, a town of New Jersey, in the county of Essex, having 1224 inhabitants.
CABAL, l. m., after Shaffbury, infat—lord Ashley.

CABARRAS, in Geography, a county of N. Carolina, with 6150 inhabitants, of whom 1234 are slaves.

CABELL, a county of Virginia, with 2717 inhabitants, of whom 221 are slaves.

CABINET, col. 2, l. 47, r. whether they be.

CABOS. Add.—The former contains 974, and the latter 1003 inhabitants.

CABOS, in Geography, a town of Caledonia, in the district of Vermont, having 886 inhabitants.

CACHOLONG. See Mineralogy, Addenda.

CADIZ, in Geography, a town of Jefferson county, in Ohio, with 1374 inhabitants.

CADMIUM, in Chemistry, the name of a metal. This metal was discovered by M. Stromeyer in the autumn of 1807, while he was officially examining the apothecaries' shops in Hanover.

Cadmium resembles tin in its colour, lustre, softness, ductility, and the found it produces when bent. Its fp. gr. is 8.6359. It melts and volatilizes at a temperature a little lower than zinc. It preserves its splendour in the air, but by heat it changes into a yellow oxide, which is not volatile, and which is very easily reduced. This oxide does not colour borax; it dissolves very readily in acids, and forms colourless salts, from which it is precipitated white by alkalis. The hydrochloric acid (solution of sulphurated hydrogen) precipitates it yellow, like arsenic. Zinc precipitates it in the metallic state.

This all which at present we know of this metal, except that it was first obtained from the sublimates which concretes in the chimneys of the zinc furnaces of Saxony; and, consequently, that it exists in the ores of zinc there employed. We understand also that it has been detected in some similar ores of zinc in this country.

CAERFILLY, &c., col. 2, l. 49, add.—It has a market on Thursday, and six fairs in the year. By the parliamentary returns of 1811, the number of houses in this hamlet of Eglwyfian parish was 196, and of inhabitants 1013, viz. 462 males, and 551 females.

CAERLEON, col. 3, l. 18 from bottom, r. The town consists, by the return of 1811, of 170 houses, and 595 inhabitants.

CAERMARTHEN, col. 3, l. 17, after it contains, add,—by the parliamentary returns in 1811, 1189 houses, and 7257 inhabitants. The charter allows three markets, viz. on Wednesday, Friday, and Saturday, but the latter is the only one numerously attended by the farmers. It has four fairs in the year, and, &c.

CAERMARTHENSHIRE, l. 7,—others reckon its length 50, and breadth 25 miles. Cary estimates its superficial contents at 512,000 acres; l. 23, The Towy is much celebrated for its fish; its salmon is highly esteemed; as is also its aman. The other rivers, not above enumerated, are, the Loughor, Llologh, or Llwyf, which separates this county for some distance from Glamorganshire, receiving in its course the Amman, which united streams discharge themelves into Caeramrthen bay, by a wide expanse called the Bury river, navigable for small vessels as high as the town of Llologh. Another river, denominated Gwendraeth vawr, or great, has its source in a lake at the upper extremity of Mynudd mawr, and joins the sea below Kidwelly: this is joined by Gwendraeth vach, or the left. Other rivers are the Pycottor, which falls into the Dethia, and the Camdwer, which augment the Towy. The river Bran unites with the Towy below Llandover; the other tributary streams are, the Sawdwy, proceeding from a lake in the Black mountain, and the Cennen, which join the Towy, as well as the Cotthy and Gwilly, already mentioned. The Corwen and the Taf unites at the village of St. Clears, and run into the Caermetheen bay at Laugharne. The lakes of this county are Lllyn Tegwyn, or pwall yr Esgob, or the Bishop's pool, situated at the northern extremity, and on the highest elevation of Mynudd mawr, an extensive bleak common, W. of Llandybie, and occupying a surface about half a mile in diameter. Another lake is situated on the Black mountain, at the foot of the almost perpendicular declivity of the Caermetheen fan, or beacon, and extending in form of a parallelogram about one mile in its greatest length. The other lakes are two, which communicate by a strait, and appear like one, situated on the banks of the river Cotthy, and near the ruins of the abbey of Talley. The mountains are part of Plynlimmon, and on the E. the long chain called the Black mountain, the summit of which, called y Fan, or Ban Sir Gaer, the Caermathenshire beacon, is the highest ground in the county. The height of this peak has been estimated at about 2600 feet above the level of the sea. It is separated by a chain from another eminence, of superior altitude, in Breconshire. Both are denominated Bannau Sir Gaer, or Caermathenshire beacons, in the plural, to distinguish them from those called Bannau Breconiego, or the Breconshire beacons. Another mountain lies on the borders of Glamorganshire, called Bettws mountain; it is a chain diverging from the Black mountain, at the upper end of the valley of Tawe, and stretching along the easterly shore of the Amman and Llologh nearly to the sea.—l. 37

—The number of parishes has been variously estimated; some having reckoned them at 76, others at 85, and others at 78, besides 12 chapelleries. The number of market towns is stated at eight. This county, by the last return in 1811, contained 14,856 houses, and 77,217 inhabitants; 9878 families employed in agriculture, and 5250 in trade and manufactures.

CAERNARVON. Add.—In 1811 the parish of Llan-

---

**CÆS**

Lebbig, in which it is situated, contained 1,000 houses, and 4,595 persons; viz. 1,982 males, and 2,613 females.

**CAERNARVON,** a township of America, &c. l. 2.,-add—containing 1684 inhabitants.—**Allo,** a township of Berks county, in Pennsylvania, having 723 inhabitants.

**CAERNARVONSHIRE,** l. 17. r. In 1811 this county contained 9369 houses, and 49,436 persons; viz. 23,379 males, and 25,957 females: 6667 families employed in agriculture, and 2087 in trade and manufactures.

**CAERWENT.**-Add—The parish of Caerwent, in 1811, contained 60 houses, and 375 persons; viz. 206 males, and 169 females.

**CAERWYN.**-Add—In 1811, the parish of Caerwys contained 209 houses, and 863 persons; viz. 416 males, and 447 females.

**CÆSARIA, r. COHAWZY.**

**CÆSIA,** in Botany, dedicated by Mr. Brown to the memory of Frederico Caesar, a young Roman nobleman, illustrious for the patronage and cultivation of science, especially of natural history, who opened the academy of the Lynæsi at Rome in 1653. This was the first institution of the kind, and is celebrated in various authors of that day. The great Galileo was among its members, as well as that indefatigable botanist Fabio Colonna, better known by his Latin appellation, Colonna. This institution died with its noble founder, in 1630; but the scientific associations of Italy, and thence of all Europe, have sprung from its ashes.

Eff. Ch. Corolla in fix deep, equal, spreading segments, deciduous. Filaments beadless, contracted at each end. Anthers attached by their cloven base. Germen of three cells, with two feeds in each. Style thread-shaped. Stigma one. Capsule scarcely valvular; tumid and lobed at the summit; or club-shaped. Seeds tumid, with an appendage to the scar.

Herbs generally annual, smooth. Root of clustered, thick fibres, or oblong knobs. Leaves grasy. Clusters either divided or simple, with aggregate or solitary flower-stalks, jointed under the corolla. Flowers whitish, or blue, erect, rarely drooping. Corolla becoming spiral after flowering, and soon falling off entire. Anthers yellow.

This genus approaches the Phalangium of Julius, but differs abundantly in the structure of the germen and seeds.

**CAFFISE,** or **Cahir,** in Commerce, a measure for corn in Spain, containing 12 fanegas. See Fanega.

**CAFFISIO,** a measure for oil in Sicily, weighing 12½ rotoli, or about 24 lbs. avoirdupois.

**CAHOKIA,** in Geography, a township of St. Clair county, in the Illinois country, with 711 inhabitants.

**CAJEPUT Oil,** l. 2. — Leaves of a species of the Mela-leuca, a tree, &c.

**CAITNESS,** By the parliamentary returns of 1811, the shire of Caithness contained 4301 houses, and 23,419 persons; viz. 10,608 males, and 12,811 females: 3270 families employed in agriculture, and 838 in trade and manufactures.

**CAKILE,** in Botany, an Arabic name, used by Serapio.

Eff. Ch. Pouch of two single-seeded joints; feed of the uppermost erect, sessile; of the lower pendulous. Obv. The lower joint is occasionally abortive.

This genus is the real Bunius of Linnaeus, nor can we see why that name should be changed for the barbarous Cakile, though we agree with Mr. Brown in removing hither several species of Myagrum, as in the Prodr. Fl. Græc.

**CALABOSO,** in Geography, a town of South America, in Venezuela, situated between two rivers, viz. Guarico to the W. and Orituco to the E. which unite their waters four or five leagues below the town. It is situated in a hot climate, in N. lat. 8° 45', 52 leagues S. of Caracas, and at about the same distance N. of the Orokonoko, and in the year 1804 its population amounted to 4900 persons.

Eff. Ch. Upper calyx-leaf rather flattened; two lower, with the petals, deflexed under the lip, flat; all glandular at the back. Lip somewhat filiform, with rows of glands on its díke. Style winged. Anther a moveable lid. Pollen powdery.

An elegant tribe of small herbaceous plants, clothed with glandular, intermixed withimple, hairs. Bulbs undivided, terminating the deflexing base of the item, inclosed in a falcate coat. Leaf solitary, nearly radial, mostly linear, enclosed by a sheath at the base. Stalk bearing one bracteà, besides those immediately accompanying the one, two, or three inodorous, variously-coloured, flowers. Anther most frequently pointed.

Mr. Brown defines thirteen gym-nine species, from various parts of New Holland. Their, as it were, ringent flowers, the petals nearly equal to the two lower calyx-leaves, and forming with them an under lip, while the upper confines of the upper leaf of the calyx, not quite so flat as the rest. To these are subjoined two species, whose petals are very long, narrow, and directed upwards; and to these, as possibly a distinct genus, the name of Lptoceras is given.

Of the true Caladenia, the first only, C. alba, has been brought alive to England, by Mr. Geo. Caley in 1810, and is marked by Mr. Aiton as a green-house plant, flowering in July and August. — The fifth species, C. alocia, is probably Arathufa cistena, Sm. Exot. Bot. v. 2. 89. t. 104.

**CALADIUM,** a name used by Rumphius, for some kinds

Eff. en. Sheath of one leaf; convolute at the base. Spadix covered at the summit with peltate many-celled anthers; glandular in the middle; covered with germines at the base. Stigma umbilicated. Berries of one cell, with many seeds.

This genus, differing from Arum chiefly in the spadix being covered in all its upper part with flowers, except in some inflorescences, a small naked point, is divided like that, (see Arum,) into three sections, similarly distinguished. Willdenow has fifteen species in all.

—Native of woods in Martinico and the Caraccas. The flowers are greenish-white, on radical flakels. Leaves a foot in breadth, of eleven elliptic, acute leaflets.

Sect. 2. Stem none. Leaves simple. Six species, to which we add one.

2. C. pinnatifidum. Pinnatifid Caladium. Willd. n. 2. (Arum pinnatifidum; Jacq. Hort. Schoenbr. v. 2. 31. t. 187.)—Stem none. Leaves pinnatifid. —Native of woods at the Caraccas, where this large species grows on rocks and trees. The leaves are two feet long, and nearly as broad, deeply pinnatifid, with great red ribs. Flowers almost seffile; blood-red in their lower half; white, like the spadix, above. The spadix.

3. C. ovatum. Ovate Caladium. (Arum ovatum; see our n. 22. Linn. Sp. Pl. 1371. Karin pola; Rheed H. Mal. v. 11. t. 23.)

5. C. sympbiloferum. Water-lily-leaved Caladium. Willd. n. 5. Ait. n. 3. (Wellisia; Rheed H. Mal. v. 11. t. 43. t. 22.)—Stem none. Leaves peltate, ovate-arrowshaped. Shoot cylindrical, with a lanceolate point, shorter than the spadix. —Native of the East Indies.

7. C. acer. Acid Caladium. Br. n. 1.—Stem none. Leaves peltate, heart-shaped. Spadix obtuse, with a very short, occasional, naked point. Shoot lanceolate, twice as long as the spadix. —Gathered in the tropical part of New Holland by Mr. Brown, who remarks that it fearfully differs, except in having anthers at the summit of the spadix, from the last, which has a manifest acute naked point, and he does not see how the latter is distinguished from Arum Colocasia.

Sect. 3. With leafy flarks. Eight species.

Parasitical on trees at the Caraccas. Sent by Jacquin, under the same name, to Willdenow.

—From the Caraccas.

CALDAIR, L. 3, for 43 r. 41. to a town of Washington county, in the district of Maine, which by the census of 1810 contained 372 inhabitants.—Alto, a town of Caledonia county, in Vermont, containing 844 inhabitants.

CALCIUM, in Chemifs, the metallic basis of lime. See Lime.

CALDARA DA CARAVAGGIO, Polidoro, in Biography, an eminent painter, was born in the Miknes, and from the humble station of a labourer became an assistant in Raphael in the works of the Vatican, and at length acquired unrivalled celebrity in his imitation of the antique bas-reliefs, which he executed in chiaro-occurso. His style was in so peculiar a fenre his own, that, having formed it, it also perished with him. His design was without manner, compact, and correct. He had the art of transporting himself, fays his biographer, into the times of which he represented, the transfigurement, the costume and rites, so that nothing modern is discerned in his works. Numerous as his performances once were at Rome, scarcely a fragment remains, if we except the fable of Niobe, left in ruins by time and the rage of barbarians. For these loaves we are compensated merely by the prints of Cherubino Alberti, and Henry Golzuers, who engraved his gods, the Niobe, and the Brennus; and also by the etchings of Santes Bartoli and Gallefruzi. On occasion of the pilgrimage of Rome by Bourbon in 1527, Polidoro fled to Naples, where he was patronized by Andrea da Salerno, and gained such reputation that he began to form a school; but declining the prosecution of this undertaking, he removed to Sicily. Having exchanged chiaro-occurso for colour, he painted at Messina a numerous composition of Christ led to Calvary, which has been highly extolled by Vafari; and not long after the completion of this work, he finished in bed by a servant, who wished to get possession of his property. His manner, as a colourist, is said to have been dim and pallid. His death in 1543, at the age of 51 years. Pilkington's Dict. of Painters by Fufeli.

Caldwell, in Geography, a town of Effex county, in New Jersey, containing 2235 inhabitants, of whom 54 are slaves.—Alto, a county of Kentucky, with 4268 inhabitants, including 2770 slaves.

Calectasia, in Botany, from nuxis, beautiful, and calea, an extension, or dilatation, alluding to the elegant flaring expansion of the corolla. —Brown Prodr. Nov. Holl. v. 1.
CAL

1. C. cyanus. Blue Calceopsis. Br. n. 1. Bot. of Terra Aufr. 77. 1. 9. —Found by Mr. Brown, on the southern coast of New Holland. —A little shrub, flowering in December, very much branched, clothed with acero remaining leaves. Flowers solitary, at the ends of the short branches. Tube of the calyx covered by the flaes of the leaves; the limb prominent, like a bright blue star, of fix equal rays, the three outermost downy underneath. This pretty genus is not very nearly allied to any other, though something like *Aphylla*; but very different in structure, and rather approaching *Dasyphoe*, hereafter to be described.

CALEDONIA, a county of Vermont, l. 2., r. 23.

add.—In 1810, it contained 18,750 inhabitants.

CALEIDOSCOPE, or KALEIDOSCOPE, from καλείδος, beautiful, ὄπως, a form, and σακτος, to see, an instrument recently invented by Dr. Brewster, and for which he has obtained a patent, for the purpose of creating and exhibiting an infinite variety of beautiful forms.

The instrument in its simplest form consists of two reflecting planes, inclined to each other, made either of two plates of glass, blackened or silvered, or two metallic surfaces, or the two inner surfaces of a solid prism of glass, or rock-crytal, from which the light scatters all reflection. The plate may be of any length; but that which is most convenient will be found to be from five to ten or twelve inches, or they may be made only two, three, or four inches long, provided the distance of vision is obtained at one end, by placing at the other end an eye-glaf, whose focal length is equal to the length of the reflecting-plane; their breadth should be about eight or nine-tenths of an inch when the length is six inches; but it should increaf be the length, in order to have the aperture of the same angular magnitude. Two edges of these reflectors, being made perfectly straight, are placed together by a particular contrivance, in such manner, that their inclination, or the angle which they form, is exactly an even aliquot part of a circle, or a fourth, fifth, eighth, tenth, twelfth, fourteenth, &c. part of 360°. When the plates are thus fixed in a tube, and the eye placed at one end, as near as can be, in the line of the interlacement of the two planes, it will perceival a circular field of view, composed of as many luminaries as the number of times the angle formed by the reflectors is contained in 360°.

These edges, excepting the one seen by direct vision, and constituting the angular aperture of the plates, are a series of images of this aperture, formed by successive refractions between the inclined reflectors. The images formed by each reflector from each of the plates lie on each side of the direct aperture, and are inverted images of that aperture; the next two images formed by two reflectors are images not inverted; and so on throughout the whole series, every two direct images being separated by an inverted one.

From these observations, it will be seen that the caleidoscope is not an instrument which produces beautiful forms by the multiplication of single forms; for it is demonstrable, that a symmetrical and beautiful pattern cannot be produced by the repetition of any single form; and if it were possible to contruct a multiplying-glas with mathematical perfection, and free from all the prismatic colours, it would be impossible to produce with it an arrangement of simple forms, marked with symmetry and beauty. The principle of the caleidoscope, therefore, is to produce symmetry and beauty by the creation and subsequent multiplication of compound forms, each of which is composed of a direct and an inverted image of a single form.

The tube which holds the reflecting plates moves in another tube; and upon the outer end of the last tube is placed a cell, or cap, for receiving a series of object-plates, containing fragments of differently-coloured glasses and other substanences places at random. When one of these object-plates is placed in the cell, the inner tube is pushed in as far as it will go; and the instrument being held in one hand, the cell containing the object-plates may be removed round with the other, and the eye of the observer being placed at the other will observe the irregular masses of colour arranged in an infinite variety of forms, mathematically symmetrical, and highly pleasing to the eye.

If the object be put in motion, the combination of images will likewise be put in motion, and new forms, perfectly different, but equally symmetrical, will succeffively present themselves; sometimes varying in the centre, sometimes emerging from it, and sometimes playing around it in double and opposite oscillations. When the object is tinged with different colours, the most beautiful tints are developed in succession, and the whole figure delights the eye by the perception of its form, and the brilliancy of its colouring.

The effects, of which we have given a general description, obviously arise from inversion and subsequent multiplication of every object placed before the angular aperture, or the luminous field seen by direct vision, and from the perfect junction of all the reflected images. When the object is moved, the inverted images all seem to move in an opposite direction, while the images not inverted move in the same direction with the object; and from these opposite motions, as well as from the entrance of new objects, by the revolution or the direct motion of the object-plate, arises that endless variety of forms which affords so much gratification to the eye.

In the preceding form of this instrument, the object must necessarily be placed close to the end of the reflectors; for if it is removed from this position, the symmetry is destroyed, and the deviation from a symmetrical form increases as the distance of the object from the reflector increases. The use of the instrument in this form is, therefore, limited to objects which can be held close to the reflector.

This limitation, however, has been superceded; and the use and application of the instrument indefinitely extended by an optical contrivance. A lens of a short focal length is placed on the object end of the outer tube, and the inner tube is drawn out till the image of objects, whatever be their distance, falls exactly on the outer end of the reflectors. When this is the case, these objects will be arranged into the most beautiful and symmetrical forms, in the same manner as if they had been reduced in size, and actually placed at the end of the reflectors. In this way, every object in nature may be introduced into the picture formed by the instrumt, and the observer will derive a new and endless source of enjoyment by the creation of pictures of natural objects, whether animate or inanimate.

As the caleidoscope is of great use in the ornamental arts, particularly to carpet and lace manufacturers, calico-printing, paper-drawing, jewellery, &c. &c., its adaptation to their purpose is effected by occasionally furnishing the instrument with a stand, in order that the pattern may be fixed while
whilst the artist is engaged in copying it. It is also capable of being used with Dr. Wollaston’s camera lucida, by which means those who would otherwise be unable to copy the patterns may do it with perfect facility and accuracy. The effects of the instrument may also be exhibited to many persons at once, on the principles of the solar microscope, or magic lantern. The instrument for scientific purposes is occasionally so constructed as to admit of the inclination of the reflectors being varied at pleasure. Under the authority of Dr. Brewster, calidoscopes of all the different forms are manufactured by the opticians with great accuracy and perfection; but the popularity of the instrument has been such as to induce a great number of individuals, who have been ignorant of its principles, to infringe upon the patent, and impose upon the public a wretched imitation of the original, professing none of the properties which are essentially necessary to the production of beautiful and symmetrical forms; and in order to justify such proceedings, it became necessary to search out for some combination of mirrors already described, which might have some resemblance to Dr. Brewster’s instrument: and the first supposed anticipation of it was found in Prop. 13 and 14 of Wood’s Optics; but professor Wood, in a letter to Dr. Brewster on the subject, has most handsomely disclaimed having in contemplation the effects produced by the calidoscope in giving the propositions alluded to. The next supposed anticipation was an instrument proposed and made by Mr. Bradley in 1717, which consisted of two pieces of silvered looking-glasses, five inches wide, and four inches high, jointed together with hinges, and opening like a book. These plates being set upon a geometrical drawing, and the eye being placed in front of the mirrors, the lines of the drawing were seen multiplied by repeated reflections. This instrument had been described long before by Kircher, and did not receive a single improvement from the hands of Bradley. It had been often made by the opticians; but no person ever thought of applying it to any purpose of utility, or of using it as an instrument of rational amusement by the creation of beautiful forms: indeed, from its construction, it is quite incapable of producing any of the singular effects of the calidoscope. As, however, the similarity between the two instruments is maintained by many persons, either from ignorance or interest; in order, therefore, to render that justice to Dr. Brewster which to us appears due, we give the following statement of the differences between the two instruments, upon the supposition of their both being applied to geometric lines upon paper.

1. In Bradley’s instrument, the length is less than the breadth of the plates.
2. Bradley’s instrument cannot be used with a tube.
3. In Bradley’s instrument, from the erroneous position of the eye, there is a great inequality of light in the sectors, and the last sectors are scarcely visible.
4. In Bradley’s instrument, the figure consists of elliptical, and consequently unequal sectors.
5. In Bradley’s instrument, the unequal sectors do not unite, but are all separated from one another by a space equal to the thickness of the mirror-glass.
6. In Bradley’s instrument, the images reflected from the first surface interfere with those reflected from the second, and produce a confusion and overlapping of images entirely inconsistent with symmetry.
7. In Bradley’s instrument, the defects in the junction of the plates are all rendered visible by the erroneous position of the eye.

To which it may be added, that professors Playfair of Edinburgh, and Pictet of Geneva, and the celebrated Mr. Watt, have each of them borne testimony to the dissimilarity of the two instruments, and to the unquestionable claim which Dr. Brewster has to the invention of the calidoscope.

CALENDAR. To the French calendar, annex—the French have abolished their new calendar, and restored the Gregorian, which was ordered to be used in all their dates after the 1st of January, 1806.

CALEYA, in Botany, a very distinct and elegant genus, thus named by Mr. Brown, in jubilee commemoration of Mr. George Caley, an able and accurate botanist, who has for several years been employed by Sir Joseph Banks, in the investigation of the vegetable productions of New South Wales, but whose discoveries are not all admitted into Mr. Brown’s work, being, we hope, destined to appear in some more popular, and more amply descriptive, publication.—Brown in Ait. Hort. Kew. v. 5. 214. (Caleana; Br. Prod. Nov. Holl. v. 1. 329.)—Clafs and order, Gymnandria. Nat. Ord. Orchidae.

There are two species, C. major and minor, both found near Port Jackson; the former sent to Kew, by Mr. Caley, in 1810. These are smooth herbs, with simple naked bulbs. Leaf radical, solitary, linear, sheathed at the base. Flowers few, brownish-green; the lip and column red. The lip is moveable, reflexed; but during rain it becomes inflated over the column, which Mr. Brown is doubtful whether to attribute to the diminution of light, or to the irritation of the rain.

Eff. Ch. Fruit uninterrupted, uniform. Receptacles cup-shaped, cartilaginous, stalked, more or less elevated, containing a compact powdery mass of seeds, forming an even disk.

Acharius defines twenty-five species of this curious and beautiful, though minute and inoffensive genus of the Lichen tribe. They form grey, white, or yellow patches, of various extent, on old wrought wood, or boards, exposed to the
CALNE. The borough and parish of Calne, in 1811, contained 750 houses, and 3547 persons; vis. 1621 males, and 1926 females: 535 families employed in agriculture, and 432 in trade and manufactures.

Eff. Ch. Calyx perish, two lower leaves under the lip. Petals small, yellow, and red. Lip longer than the calyx, fertile, pointed; beard at the margin and on the disk. Anther parallel to the stigma, permanent.

Eff. Ch. Petals five. Nectary with twelve segments, bearing the stamens. Berry globose, with one or two seeds.

Di stinguished from Pancratium, as Mr. Brown observes, chiefly by the structure of the single-celled stamens and pericarp. The flowers are small, not an inch long, either white or purple. The seeds germinate in the berry.

2. C. purpureum. Br. n. 2.—Flower-tallk earlier than the leaves. Barren segments of the nectary triangular.—Found on the southern coast of New Holland.

Gen. Ch. Cal. Perianth half-superior, of one leaf, tubinate; limb in four or five short, broad, deciduous segments. Cor. Petals four or five, ovate, twice the length of the calyx, and alternate with its segments. Stam. Filaments very numerous, in four or five sets, opposite to the petals, the claw of each set flattened, oblong, many times longer than the corolla, some of them either combined together, or partially imperfect, pinnate, or otherwise many-cleft, in the upper part, with capillary segments; anthers terminal, inserted by their base, linear-oblong, undivided. Pillo. Germe in the bottom of the calyx, small, roundish; style thread-shaped, erect, shorter than the stamens; stigma acute. Peric. Capsule clothed with the base of the calyx, and firmly united to the branch, roundish, of three cells. Seeds numeros, small, oblong.
CAL

Eff. Ch. Calyx in four or five segments. Petals four or five. Stamens numerous, very long, in several various fts, opposite to the petals; anthers linear, undivided, vertical. Capsule coated by the calyx, three-celled, permanent. Seeds numerous.

Obf. The flamen in fome species confift of uniform fets, answerable to the number of the petals; in others, two or more of thofe fets are partially combined laterally, the remainder being diminished to fimple threads, without anthers, and this is the character of the genus as M. Labillardiere underftood it and defcribed it. But Mr. Brown has, in conformity to nature and analogy, not limited it fo strictly. We adopt his views of the genus, only begging leave to conftruct the effential character without exceptions, such paraphology being left avoided. The genus before us comes next to Beaufortia, (fee that article,) and is fuch as fplendid, differing from it effentially in the ftucture of the anthers, and in having numerous feeds. From Mr. Lalaeuca, (fee that article in vol. xxiii.) the difference is ftriking, but we believe very effential, conflating in the vertical, not incumbent, anthers. To this Mr. Brown adds that the inflorefcence is unilateral.

1. C. fanguinea. Blood-red Unequal Calothamnus. Labill. Nov. Holl. v. 2. 25. t. 164.—Flowers four-cleft. Sets of flaments combined; two of them imperfect, diftinâ. Adult leaves linear-awlshaped, compressed, smooth.—Native of Lemon's land, flowering in December. A flabulif, six feet high, with round, scarred branches. Leaves scattered, flender, acute, entire, rather above an inch long; hairy when young. Flowers in small lateral fefile tufts, about the length of the leaves, confpicuous for their blood-red flaments, two fets of which unite to form a broad, wedge-shaped, concave body, divided at the top into numerous, vertical, parallel flaments, each bearing an upright linear anther; the two remaining fets diminished to fimple, awl-shaped threads, without any anthers. Capsule small, globose.

2. C. quadrifida. Four-cleft Equal Calothamnus. Br. in Eff. Ch. n. 1. Sims in Curt. Mag. t. 1506.—Flowers four-cleft. Sets of flaments equal and diftinâ, with many anthers. Adult leaves smooth, as well as the fruit.—Gathered by Mr. Brown, on the south-west coast of New Holland. Sent to Kew in 1803, by Mr. Good, along with the following. This bears splendid scarlet flowers, whose beauty however depends on the large flaments, an inch and a half long, the petals being small, pale, and inconufpicuous. The leaves are linear-chavate, or somewhat fpatulate, but extremely narrow, hardly more than an inch in length.

3. C. vilicâ. Hairy Five-cleft Calothamnus. Br. in Eff. Ch. n. 2.—Flowers five-cleft. Sets of flaments equal and diftinâ, with numerous anthers. Adult leaves villous, as well as the fruit.—Found by Mr. Brown on the south-west coast of New Holland. A green-flabulif, flowering at Kew, from July to September.

4. C. gracilis. Slender-leaved Calothamnus. Br. in Eff. Ch. n. 3.—Flowers five-cleft. Sets of flaments equal and diftinâ, with only three anthers to each. Leaves elongated, smooth, as well as the prominent calyx. Stem branched.' Native of the fame country as the last.

No other species have been hitherto defcribed.

Eff. Ch. Corolla. Crown of the flaments fimple, of five keeled fakes, attached lengthwise to the tube of the flaments; recurved at the base. Maffes of pollen, smooth, pendulous. Stigma pointif, smooth. Foliages tumid, smooth. Erect smooth milky flubs, with broad opposite leaves, and handsome large flowers, in lateral corymbofe panicles, inferted between the footstalks. Only two species are defcribed.

1. C. procrea. Bell-flowered Auricula-tree. Ait. n. 1. (Afclepias procrea; Ait. ed. 1. v. 1. 305. Willd. Sp. Pl. v. 1. 1265. Schenev. 1. c. 18. (See Afclepias, n. 29.) A. gigantea; Andr. Repof. t. 271. "Z/ga-rack; LeBrun Voy. v. 155. t. 184."—Segments of the corolla spreading.—Native of the Florid fhrub impatinent of damp and cold, flowering from July to September. The whole plant is glaucous, fix or seven feet high, with broad, fefile, entire leaves. Flowers irregularly corymbofe, numerous, larger than in most of this tribe, an inch or more in width, of a rich brownif-purple, powdered like an Auricula; pale beneath.

2. C. gigantea. Curled-flowered Auricula-tree. Ait. n. 2. (Afclepias gigantea; Linn. Sp. Pl. 312, excluding the synonmys of Plukenet and Alpinus. Willd. Sp. Pl. v. 1. 1264. (See Afclepias, n. 6.) Ericu; Rheed Hort. Mal. v. 2. 53. t. 31.)—Segments of the corolla reflexed, with twifted points.—Native of fandy ground on the coaft of Malabar. Very like the foregoing, but the corolla is differently flaped, as exprefsed in the character, and is laid to be variegated with white and purphili-red, fmmelling like a lily. We beg leave to obferve, that if priority of date were to determine generic names, without regard to the found regulations of Linnæus, Mr. Brown's elegant Calotropis must give way to Rheed's Ericu, as the appellation of this genus, in spite of law, fense, taste, and convenience.

Vol. VI.

CALVERT, in Geography. Add—This county contained, in 1811, 8005 inhabitants, including 3937 flaves.

CALYPSO, in Botany, an elegant clafical name of Mr. Salibury's, from kalypso, to cover or conceal, not merely alluding to the covering of the ifmaga, but preferring a poetical analogy between this botanical beauty, to difficult of access, and the fecluded goddess, whose ife was fabled to be protected miraculously from the obervation of navigators.—Salib. Parad. 89. Brown in Ait. Hort. Kew. v. 5. 308. Purfii 593.—Clafs and order, Gynandria Monandria, Nat. Ord. Orchidées.

CALYSTEGIA, a genus feparated by Mr. Brown, Proor. Nov. Holl. v. 1. 483, from Convulvus, and chiefly diftinguifhod by the great fize of the two leafy bracteas, including
inclining the calyx, whence the name, from καλύξ, and τεσσ. io cover. Convulvulus fünum and C. Solidmela of Linnaëus, with several others, confluence this genus, which appears to us better omitted. CALYX-YUC, denotes, according to the chronology of the Hindoos, the present or fourth age of the world.

CANALODUNUM, l. 3. Tr. Trinomaites.

CAMBERWELL, a parish of Brixton hundred, in the county of Surrey, which includes the hamlets of Dulwich and Peckham, and in 1811 contained 1849 houses, and 11,109 persons; viz. 4854 males, and 6255 females; but since that time much increased in buildings and inhabitants.

CAMBIUM, l. 3, for CORTICAL LAYERS r. Cortex; l. 39, for PITH and MEDULLARY CANAL r. MEDULLA. Col. 2, l. 5, r. Monocotyledones.

Cambio, in Geography, a county of Pennsylvania, containing 2117 inhabitants.—Alto, a township of the same county, having 868 inhabitants.

CABRIDGE, col. 4, l. 7, add.—By the return in 1811, the borough and university of Cambridge contained 1999 houses, and 11,108 persons; viz. 5288 males, and 5820 females; 80 families employed in agriculture, and 1600 in trade and manufactures.

Cambridge, in Washington county, &c. l. 2, r. census of 1810, 6730 inhabitants, and 650 senatorial electors; l. 10, for 2115 r. t. 3233; l. 38, r. 990.

Cambridge, a town of Guernsey county, in Ohio, having 474 inhabitants.

Cambridge, West, a township of Middlesex county, Maffachusettts, having 971 inhabitants.

CAMBRIDGESHIRE, col. 1, l. ult. r. In 1811, this county contained 17,489 houses, and 101,109 persons; viz. 50,756 males, including 2946 local militia, and 50,333 females; 12,831 families employed in agriculture, and 3383 in trade, manufactures, and handicraft.

CAMPDEN, a county of North America, l. 3, for 4033 r. 347.

Camden, a county in Georgia, &c. l. 3, r. containing 3241 inhabitants, of whom 2681 are slaves.

Camden, in the district of Maine, contains 1607 inhabitants.

Camden, a poft-township of Oneida county, in the state of New York, watered by the W. branch of Fith creek, containing about 1100 inhabitants, principally farmers from Connecticut.

Mr. Brown finds this genus on the Myagrum fimilem of Linnaeus, and the M. (not Altham) auffricum of Jacq. Aútr. 1. 111. The first is the only Camelina of Crantz above cited, who distinguishes it from ALTHAM, (see that article) by the connection between the style and the valves of the pouch, the style of Altham being connected with the position only. Mr. Brown's distinction depends chiefly on the position of the cotyledons; for every Altham has not toothed filaments. Of Myagrum auffricum we do not feel competent to judge, but we are disposed to keep the furwum an Altham, as in Fl. Brit. and Engl. Bot. t. 1254, unless it could be set apart along with Altham urticulatum of Linn.
equilibrium would be lost, and all counterbalance when the criffin had entered to such depth as to allow its contained vessel to go out.

For Harlepool Canal r. Hartley Canal; for Durham r. Northumberland; and for Harlepool r. Hartley.

CanaL, Bafing flake, col. 2, l. 3, after commences in, infert.—Cooper’s meadow, adjoining to the town of Bafing flake, and enters the river Wey about two miles above Weybridge; dle, l. 3, 4, 5, from Wey to Bafing flake; l. 18, after Lodden, add—The proprietors are prohibited from touching the Lodden, or any of the springs or freams that feed it.

Canandaigua, or Canandaigua, l. 11, r. In 1810, this township had 415 families, 206 featalional electors, and 2592 inhabitants.

Candarine, a money of account in China, where 1 tale is = 10 marcs = 100 candarins = 1000 catt.

Candles, Laurus relating, col. 2, l. 2, add—By 40 Geo. III. c. 98. duties of culsoms are likewise imposed; l. 8, r. c. 6.

Candy, a weight in the East Indies. At Madras the candy is 500 lbs. avoidupois, = 20 maunds. See MAUND.

Canfield, in Geography, a township of Trumbull county, in Ohio, having 454 inhabitants.

Canhada, a liquid measure in Portugal, 6 canhadas being = 1 port, r. See Almuda.

Canicular Year, c. 2, l. 16, for in r. on.

Canne, or Canne, a measure for cloth in Italy, and the south of France, Spain, &c. each canna at Barcelona being = 61.4 English inches; at Florence, = 93.1 English inches for woollen and 91.7 for silk; at Genoa, = 116.7 English inches; at Majorca, 67.5; at Malta, 81.9; at Marseille, 79; at Montpellier, 79.8; at Morocco, 101.4; at Naples, 83; at Palermo, 76.2; at Saragossa, 81.5; at Toulouf, 71.7.

Caniquaquanasing, in Geography, a townfsip of Butler county, in Pennsylvania, having 1284 inhabitants.

Cano, l. 3, r. 1601; l. 7, after Sevilla, and under Juan Martinez Montanes; l. 26, infert.—In 1643 he removed to Toledo; and upon, &c.

Cantbrbury. This city, by the return of 1811, contained 2093 homens, and 10,500 inhabitants; viz. 4603 males, and 5597 females: 508 families being employed in agriculture, and 1194 in trade and manufactures.

CANDARIUS, l. ult. dele which see respectively.

One of the most elegant insects of this genus is the scarlet cantharis: entirely of a vivid red, except the body, legs, and antennae, which are coal-black. It is somewhat more than half an inch in length. The C. bipululata is a beautiful insect, somewhat smaller than the preceding, of a very dark but elegant gilded green, with the tips of the wings, shells, red, and on each side of the thorax a triple vehicle of a bright red colour, capable of extension or retraction at the insect’s pleasure, and by the microscope exhibiting an alternate inflation and contraction, like that of the lungs in the larger animals. This species is found in the middle of summer on various plants, and particularly on nettles. Shaw.

Canticles, col. 3, l. 16, —The caufes of the apparent, &c.

Canton, in America, add—and containing 1353 inhabitants.—Alfo, a town of Hartford county, in Connecticut, having 1374 inhabitants.—Alfo, a town of Luzerne county, in Pennsylvania, having 472 inhabitants.—Alfo, a township of Washington county, in the same state, containing 1415 inhabitants.—Alfo, a town of Stark county, in Ohio, having 846 inhabitants.

Canton, in China, l. 17, after houses, infert—built of brick. Col. 2, l. 1, add—Thofe fampanes, as they are called, accommodate, at the very lowef computation, 40,000 people; l. 13, after 40,000, add—The accounts of the population of Canton are very various and contradictory. The exaggerated statement above given is that of Le Comte. Du Halde estimates it at a million; and Sonnerat, erring in the other extreme, reduces the number to 75,000.

But according to data, collected by captain King, in “Cook’s Third Voyage,” (vol. iii.) he apprehends, that the city and suburbs may probably contain about 150,000.

Cadutchou, in Chemiftry. In addition to what has been said of this Singular Substancy, we may observe that it has been lately flated to exist in a great variety of plants, though it has been hitherto unfily confounded with other Substancies. It may be separated from the defcriptions of mifeletto by water, with which it readily combines, and then in alcohol, till all the Substances soluble in these liquids may be extracted. The residuum is then to be dried and digefled in four times its weight of rectified petroleum. Express the liquid part by fqueezing the Substancy in a linen cloth. The liquid is then to be put by for some days to fettle, and after the clear part has been poured off, the remainder is to be mixed with a third part of water, and diluted. The caoutchouc remains behind.

According to Bachofel, a considerable proportion of caoutchouc is contained in opium. Mallic alio is flated to contain a Subftancy very similar to caoutchouc.

People, as they are called, accommodate, at the very lowest computation, 40,000 people; l. 13, after 40,000, add—The accounts of the population of Canton are very various and contradictory. The exaggerated statement above given is that of Le Comte. Du Halde estimates it at a million; and Sonnerat, erring in the other extreme, reduces the number to 75,000.

But according to data, collected by captain King, in “Cook’s Third Voyage,” (vol. iii.) he apprehends, that the city and suburbs may probably contain about 150,000.

Cadutchou, in Chemiftry. In addition to what has been said of this Singular Substancy, we may observe that it has been lately flated to exist in a great variety of plants, though it has been hitherto unfily confounded with other Substancies. It may be separated from the defcriptions of mifeletto by water, with which it readily combines, and then in alcohol, till all the Substances soluble in these liquids may be extracted. The residuum is then to be dried and digefled in four times its weight of rectified petroleum. Express the liquid part by fqueezing the Substancy in a linen cloth. The liquid is then to be put by for some days to fettle, and after the clear part has been poured off, the remainder is to be mixed with a third part of water, and diluted. The caoutchouc remains behind.

According to Bachofel, a considerable proportion of caoutchouc is contained in opium. Mallic alio is flated to contain a Subftancy very similar to caoutchouc.

Cape, or Cape, a name sometimes given by farris to a swelling of a weney kind, which grows on the hock of a horfe, and on the point of its elbow. It often arises from bruises, and in this cafe should be bathed with hot vinegar and alum; but when they grow gradually on both hees and elbow, blood is extravafated. When this happens, fuppuration should be promoted by rubbing the part with infimum unguents; and when matter is formed, the skin should be opened with a lancet, in more dependent

3 G parts
parts towards one side, for avoiding a fear. The subsequent
dressings may be turpentine, honey, and tincture of myrrh.

CAPEMAY, in Geography, a county of New Jersey, con-
taining 36,342 inhabitants, of whom 81 are slaves.

CARAGE of Lime, denotes the quantity of sixty-four
bushels.

CARALLIA, in Botany, Carallia of the Telingas, or
natives of Hindoostan; being one of those barbarous names
which some modern botanists have ventured to tolerate, but
which no classical one can approve.— Roxb. Coromand.

v. 3. 8.—Clavis and order, Jaffandria Monogynia. Nat. Ord.

Hesperide, Linn. Myrti, Jiff.

Eff. Ch. Calyx in six or seven segments, superior. Petals
fix or seven. Stigma three-lobed. Berry of one cell, with a
solitary seed.

1. C. lucida. Shining Carallia. Roxb. as above, t. 211.

Native of the lower region of the Circar mountains. A
small, handsome, evergreen tree, flowering in March and
April. Leaves on short stalks, opposite, elliptical, acute,
finely serrated, smooth, four or five inches long, and two
or two and a half broad. Flowers small, yellow, in little,
aggregate, axillary, flaked heads. Berry the size of a pea,
reddish. Seed large, with a strongly curved embryo. No-
thing is recorded of the qualities or uses of this plant. It
is evidently next akin to Eugenia; see that article.

CARAWAY, r. CARUM, &c.; at the end of the next
article r. CARUM.

CARBON, in Chemistry. The progress of chemical
knowledge enables us to flate, with greater accuracy and
precision, the nature of some of the compounds of carbon,
than at the period when this article in the Cyclopedia was
written.

Carbonic Oxid.—It has been shown by Gay Lussac, that
100 measures of this gas require for complete combustion
50 measures of oxygen, and that the product is 100 measures
of carbonic acid; hence it must be composed of one atom
of carbon and one atom of oxygen, or 100 parts by weight
will consist of

<p>| Oxygen   | -       | 57.14 |</p>
<table>
<thead>
<tr>
<th>Carbon</th>
<th>-</th>
<th>42.86</th>
</tr>
</thead>
<tbody>
<tr>
<td>100.00</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

And its true specific gravity must be .9722, and 100 cubic
inches of it will weigh, at a mean temperature and pressure,
29.652 grains. Carbonic oxide has the property of com-
bining with chlorine, and forming a peculiar compound,
which its discoverer, Dr. Davy, has named Phosgene gas;
which see.

Carbonic Acid.—When pure charcoal is burnt in oxygen
gas, it has been shown that the original bulk of the oxy-
gen suffers no change. Hence it is obvious, that, by sub-
tracting the specific gravity of oxygen from that of car-
bonic acid gas, we shall obtain the quantity of carbon existing
in it. The specific gravity of oxygen gas is 1.111, and that
of carbonic acid 1.52. Hence 100 parts, by weight, of
carbonic acid will consist of

<p>| Oxygen   | -       | 72.73 |</p>
<table>

</tbody>
</table>

which correspond with two atoms of oxygen and one of
carbon. See Atomic Theory.

Carburized Hydrogen.—The specific gravity of carburetted
hydrogen, according to Dr. Thomson, is .5555, and 100
cubic inches of it weigh 16.99 grains. It requires for its
complete combustion twice its volume of oxygen gas, and
produces exactly its own volume of carbonic acid; the only
remaining product is water. Hence 100 parts, by weight, of
this gas are composed of

<p>| Carbon   | -       | 75    |</p>
<table>

</tr>
</tbody>
</table>

which correspond with one atom of carbon and two of oxygen.

Olefant Gas.—The specific gravity of this gas, according
to Dr. Thomson’s experiments, is .974, and 100 cubic inches
of it weigh 29.72 grains. It requires for its complete com-
bustion three times its volume of oxygen gas, and produces,
when burnt, twice its volume of carbonic acid gas, and a cer-
tain proportion of water. Hence 100 parts, by weight, of
this gas are composed of

<p>| Carbon   | -       | 85.71 |</p>
<table>

This oily liquid, which Dr. Thomson considers as a fort
of ether, and hence names it chloric ether, burns with a green
flame, and at the same time gives out copious fumes of
muratic acid and much foot. Its specific gravity at 45° is
1.2201, water being 1.000. It boils at 152°. At the
temperature of 49°, its vapour is capable of supporting a
column of mercury 24.66 inches in height. The specific
gravity of this vapour was found by experiment to be
3.4434, which very nearly coincides with the above account
of its composition. When puffed through a red-hot porcelain
tube it is decomposed and converted into muratic acid,
and an inflammable gas containing hydrogen and carbon,
while a copious deposit of charcoal is found in the tube.
It is also decomposed when puffed through red-hot oxyd of
copper.

With respect to the carburettes, the numbers representing
them will of course require a little adjustment; this can be
easily done from the composition of carbonic acid stated above,
and from the data given under Atomic Theory.

CARDONIC Acid Gas, col. 2, l. 5, add.—According
to the accurate experiments of Meiffers. Allen and Pepys,
recorded in the Phil. Trans. the weight of a cubic inch of
this gas is .464 of a grain. Col. 3, l. 46, r. milkins.

CARDAMOM, l. 2, infert after Cardamom, angylifec-
ium, grana Paradisia, &c.

CARDIFF, col. 2, l. 9, infert after canal.—The town-
hall of Cardiff is a respectable modern building, and near it
C A R

is the county gaol, built upon Mr. Howard's plan; l. 14—
By the parliamentary return in 1811, the number of inha-
bilants is stated at 2457. The only manufactury established
here is that of iron hoops: the trade, however, is very
considerable, in consequence of the numerous collieries up
the vale, and the iron and tin works of Merthyr, Melin
Gruydydd, &c., the produce of which is conveyed here by
the canal for exportation, and which creates a large import
trade from Bristol, &c., in ship goods to supply the con-
sumption of the interior country. There are regular paffage-
boats twice a week from this place to Bristol.

Cardiff is a borough-town, and in conjunction with the
contributory boroughs of Cowbridge, Llantrant, Keaf^g,
Aberavon, Neath, Swansea, and Loughor, sends one mem-
ber to parliament.

CAREX, col. 4. l. 11, r. banata.
CAREY, in Botany, named by Dr. Roxburgh, "after its
discoverer Mr. William Carey, a good botanist, and a pro-
moter of natural history in general."—Roxb. Coromand.
v. 3. 13. Ait. Hort. Kew. v. 4. 236.—Clafs and order,
Myrti. Juif.

Eff. Ch. Calyx superior, four-cleft. Petals four. Style
one. Germen of four cells. Berry with numerous seeds,
imbbed in pulp.

1. C. herbacea. Herbaceous Careya. Roxb. as above, l.
2.17. Ait. n. 1.—Herbaceous. Flowers flaked. Outer
filaments long and without anthers.—Native of Runghope,
in Bengal, flowering in February. Rot woody, perennial.
Stems a tap root, annual, round, smooth. Leaves opposite,
obovate, crenate, smooth, from four to eight inches long,
on short stalks. Flowers terminal, corymbose, few, large
and very beautiful, the calyx and petals greenish, tinged
with red; the outer row of their innumerable flaments crin- 
forn, capillary, two inches long, recurved, without anthers, about
twice the length of the obvate petals. Berry brown, the
size and texture of a medlar.

2. C. arbores. Tree Careya. Roxb. as above, l.
(Pelou ; Rheed Hort. Malab. v. 3. 35. t. 36.)—Arbo-
reous. Flowers sessile. Inner filaments short, and without
anthers.—Native of the valleys, in various mountainous parts
of India. A large tree, with obovate, slightly ferratated, smooth,
deciduous leaves, from fix to twelve inches long. Flowers
crowded, pale yellow, appeaing with the young leaves in
March. Fruit the size of a small orange, felnid and nafenous
till quite ripe, when the pulp becomes ferratated; but Rheed
reports it to be poisonous, which, considering its affinity to
Pfludum, is not credible. Dr. Roxburgh gives no account
of this matter, but describes the wood as the colour of ma-
hogany, though lefs hard and clofe. The fibrous bark
makes tough and durable ropes.

CARGA, a measure for wine and oil at Barcelon^,
equal to 2 1 quaters.

CARGADOR, in Portugal and Holland, denotes a
ship-broker.

CARGILIA, in Botany, is dedicated to the memory of
Dr. James Carell of Aberdeen, a contemporary of Capar
Baun, in whole Prodrornus, p. 154, 155; (Mr. Brown by
mistake refers to his Theatrum,) several descriptions of Puci,
communicated by Dr. Cargill in 1603, may be seen.—Brown
Prodr. Nov. Holl. v. 1. 230.—Clafs and order, Polygama
Juif. 671.

Eff. Ch. Calyx inferior, half-four-cleft. Limb of the
corolla four-cleft. Stamens inserted into the base of the
corolla; filaments doubled. Germen of four cells, with
two seeds in each. Berry globose, closely invested with
the cup-shaped calyx.—Some flowers have fewer, and im-
perfect, flaments; others only the rudiment of a pistill.

This genus is intermediate between Diospyros and Ma^a.
See those articles.

1. C. laxa.—Leaves oblong, rather wavy, smooth. Calyx
of the male flowers four-toothed, half as long as the tube of
the corolla. Style in three or four deep segments. Young
branches lax.—Found by Mr. Brown in the tropical part
of New Holland.

2. C. alpina.—Leaves oblong, smooth, obtuse, paler
beneath; acute at the base. Calyx of the male flowers four-
cleft, as long as the tube of the corolla. Style undivided.
Found by Mr. Brown, in New South Wales.

CARMELITES. Add.—See Taro.

CARN, or Cahn. See Carnedde.

CARNESVILLE. Add.—See Franklin.

CAROLIN d'Or, or CAROLIN, a gold coin of Bavaria,
Hefle Darmfitat, and Wurtemberg, valued at 11 florins.
See Coin.

CAROLINA, N. and S. See United States.

CAROLINE, l. 4. r. 17544; l. 5. r. 10764; l. 8, r.
9453; l. 10. r. 1520.

CARORA, l. 2, infer.—15 leagues E. of Maracaybo,
in N. lat. 1°. The town is tolerably well built: the
streets are large and on a line; the air is fabulous, though
the foil is parched; the inhabitants, amounting to about
6200, live on the produce of their flocks and herds, and em-
ploy themselves in tanning and dreeing the hides and skins,
which are used in the city for boots, shoes, saddles, bridles,
and curriage. The surplus of the local consumption is spread
over the produce, or is conveyed to Maracaybo, Cartha-
gen, and the island of Cuba. They also make, with a
kind of fibre (abejlofticha,) very good hammocks, which
furnish an article of commerce. Depons.

CARPATHIAN MOUNTAINS, l. 22, r. Zemnit.

CARPHA, in Botany, so named by Sir Joseph Banks
and Dr. Solander, from xag, dry shrub or chaff, in allusion
to the habit of this genus.—Brown Prodr. Nov. Holl. v. 1.
Camarineae, Linn. Cyperaceae, Juif. Dr.

Eff. Ch. Spikelets single-flowered; scales imperfectly
two-ranked, the lower ones empty. Brilles three to six,
beneath the germen, as long as the fertile scale. Style
awl-shaped, without a joint, crowning the prismatic nut.
Stigmas two or three.

Sect. 1. Spikelets two-ranked. Stigmas three. Nut trian-
gular. Brilles feathery.

1. C. alpina.—Spikelets in a corymbose cluster. Brilles
fixed, feathered nearly to the top. Stem leafy, smooth,
Leaves rough.—Native of Van Diemen's island.

2. C. dehiscens.—Tuft terminal. Involucrum of two don-
gated
gated leaves; dilated and membranous at the base. Brilles three, feathery at the base. Stem leaflets. Leaves radical, almost bristle-shaped. —Native of Port Jackson.

These, with a non-descript species from Terra del Fuego, constitute, in Mr. Brown's opinion, the genuine genus of Carpho, the following being perhaps entitled to form one by themselves.

CARRICK. See Trankey.

CARTER, l. 1. infert E. Tenebros. Add.—It contains 1l. 4s. 6d. See Tax.

CARTERET, in Carolina, &c., l. 3. r. 4823; l. 4. r. 4190 inhabitants, 202 being claves.

CARTS, Laws relating to, col. 3. l. 49, for 1l. 4s. r. 1122.

CARTHAMUS, Chemical Properties of. Many experiments have been made on the colouring matter extracted from this plant. The last and most interesting are those of Dufour and Marchais, of which we shall present our readers with a short account.

The flowers of the carthamus contain two colouring matters; a yellow, which is soluble in water, and has hitherto been applied to no use; and a red, which is employed by the dyers, &c., and which constitutes the pigment called rouge. The yellow colouring matter readily dissolves in water, but it is difficult to separate the whole of it. Dufour effected this by expelling the carthamus wrap up in a piece of linen to the action of a stream of water. To separate the red colouring matter, he macerated for an hour the carthamus, after it had been thus washed, in a weak solution of carbonate of soda. Into this solution was put a quantity of cotton, and lemon-juice was then dropped into it till the liquid assumed a fine cherry-red colour. After standing twenty-four hours, the liquid left its red colour, the whole colouring matter having combined with the cotton, and dyed it red. The cotton was taken out and well washed, to separate a little of the yellow colour adhering to it. It was then put into a very dilute solution of carbonate of soda, and was allowed to separate the red colouring matter. This alkali separated the colouring matter from the cotton. This alkali after being removed, and also having dropped into the solution, a fine red-coloured powder gradually separated, and at last precipitated. This was the red colouring matter. This red colouring principle is insoluble in water and oils, but is soluble in alcohol and ether. The alkalis also diffuse it, but destroy its colour. When diffused, it yields a little water, scarcely any gas, a little oil, and a portion of char-
coal, equal to one-third of the original weight. When this charcoal is burnt it leaves no ashes. One thousand parts of carthamus yielded only five of this red colouring matter, but no less than 268 of the yellow colouring matter above-mentioned. Carthamus also contains a great variety of other substances according to Dufour, many of which, such as alumina, fand, &c., are evidently foreign. It is probably in some such manner as the above that the pink flowers are prepared from carthamus, though we believe the exact process is kept secret.

CARTILAGE, Chemical Properties of. See Bone.

1. C. papuanum. —Found by Mr. Brown in the tropical part of New Holland. Root perennial, tuberculous below the fibres. Herb clothed with lax hairs, much resembling Philodium in appearance. Stem leafy, simple, or slightly branched. Leaves linear, clasping, elongated. Spike terminal, of many yellow flowers, each with two unequal, leafy, permanent bracteas. The habit, as well as the permanent flamen and style, lead Mr. Brown to suspect some affinity to Philodium. Hence perhaps the true place of that puzzling genus may be discovered.

CARVER, in Geography. Add.—It contains 358 inhabitants.

CASEIN, infert.—Or CAUSEEN, l. 11, after broad, add —it may still, however, be regarded as one of the largest and most populous towns in the kingdom, and carries on a great trade with Ghilan.

CASEY, a county of Kentucky, containing 3252 inhabitants, of whom 237 are claves.

CASH, a small coin in China, and India beyond the Ganges. See Tale.

CASHERING, in Military Language. An officer sentenced by a general court-martial, or peremptorily ordered by the king, to be dismissed from the service, is said to be cashiered.

CASSAVA, or TAPICA, Chemical Properties of. This is prepared from the roots of the Jatropha manubot, an American plant. (See Jatropha.) These are peeled and subjected to pressure in a bag made of rushes. The ex- pressed juice is a virulent poison, and is employed by the Indians for poisoning their arrows; but it deposits gradually a white powder, which has all the properties of starch, and which, when washed and dried, is perfectly harmless, and highly nutritive. What remains in the bag also confits chiefly of the same starch. It is dried in smoke, and afterwards pressed through a kind of sieve. Of this substance, the cassava bread, to much employed in the West Indies, is made.

1. C. aerea. Yellow Cassinia.—Native of the south coast of New Holland. Br. Seeds were sent to Kew, by Mr. Good, in 1803. The plant is marked as a green-houe perennial herb, flowering in July and August, but we have no account of its habit or appearance.

CAST, for BRAHMS, r. BRACHMANS.

CASTELLANO, a weight for gold in Spain, 50 castel-
lanos.
CAV

Lucas being = 400 tomises or 4500 grains. Silver is weighed by the same mark of 50 obellinos, divided into 8 ounces, 65 obellinos, 128 adanneau, 384 tomises, or 4608 grains.

CASTINE. Add—It contains 1036 inhabitants.

CASTLE, New. See Newcastle.

CASTLE-CARY, l. 8, add—By the returns of 1811, the parish contained 281 houses, and 1405 inhabitants; 650 being males, and 756 females.

CASTLE-RISING, By the returns of 1811, the borough and parish contained 48 houses, and 297 persons; viz. 148 males, and 149 females.

CASTLETON, l. 9, r. 1420.

CASTLE-TOWN, a township of America, &c. l. 2, which contained, by the census in 1810, 1301 inhabitants, and 121 senatorial electors. Here are three houses for public worship, and some school-houses.

CASTOR. By the returns of 1811, the parish contained 185 houses, and 1051 persons; 487 being males, and 564 females.

Vol. VII.

CASWELL, l. 3, r. 11,575 and 4299.

CATAHULA, a parish of the territory of Orleans, having 1164 inhabitants.

1. C. syringifolia. Common Catalpa. Sims in Curt. Mag. t. 1094; and
2. C. longiflora. Wave-leaved Catalpa. (Bignonia longiflora; Willd. Sp. Pl. v. 2. 292.) are the two described species. (See Bignonia n. 1 and n. 22.) We have heard that Dr. Solander, who was first aware of this genus, and who would certainly never have admitted so unauthorized a name as Catalpa, was very desirous of having it called Solandra.

CAVVAWESSY. Add—It contains 1934 inhabitants.

CATHARINE II., col. 3, l. 140, for Persia r. Prussian.

CAT'S-EYE. See Mineralogy, Addenda.

CATTIE, a weight at Canton, in China, and in some parts of India. The catty or gin of 16 lyangs or tales weighs 19 oz. 6 dwts. 4 grs. English troy, so that 10 tales would weigh 5752 English grains. See 'Tale.'

CAVALLO, TIBERIUS, F. R. S., in Biography, the son of an eminent physician of Naples, who was born in 1759. Deined for commerce, he came to England for the purpose of acquiring himself with the principles of commerce in 1771; but literature and philosophy diverted his attention and enjoyed his preference. To those who were engaged in pursuits similar to his own, and to the editor of this Cyclopaedia, he was a very useful coadjutor. His publications on a variety of philosophical subjects, and his communications to the Royal Society, were numerous, and are well known; particularly his "Elements of Natural and Experimental Philosophy," 1803, 4 vols. 8vo. He died, much respected and eleftoned, and with the editor's sincere regret, in London in 1810.

CAUCUS, a term used in North America for a kind of electioneering committee; caucusing, as it is said, denoting electioneering. Of the origin of this unctouch term we have the following account in Gordon's Hill of the Amer. Rev. London 1788. "About the year 1730, the father of Samuel Adams, and twenty others who lived in the north or shipping part of Boston, used to meet to make a caucus, and lay their plan for introducing certain persons into places of trust. Each distributed the ballots in his own circle, and they generally carried the election. As this practice originated in the shipping part of Boston, caucus might have probably been a corruption of Cauker's meeting." See Pickering's American Vocabulary.

CAVENDONA, l. 1st. r. 80.

CAVEER, or CAREER, a money of account at Moche, in Arabia, where accounts are kept in piastras of 80 cavers current.

CAVELLO, a copper coin of Naples.

CAVENDISH, The Honourable Henry, in Biography, was the son of Lord Charles Cavendish, and born in London in 1731. In literature, mathematics, chemistry, and philosophy, he was eminently distinguished; but his temper and habits were through life singularly reclusive and economical; so that he appeared to those who were not honoured with being his intimate associates to great disadvantage. In early life his fortune was small; but by the retired manner in which he lived, and by unfrequent accumulation of property, he died very rich. His library was very valuable; and capful of access to all his literary friends; but it is to be lamented that, in other respects, he was not emulous of following the example and acquiring the reputation of his eminent friend, Sir Joseph Banks, the president of the Royal Society, whose Sunday evening meetings he constantly attended, being generally there as well as at the meetings of the Royal Society, where he was almost always present, more ready to hear than to speak. A similar reserve and taciturnity marked his character in all his ordinary social connections and secular concerns. As a philosopher, his ruling temper was not without its beneficial effects. His contributions to the Royal Society, and which may be found in its Transactions, relate to chemistry, electricity, meteorology, and alchemy. This eminent philosopher died on February 4th, 1810, in the 79th year of his age, and at that time was reckoned the greatest proprietor in the Bank of England, his wealth being estimated at nearly 1,300,000 pounds, which he left entirely among his relations.

CAVENDISH, in Geography, a town of Windor county, in Vermont, having 1295 inhabitants.

CAUK, l. 1st. add— and Barytes.

This genus is founded on Zophora oceanica of Limneus, see Cavol, Monogr. translated in Ann. of Bot. v. 2. 77. t. 6. To this Mr. Brown adds a New Holland species, C. formata, with three doubtful ones, among which is Ruppià antarctica, Labill. Nov. Holl. v. 2. 116. t. 284. We are not informed why this genus supersedes the CAULINIA we have already described; see that article.

CAULO-
CAULOPHYLLUM, Michaux Bor.-Amer. v. 1. 204. Pursh 218. See Leontice.

CAUSTIC, Lunar. l. 18. r. revised.

CAUSTIS, in Botany, xerox, forced hay or corn, alluding to the dry heads of the stem, which appear as if burnt.—Brown Prodr. Nov. Holl. v. 1. 239.—Clawed and order, Triandria Monogynia. Nat. Ord. Calamaria, Linn.

Eff. Ch. Spikelets nearly single-flowered. Scales fasciculated, the empty ones numerous. No bristles beneath the germen. Style dilated at the base. Stigmas three or four. Nut tumid, crowned with the bulbous base of the style.

Obf. One species has five fermen, a circumstance marked by Mr. Brown as very extraordinary.

These are rigid rushy plants, growing on dry heaths in New Holland. Their fermen are leaflets; round and undivided in the lower part; panicled and semi-cylindrical above; the ultimate branches awl-shaped and leaf-like. The fermen are clothed with entire withered theaths, extended on one side into an awl-shaped point, of the fame colour. Spikelets panicked, small, sometimes dioecious. Nut ovate, white, opaque. Brown.

1. C. flexuosa.—Panicles loose, zigzag; their ultimate branches smooth. Scales of the spikelets smooth.—Found at Port Jackson. C. Flexuosa.

2. C. depressa.—Panicles zigzag, rather denf; ultimate branches rough-edged. Scales of the spikelets downy.—Native of the south coast of New Holland.

3. C. pentandra.—Principal and partial branches stiff. Stamens five.—Found near Port Jackson.

CAYUGA, in Geography, a county of New York, containing 29,843 inhabitants, of whom 75 are slaves.

CECIL, l. 3; add—1816, 13,656 inhabitants, of whom 2,499 are slaves. Add at the close—containing 1,107 inhabitants.

CEDAR CREEK, a hundred of Sufh county, in Delaware, having 3,874 inhabitants, of whom 310 are slaves.

CELEMINA, a corn measurer in Spain. See Caffise.

CELESTINE Sulphate of Strontian. See Strontian.

CELIUS, Andrew, in Biography, an eminent Swedish astronomer, was born at Upal in 1701, and distinguished by his knowledge of mathematics, and more especially of astronomy, to which his attention was principally devoted. In 1730 he was appointed by the king professor of astronomy, and he contributed very much to the revival of the study of this science in his native country, where it had been much neglected. With this view, he travelled into foreign countries, visiting Germany in 1732, and Italy in 1733. From Bologna he went to Rome; and having an opportunity of measuring the power of light, he concluded from his experiments on this subject, that the light of the moon, at new moon, is eight times weaker than at full moon; and that the light of the sun is 320,000 times stronger than that of the moon; and when in the meridian, thirty times more powerful than in the horizon. From Rome he removed to Paris in 1734, and was there engaged to accompany Maupertuis and other eminent astronomers, who were appointed to measure a degree under the polar circle; a problem of great importance in determining the figure of the earth. To the success of this mission he very much contributed by his journey to London in 1736, in order to procure instruments of Graham's construc-

C Eph. Calyx in five segments, coloured. Petals none. Stamens in the rim of the calyx. Anthers glan-
dular at the back. German single-seeded. Styles vertical. New Holland Pitcher-plant. Labill. as above, 7. 1. 145. Br. 1. 4.—In marshy ground, near King George's sound and Prince of Wales Royal harbour, on the south-west coast of New Holland, flowering in December and January. Herb perennial, with scarcely any stem. Leaves at the top of each division of the crown of the root, numerous, crowded, fleshy, elliptic-lanceolate, acute, entire, smooth, or slightly hairy, an inch and a half long, intermixed with numerous, fleshy, deflexed, inflated, pitcherlike leaves, larger than the leaves; double-winged, and fringed, at the front and sides; tumid and creane at the margin; more or less closed by a convex ribbed lid. Each is half full of a sweetish watery fluid, in which ants are generally found drowned, as in Nepenthes (see that article); but these remarkable plants have no other character in common. Flower-flanks central, solitary, nearly round, hairy, leafless, twelve or eighteen inches high, each terminating in a denue, compound, obtuse calyx, of small white flowers. The fruit is unknown.

CEPHALUS, a genus of the cartilaginous order of fishes, the species of which have been united with those of the genera Diodon and Tetrodon; which see. Dr. Shaw has given the following character of this genus: jaws bony; body terminating abruptly, so as to resemble the head of a fish. The species enumerated by Shaw are, \( C. \) brevis, or tetrodon mola of Linnaeus; \( C. \) oblongus, or Tetrodon trunculus, an oblong diadon of Pennant; \( C. \) varius, with body variegated by white undulations and spots; \( C. \) Papilus, the diadon mola of Gmel. Linnaeus.

CERASI, in Chemistry, a name given by Dr. John to a peculiar vegetable substance, which has always been hitherto considered as a variety of gum. Its properties are the following.

It is a solid substance, having the general appearance and taste of gum; though it is usually harder than gum, and not so easily reduced to powder. When put into cold water it imbibes that liquid and swells up very considerably, and becomes semi-transparent and gelatinous, but is not in the liquid soluble, a property by which it is distinguished from gum. It dissolves in boiling water, but again precipitates as the liquid cools, and remains in the state of jelly. This gelatinous mass may be used like gum to paste together pieces of paper, &c. It is insoluble in alcohol and ether; but cold water, acidulated with either of the mineral acids, dissolves a small portion of it, and if heated, the whole. When an alkaline solution is dropped into the nitric solution of ceratin, a portion only of the ceratin is precipitated. If the liquid be evaporated, the remainder is obtained converted into a peculiar bitter-tasted substance.

Tragacanth gum may be considered as an example of pure ceratin. (See TRAGACANTHS.) Ceratin also constitutes a portion of the gummy matter that exudes from the prunus cerasus, (hence the name,) prunus avium, prunus domestica, xanthera halibii, &c.

Female, Calyx none. Corolla none. Stigma in many unequal segments. Berry with two seeds.

1. C. erinoides. Heath-like Ceratiola. Wild. n. 1. Pursh n. 1.—Native of Georgia and Florida, in dry gravelly soil, plentiful on the islands in the mouth of St. Mary's river. Pursh. A small shrub, determinately branched, resembling a heath; young branches finely woody. Leaves four in a whorl, fleshy, deflexed, rigid, smooth, about half an inch long. Flowers from small lateral buds, with concaev, fringed scales. Anthers large, of two cells, bursting lengthwise. Segments of the stigma often combined into two little horn-like bodies. Berry globular, red, half the size of a pea. Perhaps this might be considered as an EMPETRUM, or calyx and corolla; see that article. It forms however a better artificial genus than many daily published. We have specimens from Mr. Frazer.

CERIUM, in Chemistry, the name of a metal. This metal, or rather its oxides, is extracted from a Swedish mineral formerly confounded with tungsten, and was first obtained separately by Klaproth, who considered it as a new earth, to which
which he gave the name of ochroite. (See Ochroite.)

About the same time this mineral was examined with more attention by Hifinger and Berzelius, who gave it the name of cerit, and detected in it a peculiar substance, which they considered as a metallic oxyd, to which they gave the name of Cerium, from the planet Ceres, then lately discovered by Piazzi. They did not succeed in reducing this oxyd; nor was Gahn, who made the experiment some time afterwards, more successful. Vaquelin, however, who had formerly examined the mineral, turned his attention to the subject a second time, and he succeeded in reducing it so far as to show that its basis is a metal.

In 1814 a new set of experiments was made upon it by Laugier. He appears to have reduced it to the metallic state, but combined with carbon. Oxalic acid, according to Laugier, separates the whole of the oxyd of cerium from iron. The affinity of this chemist, however, that its oxyd is not volatile, has been denied by Dr. Thomson.

To procure the oxyd of cerium in a state of purity, the Swedish chemists employed the following method. The mineral was reduced to a fine powder, and digested in nitric acid till every thing soluble was taken up. The solution was then evaporated to dryness, and the residue dissolved in water. Into this solution ammonia was poured, till every thing precipitable by its means was thrown down. The precipitate being well washed, was redissolved in nitric acid, the acid neutralized, and then tartarate of potash added to the solution. The precipitate thus formed was then heated to redness, well washed with vinegar, and dried, and was considered as pure oxyd of cerium.

The oxyd of cerium, when first prepared, is white; but when it has been heated it becomes reddish-brown. Formed into a paste with oil, and heated in a charcoal crucible, it loses weight: when urged by a strong fire on charcoal, it does not melt but continues in powder. It exhibits, however, brilliant particles, which were proved to be of a metallic nature.

According to Vaquelin and Hifinger, cerium combines with two proportions of oxygen. The protoxyd is white: the peroxoxyd reddish-brown. The peroxoxyd contains \( \frac{11}{8} \) times as much oxygen as the protoxyd. The protoxyd, according to Hifinger, is composed of

\[
\begin{align*}
\text{Cerium} & : 100 \\
\text{Oxygen} & : 17.41
\end{align*}
\]

The peroxoxyd of Cerium is

\[
\begin{align*}
\text{Cerium} & : 100 \\
\text{Oxygen} & : 26.115
\end{align*}
\]

From Hifinger's experiments, it appears that the equivalent number for the protoxyd of cerium is 67.5, and of the metal 57.5. But if with Dr. Thomson we suppose the peroxoxyd to be a compound of two atoms of cerium and three of oxygen, the weight of the atom of peroxoxyd will be 145.

No compound of this metal with hydrogen, azote, chlorine, nor fluorine is known. The carburet formed by Laugier was a black matter, which took fire spontaneously when exposed to the air. The phosphuret, which appears to have been formed in one instance by Hifinger and Berzelius, was a hard, brown, tenacious substance, which flamed in the dark, and took fire when heated.

Hydrophosphate of ammonia throws down cerium at first of a brown colour, but it becomes deep green if the re-agent be added in larger quantity. When dry, the hydrophosphate formed is a bright green, and burns when heated, leaving a yellow oxyd of cerium. The colour of the precipitate varies, however, according to the state of oxidation of the cerium held in solution.

No alloy of cerium is known, except one with iron, obtained by Vaquelin; this was white, brittle, and dissolved with great difficulty in nitro-muriatic acid.

Salts of Cerium. Nitrate of Cerium.—Nitric acid unites with both the oxyds of cerium; with the white oxyd it combines most readily. The solution is colourless, crystallizes with difficulty, retains an excess of acid, and has a sweet astringent taste. The red oxyd dissolves with difficulty in cold nitric acid, but the solution may be readily effected by heat. The solution is yellow, and if an excess of acid be present, it yields small white deliquescient crystals. Both the nitrates are soluble in alcohol, and are decomposed by heat.

Muriate of Cerium.—This salt exists in the form of small four-sided prismatic crystals of a yellowish-white colour. They are soluble in alcohol, and deliquesc on exposure to the air. When exposed to heat they are decomposed.

Sulphate of Cerium.—Sulphuric acid dissolves the red oxyd of cerium with difficulty. The solution when obtained is of an orange-colour, and yields by evaporation small octahedral and needle-formed crystals of perphosphate of cerium. Their colour is partly lemon-colour and partly orange. This salt is not soluble in water without excess of acid. When exposed to the air, the crystals soon assume the form of a yellow powder. Sulphuric acid combines readily with the white oxyd of cerium, especially when in the state of carbonate. The solution is colourless, and readily crystallizes. There is a triple sulphate of potash and cerium.

Phosphatc of Cerium.—This is a white powder insoluble in water, but soluble in the nitric and muriatic acids.

Arsenite of Cerium.—This salt is insoluble. There is a soluble superarseniate which does not crystallize.

Boratic of Cerium.—This salt exists in the form of small granulated crystals, readily soluble in water, but sparingly soluble in alcohol, and not altered by exposure to the air.

Oxalate of Cerium.—Oxalic acid and oxalate of ammonia precipitate cerium from its solution. The precipitate with the peroxoxyd is red, with the protoxyd white. It is not soluble in excess of acid, but readily in ammonia.

Tartrate of Cerium.—The tartrate of potash throws down cerium from its solutions in the form of a white insoluble tartrate. This tartrate, however, is soluble in nitric, muriatic, and sulphuric acids, and also in pure alkalies.

Citrate of Cerium.—The citrate of cerium is insoluble, with an excess of acid, when it is readily soluble. The solution does not crystallize. The other salts of this metal are unknown, or devoid of interest. With respect to these salts in general, it may be observed, that they are either of a white or yellow colour, according to the state of oxidation of the metal, and their solutions have a sweetish taste. The hydrophosphate of potash, prussiate of potash, and oxalate of ammonia, produce in them white precipitates; while the gallic acid and infusion of galls occasion no precipitate, when added to solutions of their salts.

Cerium. See MINERALOGY, Addenda.

CERN, or CERNE-ABEAN, l. 36, add.—In 1811 the parish contained 145 houses, and 795 persons; viz. 358 males, and 427 females.

CERUMEN, or Ear-Wax, Chemical Properties of. This substance is nearly insoluble in water. Alcohol, when diluted by heat, diffuses five-eighths of the cerumen; the remainder is fixed by Vaquelin to polish the properties of albumen mixed with a little oily matter; when the alcohol solution is evaporated, it leaves a deep orange-residuum of a very bitter taste, having the smell and consistence of turpentine. It melts when heated, evaporates in a white smoke, without leaving any residuum, and in short resembles the resin of larch.
but Albumen, An infilipated oil, A colouring matter, Soda and phophate of lime.

CESAR'S CREEK, a township of Greene county, in Ohio, having 640 inhabitants.

CETIC ACID, in Chemistry. A name given by Chevreul to a substance obtained by fayingonifying fpermaceti. It may be procured by adding an acid to a fopm compofed of fpermaceti and pothaf. Cetic acid is a folid fubftance, without tafle or finell. It melts at a temperature of about 113°, but does not cryftallize on cooling, a circumfance in which it differs from fpermaceti. It is infoluble in water, but boiling alcohol difolves more than its weight of it, and as the folution cools, the cetic acid feparates in brilliant lamellar cryftals. The folution in alcohol reddens litmus. It combines readily with the different faltifiable bases, and forms falt or rather foaps, none of which appear to poifeus any fhrinking properties.

CETRARIA, in Botany, Achar. Syn. 226, a natural, but not very cafeily defined genus of Lichenus, comprising eleven species, among which are L. juniperinus, glaucus, niveus, and islandicus of Linneus. See Lichenus, n. 19 in the arrangement of Ashurius.

CEYLONITE, or PLENEASTE. See Mineralogy, Addenda.

CHACE, col. 2, l. 32, for vizier r. veneur.

This genus is diftinguifhcd from Lepotecarpus (fee that article) by the undivided ftyle, and the minute fetaeous form of the inner fcales of the very short calyx. The only species is

1. C. leoptocarpoides, found by Mr. Brown, on the fouth coast of New Holland.

CHÄTODON, col. 2, l. ult. for Japan r. Java. Add—See Tethus.

CHÄTODON Arconnus. Add—Perhaps from the Aroo iflands among the Moluccas.

CHÄTÖSPORA, in Botany, from χατος, a brifle, and σπορα, a feed.—Brown Prodr. Nov. Holl. v. 1. 232.—This genus is founded by Mr. Brown, on thofe species of the Schoenus of Linneus, and other authors (fee that article), whose seed is fubfended by brifles, which are not fo long as the fcales of the fower. Fifteen species are natives of various parts of New Holland, one of which, C. lanata, Br. n. 48, is Schoenus lanatus, Labill. Nov. Holl. v. 1. 19. t. 20. The reel appear to have been firft defcribed by Mr. Brown. Schoenus cœpmuffus and rufus of Fl. Brit. belong to Chato-

spora. See Rhytchospora for a genus fimilarly charactefized.

CHAIN, col. 2, l. 4 from bottom, r. Plate XII.

CHALK, FRENCH, r. See Slate.

Female, Calyx deeply three-cleft. Petals three. Neafer

Vol. XXXIX.

three fcales, between the petals and gernein. Styles three.

Drupa fucculent, with one seed.

1. Ch. gracilis. Slender Chamedorea. Willd. n. 1. Ait. n. 1. (Borassus pinnatifrons ; Jacq. Hort. Schoenbr. v. 2. 65. t. 247, 248.)—Native of the Caraccs and of Guiana. An elegant palm, whose trunk is ten feet high, an inch in diameter, very smooth, crowned with alternate pinate leaves, two feet long, and fending out from near the bottom ferveral long, fder, aggregate fikes, of numerous fmall yellow flowers; the male ones longeft, and pendulous. Fruit leare-

let, the fize of a pea.

Eff. Ch. Calyx of two valves, two-foated; the outer valve very fmall. Corolla of two valves. Outer fcor male, its outer valve like the inner valve of the calyx; inner female, smaller, membranous. Scales two beneath the gernein. Stigma fheath. Seed inclofed in the hardenod corolla.

1. Ch. hordaceae. Br. n. 1.—Gathered by Mr. Brown, in the tropical region of New Holland.—A perennial fgraf, with two-ranked, linear, ftraight leaves; their fylipula rounded. Spike foltary, refeembling Hordeum, with imbricated flowers, in two ranks, parallel to the zigzag common-flack, on fhort partial flacks, each of which bears, from its infide, near the top, a very long aven. It is closely allied to PAnicum (fee that article), differing chiefly in having three fylipules, which indeed is extremely peculiar.

CHAMBER, in Architecture, l. 5 from the end, r. ought not to be, &c.

CHANCEFD. Add.—It contains 996 inhabitants.

CHANCEFORD, L. 3. —Lowcr, a township of the fame county and flate, having 818 inhabitants.

CHARLEMONT, a township of America, l. 3, r. 987.

CHARLES COUNTY, l. 4 and 5, r. 20,245, including 12,435 faves.

CHARLES CITY, l. 4, r. 5186, and 3023.

CHARLES, S. L. Add.—Allo, a parih of the German coast county, in the territory of Orleans, containing 3291 inhabitants, of whom 2321 are faves.—Allo, a district in Louifiana, containing 3505 inhabitants, including 271 faves.

CHARLESTON (2d article), l. 5, r. 38,468, and 35,714.

CHARLESTON (3d article), infert in l. 1.—city; l. 11.

r. 1810, 24, 711, and 11, 671.

CHARLESTOWN, l. 3. —The population is 5283; the fenatorial electors 669, by the cenfus of 1810. Here are two Presbyterian or Dutch reformed churches, one for Baptifs, one for Methodifs, and 30 school-houfes; l. 7.—The number of inhabitants in 1810 was 28, including one slave; l. 8.—The number of inhabitants is 1530; l. 14.—The population in 1810 was 1501; l. 27, for 1800 r. 4959; l. 41, for 2022 r. 17,47, including one slave.—Allo, a township of Indiana, in Clark county, having 11 inhabitants.

CHARLETON, col. 2, l. 8, by the cenfus of 1810, the number of inhabitants was 1945, and of fenatorial electors 227; l. 12, for 1805 r. 2180.

CHARLOTTE, l. 5, for 635 r. 1679.

CHARLOTTLE, a county of Virginia, l. 3, for 10,078 r. 13,161, and for 4916 r. 7557.

CHARLTON. Add.—Allo, a town of Worcester county, in Maffachufetts, having 2180 inhabitants.

CHARTIER. Add.—It contains 747 inhabitants.

3 H. CHARTRES,
CHARTRES, l. 11, r. 48° 26' 54". E. long. 1° 29' 35".

CHEESE, Chemical Properties of. See MILK.
CHEESE-Paste, col. 2, l. 22, infer.—Agiculture, Plate, &c.
CHEILANTHES, in Botany, a genus of ferns, first distinguished from Adiantum, (see that article in the present volume,) by professor Swartz, and named from hydrogen, margin, and a, a flower, because the fructification is really inserted into the margin of the frond, not into the scales which conceal it. Such indeed was the idea hitherto conceived of Adiantum; but this was not the case with the original and best-known species, Capillus Veneris, the generic appellation was properly allowed to remain with that and its allies, under a corrected character.—Swartz Syn. Fil. 126, l. 3. Willd. Sp. Pl. v. 5. 455. Brown Prod. Nov. Holf. v. 1. 155. Ait. Hort. Kew. v. 5. 526. Sm. Prodr. Fl. Græc. Sibth. v. 2. 278. Pursh 670.—Clads and order, Cryptogamia Filices. Nat. Ord. Filices annulatus.
Dr. Swartz defines sixteen species; professor Willdenow nineteen, the latter dispersing the whole in three sections, though marked as two only, according to an inaccuracy we have often noticed in him. The following are sufficient examples.

Sect. 1. Frond simply pinnate. One species.
Ch. micropteris. Small Cheilanthes. Willd. n. 1. Sw. n. 1. 324. l. 3. f. 5.—Frond pinnate, linear; leaflets hairy, nearly orbicular, with wave-like notches.—Native of Quito. Fronds narrow, a finger’s length, with several, alternate, finely flaked leaflets, about a line in diameter.
Sect. 2. Frond doubly pinnate. Ten species.
Ch. pteroides. Pteris-like Cheilanthes. Willd. n. 2. Sw. n. 12. Ait. t. 1 (Adiantum pteroides). Linn. Mant. 130. Pteris orbiculata; “Houtt. Nat. Hist. t. 96. f. 3.”—Frond doubly pinnate; lower branches somewhat compound; leaflets ovate-elliptical, obtuse, rather heart-shaped, finely crenate. Dots crowded. Coverings imbricated. Common stalk polished.—Native of the Cape of Good Hope. A handsome fern, a foot or more in height, with stout, dark, shining fronds, and firm dark-green leaflets, half an inch long; paler beneath. This and the following might have been referred to the next section.
Ch. fragrans. Sweet-scented Cheilanthes. Willd. n. 7. Sw. n. 4. 325. t. 3. f. 6. Ait. n. 2.—Frond doubly pinnate, smooth; leaflets elliptic-lanceolate, obtuse, pinnatifid, with incurved, partly cleft segments. Common-flask somewhat hairy.—Native of the East Indies, from whence König sent specimes, which remain unnamed in the Linnaean herbarium. The Madeira plant, gathered by the same botanist, is, as Dr. Swartz inspected, a different species, being the Polypodium fragrans of Linnaeus, our Ch. fragrans, which is probably also Mr. Atton’s Ch. fragrans. The East Indian fern before us is excellently distinguished by professor Swartz, and has a more oblong frond, with curiously pinnatifid leaflets, nor can those who have seen both species ever confound them. We are unacquainted with Ch. odoras, Willd. n. 6.
Sect. 3. Frond triply or quadruply pinnate. Eight species.
Ch. dichotoma. Forked Cheilanthes. Willd. n. 15. Sw. n. 15. 335. l. 3. f. 7.—Frond three or four times pinnate, smooth; leaflets three-lobed, obtuse, somewhat crenate.—Native of mountains in Quito. A span high, slender and delicate, with alternate, tiny, almost capillary branches, and minute round-lobed leaflets.
Ch. tenuifolia. Fine-leaved Cheilanthes. Willd. n. 16. Sw. n. 15. 332. “Schkuhr Crypt. t. 125.” Br. n. 1. (Trichomanes tenuifolia; Burn. Ind. 237. Dryopteris campesiris; Rumph. Arb. v. 6. 74. l. 34. f. 2.)—Frond triply pinnate, smooth; leaflets obtuse-oblong, slightly crenate, upper ones confluent.—Native of the East Indies. This has the habit of fragrans and its allies, but is much larger.
Ch. dealbata. White-leaved Cheilanthes. Pursh n. 2.—“Frond triply pinnate; leaflets oval, distinct, crenate or emarginate at the end; white beneath.”—On rocks, on the banks of the Millfouri, in July. A very delicate small fern, much resembling Ch. tenuifolia. Pursh.
CHEKIE, or CHEQUEE, a Turkish weight: that with which gold, silver, diamonds, and precious stones are weighed, is divided into 1000 drachmas, and the drachma into 16 kilots or carats, or 64 grains. A cheque weighs 10 oz. 5 dwt. 3 grs. troy weight; and a drachma 403 grs. ditto; so that 48 cheques = 4 lbs. troy nearly. The okle = 4 cheques, or 400 drachmas; and the cheque = 11 oz. avoidopus. The cheque of goats’ hair is called Th. Turkische drachs, or 5 lbs. 10 oz. avoidopus; the cheque of opium 250 Turkish drachs = 27 oz. 10 drs. avoidopus.
CHELMSFORD, col. 2, l. 12 from the bottom, r. 4549 and 822.
CHELMSFORD, in America, l. 4, r. 1396.
CHELSEA, in America, l. 3, r. 504; l. 8, r. 1327.
CHELTENHAM, col. 2, l. 19 from the bottom, r. 8353; l. 12, r. 1568.
CHELTENHAM, a township of Montgomery county, in Pennsylvania, having 783 inhabitants.
CHEMIN CREUX, r. RAVINE.
CHENANGO, a county of New York, containing, by the census of 1810, 21,704 inhabitants, of whom 13 are slaves.
CHEPSTOW, col. 4, l. 48, for wall r. walk. Add—The parish of Chepflow contained, in 1811, 421 houfes, and 2581 persons; 1558 being males, and 1023 females. CHERAY, or CHURAY, a weight in Perú; the basin of Churay being double the basin of Taurus, and weighing 12 lbs. 4 oz. 13 drs. avoidopus.
CHERBOURG, l. ult. r. N. lat. 49° 38' 31". W. long. 1° 57' 18".
CHERRYFIELD, in Geography, a town of Washington county, in the district of Maine, with 181 inhabitants.
CHERRY.
CHELLIAN.

CHERRY-TREE, a township of Venango county, in Pennsylvania, having 391 inhabitants.

CHESHAM. The parish of Chesham, in 1811, contained 252 houses, and 2071 persons; 924 being males, and 1147 females.

CHESHIRE, col. 2, l. 4 from the bottom, r. 41,187 and 227,031.

CHESHIRE. By the returns of 1811, Aughton-upon-Mersey in this county, and in a parish of the same name (omitted in its alphabetical arrangement), appears to have then contained 156 houses, and 918 persons; 467 being males, and 451 females.

CHISHER, in America, dele L 5 and 6, and add—and 40,088 inhabitants.

CHISHER, a township, &c. l. 3, add— containing 1315 inhabitants. At the close, add—It contains 2288 inhabitants.

CHESNUT HILL. Add— containing 1128 inhabitants.

CHEST, in Anatomy, l. 2, infr. Lungs.

CHEST of Voids, dele Six-STRINGED Base.

CHESTER, col. 6, l. 17. In 1811, the city of Chester contained 3292 houses, and 16,140 persons; 7007 being males, and 9133 females: 397 families employed in agriculture, and 2296 in trade and manufactures.

CHESTER, in Nova Scotia, l. 8, r. 1534; l. 13, r. 2030; l. 17, r. 2370; l. 30, after affluents, add— It contains 1596 persons; l. 32, r. 40; l. 33, r. 39,956; l. 34, r. 71 l. 57, r. 11,497; l. 58, r. 2743. At the close, add—Allo, a town of Clinton county, in Ohio, having 1254 persons.

CHESTER, West, a county of New York, containing 30,272 inhabitants, of whom 982 are slaves.

CHESTERFIELD, col. 2, l. 4. In 1811 the parish of Chesterfield contained 951 houses, and 4476 persons; 2025 being males, and 2451 females.

CHESTERFIELD, l. 3, r. 1 408; l. 7, r. 1839; l. 15—It contains 5563 inhabitants, of whom 1639 are slaves; l. 17, r. 9979, and 6015. Add—Allo, a town of Burlington county, in New Jersey, having 1839 inhabitants.

CHESTER-LE-STREET. In 1811, the township of Chester-le-Street contained 245 houses, and 1726 persons; 800 being males, and 926 females.

CHESTERVILLE, a town of the district of Maine, in the county of Kennebec, with 430 inhabitants.

CHEWTWERT, and CHETWICK, two corn meafures in Ruffa; the former or cool being 4 ofminns = 4 paajacks = 8 chewtwicks = 64 garnitty. The latter meafures 1555.92 cubic inches, and contains 35% Winchellier gallons nearly. In bufines the ufual calculation is, that 100 chewtwerts produce 72 quarters, and 1 chetwert 53 buhfeis, Winchetler melon.

CHIESTOLITE. See Mineralogy, Addenda.

CHICHETER, in Geography. In 1811, the city of Chichester contained 1083 houses, and 6425 persons; 2878 being males, and 3547 females.

CHICHESTER, Upper and Lower. Add—The former contains 437, and the latter 511 inhabitants.

CHICHESTER, l. 4, r. 951.

CHILISQUAW. Add—Northumberland county, having 1505 inhabitants.

CHILLIKOTHE. Add—By the census of 1810, it contained 1360 inhabitants.

CHILMARK, l. 3, r. 723.

CHILODIA, in Botany, perhaps from χίλος, in allusion to its longer and more conicous lip.—Brown Prodr.

CHILLINGHAM, 1. 30.—In 1811, the township of Chillingham contained 668 houses, and 3410 persons; viz. 1580 being males, and 1830 females; 145 families employed in agriculture, and 652 in trade and manufactures.

CHITTENDEN, l. 6, r. 1810; l. 24, r. 1820. At the close, add—It contains 445 inhabitants.

Eff. Ch. Calyx bell-shaped, equally five-cleft. Corolla tubular, ringent; throat dilated; upper lip cloven; lower in three deep segments, the middle one longest. Stamens prominent. Stigma cloven, acute. Drupa dry. Nuts two, each of three cells; two lateral cells fingle-fed; middle one abortive, obliterated.

Downy shrubs, with opposite, simple, decurrent, linear, bluish leaves. Stems axillary, solitary, single-flowered, each

Brown.

1. Ch. florebradis. Br. n. 1.—Back of the leaves, and outside of the calyx, snow-white, downy. Bracteas in the middle of the flower-flasks.—Native of Port Jackson, New South Wales.

2. Ch. glandulosa. Br. n. 2.—Back of the leaves glan-
dular, and clothed, like the outside of the calyx, with lacer-
ted hairs. Bracteas at the base of the flower-flasks.

—From the same country.

CHLORATES, in Chemistry. See Chlorine.

CHLORIC Acid. See Chlorine.

CHLORINE. This name was given by Sir H. Davy to the principle formerly termed OXYMURIATIC Acid, under which head its leading properties are detailed. We have therefore to notice here some important compounds of this principle lately discovered, especially those with oxygen.

The protoxyd of chlorine, or euchlorin, has been already described under the article above alluded to. For its correct composition, see Table II. Atomic Theory.

The deutoxyd of chlorine was discovered about the same time by Sir H. Davy and the count Von Stadion of Vienna, but Davy's account of it was first published. It may be prepared by mixing together a small quantity of chlorate of potash (not more than fifty grains) in powder, with sul-
phuric acid, till the whole forms a dry paste of an orange colour. Put this paste into a small glass retort, and plunge the belly of the retort into hot water, and keep it in that position for some time, taking care that the temperature of the water never becomes so high as 212°. A bright yellow-

CHLORINE

green gas separates from the paste, which must be received in small glass jars over mercury. This gas is the deutoxyd of chlorine. Its colour, as above stated, is a bright yellowish-green. Its smell is peculiar and aromatic, without any mixture of the smell of chlorine. Water absorbs at least seven times its bulk of this gas. The solution is deep yellow, and has an astrigent and corrosive taste, leaving a disagreeable and laking impression on the tongue. It destroys without previously reddening vegetable colours, provided they are moist. It does not act upon mercury, nor any other combustible substance tried, except phosphorus, which, when introduced into the gas, occasions an explosion, and burns with great splendour. When heated to 212° it explodes with more violence than euchlorin, and emits a great light. Two volumes of deutoxyd of chlorine, when thus exploded, are converted into three volumes, according to Davy, which conflit of two volumes or four atoms of oxygen and one of chlorine, or per cent. of

</table>

And its fp. gr. will be 2.761, that of chlorine being sup-
poised to be 2.5. Accordingly, however, to the count Von Stadion's analyses, this deutoxyd is composed of one atom chlorine, and only three of oxygen.

CHLORIC Acid.—The existence of this compound of chlorine with oxygen was suspected by Berthollet, but it was first obtained by M. Gay-Lussac. It is the acid which exilts in what was formerly termed oxymuriate, but now chlorate of potash. It was procured by dissolving the chlorate of barytes in water, and cautiously adding dilute sulphuric

acid to the solution, till the whole of the barytes was sep-
tated. The chloric acid remained in solution. This acid has a strong four taste, but no sensible smell. Its aqueous solution is colourless, and reddens vegetable blues without defraying them. By a gentle heat it may be concentrated without being decomposed, or volatilized with the water. When thus concentrated, it has an oily consistency. When the heat is raised, it is partly volatilized, and partly decom-
poized into chlorine and oxygen. Muriatic acid decomposes it similarly without heat; the nitric acid does not affect it. It combines with the different bases forming chlorates, for-
merly termed oxymuriates, the most important of which will be presently described. Chloric acid has been proved to be composed of

Or of one atom chlorine and five of oxygen. See Atomic Theory, Table II.

CHLORATE of Potash.—This is the best known and most important of the chlorates. See it briefly described under Hyperoxymuriatic Acid.

CHLORATE of Soda.—This salt was first accurately described by Chenevix. It may be prepared by the same process as the chlorate of potash; but the easiest mode of obtaining it is, to diffuse carbonate of soda in chlorine acid. It does not readily crystallize, but its crystals when formed are square plates. Its taste is sharp and cooling. On burning coals it melts into globules, and emits a yellow light. When dif-
tilled it gives out oxygen, mixed with a little chlorine, and the salt left behind has alkaline properties.

CHLORATE of Ammonia.—This salt may be formed by dif-
folving carbonate of ammonia in chlorine acid, or by mixing a solution of carbonate of ammonia with a solution of an earthly chlorate. It crystallizes in fine needles, and is very solu-
ble in water and alcohol. Its taste is sharp. Placed upon burning coals, it fumilates with a red flame. When strongly heated, it is decomposed, chlorine is evolved mixed with azote and oxygen, and some muriate of ammonia remains behind.

CHLORATE of Barytes.—The earthly chlorates are formed with more difficulty than the alkaline. The chlorate of barytes may be formed by pouring warm water on a quant-
tity of the pure earth prepared by Vauquelin's method, and
calling a current of chlorine through the mixture. To separate the chlorate from the muriate, which are both equally soluble, and otherwise resemble each other, Mr. Chenevix had recourse to the ingenious expedient of boil-
ing phosphofate of silver with the compound solution; thus muriate of silver and phosphofate of barytes are formed and easily separated, while nothing but the chlorate of barytes remains in the solution, and may be easily obtained. This salt crystallizes in square prisms, terminated by an oblique face. It diffuses in about four times its weight of cold water. The solution is either precipitated by nitrate of silver nor muriatic acid. It is insoluble in alcohol. When heated it gives out oxygen gas, and an alkaline residuum is left.

CHLORATE of Strontian.—This salt was formed by a proces-
similar to the above, and resembles it in many of its properties, but is deliquecent, and rather more soluble.

CHLORATE of Lime, and Chlorate of Magnesia, may be formed as above. They are both deliquecent, and very soluble both in water and alcohol.

The metallic Chlorates may be formed by dissolving the oxyds.
CHO

The only known species are *Gh. laterificorum* and *glomeratum*, found on the south coast of New Holland, a bushy shrub, with minute scattered leaves, and small white flowers, being nearly related to *Leptosperma*; fee that article.

1. *Ch. tenellum*. Purple Chorispermum. Ait. n. 1. (Raphanus teocclus; Willd. Sp. Pl. v. 3. 561.) Pallas Voy. v. 3. 741. t. L. 3. J.—Leaves, as well as pods, fimbriate, upper ones lanceolate, toothed; lowermost pinnatifid.—Native of defarts near the Cape flan. A little annual herb, with small purple flowers. Mr. Brown's specific character indicates the existence of another species, not known to us.

**CHORIZANDRA**, from χορίς, to separate, and and, a male, because the flaments are individually separated by scales.—Brown Prodr. Nov. Holl. v. 1. 220.—A genus consisting of two species, natives of Port Jackson, nearly akin to *Chorizachene* of the same author, and to the Linnian *Corymbia*; see thefe articles. From the latter it differs in inflorescence and habit. How far they could with propriety be united, we have not materials to form a decisive opinion.

**CHORIZEMA**, a name of which there have been various explanations, (see Tr. of Linn. Soc. v. 9. 252,) is most probably derived from χορίς, to separate; but certainly not in allusion, as De Thie's lappules, to any division of the fruit. We rather believe the author of this name had in contemplation the separate filaments, of which two few invadences were known in papilionaceous flowers, at the time he wrote, and *Papilionaceae* may allude to their durative figure.—Labill. Voy. Eng. ed. v. 1. 435. Nov. Holl. v. 2. 120. Sm. in Sims and Kun. Anm. of Bot. v. 1. 526. Tr. of Linn. Soc. v. 9. 251. Ait. Hort. Kew. v. 3. 8. (Podolobium; ibi. 6.)—Clasf and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceae*. Linn. *Leguminosae*, Juss.

Eff. Ch. Calyx five-cleft, two-lipped, Corolla papilionaceous. Style curved, Stigma obtuse. Legume oblong, tumid, of one cell, with many seeds.

1. *Ch. ilicifolia*. Holly-leaved Chorizema. Labill. as above, t. 21. Sm. n. 1. Ait. n. 1.—Leaves alternate, oblong, pinnatifid, with spinous teeth: point entire, longer than the teeth. Bracteas close to the flower.—Found by M. Labillardière, at the foot of the mountains, on the south coast of New Holland, flowering in December. Sent to Kew in 1823, by Mr. Good. Stem shrubby, hardly a foot high, branching from the root. Leaves alternate, fefile, fimbriate, coriaceous, with sharp spines. Flowers in terminal clusters.

2. *Ch. nana*. Dwarf Chorizema. Sims in Curt. Mag. t. 1032. Ait. n. 2. (Pultenaea nana; Andr. Repol. t. 434.)—Leaves alternate, elliptic-oblong, bluntnoth, incised, with spinous teeth. Bracteas rather distant from the flower.—From the same country. We profit by Mr. Brown's remarks for differentiating this species, hitherto confounded by us with the foregoing. Its stature is more humble. Flowers in lateral clusters, orange, with purple veines, and a short, white, purple-tipped keel. We know not distinctly the colour of *ilicifolia*.

3. *Ch. rhomboeae*. Few-flowered Chorizema. Br. in Ait. n. 3.—"Leaves entire, flat, pointed; lower ones orbicular, somewhat

CHO
somewhat rhomboid; upper elliptic-lanceolate. Stalks with few flowers.—Native of the same country. Mr. Brown.

4. Ch. triloba. Three-lobed Chorizema. Sm. n. 2. (Podolobium trilobum; Alt. Hort. Kew. v. 3. 9. Curt. Mag. t. 1477. Pulten. ilicifolia; Andr. Repub. t. 320.)—Leaves opposite, somewhat hastate; entire or toothed, spinous. Clusters axillary, shorter than the leaf. Gernon silky.—Found near Port Jackson, New South Wales. (See Podolobium.) Young branches and leaves downy. Flowers copious, yellow, with a red radiating spot, and red keel, the latter nearly as long as the wings.

5. Ch. frondes. Climbing Chorizema. Sm. n. 3.—Leaves nearly opposite, elliptical, undivided. Clusters terminal, elongated. Calyx rather hairy. —Found by Dr. White, at Port Jackson. Stem twining. Flowers in loose pendulous clusters, yellow variegated with red.

6. Ch. fruticose. Silky-leaved Chorizema. Sm. n. 4.—Leaves mostly alternate, elliptical. Clusters axillary, the length of the leaves. Calyx silky. Standard narrow.—Gathered by Mr. Menzies, at King George's found. Stem twining. Leaves more silky at the back than in P. flaccidus; flowers three as large as in that species.

7. Ch. coriacea. Leathery-leaved Chorizema. Sm. n. 5.—Leaves roundish-elliptical, abrupt, coriaceous, scattered. Umbels axillary, injected. Calyx hairy.—From the same country. A stout, upright, rigid shrub. Leaves beautifully veiny; filly beneath. Umbel on silky stalks, much shorter than the leaves.

CHOUT, denotes in India a fourth part; and the Mahratta chout is a fourth of the revenues, exacted as a tribute by the Maharratta.

CHOWAN, l. 3, r. 5297 and 2789.

CHRISTCHURCH. In 1811 the borough and street contained 303 houses, and 1553 persons: 682 being males, and 871 females.

CHRISTIAN, a county of Kentucky, containing 10,889 inhabitants, of whom 1708 are slaves.

CHRISTIAN d'Or, a Danish gold coin, current in Holstein since 1775, worth about 13 marks lubs, or 26 marks Danish currency.

CHRISTIANA. Add—By the census of 1810, it contained 6698 inhabitants, 47 being slaves.

CHRISTINA, Santa, for Christiana. r. CHRISTIANA.

CHRISTOPHER's St., col. 2, l. 13 from bottom, r. W. long. 62° 43′.

CHROMATE of Iron. See Mineralogy, Addenda.

CHROME, or Chromium, in Chemistry, the name of a metal. (See Chrome.) Since that article was written, however, some facts have been ascertained respecting this metal and its compounds, which deserve to be briefly mentioned here.

Chrome seems capable of combining with three different proportions of oxygen, and of forming three oxyds, the green, the brown, and the yellow or chromic acid. The green oxyd may be formed by expending chromic acid to heat in close vessels, by which means a portion of the oxygen is expelled. It may be also formed in other modes, as by precipitation; in which case it has a dark green colour, and contains water. In this state it readily dissolves in acids, but if exposed to a heat a little below redness, it becomes ignited, diminishes in bulk, and its colour changes to a lighter green. It is now no longer soluble in acids, though it has lost no weight. The brown oxyd may be formed by dissolving the above green oxyd in nitric acid, evaporating the solution to dryness, and exposing the dry mafs to heat, till it ceases to give out nitrous fumes. A brown brilliant powder remains, which is soluble in alkalies but not in acids. It is not improbable, that this will be found hereafter to be a substantiate instead of an oxyd. Chromic acid, the third oxyd of chromium, is easily reduced to the state of green or protoxyd, by the action of fulphurcted hydrogen, fulphuric acid, and protoxyds of iron, copper, and tin.

The chromates have been already described. The chromate of lead is the only one much used, which has been lately employed as a painter with great success.

1807.—Battle between the French and Ruffians, in which the latter were defeated, Feb. 7.—Battle of Friedland, in which the Ruffians were defeated with great slaughter, June 14.—St. Thomas, a Danibh island, taken by the English, Dec. 21.

1808.—Battle of Vimeira, in which the whole of the French force, under general Junot, was defeated by Sir Arthur Wellesley, Aug. 21.

1809.—Cayenne taken by the English and Portuugeze, Jan. 15.—Battle of Corunna, in which the French were defeated by the English, Jan. 16.—Battle of Oporto, in which the French were defeated by Sir Arthur Wellesley, May 11.—Battle of Aspern and Esling between the French and Austrians, with dreadful slaughter on both sides, May 21 and 22.—Pope Pius VII. excommunicated Buonaparte, June 10.—At Raab, Austrians defeated by the French, July 5.—Battle of Talavera de la Reya, in which the French were defeated by the English and Spaniards, July 27.—Zante, and the ret of the Seven Islands, surrendered to the British in October.—Buonaparte divorced from the empress Josephine, Dec. 17.—General Jullerj through the kingdom, celebrating the entrance of George III. on the 50th year of his reign.

1810.—Islands of Faroe and Iceland taken under British protection, Feb. 12.—Amboyina feized by the English, Feb. 17.—Buonaparte married to Marie Louisa of Austria, April 1.—Ille of Bourbon surrendered to the British, July 10.—Battle of Buzaco, in which the French were repulsed with great slaughter by the allied army under lord Wellington, Sept. 27.—Mauritis surrendered to the British, Dec. 3.

1811.—Population of London, wellminded, Borough, and neighbouring districts, appeared to be 1,099,104, being an increase, in two years, of 133,139.—Ilnd of Java surrendered to the British, Sept. 18.—Battle of Ciudad Rodrigo, between the French and allied armies, under lord Wellington, which terminated in an orderly retreat of the latter, Sept. 23.—Cavare and Merida, the French, under general Girard, surprised and routed by general Hill, Oct. 28.

1812.—Badajos taken by storm by the British and Portuugeze, April 6.—Spencer Percival, prime minister of Britain, assassinated in the lobby of the house of commons, by John Bellingham, May 11.—Battle of Salamanca, in which the French were defeated with great slaughter by lord Wellington, July 22.—Smolensko, the Ruffians defeated by the French, Aug. 16.—Queen's Town, Canada, the army of the United States defeated by the British, Oct. 12.—Poltok, the French defeated by the Ruffians, and the place taken by storm, Oct. 20.—The French driven from Dorogobudh by the Ruffians, under Platoff, with great slaughter, Nov. 7.—At Witepk, the French, under general Victor, defeated by the Ruffians, under Witgenstein, with the loss of 3000 men, Nov. 14.—Ney's corps, 12,000 of which lay down their arms, defeated by the Ruffian general Milhamdothv, Nov. 17.—At Berezina, the contcd terminated in the capture by Wittgenstein of a French division of 8800 men, Nov. 28.—Near Vilna, a French column was destroyed by Platoff, when a general and 1000 prisoners were taken, Dec. 11.

1813.—Concordat signed between pope Pius VII. and Buonaparte, at Fontainbleau, Jan. 25.—At Bejar, in Spain, the French were defeated by general Hill and the allied Spaniards, Feb. 20.—At Lunenburg, the French were defeated by the united army of Ruffians and Prussians, with the loss of general Morand, 100 officers, and 2200 privates, and two pieces of cannon, April 2.—At Fort George, on the Niagara, the British were defeated by the Americans, May 27.—At Vittoria, the French, under Joseph Buonaparte, were defeated by lord Wellington and the allied Spaniards, June 21.—Pyrenées, Soult was defeated, with immense slaughter, by lord Wellington and the Spaniards, July 28.—St. Sebastian was taken by storm, by general Graham, July 31.—Before Dresden, the allied army of Autfrians, Ruffians, and Prussians, was defeated by the French, Aug. 28.—At Tophitz, the French were defeated by the allied Autfrians, Ruffians, and Prussians, Aug. 30.—At Dennewitz, the French were defeated with great loss by the Crown Prince of Sweden, Sept. 8.—At a Moravian village on the Thames in Canada, the British were defeated by the Americans, Oct. 5.—At Mockero, a desperate conflict occurred between the French and the allied army of Autfrians, Ruffians, and Prussians, the place having been taken and re-taken five times, terminating in a defeat of the French, Oct. 11.—Before Leipjfe, a second general engagement took place, the result of which was, a loss to the French of 10,000 men, in killed, wounded, and prisoners, with 63 pieces of artillery, and the defehtion of 17 German battalions, Oct. 18.

1814.—At Rothiere, the French, under Napoleon, were defeated by the allied Ruffians and Prussians, with the loss of 3000 prisoners, and 26 pieces of cannon, Feb. 21.—Bordeaux entered by lord Wellington, March 12.—At Tarbes, Soult was defeated by lord Wellington, March 20.—Paris entered by the emperor of Ruffia, at the head of his troops, March 31.—Buonaparte renounced, for himself and heirs, the throne of France, and accepted the Ille of Elba for his retreat, April 5.—The states of Parma, Piacenza, and Gueftella, conferred on Maria-Louisa by treaty, April 5.—At Toulouse, the French were defeated by lord Wellington, April 10.—Buonaparte embarked for Elba, April 28.—Treaty of Paris signed by the ministers of the allied sovereigns for the protection of France, May 30.—Pope Pius VII. returned to Rome, and resumed his functions in May.—The emperors of Ruffia, with the king of Prussia, prince Blucher, and other illustrious persons, entered London amidst great rejoicings, June 8.—Inquisition of Spain restored by Ferdinand VII. July 21.—A grand jubilee on celebrating the peace, and the centenary of the accession of the house of Brunswick, Aug. 1.—Tulcan, after having been ceded to Buonaparte in 1807, restored in 1814.—Washington, in North America, taken by the British, and the principal buildings destroyed by fire, Aug. 24.—Hackney chariots licensed in London, not to exceed 200.

1815.—Buonaparte quitted Elba, and landed at Cannes, March 1.—King of Candy deposed, and the sovereignty vested in Great Britain, March 2.—Buonaparte arrived at Fontainbleau, March 20.—Treaties for the maintenance of the treaty of Paris, between England, Ruffia, and Prussia, signed at Vienna, March 25.—Buonaparte abolished the slave trade, March 29.
—Potosi evacuated by the royalists and entered by the Buenos Ayres army, under general Rondeau, April 5.
—Florence evacuated by the Austrians, and entered by the Neapolitans, April 6.—Battle of Waterloo, in which the whole French army, with Buonaparte in command, was defeated by the English and Prussians, with immense slaughter, June 18. (See Waterloo.)—Buonaparte retired to Paris after his defeat at Waterloo, June 20; and abdicated in favour of his son, June 23.—Paris evacuated by the French and occupied by the allied army, July 3.—Louis XVIII. restored to Paris, and refused the government, July 8.—Buonaparte falling to fall from Rochfort to America, surrendered himself to captain Maitland of the Bellerophon, July 15.—Army of the Loire, under generals Suchet and Davoust, submitted to the government of Louis XVIII. July 16.—Bourdeaux submitted to the government of Louis XVIII. July 14.—Buonaparte transferred to Torbay from the Bellerophon to the Northumberland, and failed for the island of St. Helena, decreed by the allied sovereigns to be his residence for life, Aug. 8. —And arrived thither, Oct. 16.—The Museum of the Louvre was dismantled by the allied sovereigns of the treasures of art which had been lodged there in consequence of the depredations of Buonaparte. His palace in Italy, which was conveyed to Paris, consisted of 66 pieces of sculpture, and 47 capital paintings. Among the former, were the following chief-d'oeuvres:—the Apollo, the Antinous, the Adonis, the Dying Gladiators, the Lacooon, the Two Sphinxes, and the Tomb of the Muses. Among the latter, were the principal paintings of Raphael, Perugino, Guerchino, Annibal Carracci, Guido, Titian, and Correggio. In the national library were reposed a MS. of Josephus's Antiquities on papyrus, a MS. Virgil of Petrarch, with notes in his hand-writing, and 500 of the most curious MSS. which were in the library of the Vatican.

1816.—Treaty with the Nepaulie in India, ratified March 15.—Princess Charlotte of Wales married to the prince of Saxe-Cobourg, May 12, the annual sum of 60,000l. per annum having been previously settled upon him by parliament.—Declaration of independence of the representatives of the United Provinces of South America in general congress, published at Montevideo, July 19.—Genoa restored to the king of Sardinia.—Lotteries prohibited, on account of their immoral tendency, by the grand duke of Hesse, October.

1817.—Inhabitants of Chili restored to freedom by the Buenos Ayres army under general San Martin in February.—A revolutionary insurrection in Pernambuco in March.—Above 600 petitions for parliamentary reform, presented by sir Francis Burdett, threw over the house of commons, March 4.—The measure for repealing the penal laws against Catholics, which had been negatived in the house of commons by 213 against 195, June 1, 1810;—and again by 146 against 83, and in the house of lords by 121 against 62, in 1811;—and again in the former house by 350 against 215; and in the latter by 174 against 102, in 1812;—and again in the former house by 271 against 246, May 13, 1813;—and again in the same house by 228 against 147, and in the house of lords by 86 against 65, in 1815;—and again in the house of commons by 172 against 141, and in that of the lords by 73 against 69, in 1816;—and again in the former house by 245 against 221, and in the latter by 142 against 90, April 1817.—A bill admitting Catholics to promotion in the army and navy passed June 1817.—Loan of twelve millions advanced to the French government by English merchants.

CHYSOPRASE. See Mineralogy, Addenda.

CHYAZIC ACID, in Chemistry. See Cyanogen.

CHYLE, and CHYME, Chemical Properties of. These have

Vol. VIII.
have been already described under Digestion, and we have here only to notice briefly the late experiments of Dr. Marcet and Dr. Prout on the subject. These gentlemen were furnished by Mr. Ashley Cooper with specimens of chyle and chyme taken from different dogs, some of which had been fed on vegetable and others on animal food. Their experiments coincide almost exactly in every respect, so that it will be necessary only to mention Dr. Marcet's results. 

1. The specific gravity of the ferous portion of chyle appears to be between 1021 and 1022, whether formed from vegetable or animal food.

2. The quantity of solid residue, comprehending both fatine and animal matter, left by the evaporation of chyle at the heat of boiling water, may be generally flated to vary between 50 and 90 parts in 1000.

3. The quantity of fatine matter appears to be about 9 parts in 1000, being the same proportion of fats which is found in all other animal fluids.

4. The chyle from vegetable food appears to yield, by analysis, about three times as much charcoal as that from animal food.

5. The chyle from animal food is much diffused to putrefy, and generally begins to undergo that change in three or four days; while that from vegetable food can be kept for weeks, or even sometimes for months, without undergoing putrefaction.

6. The coagulum of chyle is more inclined to putrefy than the ferous part.

7. The chyle formed from animal food alone is always milky; and in standing, an unctuous white creamy substance collects on the surface; its coagulum is opaque, and has a pink hue.

8. The chyle from vegetable food is commonly transparent, or nearly so, like common serum. Its coagulum is nearly colourless, like an oyster, and no creamy substance rises to the surface.

9. The principal ingredient of the animal matter of chyle is albumen; but besides albumen, chyle, especially when derived from animal food, contains globules of an oily substance, which bears a strong resemblance to cream.

10. By the destructive distillation, chyle gives first a liquor impregnated with carbonate of ammonia, and afterwards a heavy fixed oil. The chyle from animal food yields a greater proportion of both these products, but the residue, whatever the mode of analysis be, contains less charcoal than the chyle from vegetable food. Iron is readily detected in the residue of chyle, mixed with the salts and carbonaceous matter.

11. Chyme from vegetable food yields much more solid matter than any other animal fluid, though it appears to contain rather less fatine matter.

12. Chyme contains albumen. It yields about four times as much charcoal as chyle from vegetable food.

13. Neither chyle nor chyme contains any gelatine.

Dr. Prout ascertained the curious fact in different animals, that albumen never exerts in the stomach, even when the food is perfectly digested, but that an albuminous principle is formed the moment it enters the duodenum and comes in contact with the bile. He was also induced to conclude, that this albuminous principle becomes more abundant, and more perfectly albuminous, the nearer it approaches the gastro intestinal system, so that it seems to undergo important changes between the intestines and thoracic duct. See Med.-Chir. Trans. vol. vi. and Annals of Medicine and Surgery, vol. i.

CIGOLI, r. Ludovico Cardi.

CIMEX, col. 2, l. 35 add.—This offensive creature was in a great degree unknown in the days of our ancestors. Its origin is traced to the year 1670, when it was imported among the timber used for rebuilding the city of London after the great fire of 1665; but it was known at a much earlier period than this, though it was much less common.

Vol. XXXIX.

than it is at present. A circumstance is mentioned by Mussal, which proves that these insects were known at Mortlake, in Surry, in the year 1783. They live entirely by fuchion, employing for this purpose their sharp and fine trunk or proboscis, which lies in a straight direction beneath the breast. Like the great and some other insects, they probably imbibe some quantity of irritating fluid into the wound they make before they suck the blood of the animal, which they attack, as the swelling is often very considerable, and attended with severe itching. In winter they conceal themselves behind the walls, wainscot, and in other neglected places; and on return of warm weather they emerge from their concealment. Mr. Baker says, in his "Microscope made easy," that the bug is one of the beet subjects for exhibiting a microscopic view of the circulation of the blood.

CIMOLIA, dele Pipe-clay.

CINCHONA, Chemical Properties of. Vaquelin some time ago published a set of comparative experiments on all the different species of cinchona which he could procure, in order to determine, if possible, how far they differ from each other, and what the constituents are on which their virtues depend. They may be divided into three distinct sets.

1. Those whose infusions precipitate the infusion of nattgalls, but not that of glue.

2. Those whose infusions precipitate glue, but not the infusion of nattgalls.

3. Those whose infusions precipitate glue, nattgalls, and tartrate emetic.

The following Table exhibits the effects of the different re-agents upon all the barks tried. It is difficult, however, as Dr. Thomson has remarked, to determine, in all cases, the real name of some of the specimens, as Vaquelin has not given us the botanical name.

<table>

</tr>
</tbody>
</table>
It is very probable, that several specimens in the above Table are duplicates, though we have no means of ascertaining this with certainty. All the above barks produced a green colour with iron, and most of them produced a green precipitate with that metal.

The substance which precipitated tannin was brown, of a bitter taste, and left soluble in water than alcohol. It precipitated tartar emetic, but not glue. It resembled the refuse in some respects, though it gave out ammonia when distilled.

Upon the whole, these experiments, though they establish the fact that differences exist among the various species of cinchona, throw very little light upon the nature of their active ingredient or its mode of operation.

**CINCINNATI**, *delh i. 9 and 10, and after paper, add—The number of public buildings, or dwellings, is from 1300 to 1400; of inhabitants, in 1810, 2540, and in 1817, 8000, all whites; the laws of Ohio prohibiting slavery, and even the settlement of free negroes, in the state, except in certain cafes. About 400 houses are built of stone or brick, many of which are three stories high, and in a superior style. The public edifices are of brick. Numerous manufactures are already established, and a very extensive commerce is carried on by river navigation with Pittsburg, New Orleans, and all the western states; and by waggons with the interior country. The manners and dress of the inhabitants resemble those of the English. Cincinnati is said to be the border of the western world, and will probably be the largest city in America at no very distant period. Forty years ago it was the resort of Indians; and the whole surrounding country was a wilderness, full of wild beasts and savages.

**CINNAMON STONE.** See Mineralogy, Addenda.

**CIONE, ORGANA, delc.**

**CIPHER, col. 36, l. 35, for syllables r. letters.**

**CIRCAR.** At the close, add—Circar denotes generally the head of an affair, or the state and government, as well as the great division of a province. It is also a name used by Europeans in Bengal to signify the Hindoo writer and accountant, employed by themselves or in the public affairs.

**CIRCLE, col. 5, l. 27 from the bottom, for 7854 r. 1571.43. Col. 6, l. 3, Plate I. add—of Astronomical Instruments. Col. 68, l. 5 from the bottom, for cannot but be.**

**CIRENESTER, col. 3, l. penult.** By the return in 1811, the borough of Cirenecaster contained 902 houses, and 4545 persons; viz. 2030 males, and 2515 females: 207 families being employed in agriculture, and 526 in trade and manufactures.

**CISTOTOME.** See Cystotomy.

**CITRIC ACID, in Chemistry.** This acid has been lately analysed by Gay Lussac and Thenard, and still more recently by Berzelius. The results obtained by the able chemists differ considerably, which are partly to be ascribed to the presence of water in the acid analysed by Gay Lussac. (See Analysis of Organized Substances.) The following Table exhibits these results.

<table>
<thead>
<tr>
<th>Hydrogen</th>
<th>Carbon</th>
<th>Oxygen</th>

<td>41.359</td>
</tr>
</tbody>
</table>

If we consider the numbers of Berzelius as most accurate, citric acid may be supposed to consist of two atoms hydrogen, four of carbon, and four of oxygen, and the weight of an integrant atom will be 72.5. Dr. Thomson, however, is disposed to consider another atom of hydrogen, or three atoms, to be present in citric acid, which supposition he states will render the weight of its integrant atom more accordant with the best analyses of the citrates.

**CLACKMANNAN.** Add—In 1811, the parish of Clackmannan contained 693 houses, and 3605 persons; viz. 1677 males, and 1928 females.

**CLACKMANNANSHIRE.** By the returns of 1811, this thire contained 1995 houses, and 12,010 persons; viz. 5715 males, and 6295 females: 850 families being employed in agriculture, and 893 in trade and manufactures.

**CLADUSIUM, in Botany, from axilis, a twig, alluding to its habit.**—Brown. *J. J. Brown Prod. Nov. Holl. v. 1. 236.—A genus founded on Schoenus Marius of Linnæus. (See Schoenus.) This plant grows in the West Indies and New Holland, as well as in Europe. Mr. Brown, who defines thirteen New Holland species, gives the following

Eff. Ch. Glumes imbricated every way, one or two flowered; the outer ones empty. Germen without bristles or scales underneath. Style deciduous, without a joint at the base. Nut naked and smooth, with a smooth kernel.

**CLADONIA, from its tufty habit, a name given by Hoffmann to a tribe of Lichens, now funk in Cenomyce, see that article.**

**CLAIBORNE, in Geography, a county of East Tennessee, having 4708 inhabitants, within 325 are slaves.**—Allo, a town of Mississippi territory, in Adams' county, containing 1238 inhabitants, of whom 14 are slaves.

**CLAIR, a county of the Illinois territory, containing nine townships, and 5007 inhabitants, of whom 40 are slaves.**

**CLAIR, St.**—Add—It is a town of Butler county, having 1180 inhabitants. Allo, a town of Columbiana county, in the same state, having 1003 inhabitants. Allo, a township of Pennsylvania, in Alleghany county, containing 3080 inhabitants.

**CLARKIA, in Botany, so named by Mr. Pursh, in honour of general Daniel Clark, the companion of the late governor Lewis, in his botanical travels.**—Pursh 260.—Clafs and order, Ophandra Monogynia. Nat. Ord. Calycantheme, Linn. Onagre, Juff.

1. *C. pulchella.* Elegant Clarkia. Pursh 1. 1.—Of the Koofkoofsky and Clark's rivers. Governor Lewis. Biennial, flowering in June. Stem erect, a foot or more in height, round, leafy, slightly branched upwards. Leaves scattered, sessile, linear, entire, smooth, an inch or two long. Flowers axillary, solitary, somewhat stalked, large and handfoine, of a fine purple or rote colour. Petals in three equal, abrupt, spreading lobes. Antères only four, involute. Stamina pale yellow, in four broad, rounded, petal-like lobes.

**CLARE, in Suffolk.** By the returns of 1811, the parish contained 253 houses, and 1170 persons; viz. 591 males, and 579 females.

**CLAREMONT, l. 6, r. 2064,—Allo, a town of Massachussets, in Hampshire county, having 987 inhabitants.**

**CLARENDON, a township of America, l. 4, after contains, inferred—1797.**

**CLARE.**—Add—The county contains 10,981 inhabitants, of whom 2695 are slaves; and the town has 538 persons, including 259 slaves.

**CLARKSBURG.** Add—Allo, a town of Massachussets, in Berkshire county, having 231 inhabitants. Allo, a county of Georgia, whose town is Athens, containing 2405 inhabitants, of whom 30 are slaves: its town contains 134, including 4 slaves.

CLAUSENBURG. See Colosvar.

CLAY, in Geography, a county of Kentucky, containing 2398 inhabitants, of whom 141 were slaves in 1810.

CLAY-STONE. See Mineralogy, Addenda.

CLEAR Creek, in Geography, a township of Fairfield county, in Ohio, containing 1126 inhabitants.

CLEARFIELD, a county of Pennsylvania, containing a town of the same name, which in 1810 had 875 inhabitants.

—Alle, a township of Butler county, in Pennsylvania, containing 288 inhabitants.

CLEARING, denotes a method adopted by the city bankers for exchanging the drafts on each other’s houses, and settling the differences. In pursuance of this method, at half-pall three o’clock in the afternoon, a clerk from each banker attends at the clearing-house, where he brings all the drafts on the other bankers which have been paid into his house during the course of the day; and he deposits them in their proper drawers (a drawer being here allotted to each banker): he then credits their accounts separately with the
C L I

articles which they have against him as found in his drawer. Balance are then struck from all the accounts, and the claims transferred from one to another, until they are found wound up and cancelled, that each clerk has only to settle with two or three others, and their balances must be immediately paid either in cash or Bank of England notes. Such drafts as are paid into a banker's too late for clearing, are sent to the houses on which they are drawn to be marked, which is understood as an engagement that they will be paid the next day. Kelly's Cambist.

CLEAVELAND, in Geography, a town of Cuyahoga county, in Ohio, having, in 1810, 547 inhabitants.

CLERGY, col. 5, l. 44. By 41 Geo. III. c. 63, no person ordained a priest, or deacon, or being a minister of the church of Scotland, shall be capable of being elected to serve in parliament as a member of the house of commons. Such person's election shall be void; and if after his election he shall be ordained a priest, &c. he shall vacate his seat; and if he sit or vote as a member of the house, he shall forfeit 100. for every day in which he shall sit or vote; provided such prosecution be commenced within twelve calendar months after such pecuniary shall be incurred. L. 54, after canon law, add—But now by 43 Geo. III. c. 84, certain provisions of 21 Hen. VIII. are repealed, and other provisions made in lieu thereof; and it is enacted, that after the passing of this act (7th July 1803) spiritual persons against whom no action shall have been brought under the recited act are indemnified; and contracts which would have been good after passing this act are valid notwithstanding that act; and proceeding may be had and in certain conditions. And any spiritual person may take to farm to himself or to any person or persons, to his use, by lease, grant, words, or otherwise, for term of life or of years, or at will, any messuage, manor, or dwelling-house, with or without orchards, gardens, and other appurtenances, although not in any city, borough, or town, notwithstanding the said first recited act or any other.

And it shall also be lawful for any spiritual person, having or holding any donative, perpetual curacy, or parochial chapelry, not having sufficient glebe or demeine lands annexed to or in right of or by reason of his benefice or cure, or chapelry, or for any flendary curate or unbenevolent spiritual person, with the consent in writing of the bishop of the diocese, to take to farm to himself, or to any person to his use for a limited number of years, any farm or farms, lands, tenements, or hereditaments, that may under all the circumstances appear to such bishop proper to be taken by such spiritual person, for the convenience and accommodation of his hospitality only, without being subject to any pains, penalties, or forfeitures, under the said first recited act or any other: provided that nothing herein contained shall extend to authorize any non-residence of such spiritual person.

CLITHEROE. In 1811 this borough contained 299 houses, and 1767 persons; viz. 826 males, and 941 females.

CLITOMACHUS, l. 2, for Carthage r. Athens.

CLOCK. In col. 52, l. 18 from bottom, we have referred to PYROMETER for the description of Troughton's new instrument, by which he tries the compensation of his tubular pendulums; but on application both then and recently made to him for permission to describe it, we were informed that this instrument has not yet been completely finished, and consequently not described by him. We can, however, now give our readers some idea of its principle and construction without a drawing. The pendulum is suspended vertically in an enclosed box of wood, made fast to a wall, and heated with lamps placed within; then a horizontal metallic bar, about thirty inches long, has one of its ends inset through the side of the box into a hole made in the centre of oscillation of the ball, while the middle of it is supported by a short bearing-piece driven into the wall, and projecting a few inches therefrom: on the remote end of this bar, a micrometer-screw is fixed, that adjoins a delicate spirit-level, borne by it; so that whenever the interior end of this horizontal bar is depressed by the elongation of the pendulum, the bubble runs to the exterior end of its tube, and indicates the quantity of elongation by its run, as measured by the micrometer during its re-adjustment; and on the contrary, when a contraction takes place in the pendulum, the bubble runs to the interior end; but when it remains stationary, on the application of heat to the pendulum, it is considered that the compensation is perfectly adjusted. Two thermometers are placed at a distance from each other in the box, and are viewed through slips of glass inserted in the front of the box near the top and bottom, to shew that the heat is equally diffused; and thus the expansion of any simple rod may be taken, while the apparatus is removed sufficiently from the heat applied within the box, while the least quantity of expansion may be ascertained, without danger of error, by means of the micrometrical level. It is hardly necessary to remark, that when a simple rod has its expansion thus ascertained in different degrees of temperature, its inferior end must rest on the inner end of the horizontal bar, while its superior end must be pressed upwards against a pin in the wall instead of being suspended; in which case, a counterpoise must be placed on the horizontal bar near the level, to hold the vertical rod up to its bearing. The peculiar advantage of trying the final adjustment of a pendulum of Troughton's construction for compensation after it has been brought to time, is, that the spring by which the pendulum is suspended is included in the determination of the total result of all the contrary expansions; which cannot be paid of any other method, except that which results from actual experience, in observing the variations of rate at opposite seasons of the year, which is a tedious method, accomplished only at the expense of much observation and loss of time after each new adjustment.

CLOCK-MAKING, col. 2, l. 13 from bottom, for radii r. diameters.

CLOWES, l. 2, for fifteenth r. sixteenth.

CLUNCH. This is also a name given to Stourbridge clay, which lies at a great depth in the earth, under the bed of coal: it is a grey clay, of a sandy nature, and better adapted for making large crucibles and fire-brick than perhaps any in Europe. Parkes's Eff. v. 4.

CLUPEA ALOSA, col. 2, l. 59, for it is not of r. it is one of.

CLYSTERS, in Farriery, are of great use in allaying many acute complaints to which horses are subject; and Mr. Clark recommends for this purpose simple elixirs of warm water or thin water-gruel. The infusion which
Cob

he prefers for administering clysters is a simple bag or ox-bladder, holding two or three quarts, tied to the end of a wooden pipe about fourteen or fifteen inches long, and an inch and a half in diameter where the bag is tied, and tapering to the extremity, where the thickness should suddenly increase, and be rounded off to the point as smooth as possible. The hole through the pipe may be made sufficiently large for admitting the end of a common funnel, by which the liquor may be poured into the bag. Mr. Clark recommends the following clysters for the several purposes to which they are applied. An emollient clyster may be composed of two or three quarts of the water-gruel, 6 oz. of coarse sugar dissolved in the gruel, and the fame quantity of olive-oil added to it. For a laxation clyster, he directs two or three quarts of thin water-gruel, 8 oz. of Glabber's salt (or common salt), and 6 oz. of olive-oil. For a purging clyster, he recommends 2 oz. of fenna, two quarts of boiling water, the fenna being infused and the liquor strained off, with the addition of syrups of buckthorn and common oil, of each 4 oz. An anodyne clyster may be prepared with one pint of the juice of common flax, or infusion of linseed, and 1 oz. or about two table-spoonfuls of tincture of opium. For a nutritive clyster, he directs three quarts of thick water-gruel well boiled; and in some cases milk-gruel might be substituted with advantage. For a diuretic clyster, in cases of strangury, or obstructions of the urinary passages, he recommends 1 oz. of castile soap dissolved in two quarts of warm water, and the addition of 2 oz. of Venice turpentine, previously broken up with the yolks of two eggs.

COACHES, Hackney, col. 4, line 8 from bottom, add—By statute 55 Geo. III. c. 159. f. 2. the commissioners are empowered to license hackney chariots; and by an act passed July 11, 1817, the holders of licences may drive either a coach or a chariot under the same licence; provided that they do not at the same time drive more than one, which is to be exprest in the licence, under a penalty of 10l. or revocation of the licence.

COAL, col. 13, l. 3 from bottom, for 2 92 Grey, &c. r. 21 92 Grey, &c. Col. 20, l. 12, for easelr r. wefherly.

COALBROOK, or Cofbrook Dale, in Geography, a township of Berks county, in Pennsylvania, containing 792 inhabitants.

COBALT, col. 7, l. 6 from bottom, for or r. on.

COBALT, in Chemistry, the name of a metal. Some circumstances omitted in their proper place require to be mentioned here.

The specific gravity of pure cobalt, according to Tafferaet, is 8.5384; according to Lampadius it is 8.7. It melts at about 130° of Wedgwood's scale, and is not capable of being volatilized by any degree of heat we can excite. Like iron, it is attracted by the magnet, and according to Wenzel is capable of being converted into a magnet, precisely similar in its properties to the common magnetic needle.

There are two oxyds of cobalt, the protoxyd or blue, and the peroxyd or black oxyd.

The protoxyd dissolves in acids without effervescence, and seems to form the basis of most of the salts of cobalt. According to Rothoff, it is composed of

\[
\begin{align*}
\text{Cobalt} & : 100 \\
\text{Oxygen} & : 73.36
\end{align*}
\]

Proust found the proportion of oxygen considerably less, that is to say, only 19.8 with 100 of the metal; and Klapproth still less, or about 18.0. If, with Dr. Thomson, we consider Rothoff's analysis most entitled to confidence, the weight of the atom of cobalt will be 36.25.

When the protoxyd of cobalt, newly precipitated from an acid, is dried by heating it in the open air, it assumes a fleabrown colour, which gradually deepens till it becomes black. This is the peroxyd of cobalt. It dissolves with effervescence in muriatic acid, and a great quantity of chlorine is evolved. From the experiments of Rothoff, it appears that this oxyd is composed of

\[
\begin{align*}
\text{Cobalt} & : 23.4 \\
\text{Air} & : 66.6
\end{align*}
\]

Hence it appears to be composed of two atoms of cobalt, and three of oxygen; and on this supposition, the weight of its atom will be 102.5.

COCALICO. Add—containing 4024 inhabitants.

COCAMA, r. see Maynas.

COCINELLA, l. 39, add—These insects are commonly known under the name of lady-birds. The C. punctata, or that of a 7-spotted body, makes its appearance in the advanced state of spring and middle of summer, and in every field and garden. One of the most beautiful of the English species is C. punctata of Linneaus, which is little more than half the size of the common red bead, and is of a bright yellow colour, with numerous (generally 18) black specks.

COCKE, a county of East Tennessee, containing 9154 inhabitants, of whom 436 are slaves.

COCKERMOUTH, l. 40, r. 2964; l. 41, r. 602.

CORDORUS. Add—It contains 1975 inhabitants.

COELACHINE, in Botany, from colochus, empty, and a nux, a nucus, alluding to the inflated glumes.—Brown Prod. N. Hall. v. 1. 187.—Clafs and order, Triandra Digynia. Nat. Ord. Gramina.

Eff. Ch. Calyx of two nearly equal, very blunt, tumid valves, two-flowered. Florets of two valves, without awns; the uppermost tailed, female. Neftary of two scales. Stigmas feathery. Seed unconnected, cylindrical, acute at each end.

1. C. pulchella. Found by Sir J. Banks, in the tropical part of New Holland. A little smooth slender græfis, resembling a diminutive Briza, very remarkable for the smaller, or imperfect, flore being female, not male.

COFFEE, col. 13, l. 1, r. 49, and 98; l. 15, r. 100.

Col. 14, l. 49, r. 43.

COHASSET, l. 3, r. 994.

COINAGE, col. 2, l. 4 from bottom, Plate III. fig. 1. Mifsellany.

COIT'S Gora, in Geography, a town of Franklin county, in Vermont, having 193 inhabitants.

COTTTSVILLE, a township of Ohio, in the county of Trumbull, having 429 inhabitants.

COKE, Sir Edward, l. 3, r. Micham.

COLEST, John Baptist, l. 16, r. XIV.

COLESTEY. In 1811, the borough of Colchester contained 2111 houses, and 12,544 persons; 5400 being males, and 7144 females: 430 families employed in agriculture, and 1152 in trade and manufactures.

COLESTON, in America, l. 7, add—containing, in 1810, 2697
COL

2697 inhabitants, of whom 7 are slaves; l. 16, add—containing 673 inhabitants.

COLCHICUM, col. 2, add—See Phil. Trans. for 1817, pt. ii. p. 262; and for Meadow r. Saffron.

COLDHAM.

In 1811 the parish contained 462 houses, and 2424 persons; 1174 being males, and 1250 females.

COLDSTREAM.

In 1811, the parish contained 397 houses, and 2384 persons; 1103 being males, and 1281 females.

COLEBROOK, l. 2, for Grafton r. Coos; l. 6, add—containing, in 1810, 325 inhabitants; l. 10, add—In 1810, it contained 1243 inhabitants.

COLEBROOKA, in Botany, so named, by the writer of this, in honour of Henry Thomas Colebrooke, esq., chief judge in the courts for the natives of Bengal, a practical and accomplished botanist.—Sm. Exot. Bot. v. 2. 111.—Clafs and order, Didynamia Gynno sperma. Nat. Ord. Fälices, Juff.

Eff. Ch. Calyx-teeth five, becoming feathery awns.

Seed solitary, brilly. Limb of the corolla unequally five-lobed.

1. C. oppugnifolia. Opposite-leaved Colebrookea. Sm. as above, t. 115.—Leaves opposite.—Found by Dr. Buchanan, by road sides in Nepal. A downy, slightly aromatic, furb, with flaked, elliptic-lanceolate, ferrigated leaves, and terminal, aggregate, whitened spikes, of innumerable, minute white flowers.

2. C. ternifolia. Three-leaved Colebrookea. Roxb. Corom. v. 3, 40. t. 245.—Leaves three or four in a whorl.

—Native of Myfory. The leaves are narrower and more drooping; the spikes much smaller than in the foregoing.

Dr. Roxburgh says the germen are four, sometimes all perfect; the flowers aggregate, with many common bracteas.

COLEFORD. In 1811, this tything in Newland parish contained 253 houses, and 1551 persons; 849 being males, and 702 females.

COLERAIN, l. 2, add—containing 834 inhabitants; l. 20, add—Allo, a township of Bedford county, in Pennsylvania, containing 1847 inhabitants.—Allo, a township of Belmont county, in Pennsylvania, containing 471 inhabitants.—Allo, a town of Rofs county, in Ohio, having 486 inhabitants.

COLERAINE, l. 3, r. and in 1810, 2016 inhabitants.

COLESHILL. In 1811, this parish contained 330 houses, and 1659 persons; viz. 789 males, and 850 females: 119 being employed in agriculture, and 196 in trade and manufactures.

COLICA, or Colic, in Farriery, a disease to which brute animals are subject; for which Mr. Taplin recommends a ball made of the following ingredients; viz. 1 oz. of pulverized anifeeds; ½ oz. of mithridate; ginger and grains of paradise, of each, in powder, 2 drs.; 1 oz. of aniseed and oil of juniper, of each, 1 dr.; and syrop g. f.: the ball to be given, according to the state of the diseafe, every two, four, or six hours. In some cases, a mixture of ginger, pepper, anifeeds, &c., ½ oz. of each, with the addition of a little brandy or gin, will give relief. In flatulent colics, a ball made of 6 drs., or 1 oz. of Venice turpentine, purified opium from 1 to 1½ dr., 1 dr. of oil of aniseeds, and 2 drs. of powdered ginger, may be administered every two, three, or four hours, according to the urgency of the symptoms.

COLLEMA, in Botany, Cœlipus, a gluttonous fululence. The name appears to have originated with Hill, and is adopted by Hoffmann and Aeharius. The latter has only admitted this genus in his two last publications.—Aeh. Lichenogr. 129. t. 14. f. 8—11. Syn. 308. Sm. in Engl.

Eff. Ch. Shields orbicular, horizontal, nearly fessile, supercilial, with a gelatinous acerose border.

Aeharius reckons up sixty-four species. These are the gelatinous Lichens of former authors. (See Lichenes, feét. 1.) They are all more or less pulpy, oliv-green, or blackish; their fronts various in form and direction. Twenty-three British species are figured in Engl. Bot.

COLLEMORE’s Range, in Geography, a township of America, in the district of Maine, and county of Lincoln, having 40 inhabitants.

COLLETON, a district of South Carolina, containing 26,359 inhabitants, of whom 5238 are slaves.

Vol. IX.

COLLISION, col. 9, three half lines, for Z r. E.

COLNE. By the return of 1811, this township contained 990 houses, and 5336 persons; viz. 2531 males, and 2805 females: 58 families being employed in agriculture, and 528 in trade and manufactures.

COLONSAY, l. 21, By the last act 786, and the number of houses 158.

COLOUR, col. 12, l. 11, for cold r. colour. Col. 22, l. 18, for tube r. tub.

COLUBER, l. ult. r. See Hydrus.

COLUGO, in Zoology. See Galeopithecus.

COLUMB, St. In 1811, the parish of St. Columb major contained 410 houses, and 2070 persons; viz. 988 males, and 1082 females: 225 being employed in agriculture, and 108 in trade, &c.; and the parish of St. Columb minor contained 229 houses, and 1126 persons; viz. 550 males, and 576 females: 147 families being employed in agriculture, and 72 in trade, &c.

COLUMB, a military order, l. 2, r. 1379. Add—See Dove.

COLUMBIA, l. ult. r. in 1810, 32,390 inhabitants, of whom 879 are slaves; l. 8, add—It contains 11,242 inhabitants, including 5980 slaves; l. 11, add—It contains 518 inhabitants; l. 31, add—It contains 2057 inhabitants.—Allo, a township of Cayuhaga, in Ohio, having 205 inhabitants.

COLUMBIANA. Add—It contains 17 townships, and 10,878 inhabitants.—Allo, a town of Kentuck, in Adair county, containing 175 inhabitants, of whom 45 are slaves.—Allo, a district of America, containing 24,623 inhabitants, of whom 5305 are slaves.

COLUMBUS. See Tantalum.

COLUMBUS, l. 6, r. Trincemake.

COMBUSTION, Theory of. See Acid, and Acidification.

COMEPHORUS, in Phibiology, a genus of the apodes, the
CON

1. The characters of which are, head large, with depressed innot; mouth large, with small teeth; body elongated, compressed, the second dorsal fin surrounded with several long naked rays. This fish is a genus of Cepede, and referred by Pallas to the genus of Callionymus among the jugular fishes. It is a native of the lake Baikal; and from its conformation seems to be capable of swimming swiftly, and of springing out of the water like the flying-fish. See Callionymus Baikalen-

sis of Gmelin's Linnaean system.

COMMIPHORA, in Botany, from καυσις, gum, and χιως, to bear, Jacq. Hort. Schoenbr. v. 2. 66. t. 249, a dioecious oentandrous shrub, of which the male only is known, found in Madagascar, and said to produce that kind of elastic gum, of which Fourcroy has given an analysis. More information on this subject is very desirable.

COMMON PRAYER, l. 15, add—2 & 3 Edw. VI.

COMPAGNIE ECCOSOIS. See GENDARMES, &c.

COMPASS, col. 6, l. 37 and 38, r. See MAGNETICAL DECLINATION, and MAGNETICAL VARIATION.

COMPENSATION, col. 18, l. 35 from the bottom, for but broader r. and narrower.

COMPSTELLA, l. 2, after capital, insert—(see Corenxa).

COMPOUNDS, in Chemistry, are divided into primary and secondary.

Primary compounds, according to Dr. Thomson, are those formed by the union of combustibles with the four supporters of combustion, oxygen, chlorine, iodine, and fluorine, and with cyanogen. Dr. Thomson also includes under this division certain compounds of combustibles with one another, and with oxygen.

Secondary compounds are those formed by the union of two or more primary compounds. These include the four classes of substances, termed hydrates, fates, hydrophilurates, and loaves.

COMREE, in Geography, a township of Berks county, in Pennsylvania, containing 217 inhabitants.

CONCORD, l. 10, insert— and had, in 1810, 2396. At the close, add—Alto, a town of Grafton county, in New Hampshire, containing 1126 inhabitants. At the close of the next article, add—containing 677 inhabitants; l. 4 from the bottom, after upwards, add—By the census of 1810, the number of inhabitants was 1633.

CONCORD, in Delaware county, add—containing 1061 inhabitants. Alto, a township of Miami county, in Ohio, having 679 inhabitants.—Alto, a town of Rofs county, in Ohio, containing 1277 inhabitants.

CONCORDIA. Add—Alto, a county and parish of the territory of Orleans, containing 2895 inhabitants, of whom 1581 are males.

CONMEMAUGH, a township of Indiana county, in Pennsylvania, containing 1167 inhabitants.—Alto, a township of Somersfield county, in the same state, having 381 inhabitants.

CONESTOGA. Add—containing 1506 inhabitants.

CONEWAGO, a township of Adams county, in Pennsylvania, having 531 inhabitants.

CONEWANGO, a township of Warren county, in Pennsylvania, having 448 inhabitants.

CONELTON, 2 half lines, r. at 944, the inhabitants at 4616, of whom 2023 are males, and 2593 females.

CONGOON, a port of Larifian, in Perhia, containing 6000 or 7000 inhabitants, and having an excellent roadstead, where a frigate may ride safely in the most tempestuous weather, and good water and fire-wood be procured.

CONIC SECTIONS, Lemmas. Def. l. 1, r. A E; l. 2, D and B; l. 3, A B. Cor. l. 1, r. A E in B; l. 3, B and D in B; l. 5, D B and D E.

CONNECTICUT. At the close, add—See UNITED STATES.

CONNELSVILLE, l. 2, for Washington r. Fayette; l. 4, r. 93 inhabitants.

CONNIOTT, a township of Pennsylvania, in the county of Crawford, having 285 inhabitants.

CONON, l. 1, for son r. father; l. 2, after Athens, r. who died in the year B.C. 393.

CONOPLEA, in Botany, Perf. Syn. Fung. 234, an obscure genus of Fungi, confining of compact, rigid, permanent fibres, generally black or brownish, interfiled with powder. Four species are described, found on rotten wood, branches, or leaves.

Roots perennial, fibrous. Stem scarcely any. Leaves sword-shaped, equitant, rough or bristly at the edges. Stalk many-flowered, capitate or corystobo, often woolly.

Four species are natives of the south coast of New Hol-

land; and one, C. americana, of the pine-barrens of New Jersey and Carolina, bearing flowers of a golden yellow, in July. The genus is almost entirely superior in this species.

Parf.

CONSTRUCTION of Boats. The plate referred to under this article has been superseded by Plate XIV. of Naval Architecture; and for the description of the latter, as far as it relates to Boats, the reader is referred to the article WOOD-MOULDING.

CONVOCATION, col. 3, l. 36, after representatives, add—The summons to the convocation must not be con- founded with that which we now mention, though the constituent parts are the same; and by modern usage the assembly of both is supposed to have been on the same day. But the one may be easily distinguished from the other by this difference: viz. the convocation is provincial, and summoned by the metropolitans of Canterbury and York, whereas the claque, commonly denominated praemunier, (from its first word,) in the writ to each bishop proceeds from the crown, and enjoins the attendance of the clergy at the national council of parliament.

CONWAY, col. 3, at the close—Population in 1811 was 10531, the number of houses 218.

CONWAY, in America, l. 8, r. 1080. Col. 4, l. 1, r. 1784.

COOLING Powers of the Gases. It is difficult to ascertain the precise conducting powers of gaseous substances, as the cooling of hot bodies in gases is influenced by a variety of circumstances besides their conducting properties. Count Rumford found, that a thermometer cooled nearly four times as fast in water as in air of the same temperature. The same philosopher also found, that rarefaction much diminishes the conducting power of air, and that hot bodies cool most swiftly of all in a Torricellian vacuum. This sub-
ject, however, has been investigated more lately with greater precision by Leslie and Dalton. Mr. Leslie ascertained, that the conducting power of all gases is diminished by rare-
faction. He has endeavoured to deduce from his experi-

ments,
ments, that the conducting power of air is nearly proportional to the fifth root of its density. Mr. Dalton, however, has rendered it probable, that it varies nearly as the cube root of its density. Vapours of all kinds, and every thing that has a tendency to dilate air, diminish their conducting powers. The conducting powers of common air, oxygen, and azote, as might be expected, are nearly equal. The conducting power of carbonic acid is rather inferior to that of air, but bodies cool in hydrogen more than twice as fast as in common air; and Mr. Leffle has endeavoured to shew, that the actual conducting power of hydrogen is no less than four times greater than that of common air.

Mr. Dalton's experiments were made with a strong phial filled with the gas to be examined, into which he introduced a delicate thermometer through a perforated cube, and observed the time it took to cool 15° or 20°. The following table exhibits the result of his experiments:

<table>
<thead>
<tr>
<th>Gas</th>
<th>Time of cooling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbonic acid</td>
<td>11°</td>

COOLSPRING, in Geography, a township of Pennsylvania, in the county of Mercer, having 521 inhabitants. COOS, in Ancient Geography. Add—See Cos. Coos, in Geography. Add—Coos is a county of New Hampshire, containing 24 townships, and 3991 inhabitants. COPAL. Add—See Vateria. COPPER, in Chemistry, the name of a metal. Some circumstances omitted in our account of this metal require to be noticed here.

There are two oxyds of copper, the protoxyd of an orange or red colour, and the peroxyd or black oxyd.

The protoxyd was observed by Prout; but Chevexis, who found it native in Cornwall, first accurately described its properties. It may be formed by mixing together 57.5 parts of black oxyd of copper, and 50 parts of copper in a state of powder, formed by precipitating it from muriatic acid by an iron plate. This mixture is to be triturated in a mortar, and put with muriatic acid into a well-rounded phial. Potash dropped into this solution precipitates the oxyd of copper of an orange colour. It may be also formed with much less trouble by adding excess of copper to muriatic acid, and letting the whole remain till the green colour disappears, and the solution becomes dark brown and opaque. In this state, dirty-white crystals like sand are deposited. If potash be added to the brown solution, or a solution of the crystals above-mentioned, the protoxyd is precipitated in abundance. According to Berzelius, this oxyd is composed of

<table>
<thead>
<tr>
<th>Copper</th>
<th>Oxygen</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>12.5</td>
</tr>
</tbody>
</table>

Hence the weight of the atom of copper will be 80.

The peroxyd or black oxidy of copper has been already described. It is composed, according to Proust and Berzelius, of

<table>
<thead>
<tr>
<th>Copper</th>
<th>Oxygen</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>25</td>
</tr>
</tbody>
</table>

Hence the quantity of oxygen in these two oxyds is as one to two; or the protoxyd may be considered as composed of one atom copper and one of oxygen, and the peroxyd of one atom copper and two of oxygen. From these determinations, the composition and weights of the atoms of the different farts of copper may be accurately estimated.

Eff. Ch. Calyx none. Petals five or fix, deciduous. Nectaries as many, hooded. Follicles membranous, stalked, beaked, with many seeds.

1. C. trifolia. Three-leaved Coptis. Pursh n. 1.—Leaves ternate, obovate. See HELLEBORUS, n. 3.

2. C. aphlenophila. Fern-leaved Coptis. Pursh n. 2.—Leaves twice ternate, pinnatifid. Found by Mr. Menzies, on the west coast of North America, and by Thunberg in Japan, this being actually Thalidium japonicum of that author, and of Willd. Sp. Pl. v. 2. 1303! The flowers are greenish.

CORACHIE, in Geography, a good sea-port in the country of Scind; which fee.

CORAL, Chemical Properties of. See VERMIS.

We do not doubt the propriety of separating this plant, and another of American origin, (see Pursh 593. n. 4) from Cymbidium; but we have some nearly allied Orchids from Neapul, which require to be examined before the limits of Corallorhiza can be clearly defined.

CORDILLERAS. Add.—The great body of the Cordilleras, as it extends from Quito northward, approaching the gulf of Mexico, and entering the kingdom of New Granada, is divided into three chains, which are almost parallel, and of which the two lateral branches are covered with sand-dune, and other secondary formations, to a very considerable height. The eastern chain divides the valley of the river Magdalena from the great plains that are drained by the Orinoco and its branches. Inclosed by a circle of mountains belonging to this chain is the high valley of Bogota, the bottom of which is no less than 7460 feet above the level of the sea. The waters of this valley are collected by the single stream of Rio de Bogota, which finds its way through the mountains to the S.W. of the town of Santa Fé: the stream where it leaves the valley is about 144 feet wide; it then enters into a rocky channel not more than 40 feet wide, apparently formed, says M. Hun. bolds, by an earthquake. From this crevice, the river precipitates itself at two bounds to the depth of 574 feet; and after this fall pursues its course to the Magdalena, about 50 miles, still descending with great rapidity, and at the rate of 150 feet to a mile. The natural bridges of Icononzo are on the western declivity of this ridge. The central chain is the highest of the three, and often attains the limits of perpetual snow, and greatly furphases it in the colossal summits of Guanacas, Baragan, and Quindiu. The western chain separates the valley of Cauca from the province of Choco, and the coasts of the South Sea. This is lower than the others, and rises so much as it approaches the isthmus of Panama, that its course can hardly be ascertained. In our ordinary
ordinary maps, there is no trace of the highest or central chain; and Mr. Arrowsmith's map of America, in 1802, makes the valley of Magdalena occupy the whole interval between the eastern and western chains. The most difficult passage of the Andes is that by the mountain Quinqui. It lies through a thick uninhabited forest, which cannot be traversed, in the frozen season, in less than ten or twelve days. The summit of the pass is at the prodigious height of 11,499 feet above the level of the sea, and the passage from ten to sixteen inches in breadth. Humboldt's Researches, &c. by H. M. Williams, 1814.

CORYLINE, in Botany, an old name of Van Royen's, from κόρυλος, a club or flask, suitable enough to the Dracene and Yucca to which it was originally applied, and which we prefix are included in the genus which now bears it. —Comm. in Jaff. 41. Brown Prodr. Nov. Holl. v. 1. 280. —Clas and order, Hexandria Monogynia. Nat. Ord. Aphi-rafy, Jaff. Asphodelo, Br.

The stem is shrubby. Leaves lanceolate, finely ribbed, elongated. Panicle terminal, of numerous, many-flowered, alternate spires, with two unequal bracts beneath each flower.

1. C. canifolia. Br. n. 1. —Leaves stalked, pointed. Clusters divided. Outer bracts acute, twice as large as the inner, which hardly equal the partial stalks. —Found by Mr. Brown, in the tropical part of New Holland.

See Dracena, of which our first and second species belong to this genus.

CORFE-Castle, i. 29, r. after return —of 1811 was 161, and of inhabitants 744.

Corinth, a town of America, i. 2, r. 1876.

Corinthian order, i. 8, for convex r. concave.

Corn, col. 3, l. 18 from the bottom, del 1. 18 to l. 14.

Vol. X.

Cornea, Opacity of. Opacity of the cornea is one of the worst consequences of obstinate chronic ophthalmia. The sight, recent, and superficial form of the disease is usually known under the name of nebula; and it is preceded by and attended with chronic ophthalmia. The iris and pupil are discernible through a sort of cloudiness, and the patient is not entirely deprived of the power of vision. The veins of the conjunctiva are greatly relaxed, turgid, irregular, and knotty, which change first affects their trunks, and then gradually extends to their ramifications near the union of the cornea with the sclerotica, and ultimately to their most minute branches returning from the delicate layer of the conjunctiva, spread over the front of the cornea. When this happens, a milky albuminous secretion begins to be superficially effused in the interstices between the red streaks, and the specks thus produced may cover only a part or the whole of the cornea.

The opacity of the cornea sometimes occurring in violent ophthalmia is essentially different from the nebula, and arises from a deep extravasation of coagulating lymph in the cellular texture of the cornea, or from an abscess between its layers. In the treatment of the nebula, the curative indications are to reforest the varicose vessels to their natural diameters; and if that be impracticable, to cut off all communication between the trunks of the most prominent veins of the conjunctiva and those on the cornea. The first object is performed by using Janin's ophthalmic ointment, or the ung. hydrarg, nitrat, together with astringent collyria. The second defideratum is fulfilled by the excision of the fasciculus of varicose veins, just at the base of the opacity, with a pair of dissecting kifeus and forceps. With respect to the deeper and more obstinate opacities, which are frequently called albigo and leucitis, they are consequences of severe acute ophthalmia, though sometimes the effects of an ulcer or wound of the cornea, when they are commonly known only by the latter appellation.

The recent albigo may sometimes be dispersed by the same treatment, which is applicable to violent ophthalmia; and when the inflammation has been subdued, the ung. hydrarg, nitrat. is the best local remedy for promoting the ab sorption of the extravasated opaque lymph. The eye may also be frequently walked with a collyrium, composed of two scruples of the murrate of ammonia, and four grains of verdigris, in eight ounces of lime-water. The treatment must be continued three or four months before the case is to be abandoned as hopeless. With respect to the leucitis arising from a cicatrix, Scarpas fets it down as absolutely incurable.

CORNISH, l. 5, r. 1810, and 1606. Add —Allo, a town of York county, in the district of Maine, having 974 inhabitants.

CORNVILLE, a town of America, in the district of Maine, and county of Somerset, having 504 inhabitants.

CORNWALL, col. 8, l. 51, r. 1811; l. 52, r. 35, 971, and 216, 667.

Cornwall, in America, l. 3, r. 1279; l. 8, add containing 1602 inhabitants.

Coro, l. 7, after perfons, add —The little commerce that is carried on is in mules, goats, hides, sheepkins, cheeves, &c. obtained from the interior of the country, and more particularly from Carora. At the clofe, r. N. lat. 10° 8' from Paris.

CORSHAM, l. 17, add —By the return of 1811, the number of house was 478, and that of inhabitants 2395.

CORTLANDTS, a county of New York, having 8800 inhabitants.

COURDUNDUM. See Mineralogy, Addenda, and Adamantine Spar.

COURNA. Add —See Compostella.

Coryveis, col. 2, l. 20, add —The African or Cape raven, des cribed by Le Vaillant, is, according to Dr. Shaw, the only variety worthy of notice.

COWEN, l. ult. r. 51 Geo. III. 288 houses, and 1417 inhabitants.

CORYSTHANES, in Botany, from κορυς, a helmet, and αιθος, a flower. —Brown Prodr. Nov. Holl. v. 1. 328. —Clas and order, Gynandria Monandria. Nat. Ord. Orchideae. Eff. Ch. Calyx ringent; upper lip vauthed, very large; lower in two linear segments, combined with the linear petals. Lip dilated, concave. Anther terminal, of one cell; and two connected valves, permanent. Maffes of pollen four. Curious little smooth plants, each with a single bulb, one roundish radical leaf; and a large, deep red, solitary flower. Nearly related to Lypenanthus nigriscus; see that article.

COT

sustended by an almost orbicular, heart-shaped, pointed leaf.

2. C. unguculata. Stalked Helmet-orchis. Br. n. 2.—

Lip without a spur, tubular, dilated and hood. Flower stalked. Flower pendulous. — Found by Mr. Bauer, at Port Jackson.

3. C. biculata. Double-spurred Helmet-orchis. Br. n. 5. (Corybas aconitiflorus; Salis. Parad. t. 83.)—Lip tubular, with two spurs at the base.—Found near Port Jackson, but, according to Mr. Brown, very rarely, nor does he seem to think it has ever been brought alive to England. We received a specimen in spirits, from Dr. White, about the year 1793: Mr. Brown’s remarks on this subject are curious.

COSMEA, a name certainly much improved from Cosmo of Cavanilles, Ic. v. i. 9.—Ait. Hort. Kew. v. 5. 152.—This genus comes next to Catasetum, and we should fearfully scruple to unite them.

COTTONIS. Add.—This town, called Cotaos or Cotales, is now an inconvenient place, inhabited by about 80 Jewish, Armenian, and Turkish families. Its rivers are extensive, and it is situated on a beautiful and fertile plain.

COTCHUNG. See Deraguz.

COTENTIN for Contentin.

COTOPAXI. This is the loftiest of those volcanoes of the Andes, which, in recent epochs have undergone eruptions. Its absolute height, according to Humboldt, is 18,874 feet; so that it is double that of Camiogu, and 2600 feet higher than Vefuvius would be it were placed on the top of the peak of Teneriffe. This is also the most dreadful volcano of the kingdom of Quito, and its expulsions are the most frequent and disastrous. The mafs of fire, and the huge fragments of rock thrown out of this volcano, cover a surface of several square leagues; and would form, if they were heaped together, a colossal mountain. In 1758, the flames rose 2900 feet above the brink of the crater. In 1774, the roaring of the volcano was heard on the borders of the Magdalena, a distance of 200 leagues. In April 1768, the quantity of ashes ejected by the volcano was so great, that in the towns of Haumbato and Tacanga the inhabitants were obliged to use lanterns in walking the streets at noon-day. The explosion in January 1803 was preceded by the sudden melting of the snow which covered the mountain. For twenty years before, smoke or vapour had been observed to issue from the crater; and in a single night, the subterraneous fire became so active, that at fun-rise the external walls of the cone were heated to such a degree as to appear quite naked, and of the dark colour peculiar to vitriined fire. At the port of Guayaquil, fifty-two leagues distant, Mijos. Humboldt and Bonpland heard the noise of the volcano day and night, like the continued discharges of artillery. In this part of the Andes, a longitudinal valley separates the Cordilleras into two parallel chains; the bottom of this valley is 5843 feet above the level of the ocean, so that Chimborazo and Cotopaxi appear no higher than the Col du Geant, as measured by Sauflure. The summit of the mountain of Chimborazo is 21,430 feet above the level of the sea, and therefore a good part is above the circle of perpetual congelation, which, in the latitude almost under the line, is somewhat higher than the summit of Mont Blanc. Humboldt’s Refereshes. See VOLCANO.

COTTON, col. 15, l. 15 from the bottom, for feed r. read COTTON-ENTRY. By the return in 1811, this city contained 3448 houses, and 17,493 persons; viz. 8197 males, and 9276 females: 123 families being employed in agriculture, and 1207 in trade, manufactures, and handicraft.

COTTONENT, in America, l. 4, add—containing 1938 inhabitants; l. 6, r. 2928; l. 8, r. 162; l. 12, add—In 1810 it contained 178 persons; l. 13, r. having 1608 inhabitants.

COUGHING, in Physiology. See Lungs.

COUCHE, col. 2, l. 5, r. the king’s premier, &c.

COURONNE des Taffes, an apparatus constructed by professor Volta, in which he arranges the component parts of the galvanic pile in a different form. (See Galvanism.) This apparatus consists of a cell of small glaffes, placed sideways of one another, and containing water or some salina folution. Metallic arcs are then procured, having one end composed of zinc, and the other of silver or copper: these arcs are inserted into the glaffes in an uniform order; each glaffe having the zinc leg of one arc, and the copper or silver leg of another arc immerfed in the fluid. The zinc and copper legs are not in contact, and they are always to be disposed in the same situation with respect to each other; i.e. one is always to be at the right-hand, and the other at the left. The pile and this apparatus operate in the same manner, and their operation is referred by the professor to his new principle (see Voltaism), by which he conceived different metals, when placed in contact, to destroy the electric equilibrium, or, in his phrase, to become movers of electricity, producing that electric motion which is supposed to be the primary and essential cause of the galvanic action.

COURT, University, col. 2, l. 4, r. 14th.

COURUPITA for Coupita.

COWBRIDGE. In 1811, the parish contained 158 houses, and 850 persons; 425 being males, and 425 females.

COW-TAIL RIVER. See Wau-ca-Hatcho.

CRACKS, col. 4, l. 15, for bone r. cone.

CRAFTSBURY, in Geography, a town of Orleans county, in the State of Vermont.

CRAIL. In 1811, the burgh and parish of Crail contained 316 houses, and 1600 persons; viz. 673 being males, and 927 females.

CRANBERRY. Add—Also, a town of Butler county, in Pennsylvania, having 543 inhabitants.

Cranborne. In 1811, the parish of Cranborne contained 144 houses, and 816 persons; viz. 429 being males, and 387 females.

CRANBROOK. Add—The parish of Cranbrook, by the return of 1811, has 511 houses, and 2994 persons.

CRAVEN, l. 4 and 5, r. 12,676, and 5050.

CRAWFORD, a county of Pennsylvania, containing fourteen townships, and 6178 inhabitants.

CRAYFORD. In 1811, the parish contained 233 houses, and 153 persons; viz. 760 being males, and 754 females.

CREAM, Chemical Analysis of. See Milk.

CREDITON, L. 8. from the end, r. and the hundred contains, by the return of 1811, 2130 houses, and 10,648 inhabitants; L. 5, after extent, add,—But the borough of Crediton contains only 425 houses, and 1846 inhabitants.

CREWKERNE, col. 2, l. 4, for 41 r. 51; L. 5, r. of houses was 589, and of persons 3021, of whom 1346 are males, and 1675 females; 281 families employed in agriculture, and 308 in trade, &c.

CRIBRARIA, in Botany, from its perforated structure, Perf. Syn. Fung. 189; one of those beautiful, though minute, genera of Fungi, whose head is formed of reticulated filaments, encircling the powdery feeds. Perfocon reckons up eleven species.

CRICKHOWEL. In 1811, the parish contained 157 houses, and 611 inhabitants. In the hundred of Crickhowel is a Roman encampment, called the Gari, situated at the extremity of the vale, on a rising ground. The dimensions are much the same with those of Caer-Bannau (see BANNA), and it is nearly of a square form. It lies on the Via Julia, which passed in this direction from Caerleon to Caerlennih in Carmarthen. We are informed that the old practice of fingling coins in the church at cock-crowing, or the earliest dawn of the morning, on Christmas-day, is still continued in the church at Crickhowel; but it merits any other appellation than that of a religious rite.

CRICKLADÉ, l. 14, r. 51; L. 15, r. 1893, and 2009; l. 16, 10,403; l. 17, 4894, and 3509; 1483 families chiefly, &c.; l. 18, r. 411.

CRISTARIA, in Botany, from the wings or crofts of the aggregate capsules, by which alone it is distinguished from SIDA (see that article).—Cavan. Ic. v. 5, 10. Pursh 453. Sims in Curt. Mag. 1675.—We can hardly at all to the establishment of this genus, its character being entirely artificial, and unaccompanied by any thing discriminative in the habit. The only species mentioned are, 1. C. glaucophylla, Cavan. Ic. t. 418. 2. C. multifida, which is our SIDA pterosperma, the last species but one in that article. 3. C. cocinea, Pursh n. 1. Curt. Mag. t. 1673, a native of the dry plains of the Mifflun, perennial and hardy in our gardens, adorned with beautiful scarlet flowers. 4. C. botanica, Cav. as above, 11, which is Malacoides betonica folio, &c. Feuill. Voy. v. 3, 40. t. 27.

CROMER. At the close, add,—the parish contains, by the returns of 1811, 170 houses, and 848 inhabitants.

CROSBY, a township of Hamilton county, in Ohio, having 981 inhabitants.

CROSS-CREEK. Add,—containing 1847 inhabitants.—Alfo, a township of Ohio, in Jefferson county, having 1152 inhabitants.

Cross-Wort. Add.—and Valentina.

CROTALUS, col. 3, l. 19, r. to have them come, &c.

CROTONEPSIS, in Botany, from xiphus, Crotos, and ephy, appearance; but the principle of the name is incorrect, insomuch as the Greek xiphus is our Ricinus, to which genus in question bears no resemblance; and if the Crotos of modern botanists be intended, such a comparative appellation is contrary to rule.—Michaux Borel.—Amer. v. 2. 185. Willd. Sp. Pl. v. 4. 380. Pursh 206.—Cliffs and order, Monocotyledonea. Nat. Ord. ?

Capsule superior, not burfling, with one seed.

1. C. argentea. Silvery Crotonepsis. Pursh n. 1. (C. lineata; Michaux 180. t. 46. Willd. n. 1. C. elliptica; Willd. n. 2.)—Native of North America, in sandy ground near the coast, in the Illinois country and on the Mifflun, flowering in July. Pursh. A slender annual herb a span high, with opposite or alternate entire leaves, variable in breadth, and loose spikes of minute white flowers. The pubescence consists of fringed silver scales, as in Crotus.

CROUDESE, r. See Ballotade.

CROW'S NECK, in Natural Language, is a kind of box, sufficient to hold a man; generally a cleft, fixed near the mast-head, to protect the observer from cold, and enable him to look out for whales, or open pieces of water.

CROYDON. The parish of Croydon, in 1811, contained 1374 houses, and 7801 inhabitants; 3616 being males, and 4185 females; 3357 families employed in agriculture, and 662 in trade, &c.

Croydon. Add.—and in 1810, 802 inhabitants.

Croydon Canal, l. 3, r. Surry.

CRUCIOSTRA, CROSS-BILL, in Ornithology, a genus of birds of the order Pufius; the characters of which are, beak thick and forked; mandibles, when at rest, inerally curved; nostrils small, rounded, situated at the base of the beak; tongue entire. Mr. Stephens, the contributor of Dr. Shaw's Zoology, mentions and describes two species; one of which, or common crows-bill, beak externally olive-green, and tail feathers; the other, or Loxia curvirostra of Linnaeus; and the crows-bill with a dull crimson body, wings black, with two white feathers, secondary quills white at the tips, and tail black, the Loxia leucoptera of Gmelin, and white-winged crows-bill of Latham and Pennant.

rather tender annuals in our gardens, of no striking appearance.

Eff. Ch. Calyx-leaves and petals linear, spreading. Flower reversed. Lip erect, sessile, dilated, undivided; concave at the base, concealing the very short column. Anther parallel to the stigma, subtended at each side by a lobe of the column.

Bulbs clustered. Leaves few, radical, fleshy, flat. Flowers in a terminal spike, dull red, ftenfent.

1. C. longifolia. (Malaxis fulvulata; Labill. Nov. Holl. v. ii. 24. 1. 2.) found at Port Jackson, as well as on the south coast;

2. C. ovata; and 3. C. eretta; are the only described species.

CRYSTAL, col. 5, l. 19, for changed r. charged.

CRYSTALOGRAPHY is the science which treats of the form and structure of crystals. (See Crystal.)

The beautiful symmetrical forms, which frequently occur in the deep clefts of mines or the fissures of alpine rocks, cannot fail to strike the most common observer with surprise. Amidst the utmost infinite variety which they present, it will be found, on a more attentive examination, that there are certain definite forms which some minerals most frequently assume, and which are rarely, if ever, seen in other minerals. Hence we might at first be led to infer, that crystallization depends on the definite action of some general law, by which the constituent parts of each mineral species are invariably arranged in the same form. When, however, it is farther considered that, besides the prevailing forms peculiar to certain minerals, the same species are not unfrequently crystallized in a variety of dissimilar forms, and that minerals of different species often present crystals of the same form, we must retract our first conclusion, and shall be more disposed to believe that the mineral kingdom has not yet emerged from a chaotic state, or that the reign of order is subject to the invasion of disturbing forces, the extent of which we have no means of ascertaining.

The labours of a few enlightened and indefatigable philosophers have recently removed, in a great degree, the obscurity in which this department of science was involved, and have demonstrated that the laws by which the particles of the minutecst crystal are arranged act with unerring precision, and are not less regular than those which govern the motions of the planets or the solar system.

Under the article Crystal (which see), some account is given of the discoveries of Romé de Lisle, Bergmann, and Hauy. The latter has ably demonstrated that all the varieties of crystalline forms are reducible to a few simple primitive forms, some one of which may be regarded as the nucleus of each crystal, however complex its form may be. The constituent particles, or what Hauy denominates the integrant molecules, of all crystals, may be conceived as arranged in rows, and a number of these rows as forming thin laminae or plates. When these laminae are parallel with all the faces or planes of a crystal, they may be removed without changing the form of the crystal; but if the laminae divide in any other direction than that which is parallel to the faces, a change of form will be produced by every division, until at last we obtain a nucleus which is divisible in a direction parallel to its sides.

In the former case, the primitive form is the form of the crystal itself. Thus, if a cubic crystal be divisible only by laminae parallel to its six sides, we may continue diminishing the magnitude of the crystal, as long as mechanical division is possible without any change of form.

When the laminae of a crystal divide in any other direction than parallel to its faces, it is called a secondary form or derivative crystal.

The primitive forms of all crystals which have been hitherto examined are six.

1. The parallelepiped, bounded by six planes, the opposite planes being parallel. This includes the cube, and varieties of the rectangular prism, the oblique angular prism, and the rhomboid.

2. The octahedron. This is a double four-sided pyramid. When the triangular faces are equalateral, it is called a regular octahedron. (Plate VII. fig. 27, Crystallography.) There are, besides this, other varieties of the primitive octahedron, in which the pyramids are longer or shorter than the regular one, or have a rhomboidal base, or a rectangular base, longer in one direction than the other.

3. The regular tetrahedron (Plate VII. fig. 13.) is bounded by four equilateral triangles.

4. The regular hexahedral prism, or equiangular six-sided prism, fig. 5.

5. Rhomboidal dodecahedron, bounded by twelve equal rhombs, fig. 12.

6. The pyramidal dodecahedron, consisting of two six-sided pyramids joined base to base, fig. 14.

The primitive forms which most frequently occur are, the parallelepiped and the octahedron. The tetrahedron and dodecahedron are very rare as primitive forms, though common as the secondary forms of crystals.

The division of secondary crystals by sections in the direction of the lamina is, in some minerals, effected with facility; in others, the joints are indefinite, and require the crystal to be heated and plunged into cold water to make them visible. The direction of the lamina is frequently rendered obvious by turning a mineral slowly round in the sunshyne, when the reflections from the internal parts will show its structure. Where no joints are discoverable, Hauy determines their direction and the form of the primitive nucleus by conjecture, from the appearances offered by the secondary crystal.

The actual mechanical division of an hexahedral crystal of calcareous spar, and the extraction of the primitive, is represented in Plate II. figs. 17, 18, 19, 20, Crystallography; and is described under the article Crystal; but the references are erroneously made to Plate I. figs. 1, 2, 3, 4, 5.

The primitive nucleus is represented fig. 21, E A, O I, G H, A K. The discovery of it in this crystal was first made by the abbe Hauy in looking over the cabinet of M. Defiance, a hexahedral prism of calcareous spar having fallen from the group to which it was attached. M. Defiance made him a present of it. One of the corners being off from the base, he attempted to detach similar corners from the other angles, and after some time he succeeded in bringing to view its rhomboidal nucleus. This first suggested to him the theory of the structure of crystals. The division of this primitive form, in another variety of calcareous spar, called the dog-tooth spar, may be seen Plate II. figs. 22 and 23. This is described under the article Crystal, with the mode of extracting the nucleus; but the reference is erroneously made to Plate I. figs. 6 and 7. The angles of the primitive rhomb are invariably 105° 5' and 74° 55'. Rhomboïds of calcareous spar, indeed, occur with different angular dispositions; but these are secondary crystals, and will not split in directions parallel to their faces. One of these, with the primitive nucleus, is represented.
CRYSTALLOGRAPHY.

represented fig. 24. The theory of their formation will be explained as we proceed.

The primitive form is not in all cases the ultimate form to which crystals can be reduced; for where the primitive form is not a parallelopiped, the division parallel to the faces necessarily produces forms which must vary from that of the primitive nucleus. See Plate V. fig. 56. Crystallography, which represents the base of a fixed-sided prism, divided by sections parallel to each of its sides: from this division the ultimate form which we can ever obtain must be that of a triangular prism; for by carrying on the division we may conceive the particles to become smaller, but their form will remain the same. We have therefore obtained the form of the integrant molecule. In parallelopedia, the form of the nucleus is also that of the molecule itself.

Thus in the cube, as represented Plate IV. figs. 48 and 49, the divisions parallel to the sides produce a series of smaller cubes, which must be the form of the integrant molecule. In some instances, the primitive forms themselves admit of division by laminae not parallel to that of the faces, from which must necessarily result a new form of the integrant molecule.

Plate II. fig. 26. represents a primitive rhomboid of tourmaline A E, O I, G H, A K, which is divisible both in the direction of its six faces and in that of the short diagonal A O, I A, V A, A K. These latter sections divide the rhomboid into six tetraedrons, which are represented surrounding the nucleus. Hairy conceivethat by these divisions, we obtain the form of the integrant molecule, or of the ultimate integrant atom of the crystallized mineral. It has been observed, that no proof can be advanced to confirm this conjecture, except the impossibility of altering the form, how far we can carry the divisions; and the obvious consequence is, that if these divisions be carried far enough, we must at last reduce the crystal to its integral particles. It is not, however, necessary to suppose, that the constituent particles themselves have any other form than that of spheres; because all the forms of the integrant molecule, which are the tetraedron, the triangular prism, and the cube, may be readily conceived to be constructed with four, six, and eight spherical particles, arranged in their forms by crystalline polarity. It deferves attention, that the forms of the integrant molecule are the most simple which can exist among solids with plane surfaces, being bounded respectively by the smallest possible number of sides, viz. four, five, and six.

If we conceive the integrant molecules to be arranged in rows, and a number of these rows to be arranged in the same planes, they will form laminae of any conceivable size. Now by a succession of plates increasing in size, the magnitude of the primitive crystal will be increased; but if these laminae decrease in extent by one or more rows of particles, the result will be a change of form, or the production of a secondary crystal. Now the laminae may either decrease on the edges by one or more rows, or may decrease diagonally on the angles by a determinate number of rows, or the decrease may take place in some intermediate direction. These are called by Hairy, decrements on the edges, decrements on the angles, and intermediate decrements. Sometimes decrements take place at once on all the edges, sometimes upon all the angles, and sometimes only on certain edges and angles. In some instances the decrements are uniform, and the same number of rows decrease from the different edges or angles. Sometimes the law of decrement varies from one edge to another, or from one angle to the other; and this happens chiefly when the nucleus has not a symmetrical form, or when it is a parallelopedic, whose faces differ in the respective inclinations of their faces, or in the measure of their angles. In certain cases, the decrements on the edges concur with those on the angles to produce the same crystalline form. It happens also, that the same edge, or the same angle, sometimes undergoes different laws of decrement that succeed each other; and, finally, there are a great many cases where the secondary crystal prefers faces parallel to those of the primitive form, and which combine with the faces produced by the decrement, to modify the figure of the crystal.

If, in the midst of such a diversity of laws, sometimes acting solitarily, and sometimes in combination upon the same primitive form, the number of ranges subtrahend were likewise variable; if, for instance, there were decrements of twenty, thirty, forty, or a greater number of ranges of molecules, of which it is very possible to conceive, the multitude of forms which might exist in each mineral species would be sufficient to make the imagination baffle the study of crystallography would present an immense labyrinth, from which even the affinities of theory could not extricate the learner.

But the force which produces the decrements of ranges appears to have a very limited action. Generally these subtractions take place by one or two rows of molecules. None have hitherto been found beyond six rows; but such is the fecundity united with this simplicity, that were we to confine ourselves to decrements by one, two, three, and four rows, and to exclude those that are mixed or intermediate, we find that the rhomboid is susceptible of 8,588,604 varieties of crystallization. Doubtless many of these varieties do not exist in nature; but there is reason to expect that discoveries in the field of inquiry will be made for many years to come.

The tetraedron and the triangular prism, when they occur as integrant molecules, are always arranged in such a manner in the interior of crystals, that, taking them in groups of two, four, six, eight, they compose parallelopedia. These parallelopedia are, by Hairy, named subjacent molecules. They are always substitutified in the place of tetraedrons and triangular prisms in considering the decrements where they produce the secondary forms.

Decrement of the Edges.—The most simple case of change of form produced by the superposition of decreasing laminae, is that which supposes ranges of molecules to be taken away on all the edges of a paralleloped, in a direction parallel to the edges. Yet this case, so simple in appearance, may give rise to forms of considerable complexity. Thus the rhomboidal dodecahedron (Plate II. fig. 27, or Plate III. fig. 28. Crystallography) may be formed in this way from a cubic nucleus. If the integrant molecule of this species be a cube, it follows that the primitive crystall EA, O I, and E'A', O'I', is formed by a congruities of cubes. Suppose these cubes of such a size, that an edge of the primitive crystal is composed of a row of seventeen cubes, placed side by side, as represented fig. 29. I O, E O: of course each face of the primitive crystal will be a congruities of 289 squares, consisting of so many integrant molecules; and the primitive crystal or cube will be a congruities of 4913 cubes. Let us suppose that a square surface or plate, of the thinnest of one integrant molecule, be applied to every face of cube; but that instead of being of the same size as the face of that crystal it is left by a single row of molecules all round; so that the sides, instead of containing seventeen little cubes, contain only fifteen each (see fig. 29); of course this square will contain only 225 little cubes, instead of the 289 that form the surface of the primitive crystal. Upon each of these first plates applied to every face,
face, let another plate be applied similar to the first, but less than it by a row of integrant molecules; so that each side contains only thirteen squares, and the whole only 169 squares. Let six other plates be applied in succession to each of the faces, decreasing by a row of little cubes all round; so that the sides consist of eleven, nine, seven, five, three, and one squares respectively. It is obvious, that by this process we have raised upon each of six faces of the cube a four-sided pyramid, the faces of which, instead of being smooth, will, by their constant diminution of bulk, represent the steps of stairs. If, however, we conceive the molecules to be extremely small, and the number of decreasing laminae to be increased, the steps of the stairs may be so small as to be imperceptible to the eye, in which case the surfaces of the pyramids will appear smooth. These pyramids having each four faces constitute twenty-four triangular faces, so that the cube is converted into a new crystal. Instead, however, of having twenty-four faces, the decrements having been equal on each edge, the triangular faces in each adjacent pyramid will be in the same plane, and form together a rhomb, which will be evident from the inspection of fig. 29; the cube will therefore be converted into a rhombohedral dodecahedron. The cubic nucleus I'I', O'O', E'E', fig. 29, is represented with the pyramids raised on three of its faces. When complete, it will have the form represented in Plate II. fig. 27. If the decrement had taken place by two ranges on each of the laminae, when applied to the cube the pyramids would have been lower; and their adjacent faces being no longer in the same plane, the secondary crystal would have terminated in twenty-four different triangles. 

In the example given (fig. 29.) it will be seen, that as each of the laminae decreases by one row on each of its edges, viz. one on I O, and another on the inferior row I'O', and the faces on the other edges, it is obvious that the pyramid decreases by two rows in breadth for every row in height; therefore the height will be equal to half the breadth at the base.

The terms decrement in breadth, and decrement in height, are thus explained by Haidy. Decrements in breadth are those in which the thickness or height of each plate or lamina is only equal to one integrant molecule; and the result of the decrement is by one, two, three, or more ranges in the direction of the breadth.

Decrement in height implies a decrement of one row in breadth on each of the successive plates; but each of these rows may have the thickness or height of two, three, or more molecules. In the latter case, the decrement is said to take place by two, three, or more ranges in height.

These two kinds of decrement are often combined together, of which we have an example in iron pyrites with twelve pentagonal faces. (Plate III. fig. 30.) This variety has a cube for the nucleus, as represented fig. 31; and may be conceived to be formed, as represented fig. 32, by decrements of two ranges in breadth in one direction, and by decrements of two ranges in height in the other. The decrements in breadth by two ranges tend to produce a more inclined face than the decrements by two ranges in height; the consequence resulting is, that the crystal will not terminate in pyramidal points, but in wedges, as seen at q p, fig. 32. The structure of this crystal is more particularly described under the article Crystal; but for Plate I. Nos. 14, 15, 16. r. Plate II. fig. 30, 31, 32. Crystallography.

Another example of decrements on the edges is deserving particular attention: it is afforded by that peculiar kind of crystal of calcaceous spar, commonly called dog-tooth spar, or which Haidy denominates the metallic crystal. (Plate II. fig. 22.) In this crystal, the edges E O, O L, I K, where the two opposite pyramids join, coincide with the edges of the primitive nucleus, as may be seen in fig. 24. The decrements set out from these edges, and do not take place on the other six edges of the nucleus. Now it is easy to conceive, that the edges of the plates, laid upon the primitive nucleus, form as many triangles, E O O', I O E' O', &c. resting upon the edges from which they set out; and as there are six in number, there will be twelve triangles, six above and six below; and these will all be scalene, in consequence of the obliquity of the edges from which they set out.

With respect to the other edges of the plates of superposition, so far from experiencing any decrement they will increase; because they must always remain contiguous to the axis of the crystal, which is an imaginary line drawn from r to s. It is from calculation combined with observation, that we must determine the law of decrement on which this dodecahedral form depends. If we suppose a decrement by one range, it may be demonstrated, that the faces produced on each side of the edge from which the decrement takes place will be in the same plane, and parallel to the axis of the primitive crystal, conditions which do not apply to the present form. The most simple hypothesis is that which supposes a decrement by two ranges in breadth. This will be more clear from inspecting Plate III. fig. 33: it represents the upper pyramid of this crystal, placed on the upper planes of the primitive nucleus, which being partly visible, admits us to perceive more clearly the progressive effects of the decrement by two ranges.

Each edge of the nucleus, as K I, I O, O E, is divided into ten; from whence it follows, that each face is an assemblage of one hundred small rhomboids, which are the exterior planes of so many molecules. This construction requires only eight plates of superposition for each face of the nucleus; and these plates being joined to each other, three and three on the edges, which correspond with the upper edges of the nucleus, form decreasing envelopes, covering each other in succession; the last of which is composed of eight little rhomboids. If we consider the position of the line E s, which represents an edge of this pyramid, as it appears to the eye, and E's, such as it really exists, we may observe that the geometrical summit of the pyramid s is placed a little above the true summit s'; but this difference is imperceptible, on account of the extreme minuteness of the molecules; and for the same reason, the channels or steps upon the pyramid are not visible. There are cafes, however, in which the channels may be perceived by the naked eye.

For determining the form of secondary crystals by calculation, it is only necessary to take the decrements at their commencement, in order to have as many planes, which, if we conceive them to be extended until they meet, would form a complete polyhedral crystal; and in this manner we only consider the initial effects of decrements mathematically, a method more simple and expeditious than that of reasoning. It is useful, however, to explain in detail the structure of a crystal, in such a manner as may enable us to arrange a number of small solids similar to primitive molecules to form a nucleus, in an order conformable to that of nature, and thus to imitate the process of crystallization. We shall give another example from that variety of calcaceous spar, called by Haidy equiaxe.

This variety, the secondary crystal, is a rhomboid, much more obtuse than the nucleus, the greater angle being 114° 18' 60". It is represented (Plate III. fig. 34) surrounding the nucleus. To extract the latter at once, it is only
only necessary to make sections cutting through the oblique
diagonals of the different faces of the secondary rhomboid.
One of the sections, for instance, that which passes through
the diagonals drawn from a to t, and from a to u, and which
cuts off the solid angle $\alpha$, coincides with the face $a, b, d$, of
the nucleus. But there are six lateral solid angles $\alpha, \beta, \gamma,$
and $t, m, u$. We have, therefore, five sections to make,
inclined three and three towards each summit; and because
the upper solid angles alternate with the inferior, the sections
which cut them off preserve the same alternation, and cross
in such a manner as to present the fix rhomboidal faces of
the nucleus.

To conceive the structure of this secondary rhomboid, let
us refer to the rhomboidal dodecahedron (Plate III, fig. 29.)
before described. We have seen that by a decrement of one
range in breadth on all the edges, there resulted two triangu-
lar faces on each edge, which being in the same plane
formed a rhomb, the short diagonal of which is I O.

Let us suppose, that the nucleus was the primitive rhomb
of carbonate of lime (a b, d f, fig. 34.), and that the laminae
of superposition decrease by one range of little rhomboids
similar to the nucleus; but the decrements to take place only
on the edges $a b, a f, a n,$ which meet at the summit $a,$ and
on the opposite edges, which meet at the opposite point $d$.
Then instead of twelve rhombes there will only be six, of
which the shorter diagonals will coincide with the edges
$a b, a f, a n, &c.$ The other parts of the laminae of super-
position, that is, those which are situated near the lower
edges, $b d, d f, f n, &c.$ will not undergo any decrement,
but will suffer variations that will tend to prolong the faces
produced by these decrements, until they intersect each
other. From hence it results, that the lamina, instead of
preferving the figure of a rhomb, as would have been the
case if the decrement had taken place on all the edges, will,
as they are further and further removed from the nucleus,
pass successively from the figure of a pentagon to that of a
triangle.

Fig. 35. $A$, a b $d f$, is the face of the face nucleus or rhomb
as in fig. 34., and what is said of this face may easily be
applied to the others. Suppose this face divided into 81
rhombes, which represent the faces of so many molecules, or
729 in the whole. The first lamina of superposition, which
we apply to the face a b, d f, will be B, fig. 35., in which U l,
Z $d$, represent the upper face, and C U b, X Z b, the
facets of the two upper edges. We must place this lamina in
such a manner on the face a b, d f, that the point $b$ shall unite
with the point $b$, the point A' with the point A, and the
point B' with the point B. We shall perceive immediately,
that the two upper ranges of the face a b, d f, fig. 35. A,
that is, the included between a b, A b, on one side, and
a f, B b, on the other, will remain uncovered, the necessa-
ary result of a decrement by one range of molecules.
The lamina B is a pentagon resulting from the subtraction
of the three little rhombes necessary to complete the rhomb.
This subtraction was required, that the lamina by its figure
might aid the effect of the decrement, as will be afterwards
explained.

The two ranges of rhomboids on each side of the lines
D d', E d', are added, that the nucleus may be covered and
continue to increase on the edges $b d, d f, d, A$, fig. 35., which
Correspond with these lines. These two ranges being
sufficient to fill up the void, it is not necessary to add similar
ranges towards the adjacent edges of the laminae of super-
position, applied on the neighbouring faces. The operation
will indicate of itself what is required in these kinds of addi-
tions.

The fig. C, 35. represents the second lamina of super-
position, which is to be applied to the former in such a
manner, that the points $t, D^2, E, d,$ shall unite with those
which are marked with the same letters in fig. B. As the
crystal will receive another increace towards the edges, which
Correspond with $F d', C d'$, we may conceive that instead of
one range added on each side $D d', E d$, in fig. B, it will be
necessary to add two on each of the two lines $E d', C d'$,
fig. C, 35.

We must place in the same manner, in succession, the two
laminae represented D and E, fig. 34.; observing that
the letters marked with an accent in each figure shall coincide
with the same letters not accented in the preceding figure.
Beyond the series which answers to fig. E, the laminae
of superposition will cease to envelope the lower edges of
the crystal, and will be reduced to simple triangles, which may
be perceived on examining the figures E, F, G, H, whose
shape will be determined according to the conditions
before stated.

The number of rhomboids which compose the laminae
being now progressively decreasing, is reduced at last to a
single rhomboid $d'$ (fig. D, 35.), which being applied on
that which is designated by the same letter in fig. H, will
form the summit of one of the lateral solid angles of the
secondary rhomboid. It will now be seen why the laminae
of superposition take successively pentagonal and triangular
faces as they recede from the nucleus. For example, every
lamina, detached from the crystal (fig. 34.), by a section which
passes any where between the angle $\alpha$, and the middle of
the lines Z t, Z u, is necessarily triangular, and has the same
structure as $P^2 t R^1$, fig. G, 35.; namely, it is really furrowed
at its base, but the ridges are imperceptible on account of
their extreme minuteness.

Decrements on the Angles.—To explain the formation
of secondary cryftals, in many infances it is necessary to admit
that the decrements take place on the solid angles. The
formation of the regular octahedron formed on the cube is
represented Plate III. fig. 36. Crystallography, and an
account of it is given under the article CRYSTAL, but the
reference is erroneously to Plate I. fig. 20.

The effect of decrements on the angles by one range of
molecules in breadth is explained in the article CRYSTAL, and
a reference made to Plate I. fig. 21, for which see Plate II.
fig. 21. Mifcellany, O I, O 8; where the face of a cubic
nucleus is represented as divided into a number of lesser
figures; and fig. 23, A, B, C, D, E, F, G, H, I, in the
same plate, represent a successive series of plates, or lamina,
placed on the cubic nucleus, each decreasing by one row on
the angles. These are described under the article CRYSTAL,
but referred to Plate I. fig. 23: by applying that description
to the proper figures as here given, the reader will be able to
comprehend this case of decrement, where a regular
octahedron is formed on a cubic nucleus. The arrange-
ment of the integrant molecules on one of the triangular
faces of the octahedron is represented Plate IV. fig. 37.
Crystallography.

If the decrements on the angles of a cube were to stop
before they terminated in points, there would remain faces
parallel with that of the cube, which will be evident from
inspecting Plate III. fig. 36. The crystal would then have
fourteen faces, eight those of the octahedron, and fix those
of the cube. Nothing is more common than to find such
crystals both in iron pyrites and in galena.

As another example of decrements on the angles, let us
take the rhomboid (Plate IV. fig. 38.), which differs some-
what from the cube. If the plates applied successively
upon all the faces of this rhomboid suffer decrements only
at the angles contiguous to the summits A and O; and that
these
these decrements take place by two ranges, then instead
of twenty-four faces, only six would be formed; and if we
suppose these prolonged till they meet each other, they
would conjointly form a very obtuse rhomboid (fig. 39.)
encircling the nucleus. The summits, A, O, coincide with
the summits of the nucleus, from which the decrements
commenced, and each of the faces A e i o corresponds with one
of the faces of the nucleus; so that the diagonal which passes
through the points e i is parallel with the diagonal E I of
the nucleus, but somewhat more elevated. This kind of
crystal is found among the secondary crystals of oligite
iron-ore.

As a further illustration of the different variations of
which the decrements, whether of the superior or inferior
angle, are susceptible, let G g be any rhomboid whatever
(Plate IV. fig. 45.), the summits of which are S. Let
S g', b G', fig. 46, be a quadrilateral figure formed by cutting
through the rhomboid G g in the direction of a plane,
formed by the two oblique diagonals S g', i G', fig. 45., and
the edges S G, S g. This quadrilateral figure, termed by
Haei the principal section of the rhomboid, is divided in
the figure into a number of small quadrilaterals repre senting
the principal section of as many molecules. Let S G, S g, S G',
fig. 47, be the face of the rhomboid, fig. 45, marked with
the same letters, and subdivided into the faces of the mole-
cules of which it is composed. If we suppose that the
angle g" undergoes a decrement by a single row of mole-
cules, the small rhomboid represented by e n = g" will be
wanting; hence it is obvious, that the edges of that plate
will have the direction a n, and that the distance between the
angle g", from which the decrement sets out, and the edge
e n, will be measured by the femidiagonal of a molecule,
or r g. If the decrement took place by two ranges, the edge
q, the first plate of superposition, will correspond with
c d, and the distance between it and the edge g" will be
measured by the diagonal molecule g n. Hence we may
conclude, that in the decrements on the angles, the distance
between one plate and the succeeding one, which is the
same as between the point of departure and the edge of the
first lamina, is equivalent to as many semidiagonals of a
molecule as there are ranges taken away, as will be further
evident by inspecting fig. 37. But in decrements on the
edges, the distance between two successive plates is equal to
the breadth of as many molecules as are taken away.

This being understood, let us suppose a decrement of two
rows upon the angle g". In that case, the quadrilateral
n r p, fig. 46, being a section made in the first plate of super-
position, the decreasing edge of this plate will coincide
with the little edge e n, since g n is the same diagonal as in
fig. 47; therefore if we draw the straight line g' g b, it will
coincide with the face produced by the decrement. But
the angle g" b being, in this case, parallel to the axis S A, as may be
demonstrated geometrically, hence it follows that the
secondary faces constitute the faces of a prism. If the
decrements went more rapidly, the faces of the secondary
crystal would have different angles of inclination to the
axis, as will be evident from inspecting Plate IV. fig. 46. If
the decrement were by four ranges, for instance, the edge
of the first plate of superposition would coincide with the
line e g; then the line g q g' indicates the position of the
face produced by the decrement. What has been stated,
where the plane is parallel to the axis, holds true with respec-
to all possible varieties of the primitive rhomboid.

Mixed Decr ements are those in which the number of ranges
taken away in breadth and height give ratios, the two terms
of which purpafs unity. As, for example, decrements by
two ranges of molecules in breadth, and three in height, or
by three ranges in breadth and two in height, &c. It is easy
to see, that the theory may with facility be reduced to that
of decrements, in which there is only one row of molecules
taken away in one of the two directions.

Intermediate Decr ements,—These will be best explained
by references to the figures.

Let A A', Plate IV. fig. 48. be a paralleloiped of any
kind, which undergoes a decrement by two ranges on the angle
E O I of its base A E O I. It is obvious, that the
dges of the plates of superposition will have the direc-
tions b o r t, parallel to the diagonal E I, and so situated
that these will be upon the sides O E, O I, two rows of mole-
cules comprehended between the angle O and the line b e,
and likewise between b e and r s. But as has been already
said, the plates applied upon the adjacent faces I O, A' K,
E O, A' H, undergo likewise auxiliary decrements, which
continue the effect of the decrement upon the angle E O I.
But such, in this case, are the effects of these decrements,
that the edges of the plates applied upon I O, A' K have the
directions e g, s t, and those of the plates applied upon E O, A' H,
the directions b o g, n t; for since the lower edge of the first
plate applied upon E O I coincides with b e, and the height
of this plate corresponds to that of a single molecule, a little
attention will satisfy us, that the plane b e g, which, on one
part, coincides likewise with b e, and, on the other, separates
from the base A E O I by a quantity measured by O g, the
height of a single molecule, is necessarily parallel to the face
produced by the decrement. The fame holds with the plane
r t s. From this it follows, that if we suppute the part
situated above r t s, we shall have a solid on which the face
r t s will repre sent the effect of the decrement which we are
considering.

Now, the direction e g, s t, of the plates applied upon
the face I O, A' K, (and the same face may be said of the face
E O, A' H), in consequence of the auxiliary decrements are
neither parallel to the edge, nor to the diagonal of the face,
but intermediate between the one and the other. This
want of parallellism will become still greater, if we suppute
the decrements upon the angle of the base E O I to take place
by three or four ranges. This is the kind of decrement to
which the name of intermediate has been given. It is ob-
vious, that it may take place in an infinite number of
rather directions, according as it deviates more or less from
its two limits, the parallellism with the edge and the dia-
gonal of the face.

In cases similar to those of Plate IV. fig. 48. we avoid
the complication introduced by these intermediate decre-
ments, by supposing them comprehended under the principal
decrement. But certain crystals exist in which all the three
decrements round the face sole angle are intermediate. In
such a case, the fimplest of the three is chosen as the prin-
cipal decrement, and the other two considered as auxiliary.
Fig. 49. represents a case of this kind: e n, which is the edge
of the first of the plates applied upon A E O I, is so situated,
that on the side of O I there are three molecules subtracted,
while on the side O E there is only one: n p, which is the
edge of the first plate applied upon I O, A' K indicates
three molecules subtracted from O I, and two from O A':
c b, which is the edge of the first plate applied upon E O, A' H,
flaws the subtraction of two molecules on O A', and
only one on O E.

It is easy to see, that the decrements take place relatively
to the different faces situated round the angle O, as if the
molecules that compose the different plates of superposition
were united invariably several together, compose other mole-
cules of a higher order, and as if the subtraction took place
by single ranges of these compound molecules. Thus there
will
CRYSTALLOGRAPHY.

will be on the base A E, O 1, a decrement of triple molecules by two ranges in height, since on one part, the quadrilateral figure $\triangle O \pi s$, which represents the base of a compound molecule, is equivalent to the bases of three simple molecules; and on the other, the line $O \rho k$, which corresponds to the height of a plate of superposition, is equivalent to the height of two simple molecules. It is easy to conceive likewise, that the decrement relative to the face $E O, A' K$, takes place by two ranges in height of double molecules; because $O \rho k$ contains the bases of two simple molecules, and $O n$ is equal to the length of three simple molecules. In the decrement which takes place upon $I O, A' K$, there is a subtraction of one row of molecules, triple in one direction, and double in the other.

Among these three decrements, the one which it appears natural to adopt as the principal, is the second which takes place upon the face $E O, A' H$; because it is the one whose direction deviates the least from that of the diagonal $E A'$, or because it takes place by double molecules, which is a more simple decrement than the other two.

To give some further examples of intermediate decrements, let us suppose $O I, I'O'$, one of the faces of cubic nucleus (see Plate IV. fig. 50. Crystallography); and that the decrement took place on the angles by the subtraction of double molecules: in this case, the edges of the laminae of superposition will be in the direction of the lines of $d n, k m, \ell r, l \ell$, always by subtraction of double molecules, but in such a manner, that there shall be three ranges taken away in the direction of the breadth, and one in that of the height: in this case, the decrements will be both intermediate and mixed. Suppose also that the edges of the laminae of superposition, situated around one solid angle $O$, had directions which crossed, so that with respect to the face $O I, I'O'$, the greatest number of the faces of the molecules should be taken away on the side $I'O'$; but on the face $E O, O E$, it should be on the side $O O'$, and with respect to face $E A, I O$, it should be on the side $E O$; the effect of these different decrements would produce three faces round each solid angle, which would be situated in an inclined manner with respect to the faces of the nucleus; and because the cube has eight solid angles, the secondary crystal would have twenty-four faces, which would tend to unite four and four, and form the summit of a pyramid round each face of the nucleus. But if we suppose the decrement to cease before these are completed, there will remain six faces parallel to those of the nucleus, and we shall have a polyhedral crystal of thirty faces, as represented fig. 52. The angles $k m, l \ell$, corresponding with those of the nucleus, are rhombs; and the faces $m l, r o$, are equal and similar trapeziums. This form is that of one of the varieties of iron pyrites.

Suppose intermediate decrements on the two lateral angles of a rhomboid $G G'$, Plate IV. fig. 47, and that these decrements take place by ranges of double molecules, parallel to the faces $u m, x y, u' m', x'y'$. It is evident, that these decrements will produce above each rhomb of the primitive nucleus $S G, S G'$, two faces, which, commencing at the angles $G G'$, will converge towards each other, and come in contact in a line situated above the diagonal $S g''$, but inclined to that diagonal; so that the complete result of the decrement will be the formation of twelve faces, disposed six and six towards each summit. Plate IV. fig. 53, represents one of these solids, with its nucleus inscribed. It is a variety of calcareous spar which sometimes occurs. The lines $a b a'$, $d e d'$, $f g f'$, represent the direction of a fracture parallel to the face $G g'', G'S'$, of the primitive nucleus. It appears from this figure, that the nucleus does not touch the secondary crystal, except by its lateral angles, which are situated in the edges $B S', D' I$, $C' S$, &c., while in the dodecahedron of Bergmann, represented in Plate II. fig. 23, and called by Hauy metaphytic calcareous spar, the lateral edges of the nucleus coincide with those edges of the secondary crystal that constitute the common bulk of the two pyramids, as is evident from inspecting Plate II. fig. 23.

Hitherto immediate decrements have been observed only in a small number of inflections, but they lead to forms as simple as the other, and give some curious results, which deserve to be studied in a mathematical point of view, without any reference to crystallography.

Compound secondary Forms.—Simple secondary forms are those which proceed from a single law of decrement, the effect of which covers and conceals the nucleus, which only touches the secondary crystal by certain angles or edges. Compound secondary forms are those which are produced by several simultaneous laws of decrement, or by one law which has not reached its limit; so that faces remain parallel to the original faces of the nucleus, which further modify the faces of the crystal.

Suppose, for instance, the law which produces the octahedron from the cube (Plate III. fig. 36.) would concur with that from which results the dodecahedron with pentagonal faces. (Plate III. fig. 31.) The drift of these laws would produce eight faces, which would have for centres the eight angles of the cubic nucleus. Each of these faces, as, for instance, that whose centre coincides with the fold angle $O$, fig. 31, will be parallel to the equilateral triangle, whose sides pass through the points $p s t$, fig. 24; in the manner, the centre that coincides with the front $O'$ will be parallel to the equilateral triangle, whose sides pass through the points $t s n$, Plate IV. fig. 54. But the second law produces faces situated as the pentagon, by the sides of the triangles $p s t, n p l$. Now the section of these triangles upon the pentagon $O s, O'n$, fig. 31, reduces the pentagon to an isosceles triangle, which has the line $t n$ for the base: the two other sides are those which pass through the points $t s, n s$. The same takes place with the other pentagons. Hence it follows, that the secondary crystal produced will be an icosahedron, bounded by eight equilateral triangles, and twelve isosceles triangles. (See Plate IV. fig. 54.) This icosahedron occurs in iron pyrites, and it is different in its form from the regular icosahedron of geometers: the latter form does not exist among crystals, and cannot be produced by any law of decrement. The same remark applies to the dodecahedron, bounded by twelve regular and equal pentagons.

Another illustration of a compound secondary form is offered in the regular six-sided prism of calcareous spar. (Plate II. fig. 17.) From the manner of dissecting this prism, (see Crystal) it is easy to conceive that the rhomboidal nucleus, fig. 21, has six of its solid angles $E, O, I, K, G, H$, situated in the middle of the lateral faces of the prism: hence it follows, that these angles are the points from whence the decrements set out from the three plane angles of the rhomb $E O I, E O A', I O A'$, which form the solid angle $O$; but it is only necessary to consider the decrements on one of them, supposing the same decrements extend on the two adjacent planes that form the solid angle. Let us then refer all the decrements to the six angles $E O I, E H G, I K G, H G K, O I K, H G O$, the drift of which are turned towards the summit $A$,
and the three left to the summit $A'$. If we suppose a decrement by two ranges of rhomboidal molecules on these different angles, fix faces will be produced parallel to the axis, as has been already observed.

The plates of superposition, at the same time that they undergo a decrement towards the inferior angles, will extend by their superior parts, so as to remain always contiguous to the axis, the length of which will progressively be augmented. The small faces produced by the decrements on the angles will gradually increase till they touch each other; we shall then have the solid represented $A A, \text{fig. 20}$, where each of these small faces, as $O O A$, is marked with the same letters as the angle to which it belongs, and which is now situated in the middle of the triangle, because it constitutes the point from which the decrements set out. As new plates are applied, the points or line $O O$ rise up, and the point $O$ sinks down; so that at a certain period we shall have the solid represented $\text{fig. 19}$, where the faces produced by the decrements become pentagons $O E I$.

Let us now suppose a second decrement to concur with the first, and to take place by a single range upon the superior angle $E A I$ and the inferior angle $H A K$, and also on the other faces of the rhomb which form the solid angles $A$ and $A'$; the effect of this will be to produce two faces perpendicular to the axis; and when it has reached the point at which these faces cut the fix faces parallel to the axis which are produced by the first decrement, the second foliy will be completed, and will be a regular fix-sided prism. (Plate II. fig. 17.) It has been already said, that the result is general, whatever be the form of the primitive rhomboid. It may now be seen why, in the mechanical division of the prism, the section $P P, O O$, has the faces $P P, O O$, parallel to each other, and to the diagonal of the nucleus $E F$, fig. 21. Since the two decrements taking place, one upon the angle $E O I$, the other upon the angle $E A I$, the plates of superposition ought to have the edges formed by the decrements parallel to the same diagonal, or to $E I$.

In the case we have been considering, and which is the most common, the axis of the secondary crystal is longer than that of the nucleus; but if we suppose the two decrements to commence at the same time, then the axis of the prism being equal to that of the nucleus, both the lateral angles and the summits of the nucleus would touch the prism, the one on the sides, and the other the bases. If the decrement were to commence on the superior angles prior to the lateral decrements, the summits of the nucleus would then be contiguous to the bases of the prism, whilst its lateral angles would be wholly within the prism, between its planes and axis. This is the case with certain crysallals, in which the prism is very short, and resembles an hexagonal plate.

Another remarkable example is offered in that variety of calcareous spar, called by Haüy analogique. (See Plate IV. fig. 55.) It is composed of twenty-four trapezoidal faces, of which fix are vertical faces, as $a b c d, d b e$, and twelve others, disposed fix and six, as $e f a b$, and $e f a b$, &c. and fix terminal faces, as $p a b$. The vertical trapezoids result from the same law that produces the hexahedral prism (Plate II. fig. 17.); the second result from the law which produces the metallic crystal, fig. 22. In comparing fig. 55 with fig. 21, we may see that the vertical faces cut those of the metallic crystal, so as to intercept the lateral solid angles $E O I K$, &c. figs. 22 and 23; and, lastly, the terminal faces result from a decrement similar to what produced the equiangular prism. (Plate III. fig. 54.)

Fig. 55: $A, B, C, D$, represents the different trapezoidal faces of this crystal. Various relations of proportion between their sides and angles are given by Haüy, Mineralogie, tom. i. p. 85, 86.

It is a character common to all the primitive forms to be divisible, parallel to their faces. In the parallelopiped, where this division is not joined with some other in a different direction, it leads us obviously to the form of molecule similar to that of the primitive crystal. In the regular fix-sided prism, it gives us for a molecule the triangular prism, as has been before observed. (See Plate V. fig. 56.)

In the octahedrons, it appears to produce two kinds of molecules, tetraedrons and octahedrons. Haüy, in this case, conceives that the tetrahedron is the integrant molecule, and that the octahedrons are empty spaces between them. The difficulty is removed, by conceiving the molecules to be an assemblage of spherical particles, as we have before observed. The dodecahedron, with its octahedrons triangular faces, cannot have molecules extracted, without dividing it in directions different from those which are parallel to the face. The cutting-planes must pass through the axis, and through the edges contiguous to the summits, from whence will result irregular tetraedrons. Some other primitive forms divide also in directions which are not parallel to the faces, as we have seen in the case of the tournamente. See Plate III. fig. 26.

Thus, besides parallelopipeds, there are two other forms which integral molecules assume, namely, the tetrahedron and the triangular prism; but it deferves particular attention, that the tetrahedral and primitive molecules are always arranged in such a manner in the interior of crysallals, that, taking them in groups of two, four, fix, or eight, they compose parallelopipeds, so that the ranges subtracted by decrements are no other than these parallelopipeds; and we may conceive such decrements as taking place by one or more ranges of rhomboidal molecules. If, for example, we take the regular fix-sided prism (Plate V. fig. 56.), suppose one base of this prism divided by sections parallel to its sides into small triangles, which form the bases of the integrant molecule; it is evident that any two adjoining triangles, $A, B, C, D, F, G$, compose a rhomb, and by their union the two little triangular prisms to which these bases belong would form by their union a rhomboidal prism or parallelopiped. It is obvious, therefore, that we may conceive the larger prism to be composed of similar rhombs. Now, if we conceive a series of plates piled upon the hexagon $A, B, C, D, F, G$, and which undergo, for example, on their different edges, a subtraction of one range of these parallelopipeds, these edges will successively correspond with the lines of the hexagon $i m n r b h, k u x y g e r$, &c. from which we see that the quantity by which each plate decreases is a sum of parallelopipeds, or prisms with rhomboidal bases; and if the decrement attains its limit, we shall have a right fix-sided pyramid, which will have for its base the hexagon $A, B, C, D, F, G$. These parallelopipeds, composed of tetraedrons or triangular prisms, are called by Haüy sublative molecules; and as far as the theory of crysallals is concerned, we may conceive all crysallals to be composed of parallelopipeds.

Plate V. fig. 58. refers to a particular case described in a note by Haüy (tom. i. p. 96.), to explain the vacuities on the edges $b, e, i, n$; but being of less importance, we proceed to flate the observations of M. Haüy on some apparent anomalies in crystallography.

In common crysallals, the faces adjacent to each other always form saineit and never re-entering angles; but certain crysallall forms exist, which present the latter angles. Let $B, D$, Plate V. fig. 60, represent an oblique prism with rhomboidal
rhomboidal bases, situated in such a manner, that the faces A, D, a, d, and C, D, c, d, are vertical, and B, D, are the acute angles of the base, and that these proceed in an ascending direction from A to C. Let us suppose also, that the prism is cut into two equal parts by a plane which passes through the diagonals drawn from B to D, and from b to d, and that the one half remained fixed, whilst the other is removed without being separated from the former. The crystal will then be presented under the aspect seen in fig. 61, where the triangle v, d, c, which was one of the halves of the inferior base, fig. 60, is now situated in the upper part, fig. 61, and forms a faient angle or projecting edge with the triangle A B D. Whilst the triangle B D C, fig. 61, which was one of the halves of the superior base, fig. 60, is transported into the lower part, fig. 61, and forms a re-entering angle with the triangle a b d, we may easily conceive that the plane of junction D B, b d, of the two halves of a rhomboid is situated like a plane drawn, formed by a decrement on one range or other of the edges A a, C c, fig. 60, and thus the manner in which these halves join is in strict relation with the structure.

Now if we imagine a secondary form, which has for its nucleus a similar prism to the above, and if we suppose that it has been cut in the direction of the plane D B, b d, and that one of the halves has been reversed as in fig. 61, the arrangement may be such, that there will still be a re-entering angle at one termination, and a faient angle at the other, resulting from the mutual incidences of the faces produced by the decrements.

In certain cases, the plane of junction on which the two halves of the crystals are joined is situated parallel to one of the faces of the nucleus, and the arrangement does not admit of presenting a re-entering angle opposite to a faient one.

These crystals which are here described are called by Hauty hemihypran, or half reversed. Romé de Lisle has called such crystals marles.

Another accident extremely common is the manner in which crystals in groups are infected into each other. This kind of penetration is subject to many diversities; but on accurate examination, we shall find that they are subject to certain laws always analogous to those of structure, and that these crystals, instead of being precipitated confusedly on each other, have a certain kind of arrangement. In illustration of this, let Plate V. fig. 62. be a cube, and M N R an equilateral triangular face, produced by a decrement of one range round the angle A: let us suppose a second cube modified in the same manner, and attached to the former by a facet resulting from a similar decrement; we shall have the combination represented fig. 63.

We may also conceive that one of these cubes, for instance the lower one, is increased in all its dimensions, except in those places where the other forms an obstacle to its progress. As the increment continues increasing, it will more and more envelop the upper crystal, and may finally by covering it entirely. We observe crystals fink into each other at different degrees of depth, but always in such a manner, that their plane of junction has a position analogous to planes resulting from decrement; so that both follow their common progress to this plane, which serves as their respective limit. Cubes of fluor spar inserted into each other have the lamina of each extended without interruption, until they are stopped by the common plane of junction.

The example here cited relates to a very simple and regular law of decrement. But frequently the laws which determine the plane of junction are more or less complicated, and there are a few which are rather extraordinary. When two prisms cross towards the middle of their axis, there are two planes of junction which unite crossing each other, as in the mineral called tautosite, and these planes have positions analogous to those which would be determined by the known laws of decrement.

In the preceding theory of crystallography it has been constantly fupposed, that the laminae composing crystals of the same species proceed from a common nucleus, undergoing decrements subject to certain laws, on which the forms of these secondary crystals depend. But this, says Hauty, is only a conception adopted to make us more easily perceive the mutual relations of the forms we are treating of. Properly speaking, a crystal taken as a whole is only a regular group of similar molecules. It does not commence by a nucleus of a size proportioned to that it afterwards acquires, or that which we can extract from it by mechanical division; and the laminae which cover this nucleus are not applied successively over each other in which the theory considers them. The proof of this is, that among crystals of different sizes that are often attached to the same support, those which can only be distinguished with the microscope are as complete as the largest; from whence it follows that they have the same structure, that is to say, they have already within them a small nucleus proportioned to their diameter, and enveloped by the requisite number of decreasing laminae to form the faces of the secondary crystal. We must therefore conceive, that from the first commencement a crystal similar to the rhomboidal dodecahedron is already a small dodecahedron, and contains a cubical nucleus proportionally small, and that this kind of embryo continues to increase without changing its form by the addition of new laminae on all the sides, so that the nucleus increases on its part, always preserving the same relation with the entire crystal.

We shall render this idea distinct by a construction which refers to the dodecahedron, and represented by a plane figure. What is said of this figure may easily be applied to a fold, since we can always conceive a plane figure to be a section made in a fold: let t s z s', Plate V. fig. 59. A, be an assemblage of small squares, in which the square B N, D G, composed of forty-nine squares, represents a section of the nucleus, and the extreme square p b j f s, &c. the steps formed by the laminae of superposition. We may conceive that the assemblage commenced by the square B N, D G, and that different piles of small squares are afterwards applied on each of the sides of the central square; for instance, on the side B N, the five squares comprehended between f and d, afterwards the three squares contained between c and e, and then the square s. This progression corresponds with what would take place if the dodecahedron commenced with a cube proportioned to its volume, and which afterwards increased by an addition of laminae constantly decreasing.

But we may also suppose, that the assemblage of molecules commenced as represented Plate V. fig. 59. C, in which the square B N, D G, is only composed of nine molecules, and had on each side of it only a single square, t s, s' z. If we refer this assemblage in imagination to the fold, of which it is a section, we shall easily perceive that this fold had for its nucleus a cube composed of twenty-seven molecules, and that each face composed of nine squares had placed on the middle one a little cube, so that the decrement of one range is already seen in the initial dodecahedron.

By the addition of new squares, this assemblage will become that of B, fig. 59, in which the central square B N, D G, is formed of twenty-five small squares, and supports on each of its sides a range of three squares, besides the terminal squares t' s, s' z. Here we have already two laminae of superposition instead of one only. Lastly, by a further
In some cases, it is necessary to indicate the analogous edges and angles: this is done by similar small letters; the angles analogous by a E, I O, are represented by a i, i o, and the same with the edges. But it is seldom necessary to mark these small letters in the figure; it is sufficient to introduce them into the symbol of the crys tal, because the place which every one should occupy in the figure may easily be conceived.

To indicate the effects of decrements by one, two, three, or more ranges in breadth, the figures 1, 2, 3, 4, &c. are employed in a manner to be immediately explained; and to indicate the effects of decrements by two, three, &c. ranges in height, the fractions 2, 3, 4, &c. are employed.

The three letters P, M, T, serve to distinguish either the form of the nucleus without any modification when they alone constitute the symbol of the crys tal, or the faces parallel to those of the nucleus in the case where the decrements do not reach their limit; and then these letters are combined in the symbol of the crys tal with those which relate to the angles or edges that have undergone decrements.

Let us suppose that one of the solid angles O, fig. 64, is intercepted by a single additional face. The decrements which produce this face may take place either on the upper base P, or on the plane T, which is on the left of the observer, or on the face M, which is on the right. In the first place, the figure marking the decrement is placed above the letter O; in the second case, the figure is placed on the left-hand, a little above the letter; and in the third case, it is placed on the right-hand. Thus O denotes the effect of a decrement by two ranges in breadth, parallel to the diagonal of the base P, that passes through I, E; O denotes the effect of a decrement by three ranges in breadth, parallel to the diagonal of the face M, which passes through the angle E; and O indicates the effect of a decrement by four ranges in breadth, parallel to the diagonal of the face T, that passes through the angle O.

When the decrement takes place on one of the three other solid angles I, A, E, the observer is supposed to move round the crys tal till he is opposite to that angle, or to turn round the crys tal till the solid angles E, A, I, are exactly opposite to him; and it is relative to that position that the decrement is said to take place to the right or to the left.

For example, if we are speaking of the solid angle A, the figure A will represent a decrement by two ranges on the surface A E, r, fig. 66, or opposite to T; and A will represent the effect of a decrement by three ranges upon the face A I, r, opposite to M.

As to the decrements on the edges, those which take place towards the boundary of the upper base B, C, F, D, are expressed by a letter placed above or below the letter as the effects occur above or below the terminal edge, supposing them to set off from the edge to which they are referred, whilst those which take place on the lateral edges are conducted by an exponent placed on the right or to the left of the letter, according as they occur in one direction or the other.

Thus D expresses a decrement by two ranges proceeding from D towards C: Č, a decrement by two ranges proceeding from C towards D: D, a decrement by two ranges defecing upon the face M: H, a decrement by three ranges, proceeding from H towards G: G, a decrement of four ranges proceeding from G towards the edge opposite to H, or A r, fig. 66. When it is necessary to denote by a small letter, such as D, a decrement upon the edge r, fig. 66, opposite to the edge denoted by the capital letter D, fig. 66,
CRYSTALLOGraphy.

To decrement, we must suppose the faces of the crystals reversed. Hence, \( d \) will express a decrement by two ranges upon the other base \( D \), just as \( D \) expresses a similar decrement on the base \( P \). For the same reason, \( c \) will express a decrement by three ranges proceeding from \( r \) to \( E O \).

If the fame solid angle, or the fame edge, undergo several successive decrements on the fame side, or different decrements which take place on different sides, the letter pointing out the angle or edge is repeated as often as the decrements, varying the figure each time, to make it correspond with the particular decrements denoted. Thus, \( D, D, D \) will denote two decrements upon the edge \( D \), one of two ranges on the base \( P \), and another of three ranges upon the face \( M \); and \( H, H, H \), will denominate two decrements, one by two ranges on the left, the other by four on the right of the edge \( H \).

Mixed decrements are marked according to the fame principles, employing the fractions \( \frac{1}{2} \), \( \frac{3}{2} \), which represent them; the numerator referring to decrements in breadth, and the denominator to decrements in height.

The intermediate decrements are thus described. Let \( A E, I O \), (Plate VII. fig. 67.) be the fame face as in fig. 66, but divided into rows or ranges; let us suppose a decrement by one range of double molecules, according to the lines parallel to \( x \) \( y \); so that \( O y \) measures the double length of a molecule, and \( O x \) that of a single molecule.

This kind of decrement is thus expressed, \( O, D', F' \); the parenthesis indicates that the decrement is intermediate; \( O \), that it takes place by one range on the solid angle marked by that letter in fig. 64; \( D' \), that there is one length of a molecule taken away along the edge \( D \); and \( F' \), that two lengths are taken away along the edge \( F \).

The written language to denote the symbols, that they may be easily expressed when dictated, would be thus: \( O = \text{O two on the right, O three on the left;} \ O, O, \) read, \( O \) under two, \( O \) above four. And the symbol \( O, D', F' \), read, in a parentheses, \( O \) under one, \( D \) one, \( F \) two.

The order in which these letters must be placed to denote a secondary crystal remains to be explained. If the alphabetical order were adopted, there would result a degree of confusion in the picture which the formula prevents. It is more natural to conform to the order that would direct an observer in the description of the crystal; that is, to begin with the prism or middle part, and to indicate its different faces as they present themselves successively to the eye; then to pass to the faces of the summit or the pyramid.

Suppose (Plate VI. fig. 68.) that variety of felspar which Haüy calls binariv, viz., where there are two decrements by two rows each. The primitive form is represented figs. 64 and 66. In this form of the crystal, the face \( l \) results from a decrement by two ranges on the edge \( G \), fig. 64, going towards \( H \); the face \( M, \) fig. 68, corresponds with \( M, \) fig. 64; the face \( T, \) fig. 68, is parallel to \( T, \) fig. 64; the pentagon \( x \) comes by a decrement of two ranges on the angle, corresponding with the angle \( l, \) fig. 64; and parallel to the diagonal \( A O \). As this decrement does not reach its limit, the summit exhibits a second pentagon \( P \), parallel to the base \( P \). All this description may be exhibited by five letters in symbic language: thus \( G M T \) \( P \) denoting a decrement by two ranges on the edge \( G \), and a decrement by two ranges on the angle \( I \), fig. 64.

It is customary, in order to prevent any ambiguity, to place under the different letters that compose the symbol those that correspond to them in the figure. Thus in the binitary felspar, fig. 68. \( G M T \), \( \text{I} \) \( P \), the letters in the line below those of the symbol enable us to compare the symbol with the figure, and thus to decipher the meaning with facility, however complicated it may be.

Where the primitive form has great simplicity, as in the cube and rectangular prism, when the opposite angles are equal, one letter will denote them both, and when the opposite edges are equal, the same letter will denote either; for everything that denotes one of them, takes place also in the other. If, for instance, we suppose fig. 64, to become more symmetrical, and that certain solid angles which were before unequal are become equal, they should be marked with the same letter. If, for instance, the primitive form be a rectangular prism, which has oblique-angled parallelograms for its bases, one side of which is longer than the other, fig. 60; in this case, we have the angle \( O = A \), \( I = E \); we may substitute in each case the second letter for the first, as is done fig. 69.

If we review the different kinds of parallelograms we shall find them acquire different degrees of simplicity, which occasions new equalities in the angles and edges, and new substitutions of letters. The oblique prism with rhomboidal bases is represented fig. 70. The rectangular prism with rectangular bases fig. 71. The rectangular prism with rhomboidal faces fig. 72. The rectangular prism with square bases fig. 73.

The cube is represented fig. 74; here only the superior base is marked, because what takes place with respect to this may be applied indifferently to any of the other faces.

The same mode is employed in writing the symbols for these regular forms, only the letters that have the fame name and the same figure are not repeated. An example will render this method evident. Fig. 75. represents the most common variety of the chrysoberyl, or crymophane (see Chrysobéryl) the nucleus of which is a rectangular parallelopiped, such as represented fig. 71. The symbol of the secondary crystal, \( \text{G} \), fig. 75, will be \( M T \times G \), \( B A \). This variety is called by Haüy annular crymophane.

To understand this expression better, let us mark each angle and edge with a particular letter, as in fig. 76. In this case, the symbol would become \( M T \times G \), \( B F \). If we compare fig. 71. with 76, we shall see that \( H = G \), \( F = B \), \( O = A \); hence if we substitute instead of their first letters their equal values, we get \( M T \times G \), \( B B A \). which becomes the fame as the one before given, when the useless repetition of \( B \) is suppressed.

From the preceding statement, it is evident that we must not confound such symbols as \( G, G \), with \( G, G \); the first symbol indicates the decrements which take place on the face \( T \), fig. 71. and on the edge opposite to it, going from the edges \( G \) towards \( T \) that correspond with them behind the parallelopiped. The second symbol indicates the decrements which take place upon the face \( M \), and which meet each other in the middle of that face. If these two decrements took place simultaneously, these symbols would be \( G \).
In the preceding symbols, each letter, such as on \( G \) or \( ^2 G \), can only be applied to a single edge situated to the right or left, as the letter is itself; but \( ^2 G \) applies differently to the one edge or the other; hence it is needless to repeat the letter.

If we take Plate VI. fig. 77, as another example, and suppose fig. 79. to represent its primitive form, we shall have for the symbol of the variety of crystal here represented,

\[
\begin{align*}
^2 G & \quad M \quad B \quad B \quad E \quad E \quad P \\
& \quad B \quad E \quad S \quad u \quad P.
\end{align*}
\]

In this symbol, \( ^2 G \), indicates two different faces formed on each side of each edge, but it is not necessary to place two letters under that symbol, because all the faces situated in the same manner being distinguished by the same letter in the figure; it is sufficient to point out that the symbol \( ^2 G \) applies to the faces marked with the letter \( a \), and this requires only to write the letter \( a \) under the symbol.

From the same principles it follows, that the rhomboidal dodecahedron derived from the cube, fig. 74, is expressed by the symbol \( B \). The octahedron derived from the cube is thus expressed \( A \).<sup>1</sup>

The rhomboid, imposing itself in the most natural aspect, so that the two facial angles, composed of three rhomboidal plane angles, are in the same vertical line, has, properly speaking, no base, but merely summits, which are the extremities of its axis. Its edges and angles are marked as in Plate VI. fig. 78.

If all the lateral angles were indicated by letters, those that are nearest the summit \( A \) would have the letter \( E \), and those which are nearest the inferior summit the letter \( e \). As the rhomboid has six faces equal and similar, it is only necessary to consider the decrements relative to one of these faces; as, for example, that marked \( P \), fig. 78, because all the others are mere repetitions of this. The decrements which set out from the superior angle \( A \), or the superior edge \( B \), will have the figure indicating the number of ranges placed below \( A \) and \( B \). Those which set out from the lateral angles \( E \), will have their figures situated at the side and towards the top of the letter. Those decrements which set out from the inferior angle \( e \), or the inferior edge \( D \), will have the figure placed above the letter \( e \) or \( D \).

Suppose, for example, that fig. 79. represents the variety of calcareous spar, called analogous by Haiyi, its symbol would be \( e D eB \), the interpretation of which will be evident.

What has been said of the rhomboid may be applied to the other primitive forms, of which we shall give examples: fig. 80. represents the octahedron with scalene triangles; fig. 82. the regular octahedron. In placing the figures that accompany the letters in the symbols, and the figure denoting the decrement is placed below the letter \( A \) or \( B \), to represent decrements setting out from the angle \( A \), or the edge \( B \), the figure is placed above the letters which set out from the edge \( D \), and at the side for those which set out from the angle \( E \).

If we want to denote a decrement by one range upon all the angles of the regular octahedron, fig. 82, we have only to write \( A \). To indicate a decrement by one range on all the edges we write \( B \). The first of these decrements produces a cube, the second a rhomboidal dodecahedron. In some mineral species, as in the nitrate of potash, the primitive octahedron, which is composed of eight isof-

The tetrahedron being always regular when it becomes a primitive form, it will be expressed as in fig. 85, and the decrements marked as in the octahedron.

In the rectangular six-sided prism, fig. 86, the figures are written precisely in the manner already described for the four-sided prism. But it happens sometimes, that three of the solid angles taken alternately are replaced by faces, whilst the intermediate angles remain untouched. In that case, the prism is distinguished as in fig. 87. In the rhomboidal dodecahedron, fig. 88, each solid angle composed of three plane angles may be assimilated to a summit of the obtuse rhomboid; hence it is only necessary to give letters to one face, as may be seen in the fig. A, E, B, B, P. Where the parts of crystals opposed to those which undergo certain decrements remain untouched, it is easy to mark this peculiarity by zeros. This case belongs chiefly to the tourmaline. One variety of the tourmaline is represented fig. 90, and the primitive form fig. 89. The prism, which is nine-sided, has six of its faces, namely \( s \), produced by the subtraction of one range upon the edges \( D \), fig. 89, and the three others, as \( l \), by the subtraction of two ranges only on three angles \( e \). The inferior summit has simply three faces parallel to those of the nucleus; while on the superior summit the three edges \( B \), fig. 89, are replaced each by a facet \( n n \), fig. 90, in consequence of a decrement which has not reached its limit. This crystal is represented by the following symbol:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad b & \quad b & \quad b \quad b
\end{align*}
\]

\( E \) and \( b \) indicate the one that the angles \( E \), fig. 89, opposite to \( e \), undergo no decrement; the other, that the edges parallel to \( B \) remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad E \quad P \quad B \quad b
\end{align*}
\]

\( E \) and \( b \) indicate the one that the angles \( E \), fig. 89, opposite to \( e \), undergo no decrement; the other, that the edges parallel to \( B \) remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad E \quad P \quad B \quad b
\end{align*}
\]

\( E \) and \( b \) indicate the one that the angles \( E \), fig. 89, opposite to \( e \), undergo no decrement; the other, that the edges parallel to \( B \) remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad E \quad P \quad B \quad b
\end{align*}
\]

\( E \) and \( b \) indicate the one that the angles \( E \), fig. 89, opposite to \( e \), undergo no decrement; the other, that the edges parallel to \( B \) remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad E \quad P \quad B \quad b
\end{align*}
\]

\( E \) and \( b \) indicate the one that the angles \( E \), fig. 89, opposite to \( e \), undergo no decrement; the other, that the edges parallel to \( B \) remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad E \quad P \quad B \quad b
\end{align*}
\]

\( E \) and \( b \) indicate the one that the angles \( E \), fig. 89, opposite to \( e \), undergo no decrement; the other, that the edges parallel to \( B \) remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[
\begin{align*}
D & \quad E \quad P \quad B \quad b \\
& \quad b \quad P \quad n \\
E & \quad E \quad P \quad B \quad b
\end{align*}
\]
CRY

The preceding illustrations of M. Haüy's mode of denoting the structure of crystals by symbols, are given in detail to enable the student to make a figure of a crystal from the symbol representing the laws of its formation. Shorter rules for enabling the student merely to read and understand this mode of notation will suffice.

1. The letters P, M, T, denote the faces of the nucleus or primitive crystal, or indicate that the faces are parallel to the faces of the primitive crystal marked with the same letters.

2. Every vowel in the symbol indicates a fold angle, marked with the same letter as in the nucleus. Every consonant indicates the edge which has the same letter in the figure. It is understood.

3. Each letter contained in the symbol is understood with the figure belonging to it to represent all the same letters, and the edges or angles which have the same function.

4. Every number joined to a letter indicates a decrement setting out from the angle or the edge denoted by that letter. If the number be a whole one, it indicates the ranges in breadth, supposing each plate to have only the thickness of one molecule. If the number be a fraction, the numerator indicates the number of ranges subtracted in breadth, and the denominator the number of ranges subtracted in height.

5. The number is placed above the letter to shew that the decrement ascends, or below it to shew that it descends, setting out from the angle or edge marked by the letter. If it be placed either on the right or left hand of the letter, it indicates a decrement to the right or left of the edge or angle marked by the letter.

6. When a letter is twice repeated with the same number placed on different sides, as G G, or G G A A, the two edges or two angles which it marks should be considered in the figure in the same relative positions. Thus G G indicates the effect of decrement by two ranges on the edge G situated at the left, and of a similar decrement on the edge G situated at the right.

7. When a letter has the same number both on the right and left side, as 1 G 1, it applies equally to all the edges G. The same applies to the letters which denote the angles.

8. The parenthesis, as, for example, (O D D', F' s) indicates an intermediate decrement. The letter O indicates, that an ascending decrement of three ranges takes place on the angle O; D, that one molecule is subtracted along the edge D; and F', that two molecules are subtracted on the edge F.

9. Every small letter in the symbol indicates the angle or the edge diametrically opposite to that which has the same capital letter in the figure, where the small letter is omitted as superfluous. The letter e is, however, never omitted in the rhomboïd; it indicates, according to the principle, the letter opposite to E.

10. When the large and small letters of the name are introduced into the symbol with different numbers attached to them, the two opposite edges or angles denoted by these letters are conceived to undergo exclusively the law of decrement, indicated by the number attached to the letter.

11. Every letter, whether large or small, marked by a number having a zero attached to it, as E, indicates that the decrement denoted by that number does not take place on the angle or edge which the letter represents.

The above account of the theory of crystallization, and the notation of crystals, may suffice with what has been before given under the article Crystal, to convey ample information of the abbé Haüy's ingenious system, so far as relates to the structure of crystals, and the symbolic mode of describing the decrements by which the secondary crystals are formed. The figures in Plates II. III. IV. V. VI. Crystallography, which we have described, are copied from Haüy's Traité de Minéralogie, tom. i.; and contain what he has given in illustration of the theory of crystallization. The application of geometry and analysis, to determine the laws of decrement from the measurement of the angles, which has been so ably made in the above-mentioned work by this illustrious crystallographer, would require for its explanation a more ample space than would be consistent with the present article, which is intended to supply what was defective in the explanation of the plates under the article Crystal, and to correct the references that were there erroneously given. (See Crystal.) We omitted to state, that Plate II. fig. 25, represents the secondary rhomb, fig. 24, with the three superior edges, and the three inferior ones cut off or truncated r, r, r', r', r' by cutting other lamina parallel to each of the faces r, r, r, &c. we shall at length extract the primitive nucleus A E, O I, fig. 24.

CSHATRIYA, or CHATERIE, denotes in India a man of the second or military cast. See CAST.

CUCKFIELD. In 1811, the parish of Cuckfield contained 300 houses, and 2088 persons; viz. 1063 males, and 1025 females: 251 families being employed in agriculture, and 123 in trade, &c.

CUCKOW-SPIT. Add—This cuckow-spitte encompasseth the larva of a species of cicada, which is denominated C. ipumaria, or cuckow-spit cicada, from the circumstance of its larva being constantly found enveloped in a mass of white froth adhering to the leaves and stems of vegetables. This froth, called cuckow-spit, is found during the advanced state of the summer, and is the production of the included larva, which, from the time of its hatching from the egg deposited by the parent insect, continues occasionally to suck the juices of the insect that it refines, and to discharge them from its vent in the form of very minute bubbles, till it covers itself with a large mass of froth, and it is sometimes so overcharged with moisture that a drop may be seen hanging from its under surface. Shaw's Zoology, vol. vi.

CUCULUS, l. 4. add—Dr. Leach, however, observes, that this property does not belong to this kind of feet, which can be considered merely as simple feet, having two toes before and two behind. Col. 2, l. 21, after insects, add—and on larve or caterpillars; l. 35, add—for the natural history of this bird, see Dr. Jenner's curious paper in the Phil. Trans. for 1788, pt. ii.

CUD-BEAR. See LICHEN TARTAREUS.

CULLUMIA, in Baines, dedicated by Mr. Brown, to the honour of the late John Cullum, bart. an elegant and accomplished scholar and botanist; as well as of his brother the present for Thomas Gery Cullum, bart. F.L.S. an excellent British botanist, one of the most ardent cultivators of this lovely science, whose friendship alone can be more valued than his various and extensive information.—Br. in Ait. Hort. Kew. v. 5. 135.—Clas and order, Polygami-fraction. Nat. Ord. Compositae. Linn. Corymbifera, Jaff. Eff. Ch. Receptacle cellular. Seeds smooth. Downnone. Common calyx of one leaf, covered with imbricated scales.

2. C. setosa. Recurved smooth-leaved Cullumia. Ait. n. 2. (Berkleya setosa; Willd. ibid, excluding Commelina's
CUR

(Cyn.)—Leaves ovato-lanceolate, smooth, recurved, fringed with prickles.

3. C. squarrosa. Recurred awl-leaved Callania. Ait. n. 3. (Beckhaye squarrosa ; Willd. 2272. "Rohria squar-

rota ; Thumb. in Act. Soc. Nat. Scrut. Hafn. v. 3, part 1. 1802, t. 5")—Leaves awl-shaped, recurved or spreading, fringed with prickles; furrowed beneath; nearly smooth like the branches.

These are green-house shrubs, with yellow radiant flowers, all natives of the Cape of Good Hope.

CULLUMPTON. By the return of 1811, the parish contains 699 houses, and 2917 inhabitants.

CULPEPPER, l. 3, r. 1810, 18,697, and 8312.

CULROSS. In 1811, the burgh and parish contained 279 houses, and 1611 persons; viz. 725 males, and 886 females: 78 families being employed in agriculture, and 183 in trade, manufactures, and handicraft.

CUMANA, l. 4, r. Wolfe.

CUMBERLAND, l. 23, r. and by the return of 1811, 24,002 houses, and 133,344 inhabitants.

Cumberland, in Maine, l. 7, r. 24 towns; l. 9, r. 1810, is 42,831.

CUMMINGSTON, l. 3, r. 1009.

CURCULIO, l. 17, add—Mr. Marsham, in his "Ento-
mologia Britannica," enumerates no fewer than 234 Bri-
tish species; l. 27, add—The larva, when properly fried and boiled, is considered as one of the best dainties in the West Indies. P. 3, C. GRANARIUS, add—See WEevil. P. 5, col. 2, NUCUM, add—The various changes which the nut-maggot passes through, from its introduction into the nut in August to its escape, are worthy of attention. Dr. Darwin, in his "Botanical Garden," thus beautifully de-

Script. of this infest from the cavity of the nut:

"So sleeps in silence the curculio, shut
In the dark chambers of the cavern'd nut;
Erodes with ivory beak the vaulted shell,
And quits on silny wings its narrow cell."

CURD, Chemical Properties of. See MILK.

CURIA CLAUDENSA, a writ that lies against him who should fence and inclose the ground, but refues or defers to do it.

CURIA Adovare vult, a deliberation which the court

sometimes takes, before judgment is given in a cause, with regard to which there seems to be any point of difficulty.

CURRIE, JAMES, M.D., in Biography, distinguished both as a physician and a writer, was the son of an esta-

blished minister at Kirkpatrick-Fleming, in Dumfriesshire, in which parish he was born in the year 1756. Originally designed for commerce, he was educated with that view; but upon a change of his destination, he commenced, in 1776, a course of medical study at Edinburgh: and having graduated in that university, settled, in 1787, at Liverpool, where he soon rose to eminence in his profession and in his literary character. His first performance as a writer was an
elegant tribute to the memory of his intimate friend, Dr. Bell of Manchester, published in 1785 in the first volume of the Manchester Transactions. His paper on Tetanus, &c. was published in the Memoirs of the London Medical Society, vol. iii. In 1792 he was elected a member of the Royal Society; and his curious paper on the lamentable effects of a shipwreck was printed in the Phil. Trans. for that year. Disapproving of the war between this country and France in conformance of the revolution, he was sup-

posed to be the author of an interesting pamphlet, which appeared in 1793 under the title of "A Letter, Commer-
cial and Political, addresed to the Right Honourable Will-

liam Pitt, by Jasper Willon." In 1797 his medical reputa-

tion was much advanced by a treatise entitled "Medical Reports on the Effects of Water, cold and warm,

but disguised by Dr. Wright's narrative in the London Journal, was much extended. With a view to the relief of the
difficulty family of the rustic poet, Robert Burns, with whom he became acquainted in 1792, he published in 1800 an edition of his works, with an account of his life, &c. in 4 vols. 8vo. It is with real regret we farther report, that Dr. Currie's health began to decline in 1804, and that his friends and patients at Liverpool were deprived of the pleasure of his society and advice by his removal, towards the close of the year, to Clifton and Bath. His disorder, which was of the pulmonary kind, somewhat abated in con-

sequence of the change of his situation, and at the com-
mencement of the following year he began to profife in his profession with encouraging prospects of succces. But it again recurred with alarming symptoms, and he was under a necessity of removing to Sidmouth, where his valuable life terminated on the 31st of August, 1805, in the 50th year of his age. The caufe of literature and science, and the interests of humanity and benevolence, suffered great loss by his death.

CURVO, in Geography, a township of America, in the diriict of Maine, and county of Somerset, containing 275 inhabitants.

CUSERUND, a town of Mekran in Peria, situated in a fertile valley, about 21 miles broad, with a river running through it. It contains 500 huts, and a large mud fort. Wheat, rice, and dates, are abundant; and the town belongs to an independent chief, whose revenue is about 1000 rupees a year.

CUSHING, l. 3, r. 532.

CUTIFIS, Chemical Properties of. See INSECTUMS.

CYANOGEN, in Chemistry, the name given by M. Gay Lussac to the recently-discovered gases of the prussic acid, and which he has demonstrated to be a compound of carbon and azote. The name is derived from ammonia, blue. Cyanogen may be obtained by exposing dry prussiate of mercury in a small retort, to a heat rather under redness. The salt blackens, and a gaseous fluid is extracted in abundance, which must be collected over mercury. This gas is cyanogen. It is colourless, and possesses the mechanical properties of common air. Its smell is quite peculiar, and very strong and disagreeable. Its specific gravity, as ascertained by Gay Lussac, is 1.8664. It is inflammable, and burns with a purplish-blue flame. It is not decomposed by exposure to a red heat. Water diffuses 4 3/4 times its volume, and alcohol 23 times its volume of this gas. It reddens tincture of limon. Phosphorus, fulphur, and iodine, may be volatilized in it without alteration. Potassium burns in it, and absorbs it. For complete combustion, it requires twice its volume of oxygen gas; and the products are twice its volume of carbonic acid, and its own volume of azotic gas. Hence it is

obviously
obviously composed of two atoms or volumes of carbon, and
one atom or volume of azote, or per cent. of

See Atomic Theory, Table III.

Cyanogen is capable of combining with chlorine, and
forming an acid which has been named chlorocyanic acid. It
also combines with hydrogen, forming hydrocyanic acid; with
fulphur, forming fulphocyanic acid; and with iron, forming
ferrocyanic acid: of each of which acids we shall here give a
brief account.

Chlorocyanic Acid. — This is the oxyphoric acid of Ber-
thollet, who first demonstrated its existence. Its properties
were afterwards more thoroughly investigated, and its true
composition pointed out by M. Gay Lussac, who gave it the
above name. The acid was formed by M. Gay Lussac by
passing a current of chlorine gas through a solution of hydro-
cyanic acid (prussic acid, see below) in water, till the liquid
discoloured indigo dissolved in sulphuric acid. To separate
the excess of chlorine, the mixture was digested with mer-
cury. The chlorocyanic acid was subsequently separated
by an ingenious process. A glass cylinder, filled two-thirds
with mercury, was filled to the brim with the above mixture,
and then inverted into a basin of mercury. The appara-
atus was put under the receiver of an air-pump, and the
exhaustion carried on till the whole of the mercury and
liquid was displaced, and the cylinder filled with chlorocyanic
acid in a state of vapour. On heating the air again into the
receiver, the vapour was condensed into a liquid, and thus
collected upon the surface of the mercury in the cylinder.
Chlorocyanic acid thus obtained is a colourless liquid, having
a strong and peculiar odour, which excites such irritation as
to induce a flow of tears. It reddens litmus, is not inflamm-
able, and does not detonate when mixed with hydrogen or
oxygen. Its solution in water does not precipitate nitrate of
silver, nor barytes water. The alkalies absorb it rapidly,
but it requires an excess of them to destroy its odour com-
pletely. It throws down iron from its solution of a green
colour. But some of its compounds appear of a very per-
manent nature. Gay Lussac has shown that this acid is
a compound of one atom or volume of cyanogen, and one
atom or volume of chlorine, united together without change
of bulk. Hence it will be composed per cent. of

And its specific gravity in a state of vapour will be 2.152.

Hydrocyanic Acid. — This was formerly denominated
Prussian Acid; which see. Hydrocyanic acid may be pre-
pared in the manner pointed out in the above article; but the
method more lately recommended by Gay Lussac consists in
decomposing the prussiate of mercury by means of muriatic
acid in a retort with heat. The products are to be passed
through a tube two feet long, the first one-third of whose
length is to be filled with fragments of marble, to retain the
muriatic acid that may come over, and the remaining two-
thirds with dry muriate of lime. A small receiver covered
with ice is to be adapted to the end of this tube in which the
hydrocyanic acid may be collected on application of
a moderate heat to the retort. The properties of this acid
are correctly described under Prussian Acid. It is a most
violent poison. From Gay Lussac's experiments, it appears
to be composed of one atom or volume of cyanogen, and one
atom or volume of hydrogen, united together without
condensation. Hence it is composed per cent. of

And the specific gravity of its vapour will be .9367.

Hydrocyanic acid cannot be preserved for any length of
time without undergoing decomposition, ammonia is formed,
and a quantity of cherry matter is deposited. Iodine vola-
tilizes in this acid fuffers no change. Oxygen decomposing
it with combustion. Chlorine displaces the hydrogen, and
forms chlorocyanic acid. Neither azote, hydrogen, carbon,
boron, silica, nor phosphorus, have any known action upon it.
Sulphur decomposes it, appearing to displace the hydrogen
and combine with the cyanogen, and thus forming fulphocyanic
acid. Potassium, sodium, potash, soda, and barytes, combine
with the cyanogen and liberate the hydrogen. The vapour
of hydrocyanic acid is decomposed when passed through red-
hot iron or platina; also when passed through the peroxys
of copper. The peroxys of manganese completely absorbs
the vapour of hydrocyanic acid in a few hours, water is
formed, but cyanogen is not evolved. When the red oxyd
of mercury is heated in hydrocyanic acid vapour, so much heat
is evolved from the violent action that takes place that the
compound is destroyed. If heat be not applied, the vapour
is absorbed by the oxyd, and when the compound is after-
wards submitted to heat, water is diffigeaged, and the
cyanide, or prussiate of mercury, as it was formerly termed,
is left behind. See further under Prussic Acid.

Sulphocyanic Acid. — This is the sulphuretted chyanic acid of
Mr. Porrett, who discovered it in 1808. It may be formed by
dissolving one part of sulphuret of potash in water, and
boiling in this solution three or four parts of prussian blue,
added at intervals. Sulphuret of iron is formed, and a
colourless neutral liquid containing a considerable quantity
of fulphocyanic acid combined with potash. This liquid
is then to be rendered decidedly acid by sulphuric acid,
and the mixture kept at the boiling point for some time.
When cold, a little peroxys of manganese is to be added,
which will give to the solution a fine crimson colour. This
crimson liquid is to be filtered, and a solution composed of
two parts of the perulphate of copper and three of the
protosulphate of iron is to be added, till the crimson colour
disappears. A copious white precipitate, composed of
fulphocyanic acid and protoxys of copper, takes place.
The copper may be sepetrated by boiling with a solution of
potash, and the sulphocyanate of potash thus formed after-
wards decomposed by sulphuric acid; the sulphocyanic acid
may be then obtained by distillation in a retort. If any ful-
phuric acid adheres to it, this is to be separated by a little
carbonate of barytes.

Sulphocyanic acid thus formed is a transparent colour-
less liquid, having an odour as strong, and somewhat refel-
bng acetic acid. Its specific gravity when most con-
centrated was 1.022. According to Mr. Porrett's analysis, it
is composed of

Dr. Thomson seems inclined to consider this acid as com-
posed
posed of cyanogen and sulphur, but it is probable that Mr. Porrett’s view of its composition will be hereafter found correct.

The *sulphocyanates* of potash, soda, ammonia, barytes, fronton, lime, and magnesia, are all deliquescent salts soluble in alcohol. The sulphocyanate of soda, lime, barytes, and fronton, are capable of crystallizing, the others are not. The sulphocyanate of alumina is not deliquescent, and readily crystallizes. The sulphocyanate of the protoxyd of iron is colourless, and very soluble. The sulphocyanate of the pyroxyd of this metal is of a beautiful crimson colour, deliquescent, and does not crystallize, and this is one of the most striking characteristics of this acid. The sulphocyanate of the pyroxyd of copper is a white powder insoluble in water and molybdate acids. The other salts are not remarkable, and consequently possess little interest. The following is a short account of some of the salts formed by this acid.

**Ferrocyanic Acid; the Ferrvitretd Chyazic Acid of Mr. Porrett its Discoverer.** — This is the acid which combines with different bases, and forms what were formerly denominated *triple prussiates*, iron being supposed to form part of their base, whereas Mr. Porrett has demonstrated that this metal forms a constituent of the acid itself. This acid may be obtained by the following simple process: — Diffuse in cold water any quantity of the *triple prussiate of barytes*, and for every ten grains of the salt add about 0.55 grains of real sulphuric acid, agitate the mixture and let it stand some time. The barytes will be precipitated in union with the sulphuric acid, and leave the ferrocyanic acid in solution in the water. When obtained, it has a pale lemon colour, and is deficient of smell. It is decomposed by a gentle heat and exposure to a fijrong light, hydrocyanic acid being formed, and the white triple prussiate of iron deposited. When combined with the different bases, it forms at once the salts formerly termed triple prussiates. It displaces acetic acid from all its combinations without heat, and displaces all other acids when it forms insoluble compounds with the bases to which they were united. Mr. Porrett, from his analysis, concludes that this acid is composed of

Of the remaining species we have no account.

**Cynodon, from *κυθος*, a dog, and *δος*, a tooth, a genus founded by some authors on the *Pantum Daffylon* of Linnaeus, a grass known in many of the temperate or warm parts of the globe, to which Mr. Brown adds two tropical New Holland species. See his Prodr. v. i. 1875. This genus is closely related to the *Chloris of Swartz*. See *Panicum*, at the end of sect. 1. of that article.

**Cyntheana, in Geography, a town of Kentucky, in Harrison county, containing 356 inhabitants, of whom 116 are slaves.**

Eff. Ch. Calyx ringlet, pointless. Petals spreading, nearly equal to the lower calyx-leaves. Lip dissimilar, direct, flat, obtuse, undivided, with two calliostylos at the base. Anther a terminal permanent lid; the cells close together. Masses of pollen two in each cell, powdery, compressed.

1. *C. reniformis.* — Gathered by Mr. Brown, at Port Jackson, New South Wales. Habit like *Acianthus*, (see that article,) to which this plant is perhaps near akin. Leaf—kidney-shaped, many-ribbed. *Flowers* generally turned, or, in one sense, reversed. *Malaxis lipifolia* (see that article, n. 11) is thought by Mr. Brown to approach this plant in structure of flowers, though different in habit. We have already observed how imperfectly that species, with our *Cordifolia* and *Lobellia* answer to *Malaxis*.

**Cythis.**

Eff. Ch. Calyx leafy. Corolla closed, like a lid, splitting transversely; the torn face permanent. Stamens inserted into the receptacle, permanent. Nectariferous scales none. Capsule with many seeds; receptacles pendulous from the top of the central column.

1. \textit{C. spongiosa}.—Native of Van Diemen's island. A \textit{fbruk}, resembling \textit{Spongiosa}, \textit{Poncefia}, and \textit{Cynarea}, except the branches being marked with annular scars after the fall of the leaves. A short-leaved variety grows on the mountain tops, but on their shady sides the plant bears more elongated, spreading, recurved leaves.

CYSTITIS. Inflammation of the bladder is rarely a primary disease, but generally comes on as a consequence of some other affection in the neighbouring parts; or of lithotomy, accidental injuries, &c. The symptoms attending it are, tension and pain over the pubes, with a frequent desire to make water, difficulty in voiding it, or a total retention, with tenesmus and fever.

The treatment recommended for \textit{Nephritis} is here also applicable. In particular, venefication, leeches to the hypogastric region, the warm bath, aperient medicines, and emollient ointments, must be employed. When the bladder and peritoneum inflame after wounds, or the surgical operation of lithotomy, blisters are often of great service; but bleeding should be strict practised. In chronic inflammation and thickening of the bladder, the symptoms and pain may be allayed with anodyne emollient ointments, which are far better than injections into that organ itself. Opium, cicutum, hylocyamus, the uva urbi, &c. with a perpetual blister, may also be tried.

CYSTOTOMY, \textit{Cystostoma}, from \textit{xysto}, the bladder, and \textit{tekn}, to cut, the operation of cutting into the bladder. See Lithotomy.

D.

DAGESTAN, l. 2, after Asia, infer—almost entirely mountainous, as its name implies.

DAGOTI. See Gauthier.

DALIBARDA. See Gauthier.

DAMPAN. See Sunnun.

DAMPIERA, in \textit{Botany}, dedicated by Mr. Brown, to the memory of William Dampier, the famous navigator, who first brought one of the species, \textit{D. incaus}, Br. n. 7, from the west coast of New Holland, along with several other speciemem prepared at Oxford, the earliest botanical tribute from that remote country.—Br. Prodr. Nov. Holl. v. 1. 587.—Class and order, \textit{Pennandra Monogynea}. Nat. Ord. Goodeniaceae, Br.

Eff. Ch. Corolla two-lipped; tube split at one side; segments of the upper lip auricled at their inner margin. Anthers closely combined. Cover of the stigma naked at the edge. Nut inferior, crustaceous, with a solitary kernel. Dry, downy, perennial herbs, or \textit{fbrubs}, with undivided, alternate, often toothed, coriaceous leaves. Flowers blue or purple. Calyx small, or none. Stamens permanent, sheathing the style.

Thirteen species, from various parts of New Holland, are described, among which is \textit{D. fricta}, Goodenia fricta; Sm. Tr. of L. Soc. v. 2. 340. Willd. Sp. Pl. v. 1. 955.

DAOURIAN. See NERTSKINSKI.

DARABGERD. Add—Although a great part be in
ruins, it is said to contain between 15,000 and 20,000
inhabitants. It is beautifully situated on an extensive plain,
and surrounded with groves of orange and almond trees, the
juice of which is exported to every part of Persia. Its
s tobacco is highly esteemed for its mildness.

DARBY. Add—The former containing 966, and the
latter 1085 inhabitants.

DARIEN. Add—It contains 107 inhabitants, of whom
10 are slaves.

DARK-RAYS, l. 17, r. see Heat and Rays of Heat.

DARTINGTON, l. 6, from bottom, after Darlington,
inferred, containing of three divisions, contained 7184
housies, and 39,001 persons; 18,775 being males, and
20,276 females; and the township of Darlington con-
tained 818 housies, and 5059 persons; 2351 being males, and
2708 females.

Darlington, in Carolina. Add—It contained in 1810,
9047 inhabitants, of whom 2731 are slaves.

Darryfield. Add—See Deerfield.

DARTON, in Rural Economy, a kind of feabs or ulcers
which lams are subject, and which extending to the
mouth often prove fatal. The remedy proposed is washing
the fores with vinegar, and applying a faile made with
equal parts of tar and hog's-lard.

DARTFORD, col. 1, l. ult. r. 1811; col. 2, l. 1, r. 526
and 3177.

DARTMOUTH, l. 31, after housies, inferred—in the
parishes of St. Petrox, St. Savion, and Townfall, which
form the borough of Clifton Dartmouth, was
364 houses, and that of inhabitants 3595.

DARTMOUTH, in America, l. 9, for 2660 r. 329.

DARWINIA, in Botany, in memory of the late ERAS-
MUS DARWIN, M.D. the elegant poet, and ingenious
botanical physiologist; see that article.—Rudge Tr. of Linn.
Soc. v. 11. 299.—Clafs and order, Decandria Monoxygyn.
Nat. Ord. . . .

Eff. Ch. Calyx none. Corolla tubular, funnel-shaped,
tumid, with five marginal imbricated segments. Stamens
concealed, inferted in two rows into the throat. Anthers
kidney-shaped. Gernen somewhat oblique. Style pro-
minent. Stigma simple.

1. D. facicularis. Ibid. t. 22.—Found in New South
Wales, by Mr. Joseph Bank's and Dr. Solander. A branched
branch, with crowded needle-like leaves, and terminal deni
tuffs, of elegant, small, red flowers.

DASYPOGON, from dasy, thick and briskly, and pygon,
a beard.—Brown Prod. Nov. Holl. v. 1. 263.—Clafs and

Eff. Ch. Calyx inferior, tubular, three-clawed. Petals
three, with long claws, connected with the stamens. An-
thers incumbent. Stigma simple. Capsule of one cell, not
buried, witted with the hardened calyx.

1. D. brongiifolius. Br. n. 1. Terr. Authr. 76. t. 8.—
Found on the shores of King George's found, New Holland.
_Herb one and a half or two feet high, somewhat thirubby,
DEE

Flowers in small, nearly simple, clusters, about the ends of the branches, white, minute. Rumphius relates that the bark and leaves, which may be preferred dry for the purpose, are of great use, instead of alum, in dyeing, to improve and fix the red colours afforded by several Indian woods and roots.

DECAGON. Add—See Dodecagon.

DECANDRIA, in Botany, from δέκα, ten, and ἄνδρα, a man, the tenth clas of the sexual or artificial system of Linnaeus, containing such plants as have ten stamens, in the same flower with the pistil. Hence it admits several papilionaceous plants so circumstanced, notwithstanding their natural affinity to others which belong to the seventeenth clas, Diadelphus, the latter containing only such as have some sort of union or combination in their filaments, and whose filaments are moreover of a peculiarly flat membranaceous structure, altogether different from those of proper decandrous flowers. (See Diadelphus.) The tenth clas is divided into five orders, and comprises various natural tribes or families, many of which have allies in other parts of the system, and several of the genera have species whose parts of fructification are irregular in number.

A genus of elegant shrubs, found on the south coast of New Holland, with scattered falked leaves, and terminal drooping spikes of red flowers. Berries violet.

DEDDINGTON. In 1811, the parish contained 252 houses, and 1,296 persons; 635 being males, and 661 females.

DEEDHAM. In 1811, the parish contained 264 houses, and 1,472 persons; 697 being males, and 775 females.

DEEPING-MARKET. In 1811, the parish contained 166 houses, and 899 persons; 426 being males, and 473 females.

DEER, in America, l. 2, r. 674. Add—Alfo, a township of Wellmoreland county, in Pennsylvania, having 2380 inhabitants.

DEER Creek, a town of Ohio, in the county of Pickaway, having 853 inhabitants.

DEER, is, col. 2, l. 11, r. 1057.

DEERFIELD, l. 10, r. 1750; l. 16, r. 1851. Add—Alfo, a town of Ohio, in Portage county, having 394 inhabitants.—Alfo, a town of Ohio, in Rofs county, having 619 persons.—Alfo, a town of Ohio, in Warren county, having 1181 persons.

DEERING, l. 3, r. 1363.

DE S E R T  I S L A N D,  M o u n t.  A d d.—Mount Defert contains 1307 inhabitants. See Eden.

D E S M A N T H U S, in Botany, so called by the late professor Willdenow, who first separated the genus we are about to describe from Mimosa; see that article, and Acacia of the present volume. This name seems to be composed of *Rheede*, a homonym, and *nearly* a flower; alluding perhaps to the strap-like filaments of the neutral flowers, common to every species.—Wild. Sp. Pl. v. 4. 1044. Allt. Hort. Kew. v. 5. 457.—Clauf and order, Polygama Monacica; or rather perhaps Decandria Monogynia. Nat. Ord. Lomcientae, Linn. Leguminosae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five teeth. Cor. of one petal, funnel-shaped, regular, more or less deeply five-cleft, sometimes of five petals. Stam. Filaments ten, rarely but five, capillary, equal, very long; anthers incumbent, oblong. Pler. Germin superior, ovate-oblong; style thread-shaped, the length of the flaments; stigma dilated, abrupt. Peric. Legume oblong, compressed, of two flat valves, and one cell, separated into several by transverse opposite striae in the valves. Seeds numerous, oblong, flattened. Several flowers, below the perfect ones, are neuter, having dilated lanceolate flaments, without anthers, no efficient pistil, and sometimes no corolla.

Obf. Although the definition of this genus is not so striking as could be wished, it seems to us tolerably natural, being distinguished from Acacia by the definite number of its flaments, always twice as many as the divisions of the corolla, and by the presence of several neuter flowers, in the lower part of each tuft, or spike, known by their dilated, strap-like flaments, dilute of anthers, and more or less different in colour from the perfect flowers. We are nevertheless aware, that generic characters founded on such anomalies or imperfections, are always the least solid; these neutral flowers, apparently created for no end, being doubtless liable to become, according to circumstances, perfect in one organ of impregnation or the other. The habit of the genus before us is very uniform, having doubly pinnate leaves, with numerous, oblong, obtuse, crowded *fascicles*; axillary, solitary, flattened, oblong *spikes*, of crowded tassel-like flowers; and flat, generally broad, elliptic-oblong, smooth *legumes*, whose transverse striae make them resemble the jointed fruit of what now remains as Mimosa, but their valves do not split at those striae. As only ten species of Desmanthus are described, we shall give the whole. They are all of tropical origin; partly herbaceous, and sometimes annual, with fleshy leaves; partly herbaceous.

Sect. I. Without thorns.

1. D. latifolius. Lake Defansatus. Willd. n. 1. (Mimosa leucrythra; Humb. and Bonpl. Pl. equinoct. t. 16.)—Thorns none. First division of the leaves of two or three pair; second of many rough-edged leaves. Stipulas pointed. Spurs globose. Stalks bracteate. Stems prostrate; triangular in their upper part.—Native of the dry borders of fields at Tranquebar. König in the Linnean herbarium. Root woody, perennial. Stems several, from a foot to a foot or more in length, herbaceous, profificate, rather zigzag, leafy, smooth, somewhat glaucous, scarcely bracted; nearly round at the bottom, but triangular above. Leaves about half the size of the former, on much shorter stalks, and effentially distinguished, if we mistake not, by the roughness of their edges, caused by small close-preened bristles. The *flippus* are obliquely ovate, ribbed, with a tapering bristle point, which we do not find in D. natans. *Flowers*—*stalks* not much longer than the leaves, each bearing one or more broad clapping *bracteatas*. *Spikes* short and roundish. *Legumes* elliptico-oblong, obtuse, with four, five, or six seeds.

2. D. natans. Floating Defansatus; or Aquatic Sensitive. Willd. n. 2. Allt. n. 1. Andr. Repert. t. 629. (Mimosa natans; Vahl Symb. v. 3. 102. Roxb. Coro-
mand. v. 2. 115. t. 110. M. orientalis non pinosa, rariari-

—Thorns none. First division of the leaves of three pair; second of many smooth-edged leaves. Spikes oblong, interrupted. Stalks mossily without bracteas. Stem round, floating, with tufted roots from the lower joints.—Native of fresh-water lakes, pools, and flow streams, in the East Indies, Cochinchina, &c. Loureir says it is cultivated in the last-mentioned country, as an ingredient in falads, being tender and agreeably sweetish, though not very palatable to the stomach. The plants are tied to stakes, to prevent their being carried away with the stream. The root is annual, entirely floating, as well as the round, smooth, branched, leafy *flava*, whose lower joints lend forth tufts of compound radicles, their interfaces being often sullen, or pungent, at one side, as if to render the herb more fruayant. *Leaves* alternate, flattened, doubly pinnate, smooth, bright green; secondary divisions from one to two inches long, each of twelve or thirteen pair of elliptical, entire *legumina*, which fold together slowly when touched; their edges smooth. *Sipulas* membranous, half-ovate, or heart-shaped, obtuse. Common *flower-stalks* generally naked; sometimes furnished with a *bractea* or two. Spike oblong, more or less crowded. *Corolla* greenish. Abortive filaments of the lower flowers large, lanceolate, yellow, very conspicuous. *Legumes* five or six from each spike, an inch in length, purplish-brown, smooth, elliptico-oblong, pointed. *Seeds* oval, from four to eight, forming a central row, infected by a slender thread alternately to each margin of the legume. König fent specimens of the following to Linneus, but not, as far as we can discover, of the present species; while the information he communicated regarded both species, which possibly he might originally confound, thinking the *triceras* variety caused by growing out of the water. However this might be, his *natans* is certainly the present plant, to which alone that name can apply.

3. D. triceras. Triangular-stalked Defansatus. Willd. n. 3. (Mimosa triquetra; Vahl Symb. v. 3. 102. M. natans; Linn. Suppl. 439.)—Thorns none. First division of the leaves of two or three pair; second of many rough-edged leaves. Stipulas pointed. Spurs globose. Stalks bracteate. Stems prostrate; triangular in their upper part.—Native of the dry borders of fields at Tranquebar. König in the Linnean herbarium. Root woody, perennial. Stems several, from a foot to a foot or more in length, herbaceous, profificate, rather zigzag, leafy, smooth, somewhat glaucous, scarcely bracted; nearly round at the bottom, but triangular above. Leaves about half the size of the former, on much shorter stalks, and effentially distinguished, if we mistake not, by the roughness of their edges, caused by small close-preened bristles. The *flippus* are obliquely ovate, ribbed, with a tapering bristle point, which we do not find in D. natans. *Flowers*—*stalks* not much longer than the leaves, each bearing one or more broad clapping *bracteatas*. *Spikes* short and roundish. *Legumes* elliptico-oblong, obtuse, with four, five, or six seeds.

DESMANTHUS.

Stem prostrate, compressed. Stamens five.—Gathered in flagrant waters at Vera Cruz by Dr. Houillon, who sent seeds to Miller. The latter records that the flmmus, though naturally floating, grew more erect when the plant was cultivated on dry ground. The root is annual, according to Willdenow, Aiton, and Linnaeus, who had this species in the stove at Upfal. Stems herbaceous, smooth, a little zigzag, a foot or two in length, floating or decumbent, slightly branched. Leaves: sensitive, larger than those of D. nana, the lower pair, oblong-obovate, and the upper ones as large as Common Clover, yellow, recurved, on stalks nearly as long as the leaves, bearing two dilatant, ovate, sheathing bracteas. Stamens but five, those of some of the lower flowers changed to long lanceolate petal-like leaves, which give the flowers a double appearance, and render them truly so, according to the analogy of flowers in general. Hence the specific name given by Linnaeus; but this circumstance is common to the whole genus of Desmanthus, as above described. In this and similar cases it seems best to retain the original name, as indicating the first known species, and therefore the history of the genus. The legume is drawn by Houtoult elliptic-oblong; slightly curved, with a furrow, or double edge, along the back. Seeds numerous, ovate. The leaves are fenitive in this and the three preceding.

5. D. depressus. Depressed Desmanthus. Willd. n. 5. 6—Thorns none. First division of the leaves of two pair; second of eight or ten pair of linear oblate leaflets. Spikes capitate, of a few decandrous flowers. Legumes linear. Stem prostrate.—Found by Humboldt and Bonpland, in South America. Root woody, perennial. Stems several, from a span to a foot long, diffuse, smooth; branched and round at the bottom; obliquely quadrangular above. Spikes stalked, without bracteas. Legume an inch and a half long, pointed, with many seeds. Akin to the two following, as to the shape of the spike and of the legume, though easily distinguishable by the specific characters. Willdenow.

6. D. diffusus. Prostrate Desmanthus. Willd. n. 6. Ait. n. 3. (Mimofa pernambucana; Linn. Sp. Pl. 1502. M. inermis decumbens, folis duplicito-pinnatis, epis cerumini, floribus pentandris, inferiioribus cafratis; Linn. Hort. Uppl. 145. n. 6. M. americana pigra, folis longis angustis, allium olentibus; Pluk. Amag. 252. t. 307. f. 3.)—Thorns none. First division of the leaves of four or five pair; second of twelve pair. Spikes capitate, of a few petandrous flowers. Legume linear. Stem prostrate.—Native of South America. Stem shrubby. Willdenow, who had examined dried specimens, says this species is extremely similar to the following, but differs in having mock commonly five primary divisions in the leaves, a prostrate stem, and only five flowers. We have never seen the present species, which probably has not appeared in the gardens since Miller's time, but we venture to transfer the synonym of Zanoni to the next, on account of the upright stem of his plant. Hence the Linnean specific name pernambucana, taken from Zanoni, becomes peculiarly unsuitable, and is fortunately changed by Willdenow.

7. D. virgatus. Upright Angular Desmanthus. Willd. n. 7. Ait. n. 4. (Mimofa virgata; Linn. Sp. Pl. 1502. Jacq. Hort. Vind. v. 1. 34. t. 80. M. spuria de Pernambuco, detta Mimofa italicca; Zanoni. Fl. 18. t. 60. M. inermis, folis duplicito-pinnatis, folis linearibus glabris; Linn. Hort. Clifford. 209.)—Thorns none. First division of the leaves of four pair; second of twelve pair. Spikes capitare, of a few decandrous flowers. Legume linear. Stem erect, angular.—Native of South America, where Jacquin observed it in various places; and not of the East Indies, Burmann's M. virgata being probably our D. nana, at least according to the synonymy of Plukenet and Rheede, cited by that author. The late professor Jacquin sent seeds of this present species to Kew, in 1774, where it flowers in the stove in July and August. His plant is precisely that of Linnaeus, mentioned in the Hortus Cliffortianus as of American origin, but confounded with several other things in his Fl. Zeylanica. 316, n. 505. D. virgatus has an erect shrubby stem, with wand-like branches, angular when young, but lefs so as they become older. Flowers oblanceolate, with a pubescent auricle. Common footstalks with a round depressed gland between the two pair of subdivisions. Leaflets linear, obtuse, fringed, glaucous beneath. Flower-footstks the length of the leaves, erect, with small deciduous bracteas near the top. Heads slightly drooping while young, pale or whitish. Several of the lowermost flowers furnished with ten linear, very narrow, almost thread-shaped, abortive filaments, in the place of flaments. Anthers of the upper flowers roundish, yellow. Legumes about five from each head, almost erect, full two inches long, linear, not one-eighth of an inch broad, acute, thick-edged, smooth. Seeds very numerous, elliptic-oblong, obliquely disjosed in a central row. Miller's remark, cited by Willdenow, after Linn. Mant. 2. 503, does not belong to this species, and is excluded by Linnaeus himself in his MSS. Probably it may relate to D. plenus.

8. D. punctatus. Spotted-stalked Desmanthus. Willd. n. 8. Ait. n. 5. (Mimofa punctata; Linn. Sp. Pl. 1502. M. frutecens mediae alpinae, foliis duplcatis falcatis et umbellatis, pedunculo longifloro; Browne Jam. 253. Achlyonomea mitis prima; Comm. Hort. v. 1. 61. t. 31.)—Thorns none. First division of the leaves of four or five pair; second of many. Spikes ovate. Flower-stalks bracteate at the base. Legume oblong, obtuse, wavy.—Native of Jamaica, from whence it was introduced very early into the European fiowers. Our specimen was sent by Dr. Browne to Linnaeus. The stem is besprinkled with small callous points. Branches angular. Leaves a span long, with a gland on the common footstalk between the first pair of wings. Leaflets about twenty pair, fenitive, linear-oblong, smooth, obtuse with a small point. Flower-stalks scarcely so long as the leaves, each bearing, near the base, two large ovate, or heart-shaped, bracteae. Spike drooping, ovate, of numerous, crowded, pale flowers, the lower ones with thin lanceolate petals, in the place of the five flaments of the more abundant upper ones. Legumes about three from each spike, stalked, horizontal, compressed, oblong, obtuse at each end, with a small terminal point; their length an inch and a half; breadth one-third of an inch. They betray an inclination to split across, like the true Mimofa. Seeds about twelve, ovate. This species does indeed, as Willdenow observes, much resemble D. plenus; but is nevertheless much too different to be confounded therewith.

Se&. 2. Thorny.

9. D. cinerulus. Ash-coloured Desmanthus. Willd. n. 9. Ait. n. 6. (Mimofa cinerula; Linn. Sp. Pl. 1505. Roxb. Coromand. v. 2. 39. t. 174. M. n. 215; Linn. Fl. Zeyl. 96. Acacia spinosa, ex alis spicata, foliis pennis avium referentibus; Burm. Zeyl. 3. t. 2. A. maderapatana, minutissimis foliis, aculeis feroxibus, alternis, frondosa; cortice itidem cinereo; Pluk. Almag. 3. Phyt. t. 121. f. 5.)—Branches becoming solitary spines. First division of the leaves about nine pair; second of many. Spikes solitary, cylindrical, drooping; tapering at the base. Legumes linear, curved.—Native of the East Indies; in forests and low barren lands, according to Dr. Roxburgh, who observes that the wood is remarkably hard, but, owing
owing to the smallness of the tree, of little use. Miller cultivated this plant at Chelsea in 1739, and it is marked by Mr. Aiton, as flowering in the House about June and July. A low, irregular, rigid frutic, with a grey bark, and zigzag branches, short, alternate, lateral shoots spreading horizontally, and each finally becomes tipped with a hard sharp thorn. These branches bear very fine and delicate foliage, whose very minute oblong leaflets are smooth above, hairy at the back, and appear to be sensitive; their common flalk also is hairy. Spikes axillary, flaked, an inch or two long, swelling upward, obtuse, dense, and many-flowered. Perfect flowers numerous, yellow, with ten flaments, whose anthers are ovate, of two cells, and tipped with a small round gland. The lower flowers, less numerous, are pale rose-coloured, abortive, having ten linear, obtuse, trap-like leaves instead of flaments. Legume falcate, linear, compressed, but not flat, about three inches long, and one-fourth of an inch broad, smooth, obtuse. Seeds ten to fifteen, oblong, yellow.

10. D. divergens. Spreading-branched Definanthus. Wild. n. 10. ('Ergott Dimmo; Bruce's Travels, v. 5. 34, with a plate.')—Branches becoming solitary spikes. First division of the leaves of eight pair; second of many. Spikes in pairs, cyindrical, pendulous. Legume twelled.'—Native of Abyssinia? A frutic, fix feet high, with divaricatet inflated branches, besprinkled with white warts. First divisions of the leaves from fix to nine pair. Leaflets numerous, linear, angular at the base, and fringed at the edges. Thorus rigid, ftraiht, awl-shaped, sometimes in pairs. Legume linear, contorted. Wildenow, who made this description from a living specimen, says the gardeners call this species Mimosa diversicata. But what is so designated in Donn's Hort. Cant. ed. 5. 240, comes from Carolina, and, as far as we can discover, does not occur in Hort. Kew. Bruce's figure above quoted was thought by Wildenow to answer exactly to his own garden frutic, except the want of thorns; but as these occur on the older branches only, they might be overlooked. We have not seen specimens of either Bruce's or Wildenow's plant.

DE TOIT. Add.—The civil district of Detroit, which is one of the divisions of the territory of Michigan, contains, by the census of 1810, 2227 inhabitants, of whom 17 were slaves.

DE VAUXIA, in Botany, far named by Mr. Brown, in honour of M. Devaux, author of a dissertation on the natural family of Junci, in the Journal de Botanique. M. Labillardiere had previously published this fame genus under the appellation of Centrolepis, from ungus, the centre, and lepis, a scale; which, giving an erroneous idea of the structure of the flower, it was found necessary to change.—Brown Prodr. Nov. Holl. v. 1. 272. (Centrolepis; Labill. Nov. Holl. v. 1. 7.)—Clafs and order, Monandria Polygynia. Nat. Ord. Rhytipteris, Brown.

Gen. Ch. Cal. Sheath of two concave, keeled, permanent, alternate valves, clasping each other at the base, containing an indefinite number of flowers. Car. of two oblong, membranous valves, sometimes accompanied by small accccory scales. Stam. Filament one, capillary, drooping, rather longer than the largest valve of the corolla; another simple, oval. Pf. Germins several, from three to twelve, ovato-oblong, superior, inserted into one side of a central oblong receptacle, and all turned one way; style as many, thread-shaped, either dilinct at the bottom or combined, spreading or deflexed at the summit; stigma linear, downy. Peric. Capsules as many as the germins, membranous, oval, of one valve and one cell, burbling along one side. Seed solitary, obovate, pendulous.

This genus, of which we have already spoken as akin to Alepyrum, (see that article,) consists of small herbaceous plants, growing in tufts, and resembling the lefier species of Scirpus. The roots are fibrous and tufted. Stem none.

Leaves radical, bristle-shaped, half sheathing at the base. Flower-flalks radical, thread-shaped, undivided, naked. Sheath solitary, terminal, its valves either awned or not. Nine species are described by Mr. Brown, as follows.

Sec. 1. Receptacle scaly.
1. D. pulvinata. Cushion Devauxia.—Receptacle scaly. Styles fix or seven, dilinct. Sheath pointlets; lower valve rather hifpid; upper smooth. Leaves nearly as tall as the flower-flalks.—Gathered by Mr. Brown, in Van Diemen's island.

2. D. Paterfani. Paterfon's Devauxia. (Centrolepis annula; Rudge Tr. of Linn. Soc. v. 10. 284. 112. f. 2.)—Receptacle scaly. Styles eight or nine, dilinct. Sheath pointed, many-flowered; upper valve nearly smooth; lower hifpid. Adult flower-flalks hairy, as well as the leaves, which are only one-third as tall.—Gathered by Col. Parfon and Mr. Brown, near Port Jackson, New South Wales. Leaves very narrow, an inch long. Flower-flalks above two inches high. Sheath tumid, fiercely riling above the flower.

3. D. Ariogia. Brilly Devauxia.—Receptacle scaly. Styles from five to seven, dilinct. Sheath pointets; both valves hifpid. Adult flower-flalks smooth, three as long as the finely hifpid leaves.—Found by Mr. Brown, on the southern coast of New Holland.

Sec. 2. Receptacle without scales. Sheaths hifpid.

4. D. tenon. Slender Devauxia.—Receptacle naked. Styles four or five, combined at the base. Sheath almost pointets, brilly as well as the leaves. Flower-flalks slightly hairy.—Found in the island of Van Diemen, by Mr. Brown.

5. D. Billiardiere. Labillardiere's Devauxia. (Centrolepis fasicularis; Labill. Nov. Holl. v. 1. 7. 1. C. cuspidiger; Rudge Tr. of Linn. Soc. v. 10. 283. 112. f. 1.)—Receptacle naked. Styles two or three, combined at the base. Sheath brilly; with awns nearly as long as the valves. Leaves rather hairy. Stalks smooth.—Native of Port Jack- son, as well as of Van Diemen's island. Brown, Labillardiere. The numerous brille-shaped leaves are about an inch and a half long, erect, those which clasp the base of each flower-flalk, which is half as tall again, are toothed at their inner margin towards the base. Valves of the sheath twice as tall as the flowers. Corolla toothed, obtufe.

6. D. esfera. Prominent-flowered Devauxia.—Recep-tacle naked. Styles from seven to ten, dilinct. Sheath pointets, brilly, not quite so long as the flowers. Stalks and leaves downy.—Gathered by Mr. Brown, in the tropical part of New Holland.

Sec. 3. Receptacle without scales. Sheaths smooth.

7. D. Bankfi. Bankfiian Devauxia.—Receptacle naked. Styles from eight to ten. Sheath pointets, very smooth, many-flowered, membranous at the edges. Stalks three or four times the length of the leaves.—Gathered by Mr. Joseph Banks, in the tropical part of New Holland.

8. D. pufilla. Little Devauxia.—Receptacle naked. Styles fix or seven. Sheath pointets, very smooth, mem-branous at the edges, with but few flowers. Stalks and leaves
leaves both smooth, and nearly equal in length.—Observed by Mr. Brown, in the tropical part of New Holland.

Mr. Rudge, very commendably anxious to retain, if possible, Lablellated, or original generic name, has, by taking refuge for a prickle, as it undoubtedly means a point, or {sharp fife}, made Centropis to express a prickle shield, aluding to the habited {fheath} of some species. But this is not apposite, the scales, or glumes of the flower, to which the original name applied, being, in no fene, pointed, or prickle; nor do we fee that this name can be forced into any appropriate meaning, the {fheaths} being acknowledged on all hands not to be central.

DEVIZiES, col. 2, l. penult. r. 696, and 1750.

DEVONSHIRE, col. 6, l. 11 and l2, r. 623,318, and 383,308.

Dew. To this article we shall subjoin some appropria
t remarks, selected from an "Effay on Dew, &c. by the ingenious Dr. Wells, lately (viz. 1819) republished in an edition of his works, to which is prefixed a Memoir of his life written by himself. To this author it occurred in 1784, that the formation of dew is attended with the production of cold. The same opinion was announced in 1788 by Mr. Wilfon of Glasgow (vol. i. Edinb. Tran.), and also by Mr. Six of Canterbury (Phil. Tran. for 1788, and in a posthumous work printed at Canterbury in 1794.) All these writers at firft concurred in regarding the cold which accompanies dew as an effect of the formation of that fluid. Dr. Wells, however, upon mature confideration of the subjed, was led to fufpect that this opinion was erroneous; and his fufpicion was afterwards juftified by a variety of obfervations and experiments. Although Dr. Wells agrees, in general, with Arifotle and other writers, and maintains that dew appears only on calm and fenere nights, yet this opinion is not univerfally true; for he frequently found a small quantity of dew on grafts, both on windy nights, if the flank was clear or nearly so, and on cloudy nights, if there was no wind; but he never perceived dew to fall in both cloudy and windy nights. Dew, he says, probabably begins, in this country, to appear upon grafts, shaded from the flank, during clear and calm weather, fooner after the heat of the atmosphere has declined; and it continues to form, in shaded places, after fun-rife; the interval between fun-rife and its ceafing to form being considerably shorter than that between its firft appearance in the afternoon and fun-fet. If the weather be favourable, however, more dew forms a little before, and in shaded places a little after fun-rife, than at any other time; whereas Mufchenbroeck afferts, that dew does not form after the sun has rifen. Our author alfo maintains, in opposition to the opinion of M. Pricur, that dew, after it has once commenced, continues during the whole night, if the weather remain flill and fenere. During nights that are equally clear and calm, whether they be longer or shorter, dew often appears in very unequal quantities; the quantity of moifure in the atmosphere ferving to increase the production of dew; and, accordingly, in equally clear and calm nights, dew is more abundant soon after rain than during a long continuance of dry weather; it is also more abundant in Europe, and in fome parts of Asia and Africa, with foutherly and wetferly winds, than with thofe which blow from the north and the eait. Another circumfance upon which the quantity of dew depends, is the diminution of the weight of the atmosphere; for though the falling of the mercury in the baro-

Dew meter is commonly attended with wind or clouds, both unfavourable to the production of dew, yet the greatest dew observed by our author occurred while the barometer was falling. M. De Luc alfo has observed, that rain may be foretold when dew is uncommonly abundant in relation to the climate and feaon. We have already observed, that dew is commonly more plentiful in spring and autumn than in summer, a fac which our author alfo has noticed; it is always very copious on clear and calm nights which are followed by milfy or foggy mornings; and on a clear morning which succeeds a cloudy night. Heat of the atmosphere, if other circumfances are favourable, occasions a great formation of dew; and upon the fupputation of the fame clearnefs and flillness of the atmosphere, more dew is formed between midnight and fun-fet than between fun-fet and midnight; the cold of the atmosphere being greater in the latter than in the former part of the night. Our author's experiments ferve to fhew, that various differences with regard to fition, mechanical flate, and real nature of bodies, have a very considerabfe influence upon the production of dew. As to fition he observes, that whatever diminishes the view of the flky, as feen from the expofed body, diminishes the quantity of dew that is produced; and hence the quantity is greater when the expofure to the flky is more complete. There are other circumfances, regarding fition, which ferve to augment or diminish the quantity of dew that is produced, when the fubftances that are used for indicating it are the fame.

- It is observed farther, that when other circumfances are similar, a difference in the mechanical flate of bodies has an effect with regard to the quantity of dew which they attract; and hence it is, that fine raw filk, fine unwrought cotton, and flax, were found to attract more dew than the wool employed by our author in his experiments; the fibres of wool being thicker than those of the other fubftances juft mentioned. Bright metals also attract dew much lefs powerfully than other bodies: this fac was observed by Mufchenbroeck and Dufay; but they erroneously afferted, that dew never appears on the upper furface of bright metals. There are others, and our author in particular, who have known dew to be formed on gold, silver, copper, tin, platina, iron, steel, and lead. This imputation of metals to attract dew is communicated to bodies of a very different nature, which touch or are near to them. Wool, says our author, laid upon a metal, will acquire much lefs dew than an equal quantity laid upon grafts in the immediate vicinity. It is maintained, that the upper furfaces of metals are moft readily and moft copiously dewed on thofe nights and in thofe parts of the night, during which other fubftances are the moft readily and the moft copiously dewed. All metals, our author remarks, do not refit the formation of dew with the fame force. "I faw," he says, "for example, platina one night f Uttarly dewed, while gold, silver, copper, and tin, though fimilarly situated, were entirely dry; and I have alfo feveral times feen these four metals free from dew, while iron, steel, zinc, and lead, were covered with it." Our author proceeds to investigate and afcertain the degree of cold connected with the formation of dew. Mr. Wilfon, he thinks, is the firft philofopher who ever fufpected the exiftence of fuch a conjufion; though dew is often fpoken of as cold by our popular writers. Herodotus mentions it as poffefing this quality; Cicero and Virgil apply to it the epithet of "gelidus" Milton that of "chill;" and Collins that of "cold." With thermometers adapted to the purpofe, he has, in fenere and flill nights, examined the temperature of dewed grafts, and con-

3 N

flantly
flantly found it to be less than that of the air, any where between one inch and nine feet above the ground, the latter being the greatest height at which he ever marked the heat of the atmosphere in these experiments. At the height of four feet above the ground, and in calm and clear nights, he frequently found the graps seven, eight, or nine degrees colder than the air at that height; several times it was 10° and 11°, and once 12°, colder than the air. In some few observations, the greater coldness of graps than of the air began to appear, in clear and calm weather, in places sheltered from the afternoon sun, and yet open to a considerable portion of the sky, soon after the heat of the atmosphere had declined. A similiar coldness continued upon graps in still and serene mornings, for some time after the rising of the sun, in places shaded from its direct light, but otherwise open to the sky. In cloudy nights, particularly with wind, the graps was never much colder than the air. Sometimes the temperatures were the same; at other times that of the graps was higher, even when it had been wetted by preceding rain, and when it must have cooled by evaporation. When the night changed from clear to cloudy, though without change as to calmness, a considerable alteration in the temperature of the graps always ensued, and this change occurred sometimes very suddenly. On one night, the graps, after having been 12° colder than the air, became 2° colder, the temperature of the air at both observations being the same. On a second night, the graps became 9° warmer in an hour and a half. On a third night, in less than forty-five minutes the temperature of the graps rose 17°, while that of the neighbourhooding air increased 38°.

On a fourth night, the temperature of the graps at half-past 9 o'clock was 32°; in twenty minutes afterwards it was found to be 30°, the sky in the mean time having become cloudy. At the end of twenty minutes more, the sky being clear, the temperature of the graps was again 32°. On the connection of fog or mist with cold, Dr. Wells made several experiments, which we cannot recite. He observes, that he has always found on dewy nights the temperature of the earth half an inch or an inch beneath its surface much warmer than the graps upon it; and the earth at this depth was also almost constantly warmer on dewy nights than the air. Metals, says our author, furnish proofs of the predilection of dew with cold in the substances on which it forms superior to that of the neighbouring atmosphere. Upon the whole, our author's experiments, which we cannot minutely detail, shew, that when bodies which had been equally exposed to the night air were examined at the same time, those which were most dewed were the coldest. In the prosecution of experiments with other substances besides graps, he found that those of the filamentous downy kind were the most productive of cold. Thus, wool of moderate fineness, very fine raw silk, very fine unspun cotton, fine flax, and flax-down, were not only more readily cold, upon clear and calm nights, than graps, but also gave rise to a greater degree of cold than was almost at any time observed upon it even in its best state. Wool produced the least cold, and we have found before, that it attracted less dew than silk, cotton, and flax. Fresh, unbroken straw, and threads of white paper, were found to be a little more productive of cold than wool. The next class confined of bodies in the state of powder; these were, clean river sand, graps, charcoal, lamp-black, and a brown cake of iron. Chalk produced the least, and the three last substances produced the greatest cold. Solid substancess, exposing to the sky a surface of at least twenty-five inches square, formed a third class, on which our author made experiments. The substances of this description subjected to trial were, graps, brick, cork, oak-wood, and wax; all of which were found inferior to the filamentous substancess. His principal experiments, however, of this kind were made on snow.

The next subject to which Dr. Wells directs his attention is the theory of dew. According to Aristotle among the ancients, and many philosophical writers among the moderns, dew is a species of rain, formed in the lower atmosphere, in consequence of its moisture being condensed by the cold of the night into minute drops. But opinions of this kind have been found erroneous, by the confederacy of a fact first noticed by Gersten in 1753; viz. that bodies a little elevated in the air often become moist with dew, while similar bodies, lying on the ground, remain dry, though necessarily, from their position, as liable to be wetted, by whatever falls from the heavens, as the former. It was soon afterwards observed by Mulchenbroeck, that metals will be free from dew, while other bodies attract it copiously; hence Dufay concluded, that dew is an electrical phenomenon, since it leaves untouched the bodies which conduct electricity, whilst it appears upon those of which it cannot transmit that influence. Against this hypothesis several objections have been urged, however plausibly it has been supported. It has been alleged that charcoal, which next to the metals is the best solid conductor of electricity, attracts dew more powerfully; and dew, as we have seen above, frequently forms upon metals themselves. It has also been urged against this hypothesis, that dew forms in different parts of the night, in quantities disproportional to the degrees of electricity found in the atmosphere at the same time. Thus, it is commonly more copious in the morning than in the evening, though the air is observed to be, in the latter season, more highly electrical than in the former. But another argument applies alike to all the theories which have hitherto been made public on the cause of dew; and this is, that none of them include the important fact, that its production is attended with cold. Mr. Wilfon and Mr. Six have indeed maintained, that the formation of this fluid is the cause of the cold that accompanies it. Dr. Wells once held the same opinion; but finding that bodies would sometimes become colder than the air without being dewed, and that when dew was formed, its quantity, and the degree of cold which appeared with it, were very far from being always in the same proportion to each other, he first doubted its truth, and at length became convinced that it was erroneous; and by farther inquiry he was led to conclude, that dew is the production of a preceding cold in the substances upon which it appears; and that it has precisely the same immediate cause as the presence of moisture upon the outside of a glass or metallic vessel, when a liquid considerably colder than the air has been poured into it shortly before. This fact is applied by our author, to the explanation of several atmospheric appearances.

I. The variety in the quantities of dew, which were found by me upon bodies of the same kind, exposed to the air during the same time of the night, but in different situations, is now seen to have been occasioned by the diversity of temperature, which existed among them.

II. Agreeably to the opinion of Mr. Wilfon and Mr. Six, the cold connected with dew ought always to be proportional to the quantity of that fluid; but this is contradicted by experience. On the other hand, if it be granted, that dew is water precipitated from the atmosphere, by the cold of the body on which it appears, the same degree of cold, in the precipitating body, may be attended with much, with little, or with no dew, according to the existing state of the air in regard to moisture; all of which circumstances are found actually to take place.

III. The
DEW.

"III. The formation of dew, indeed, not only does not produce cold, but like every other precipitation of water from the atmosphere, produces heat.

"IV. In very calm nights, a portion of air, which comes in contact with cold grass, will not, when the surface is level, immediately quit it, more especially, as this air has become specifically heavier than the higher, from a diminution of its heat, but will proceed horizontally, and be applied successively to different parts of the same surface. The air, therefore, which makes this progress, must at length have no moisture to be precipitated, unless the cold of the grass which it touches should increase. Hence in great measure is to be explained, why, on such nights as have been just mentioned, more dew was acquired by substances placed on the raised board, than by others of the same kind on the grass, though it began to form much sooner in the latter than in the former situation, those on the raised board having received air, which had previously deposited leafs of its moisture.

"A reason is now also afforded, why a flight agitation of the atmosphere, when very pregnant with moisture, should increase the quantity of dew; since fresh parcels of air will hence be more frequently brought into contact with the cold surface of the earth, than if the atmosphere were entirely calm.

"V. Dew, in agreement with the immediate cause which has been assigned by me for its production, can never be formed, in temperate climates, upon the naked parts of a living and healthy human body, during the night; since their heat is never less in this season, in such climates, than that of the atmosphere. I have, in fact, never perceived dew on any naked part of my own body at night, though my attention was much occupied, for three years, with every thing relative to this fluid, and though I had been, during that period, much exposed to the night air. On the other hand, in very hot countries, the uncovered parts of a human body may sometimes, from being considerably colder than the air, condense the watery vapour of the atmosphere, and hence be covered with a real dew, even in the day-time.

"VI. Hygrometers formed of animal or vegetable substances, when exposed to a clear sky at night, will become colder than the atmosphere; and hence, by attracting dew, or, according to an observation of Sauffure, by merely cooling the air contiguous to them, mark a degree of moisture, beyond what the atmosphere actually contains. This serves to explain an observation made by M. De Luc, that in fenere and cold nights, the humidity of the air, as determined by an hygrometer, increases about, and after fun-fet, with a greater rapidity, than can be attributed to a diminution of the general heat of the atmosphere."

Having established the fact, that bodies become colder than the neighbouring air, before they are dewed, and applied this fact to the explanation of many atmospheric appearances, we shall now proceed with the author to complete the investigation of his theory with respect to the cause of dew; and hence he avails himself of the discoveries on heat and its radiation, that have been made by professor Leflie, Dr. Herschel, and count Rumford. (See Heat.)

"The experience of molt perfons," says Dr. Wells, "respecting the communication of heat among bodies in the open air, is confirmed to what happens during the day; at which time, those that are situated near to one another are always found to pollese the same temperature, unless some very evident reason for the contrary should exist. To many, therefore, it may appear incredible, that a perfectly dry body, placed in contact, on all sides, with other bodies of the same temperature with itself, shall afterwards, without undergoing any chemical change, become much colder than they are, and shall remain so for many hours; yet these circumstances are found to occur in substances attractive of dew, when laid on the surface of the earth, in a still and clear night, and are in perfect agreement with the doctrine of heat, now universally admitted to be just.

"To render this more easy of apprehension, let a small body which radiates heat freely, and poissles a temperature, in common with the atmosphere, higher than 35°, be placed, while the air is clear and still, on a slow conductor of heat lying on the surface of a large open plain, and let a firmanent of ice be stopped to exist at any height in the atmosphere; the consequence must be, that the small body will, from its situation, quickly become colder than the neighbouring air. For, while it radiates its own heat upwards, it cannot receive a sufficient quantity from the ice to compensate this loss; little also can be conveyed to it from the earth, as a bad conductor is interpowed between them; and there is no solid, or fluid except the air, to communicate it laterally either by radiation or conduction. This small body, therefore, unless it shall receive from the air, nearly as much heat as it has emitted, which, considering the little that can be communicated from one part of the atmosphere to another, in its present calm state, must be regarded as impossible, will become colder than the air, and condense the watery vapour of the contiguous parts of it, if they should contain a sufficient quantity to admit of this effect. But events similar to these occur, when dew appears in an open and level grass field, during a still and clear night. The upper parts of the grass radiate their heat into regions of empty space, which consequently send back no heat in return; its lower parts, from the smallness of their conduction power, transmit little of the earth's heat to the upper parts, which at the same time receiving only a small quantity from the atmosphere, and none from any other lateral body, must remain colder than the air, and condense into dew its watery vapour, if this be sufficiently abundant, in respect to the decreased temperature of the grass.

"This subject may be further illustrated by a reference to what happens in the experiment, which has been used to prove the reflection of cold.

"In the simplest form of this experiment, a small body, the bulb of a thermometer, poissling the temperature of the atmosphere, is placed before a larger cold body, rendered equal in effect to one half larger, by means of a concave metallic mirror. In this situation, the small body radiates heat to the larger, without receiving an equivalent from it, and, in consequence, becomes colder than the air through which its heat is sent, notwithstanding that it is continually gaining some heat, both from the air which surrounds it, and from the walls and contents of the apartment, in which the experiment is made. Dew, therefore, would as readily form upon the thermometer in this experiment, as it would upon one suspended in the open air at night, under a clear sky, provided that the two instruments were equally colder than the atmosphere, and that this was in both cases equally near to being replete with moisture.

"Regarding now as established, that bodies situated on or near to the surface of the earth become, under certain circumstances, colder than the neighbouring air, by radiating more heat to the heavens than they receive in every way, I shall in the first place offer a few remarks on the extent and use of this occurrence, and shall afterwards apply the knowledge of it to the explanation of several more of the appearances described in the former part of this Essay, and..."
of some others, which have not hitherto been mentioned by me.

Radiation of heat by the earth to the heavens must exit at all times; but, if the sun be at some height above the horizon, the degree of which is hitherto undetermined, and probably varies according to season, and several other circumstances, the heat emitted by it to the earth will overbalance, even in places shaded from its direct beams, that which the earth radiates upwards.

In a calm and serene night, however, when consequently little impediment exils to the escape, by radiation, of the earth's heat to the heavens, and when no heat can be radiated by the sun to the place of observation, an immense degree of cold would occur on the ground, if the following circumstances did not combine to lessen it. 1. The incapacity of all bodies to prevent, entirely, the passing of heat, by conduction, from the earth to substances placed upon them. 2. The heat radiated to these substances by lateral objects. 3. The heat communicated to the same substances by the air. 4. The heat which is evolved, during the condensation of the watery vapour of the atmosphere into dew.

The extent of the effect of all these checks upon the production of cold, by the nightly radiation of heat from bodies on the surface of the earth, cannot, in the present state of our knowledge, be properly estimated; but facts shew that, notwithstanding their operation, the cold originating in this source must be often very considerable.

I shall add, with the greatest diffidence, a few words upon a final cause of the radiation of heat from the earth at night, and upon some of the circumstances which modify its action, though fully conscious of the danger of error, which is always incurred in the attempt to appreciate the works of our Creator.

The heat which is radiated by the sun to the earth, if suffered to accumulate, would quickly destroy the present constitution of our globe. This evil is prevented by the radiation of heat by the earth to the heavens, during the night, when it receives from them little or no heat in return. But, through the wise economy of means, which is witnessed in all the operations of Nature, the prevention of this evil is made the source of great positive good. For the surface of the earth, having thus become colder than the neighbouring air, condenses a part of the watery vapour of the atmosphere into dew, the utility of which is too manifest to require my speaking of it. I may remark, however, that this fluid appears chiefly where it is most wanted, on herbage, and low plants, avoiding, in great measure, rocks, bare earth, and considerable masses of water. Its production too, by another wise arrangement, tends to prevent the injury, that might arise from its own cause; since the precipitation of water, upon the tender parts of plants, must leffen the cold in them, which occasions it. I shall observe in the last place, that the appearance of dew is not confined to any one part of the night, but occurs during its whole course, from means the molt simple and efficacious. For after one part of the air has deposited its moisture, on the colder surface of the earth, it is removed, in consequence of that agitation in the atmosphere which exists during its fullest states, and gives place to another having its quantity of water diminished; and, again, as the night proceeds, a portion of air, which had before deposited all the moisture, which circumstances at that time permitted, is rendered fit, by the general increase of the cold of the atmosphere, to give out a fresh parcel, when it comes anew into contact with the ground.

The first fact, which I shall here attempt to explain, is the prevention, either wholly or in part, of cold, from radiation, in substances on the ground, by the interposition of any solid body between them and the sky. This evidently appears to arise in the following manner. The lower body radiates its heat upwards, as if no other intervened between it and the sky; but the lofs, which it hence suffers, is more or less compensated by what is radiated to it, from the body above, the under surface of which poffefles always the fame, or very nearly the fame temperature as the air.

No direct experiments can be made to ascertain the manner, in which clouds prevent, or occasion to be small, the appearance of a cold at night, upon the surface of the earth, greater than that of the atmosphere; but it may, I think, be firmly concluded, from what has been said in the preceding article, that they produce this effect, almost entirely, by radiating heat to the earth, in return for that which they intercept in its progress from the earth towards the heavens. For although, upon the sky becoming suddenly cloudy during a calm night, a naked thermometer, suspended in the air, commonly rises two or three degrees, little of this rise is to be attributed to the heat evolved by the condensation of watery vapour in the atmosphere, as was supposed by Mr. Wilfon; since, in consequence of the ceasing of that part of the cold indicated by the thermometer, which was owing to its own radiation to a clear sky, the temperature of the atmosphere may seem to increase 2°, or more, notwithstanding that it has received no real addition. Besides, the heat which is extracted by the condensation of vapour, during the formation of a cloud, must soon be diffipated; whereas the effect of greatly lessening, or preventing altogether, the appearance of a superior cold on the earth to that of the air, will be produced by a cloudy sky, during the whole of a long night.

Dense clouds, near the earth, must poffess the fame heat as the lower atmosphere, and will therefore tend to the earth as much, or nearly as much, heat as they receive from it by radiation. But similarly dense clouds, if very high, though they equally intercept the communication of the earth with the sky, yet being, from their elevated situation, colder than the earth, will radiate to it less heat than they receive from it, and may, consequently, admit of bodies on its surface becoming several degrees colder than the air. In the first part of this Effay, an example was given of a body on the ground becoming at night 5° colder than the air, though the whole sky was thickly covered with high clouds.

Islands, and parts of continents clofe to the sea, being, by their situation, subject to a cloudy sky, will, from the smaller quantity of heat lost by them through radiation to the heavens at night, in addition to the reasons commonly assigned, be less cold in winter, than countries considerably distant from any ocean.

Fogs, like clouds, will arrest heat, which is radiated upwards by the earth, and, if they be very dense, and of considerable perpendicular extent, may remit to it as much as they receive. Accordingly, Mr. Wilfon found no difference at night, in very foggy weather, between the temperature of the surface of snow, and that of the air.

In mists and low fogs it was found by profesor Leslie, that the diminution of the fun's heat is small, when compared with what occurs, when the sky is obscured by a dense body of clouds; and it will, I presume, be readily granted, that the same state of the atmosphere, which allows the heat of the fun to pass copiously, will also give a ready transit to heat radiated by the earth."

From previous reasoning, the author concludes, therefore, that "fogs do not in any instance furnish a real exception to the
DEW.

the general rule, that whatever exists in the atmosphere, capable of stopping or impeding the passage of radiant heat, will prevent or lessen the appearance at night of a cold on the surface of the earth, greater than that of the neighbouring air.

"It follows also, from what has been said in this article, that the water deposited upon the earth, during a fog at night, may sometimes be derived from two different sources, one of which is a precipitation of moisture from a considerable part of the atmosphere, in consequence of its general cold; the other, a real formation of dew, from the condensation, by means of the superficial cold of the ground, of the moisture of that portion of the air, which comes in contact with it. In such a state of things, all bodies will become more or less cold, especially those which most readily attract dew in clear weather. I have had no opportunity, however, of trying this conclusion by the test of observation, since it occurred to me.

"When bodies become cold from radiation, the degree of effect observed must depend, not only on their radiating power, but in part also on the greater or less exposure, with which they can derive heat, by conduction, from warmer substances in contact with them. Thus, grasses, on a clear and still night, were constantly colder, sometimes very much colder, than the gravel-walk, though a small quantity of sand, placed upon grasses, was almost nearly as cold as this substance. In this case, the difference in temperature between the gravel-walk and sand, evidently depended on the different quantities of heat which they received from the parts beneath. A like reason is to be given for dew appearing in greater quantity on shavings of wood, than on the same substance in a more dense and compact form; and for filamentous and downy substances becoming colder than all others, even than lamp-black, which is placed by Mr. Leslie, at the head of the belt of radiating heat. For the lamp-black exposed by me, being about two lines in depth, polished, in consequence, a fund of internal heat, which would more readily pass to its cold surface, than the heat of the lower parts of the downy substances would to their upper surface.

"Bodies, exposed in a clear night to the sky, must radiate as much heat to it during the prevalence of wind, as they would do if the air were altogether still. But in the former case, little or no cold will be observed upon them above that of the atmosphere, as the frequent application of warm air must quickly return a heat equal, or nearly so, to that by which they had lost by radiation. A slight agitation of the air is sufficient to produce some effect of this kind; though, as has already been said, such an agitation, when the air is very pregnant with moisture, will render greater the quantity of dew, one requisite for a considerable production of this fluid being more increased by it, than another is diminished."

Theophrastus remarks, and the remark has been confirmed by other writers, that "the hurtful effects of cold occur chiefly in hollow places. If this be restricted to what happens on ferny and calm nights, and it does not, I believe, hold true in any other circumstances, two reasons from different sources are to be alligned for it. The first is, that the air being fuller in such a situation, than in any other, the cold, from radiation, in the bodies which it contains, will be less diminished by renewed applications of warmer air; the second, that from the longer continuance of the same air in contact with the ground, in depressed places than in others, less dew will be deposited, and therefore less heat extricated during its formation. It will be seen in the last part of this Essay, that, in the East Indies, depreffions in the earth are artificially made, for the purpose of increasing the cold, which appears in ferene nights. On this subject, however, it is to be observed, that if the depreffed or hollow places be deep, in proportion to their horizontal extent, a contrary effect must follow; as a cafe will occur more or less familiar to that which existed in some experiments formerly related by me, in which a small portion of graves was surrounded by a hollow cylinder.

"An observation closely connected with the preceding, namely, that in clear and still nights, frosts are less prevalent upon hills, than in neighbouring plains, has excited more attention, chiefly from its contrasting what is commonly regarded an established fact, that the cold of the atmosphere always increases with the distance from the earth. This inferior cold of hills, is evidently a circumstance of the same kind, with that ascertained by Mr. Piétet and Mr. Six, respecting the increasing warmth, in clear and calm nights at all seasons of the year, of the different parts of the atmosphere, in proportion as these are more elevated above the earth. As the greater cold of the lower air is the less complicated fact, I shall attempt to explain it in the first place. Mr. Piétet, indeed, furnished an explanation himself, by ascribing it to the evaporation of moisture from the ground. But to shew that this is not sufit, it need only be mentioned, that the appearance never occurs in any considerable degree, except upon such nights as are attended with some dew, and that its great degree are commonly attended with a copious formation of that fluid; since it cannot be thought, that the same stratum of air will deposit moisture on the ground, from an insufficiency of heat, at the very time it is receiving moisture from the ground, in the state of pellicular vapour, as this presupposes, that it is not yet replete with water."

Aristotle and Plutarch, and of late Mr. Jefferson (Notes on Virginia,) have observed that dew is much less copious on hills than it is upon plains. In order to account for this fact, we may allow, at first, that the surface of the ground is in both situations equally colder than the air contiguous to it; yet, "as the production of dew must be in proportion to the whole depression of the temperature of the air which furnishes it, below what its heat had been in the preceding day, and as one part of this depression, the general cooling of the atmosphere, is much more considerable on the plain than on the hill, moisture must necessarily be deposited more copiously in the former than in the latter place. If the greater agitation of the atmosphere, and the less quantity of moisture, during clear weather, in its higher region than in the lower, be added, it may readily be inferred, that dew shall sometimes be altogether wanting on a hill, though abundant on a plain at its foot, agreeably to what has been actually observed by Mr. Jefferson.

"The leaves of trees often remain dry throughout the night, while those of grass are covered with dew. As this is a similar fact to the smallhefs of dew on hills, I shall in accounting for it do little more, than enumerate the circumstances on which it depends.

1. The atmosphere is several degrees warmer near the upper parts of trees on dewy nights, than close to the ground. 2. The air in the higher situation is more agitated, than that in the lower. 3. The air at a little distance from the ground, from being nearer to one of its sources of moisture, will on a calm evening contain more of it, than that which surrounds the leaves of elevated trees. 4. Only the leaves of the very tops of trees are fully exposed to the sky. 5. The declination of the leaves from an horizontal position will occasion the air, which has been cooled by them, to slide quickly away, and be succeeded by warmer parcels. 6. The
6. The length of the branches of the trees, the tenderness of their twigs, and the pliancy of the footstalls of their leaves, will cause in the leaves an almost perpetual motion, even in states of air that may be denominated calm. I have hence frequently heard, during the stillness of night, a rustling noise in the trees, which formed one of the boundaries of the ordinary place of my observations, while the air below seemed without motion.

"Nearly in the same manner is to be explained, why shrubs and bushes also receive dew more readily than lofty trees.

"Bright metals, exposed to a clear sky in a calm night, will be less dewed on their upper surface than other solid bodies; since of all bodies they will, in such a situation, lose the smallest quantity of heat by radiation to the heavens, at the same time that they are capable of receiving, by conduction, as least as much heat as any others from the atmosphere, and more than any others from the warmer solid substances, which they happen to touch.

"If the exposed pieces of metal be not very small, another reason will contribute somewhat to their being later and less dewed than other solid substances. For, to the conductive power of dew cannot form upon them, unless their whole mass be sufficiently cold to condense the watery vapour of the atmosphere; while the same fluid will appear on a bad conductor of heat, though the parts a very little beneath the surface are warmer than the air."

It appears from the discoveries of professor Leslie, that the metals differ in their capacities of radiating heat; and hence will arise a difference among themselves with regard to their attraction of dew. Gold, silver, copper, and tin, as we have already said, reflect the formation of dew more strongly, than other substances of the same class; but these metals, according to Mr. Leslie, radiate heat the most sparingly. On the other hand, lead, iron, and steel, which, according to the same author, radiate heat more copiously than the former metals, were found by Dr. Wells to acquire dew more readily. The fame observations may probably be applicable to platinum and zinc. In the article Dew, we have already taken some notice of the opinion of those who maintain, that it rives from the earth at night. The first trace of this opinion, according to Dr. Wells, occurs in the Hist. Acad. Sci. for 1687. Germaine advanced it anew in 1733. It was embraced by Munchenbroek and Dyck; the latter who, before he admitted that dew sometimes falls. Mr. Wacker of New England has adopted the same opinion. We refer those who wish to see the arguments for and against this opinion fully ratted to Wells's Essay.

Agreeably to another opinion on the origin of dew, that which is found upon growing vegetables, is said to be the condensed vapour of the plants on which it appears. "But this seems," says our author, "to be erroneous for several reasons. 1. Dew forms as copiously upon dead as upon living vegetable substances. 2. The transpired humour of plants will be carried away by the air which passes over them, when they are not sufficiently cold to condense the watery vapour contained in it; unless, which is almost never the case if mists does not already exist, the general masses of the atmosphere are incapable of receiving moisture in a admirably form. Accordingly, on cloudy nights, when the air, consequently, can never be cooled more than a little below the point of repletion with moisture, by bodies in contact with it, dew is never observed upon any plants, that are elevated a few feet above the ground. 3. If a plant has become, by radiating its heat to the heavens, so cold, as to be enabled to bring the air in contact with it below the point of repletion with moisture, that which forms upon it, from its own transpiration, will not then, indeed, evaporate. But other moisture will, at the same time, be communicated to it by the atmosphere; and when the difference in the copiousness of these two sources is considered, it may, I think, be safely concluded, that almost the whole of the dew, which will afterwards form on the plant, must be derived from the air; more especially when the coldness of a clear night, and the general inactivity of plants in the absence of light, both lessening their transpiration, are taken into account.

"An experiment, however, has been appealed to in proof, that the dew of plants actually does originate from fluid transpired by them; that namely, in which a plant, put up in an air-tight cafe, becomes covered with moisture. But this experiment, if attentively examined, will be found to have little weight. First, the inclosed plant being exempt from the cold, which its own radiation would have produced in its natural situation, on a dewy night, will transpire a greater quantity of fluid, than a similar plant exposed at the same time to the open air. Again, the small quantity of air, contained in the cafe, must soon replete with moisture, after which, the whole of what is further emitted by the plant will necessarily assume the form of a fluid, whatever may be the condition of the external atmosphere; whereas, during even the clearest night, only a part of the smaller quantity of moisture, emitted by the exposed plant, will be condensed on its surface. In the last place, notwithstanding the circumstances which favour the appearance of moisture upon inclosed plants from their own transpiration, still the quantity observed on them is said to be, for I have made no experiment myself reflecting this matter, much less considerable, than what is seen upon plants of the same kind, exposed to the air for the same time, during a calm and ferene night." For several appearances connected with dew, we are under a necessety of referring to the third part of Dr. Wells's Essay.

DEWAN, or DUAN, a term which has various significations in India. It denotes a place of assembly, a native minister of the revenue department, and chief justice of civil cause within his jurisdiction, and receiver general of a province. The term is also used to designate the principal revenue servan under an European collector, and even of a Zemindar. By this title, the East India company are receivers of the revenues of Bengal, under a grant from the Great Mogul. Accordingly Dewannu denotes the office or jurisdiction of a Dewan. DEWEYSBURG, in Geography, a town of Caledonia county, in Vermont, having 200 inhabitants.

DEZPHOL, a town of Períin, in Kuzfítan, or Chufftan, 28 miles W. of Shuffter, containing nearly as many inhabitants as that city, and situated on the eastern bank of the Abuz, on a beautiful and spacious plain. Its only ornament is an elegant bridge of twenty-two arches, erected by command of Sapor, notorious for destroying as well as famous for building cities. The bridge is 450 paces in length, 20 in breadth, and about 40 in height. The piers are made of large stones, and the arches and upper parts of burnt brick.

DIAL-Work of a Clock, col. 2, l. 24, for Plate XXIII, r. Plate XVIII.

DIALLAGE. See Mineralogy, Addenda.

DIAMOND, col. 4, l. 455. Add—With a small portion of oxygen, as for Humphry Davy has lately discovered.

DIANA, col. 20 from the bottom, for 27 r. 30.

DIANELLA, in Botany, a poetical name, in honour of the sylvan goddess Diana, to whom Commeron its author thought so beautiful an inhabitant of the woods peculiarly appropriate.
From the text provided, it appears to be a page from a botanical text discussing various plants. The page includes descriptions of plants such as Dianella ait., which is described as having leaves, flowers, and being native to South Holland. Other plants mentioned include Cyanophyllum, which is noted for its flowers and being native to Siberia, and Dierbek, which is described as having leaves and being native to South Holland.

The text seems to be discussing the botanical characteristics of these plants, including their leaves, flowers, and distribution. The author also mentions the use of some of these plants in various contexts, such as being used for medicinal purposes or as decorative elements in gardens.
of the corolla; the third imperfect. Stigma two-lipped, in three deep segments. Seeds depreessed.

1. D. Morea. Labill. as above, t. 15. Br. n. 1. (Morea diandra; Vahl Enum. v. 2. 154.)—Native of the south coast of New Holland, flowering in May. The flowers are very short-lived, white; their inner segments variegated. This plant differs from Patersonia, (see that article,) chiefly in the irregularity of its flower.

Eff. Ch. Calyx of two lax, membranous, awned valves, single-flowered. Corolla of two valves; outer with three awns, of which the middle one is twinned, unlike the rest; inner with two awns.

1. D. setaceus. Setaceous Diplopon.—Gathered by Mr. Brown, on the southern coast of New Holland. A grafs perfectly resembling Amphipogon laguroides, (see that supplementary article,) in habit and inflorescence, in the spike being capitate, and the outermost flowers likewise abortive, composin a kind of involucrem. Brown.

DIP-MICROMETER, and DIP-SECTOR, instruments invented by Dr. Wollaston, to correct the variation of the real dip from that given in the tables; arising principally from the difference between the temperature of the sea and that of the atmosphere.

DIPDIUM, in Botany, from δίς, and δίς, alluding to the two separate flanks, or feet, by which the males of pollen attach themselves to the stigma.—Brown Prod. Nov. Holl. v. 1. 330.—Clasfs and order, Gynandra Monandra. Nat. Ord. Orchides.

Eff. Ch. Calyx-leaves and petals uniform, spreading. Lip three-lobed; disk bearded; base with a short spur. Column semi-cylindrical. Anther a terminal deciduous lid. Males of pollen solitary in each cell, with an inner lobe, each attached by a separate thread to the gland of the stigma.

Leaflets smooth herbs, growing on the ground, with a thick, branching root. Base of the stem sheathed with imbricated scales, more dilant on its upper part, where they become bracteas. Flowers numerous, in a simple clustor, purple, very handsome. Two species are mentioned.

DISPASC.É.É. 1. 3. after cotyledons, inferif—two.

Eff. Ch. Calyx inferior, five-cleft; two segments sub-sequently much enlarged. Petals five. Capsule oval, of one cell. Seed solitary.

1. D. turbinatus. Wood-oil Dipterocarpus. Roxb. as above, t. 213.—Native of various countries eastward of Bengal, flowering early in the hot seafon, and famous for its liquid balsam, much used for painting houses and ships. This is copiously procured by wounding the trunk, and lighting a fire near the part. The tree is very large. Leaves alternate, flat-keeled, ovate, acute, wavy or ferrated, smooth, from four to twelve inches long. Flowers in simple, axillary clusters, large, white, with yellow anthers. Wings of the calyx in fruit erect, oblong, three inches in length.

DISCHARGED WORK. See Paste-Work and Discharging of Colour.

DONIA, in Botany, fo named by Mr. Brown, in memory of the late Mr. George Don, of Forfar, a most acute and indefatigable Scottish botanist.—Br. in Ait. Hort. Kew. v. 5. 82. Pursh 559.—Clasfs and order, Syngenesia Polysigma superflua. Nat. Ord. Composita, Linn. Corymbifera. Jaff.

Eff. Ch. Receptacle naked. Seed-—down briskly, deci-

duous. Calyx imbricated, hemispherical.

1. D. glutinosa. Glutinous Donia. Alt. n. 1. (After glutinosus ; Cav. Jav. v. 2. 253. t. 168. Doronicum glutinosum ; Willd. Sp. Pl. v. 5. 2115.)—Leaves ovate-oblong, sharply ferrated, glutinous, as well as the upright-scaled calyx.—Native of Mexico. A green-house férub, raised from Spanish feeds by Mr. Lambert, flowering in Auguf and September. The leaves are sessile. Flowers terminal, solitary, near two inches broad, yellow, white, with many rays.

DRE

herbaceous. Leaves much narrower than the foregoing. Flowers yellow, with a balsamic scent.

DONNINGIA, l. 19, r. 1811; l. 20, r. 316; l. 21, r. 1528.

DOODIA, in Botany, named after Mr. Samuel Doody, F.R.S. one of the earliest and best British Cryptogamists. He was an apothecary in London, and died in 1706.—Brown Prodr. Nov. Holl. v. 1, 151. Ait. Hort. Kew. v. 5, 523. We fear this genus cannot be separated from Woodwardia; see that article.

DOOSSAK, in Geography, the present capital, and the residence of the prince of Seiland, in N. lat. 31° 8'. E. long. 62° 10', eight or nine miles from the river Heermund. See Zarang.

DRAINYON. Add—The part of this parish that lies in Salop county contained, by the return in 1811, 599 houses, and 3370 persons; the other part, formerly denominated Tytrey, now Drayton-in-Hales, situated in the hundred of North Pirehill, in the county of Stafford, consists of three townships, having 104 houses, and 657 inhabitants.

DRESDEN, in America. Add—It contains 1096 inhabitants.

DRESSING, in Rural Economy, and the Manage, de vol. XXXIX.

DRY

notes the periodical application of friction, by means of brushes, cloths, &c. to the hides of animals, with a view both to cleanliness and health. (See CURRING.) Friction on the surface of the body, by means of the curry-comb and brth, contributes to promote the circulation of the fluids, and that inefensive perpiration through the pores of the skin, which greatly conduce to the health and activity of the animal. Columella observes, that the bodies of cattle ought to be rubbed down daily, as well as the bodies of men; and frequently it does them more good to have their backs well rubbed down, than to have their bellies filled with large quantities of provender. Of the practice which is so common on the post-roads of throwing pailsfuls of cold water on horses when they are over-heated at the close of a stage, Mr. Clark speaks doubtfully; although it is said that no bad consequences ensue, probably because they have little interruption of exercise; but he is of opinion, that if they are well rubbed down after exercis, there will be no occasion for washing, or rather drenching them with cold water. See Horde.

DRIFIELD, l. 4, r. 399, and 1857.

Five species, from Southern Africa, are described by Jacquin and Willdenow, and figured in Jacc. Ic. t. 373—377. They have falcate leaves, linear-lanceolate, coming after the fall, flaked cluster, of numerous greenish flowers. D. elata, Curt. Mag. t. 822, and D. pusilla, Jacq. t. 374, are the only ones in Hort. Kew.

DROITWICH, l. penul. r. 423, and 2079.

DROMORE, l. 3, r. 1295.

DRONFIELD, l. 4, r. 267 and 1343.

DRYANDRA, in Botany, received its name from Mr. Brown, in honour of his friend Jonas Dryander, M.A. a distinguished pupil of the great Linnaeus, who succeeded the celebrated Solander in the place of librarian to Sir Joseph Banks; and after rendering eminent services to science, died under the roof of his illustrious friend and patron, in October 1810, aged 62. Mr. Dryander has erected to himself a lasting monument in his Catalogus Bibliothecae Historico-naturales Josephi Banks, the most elaborate and complete work of the kind, and the most perfect specimen of correct execution, that perhaps any department of science can boast. His papers on Begonia, Lindsea, and other subjects, in the Transactions of the Linnean Society, richly entitle him to botanical commemoration; to say nothing of his abilities as editor of the first edition, and part of the second, of Mr. Aiton's Hortus Kewensis, as well as of Dr. Roxburgh's Plants of Cornomandel; or his various services to natural science in other respects. Thunberg had long ago published a Dryandra (see our former article); but that proving not distinct from Forster's Alkerites, previously established, Mr. Brown has happily chosen a most distinct genus, next akin to Banksia, and fearlessly lefs rich in number and beauty of species.—Brown Tr. of Linn. Soc. v. 10. 211. t. 3. Prodr. Nov. Holl. v. 1. 396. Ait. Hort. Kew. v. 1. 219.

Gen. Ch. Common Calyx, hemispherical, of numerous, permanent, imbricated scales, many-flowered. Cor. of one petal,
petal, in four deep linear segments, at length separating more or less completely, slightly dilated and concave at their summits. Nectary four scales at the base of the germen. Stam. Filaments four, very short, inserted into the base of the cavity of each petal; anthers linear-oblong. Pf. Germen superior, very small, of two single-feaded cells; style cylindrical, rigid, erect, about the length of the corolla; stigma undivided. Peric. Follicle woody, obliquely turbinate, of two shallow cells; the partition unconnected, deeply cloven transversely, chalicy. Seeds solitary, compressed, oblong, with a lateral crescent-shaped membranous wing. Common receptacle flat, befit with oblong scales or bristles, rarely wanting. 

This genus confides of New Holland shrubs, mostly of humble growth; their branches, if any, either scattered or umbellate. Leaves scattered, pinnatifid or cut, alike in young or old plants. Flowers solitary, sessile, terminal, rarely lateral, accompanied with crowded leaves, of which the innermost are sometimes diminut. as it were imperfect, and accompanied at the base with clove-prefted bracteas, some of them occasionally furnished with a terminal appendage. Style for the most part hardly longer than the corolla, and not forced into a curve as in Bankia.

We follow Mr. Brown's names and numbers throughout.

1. D. floribunda. Many-flowered Dryandra. Ait. n. 1. —Leaves wedge-shaped, deeply and sharply serrate. Calyx-scales fringed; the outermost nearly smooth. Tips of the corolla smooth. Stigma obtuse, slightly club-shaped. —Native of Lewin's land, growing on rocky hills. Mr. Menzies favoured us with a specimine from King George's found. This shrub flowers at Kew molt part of the year. The branches sometimes bear a few long, loose, spreading hairs. Leaves sessile, rigid, an inch and a half or two inches long, finely reticulated on both sides, the minute interstices of the veins curiously prefted beneath. Flowers terminal, in a close cylindrical head, reftembing fame Thistle or Sarracenia, shorter than the crowded surrounding leaves. Calyx brown, of many sharp imbricated scales, the inner ones gradually longef, and hairy. Corolla threc as long, yellow, externally hairy, except at the tips lodging the flaments, which are smooth, keeled, obtuse, minutely haired. Mr. Brown observes that the scales of the receptacle, feparating the flowers, are sometimes wanting.

2. D. cuneata. Wedge-leaved Dryandra. Ait. n. 2. —Leaves wedge-shaped, deeply serrate, spinous, flanked. All the calyx-scales even and silky. Tips of the corolla bordered. Stigma slender, awl-shaped, acute. —Found by Mr. Brown, on rocky hills in Lewin's land. He notices two varieties: one with leaves scarcely an inch and a half long, whose three terminal teeth are all nearly equal; another, which possibly be a different species, with leaves two inches long, whose dilated extremity has the middle tooth shorted, the adjoining finufes broader.

3. D. armata. Acute-leaved Dryandra. Ait. n. 3. —Leaves pinnatifid; lobes triangular, flat, decurved, straight, spinous-pointed; reticulated with naked veins beneath; the terminal one longer than the next. Branches, and tips of the corolla, smooth. Style downy at the base. Stigma awl-shaped, furrowed. —Found by Mr. Brown, on rocky hills in Lewin's land. Mr. Good fent this species to Kew in 1805, but it has not yet flowered there, nor have we seen a specimine.

4. D. falcatn. Curve-leaved Dryandra. Br. n. 4. —Leaves pinnatifid; lobes triangular-awl-shaped, decurved, falcate and recurved, spinous-pointed; reticulated with naked veins beneath: the terminal one shorter than the next. Branches downy. Tips of the corolla, as well as the style, longitudinally smooth. Stigma club-shaped, without furrows. —Found by Mr. Brown, in the fame country as the last.

5. D. formosa. Splendid Dryandra. Br. Tr. of Linn. Soc. v. 10. 213. t. 3. —Ait. n. 4. —Leaves linear, elongated, deeply pinnatifid; lobes unequally triangular, pointlee, flat; downy beneath. Calyx-scales hairy; the innermost linear-oblung, reflexed. Receptacle chaffy. —Discovered by Mr. Menzies, near King George's found. Mr. Brown met with it likewise, in barren ground near the coast of Lewin's land. This truly beautiful species was fent to Kew, by Mr. Good, in 1803, and it is marked by Mr. Aiton as flowering there molt part of the year. The leaves are falked, from four to six inches long, and barely one-third of an inch broad, cut to the mid-rib, into numerous, clofe, regular segments, whose upper margin is direét, lower curved; the under fide finely downy, fnow-white, turning rufly with age, or long keeping. Stem branched, downy. Flowers terminal, two or three inches in diameter, embofmed in leaves. Calyx-scales purplifi-black, ftriated and naked on the inside. Flowers of a tawny yellow, clothed with long faming hairs to the very point. Style yellow, floft and smooth. Stigma cylindrical, furred. Follicles small; tapering and hairy at the base; rounded at the margin; gaping widely, overtopped by the linear scales of the receptacle.

7. D. plumosa. Feather-flowered Dryandra. Ait. n. 5. —Leaves linear, elongated, deeply pinnatifid; lobes equally triangular, pointed, flat; downy beneath; slightly revolute at the margin. Inner calyx-scales with feathery tips. Receptacle without scales. —Discovered by Mr. Brown, on the rocky fides of hills, in Lewin's land. Sent to Kew by Mr. Good, in 1803, but has never blossomed there. 

8. D. obtusa. Obtuse-leaved Dryandra. Ait. n. 6. —Leaves linear, pinnatifid, longer than the downy reftem; lobes triangular, obtuse; downy beneath; thickened and recurved at the edges. Outer calyx-scales ovate; inner linear-oblong. —Gathered by Mr. Brown in Lewin's land, in dry open situations near the shore. This also was fent to Kew, at the fame time as the last, but has never yet produced flowers.

9. D. nivea. White-leaved Dryandra. Ait. n. 7. —("Bankiana nivea; Labill. Voy. v. 1. 412." t. 27. —N.C. Nov. Holl. v. 2. 118.) —Leaves linear, pinnatifid, about as long as the smooth flem; lobes unequally triangular, acute, pointed; white and mealy beneath; recurved at the margin. Calyx-scales linear-lanceolate, smooth, fringed. Corolla hairy from top to bottom, much shorter than the style. —Gathered by Mr. Menzies at King George's found; by Labillardiere and Brown in rocky places near the coast of Lewin's land, flowering in December. The flem is usually from one to three inches high, greatly overtopped by the very long, narrow, erect leaves, which are not quite so deeply pinnatifid as most of the foregoing: each lobe has two or three prominent ribs beneath, and is clothed on that side with a snow-white mealy pubescence, unaltered by time in our original specimine. Flowers solitary, sessile among the leaves,
leaves, smaller than those of D. formosa, with a purplish-brown calyx, and yellow, or tawny corolla. Style purplish, angular, smooth. Stigma small, pyramidal, obtuse, not well represented in the plate; at least not in our English edition. This flowers at Kew from July to September. Mr. Brown notices a variety in which the lobes of the leaves are somewhat divaricated, fimbriated, and the stigma hardly thicker than the style.

—Leaves linear, pinnatifid, very long, acute; downy beneath; tapering and entire at the base; lobes triangular, acending, decurrent, recurved at the margin. Calyx- scales linear, awl-pointed, smooth, fringed. Corolla woolly at the base; downy upwards; rather hairy at the tips. Stem downy.—Discovered by Mr. Brown, on rocky hills in Lewin's land. The pubescence of the backs of the leaves is greyish, not white. This plant was raised at Kew in 1805, but has not yet borne any flowers.

—Leaves linear, elongated, pinnatifid, rather abrupt; flow- white beneath; entire at the base, and tapering into a foot- stalk; lobes triangular, deciduous, divaricated, recurved at the margin. Calyx as long as the flowers, downy; outer scales ovato-lanceolate. Corolla almost as long as the style; woolly at the base; smooth upwards; slightly fimbriated at the tips. Stem smooth.—Gathered by Mr. Brown, in heathy ground at Lewin's land. It flowers at Kew from March to May.

—Leaves deeply pinnatifid, longer than the downy stem; lobes linear, acute, pointed, decurrent, dilated at their base. Calyx-scales downy, ovate.—Gathered by Mr. Brown, in Lewin's land, on the stony fides of hills.

—Leaves deeply pinnatifid, longer than the downy stem; lobes oblong, obtuse, fimbriate, pointed, three-ribbed, somewhat revolute, scarcely dilated at the base.—Gathered near King George's found by Mr. Menzies, to whom we are obliged for a specimen, without flowers, with which Mr. Brown likewise was unacquainted; but the resemblance of the plant to the half-described, induced him to consider it as belonging to the prent genus. The short stem is clothed with dense, soft, rufy pubescence. Leaves resembling a Cycas in texture, as well as form, though only a foot high; the early ones smaller, with very broad rounded lobes, clothed beneath with white woolly down; the pubescence of the more full- grown leaf only, in our specimen, is become rufy.

DUBASH, a name applied at Madras to the same per- son who is denominated Banian in Bengal: it signifies a person who can speak two languages.

DUBLIN, in America, l. 4. r. 1184; l. 8. r. 2194; l. 10, r. 970. Add—Allo, a township of Bedford county, in Pennsylvania, having 820 inhabitants.

DUBOISIA, in Botany, in memory of Mr. Dubois, a botanist of the time of Dilleni, who appears, by Ray's

SYNOPTIS, ed. 3. 17, to have had a garden at Mitcham in Surrey, and whose son, or brother, Charles, was an affiduo- us cryptographer. His copy of Buxbaum is in our hands.

DUBUDU. See DUBU.

DUCHESSNEA, in Botany, a genus announced at the end of our article FRAGARIA, and since published in Tr. of Linn. Soc. v. 10. 371. It was supposed to differ essentially from Fragaria and Potentilla, (with both which the calyx agrees, and with the latter more particularly the habit,) in having the compound berry of a Rubus. Some garden speciments have led us to suppose it to be a orphan of botanists who have described the ripe fruit, which in those speciments was certainly that of Fragaria, a succulent receptacle fluided with dry seeds. Whether the latter becomes pulpy at any more advanced period, remains to be proved. Meanwhile this plant stands as F. indica, in Alt. Hort. Kew. v. 3. 275.

DUCK CREEK, in Geography, a hundred of Kent county, in Delaware, containing 3590 inhabitants, of whom 167 are Slaves.

DUDLEY, l. 3. r. 2621 houses, and 13,925 inhabitants.
Add—Dudley is partly in Otsego hundred, Staffordshire, in which Dudley is locally situated.

DUDLEY, in America, l. 2, r. 1220.

DUEL. At the close, add—Duelling, says a late excellence writer, in the modern sense of the word, exclusive of casual frays and single combats during war, was unknown before the 16th century. But we find one anecdote, which seems to illustrate its derivation from the judicial combat. The duke of Lancaster and Brunswick, having some differences, agreed to decide them by duel before John, king of France. The lists were prepared with the solemnity of a real trial by battle; but the king interfered to prevent the engagement. The barbarous practice of wearing swords as a part of domestic dress, which tended very much to the frequency of duelling, was not introduced till the latter part of the 15th century. Our author says, that he can find only one print in Montfaucon's Monuments of the French Monarchy where a sword is worn without armour before the reign of Charles VIII.; though a few as early as the reign of Charles VI. have short daggers in their girdles. Hallam's State of Europe during the Middle Ages, vol. ii. ch. 9. part ii. p. 441. London, 1818.

DUFEREN. See DEUREN.

DUFIOREIA, in Botany, so named in honour of a French botanist.—Achar. Syn. 246. — "Lichenogr. 103. t. 11. f. 2." A genus of the order of Lichenes, composed of L. flammeus, Linn. Suppl. 431. Hoffm. Pl. Lich. t. 1. f. 5; L. madrepormis, Wulf. in Jacq. Coll. v. 3. t. 3. f. 2; and three other species. The frond is tubular, branched, membranous in its middle, with a border from the frond. We much shelter ourselves under the doubt, expressed by the author himself, respecting this genus.

DUKE'S COUNTY, l. 5, r. 3290.

EDSTITUTE, a township of Berks county, in Pennsylvania, having 805 inhabitants.

EDISTO, l. 9. r. 752.

EDINBURGH, col. 2, 1, r. 1657.

EDGARTON, l. 5. r. 1557.

EDGARTON, a township of Putnam county, in Georgia, having 73 inhabitants.

ECHENEIS, l. 4. add—Or, according to Dr. Shaw, head furnished above with a flat, ovate, transversely calcated shield, gill-membrane fixed, and body without scales.

ECLIPTIC, Obliquity of, col. 2, l. 6 from bottom, add—And he found the obliquity of the ecliptic at the summer solstice to be 23° 27' 51'', and at the winter solstice 23° 27' 47'', 35'. The difference he conceives to depend upon refraction. At the observation of the summer solstice in 1812 with the new mural circle, he found the obliquity of the ecliptic to be 23° 27' 52'', 25; from that of the winter solstice he deduced it 23° 27' 47'', 35'.

ECTROSIA, in Botany, from έκτροςεις, an abortion, alluding to the number of abortive flowers.—Brown Prod. Nov. Holl. v. 1. 185.—A genus of grasses, allied to Eleusine, (see that article,) and to Cbloris of Swartz, all whose characters require investigation.

EDINGTON, in Geography, a town of America, in Maine and county of Hancock, having 205 inhabitants.

EDDYSTONE, col. 2, l. 1, for 8vo. r. folio.

EDEN, in America, l. 4. add—containing 657 inhabitants; l. 5, add—containing 264 inhabitants.

EDDA, or Odla, at present denominated Orla, after having been the residence of the Courtenseys, counts of Edela, and having been taken by Zhenghi or Zangi, was sacked by the Moguls in the 13th century, and by Timur in the 804th year of the Hegira. It is now subject to the grand signior, and the residence of a pasha of two tails. It is situated in a barren country, 67 miles from Bir, and 232 from Darike. It is surrounded by a stone wall, and defended by a citadel. The houses are well built, and the inhabitants, composed of Turks, Arabs, Armenians, Jews, and Neflarians, are said to amount to about 20,000 souls. The chief ornaments of this city are, a mosque, consecrated to Abraham, and the cathedral of the Armenians, now decayed.

EDGARTON, l. 7. r. 1365.

EDGCOMB, l. 3. r. 1288; l. 9. r. 12423 and 5107.

EDGEFIELD. Add—It contains 23,160 inhabitants, of whom 87,6 are slaves.

EDGEMONT, l. 2. r. 611.

EDINBURGH, col. 7. l. 7. add—By the parliamentary return of 1811, the city and burgh of Edinburgh contained 7110 houses, and 102,987 inhabitants; 43,982 being males, and 59,005 females. The fires of Edinburgh contained 8679 houses, and 45,620 inhabitants; 21,022 being males, and 24,598 females.

EDINGT. In 1811 the parish contained 85 houses, and 417 persons; 196 being males, and 222 females.

EDM. r. Poxon.

EDWARDSIA, in Botany, (see that article,) is thus defined by Mr. Brown, in Ait. Hort. Kew. v. 3. 1.—Caylx five-toothed. Corolla papillaceous. Legume with four wings and many seeds.

ELAN, in Chemistry, a name given by Chevrel to a principle exiling in animal tallow or fats. To obtain it, he distilled the tallow in alcohol, and suffered the stearin (see Stearin) to crystallize; the alcohol was then distilled off, and thus the elan separated. Braconnet procured it in a different manner. He submitted the tallow to preasure between folds of blotting-paper, which absorbed the elan. The paper was then soaked in water, and again subject to preasure, by which the elan was forced out, and could thus be obtained separately.

Elan thus obtained has much the appearance of a vegetable oil, and is quite liquid at a temperature of 55°. Sometimes it is distinctly of smell and colour, but most commonly it poises both, owing probably to the presence of foreign bodies, from which it is impossible to free it. Chevrel examined the elan from the tallow of the human subject, the sheep, the ox, the hog, the jaguar, and the goose, all of which differed slightly from one another. Their specific gravity varied from 913 to 929; those of the human subject and ox being lightest, and that of the goose the heaviest. Those of the sheep, ox, and hog, were nearly colourless, and of little smell; all the others were more or less of a yellow colour, and pellucid more or less odour. The elan of the sheep was most soluble in alcohol, 100 parts of which liquid, specific gravity .792, distilled 81.17 of elan at a temperature of 167°. The elan of the jaguar was least soluble, only 80.89 parts of the elan being soluble in the same quantity of alcohol at the same temperature. See further on this subject under Stearin.

ELALITE. See Mineralogy, Addenda.

ELBERTON, l. 6, r. 4291 and 45.

ELBERTON, l. 3. add—it contains 58 inhabitants.

ELBURZ, a range of mountains in Khorafin in Persia, which detaches several branches that expand over the country between Alerabad and Meheid, also over a great way to the east and north of that city, form a junction with the ridge of Banian, and finally link into the defect plains of Khorasan.

ELECTRIC, Wells, dele.

ELECTRICITY, Medical. (See Medical Electricity.)

This subject was terminated rather abruptly in the article above referred to, we shall therefore endeavour to supply what was there omitted, or has since been observed upon the subject.

The powers of electricity in removing discharges were much over-rated by the earlier electricians, as for the most part
ELECTRICITY.

For the phenomena of that modification of electricity termed galvanism, and its general effects upon the animal economy, we refer our readers to Voltaism, where they will find these subjects discussed; we shall therefore chiefly confine our attention here to the exhibition of galvanism as a remedy. The general principles of the application of galvanism differ in no respect from those of the application of electricity, nor do the effects of this form of electricity upon the animal economy differ in any respect whatever from those produced by common electricity; from the mode, however, in which this variety of the electric energy is excited and brought into action, a little difference in the mode of applying it is necessary. The application of galvanism in the form of shocks and sparks is out of the question. It is always applied in the form of a continued or interrupted stream, or sometimes in the form of aura; hence the conductors generally require to be in contact with the skin of the patient, which should be kept moist. The greater the surface of the conductor in contact with the skin within certain limits, caters paribus, the greater the effect produced, and vice versa. The interrupted stream, or that produced by the frequent removal and re-application of the conductor in contact with the skin, or by otherwise breaking the chain of communication, approaches in its nature more to that of the electric shock than the continued stream, a circumstance which should be kept in mind by the operator. Indeed with an apparatus composed of small plates, the stream requires to be occasionally interrupted, otherwise the effects will be very much diminished. See Voltaism, last section.

With respect to the magnitude of the battery proper for medical purposes, no very general rule can be given. The greater the number of plates, especially when of small size, the more do the effects produced upon the animal economy re semble those produced by common electricity. Large plates are best adapted for keeping up the continued stream, which is doubtless one of the best modes of exhibiting galvanism, and of ensuring its specific operation, if it exerts any. A medical galvanist can seldom require a battery composed of more than fifty or sixty pairs of plates, from four to six inches square, and a greater or less proportion of these must be employed according to the energy of action in the battery, and the circumstances of his patients. Dr. Wilfon Philip plates, that few patients can bear, for any length of time, more than from eight to sixteen pairs of plates, fourteen inches square, when administered as described below. The same author, however, remarks, that patients can often bear double this number, for a short time, before any disagreeable sensation is produced.

Dr. Wilfon Philip has lately attempted to shew that the galvanic battery may be substituted for the nervous energy in animals. His experiments on this subject are extremely interesting, and their results led him to employ galvanism as a remedy in several fe deases to which it was never previously applied. These therefore remain to be briefly noticed.

Aphonia and Dyphonia.—Dr. Philip states, that he has employed galvanism in many cases of habitual aphonia, and almost uniformly with relief. The good effects began to appear usually from five to fifteen minutes after the application of the remedy. His battery consisted of thirty plates fourteen inches square, more or less of which were employed according to the degree of sensation produced; and his rule was to begin with a low power, and gradually increase it by moving one of the wires from one division of the trough to another. His method of exhibiting it in this defea was to apply two thin plates of metal, about two or three inches in diameter, moistened with water, one to the nape of the neck, and the other to the pit of the stomen,
mach, or a little lower, which plates were connected with the wires leading to the opposite ends of the battery. He directs that the wires should be constantly moved upon the metallic plates, particularly the negative wire, otherwise the cuticle is apt to be injured where they rest. The relief seemed much the same whether the positive wire was applied to the nape of the neck, or the pit of the stomach. The different effects, therefore, ascribed by some to positive and negative electricity seem doubtful. When relief was obtained, nothing appeared to be gained by continuing the operation longer.

The galvanism was seldom used more than once a day, except in some severe cases. About a sixth part of those upon whom it was tried received a permanent cure. It gave decided relief in all cases, and only failed to give considerable relief in about one-tenth of the whole number of cases.

Similar good effects are ascribed by Dr. Philip to have been experienced in dyspepsia, provided no inflammatory symptoms were present. Dr. Philip, however, seems to doubt if it will be found useful in domestic affections.

In Dyspepsia, likewise, Dr. Philip thinks it will prove an excellent remedy; also in torpor of the liver and bilious ducts; and a recent writer states, that he has found it very advantageous in chronic hepatitis, constipation, &c. See an Experimental Enquiry into the Laws of the Vital Functions, by Dr. A. P. Wilson, Philip.

**ELECTROPHORUS**, col. 2, l. 19 from bottom, for hair-flake r. harc-flake.

**ELEOCARIS,** in Botany, loco a marit, and zygo, an ornament or favour, from its general place of growth.—Brown Prodr. Nov. Holl. v. i. 224.—A genus separated from Scirpus by Mr. Brown; near akin to Dichromena, in character, but very different in habit; see those articles. Though the definition is not without exceptions, the genus is thought a natural one by its learned author, embracing Scirpus palustris, geniculatus, mutatus, and arcuatus of Linnaeus with several others. There are eight New Holland species.

**ELEPHAS,** col. 10, l. 21 from bottom, for thirteen r. three.

**ELETTARIA,** in Botany, so called by Dr. Maton, V.P.L.S., from the Malabar name Eleetari, or Ela-tari, which has always been appropriated to this very plant. If any names of barbarous origin may be retained, and many are now established, even by Linnaeus himself, who in the vigour of his judgment and authority protected against them, the above may well be admitted, for the following reasons. It exclusively belongs to a very important plant, confituting, as far as we know, a genus by itself, and it is perfectly unexceptionable in form and construction, as well as free from all ambiguity. Were this name nevertheless to be finally rejected, we should gladly submit it in the stead of that of Matonia, in honour of our learned and valued friend, who has so clearly established the genus.—Matton Tr. of Linn. Soc. 1814. Richd. H. Mal. v. xi. 9.—Cliffs and Order, Monandria Monognyna. Nat. Ord. Scitamineae, Linn. Canne Jaff.

Gen. Ch. Cal. Perianth superior, of one leaf, tubular, cylindrical, elongated, minute and irregularly toothed at the margin, permanent. Cor. of one petal; tube longer than the calyx, cylindrical, slender, curved; outer limb in three equal, oblong, recurved segments, not half the length of the tube; inner a somewhat obovate, large, notched, crenate, undivided lip, with a short claw. Stam. Filament

one, rather longer than the claw, flout, erect, with a lanceolate, acute, horizontal lobe, about its own length, on each side at the base, the summits simply notched, without any cret or extension beyond the anther, which consists of two oblong, divergent, marginal lobes, about half the length of the filament, attached by their backs, their extremities on a level with the top of the filament. *Pit.* Germen inferior, nearly globular; stigma thread-shaped, lying close to the filament, between the lobes of the anther; stigma funnel-shaped, small, erect, nearly on a level with the top of the filament. *Peric.* Capsule fleshy, elliptic-oblong, or somewhat ovate, triangular, fluted, of three cells, and three coriaceous valves. *Seeds* numerous, roundish, somewhat angular, rough, each with a fine, membranous, evanescent tunic. *Peric.* central, shorter than the capsule when dry, winged with three longitudinal membranes, originally connected with the central ridge of each valve.

Ell. Ch. Anther of two distinct lobes. Filament with two transverse lobes at the base; emarginate and simple at the summits. Outer limb of the corolla in three oblong lobes; inner a single lip. Capsule of three cells, and three valves, with a central receptacle. Seeds rough, tenaciate.

1. *E. Cardamomum.* Leffer, or Malabar, Cardamom. Maton as above, (Amomum repens; Sonnerat Ind. Or. v. 2. 240. t. 136. Rofe. Tr. of Linn. Soc. v. 8. 353. Wildl. Sp. Pl. v. 1. 9. A. Cardamomum minus; Math. Valgr. v. 1. 25. Camer. Epit. 17. f. 3. Bont. Hist. Nat. 126, the three rounder fruits only. Clus. Exot. 187. Ger. Em. 1542. Dale Pharmac. 276. C. simplicior in officinis dictum; Buxh. Phil. 414. C. cum siliquis quill thess. bivibus; Bauh. Hist. v. 2. 205. Elettari; Rheede Hort. Mal. v. 11. 9. t. 4. 5.)—Capsule ovate-oblong, obliquely triangular. Calyx notched.—Native of the mountainous parts of Malabar, on lofty cloudy hills, flowering when the rainy season begins, in April and May; ripening seed in October and November. *White, Roxburgh.* Root perennial, tuberous, with many fibres. Leafy stems from six to twelve feet high, erect, strait, pale green, not red or brownish, at the base. Leaves elliptic-lanceolate, pointed, from nine inches to two and a half feet long, and from one to five inches broad, spreading, dark green, smooth, entire; paler and more glossy beneath. Stipulae emarginate, round, smooth. *Pinnas* lateral, several from the tuberous base of each stem near the root, a span long, much branched, many-flowered, spreading horizontally on the ground, jointed, smooth. *Bractea* alternate, ovate-oblong, acute, at the base of each partial stalk, withering; *partiales* solitary, tubular, closely embracing the germen and calyx, allmost as long as the latter, and resembling it in shape, but deciduous. Outer limb of the corolla green; *tip* white, veined with crimson. Capsule when fresh fleshy, smooth, nearly globular, but becoming bluntly triangular, coriaceous, and pale brown, when dry. *Seeds* blackish, gracefully aromatic and pungent, with a flavour of Camphor, esteemed more agreeable and useful in food and medicine, than any others of this tribe. (See CAR

DAMOM, excluding what regards Cardamomum majus, &c.) This subject will be found explained under our supplementary article *Amomum.* Mr. White, who has given a most accurate and perfect history of this plant and its cultivation, under the name of *Amomum Cardamomum,* in Tr. of Linn. Soc. v. 10. above quoted, speaks of its seeds as one of the most valuable articles of modern luxury, regarded as a necessary of life, by most of the inhabitants of
Axia—a grateful and fabulous acciosophy of diet—whose general adoption by the civilized nations of the other quarters of the world is prevented only by its limited importation." This is certainly quite a new idea to us Europeans, who value this drug merely as a grateful and wholesome stimulant, on which account it becomes an article of commerce, having supplanted all its relatives in the apothecary's shop. Its general use in Axia, indeed, renders the plant a very important and profitable object of culture, though the harvest, occurring at the most unhealthy season, is not unattended by serious dangers. Fevers, fluxes, the bite of innumerable minute leeches, and the infantly fatal sting of the whip-snafe, are mentioned as not uncommon mischiefs, to which is added the caustic quality of a shrubby plant, whose botanical characters have not been ascertained, but whose leaves produce dangerous, and sometimes fatal, ulcerations of the skin. The profit of the Cardamom farms, however, is so considerable, as to overcome all difficulties in their cultivation, and Mr. White thinks they might easily be greatly extended.

2. E. major. Greater Oblong Cardamom. (Cardamomum majus; Dole Pharm. 276. Born. Hist. Nat. 127, the fruit only? C. majus officinarum; Bauh. Pl. 413. C. majus vulgar; Ger. Em. 1542. Clus. Exot. 187. Lob. l. v. 2. 222. C. medium t Mattth. Valgr. v. 1. 25. Calcar. Epit. 11. f. 2. Barrel. l. obs. 1395. t. 974, the longest fruit. C. cum filiis five thecs longis; Bauh. Hist. v. 2. 205. Enst.; Herm. Muf. Zeyl. 66. Zingiber Enst.; Gernt. t. 1, f. 5.)—Capsule lanceolate-oblong, acutely triangular, with flat sides. Calyx three-lobed.—Native of Java, according to Dale, who remarks that this kind of Cardamom was, even in his time, rarely used, some substituting for it Grains of Paradise, others the Amomum verum. (See Amomum.) Specimens of this species are indeed, at present, only to be found in the cabinets of collectors. We are persuaded they must belong to the same genus as the Malabar Cardamom. They appear to have a similar panicled inflorescence, and the structure of the fruit, with its central receptacle, coriaceous fringed valves, and angular rough or rugged seeds, are the fame in this as in the last. These seeds, however, are of a brighter, or reddish hue, and very inferior in flavour, far less powerful and less agreeable. The shape of the capsula is essentially different, being usually thrice as long, and much more acutely and flirkingly triangular, flattened at the sides, and more evidently curved. It is similarly crowned with a long, cylindrical, permanent calyx, decidedly three-lobed, whereas that of the former is only crenate, or jagged. This part is unfortunately often rubbed off by those who collect the fruits for sale. If Bontius be right, there is so wide a difference between these two plants in the situation of their flowers, as would almost overturn their generic identity. He gives, under the title of Cardamomum majus, a figure with large, terminal, simply racemose inflorescence, which he compares to that of a Hyacinth, describing the plant as taller than a man, with very large leaves, flowers white with a purple limb, and the whole very beautiful. Two capsulae, not unlike our plant, though by no means very like it, being represented cylindrical, not triangular, and described as long as the finger, accompany the above figure. We cannot, on mature consideration, think the synonym of Bontius rightly applied. Nevertheless, he speaks of the qualities as agreeing with his G. minus, supposed to be our Amomum Cardamomum, or Amomum verum of old writers, not the preceding Eleuttaria Cardamomum. Clusius, Gerard, &c. rather copy the fruit from Bontius than from nature, and seem to take the calyx for the flalk.

EMBANKMENT, col. 25, l. 4 from bottom, infect—In 1809 about 6000 acres of land were obtained by an embankment of the sea upon Cartmel sands, in Lancashire. The embankment at Tre-Madoc, in Carnarvonshire, was completed in 1811.

EMDEN, in Geography, a township in the district of Maine, and county of Somerfet, having 351 inhabitants.

EMERY,
ENF

EMERY, l. 11, after Tennant, infert.—(Phil. Trans. for 1802, p. 401.)

EMETIN, in Chemisty, a name given by MM. Majendie and Pelletier to a substancc extracted by them from ipecacuanha, and so called because it constitutes the principle to which that root owes its emetic qualities. Emetin may be obtained if digested ipecacuanha in sulphuric ether, and afterwards in alcohol. The alcoholic soluticn is then to be evaporated to dryness, redissolved in water, and acetate of lead dropped into the solution. The copious precipitate thus obtained being well washed and diffused through water is then to be exposed to the action of sulphuretted hydrogen. The lead is thus precipitated while the emetin remains dissolved in water; and the liquid being filtered and evaporated to dryness, the emetin will be obtained in a state of purity.

Emetin thus obtained exists in the form of brownish transparent scales. Its taste is bitter and a little acrid, but not disagreeable. It has no smell. At the temperature of boiling water it is not changed. When exposed to a higher heat it does not melt, but swells, becomes black, and is converted into water, carbonic acid, a little oil, and acetic acid, but yields no trace of ammonia, which indicates that it does not contain azote. A very fpongy and light coal remains. When exposed to the air, emetin undergoes no change, except the air be very damp, when it deliquesces. It diffuses readily in water and alcohol, but not in sulphuric ether. It does not crystallize.

Sulphuric and nitric acids, when concentrated, decompose it. Muriatic and phosphoric acids diffuse it without alteration, and it may be separated from them by saturation with an alkali. Acetic acid is one of the best solvents of it. Gallic acid and infusion of galls precipitate it immediately, as do solutions of most of the metallic salts.

Half a grain of this substance occasions violent vomiting, followed by sleep, and the animal awakes in a state of Health. A larger quantity, as twelve grains, or even six grains, produces violent vomiting and sleep, followed by death, which appears to take place in consequence of the severe inflammation of the lungs and intestinal canal, produced by large doses of this solution.

ENAMEL of the Teeth, Chemical Properties of. See TEETH.

Eff. Ch. Calyx five-cleft; pupil and closed in the fruit. Stamens inserted into its bale. Stigmas two or three, thread-shaped. Capsule membranous, covered. Seed depressed.

Procumbent shrubs, very much branched, with alternate filby leaves, and axillary, solitary, sessile flowers, without bracttes. There are two New Holland species.

ENDIAN. Add—It lies in N. lat. 39° 18', 20 miles from Zeitoon, occupies both banks of the Tab, and is nearly two miles in circuit. It trades with Baffora and Behaban, and its population is between 4000 and 5000 souls.

ENDIANDRA, in Botany, Br. Prodr. Nov. Holl. v. 1, 402, a triandrous genus, perhaps hardly distinct from Cinnamomum, which Mr. Brown separates from Laurus of Linnæus; and also very near his Cryptocarya, see that article.

ENFIELD, l. 4, after parliament, infert—in 1811, 1115 houses, and 6656 inhabitants. The town has only 524 houses, and 5055 inhabitants, and is one of the four quarters into which the parish is divided.

ERBILLE, in Geography, a town of Peru, which is probably that Arbel on famous for the final victory obtained by Alexander over Darius, and the capital of the province of Audiabe, is now reduced to a wretched mud town, with a population not exceeding 3000 souls. N. lat. 36° 16'.

Eff. Ch. Calyx in five deep segments; changed and membranous in the fruit. Cor... Stigma undivided. Drupes dry, with four cells, and four seeds.

Two rufh-like shrubs, E. oppositifolia and alternifolia, found on the inhospitable south coast of New Holland. Their leaves are semi-cylindrical. Flowers solitary, flaked.

3 P ERIACHNE.
ERK

A genus of tropical grasses, akin to Arina, generally downy; their leaves narrow, flowers paniced. Mr. Brown describes ten New Holland species, none of them in any other author. In six of them, the outer valve of the corolla has a terminal awn.

ERIE, l. 2, r. 3758; after Erie, add—northern, containing 394 inhabitants, of whom, in 1810, 14 were slaves.

Eff. Ch. Calyx ringent; lower leaves strangled, under the lip. Petals smaller, erect. Lip flanked, lip downy, without glades. Column fimicircular; simplest at the top. Anther terminal, permanent, pointleaf; cells close together. Maffes of pollen four in each.

1. E. autunnalis. Br. n. 1. (Epipacis cunnulata; Labill. Nov. Holl. v. 2. 61. t. 211. f. 2.)—Native of the east and south parts of New Holland. Bulb globular. Leaf radical, enclofed in a sheath, with the base of the flalk, which is four or five inches high, naked, bearing from one to three white or purplish flowers. Akin to Caladenia.

ERIVAN. Add.—By various species, the hill of which was in the year 1806 by the Turkish was named; this town is reduced to a ruinous condition. It has been repeatedly taken both by the Turks and Persians, and has remained in the possession of the latter from the peace of Nadir Shah in 1748. This city, which gives name to a province bounded on the N. and W. by the Molian hills, on the S. by the Araxes, and on the E. by the district of Karabahg and Karadag, is situated on the banks of the river Zengui, and defended by a fortess, of an elliptical form, upward of 6000 yards in circumference. The N.W. side of the town is built on a precipice, impeding over the river 100 toises in height; but is surrounded by the fort which is encompassed by two strong walls, flanked with towers.

ERKOOK, in Ornithology, a bird of Abyfinia, which belongs to a large tribe, differing principally in the beak and horn. The horn is sometimes seen upon the back, and sometimes upon the forehead, above the root of the beak. In the east part of Abyfinia, it is called Abba Gumba, in the language of Tigré; but on the westem side of the Imer, it is called Erkoom. Its groaning noise gives occasion to the name of its name. By naturalists, this bird is called the Indian crow or raven. The colour of the eye is a dark brown, or rather of a reddish cast; the eyes—ladies are large; its length from the tip of the beak to the extremity of the tail is three feet ten inches; the length of the beak is ten inches, and the length of the horn three and a half inches. The colour of this bird is footy-black; the large feathers of the wing are ten in number, milk-white both without and within; the tip of his wings reaches nearly to his tail; and at his neck he has those protruberences like the turkey-cock, which are light blue, but turn red upon his being chafed, or when the hen is laying. He seems to prefer running upon the ground to flying; but when he is raised, he flies to a considerable distance. Its smell is rank, and he is said to live in Abyfinia upon dead carcasses; but this Mr. Bruce conceives to be a mistake, as he never follows the army like birds of prey. His food seemed to be the green beetles that are found upon the tops of the trees, and in order to obtain them, he frequents fields of this grain.

He builds in large thick trees, and if he can, always near churches, and his nest is covered like that of a magpie. Mr. Bruce, in the Appendix to his Travels, has described this bird, and accompanied his description with a drawing.

ERROL, l. 2, for Grafton r. Coos. Add—and in 1810, contained 38 inhabitants.

ERVING's GORE, in Geography, a town of Hampshire county, in Massachusets, having 106 inhabitants.

ERZERUM, I. 11, after church, add—Mr. McKinnie estimates the whole number of inhabitants at 100,000; 15,000 of whom are Armenians, and the rest Turks, with the exception of 200 or 500 Greeks. Here are nearly 40 mosques, four of which are handsome, a Greek church, a large Armenian chapel, and at a distance from the city three celebrated monasteries. The bazaars are extensive. In winter the cold is intense; but the air being pure, and the water good, the natives are fat and healthy. N. lat. 39° 57'. E. long. 40° 57'. The pachalic of Erzerum is the most considerable in Armenia; it is divided into twelve districts, and governed by a pacha of three tails, who resides at Erzerum.

ESTLE, a county of Kentucky, containing 2082 inhabitants, of whom, in 1810, 133 were slaves.

ETH

ETHER, in Chemistry. The specific gravity of sulphuric ether, as recently determined by M. Theodore de Saufriure, is 1.155 at 68°; and it boils in vacuum at 20°, and not at 20°, as stated in the Cyclopaedia. The specific gravity of the vapour of sulphuric ether, according to Mr. Dalton, is 2.25; according to M. Gay Lussac, whose experiments were made with great care, it is 2.586, that of air being 1. M. Theodore de Saufriure has lately published an analysis of sulphuric ether: according to this ingenious chemist, it is composed of

- Hydrogen
- Carbon
- Oxygen

Which proportions are nearly equivalent to

- Olefiant gas
- Water

Dr.
Dr. Thomson, however, seems to doubt the perfect accuracy of this analysis, and supposes rather that it is a compound of four atoms of olefiant gas and one atom of water, which supposition nearly agrees with the specific gravity of the vapour of ether above-mentioned, as determined by M. Gay Lussac. Thus the fp. gr. of olefiant gas is 0.974.

Two volumes of it will weigh 1.948
The fp. gr. of the vapour of it
water is - - - - - 0.625

2.573

which certainly differs but little from 2.586, the true fp. gr. according to M. Gay Lussac.

Nitric Ether.—The properties of this singular substance have been lately investigated by Thenard. This eminent chemist found the following to be the best mode of preparing it. Equal parts of alcohol and nitric acid, of the fp. gr. 1.283, were put into a retort, to the beak of which was bared a glass tube, which was plunged to the bottom of a long narrow glass jar, half filled with a faturated aqueous solution of common salt. From the top of this jar passed another tube, which went to the bottom of another similar jar, filled with the fame solution. In this manner, five other similar jars were connected with each other, and from the last a tube passed to a water-trough, to receive the gaseous products in proper vessels. Each of these jars was surrounded with a mixture of snow and salt, to keep it as cool as possible. A moderate heat was then applied to the retort, which produced so violent an effervescence, that it became necessary to moderate it by withdrawing the fire, and applying cold water to the outside of the retort. At the end of the operation, the ether was found floating on the surface of the solution in the different jars, but more especially in the first. It was separated, and to remove the nitrous and acetic acids with which it was contaminated, it was agitated in a clofe phial with a sufficients quantity of chalk. This purified, it exhibited the following properties.

It has a slightly yellow colour, and a very strong etheral odour. Its taste is likewise strong and peculiar. It is rather heavier than alcohol. It is much more volatile than sulphuric ether, the heat of the hand being sufficient to make it boil; hence it produces a very considerable degree of cold by its evaporation. It is lighter than water, and requires about forty-eight parts of that fluid to diffuse it. The solution has an agreeable odour, like that of apples. It is soluble in alcohol in every proportion. It is very inflammable. When kept for some time, both nitrous and acetic acids are formed in it. The same acids also are produced if it be heated, or even agitated with water. It has also the property of absorbing these acids very readily, and acquiring the property of reddening vegetable blues. Its vapour is much more chalcic than that of sulphuric ether.

According to Thenard, it is composed of

<table>
<thead>
<tr>
<th>Hydrogen</th>
<th>Carbon</th>
<th>Oxygen</th>
<th>Azote</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>8.54</td>
<td>28.45</td>
<td>48.52</td>
<td>14.49</td>
</tr>
</tbody>
</table>

But Dr. Thomson does not seem to place much reliance in the accuracy of this analysis.

Muriatic Ether.—Since the article Ether was written for the Cyclopaedia, this species of ether has been examined with great care by Gehlen, and still more recently by Thenard, which latter chemist has given the following as the best mode of preparing it.

A retort is to be nearly filled with a mixture of equal bulks of muriatic acid and alcohol, both as strong as possible. To prevent the effects of the violent ebullition which would otherwise take place on the application of heat, a few grains of sand are to be introduced into the retort. From the beak of the retort a tube passes into a glass jar, twice the size of the retort, and furnished with three mouths. This jar should be half filled with water of the temperature of about 70°. Into the second mouth a short tube of safety is to be luted; and into the third, a tube which passes into a water-trough to receive the gas. On the application of heat, the ether escapes in the form of gas. This gas is colourless, does not affect vegetable colours nor lime-water. Its fp. gr. is 2.219, that of air being 1. At the temperature of 54°, water dissolves its own bulk of it. At the temperature of 52°, it becomes liquid ether.

Muriatic ether in its liquid form is colourless like water, very liquid, has no action on vegetable blues, and has the same smell and taste as in the gaseous state. At the temperature of 41°, Thenard ascertained its fp. gr. to be 0.874. It is much more volatile than alcohol, or even sulphuric ether. None of the usual tests indicate the presence of muriatic acid in it. When burnt, however, a considerable proportion of this acid is disengaged, a fact first observed by Gehlen, and since fully confirmed by Thenard. From Thenard’s analysis, it appears that this singular compound is composed of

<table>
<thead>
<tr>
<th>Muriatic acid</th>
<th>Carbon</th>
<th>Oxygen</th>
<th>Hydrogen</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>29.44</td>
<td>36.61</td>
<td>23.31</td>
<td>10.64</td>
</tr>
</tbody>
</table>

Dr. Thomson is disposed to consider it as a compound of one volume of olefiant gas, and one volume of muriatic acid gas, condensed into one volume; or, what is the same thing, of four atoms olefiant gas, and one atom of muriatic acid. On this supposition, its constituents will be

<table>
<thead>
<tr>
<th>Five atoms hydrogen</th>
<th>Four atoms carbon</th>
<th>One atom chlorine</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.25</td>
<td>30.00</td>
<td>45.00</td>
</tr>
</tbody>
</table>

And the weight of its

atom will be - - - - - - 81.25

Hydriodic Ether.—This ether was discovered by M. Gay Lussac. He formed it by mixing together two volumes of absolute alcohol, and one volume of hydriodic acid of the fp. gr. 1.7, and distilling in a water-bath. Hydriodic ether, after being well washed with water, is perfectly neutral. Its odour is strong, and analogous to that of other ethers. In a few days it acquires a reddish colour, which is instantly removed by mercury or potash. Its fp. gr. at 72° is 1.926. It boils at the temperature of 148°. It is not inflammable, but merely gives out purple vapours when put upon burning coals. When passed through a red-hot tube, it is decomposed, an inflammable carburetted gas is obtained, hydriodic acid evolved, and some charcoal deposited. This ether has not been analysed; but Dr. Thomson is disposed to believe, from analogy, that it has a composition similar to that of muriatic ether, or that

3 P 2
it is composed of four atoms olefin gas, and one atom of hydriodic acid.

Acetic Ether.—The original experiments of Laurus and Scheele have been lately repeated by other chemists, and particularly by Thénard. Thenard succeeded in forming this ether, by repeatedly distilling together very concentrated acetic acid and alcohol. No gaseous product was evolved. The superfluous acid was neutralized by potash, and the ether finally obtained by a cautious distillation of the resulting liquid from acetate of potash. Acetic ether thus procured is limpid and colourless. Does not redden vegetable blues. Poffelles a peculiar taste, quite different from that of alcohol. Its fp. gr. at 44° is .866. It boils at the temperature of 105°. It burns with a yellowish-white flame, and acetic acid is evolved during its combustion. At the temperature of 62°, it requires more than seven times its weight of water to diffusely it. It appears from these and other properties to be a compound of acetic acid and alcohol.

Formic Ether.—This was first formed by Gehlen. It may be prepared, precisely in the same way as acetic ether, merely substituting the fornic acid for the acetic acid. Formic ether has an agreeable odour, similar to that of peach blossoms. Its taste is likewise similar, leaving an impression of ants. At a temperature of 63°, its fp. gr. is .9157. It burns with a blue flame, having yellow edges, and at the above temperature is soluble in nine times its weight of water. This ether has not been analysed.

ETON, col. 3, l. 25, r. to be seen; l. 57, r. 314 and 2279.

Eff. Ch. Spikelets generally single-flowered; scales imbricated, moisty empty. Stamens twelve or more. Nut cylindrical, crustaceous, without bristles at the base; kernel smooth. Tall bog-plants, from the south coast of New Holland. Scales blackish externally; upper ones filky internally. Somewhat allied to Chrysitrin. There are two species.

EUCHILUS, Brown in Ait. Hort. Kew. v. 3. 17, seems to us a Pulteriæ; see that article.

EUCHLORINE, in Chemistry. See Oxyumaria Acid.

EUCLID, in Geography, a township of Cayahoga, in Ohio, containing 283 inhabitants.

EUCLIDIUM, in Botony, from w, well, and ojvodic, to float up, because of the firmly-clasped seed-veil. —Br. in Ait. Hort. Kew. v. 3. 74.—Clafs and order, Tetradynamia Siliculae. Nat. Ord. Siliculae, Linn. Cruraceae, Jaff.

Eff. Ch. Calyx four-toothed, superior. Petals closely united into a deciduous lid, with four furrows. Stamens in four sets, alternate with the calyx-teeth, combined at the base. Capsule of four cells, opening at the top. Seeds numerous.

1. E. tetragona. Br. as above, t. 3.—In exed places near the shore, about Lucky bay, on the south coast of New Holland, flowering and bearing fruit in January. Br. A florin, three to five feet high, with square, bordered branches. Leaves stalked, ovate-oblong, mostly opposite, coriaceous, four or five inches in length, entire, glaucous, dotted with retinuous points. Umbels axillary, stalked, of three or four flowers, whose numerous white flamen spread conspicuously after the lid is fallen. We believe this fine plant is living in the green-house of the Comete de Vandé, at Baywater.

EXTRACT—Extractive Principle, in Chemistry. Great confusion exists in different chemical authors respecting these terms. Formerly the term extract was applied to all those substances which were extracted from plants by means of water or spirits; but of late it has been confined by many to a substance which is suppos’d to exist in many plants, and which may be obtained tolerably pure from the work of the cinchona officinalis, according to the experiments of Schrader. Other chemists, however, still use the term extract in its original sense; hence Dr. Thomson’s, to prevent the ambiguity, it has been chosen to dilate the principle of Schrader under the term extractive. The following are the properties of extractives, according to Dr. Thomson.

1. Soluble in water, and the foliage is always coloured. When the water is slowly evaporated, the extractive matter is obtained in a solid state, and transparent; but when the evaporation is rapid, the matter is opaque.

2. The taste of extractive is always strong, but it is very different according to the plant from which it is obtained.

3. It is insoluble in absolute alcohol and in ether, but soluble in alcohol when it contains water.

4. By repeated solutions and evaporations, the extractive matter acquires a deeper colour, and becomes insoluble in water. This change is considered as the consequence of the absorption of the oxygen of the atmosphere, for which the extractive principle has a great affinity. But if the solution be left to itself, exposed to the atmosphere, the extract is totally destroyed in consequence of a kind of putrefaction which speedily commences.

5. When chlorine is poured into a solution containing extractive, a very copious dark yellow precipitate is thrown down, and the liquid retains a light lemon colour. These flakes are considered as oxygenized extractive; it is now insoluble in water, but hot alcohol dissolves it.

6. The extractive principle unites with alumina, and forms with it an insoluble compound. Accordingly, if sulphate or muriate of alumina be mixed with a solution of extractive, a flaky insoluble precipitate appears, at least when the liquid is boiled; but if an excess of acid be present, the precipitate does not always appear.

7. It is precipitated from water by concentrated sulphuric acid, muriatic acid, and probably by several other acids. When the experiment is made with sulphuric acid, the fumes of vinegar generally become fusible.

8. Alkalies readily unite with extractive, and form compounds insoluble in water.

9. The greater number of metallic oxys form insoluble compounds with extractive. Hence many of them, when thrown into its solution, are capable of separating it from water. Hence also the metallic salts modify precipitate extractive. Muriate of tin poiffèés this property in an eminent degree. It throws down a brown powder, perfectly insoluble, composed of the oxys of tin and vegetable matter.

10. If wool, cotton, or thread, be impregnated with alum, and then plunged into a solution of extractive, they are dyed of a fawn-brown colour, and the liquid loses much of its extractive matter. This colour is permanent. The same effect is produced if muriate of tin be employed instead of alum. This effect is still more complete if the cloth be soaked in chlorine, and then dipped into the infusion of the extractive. Hence we see that the extractive matter
mater requires no other mordant than oxygen to fix it on cloth.

11. When distilled, extractive yields an acid liquid impregnated with ammonia.

It cannot be doubted, continues Dr. Thomson, that there are many different species of extractive matter, though the difficulty of obtaining each separately has prevented chemists from ascertaining their nature with precision. Watery extracts, when obtained by slow evaporation to dryness, always have an acid taste, and redden litmus. They all yield a precipitate while liquid on the addition of ammonia. This precipitate is a compound of lime and insoluble extractive. Lime always causes them to exhale the odour of ammonia. It has been ascertained, that the extractive principle is more abundant in plants that have grown to maturity than in young plants.

All the extracts prepared by apothecaries are compounds of the extractive principle with several others, even as many as eight or more, according to Dr. Thomson. In short, this department of vegetable chemistry is at present in a very confused and imperfect state.

### VOL. XIV.

**EYE, Physiology of the,** vol. 6, l. 26 from bottom, for an inch r. one-tenth of an inch.

**EYE, Humours of: Chemical Properties of.** Some experiments have been made on these fluids, the results of which defer to be briefly mentioned.

**Aqueous Humour.**—Mr. Chenix found the sp. gr. of the aqueous humour of the sheep at 60° to be 1.009. This fluid scarcely affects vegetable blues while fresh. On exposure to heat, a flight coagulum is formed. Tannin occasions a precipitate in it, both before and after boiling. Nitrate of silver likewise produces a precipitate, but no other metallic salt. According to Berzelius, 100 parts of it consist of

The peculiar matter of the lens possesses all the chemical properties of the colouring matter of the blood, except colour.

The humours of the human eye are composed of the same ingredients as those of the sheep; but they differ in their sp. gr. Thus the sp. gr. of the human aqueous and vitreous humour is 1.0253; that of the crystalline 1.0790. The humours of the eyes of oxen also resemble those of the sheep. The sp. gr. of the aqueous and vitreous humours is 1.0088; that of the crystalline 1.0765. The crystalline of the ox weighed thirty grains. When the whole was pared away, except fix grains in the centre, the sp. gr. was found to be 1.194.

Sir H. Davy found the same constituents in the eyes of birds; but the sp. gr. of the vitreous humour in these animals is greater than the sp. gr. of the crystalline.

**Pigmentum Nigrum.**—This curious substance has been examined by Gmelin. From 500 eyes of oxen and calves he collected 75 grains. Its colour is blackish-brown. It is talciferous, and adheres to the tongue like clay. It is insoluble in water, alcohol, ether, oils, lime-water, and acetic acid. It dissolves in potash and ammonia by the assistance of heat, and is again precipitated by acids. Sulphuric acid dissolves it, and becomes black. Muriatic acid also forms an imperfect solution. Nitric acid dissolves it, and changes its colour to reddish-brown. When distilled it yields water, brown oil, and carbonate of ammonia. The residuum consists almost entirely of charcoal.

**EYE, col. 2, l. 4.** In the year 1811, the town and parish consisted of 326 houses, and 1893 inhabitants.

**EYMOUTH.** Add—By the return of 1811, the parish contained 115 houses, and 562 inhabitants.

**EYNHAM, or ENSHAM, l. ult.**—In 1811, the number of inhabitants was 1418, and of houses 246.
FABER, JACOBUS STAPULENSIS. See FEVER.

FAHRENHEIT, l. 2, Hamburg or Danzig.

FAIRFAX, l. 3, r. 13,117 inhabitants, of whom 5942 were slaves in 1810. At the close, add—Also, a town of Maine, in Kennebec, containing 924 inhabitants.

FAIRFIELD, l. 4, r. 17; l. 5, r. 40,950; l. 6, r. 83; l. 17, r. 4,125; l. 24, add—divided into 15 townships, containing 11,361 inhabitants. For Kennebec r. Somerset; l. 26, r. 1,348; l. 30, r. 1,618; l. 36, add—containing 2,279 persons; l. 43, r. 1,975; l. 47, add—It contains 11,857 inhabitants, of whom 4,034 are slaves. Also, a township in Crawford county, in Pennsylvania, having 421 inhabitants.

Also, a township of Butler county, in Ohio, having 1,414 inhabitants. Also, a township of Columbiana county, in Ohio, having 852 persons. Also, a township of Highland county, in Ohio, having 1,157 inhabitants.

FAIRFIELD, New. See NEW, &c.

FAIRFORD. In 1811, the parish contained 299 houses, and 1,444 persons;viz. 688 males, and 756 females.

FAIRHAVEN, l. 5, r. 645; add—Also, a small township of Maine, in Somerset county, having 116 inhabitants.

FAIRLIE. At the close, add—983.

FAIR VIEW, a town of York county, in Pennsylvania, containing 1,298 persons.

FALLHERZ. See MINERALOGY, Addenda.

FALLOWFIELD, Earl and West. Two townships in Chelten county, in Pennsylvania, the former containing 991, and the latter 1,157 persons. Also, a township of Washington county, in Pennsylvania, containing 1,934 inhabitants. Also, a township of Crawford county, in Pennsylvania, containing 551 persons.

FALLS, a township of Bucks county, in Pennsylvania, containing 1,409 persons. Also, a township of Muncingum county, in Ohio, containing 931 inhabitants.

FALMOUTH. At the close, add—By the return of 1811, the town of Falmouth contains 465 houses, and 3,933 inhabitants.

FALMOUTH, in America, l. 3, r. 4105. Col. 2, l. 11, r. 2237.

FANNET, a township of Franklin county, in Pennsylvania, containing 1,398 inhabitants.

FAQUERIE, l. 3 and 4, r. 22,489 inhabitants, of whom 10,361 are slaves.

Fareham. In 1811, the parish contained 596 houses, and 3,325 persons; viz. 1,592 males, and 1,733 females.

FARMER, col. 5, l. 9 from the bottom, for LEAFARMS r. LEAFARMS.

FARMER, Richard, col. 2, l. 12, for which he exchanged for r. for which he exchanged.

FARMINGTON, l. 7, r. 1639. After Bolton, add—

FEA, a town of Strafford county, in New Hampshire, having 1,272 inhabitants; l. 15, r. 2748.

FARRIERY, denotes the business or practice of a farrier, which, in its more limited sense, pertains to the shoeing of horses, (see SHOEING,) and the various circumstances attending it; but in its more extensive sense, and as it is often used and understood, it comprehends the whole veterinary art, as it relates to the management of animals in general, including the knowledge and proper treatment of their diseases. See each disease under its appropriate term.

FARRINGDON. In 1811, the parish of Great Farringdon contained 327 houses, and 1,843 persons; viz. 990 males, and 943 females: 175 families being employed in agriculture, and 131 in trade, manufactures, and handicraft.

FARSETIA, in Botany, a genus originally founded by Dr. Antonio Turra, of Vicenza, in a quarto dissertation, (published at Venice in 1765,) reduced by Linnaeus to Cheiranthus, is restored by Mr. Brown, in Art. Hort. Kew. v. 4. 96. It commemorates Philipp Farfeti, a noble Venetian, celebrated for his botanical erudition. Mr. Brown gives the following:

Eff. Ch. Pouch-elliptic-oblong, siliqua, compressed, with flatish valves. Cotyledons accumbent. Seeds several; either bordered, or some of the filaments are toothed. Six species are defined in Hort. Kew.

FARSISTAN, l. 6, after province, add—is divided into the Germaefer and Sirhid, or the warm and cold climates. The former is that tract which extends from the sea to the latitude of Kazeroon, and runs parallel with the gulf, from the banks of the Tab to the confines of Larifan. The Sirhid, denoting boundary, and metaphorically applied to a cold region, comprehends most of the mountainous part of Fars, extending from the latitude of Kazeroon to that of the town of Yezdekha, situated on the bed of a former river, which separates this province from Irak. Fars, &c.

FAVART, l. 23, for retrofile r. retrofile.

FAVERSHAM, col. 3, l. 30, r. in 1811—672—3872.

FAWN, l. 3, r. 1402.

FAVYETTE, l. 4, r. 9; l. 6, 24,714 inhabitants, of whom 98, in 1810, were slaves. Also, a county of Ohio, containing 1,854 inhabitants. Col. 2, l. 4, r. 8239; l. 5, r. 2905; l. 9, r. 804; add—Also, a township of Alleghany county, in Pennsylvania, containing 2,016 inhabitants.

FAYSTON, a town of Chillendon county, in Vermont, having 149 inhabitants.

FEARING, a town of Ohio, in Washington county, having 454 inhabitants.

FEATHERS, dry-pulled, scalded, dele the reference to Bed.

FEISAPAR. See Felspar and Mineralogy, Addenda.  

FEISPAH or DOHRAK, one of the principal towns of Chufistan or Kuziflan, in Persia, founded by Sheikh Soliman when the ancient Dorak, one of the eight cities of Sufiana, was abandoned. It is situated in low marshy ground, on the banks of two of the branches of the Jerahi, surrounded with mud walls, sixteen feet thick and two miles in circumference, flanked at intervals with towers. The inhabitants, amounting to 8000, live chiefly without the walls in the suburbs. This town is celebrated for the manufacture of the abba, or Arabian cloak, which is transported in great numbers all over Persia and Arabia.

FELSPAR. See Felspar and Mineralogy, Addenda.

FELUGIA, or AXBAR, in Geography, a town in the pachalic of Bagdad, which, under the appellation of Perifurabur, is ranked, in the history of the campaigns of Julian, as the head city in Asia. The city was reduced to ashes, and on its ruins a palace was erected by Soliman the Great, pacha of Bagdad. Pilgrims going to Kerbela generally cross the river at this spot, on a bridge of boats.

FENCE, col. 2, l. 20, dele low. Col. 3, dele hedge, laft word, and the comma in l. 4, for thus above r. thus formed above; l. 34, 35; for under the plough r. into grafts.

FEREDUN, in Geography, a small district of Irak, in Persia, behind the S.W. ridge of the mountains of Khonfar, peopled with Georgians and Armenians, brought hither by Abbas the Great. The former, amounting to 1000 families, are Mahometans, who never intermarry with either Persians or Armenians. The capital of the district is Pushish.

FERGUSON, a township of Centre county, in Pennsylvania, having 1666 inhabitants.

FERMANAGH, l. 2, r. 1954.

FERMAGH, a town in the county of Fermanagh, in Ireland, having 3174 inhabitants.

FERMENTATION, Viscous, in Chemistry. The recent observations of chemists enable us to state with greater precision the changes which sugar undergoes during its conversion into alcohol, than could be done when this article was written for the Cyclopaedia.

Sugar is composed, according to Dr. Prout's analysis, of

\[
\begin{array}{ccc}
\text{Hydrogen} & - & 6.66 \\
\text{Carbon} & - & 40.00 \\
\text{Oxygen} & - & 53.33 \\
\end{array}
\]

which correspond with 1 atom of each element.

Alcohol, according to Dr. Thomson, is a compound of about

\[
\begin{array}{ccc}
\text{Hydrogen} & - & 13.04 \\
\text{Carbon} & - & 52.16 \\
\text{Oxygen} & - & 34.80 \\
\end{array}
\]

which correspond with 3 atoms of hydrogen, 2 atoms of carbon, and 1 atom of oxygen; and carbonic acid gas is composed of

\[
\begin{array}{ccc}
\text{Carbon} & - & 27.27 \\
\text{Oxygen} & - & 72.72 \\
\end{array}
\]

or of 1 atom of carbon and 2 atoms of oxygen.

Hence, if we suppose (for the sake of round numbers) 3 atoms of sugar to be decomposed during the process of fermentation, they will be converted into 1 atom of alcohol and 1 atom of carbonic acid; for

<table>
<thead>
<tr>
<th>Hydrogen</th>
<th>Carbon</th>
<th>Oxygen</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 atoms</td>
<td>2 atoms</td>
<td>1 atom</td>
</tr>
<tr>
<td>3 atoms</td>
<td>1 atom</td>
<td>2 atoms</td>
</tr>
</tbody>
</table>

which make together 3 + 3 + 3.

or three atoms of sugar.

Now this determination very nearly coincides with the actual experiments of Lavoisier, and the more recent determination of Thenard, respecting the proportional quantities of these two products obtained by the fermentation of sugar. Thus 100 parts of sugar (as deduced by Dr. Thomson from Thenard's experiments) were converted into

| Alcohol | - | 57.44 |
| Carbonic acid | - | 42.56 |

Whereas the proportions, according to the above calculations, ought to have been

| Alcohol | - | 51.12 |
| Carbonic acid | - | 48.88 |

A coincidence as near as could have been expected, considering the very difficult nature of the experiment.

With respect to the modus operandi of fermentations, we have nothing to add, but that the subject still remains a mystery. See Wine, and Yeast.

FERREY, in Geography, a town of Mazanderan, in Persia, situated at the mouth of a river, 30 miles E. of the village of Meshid Sir, which carries on a small trade in rice, salt, fish, and pottery.

FIROZEABAD, an ancient city of Fars, in Persia, founded by Arta-xerxes Babegon, which became the capital of Firoze Shah, the grandson of Nahrwan. Its ruins occupy a large space in a plain about 17 miles in length, and half as wide. Here are the remains of Attalah Kudda, or fire-temple of Firoze Shah.

FIROZABAD. See the preceding article.

FISSCAND, L. ult. r. 250. Col. 2, l. 3, r. 1811–1829; l. 1, deU lately and received ; l. 15, for Fridays r. Thursdays; l. 22, deU having been recently affixed by the erection of a pier; l. 28, for about fifty r. severals; l. 29, r. from 30 to 100 or more tons burthen; l. 40 and 41, r. at a distance near St. David’s is a vail, &c.

FISCHERA, in Botany, so named by professor Sprengel, in honour of his pupil Mr. Ferdinand Fichter, now curator of the Razoomofsky garden, near Moscow.—Spreng. Prodr. Umbell. 27. (Azorella; Labill. Nov. Holl. v. i. 73.)—Clafs and order, Pentandria Digna. Nat. Ord. Umbellata.

1. F. lanceolata. Lanceolata Fichtera. Spr. n. 3. (Azorella lanceolata; Labill. 74. t. 99.)—Leaves linear-lanceolate, keeled, of Native of Port Jackson, New South Wales.

Dr. White; of Lewin’s land, Labillardiere. Stem thrummy, twelve or eighteen inches high, with roughish branches. Leaves scattered, numerous, spreading, entire, smooth, an inch and a half long; tapering at the base. Umbels terminal, falked, compound, many-flowered.

2. F. ovata. Ovata Fichtera. Spr. n. 4. (Azorella ovata; Labill. 74. t. 100. Trachymene ovata; Spr. Umb. 8.)—Leaves ellipticovate, triple-ribbed.—From the fame countries. Differs from the foregoing chiefly in the broader shorter figure of the leaves, and the more evident combination of their ribs. We suspect Labillardiere has confounded a more lanceolate variety of the present with his real lanceolata.

3. F. linearis. Linear Fichtera. (F. linearifolia; Spr. n. 2. Azorella linearifolia; Cavan. 1c. v. 5. 57. t. 485.)—Leaves linear-awl-shaped.—Native of Port Jackson.

Dr. White; Like the two former in habit, but the small, narrow, heart-like leaves seem to differ from it, if the foliage of this genus can at all be trusted for specific characters.

We conceive the compound umbels, totally different habitat, more oblong less flattened fruit, and other characters above indicated, must keep these plants genetically distinct, both from the original Azorella, (see Bolax,) and from Mr. Rudge’s Trachymene, hereafter described, though the learned Sprengel now refers them to the latter. His T. comprima (Azorella comprima; Labill. t. 101.) appears not well to accord with either, in character or habitat. The fruit is broader than long, tumid and reticulated, not rough. Umbels compound.

FLINDERSIA, in Botany, in honour of capt. Flinders; commander of the botanical expedition in which Mr. Brown was employed.—Br. Bot. of Terr. Auatr. 63.—Clafs and order, Pentandria Monogyne. Nat. Ord. Cereales, Br. Eff. Ch. Calyx five-cleft, inferior. Petals five, Nectary cup-shaped, bearing the flaminis, with five intermediate barren filaments, opposite to the petals. Capsule woody, of five valves, and five cells, with as many loofe partitions. Seeds winged, two in each cell.

1. F. australis. Br. l. 1.—A tree found on the east coast of New Holland, lat. 23°. Leaves ternate or pinnate entire. Panicles cymose, downy. Capulas muralcates. Arbor radulfera, Rumph. Amb. v. 3. 201. l. 129, is apposited to belong to this genus.

FLOAT-STONE. See MINERALOGY, Addenda.

FLOOR, in Building, col. 2, l. 37, for heading points r. heading joints.

FLORAL GAMES, l. 10, add.—It is said that Clementina-Hauna, countess of Thouleou, published an edict that attended all the poets of France with artificial crowns, drested with flowers, &c. Walton’s Hill of Poetry, vol. i. p. 467.

FLORIDA, col. 2, l. 1, after Appalachica, add—and Pearl river, N. by 31° N. lat. and S. by Bayou Iberville, Amite river, and lakes Maurepas and Pontchartrain; extending over 4850 square miles of surface. Soon after the incorporation of this part of W. Florida into the state of Louisiana, it was divided into the four parishes of Baton Rouge, New Feliciana, St. Helena, and St. Tammany. The rivers are, the Misissipi, the Comite, Amite, Tickfah, 3 Q. Tangipoo.
Tangipoo, Chisneté, Bogue Chito, and Pearl. The Courbe rises in Wilkinson county, in the Mississippi territory, and, after a course of forty miles, falls into the Amite. The Amite rises in the same territory in Amite county, and having joined the Iberville, falls into lake Maurepas, after a course of 100 miles. The Tickfah rises in the same territory, and after entering W. Florida, becomes much augmented, and pursuading a part of its course of fifty miles falls into lake Maurepas. The Tangipoo rises in the same territory, and running nearly S. 70 miles, falls into lake Pontchartrain. The Chisneté rises in W. Florida, and Pursuading a course of about 60 miles, enters into lake Pontchartrain. The thriving town of Madisonville lies on its banks. The Bogue Chito has its source in the Mississippi territory, and after a S.E. by S. course, enters the Pearl River; which see.

FLORIDA, a town of Berkshire county, in Massachusetts, containing 302 inhabitants.

FLORIN, col. 2. l. 19. after divisions, add—A florin is a silver coin in Holland, Flanders, and Germany, called also "Guilder," or "Gulden." Accounts are kept in Holland in gilders or florins of 20 schillings each subdivided into 16 pennings. A rix-dollar is worth 21 florins, and a pound Flemish is equal to 6 gilders; hence, the rix-dollar being 13. 4d. Flemish, the guilder is 13. 4d. Flemish. A gold guilder, with which accounts are kept in the corn-trade, is worth 28 florins. Among the coins are stamped gold florins at 28 florins, un stamped at 26 florins. A gold guilder of 28 florins must weigh 407 Dutch assels, or 301 English grains. In Germany, they have gold florins, or gulden, which are chiefly current in the countries on the banks of the Rhine, passing generally for 2 rix-dollars, current, and they are to contain 18 1/2 carats of fine gold, 23 carats of fine silver, and 1 1/2 carats of copper. The Hanoverian guilder contains 18 1/2 carats of gold, 23 carats of silver, and 1 1/2 carats of copper. The gold florin is a gold coin in Hanover, and other parts of Germany; but the gold guilder in Holland is a silver coin. See Table of Coins under Coin and Exchange.

FLOYD, l. 4, r. 3453 and 113.

FLUATES, in Chemistry. See FLORIC Acid.

FLUGEL-MAN, in Military Language, a well-drilled intelligent soldier, advanced in front of the line to give the time in the manual and platoon exercises. The term flugel is derived from the German, and signifies a wing; the man having been originally posted in the front of the right wing.

FLUIDS, Animal, Chemical Properties of. The blood is the general source of all other animal fluids, most of which, more or less, re semble it in their properties. The operation by which other fluids are formed from the blood is termed secretion. See Blood and Secretion.

Berzelius divides secreted fluids into two classes; namely, the secretions properly so called, or the fluids intended to fulfill some ulterior purpose in the animal economy; and the excretions, which are directly discharged from the body. The fluids of the former class, according to this distinguished chemist, are all alkaline; of the latter, all acid. The excretions are, the urine, the perspirable fluid, and the milk; all the other fluids appear to belong to the former class. The alkaline secreted fluids may be divided into two very distinct species. The former of these contains the same quantity of water as the blood, so that the change induced by the nervous influence seems to be confined to that of altering the chemical form of the albuminous materials, without affecting their relative proportions to the water and other substances dissolved in the blood. The bile, perspirable fluid, &c. are of this kind. The latter species consists of fluids, in which the influence of the nervous system has separated a large portion of the albuminous matter, and left the remaining liquid proportionally more watery. The flava, the humours of the eye, and the effused serum of membranes, are of this species; and in these, the quantities of salts, and in general all of alkali, are the same as in the blood.

The influence of the chemical agent of secretion is therefore, according to Berzelius, chiefly spent upon the albuminous materials of the blood, which seem to be the source of every substance that peculiarly characterizes, and is the principal constituent of each secretion, and which is fat generis. All the other parts of the secretion seem to be rather accidental, and to be found there only, because they were contained in the blood out of which the secretion was formed. The excretions are of a more compound nature. They all contain a free acid, which is the lactic, and in the urine this is mixed with the uric acid. Urine seems to contain only a single peculiar characteristic matter, but milk has as many as three, namely, butter, curd, and fugar of milk. The perspired fluid appears to have no peculiar matter, but to be a mere watery liquid with hardly a vestige of the albumen of the blood, and in short to be the same as the other excreted fluids would be if deprived of their peculiar matter.

An account of most of the animal fluids will be found under their proper heads. The following is a tabular view of the analyses of what have been termed albuminous fluids, many of which have been omitted.

The above are the results of Dr. Bostock's experiments, with the exception of the fluid from a blister marked *, which is taken from Margueron.

With respect to the nature of the incoagulable matter and fats, they are the same as those constantly found in the serum of the blood; we refer our readers therefore to what we have said on this subject under the article Blood.

FLUORIC ACID, in Chemistry. See FLORIC Acid.

FLUORIC Acid. Since this article was written for the Cyclopaedia, many important additions have been made to our knowledge respecting fluoric acid, which deserve to be mentioned here.

Pure fluoric acid, according to Gay Lussac and Thenard, may be obtained by distilling together in lead vessels a mixture of one part of white flour spars in a flake of powder, and two parts of concentrated sulphuric acid. The lead receivers must be kept as cool as possible by a mixture of common salt and snow or ice.

Florid acid thus obtained is, at 32°, a colourless liquid, like water. It remains a fluid between 40° and 65°. Its boiling point has not been determined, but it is low. When exposed to the air it fumes violently, giving out a smell similar to that of muriatic acid, but much stronger. It is very speedily diffused in the open air, and can only be preserved in metallic vessels. Thifie best adapted for the purpose are made of pure silver, with air-tight silver stoppers. This acid, according to Davy's experiments, when as concentrated as possible,
possible, contains no water. In this state, its specific gravity is 1.0609. When united to a certain portion of water, its specific gravity becomes as high as 1.250. When a drop is let fall into water, a hissing noise is heard, similar to that occasioned by a hot iron. When a few drops of water are let fall into fluoric acid, it enters into solution. A large proportion of water may be added without destroying its fuming property. Care must be taken not to breathe the fumes of this acid, as they are very deleterious. When a drop of it falls upon the skin, it acts as a powerful corrosive, and occasions a sore which does not heal.

Reflexing the nature of this acid, the opinion of the older chemists, and even of Gay Lussac and Thenard, was, that it is compounded of an unknown base and oxygen. M. Ampere, however, hinted the notion that it is analogous to muriatic acid, or a compound of hydrogen, and a supporter of combustion, to which the name of fluoric has been given; and this opinion has been since supported by Sir H. Davy, and though its truth has not been absolutely demonstrated, yet upon the whole perhaps it is the most probable.

On this supposition, fluoric acid is a compound of one atom of fluorine, and one atom of hydrogen. See Simple Bodies.

Fluoric acid combines with all the bases forming fluates. Fluoric of Ammonia.—This salt may be formed by saturating pure fluoric acid with ammonia. It is neutral when first formed, but becomes acid when evaporated. It does not crystallize, but when heated, flies off in thick white vapours.

Fluoric of Potash.—This salt may be formed in the same manner as the last. It has a very sharp taste, crysallisizes with difficulty, is very deliquescent, and of course soluble in water. When heated, it undergoes first the aqueous, and afterwards the igneous fusion. Sulphuric acid decomposes it, driving off fluoric acid in vapour.

Fluoric of Soda.—This salt may be formed as above. It has much less taste than fluoric of potash. It is not altered by exposure to the air, and is rather more soluble in hot than in cold water. On cooling, therefore, it separates in small crystals, or more frequently in the form of a solid and transparent crust on the surface of the water.

Fluoric of Lime.—This salt exists abundantly native. It is called Fluor spar (which see), and is the substance from which this acid is always obtained. It is composed, according to Davy's analysis, of

| Fluorine  | 20.0 | 100.0 |
| Calcium   | 26.25 | 131.25 |

Fluoric of Barytes.—This salt is tasteless, insoluble in water, but soluble in excess of fluoric acid, and likewise in nitric and muriatic acid. It is composed of

| Fluorine  | 20.0 | 100.0 |
| Barium    | 87.5 | 437.5 |

Fluoric of Strontian.—This salt possesses the same properties as fluoric of barytes.

Fluoric of Magnesia.—This is a tasteless powder, insoluble in water, and fearfully soluble in acids.

Fluoric of Yttria, Fluoric of Alumina, and Fluoric of Zirconia, are likewise white insoluble powders. The

Fluoric of Glucina is soluble in hot water, and precipitates in small crystals as the water cools.

It is extremely probable, as Dr. Thomson remarks, that the above salts are in reality fluorides, or compounds of fluoric, with the metallic bases of the earths.

The metallic fluorides are not upon the whole an interesting class of bodies. The fluoride of iron, manganese, zinc, and tin, are white insoluble powders. The fluoride of cobalt is of a red colour. The fluoride of lead exists in the form of brilliant plates. The fluoride of copper, of small blue-coloured soluble crystals. The fluoride of mercury of small lamellar yellow crystals. The fluoride of silver is very soluble in water, and does not crystallize. It cannot be formed by the direct union of fluoric acid and silver, but it is formed when fluoride of mercury is made to act upon silver.

Fluoric Acids.—Fluorine has the property of combining with boron, and forming an acid which has received the above appellation. It may be formed by mixing together in a retort one part of finely pounded fused boracic acid, and two parts of fluor spar in powder, and twelve parts of sulphuric acid. The heat of a lamp is then to be applied, and the acid comes over in the form of a gas, which must be received over mercury. For this process we are indebted to Dr. John Davy, but the acid itself was first discovered by Gay Lussac and Thenard in 1808.

Fluoric acid thus obtained is colourless, and possesses the mechanical properties of common air. Its smell is similar to that of muriatic acid, and its taste is exceedingly acid. It instantly gives a red colour to vegetable blues. Its specific gravity, as determined by Dr. Davy, is 2.5795. Water absorbs about 700 times its bulk of this gas, and becomes slightly viscid, like sulphuric acid, and like it requires a high temperature to make it boil. It also chars animal and vegetable substances, and is capable of forming an ether when distilled with alcohol. It combines with the different bases, and forms a class of salts called fluoborates, which have been little examined. On the supposition that it is a compound of fluoric acid and boron, which seems to be the most probable opinion, its composition will be

| Fluorine | 20.0 | 100.0 | 228.57 |
| Boron    | 8.75 | 437.5 | 100.0 |

Fluoboric Acid.—Fluorine has also the property of combining with silica, and forming a powerful acid. This compound was first discovered by Scheele, but it is to Dr. J. Davy that we are principally indebted for the correct account of its properties. It may be formed by putting a mixture of equal parts of pounded fluor spar and glaef into a retort, and pouring over the mixture sulphuric acid sufficient to convert the whole into a paffe. Heat is then to be applied, and the acid speedily comes over in the form of a gas, and may be collected over mercury. Fluoboric acid gas is colourless, and possesses the mechanical properties of common air. Its smell resembles that of muriatic acid. It smokes when allowed to escape into the atmosphere. It instantly reddens vegetable blues. Its specific gravity, according to Dr. Davy, is 3.5735. Water absorbs about 265 times its bulk of it, but at the same time it is partly decomposed, and silica is deposited. When passed through liquid ammonia, the whole of the silica is deposited in the form of silica; this enabled Dr. Davy to effect its analysis, the result of which appears to shew that it is a compound of one atom silica and one atom fluorine.

The fluoborates have not been much examined. The fluoborate of lime exists abundantly native, and has not hitherto been distinguished from fluor spar. It may, however, be easily recognized by heating it in metallic vessels with sulphuric acid, when it yields fluoboric acid gas, while fluor spar does not.

FORFAIR, l. 21, r. 1811; l. 22, r. 759—552.

FORFAIRSHIRE. Add—By the return of 1811, this county had 16,135 houses, occupied by 107,264 persons; 48,151 being males, and 59,113 females; 4980 families employed in agriculture, and 15,616 in trade and manufactures.

FORICULA, col. 2, under Agricultura, add—The popular dread in which this insect is held, from an apprehension of its entering the cavity of the ear, and piercing the tympanum, is now generally considered as an ancient and vulgar error.

FORMIC Acid, in Chemistry. The distinct nature of this acid appears now to be generally admitted by chemists. In its lefiable properties, it approaches the acetic acid. But Suerfen has shewn, that it has the property of neutralizing much of the alkaline bodies than acetic acid. Gehlen also has shewn, that the formates of soda and copper, differ altogether from the acetates of the same bases. Berzelius has lately analyzed this acid with his usual precision; according to him, it is composed of

Hydrogen 2.844 which nearly corre—1 atom hydrogen.
Carbon 32.492—respond with 2 atoms carbon.
Oxygen—64-78—3 atoms oxygen.

Hence it appears to resemble oxalic acid closely in its composition.

FUNGI, Chemical Properties of the. Braconnot has lately detected three distinct new principles in this class of plants. Two of these are acids, one of which he has denominated boletic acid, the other fungic acid; the third is a principle neither acid nor alkaline, to which he has given the name of fungin. We shall briefly describe here the leading properties of each of these principles.

Boletic Acid.—This was obtained from the juice of the boletus pumulo-ignarius. Its colour is white; it is not altered by exposure to the air, and its crystalls are irregular four-sided prisms. Its taste is similar to that of tartar. It is soluble in 180 times its weight of water at a temperature of 68°, and in 45 times its weight of alcohol. The aqueous solutiion reddens vegetable blues. It combines with the different bases forming boletates, which have been but little examined. The boletate of ammonia crystallizes in flat four-sided prisms, and is soluble in 26 times its weight of water at 68. The boletate of potash is very soluble in water, and crystallizes with difficulty. The boletate of lime crystallizes in flat four-sided prisms, and is soluble in about 110 times its weight of water at 72°. No one hitherto appears to have repeated the experiments of Braconnot on this acid.

Fungic Acid.—This was extracted from the boletus juglandis, and other fungi. This acid is colourless, does not crystallize, has a very four taste, and when evaporated to dryness, deliquesces on exposure to the air. The fungates of potash and soda do not crystallize, are very soluble in water, but not in alcohol. The fungate of ammonia crystallizes in regular fixed prisms. The fungate of lime is not altered by exposure to the air, and is soluble in about 18 times its weight of water at 73°.

Fungi.—This substance approaches woody fibre in its properties, but seems to be sufficiently distinguished from it by various characters, particularly by constituting a nourishing article of food, and by being less soluble in alkaline leys.

FUNKUS of the Anthru, l. 13, for he r. she.

F. gigantea, De C. Pl. gr. (Agave Fexa, Linn.) and F. tubersa, (A. tuberosa, Willd. Sp. Pl. v. 2. 194.) are the only species.

FURIES, col. 3, l. 22, r. these serpents.

FURR, in Heraldry, the 4th paragraph, r. Furrs either conflit of one colour (which is white, but cannot be used in arms singly), or more than one; and these either two, or more than two.

FURRINGS, in Architecture. Add.—Joists are furred, by which operation the uneven joints of an old floor are levelled for the reception of the flooring boards.

FURZE, col. 4, l. 18, for f. 165. r. 31. 122., the furze being cut only every other year.

FURZE-Mill, col. 2, l. 20, for melted cake r. melted coke.

FUSION, col. 2, l. 20 from the bottom, del all and except gold.

G.

G, l. 21, after ring, &c. add.—It has been asserted, however, by an ingenious correspondent, that G hard is easily founded with any of the vowels, either before or after it, whilst the tongue is probably kept at the bottom of the mouth; nor does he believe that the pressure here described is at any time necessary for the pronunciation of this letter. It does indeed take place in two of the three examples here given, viz. gate, go, and gold; but it is for the formation of the letters t and l. This pressure takes place also with the G soft.

GADUS. Obi. Some species, viz. Molva, Albidos, Tau, Lota, Muflela, Tricirratus, and Cimbrias, all bearded, are arranged in the same division, the character of which is without boards.

GADE, in Carpentry, l. 9, for a staff r. the stcck; for to strike r. or strike; l. 10, for stafF r. stuff; l. 11, for it r. the tooth.

GAINSBOROUGH, l. 9 from bottom, for quadrangular r. quadrangle.

GALANGAL, l. 3, add.—See Alpinia, Addenda.

GALAPAGOS, col. 1, l. 5 from bottom, for 68° r. 86° or 89°; del the paragraph.

GALARDIA, in Botany, Lamapeck Dict. v. 2. 590. Illstr.
GAL

We have already announced this genus under the Virgilia now established. There are two more species, G. fimbriata and arilata, from N. America.

GALEOPITHECUS, CALUGO, in Zoology, a genus of the order Primates, the characters of which are, that it has no front teeth in the upper jaw; that those in the lower are high, short, broad, dilated, and pectinated; that the canine teeth are very short, triangular, broad, sharp, and serrated; that the grinders are four, truncated and muricated with conical protuberances; and that it has a flying-film surrounding the body, limbs, and tail. For the description of this genus with appropriate figures, naturalists are indebted to Dr. Pallas, and it may be found in the Transactions of the Academy of Peterburgh for the year 1780. The galeopithecus volans, or flying colugo, is the Lemur volans of the Linnean system, and the flying macaco of Pennant's quadrupeds. It is a native of the Molucca and Philippine islands, where it feeds principally on fruits, and almost constantly resides on trees. It has two young ones, which are able to adhere to its breasts by the mouth and claws. Its whole length is about three feet, and of the same breadth when expanded; the tail is slender, and about a foot long. Its expansive skin, which enables it to fly, is continued on each side from the neck to the fore-feet; thence to the hind-feet, and again to the tip of the tail. It is covered with fur, like the body of the animal; the upper side of which is generally of a deep ash colour; the back, in animals that are full grown, is crossed transversely with blackish lines, having towards the edges a tinge of yellow; and the whole underside, both of the body and membrane, is of a yellowish colour. The head is long, the mouth small, and the tongue fleshy, broad, rounded, attenuated on the edges, and ciliated with papilae, and also slightly beft with papilae on its surface. The legs are clothed with a soft yellow down, and on each foot are five toes, united by a common membrane, and terminating in very sharp crooked claws. The animal is called by the Indians cugungo, colugo, and gigon. It is a gregarious animal, lives chiefly in the evening, and its body is said to be about the size of a cat. M. Geoffroy says there are two varieties; viz., one of the colour usually described; the other of a fine cinnamon or ferruginous colour, vivid on the back and paler beneath, and without any variegations. It is suggested, that these may be merely sexual differences. Dr. Shaw has availed himself of Pallas's description and figure in the first vol. of his Zoology, to which we refer.

GALINSOGEA, in Botany, after the superintendant of the Madrid garden. " Ruiz and Pav. Prod. 110."

GALLICIA, New. l. 5. r. Zucatecas.

GALLIPOLIS, a township of Ohio, in the county of Gallia, containing 448 inhabitants.

GALVANISM, col. 3. l. 25. after inch, inch—a part.

GALVANISM, Medical. See VOLTAISM, and particularly ELECTRICITY, Medical.

GALVANOMETER, an apparatus constructed by Mr. Pepsy, by an alteration in Bennett's electrometer, adapted for measuring very minute quantities of electricity, and which perhaps could not be rendered feasible by any other means. This apparatus consists of a glass cylinder, covered with a lid, which is composed of two circular plates of brass, attached to a cork that fits into the cylinder. To the lid is fixed a thin flap of silver, the end of which hangs down in the body of the cylinder, and has a pair of gold leaves attached to it; and the whole is so contrived as to be capable of being moved nearer to, or farther from, the pieces of zinc which rest up from the bottom of the cylinder. The pieces of zinc are so contrived, that the parts of them which project upwards from the bottom of the cylinder may be fixed at different distances from each other by means of a slide and screw. See a description and figure of this instrument in Bolck's "History of Galvanism," 8vo. 1819.

GAMING, col. 5. l. 39. r. 8 Geo. I.

GARDENING, l. 17. r. Loudon.

GARDINER. Add—containing 1029 perfoms.

GARDNER, l. 4. r. 815.

GARLIE, a disease of horned cattle, which consists of an external hard swelling in the dewlap, which afterwards spreads to the breast and throat. For the cure, profuse bleeding is recommended; and then an opening is to be made in the dewlap at the seat of the swelling, into which are
are introduced the leaves of bear’s-foot pounded; the opening is then fever with two or three inches, and thus will be produced a running which will cure the disease; or a common rowel will answer the purpose.

GARRARD. Add—It contains 8926 inhabitants, of whom, in 1810, 2000 were slaves.

GARSTANG, l. 3, r. 178 and 790.

GARUGA, in Botany, a very barbarous Indian name.

Eff. Ch. Calyx bell-shaped, five-cleft, bearing the stamens and the five equal petals. Stigma five-lobed. Drupa with several nuts.

GAS, col. 2, l. 25; after atmosphere, add—will be found under Atmosphere, &c.; delineated under the head of Pneumatics.

GAS, in Chemistry. Great revolutions have taken place in the chemistry of the gases since this article was written for the Cyclopaedia. Not only have their number been increased, but the laws of their combination, expansion by heat, &c. have been further investigated, and in many instances found very different from those stated under the above article. Several of these particulars have been already given under the article Atomic Theory, a few others remain to be mentioned here. The following table from Dr. Thomson includes the gases at present known.

b Oxygen and a solid base. Sulphuric acid, fulphuretted acid. Carbonic oxide, carbonic acid.

c Hydrogen and a solid base. Cyanogen, sulphurered hydrogen, olefiant gas, carbetred hydrogen, hydroguret of phosporus, hydroyduret of phosporus.

d Fluorine, chlorine, and cyanogen with a base. Fluoboric acid, chloro-carbonic acid, hydrocyanic acid, chloro-carbonic acid.

e Two solid bases. Sulphuret of carbon.

f. Triple or quadruple compounds. Hydroidic ether, chloric ether, sulphuric ether, muriatic ether, alcohol, oil of turpentine.

Combination of Gases with one another.—The important law first observed by Gay Lussac respecting the combination of gaseous bodies, and alluded to in our original article, is now, we believe, nearly universally admitted. This law is, that gaseous bodies always unite with reference to their volumes; that is to say, that either equal volumes of different gases combine together for one volume of the one, with two, three, or more of the other, and not with any intermediate proportion; and further, that when a gaseous refract is obtained by such union, the volume of this is either equal to the united volumes of the two gases, or to half, one-fourth, or some other submultiple of the original volumes.

The combinations of gases with one another have been arranged by Dr. Thomson under the following heads.

1. Gases that unite by mere mixture, such as: Oxygen with nitrous gas, forming nitrous or nitric acid. Ammonia with vapour, forming liquid ammonia— with muriatic acid, forming muriate of ammonia— with fluoboric acid, forming fluoborate of ammonia— with fluobisic acid, forming fluobislicate of ammonia— with carbonic acid, forming carbonate of ammonia— with sulphurous acid, forming sulphite of ammonia— with sulphuretted hydrogen, forming hydro sulphuret of ammonia.

2. Gases that may be mixed without any striking combination, though they are capable of uniting in certain circumstances, such as: Oxygen with hydrogen, forming water— with carboxylic oxyd, forming carboxylic acid— with azote, forming nitric acid— with chlorine, forming chloric acid— with sulphurous acid, forming sulphurous acid— with nitrous oxyd, forming nitric acid.

Hydrogen with chlorine, forming muriatic acid— with iodine, forming hydriodic acid— with cyanogen, forming hydrocyanic acid. Chlorine with carboxylic oxyd, forming chloro-carbonic acid.

3. Gases which mutually decompose each other when mixed together, such as: Oxygen with phosphuretted hydrogen. Chlorine with ammon— with sulphurered hydrogen— with carbetred hydrogen— with olefiant gas— with sulphurered hydrogen— with nitrous gas. Sulphurered hydrogen with nitrous gas—with sulphurous acid.

4. Gases which mix without spontaneous decomposition, but which may be made to decompose each other in particular circumstances, as on the approach of an ignited body, when electric explosions are passed through them, &c. These are more numerous than the preceding, and are as follow: Oxygen with sulphurered hydrogen— with carbetred hydrogen—olefiant gas— vapour of ether— vapour of alcohol. Nitrous oxyd with hydrogen— with phosphuretted hydrogen— with sulphurered hydrogen— with carboxylic oxyd— carbetred hydrogen— olefiant gas— vapour of ether— vapour of alcohol— sulphurous acid.

Combination of Gases with Liquids. Gases may be considered with reference to their combination with water and with other fluids. With respect to water, by far the most important of all fluids, gases may be divided into two classes; those that are absorbed in a small proportion, and those that are absorbed in a great. Almost all gases belong to the first class. In the following list of this class, the gases are arranged in the order of their absorption, beginning with the least absorbable: azotic gas—hydrogen gas—arlenical hydrogen— carbetred hydrogen—carbonic oxyd— phosphuretted hydrogen—oxyd gas— nitrous gas— olefiant gas— nitrous oxyd— carboxylic acid— sulphurered hydrogen.

The following laws seem to be pretty well established respecting the absorption of gases by water.

1. When the pressure, temperature, and purity of the water, are the same, water absorbs a determinate quantity of every individual gas.

2. Water

2. Water of the same temperature always takes up the same bulk of each gas, whatever be its density.

3. The proportion of any gas absorbed by water depends greatly upon the nature of the gaseous residue.

4. The proportion of gases absorbed by water is considerably influenced by the temperature.

All the very absorbable gases belong to the class of supporters, acids, or alkalies. The following is a list of such as they have been hitherto examined, arranged in the order of their absorbability. Chlorine, cyanogen, sulphuretted hydrocarbon, fluorine, muriatic acid, fluoboric acid, ammoniacal gas.

When water is saturated with the above gases its bulk is augmented. Thus one cubic inch of water saturated with

<table>

With respect to the absorption of gases by other fluids less is known. It appears, however, that in general alcohol and oils absorb a much greater proportion of gases than water.

Our limits will not permit us to enter upon this subject so much as its importance demands, we must therefore content ourselves with presenting our readers with the following table of the proportions of different gases absorbed by water, according to the best experiments.

**Combination of Gases with Solids.**—The simple gases are only four, oxygen, chlorine, hydrogen, and azote. Oxygen combines with all the simple bodies known. Chlorine, with by far the greater number. Hydrogen, with carbon, phosphorus, and sulphur, and some of the metals. Azote, as far as is known, with carbon only.

Of the union of compound gases with solids little is known, and such combinations are very rare.

With respect to the weights of the atoms, specific gravities, composition, &c. of the different gases of bodies that have been well ascertained, they will be found in the titles appended to the article Atomic Theory, to which, therefore, we refer our readers. Other particulars, such as their chemical properties, &c. will be found under their respective heads.

**Expansion of Gases by Heat.** (See Expansion.)—To what has been there advanced we may add, that it is now considered as established, that all elastic fluids expand equally and uniformly by heat; and the following table gives us nearly the bulk of a given quantity of air at all temperatures, from 32° to 212°, by the aid of which the expansion of gases for all other temperatures may be easily ascertained.

GENESEE, l. 8. r. 1810, and 12,558 persons.

GENEVIEVE, 1. 7. add—and district. In 1810, it contained 4620 inhabitants, of whom 988 were slaves. This town is famous for its lead-mines, which occupy an extent of country, commencing about 30 miles W. of the Missisipi, and extending W. and N.W. It was the discovery of these lead-mines that gave rise to the famous Missisipi scheme, projected by Law in 1719, which ruined hundreds of families in France, as they were then duped to be a silver-mine: and though the bubble burst immediately, yet Du Prat, who wrote thirty-nine years afterwards, perfided in the error, and speaks of a silver-mine on the Marameg in his account of Louisiana. The Marameg is now called the Marawaal, on a branch of which, called the Negro-Fork, the mines of St. Genevieve are situated. These mines have been worked since about the year 1725; and they belong to a number of proprietors mostly held by grants from the Spanish governors, formerly residing about St. Louis. Bradbury's Travels, &c.

Vol. XXXIX.
This, we believe, is now admitted by all those who have had the most extensive range of observation.

"The secondary strata are local formations, and some of the upper strata were evidently formed in detached lakes or inland seas. A still more comprehensive view will prove that even all the stratified rocks above the red sand-flate and alpine lime-flate are also local formations, which had their origin in detached hollows or seas of great extent, but which were limited to certain portions of the globe. The observation of travellers in different parts of the world incontrovertibly proves that these formations are local. I am even inclined to consider the red sand-flate and alpine lime-flate as local formations, but of greater extent than any of the strata above them. If this view of the subject was admitted, geologists would be relieved from the great difficulties under which the science labours at present, and it would go far to establish a simple and periphrastic system, which will at once account both for the similarity and diversity of rock formations in various parts of the world. If the mountains were once much higher than at present, it must be admitted, that before the formation of the secondary strata the valleys and hollows were deeper in a far greater proportion, because of the height of the surrounding mountains we must add the whole depth of the secondary strata which were then wanting. By whatever process the secondary strata were formed, the existence of organic remains in them incontrovertibly proves that they were deposited in succession, and the regular manner in which they are spread over each other further proves that the greater part of them were deposited in a fluid medium. As there are incontrovertible proofs that water once covered nearly all the existing continents, it follows, that when the ocean retired, or, which is the same thing in effect, when the dry land emerged from the sea, vast inland lakes or seas would be left at the bottom, of which the secondary strata were formed. As the sea retired further, the higher grounds being left dry, these inland seas or lakes would become contracted, and a number of smaller lakes would occupy the lowest cavities and depressions, in each of which separate depositions of strata might take place. The lower strata would be the most widely spread, and the upper would constitute detached or isolated formations of greater or less extent, in which there might be a great similarity in some situations, and a great diversity in others. Now such is found to be the fact." (Bakewell’s Introduction to Geology, 2d ed. chap. x.) This view of the subject, we think, receives much support from the position of the mountain ranges in Europe, as may be seen in Mr. Arrowsmith’s excellent map, in which the physical geography is distinctly marked. These ranges form the borders of numerous basins, which must evidently have once been the boundaries of inland seas when the ocean retired from the present continents.

Though great diversity may prevail in the succession of the strata in different parts of the world, yet there are certain rock formations that we may regard as universal, without altering that they were formed at the same epoch in very distant countries; for it is only where organic remains of the same species occur in rocks that we may infer that their formation was contemporaneous. In the present state of our information, we may regard granite as the lowest and most extensive rock, forming the foundation of all other rocks or strata, where we have opportunities of tracing their succession. With granite we include gneiss, and also mica-flate, which may be regarded as granite in a schistose form, but with one or other of the ingredients nearly wanting, or occurring in a very small proportion. (See Rocks, Granite, Gneiss, and Mica-Slate.)

Clay-flate (see Slate) generally covers the granite, gneiss, or mica-flate, and may be regarded as a universal formation, or, perhaps more correctly, as a general covering of granite, gneiss, and mica-flate. The flate formation contains various anomalous beds of porphyry, compact feldspar, lime-flate, hornblende, serpentine, and felspar. (See Porphyry, Felspar, &c.) No observable regularity has yet been discovered in the succession of these latter rocks in different countries, and some of them may often be observed piling by gradation into each other. They have generally a crystalline structure in the vicinity of granite (see Rocks), and have not been observed to contain organic remains.

The beds of rock which cover flate appear, many of them, to be a coarser kind of flate, with an intermixture of quartz, or other minerals, until at last they lose the character of flate, and become sand-flate. This coarse flate, in its pafage from flate to sand-flate, forms that kind of rock which has been denominated grey wacke or waccé. Various beds of lime-flate occur in the coarser flate. Of thele, the most considerable in England is called the mountain lime-flate: it has a subferyllantine structure; it abounds in organic remains in many parts, and contains metalliferous veins, principally of lead and zinc. This lime-flate lies below all the principal coal formations in England and Wales. (See Strata.) Between this lime-flate and a dark grey compact lime-flate called lias, occur the coal strata, with the various beds of sand-flate and flate. The order of succession of these beds is not similar in different districts. The lias stratum is the most remarkable in England, both for its regularity and extent, and the organic remains which it contains. The same flate occurs in Flanders. The strata above the lias were first correctly described by Mr. Faye, whose account we have given in the article Strata. (See Strata.) The strata above the lias occur with remarkable regularity over a great part of the eastern side of England, described by Mr. Bakewell, in his Geology, as the "low districts," extending in a waving line from Dorsetshire to the county of Durham, and delineated in his map. These strata consist of a succession of beds of rock-flate, or oolite, (see Oolite,) and coarse lime-flate, with thick beds of sand and clay, over which occurs the chalk. These beds are arranged with great regularity compared with other beds that occur between the lias and the mountain lime-flate, but the order of succession and thicknesses, particularly of the oolite, is variable; for in many parts, beds of variegated oolite occur which are not found in other situations, and in some situations the oolite is entirely wanting, and the green sand, instead of covering it, rests immediately on the lias. See Mr. Bakewell’s section of the strata, Plate III. fig. 2. Geology.

A tabular arrangement of the strata of England, given by Mr. Buckland, professor of mineralogy at Oxford, has recently been published, which we shall present to our readers. At the same time we must observe, that they would be greatly mislaid were they to suppose that the whole of these rock formations had ever been observed in any one situation in England or elsewhere, or that the strata prefer the same order throughout their whole extent. There is no part of England, we believe, in which all the strata here enumerated could be found, were it possible to perforate through them. The table may be regarded as an approximation to the true order of succession whenever several of these formations occur in the same district, and the localities annexed will make it both interesting and useful. Persons who study nature in their closets are disposed to believe, that the thicknesses of the strata
fracta between the chalk near London, and the granite of Devonshire, is much greater than what it really is, taking it for granted that the dip of the fracta is always regularly to the east; but this is not the case. A fractum of any considerable extent has waves and irregularities, by which it is generally spread over a large space compared with its true thickness and fupposed angle of inclination. A fractum not more than seventy yards in thickness may extend in the line of its dip ten miles or more, and may appear to have a considerable dip when observed in certain situations; and were we to calculate its thicknesses from the extent of ground which it covers, and from the dip, we might infer that it exceeded two thousand yards or more. More accurate observations will convince us, that the numerous fractures or bedding of the fracta in the line of their dip generally spread them over a much wider space than the angle of inclination and thicknesses would lead us to believe; and the comparison which has been made of sliding a number of books under each other to represent the fupposed thicknesses of the whole fracta of England is utterly inapplicable to the case. In fections of particular districts, to represent the arrangement and dip of the fracta, it is impossible to delineate the irregularities and wavages of the fracta on a small scale. In the fection of England by Mr. Bakewell, (see Plate III. fig. 1. Geology,) the various fracta from the German ocean to Croyf-fell are represented rifing regularly from under each other, like a number of books in a flanting position, it being impracticable to represent on such a small scale all the irregularities of each fractum. In Plate III. fig. 2, the fection is on a larger scale, and the lis fractum, d, d, d, d, is represented rifing from under the green land b, b, b, near Bridport in Dorsetshire, and continued to the valley, M, at Axmouth; whereas had not the fracta been di fluorated by a great number of fractures, as represented in the fection, the lis fractum d would have terminated or cropt out eal of the letter L, which represents the situation of the town of Lyme. The aggregate thicknesses of all the beds of lis cannot be more than two hundred yards, and the regular inclination is at least one yard in twenty, which would make the lowest bed of lis crop out about four thousand yards, or two miles and a quarter west of its firt appearance near Bridport.

Plate III. fig. 6. Geology, represents the waving structure of the beds of slate, provincially called shillett in Devonshire. In some fitions, as near Moreton, beds of black lime-done are interposed, and take the twilled form of the slate. Now in palling from Exeter to Dartmoor over the fractured edges of the fracta, as represented fig. 6, the traveller may crofs portions of the fame fractum a, a, a, repeatedly at a considerable distance from each other, and were he to suppofe each of thefe portions to be a separate fractum, and to calculate accordingly, the thicknesses of the whole bed of slate, from the red ground on the eait, to Dartmoor on the weft, he would make it not lefs than ten miles; whereas in all probability it may not exceed three or four hundred yards. On a smaller scale, the fracta are often extended over a large space by fractures in many of the coal districts; by which a bed of coal is brought near the surface several times in the line of its dip, as represented Plate I. fig. 1. Geology, and decribed in the article Coal. See Coal, and Veins, Mineral.

It too frequently happens, that geological obervers measure nature by the flandard of their own limited experience in palling through a country, and describe certain rock formations as defitute of organic remains, because they have not found them in travelling through a district. The alpine part of Westmoreland and Cumberland near the lakes consists of grey wacke, clay-slate, compact feparl, porphyry, linite, trap, clinehtone, and granite; a thin bed of stratified lime-done is interposed, and runs through a space of fifteen miles, containing organic remains of corals, though the rocks which cover this lime-done, to a great depth, and the rocks on which it refts, contain no observable vetiges of organic life. Their relative poition in the valley of Long Sleddale in Westmoreland, is represented Plate III. fig. 5. Geology. The slate which covers the lime-done appears to dip at an angle of seventy degrees; but on more attentive examination it will be found, that what might be mistaken for regular fracta are merely the fchifte laminae of the slate arranged in the direction of the cleavage, the dip of the slate being in reality the fame as that of the lime-done on which it rests. Under the lime-done occurs a bed of horn-done, refembling compact feparl, but infufible; this is eighty yards thick, and rests on other beds of fchat, as represented Plate III. fig. 5. Geology. This fchifte and horn-done contain no organic remains, and appear to be connected with the granite, which makes its appearance in the adjacent valley at no great distance. The discovery of original remains under rock formations of great extent which are defitute of them is a circumstance of great interest to the geologist wherever it occurs, and proves the nececity of caution in deciding whether certain rocks were formed prior to the exiflence of organic beings. Bafaltic or trap rocks, whole fitution is not confrormable with the general dip or poition of the fracta, and which bear a near similarity to volcanic rocks in appearance and composition, are decribed under the articles Trap, Rowley-Ragg, Whinstone, and Veins, Mineral; and also the article Basalt, Addenda; which fee. Plate IV. fig. 2. Geology, represents the arrangement of a series of columnar and amorphous beds of basalt placed over regular fracta in an unconformable poition, and interfected by veins or dykes of basalt b, b, in which the ftructure is columnar; but the columns or bafaltic prifms in these dykes are arranged horizontally.

Plate IV. fig. 1. Geology, reprefents the fection of a regular metallic vein, which divides into two, and meets again, leaving an intervening space, filled with earthy minerals called rider. The vein is reprefented as separated from the rock by a thin lining of clay e, which generally accompanies veins. The interfecion of metallic veins in the fame plate reprefents two veins containing the fame kind of ore, and having the fame dip a, a, a, a, interfected by a vein of a different kind b, b, which has cut through and displaced the former; in these inftances, the vein bb is fuppofed to be of posterior formation to the veins a, a, a. In the fame fig. is fhewn the displacement of a vein without any interfecion of other veins. (See Veins, Metallic.) For an account of volcanic rocks, fee the articles Volcano and Volcanic Products, and alfo Systems of Geology. For an account of the organic remains in rocks, fee Petrifications, Rocks, Strata, and Fletz Rocks. For an account of the organic remains of extinct species of large quadrupeds in alluvial foil, fee Mammoth, Mastodon, Megalonix, and Megatherium, Addenda.

Calcereous grit

Siliceous sand and lime

Coarse sandy lime-flone

Oolite concretions, and shelly
fragments, periliable free-
flone

Sometimes bituminous

Calcereous-silecious free-flone,
with beds and nodules of
chert

Strata of sandy clay and marl,
alternating with beds of
coarse shelly lime-flone

No 6.

Iron-flone

Contains beds of clay

— — — of ochre

— — — of fullers’ earth

Leat coloured

Tetsworth clay

Micaceous sandy, and almost
black

Sand and sand-flone, with
grains of green earth
Alternating, and passing into
grey flone

Sometimes cemented by cal-
careous earth

Containing beds of chert

— — — specks of mora

Green sand-flone

formation

Third sand-flone of
Werner

Localities. Greatest observed

No 7.
In the preceding part of the present article we have stated, that this arrangement of the strata may be taken as an approximation to the truth with certain limitations. It must be observed also, that the trap rocks, No. 9, most frequently occur covering or between many of the lower secondary rocks, precisely similar to what would have been the case had they been formed like volcanic rocks at different and distant epochs. The occurrence of basalt in or over chalk, or any of the formations above the lias, is extremely rare. See Systems of Geology.

GEORGE, ST., l. 15, add—The hundred of St. George’s, in Delaware, contains 2880 inhabitants, of whom 314 are slaves. —Allo, a town of Maine, in the county of Lincoln, having 1168 inhabitants. GEORGE-Town, col. 2, l. 14, r. 1993; l. 29, add—Allo, a district of North Carolina, containing 15,679 inhabitants, of whom 13,867 are slaves.

GEORGE, a township of Fayette county, in Pennsylvania, having 2036 inhabitants.

GEORGIA, in America, l. 2, r. 1760.

GERMAN, l. 2, p. 2079.

GERMAN-Town, col. 2, l. 1, r. 29; added—Allo, a town of Ohio, in the county of Montgomery, having 1256 inhabitants.

GERRY, l. 5, p. 839.

GEYSERS, celebrated fountains situated on the side of a hill, about 16 miles to the N. of Skallbitt; for an account of which we refer to the article Uxahyer.

GEZANGABEEN, or Persian Manna. This substance has been lately affected by Capt. E. Frederick, of the Bombay Establishment, to be the production of insects. It is obtained, according to the same gentleman, from a small shrub somewhat resembling the broom, on which the insects refuse, by beating the bushes with a stick. When first separated, it is a white flicky substanee, not unlike hoar frost, of a very rich sweet taste. It is purified by boiling, and then mixed up with rofe-water, flour, and pittatcho-nuts into cakes, and in this form constitutes the sweet-meal, called in Peria gezangabeen, and which by the Persians is highly valued. This substanee, in its original state, is faid to liquify at a temperature of about 68°. The Persians, however, themselves consider this substanee as a spontaneous exudation from the tree on which it is found; hence the term gezangabeen, a term meaning literally juice of the gro, which is the Persian name of the tree producing it. Thomson’s Annals of Philosophy, vol. xii. See MANNA.

GHAUT. See GALT.

GHONI, a large market-town of Mingrelia, carrying on some trade, situated between the Aradcha and the Hippas.

GHURZI
GLU

GHURZI, a well-built and populous town of Min- grelia, on the left bank of the Taghuril.

GILBERT, col. 2, l. 32, r. 1759.

GILDER, or GILDER. See FLORIN.

GILEAD, in Geography, a town of Maine, in the county of Oxford, having 215 inhabitants.

GILES, a county of Virginia, containing 3475 persons, of whom 242 are slaves.

GILL, l. 4, r. 762.

GILLINGHAM, l. 4 and 5, r. 875, and 5135.

GILMANTOWN, l. 4, r. 4338.

GILSON, or GILSON, l. 2, r. 513.

GIRARDEAU, Cape, a district of Louisiana, containing 3888 inhabitants, of whom 89 are slaves.

GIRVAN, l. penult. and ult.—In 1811, the number of houses was 533, and of inhabitants 3097, of whom 358, &c.

GISBOROUGH, or GISBOROUGH, l. 5, r. 1811—435; l. 12, r. 2094.

GLAMORGANSHIRE, last parag. — Glamorganshire is divided into ten hundreds, exclusive of the two towns of Cardiff and Swansea, and 118 parishes, which, in 1811, contained 85,667 inhabitants; 41,365 being males, and 43,472 females: of whom 7915 families were employed in trade and manufacture, and 8217 in agriculture.

GLANCE CoAL. See MINERALOGY, Addenda.

GLASGOW, col. 2, l. 11 from the bottom, add—By the parliamentary returns of 1811, the city and burgh of Glasgow contained 17,543 houses, and 100,749 inhabitants; 45,273 being males, and 55,474 females: of whom 17,669 families were employed in trade and manufactures, and 544 in agriculture.

GLASS, Laws relating to, l. 14, add—By 49 Geo. III. c. 63, the former duties upon crown glasses and broad glasses were repealed, and new duties were imposed. This act also contains directions and regulations with regard to the construction and use of the annealing arch or oven.

GLASTONBURY, col. 2, l. 42, r. 1811—448; l. 43, r. 2337—121.

GLASTONBURY, in America, l. 2, r. 76; l. 5, r. 2766.

GLOUCESTER, col. 6, l. 6, r. 1811; l. 7, r. 1509—8280; dele the next paragraph, and infer—3726 being males, and 4554 females: of whom 1312 families were employed in trade and manufactures, and 12 families in agriculture.

GLOUCESTER, in America, l. 3, r. 5945; l. 21, r. 2319. Col. 2, l. 2, for Woodbury infer—Weymouth; l. 9, r. 19774; l. 10, r. 74; l. 17, after Philadelphia, add—having 555 inhabitants.—Also, a town of the same county, having 1726 inhabitants—l. 25, r. 10,427 inhabitants, of whom 5798 were slaves in 1810.

GLOUCESTERSHIRE, col. 2, l. 26, infer after amounted to—52,042, of inhabitants 285,514, of whom 133,192 were males, and 152,322 females; 29,088 families being employed in trade and manufactures, and 20,782 in agriculture.

GLOVER, l. 3, r. 378.

GLUCINA, in Chemistry, the name of an earth. (See GLYCINE.) Dr. Thomson, from the experiments of Berzelius and others, estimates the weight of the atom of glucina at 22.5.

GLUCINUM, the metallic basis of glucina. When glucina was heated by sir H. Davy with potash, that metal was converted into potash, and grey metallic particles were observed mixed with the potash, when put into water gradually evolved hydrogen gas, and were converted into glucina. This is all we know at present respecting this metal.

GLUTEN, supposed to be the active principle of yeast. See YEAST.

GLUTTON, r. Ursus Gulo.

GLYN, l. 4, r. 3417; of whom, in 1810, 28,45 were slaves.

GLYPHIS, in Botany, from γλυψειν, to embos, expressing the appearance of the warty crust. — Achar. in Tr. of Linn. Soc. v. 12. p. 12, t. 2, 3.—A genus of crustaceous Lichens, of which four species are described and figured, found on the banks of different tropical trees. See CYNODONTON.

Eff. Ch. Warts flatish, of the substance of the crust. Receptacles superficial, numerous, irregular, black, solid, each with a depreffed disk, and tumid margin.

GODALMING, l. 2, r. 672, and 3543.

GOFFSTOWN, l. 5, r. 2000.

GOLD. See GOLD, and Mineralogy, Addenda.

Gold, in Chemistry. A few particulars latterly ascertained respecting this metal deserve to be briefly noticed here.

Sulphur is rated in the Cyclopædia to exert no action on gold, and this is true in ordinary cases. But if an alkaline hydrofulphuret be dropped into a solution of gold, a black powder falls to the bottom, which is found to be a fulphuret of gold; and which, according to the experiments of Bucholz and Oberkamp, is composed of:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Bucholz.</th>
<th>Oberkampf.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold</td>
<td>100</td>
<td>100</td>
</tr>
<tr>
<td>Sulphur</td>
<td>24.39</td>
<td>24.39</td>
</tr>
</tbody>
</table>

With respect to the oxys of gold, there are still very great confusion and uncertainty. According to Berzelius, who is one of the most recent experimentalists on gold, the purple oxyd is a compound of 100 gold + 12.077 oxygen; and the protoxyd of 100 gold + 4.026 oxygen. On this supposition, the weight of an atom of gold, as estimated by Dr. Thomson, will be 248.75, and this determination agrees tolerably well with Oberkampf’s analysis of the fulphuret of gold above-mentioned. Still, however, these results are by no means satisfactory.

GOLDENSYNN, r. Goldenfyn.

GOMPHEUS, in Ichthyology, a genus of fishes of the Thoracici order, instituted by count de Cepede from the MSS. of Commeron; the characters of which are, that the jaws are lengthened into a tabular snout, and that the teeth are small, those in front being larger. There are two species, both natives of the Indian seas, viz. G. carinus; or G. entirely of a blue colour, about the size of a tench, with a blackish cast on the pectoral fins; body arched above, and in a greater degree beneath; front about one-seventh of the whole fish; upper jaw larger than the lower; the sides of the mouth smooth and blue, head and gill-coverings plain, the rill of the body covered with scales, the lateral line through its whole course marked with small streaks like Chinefe characters: and G. variegatus, or variegated with red, yellow, and blue; a beautiful fish, observed by Commerson about the coasts of Otaheite.

GOOCHLAND, l. 4, r. 10,203 inhabitants, of whom 5662 were slaves in 1810.

GOODYER, in Botany, dedicated by Mr. Brown, to the worthy memory of Mr. John Goodyer, a Hampshire botanist, celebrated in various parts of Gerard’s Herbal, (see ed. 2. 1018, 322, &c.)—Br. in Alt. Hort. Kew. v. 5.
GROSHAM, l. 4, r. 2632.

GOSHEN, in America, l. 4, r. 692; l. 7, containing 86 inhabitants; l. 8, r. 1273; l. 10, r. 1641. At the close, add—Alto, a town of Cheshire county, in New Hampshire, having 563 inhabitants.—Alto, a town of Lincoln county, in Georgia. See Lincoln.—Alto, a township of Columbiana county, in Ohio, having 277 inhabitants.—Alto, a town of Ohio, in Tuscarawas county, having 320 inhabitants.

GOSPORT, col. 2, l. 30, r. 1439.

Gosport, in America, l. 3, r. 72.

GOTHEBOURG, col. 2, l. 5, r. amounted in 1811 to 24,856 persons, &c.

Gouldsborough. Add—the town contains 471 persons.

Grabs, the name of vessels peculiar to the Malabar coast, generally with two masts, and of 180 tons burthen, but sometimes with three masts, and about 300 tons burthen. They are so constructed as to draw little water, being very broad in proportion to their length, becoming narrow from the middle to the end, and having a prow projecting like that of a Mediterranean galley: others are constructed with a strong deck fixed with the main-deck of the vessel, from which, however, it is separated by a bulk-head that terminates the forecastle; on the main-deck under the forecastle are mounted two pieces of cannon, of nine or twelve pounders; the cannon of the broad-side are from six to nine pounds.

Granton, l. 4, r. 1365; l. 8, r. 35; l. 9, r. 28,462; l. 12, r. 931; l. 18, r. 940.

Grain, as a weight, l. 11, dcle bread.

Grains of Paradise. See Amomum and Cardamom.

Grainger, l. 6, r. 6397 and 537.

Grampound, l. penult. r. 601 and 96.

Granby, l. 5, r. 850; l. 8, r. 2696.

Grand Isle. Add—It contains 3445 inhabitants by the census of 1810.

Grand Junction Canal, l. 16 from bottom, for began r. begun.

Grand View, a township of Ohio, in Washington county, having 463 inhabitants.

Granley, a township of Essex county, in Vermont, having 120 inhabitants.

Grantham. In 1811, the borough and parish contained 673 houses, and 5346 persons; viz. 1677 males, and 1969 females; 61 families being employed in agriculture, and 430 in trade and manufactures.

Granville, l. 2, r. 15576; l. 3, r. 7746; l. 9, r. 1504.

Granville, a township of Licking, in Ohio, having 674 inhabitants.

Graphite. See Plumbago, and Mineralogy, Addenda.

Gravesend, col. 2, l. 3, r. 3119; l. 4, r. 525.

Gray, l. 3, r. 1310.

Grayson, l. 2, r. 4941 inhabitants, of whom 270 were slaves in 1810; add—Alto, a county of Kentucky, containing 2301 inhabitants, of whom 103 were slaves in 1800.

Green, l. 6, r. 19,536 inhabitants, of whom 367 were slaves; l. 10, r. 12,544; l. 14, r. 6653; of whom 1354 were slaves; l. 16, r. 4507 and 1842; l. 19, r. 1277; l. 23, r. 1497; l. 24, for Franklin county, add—Alto, a township in Washington, r. Green, adding after state—with 1708 inhabitants; then add—Alto, a township of Ohio, in Fayette county, with 290 inhabitants.—In Gallia county, with 421.—In Hamilton county, with 916.—In Jefferson county, with 875.—In Ross county, with 1183.—In Scioto county, with 507.—In Trumbull, with 559.—In Columbiana county, with 338 inhabitants; all in the district of Ohio.

Green Briar, l. 4, r. 5914 inhabitants, of whom 404 were slaves in 1810.

Green Earth. See Mineralogy, Addenda.

Greene, l. 2, r. 9713 and 655; l. 7, containing, together with Greenbough town, 11,769 inhabitants, the county having 4992, and the town 2440, in the above number; l. 12.—By the census of 1810, it contains 5797 persons, and 5076 perpetrators.

Greene, in Pennsylvania. See Greene.

Greene, in Maine. See Greene.

Greene, a town of Adams' county, in Ohio, having 393 inhabitants.

Greenfield, l. 5, r. 1165; l. 7, r. 980; add—Alto, a township of Bedford county, in Pennsylvania, having 855 inhabitants.—Alto, a township of Ohio, in Fairfield county, having 743 inhabitants.

Greenland, in America, l. 3, r. 592.

Greenlaw, col. 2, l. 2, r. In 1811, it contained 253 houses, and 1260 inhabitants.

Greeneock, l. 3, after Glasgow, add—The parish, including East, Middle, and West Greenock, contained, in 1811, 1138 houses, and 19,612 persons.

Greensborough, in Georgia. See Greene, l. 6, r. 566.

Greensburgh. Add—It contains 132 inhabitants, including 42 slaves.

Greenstone, in Geology, granuline, Werner, a species of granular trap or basalt, composed of hornblende and felspar, and described in our article Trap. (See Trap.)

It has recently been discovered, that the mineral called augit, or pyroxene by Hauy, is a constituent part of many rocks of greenstone, which confirms still further the similarity between volcanic and bafaltic rocks. See Volcanic Products.

Greensville, l. 3, r. 6853 inhabitants, of whom 4599 were slaves in 1810.

Greensville, l. 3, r. 13133 and 2355.

Greensup, a county of Kentucky, containing 2369 persons, of whom 484 were slaves in 1810.

Greenwich, col. 4, l. 28 from bottom, r. 16,947 and 2315.

Greenwich, in America, l. 3, r. 1225; l. 6, add—containing 2858 persons; l. 9, in 1810, 2728; l. 13, add—in 1810, 858 inhabitants; l. 12, r. 3533. Add—Alto, a township in Berks county, in Pennsylvania, having 1104 inhabitants.

Greenwich, East, l. 3, r. 1530.

Greenwich, West, a township in the same county and state, containing 1619 inhabitants.

Greenwood, l. 1, r. Northumberland; l. 2, r. 1028; add—Alto, a township in Cumberland county, having 1102 inhabitants.

Gregory, David, l. alt. It appears by the inscription on his monument in St. Mary's church, Oxford, that he died Oct. 10, A.D. 1708; and not, as the writer of his life in the Bosc, Brit. Jams, in 1710, whence this date is cited. He died at an inn at Maidenhead, in his way to London from Bath, and was buried in this town.

Greenatte. See Mineralogy, Addenda.
GUARD

Vol. XVII.

GREY Antimony Ore. See Mineralogy, Akad.t.

GRIESBACH, John Jacob, in Biography, an eminently learned divine of Germany, was born in 1745, in Heß-Darmskadt; and at the Gymnasmum at Frankfort, and the university of Tubingen, acquired that acquaintance with the learned languages, for which he was so distinguished, and which he applied to the most valuable biblical purposes. He fought further means and opportunities for improvement at Hall and Leipzig. In order to acquaint himself with the variety of religious sects, and for the purpose of consulting public libraries, he commenced in 1769 an extensive tour, visiting Holland, England, and Paris. In 1770 he returned to Frankfort, with a view of arranging the archives which he had collected. In 1773 he was appointed professor extraordinary of divinity at Halle; and in 1774-1775 appeared his first great work, which was a critical edition of the historical books of the New Testament in Greek. From Halle he removed to Jena in 1775, and became third professor of divinity. Having previously published several critical disquisitions in reference to biblical subjects, he completed, in 1777, his edition of the whole Greek Testament in 2 vols. As his reputation increased, his appointments and labours multiplied. But the great object to which his attention was principally devoted, was the completion of his edition of the New Testament, which appeared in 1805, 4, 6, and 7, in 4 vols. A larger edition, begun in 1796 and finished in 1806, was adapted for sale in England as well as in Germany; and was liberally encouraged by the munificence of the late duke of Grafton. In 1811 professor Griesbach's health began to decline, and in 1812 he was under a necessity of giving up the province of lecturing; and a disorder in the chest terminated his life on the 24th of March 1812, in the 68th year of his age. His corporeal form was athletic, his aspect grave and somewhat austere; but he possessed a kind heart, excellent moral principles, an independent spirit, and universal philanthropy.

GRIMSBY, l. 19 from bottom, after Grimby infert—(both bargain and parish)—l. 18, r. 619 and 2747.

GROGGINESS, in Furnery, a stiffness in the foot of a horse occasioned by battering the hoof on hard ground, which is often succeeded by swelling of the leg and contraction of the sinews. A horse that bears altogether upon his heels in trotting is denominat'd "groggy;" and the defect is generally incurable.

GROTTON, l. 3, r. 549; l. 6, r. 449; l. 8, r. 1886; l. 11, r. 4451.

GROTTO, col. 2, l. 36. Add—The grotto in Savoy is a prodigious work, said to have been begun by Caesar, but principally executed by Charles II. duke of Savoy in 1750. It is a passage cut through the mountain near the delightful valley of Echelles to the length of 5000 yards, and in perpendicular height above 100 feet; it is wide enough for two carriages to pass. About half way is a complete tunnel, running in another direction, 1000 feet long, and 36 feet high, cut by order of Buonaparte for the conveyance of cattle. Six years, both night and day, were devoted to the completion of it.

GRYPILL. Under genus Gryillus, species Gryillus, add—See Locust and Acridophagi.

GUADALAJARA, col. 2, l. 3, after annually, add—The population is estimated at 75,000, but according to Humboldt 19,500 in 1803, and that of the administration 5,630,500. N. lat. 20° 50'. W. long. 105°.

GUAIAUCUM, Chemical Properties of. Guaiacum was formerly considered as a resin, though in its properties it differs considerably from resins. Guaiacum always affumes a green colour when exposed to the light in the open air. When heated, it melts and diffuses at the same time rather a fragrant odour. Its &p gr. is 1.2285. It is very sparingly soluble in water, but imparts to that fluid a greenish-brown colour, and a sweetish taste. Alcohol diffuses it with facility, and forms a deep brown coloured solution. Sulphuric ether also diffuses it, but not in such large proportions as alcohol. It is readily soluble in alkaline solutions. Most of the acids also act upon it with considerable energy; thus sulphuric acid diffuses it, and forms a deep red solution. Nitric acid diffuses it completely with effervescence, and when the solution is evaporated, it yields a very large proportion of oxalic acid, but no artificial tannin. Muratic acid acts but slightly on guaiacum. When guaiacum is submitted to destructive distillation, it yields a little acridulous water, a considerable proportion of brown empyreumatic oil, some gaseous products, and a quantity of charcoal is left on the retort nearly equal to one-third of the original weight of the guaiacum.

GUANAJUATO, l. 2, r. Quaratáro, and between 21° 50' and 23° 30' N. lat., and 100° and 105° W. long., extending from N. to S. 75 miles, from E. to W. 85 miles. Humboldt estimates the population of the administration in 217,500, and of the capital, in N. lat. 21°. W. long. 105°, at 41,000.

GUANARA, at the end, r. Depons &c.

GUAXACÁ, l. 5, after distance, add—between 16° and 18° N. lat., and 112° and 117° W. long.; from E. to W. 230 miles, from N. to S. 175 miles.—l. 32, after persons—that of the province 354,800. At the close—W. long. 96° 25'.

GUERNSEY, a county of Ohio, containing 9 townships, and 3050 inhabitants.

GUGAH, a town of Scind, in the Persian empire, built at the foot of a hill, at the bottom of which runs a small creek in N. lat. 24° 45'. E. long. 68° 7', and containing 900 inhabitants.

GUILDER, or GILDER. See Florin.

GUILDFORD, lat lines, r. 495 and 2974.

GUILDFORD, l. 3, r. 544.

GUILDFORD, l. 2, r. 1961; l. 4, r. 1872.

GUM, Chemical Properties of. The best test for gum in solution, according to the experiments of Dr. Thomson, is infus'd with water. When added to a very dilute solution of gum, it produces a white flaky precipitate. Gum arabic is composed, according to

<table>
<thead>
<tr>
<th>Component</th>
<th>Weight in Grains</th>

</tr>
</tbody>
</table>

The varieties of gum are very numerous, and probably differ considerably in their chemical properties, though few of them have been examined. (See CERAMIX.) It has been remarked by Mr. Barrow, and probably also by others, that all trees which yield gum have an astringent bark.

GUNPOWDER, col. 2, l. 31 from the bottom, after 1326, add—or, as others say, 1534. (Watson's Chem. Eff. vol. ii.)

GUN-SHOT WOUNDS. At the end, add—See Wounds.

GUREL, r. a small country of Asia.

GURMSYL, or GURNESSER, meaning a warm climate, a district of Mekran, which is a narrow tract, about five

days'
GYM

days' journey N.W. of Noofley, probably the bed of a river, half a mile wide, between two high banks, fertile in grain, and being watered by the Heermund river, needs little cultivation. The inhabitants are notorious robbers, composed of the outcasts of the surrounding country.

GYMNADENIA, in Botany, Br. in Ait. Hort. Kew. v. 5. 191, (Orchis conopiata of Linnaeus, &c.), is separated from Orchis, (see that article,) merely because the glands supporting the pollen, are, as the name expresses, naked, or not enclosed in any hood; a character which appears to us not essential.

GYMNETRUS, in Ichthyology, a genus of the Thoraci order of fishes; the characters of which are, body very long, compressed; teeth numerous, subulate; gill-membrane four or five rayed; and deltate of anal-fin. The species are, G. Aflatani, or flagy G. speckled longitudinally with brown points. A native of the northern hemisphere, and probably first described by Alcarius, in his "Icones rerum naturalium," and length ten feet, diameter about six inches; head short, mouth small, and eyes rather large. This fish is said to be generally seen neither preceding or accompanying the schoal of herrings in the northern seas, and therefore is popularly known by the appellation of "king of the herrings." Of this there is a variety, as Dr. Shaw suggests, called the Russian Gymnetrus.

G. argentio-ceruloeus, or a blue-hilferly G. with oblique, linear, brown bands, and rounded spots, red fins, and four central processes. A native of the Indian seas, and occasionally seen in tole of Europe.

G. cepedian is a doubtful species, of a gold colour, shaded with brown. See Shaw's Zoology, vol. iv. pt. ii.

GYMNISAS. Add.—The name of Gymnias, according to Rennell's "Illustrations of the History of the Expedition of Cyrus, &c." was a town and village, named by others Camoufl, and by others Counda and Kumaia, which stands on the northern bank of the river Areth, about 31 miles below its source, and on the eastern border of Peria, in the country of the Phashani.

H.

HACKENSACK, in Geography, a town of Bergen county, in New Jersey, having 1918 inhabitants.

HACKNEY, l. 3 from the bottom, r. given by Mr. Decayer. By the returns of 1811, the parish of St. John, Hackney, contains 2699 houses, and 16,771 inhabitants: but this, like the other villages in the neighbourhood of London, is daily increasing.

31,031; l. 13, r. containing together with its town 15,330 inhabitants, of whom the flaves in the county are 6278, and in the town 78; l. 19, r. 10439; l. 23, r. 1183; l. 26, r. 311.
HANIFAH, Abot, in Biography, a celebrated Mahometan doctor of the 8th century, who was the founder of the sect denominated Hanities, and who was imprisoned at Baghdad by the caliph Almanfer, because he would not subscribe to the doctrine of absolute predetermination. He was born at Cufa in the year 700, and died in prison in the 70th year of his age. After his death his doctrine acquired reputation; and in the year 1092 a mausoleum was erected to his memory, and also a college for the votaries of his sect. This brief account of him may not be unanonymously clofed with the following anecdote:—Having received from an adversary a rude blow on his face, he faid to the perfon who thus affaulted him, "I could return you outrage for outrage, but I will not; I could accuse you to the caliph, but I will not; I could pray to God to avenge the affront, but I will not: if the day of judgment were now come, I would pray to God that I might enter heaven with you." D'Herbelot, Bibl. Orient.
HANOVER, col. 3, l. 6, after Pennsylvania, add—
with 63 inhabitants; l. 9, add—the former having 1387, and the latter 2461 persons; l. 14, r. 1711; l. 16, add—
containing 2135 inhabitants; l. 22, add—containing 2843 inhabitants.
Hanover, a town of Burlington county, New Jersey, having 2536 persons;—l. 25, r. containing 15082 persons, of whom 8454 are flaves.
Hanover, a township of Ohio, in Columbian county, having 735 inhabitants.—Alfo, a township of Ohio, in Licking county, having 651 inhabitants.
Hanover, New. Add—Alfo, a county of New Orleans, having 11,465 persons, of whom 6442 are flaves.
Hanover, Upper, a township in Montgomery county, in Pennsylvania, with 725 inhabitants.—Alfo, a township in Northampton county, in the fame flate, having 939 persons.
—Alfo, a township in Beaver county, in the fame flate, having 1005 persons.
Haran. Add—This is a town of the pachalic of Orfa, inhabited by wandering Arabs, who were led hither by a plentiful supply of water, and situated in N. lat. 36° 52'. E. long. 36° 5', on a flat sandy plain. See Haran.

wooden manufacture has lately been established here.
HAYLING, l. 7, r. 1811—110—620.
HAYNES, a township of Centre county, in Pennsylvania,
having 1791 inhabitants.
HAY'TI, a name given by the natives to the island of
St. Domingo (which fee). The dimenions are differently
stated by different writers. Some fay, that it extends 140
or 150 miles in breadth from N. to S., and about 400 miles
in length from E. to W. Mr. R. Edwards affigns 390 for the
length: Rainsford fays, that it is more than 450. The
abbé Raynal represents it as 200 leagues in length, and 60,
in some places 80, in breadth. When the French had this
island, a proclamation, announcing its independence, was
published, signed by Deflalines, Christophe, and Cherveux,
dated Nov. 29, 1803. The liberated blacks now determined
on discarding the appellation which the island had received
from Europeans, and reviving the name of Hayti, by which
it was designated by the aboriginal inhabitants when first
visited by Columbus. On the 11th day of the year 1804, the
general and chiefs of the army, in the name of the people
of Hayti, signed a formal declaration of independence, and
took a solemn oath to renounce France for ever, pledging
themselves to each other, to their posterity, and to the uni-
verse, to die rather than submit again to her dominion.
At the same time, they appointed Deflalines governor for life,
with power to enact laws, to make peace and war, and to
nominate his successor. One of the first acts of his govern-
ment was to arrange the return of negroes and mulattoes
from the United States of America. He also treated with
the British agent for Jamaica, offering to open his ports to
slave ships, and to allow the people of Jamaica the exclu-
sive privilege of selling negroes in Hayti: intending thes
not for slavery, but for military service. Some of the
French inhabitants had remained upon the general evacu-
ation of the island, confiding in the favour and mercy of
Deflalines. But their confidence was misplaced; for in a
few weeks he mediated their destruction, and issued man-
dates, no less pernicious than cruel, for a general massacre.
He then proceeded to the subjugation of the few Spaniards
who inhabited the eastern part of the island, and with laying
fierce to the city of Domingo, which was poffeffed by a
small detachment of French troops. In this siege he was
unsuccessful; and after his return from it, he assumed the
title of emperor. The empire was divided into fix military
divisions, with a general over each, independent of one an-
other. The generals of division and brigade composed the
Council of state, and they had a minister of finance, another
of war, and a secretary of state. All persons decided their
differences by arbitration, military crimes were subjected to
special jurisdiction: no predominant religion was admitted,
nor was the state to provide for the maintenance of any reli-
gious institution. Marriage was declared to be an act purely
civil, and divorce in some cafes was allowed. In a census,
taken in 1805, of the inhabitants of the part of the island
under the power of Deflalines, the returns were about
380,000, to which some incidental omifions 20,000 were
added, making the whole number 400,000. The regular
army confisted of 15,000 men, of whom 1300 were cavalry.
Considerable attention was paid to the subject of education.
The young Haytians were generally taught to read and write.
Deflalines, whilst he poffeffed several good qualities, was fer-
ocious and cruel; and at length his atrocious acts of tyranny
caused an infraction of the army, which was followed by his
premature death by violence, on the 17th of October,
1806. Christophe, who, since the expulsion of the French,
had been fecond in command, immediately assumed the
supreme power. He had been a slave in St. Domingo at
the revolution in 1791, and an early friend and faithful
adherent of Toufaint, whom he reffembled in charact.
Discarding the pompous title of emperor, he modestly de-
gnified himself “chief of the government of Hayti.” He
made several enactments, and issued proclamations favourable
to commerce. Petion, however, soon appeared as a candi-
date for the sovereign power; the struggle between him and
Christophe was fierce, and in a battle fought January 18,
1807, between the two armies, Petion was defeated, and
fared himself by flight. In a council convened at Cape
François, a new constitution was published Feb. 17, 1807,
in which slavery was for ever abolished in Hayti; and the
government was reveled in a chief magistrate for life, who
appointed his successor. The council of state confisted of
nine members, two-thirds of whom were generals; so that the
government approached nearly to an oligarchy. The strug-
gle for sovereignty still continued, and was carried on for
several years; many battles being fought, in some of which
Christophe, and in others Petion was victorious. In the
spring of the year 1811, Christophe changed the title of
president for that of king, and the royal dignity was esta-
blifhed by a constitutional act in his person and family.
In July 1816, after Louis XVIII. was restored to the throne,
commissioners were sent to St. Domingo, entrusted with the
administration of all the affairs of the island, both civil and
military. These commissioners addressed letters to Chris-
tophe, which gave offence. Although the two governments
which rule the northern and southern districts have not esta-
blifhed any relations of mutual amity, they have remained
HEAT.

in a state of perfect tranquillity, and have devoted their attention to the cultivation of their respective territories, and to the civilization and improvement of their people. Schools upon a Lancastrian plan have been established. From the zeal manifested by both chiefs in this noble cause of public instruction, and the progress already made in carrying their wife and benevolent designs into effect, there is great reason to hope, that in a few years the island of Hayti will exhibit a population as generally educated as that of any country on the face of the globe. See History of the Island of St. Domingo, &c. London, 1840.

HEARING, col. 2, l. ult. after ear—(see EAR.)

HEAT, col. 2, l. 2, after CALORIMETER—in the sequel of this article.

HEAT. Many important additions have been made to our knowledge respecting heat and its effects, which our limits will only permit us to mention very briefly here. In doing this, we shall follow the same arrangement as that adopted in the original article, and confine ourselves chiefly to the results.

Capacity for Heat, or Specific Heat.—In the year 1813, a most elaborate set of experiments was published by Delaroche and Berard, on the specific heat of the gaseous bodies. The results of former experimentalists respecting this part of the subject were not, as we remarked, very satisfactory; but from the care with which the present experiments were made, philosophers in general appear inclined to admit their accuracy.

From the recent experiments of Dulong and Petit it appears, that the capacity of solid bodies follows the same law as that of liquids, that is to say, it increases with the temperatures measured by an air-thermometer. They would be even increasing according to the experimentalists, if we were to employ a mercurial thermometer. See the section Expansion of Heat below. Thus, The mean capacity of iron, from 0° to 100° = 0.1098. 0 to 200 = 0.1150. 0 to 300 = 0.1218. 0 to 370 = 0.1255.

In the following table, for the other metals they have only given the measures taken at 100°, and at 200°.

Combustion, Heat produced by.—A great number of laborious experiments were made by the late count Rumford on this subject, the general results of which we shall briefly mention, as they differ in some degree from those of his predecessors. Thus, according to him, 1 lb. of

<table>
<thead>
<tr>
<th>lbs. Ice.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Olive-oil when burnt melted</td>

</tr>
<tr>
<td>Sulphuric ether</td>
</tr>
<tr>
<td>Naphtha</td>
</tr>
</tbody>
</table>

This philosopher likewise extended his experiments to the combustion of woods, with the view of ascertaining which gave out most heat, and under what circumstances. The general results were, that the wood of the lime-tree gives out most heat, and that of the oak the least, during combustion. The extreme limits of his table, which we regret we cannot give, were, that 1 lb. of lime-wood, highly dried over a chaffing-dish, melted 34,210 lbs. of ice, while 1 lb. of oak, similarly dried, melted only 39,728 lbs.

Expansion of Bodies by Heat.—The law, as recently established by Dulong and Petit, respecting the expansion of the gases has been given under Gas. We confine our attention here, therefore, to the expansion of liquids and solids. The experiments of Dulong and Petit shew, that the expansion of bodies by heat is not uniform, and that the laws of expansion, as laid down by Mr. Dalton, are not to be depended upon. Thus in the following table of the absolute dilatation of mercury, it will be found that the expansion above the boiling point of water increases as the temperature increases according to the air-thermometer, which from the uniform expansibility of the gases is the only one that indicates equal measures of temperature.

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>300</td>
<td>352.9</td>
<td></td>
</tr>
</tbody>
</table>

In the above table, on the dilatation of glass, the third column shews that its expansion is not uniform, but increases, except between 0° and 100°, where it is the same as indicated by Lavoisier and Laplace. The last column contains the degrees which would be indicated by a thermometer formed of...
HEM

of a glass plate, whose increase in length would serve as a measure of temperatures.

<td>100°</td>
<td>328.8</td>
<td>100°</td>
<td>311.6</td>
<td></td>
</tr>
</tbody>
</table>

When we compare these results with those obtained from glass, it is seen that the expansibility of solids referred to an air-thermometer is increasing, and that it is unequally so in each of them.

Our readers will observe, that MM. Dulong and Petit used the centigrade thermometer. See further on this subject under Refrigeration.

See an Essay which gained the prize voted by the Academy of Sciences in 1818, entitled Researches on the Measure of Temperatures, and on the Laws of the Communication of Heat, by MM. Dulong and Petit.

Animal Heat.—The above determinations of the specific heats of oxygen gas and carbonic acid by Delaroch and Berard, very much diminish the probability of Dr. Crawford's theory of animal heat. But the most formidable objections to this theory result from the experiments of Mr. Brodie. This gentleman found that when artificial respiration is kept up in the lungs after decapitation, the usual proportion of carbonic acid gas is formed, and the circulation continues nearly as usual, yet that in these animals the heat diminishes more rapidly than in the dead animal in which artificial respiration is not kept up. From these experiments, Mr. Brodie concludes that the production of animal heat is owing to the action of the brain, and not to respiration. See Respiration.

HEALTH, in Geography, a town of Hampshire, in Massachusetts, containing 917 inhabitants.

HEMATIN, in Chemistry, the name given by Chevreul to the peculiar matter constituting the colouring matter of the hematoxylon campechianum, or logwood.

Hematin may be obtained by digesting, for several hours, logwood-powder in water, of the temperature 125°. The liquid is then to be filtered, evaporated to dryness, and digested for a day in alcohol of the sp. gr. .857. Filter the alcohol, concentrate it by evaporation, then add a little water, evaporate a little further, and leave it to itself. Crystals of hematin are deposited in abundance. Thus prepared, it is in the form of small brilliant crystals, of a reddish-white colour, and a slightly astringent bitter and acrid taste. It is readily soluble in boiling water, and the solution is of an orange-red colour when warm, which becomes yellow as it cools, but heat again restores the original colour. Acids render it at first yellow, then red; sulphurous acid destroys it altogether. The alkalies and alkaline earths give it a purplish-red colour, and if in excess appear to decompose it. Most of the metallic oxides unite with hematin, and give it a blue colour. Gelatine throws it down in reddish flocks. The other properties of this substance do not appear remarkable.

HEMEL-HEMSTED. At the close, infert.—The population of the parish, by the return of 1811, amounted to 3240, and the number of houses to 638.

HEMIONUS. See Equus.

HEMLOCK, in Geography, a township of Northumberland county, in Pennsylvania, having 879 persons.

HEPATIC, in Botany, fo named by the earlier botanists and physicians, from a resemblance in the leaves to those of the human liver, it is restored to a distinct genus from Anemone, (see that supplementatory article,) by professor De Candolle, in his Syll. v. 1. 215, merely because the Stellaria is placed very near to the flower, (some have thought it an actual plant), and its leaves undivided. We hesitate to follow our learned friend in this measure, the certain species of Hepatica being scarcely more than one or two, so that nothing is gained as to convenience, nor is the character very decided. These species are,

2. H. angulosa. Angular, or Serrate, Hepatica. Lamiack Dict. v. 1. 169.—Leaves palmate, with five serrated lobes. Cultivated formerly at Paris, but now lost. It is much to be wished that we could learn more concerning this plant, and a slightly different.

3. H. integripetala, with ovate entire leaves and very hairy stalks, found by baron Humboldt in South America, is not clearly an Hepatica.

HEPATITE. See Mineralogy, Addenda.

HERAT. Add.—The ancient Aria or Artaxacona, capital of Aria; l. 4, after name, infert.—Or Herirood; l. 5, after which, add—gives fertility to the plain, 30 miles long and 15 broad, upon which Herat is situated, and which,
which, though surrounded with lofty mountains, is highly cultivated, and covered with villages and gardens. The Her- 
rat, or Herirood, afterwards runs, &c.; l. 5, for l. r. Herat 
embraces an area of four square miles, and, &c.; l. 6, add— 
This castle is of a square form, elevated on a mound, flanked 
towers at the angles, and bastion of burnt brick. The 
character is grand in each face, and two in that which fronts 
the north, and from each gate a spacious and well-supplied 
bazaar leads up towards the centre of the town. It is 
well supplied with water, every house almost having a fountain 
independent of those that are public on either side of the 
bazaars:—l. 23, add— The residence of the prince is a mean 
building, having a gallow in the centre of the square, which 
is situated in its front; and the chief mosque, once a noble 
edifice, enclosing an area of 800 square yards, is falling into 
decay. Herat is computed to contain 100,000 inhabitants, 
10,000 being Patans, and the rest Afghans, a few Jews, and 
600 Hindus, the last-mentioned of whom are highly 
respected, and they only possess capital or credit; hence they 
derive a very considerable influence. The trade of this 
city, as we have already said, is extensive, and accordingly 
it is the emporium of the commerce carried on between 
Cahul, Cashmere, Bucharah, Hindoolan, and Persia. From 
the former, they receive flax, indigo, sugar, chintz, mufin, 
leather, and Tartary flax, which they export to Mebed, 
Yerd, Kerman, Isla, and Bouliau, receiving in return 
chiefly dollars, tea, china-ware, broad-cloth, coffee, pepper, 
and sugar-candy; dates and flax from Kerman and car- 
petts from Ghaen. The staple commodities of Herat are, 
flax, coffee, and asfaaritida, which are exported to Hindu- 
flan. The city has a great number of mulberry-trees, cultivated 
merely for the sake of the silk-worm, and the adjoining 
plains produce asfaaritida. The winters here are very 
severe, and the cold often injures the crops; but the fer- 
tility of the plain is such that it affords an immense pro- 
duce both of wheat and barley, and almost of every 
kind of fruit known in Persia. The cattle are small, but 
not plentiful, and the broad-tail sheep are abundant. 
The revenue of this city is estimated at 24 lacs of rupees. 
The prince in possession pays a tribute to his Persian ma-
jesty of 50,000 rupees a year. N. lat. 34° 12'. E. long. 
65° 14'.

HEREFORD. At the close, add—By the return of 
1811, Hereford contains 1583 houses, and 7366 inhabitants. 
HEREFORD, a township of Berks county, in Pennsylvania, 
has a population of 2000.

HEREFORDSHIRE, col. 2, l. 7 from bottom, r. 
1811—18,772—04,772.

HERKIMER, a county of New York, containing 
22,046 inhabitants, of whom 64 are slaves.

HERMINIUM, in Batony, a name by which Linneus 
its author seems, in Phil. Bot. 1717, to allude to Hermes, or 
Mercury, but without any explanation.—Linn. Gen. cd. 1. 
ed. 2. 130.—Clafs and order, Gynandra Monandria. Nat. 
Orch. Orhidae.

Eff. Ch. Calyx spreading. Petals three-lobed, like the 
lip, which has no spur. Anther fixed, nearly terminal.

1. H. monorchis. Milk Herminium. (Ophrys monor- 
chis; Linn. Sp. Pl. 1342. Engil. Bot. t. 71.)—" Radical 
leaves two, lanceolate."— Native of chalky pastures in 
Europe. A small plant, with yellowish whitely-feeted 
flowers. No genus is better defined, but we know nothing of 
any other species indicated by Mr. Brown's specific 
character.

HERO, North, l. 2, of Grand Ile country; l. 3 and 4, 
r. 1810—552.

HERO, South, l. 3, r. 826; l. ult. r. 623.

HERriot. See HARIOT.

HERTFORD, col. 2, l. 13 from the bottom, r. 1811— 
3900; l. 12, 2038—1862; l. 11, r. 592.

HERUS, in Mythology. See DRUIDS.

HEXHAM, l. 4. In the year 1811, Hexham parish, 
divided into four wards, or townships, comprehended 478 
houses, and 3518 persons; and Hexhamshire, including four 
quarters or townships, had 251 houses, and 1328 persons.

HEYNE, CHRISTIAN GOTTLOB, in Biography, was 
born at Chemnitz, in September 1729, and rose from humble 
life, after struggling with many difficulties, in 
account of the penury of his condition, to an eminent rank, 
as a critical scholar and philologist. Although his parents 
were hardly able to derive a decent subsistence from their 
labour, he was sent to school, and made such proficiency in 
learning, that in his tenth year he was able by teaching 
others to defray the expenses of his own education, and by 
the assistance of a neighbouring clergyman, he entered 
himself at a grammar-school; and having acquired a competent 
knowledge of the Latin and Greek languages, he was sent 
to the university of Leipzic. Private teaching, however, 
was his resource for further supplies, and thus furnished 
he devoted himself to the profession of the law; and industrious 
in his study of the Roman law and history, he was qualified 
for reading lectures, which were much approved, on the 
Roman antiquities. Under the patronage and recommendation 
of count Bruhl, the Saxoon minifter, which he obtained 
by a Latin elegy, he was invited to Dresden, where he 
repaired in 1522 with flattering expectations, which were 
evertheless disappointed; so that he was reduced to a state 
of indigence and differe, without the means of providing 
either food or lodging. At length necessity compelled him 
to become a writer, and by one of his performances as a 
translater of a Greek romance, he acquired that taste for 
criticism which raised him to that eminence in this depart-
ment of literature which he afterwards occupied. His next 
work was an edition of Tibullus, which was followed in 
1756 with his first edition of Epictetus. But his prospects, 
which appeared promising in consequence of his access to 
the Bruhelian library, were again precluded by the incursion 
of the Prussians into Saxony, which occasioned the sudden 
departure of count Bruhl from Dresden, and the dispersion 
of his library. After some changes of situation, he repaired 
to Dresden in the year 1763; and in the following year 
married a lady, named Theresia Weisa, to whom he had for 
some time been affectionately attached. In 1763 he was 
invited to Gottingen to supply the vacant professorship of 
John Matthias Gewler. The subjects of his first academic 
lectures were, Horace, the Georgics of Virgil, and some 
parts of the Tragic writers. In 1766 he explained the 
Iliad, and afterwards the Greek antiquities. His leisure 
hours, after his first settlement at Gottingen, he employed 
as a writer and translator. Having been appointed, in 
1763, first librarian to the university, he obtained, in 1770, 
the title of unive council, and became secretary to the 
Royal Society of Sciences, and editor of the Literary 
Gazette. In 1771, he collected the papers presented to 
the society for sixteen years, which had been neglected, and 
published the first volume of the "Commentaria Novi," 
which was dedicated to the king. The first edition of his 
"Catalogue of the Library," begun in 1777, was completed in 1787, and extended to 
about 150 volumes in folio. But his opus majus, on which he
he bestowed the greatest part of his attention and time, was his edition of Homer, which he began in 1787, and which was presented to the public in 1802. A second edition of his Virgil appeared in 1788; in the revival and improvement of which he derived great applause from his literary friends, particularly Van Santen in Holland, and Jacob Bryant in England. During the autumn of this year, he made a tour to Switzerland, and formed an acquaintance with several of the most eminent literary characters in that country; and on his return he was offered the place of chief librarian at Dresden, and a professorship at Copenhagen, both which he declined. The principal object of his attention was the Royal Society of Göttingen, of which he was secretary; and which was enlarged by the admission into the number of its members of several French literati. By means of his reputation and influence, he preferred the society, in 1803, from the miferies incident to a state of war, and from any molestation on the part of the French army. After a tour to Armidale in 1806, on a visit to one of his daughters recently married, his infirmities increased, so that in 1809 he resigned his office as professor of eloquence. In 1810 he was made a knight of the Weitphalian order of the crown, and died in the month of July 1812.

HICKMAN, in Geography, a town of West Tennessee, containing 2,881 persons.

HICKUP, l. 7, add—See Lungs.

HIETANS, the name of a people of North America, who travel in a region extending from the limits of the state of Louisiana to the Rio Gila, and to the eastern declivity of the Californian coast, within a short distance of the shores of the Pacific ocean. In following the herds of buffalo, which change their pastures with the feasons, they resemble the wandering tribes of Tartars and Arabs, who have no settled residence. Encamped where they find water and their prey, they remain as long as they can obtain a supply. The Hietans have domesticated the horfe, and live with the most civilized people in their management of this useful animal, in mounting it and applying its force to the purposes of chase or war. They are the only people, aborigines of this continent, who seem to have acquired the ability to withstand the shock of cavalry furnished with the principles of European tactics.

HOLLY, Mount, in Geography, a town of Rutland county, in Vermont, having 902 inhabitants.

HOLCENTRUS, in Ichthyology, a genus of the Thracici order of fishes; the characters of which are, habit of the genus Perca; grill-covers scaly, serrate, and aculeated; and scales, in most species, hard and rough. The species enumerated and described by Dr. Shaw are as follow: H. 

1. With forked or lunate tail.

SAGO. Silvery-red H. with longitudinal yellow lines on each side, very beautiful, about a foot long, resembling a carp, but of a more square form, and becoming suddenly flender near the tail, eyes large and gold-coloured, scales large, and denticulated at the edges. Native of the Indian, American, and Mediterranean seas, and held in high estimation for the table.

SCHRAETTER. Brownish H. with four longitudinal black lines on each side, silvery abdomen and naked head; the perca schraetter of Gmelini's Linnaeus. Native of the Danube, and of its tributary streams, esteemed for food.

RADULA. H. with the body lined with white spots; P. radula of Gmelini's Linnaeus. Native of India.

GATERINA. Bluish H. with black spots and scattered spots; Scena gaterina of Gmelini's Linnaeus. Native of the Arabian seas, varying in size and colours.

QUINQULENEIS. Yellowish H. with brownish back, and body marked on each side by five longitudinal blue lines. Native of Japan.

BENGALIENSIS. Subfalcatus H., silvery beneath, and marked on each side of the upper part by five longitudinal blueish bands, margined with black. Native of Bengal.

TIGRINUS. White H. with the body transversely banded, and fins spotted with black. Native of the Indian seas, and esteemed for the table.

DECUSATA. White, with brown back, and body marked by
by two longitudinal and seven transverse brown bars. Native
of the American seas.

Pteronotus. Sclaterius H. with brownish back, body
marked by transverse brown bands; dorsal fin rameinfe be-
hind, and marked by a black spot. Native of unknown
regions.

Argentinus. Brownish H. with silvery sides. Native of
regions unknown.

Ponger. Black H. with extremely minute scales: found
about the coast of Cornwall.

Amercius. With fourteen soft and seventeen spiny rays
in the dorsal fin; perca acerina of Gmel. Linn. Native of
the Euxine sea, and esteemed as food.

Ceruleuscens. Bluish H. with all the fins yellow.
Native of the Indian seas.

2. With undivided or rounded tails.

Variegatus. Red H. with seven transverse black lines,
and the head and abdomen varied with blue streaks: perca
marina of Linn. Gmel. Native of the Mediterranean and
northern seas.

Cottaidea. With all the fins marked by two speckled
lines. Native of the Indian seas.

Gigas. Ochraceous H. with brown clouds, three-
spined gill-covers, and eleven dorsal spines: perca gigas of

Forskalii. Red H. with four broad transverse whitish
bands: perca fasciata of Linn. Gmel. Native of the Red
sea.

Tauvina. Linear-oblong H. with blackish ferruginous
spots: perca Tauvina of Linn. Gmel. Native of the Ara-
bian seas.

Oro. Brown H. with the body marked transversely
by elongated spots, and the dorsal, anal, and caudal fins
spotted with yellow. A native of Japan.

Auratius. Gold-yellow H. with red specks. Native of
the East Indies.

Quadrilineatus. Silvery H. with brownish back, and
body marked above by four longitudinal black lines on
each side. Native of the East Indies.

Fasciatus. Green-yellowish H. with transverse brown
bands divided beneath. Native of a region unknown.

Punctatus. Yellow H. sprinkled over with black
spots and red points. Native of the Brazilian seas.

Calcarifer. Subargentous H. with brownish back,
large scales, and spotted gill-covers. Native of Japan.

Surinamensis. Brownish H. with subluteous clouds,
red head, and anterior gill-covers spine-ciliated. Native of
Surinam.

Afer. Oblong-ovate brown H. with small scales and
short tail. Native of the coasts of Guinea, in high estima-
tion for food.

Japanicus. Red H. with small scales, and blue and
yellow irises. Native of Japan.

Mex. White H. spotted on all parts with brown.
Native of the Japanese seas.

Testudineus. Subluteous H. with slightly branching
brown bands, blue-striped gill-covers, and blackish fins.
Native of the northern seas.

Margiatus. Bluish H. with brownish back, red fins,
and dorsal fin edged on the fore-part with black. Native
place unknown.

Sonnerathii. Yellowish H. with three transverse silvery
bands, edged with brown. Native of the Indian seas.

Lanceolatus. Silvery H. transversely banded with
Vol. XXXIX.

brown, and with the dorsal, anal, and caudal fins sublan-
cocate. Native of the East Indies.

Ceruleo-Punctatus. Bluish H. with pale yellow clouds,
and deep-brown fins spotted with blue. Native country
unknown.

Biocolur. Bluish H. with irregular white spots. Shaw’s

HUNTINGTON, in Connecticut. See Huntington.

HUNTSBURG, l. 3, r. 734.

HUR, Richard, in Biography, an eminent English prelate, was the son of a reputable farmer, in the parish of Teterhall, in the county of Stafford, and born in January 1719-20. After a preparatory school-education, he was sent to Emanuel college in the university of Cambridge, where he was graduated M.A., and was elected a fellow in 1742. In 1744 he received priest's orders. As a writer, he began his career by an anonymous work, which was, "Remarks on a late Book, entitled An Enquiry into the Rejection of the Christian Miracles by the Heathens, by William Welton, B.D. &c." and which was highly commended by Dr. Warburton. As a literary critic, he first laid the foundation of his future fame in 1749, by an an-

nymous publication, entitled "Horace's Epistles to the Pilos, with an English Commentary and Notes," and also of his fortune by a compliment paid in the preface to Warburton, whom he afterwards reeled, not only in his advancement, but in his mode of thinking and of writing. By his recommendation to Bishop Sherlock, he was appointed, in 1750, one of the Whitehall preachers. In 1751, he published a "Commentary on Horace's Epistle to Augustus," reeling in learning and ingenuity his former commentary. Both these Commentaries were reprinted in 1753, with two differations on dramatic poetry and poetical imitation. This volume was dedicated to Warburton in a high style of panegyric; and it was followed, in 1755, by a piece, entitled "Delicacy of Friendship," in which the anonymous author, known to be Hurd, paid homage to his patron by an attack on Dr. Jortin, who, in his "Six Dissertations," had not treated Warburton with that respect to which, in the estima-

tion of his admirers, he was thought to be entitled. By this pamphlet he gained no reputation, and it is said, that in conformance of some remarks on his subervient disposition, he was devisor of suppressing it, though it has been since reprinted in a late edition of his works. His first churc

HURD's church preferment was a college living at Thurlston in Leicester, to which he was inducted in 1756, and here he lived for several years in retirement. Soon after Hume's "Effay on the Natural History of Religion," was published, a pamphlet of "Remarks" upon it appeared, of which Hurd was thought to be the author, and which Hume noticed in the following terms: "Dr. Hurd wrote a pamphlet against this work, with all the subervient petulance, arrogance, and feverity which distinguished the Warburtonian school." These Remarks have been thought to be the joint production of the master and disciple. Hurd's "Letter to Mr. Mamon on the Marks of Imitation," published in 1753, is represented by his biographer as "one of the most agreeable and ingenious of the writer's works on elegant criticism." Our author's "Moral and Political Dialogues," which appeared in 1759, contributed to the increase of his literary reputation; and those in particular that relate to the English constitution since the writer's attachment to Whig principles. In 1762 appeared, without his name, an amusing work, entitled "Letters on Chivalry and Romance," 12 mo.; and in 1764 was published another dialogue on "The Uses of Foreign Travel." The several dialogues now recited were published in 1765, in 3 vols. 8vo. Introduced with a preface on the manner of writing dialogue. The defence of his patron and friend had in the mean time occasioned a "Letter to the Rev. Dr. Leland of Dublin college," in which he vindicates Warburton's idea of an inspired language, flated in his "Doctrine of Grace."

Hurd's preferments in the church had not corresponded to his growing literary fame; but in 1765 he was recommended by bishop Warburton and Mr. C. York to the office of preacher at Lincoln's-Inn; and in 1767 he was collated by the bishop to the archdeaconry of Gloucester. In the fol

lowing year, he was graduated D. D. at Cambridge, and appointed to preach the lectures on prophecy, established at Lincoln's-Inn by Warburton; these were comprised in twelve discourses, which formed a volume of highly valuable theological literature, published in 1772, 8vo. with his explanation of the double sense of prophecy, called by him a "divine artifice." With that excess of ingenuity which in some cases seems to derogate from the simplicity of the gospel, some have been dissatisfied. Having established his reputa-

tion both as an elegant writer and an ingenious theologian, Dr. Hurd was promoted without solicitation to the fee of Lichfield and Coventry in 1775; and in his first charge to

the
the clergy of his diocese, the subject to which he directed their attention was the excellence of the liturgy, inculcating at the same time the duty of submitting all alterations to the wisdom of the church, and thus guarding against that disposition to reform which was manifesting itself among those who formed a considerable party pertaining to the establishment.

In the following year, the learned prelate had the honour of being preceptor to the Prince of Wales and his brother the duke of York. In the same year, he published a volume of sermons preached at Lincoln's-Inn; to which, in 1780, he added two additional volumes, containing a variety of elegant discourses, orthodox with regard to their theology, and conformable to the articles of the church, which he professed highly to venerate. His translation to the see of Worcester took place in 1781, when he was also nominated clerk of the closet; and though he was offered the primacy in 1783, he declined the acceptance of this high dignity. In his retired station at the episcopal seat of Hartlebury, he palled the remainder of his life in attending to the concerns of his diocese, pursuing his literary avocations, and collecting a noble library, which he bequeathed as an heir-loom to the see of Worcester. Of his minor publications, both before and after this period, we shall take no notice; but content ourselves with mentioning his edition of the works of his esteemed friend the bishop of Gloucester, prefixed to the public in 7 vols. 4to, in 1788; adding afterwards, viz. in 1794, an account of the life, writings, and character of the author. With this performance he terminated his literary labours; and after a gentle and easy decline, he expired, in his sleep, in May 1808, four months after the completion of his 88th year. The literary character of this prelate may be duly appreciated by a perusal of his writings; but with regard to his private character and conduct, we shall adopt the opinion and language of a candid biographer, who says of him, "if a fair abatement be made on account of some literary arrogance and acrimony, probably derived from the fame-sources," (referring to familiarity with the writings of Warburton,) "they will merit unqualified praise. His strict regard to decorum, his liberal courtesy, his warmth of friendship, his moderation and disinterestedness, rendered him equally an object of regard and esteem." Gen. Biog.

HURON, in Geography, a town of Cayahuga county, in Ohio, on Huron's River.

2. H. alpina. Alpine Hutchinsia. Ait. n. 2. see Lepidium alpinum.—Leaves pinnatifid. Petals twice as long as the calyx. Style hyat.

HYALITIC. See TOXICODENDRON.

HYALITE. See MINERALOGY, Addenda.

HYDE, t. 4, r. 629—1882.

HYDEPARK, t. 2, r. 261.

HYDROGEN. For the recent determinations respecting the specific gravity, &c. of this gas, see Atomic Theory.

HYDROGEN, Arsenical. See Arsenic.

HYDROGEN. Boroured, the name of a gaseous compound of hydrogen and boron. The existence of such a gas, however, seems somewhat uncertain. Dr. Thomson thinks Gmelin succeeded in forming it by mixing together four parts of iron-filings, and one part of boracic acid, and exposing the mixture to a strong heat for half an hour. When this fused mass was dissolved in muriatic acid, an effervescence took place, and a gas, suppose to be borourated hydrogen, was extracted; but it was not satisfactorily examined. Sir H. Davy endeavoured in vain to unite boron with hydrogen by heating them together.

HYDROGURET of Carbon, Phosphorus, and Sulphur, the names by which some have chosen to distinguish the xeric of hydrogen with these respective subfiances, and which were formerly called carburetted, phosbur'ated, and fulphuretted hydrogen.

HYDROPHILUS. At the clofe, add.—The genus like, that of dytkus, has been greatly inceafed by the perfevering researches of modern entomologists. Mr. Marsham enumerates twenty-eight British species.

HYDROPHOSPHORIC Acid, Hydrophosphoric Acid, Hydrothionic Acid, in Chemistry, names which have been given, the first to phosbur'ated hydrogen, the two last to fulphuretted hydrogen.

HYGROMETRY, col. 13, l. 22, add.—Mr. Leslie's improved hygrometer is compofed of a tube of ivory, containing quickfiver, with a glafs tube adapted to it, to which a scale of equal parts is attached. When the ivory yields moisture to the air, which it does according to the dryness of the atmosphere, it contracts, and preffes the quickfiver higher in the tube;—when it imbibes moisture from damp air, it swells, and allows the quickfiver to reflide. Mr. Leslie finds, however, that thefe variations do not correpond with the real moifures of atmospheric dryness or humidity: near the point of extreme dampness, they are much fegmented; while they diminifh rapidly towards the other extreme. The addition of another scale, therefore, correponding to this inequality, is neceffary; and even with this, it cannot be regarded as either an accurate or delicate instrument.

There are other circumstances, fays the profeflor, connected with evaporation, on which an hygrometer may be conftructed; particularly the dilatation imparted to the air by the vapour, and the defepufion of temperature produced on the humid surface.

On the firft of these he has invented an hygrometer conftituting of a small tube, the mouth flat, having a hole ground through the bottom, in which is cemented a fender recurved tube, like a fephy, containing a portion of coloured oil. A few drops of water being put on a glafs plate, and the tube being flipt on this, the included air difdibles moisture propofitional to its dryness; and the increased elasticity, thus communicated to the air, caufes the column of oil in the tube to afcend. This instrument, however, requires address in its management, which renders it difficult to obtain with it refults perfectly precise.

On the other principle, Mr. Leslie has conftructed what he
HYGROMETRY

he regards as the most accurate hygrometer. It is a happy application of the differential thermometer. One of the balls is coated with fine cambric paper, and the paper is moistened with pure water. Evaporation takes place; and, from the cold which accompanies this, the liquid falls in the opposite item. The extent of its descent is measured by the scale attached. This indicates the degree of cold; this, again, the extent of evaporation; and this, lastly, indicates the relative dryness of the air, the evaporation being proportionally greater as the air is more free from moisture. The full effect is very soon obtained—generally in about two minutes; and it continues permanent under the same circumstances, as long as moisture is supplied to the covered ball.

This ingenious author observes, in consequence of experiments adapted to the purpose, that the condition of the atmosphere, with regard to dryness, is extremely variable.

In our climate, the hygrometer will, during winter, mark from 5 to 25 degrees; but, in the summer months, it will generally range between 15 and 55 degrees, and may even rife, on some particular days, as high as 60 or 90 degrees.

In thick fogs, the instrument stands almost at the beginning of the scale: it commonly falls as the rain, and remains low, during wet weather; but it mounts powerfully in continued tracts of clear and warm weather. The greatest dryness yet noticed was at Paris, in the month of September, when it reached 120 degrees. But for want of observations, we are totally unacquainted with the real state of the air in the remote and tropical climates.

When the indication of the hygrometer does not exceed 15 degrees, we are directed by our feelings to call the air damp; from 30 to 40 degrees we begin to reckon it dry; from 50 to 60 degrees we should account it very dry, and from 70 degrees upwards we might consider it as intensely dry. A room is not comfortable, or perhaps wholesome, if it has less than 30 degrees of dryness; but the atmosphere of a warm occupied apartment will commonly produce an effect of upwards of 50 degrees.

Mr. Leffie has invented another instrument, which gives indications of the quantity of evaporation from a humid surface in a given time—which he has named the aerotermometer. It consists of a thin ball of porous earthen-ware, two or three inches in diameter, with a small neck, to which is cemented a long and rather wide tube, bearing divisions, each of them corresponding to an internal annular fiction, equal to a film of liquid that would cover the outer surface of the ball, to the thickness of the thousandth part of an inch. To the top of the tube is fitted a brass cap, having a collar of leather, which, after the cavity has been filled with distilled or boiled water, is screwed tight, to prevent the transfusion of the liquid from being so copious as to drop from the ball. Evaporation of the water takes place from the external surface, the instrument being suspended in the air; and the quantity evaporated in a given time, is discovered by the descent of the liquid in the tube. The use of this instrument will require some dexterity, particularly in adjusting the pressure of the collar; and its indications are slow—but it may often be employed with advantage, where it is of importance to ascertain the actual rate of evaporation.

From a variety of observations on the subject of evaporation he infers, that air has its dryness doubled at each rife of temperature, answering to 15 centigesimal degrees. Thus, at the freezing point, air is capable of holding a portion of moisture represented by 100 degrees of the hygrometer; at the temperature of 15 centigrade, it could contain 200 such parts; at that of 30, it might dissolve 400; and at 45 on the same scale 800. Or, if we reckon by Fahrenheit’s divisions, air absolutely humid holds, at the limit of congelation, the hundred-and-sixtieth part of its weight of moisture; at the temperature of 59 degrees, the eightieth part; at that of 86 degrees, the fortieth part; at that of 113 degrees, the twentieth part; and at that of 140 degrees, the tenth part. While the temperature, therefore, advances uniformly in arithmetical progression, the dissolving power which this communicates to the air mounts with the accelerating rapidity of a geometrical series.

The theory of the precipitation of rain, which he founds on this principle, requires, as he says, the assumption, not merely of the mixture of two masses of air at different temperatures, saturated with moisture, but the continued contact of two currents of air under these conditions; as it is thus only that a sufficient quantity of water will be furnished to form that copious precipitation which constitutes rain. And he adds a calculation, founded on the preceding law, which illustrates this, and illustrates exceedingly well, the general theory.

We shall here take occasion to observe, that as the capacity of air for heat is increased by its rarefaction, its disposition to hold moisture in solution appears to be increased by the same cause; and at the same time the removal of pressure, which is the consequence of the rarefaction, facilitates the transition of water into vapour. From these causes, if the hygrometer be suspended within a large receiver, from which a certain portion of air is quickly abstracted, it will sink with rapidity. But the effect is only momentary, for the rarefied air soon becomes charged with moisture, and consequently ceases to act on the wet ball of the thermometer. Hence there is every reason to believe that the higher regions of the atmosphere are drier than those beneath: and, without this condition, Mr. Leffie remarks, our globe must have been shrouded in darkness for the cold which reigns in the upper strata, would have prevented the humidity from ascending to a great elevation, and have precipitated it in continual fogs or clouds. In the actual state of things, the diminution of temperature, in ascending, predominates at first over the augmented power of aqueous solution; and the air becomes damper till a height be reached, at which the opposite effects of cold and rarefaction are balanced. Above this, which is the proper region of the clouds, the influence of the rarity of the medium exceeds that of the cold, and the air therefore becomes progressively drier, until it melts away into the clear ethereal expanse.

On this principle is founded the very beautiful experiment invented by Mr. Leffie, of causing water to freeze by the cold produced by its own evaporation. The peculiar arrangement for this consists in placing water in a porous earthen cup, suspended within the receiver of an air-pump, and placing, at a short distance beneath it, sulphuric acid in a broad shallow vessel, so that an extensive surface of the acid shall be presented. On rarefying the air, the evaporation of the water is accelerated, and of course the degree of cold produced by that evaporation is increased. This, however, would soon be checked by the presence of the watery vapour; but this the sulphuric acid absorbs, almost as quickly as it is formed; keeps, therefore, the rarefied air always dry; and thus allows the evaporation to proceed with the same rapidity. The temperature, therefore, continues to fall, until the water freezes into crystals of ice; and even after it is entirely congealed, the ice continues to suffer evaporation, until it wholly disappears. See Leffie’s Short Account
HYR

HYPERSTONE. See Mineralogy, Addenda.

HYPOPOTHOUS ACID. See PHOSPHORUS.

HYPOSULPHUROUS ACID. See SULPHUR.

HYREUS, in Ornithology, a genus of birds of the order Passeres; the characters of which are, beak conic, straight and ferrated; nostrils ovate; tongue short and obtuse; rect with three toes, two before and one behind. There is one species, viz. H. Abyssinicus, or black plant-cutter, with the head, throat, and jugulum red, wing-coverts brown, with white margins. It is found in Abyssinia, and, according to Mr. Bruce, it is a solitary species, and infibits on the kernels of almonds and other seeds, which it easily breaks with its strong ferrated beak. It frequents woods, and is called "Guifso batio dimmo-on jercq."

I and J.

JACKSON, l. 2, containing, together with its town Jefferson, 10,589 inhabitants, the slaves in the county being 1789, and in the town 27; l. 5, r. Welch Tennesees, adding—containing 5401 inhabitants, of whom 481 were slaves in 1810.

JACKSONBOROUGH, l. 2, after Carolina, add—in Screven county. At the close, add—containing 2663 inhabitants, of whom 2000 were slaves in 1810.

JAFFREY, l. 4, r. 1336.

JAGHIRE, l. 7, after hereditary, add—There are two species of jaghire; one personal, for the use of the grantee; and the other, in trust, for some public service, commonly for the maintenance of troops.

JAYADEN, l. 4, for Kari r. Kafi; l. 7, for Sina r. Siva.

ICE, col. 4, l. 43, add—clouds and frequent changes of wind being certain preventives of its formation; l. 44, Dr. Wells, in his Essay on Dew, &c. has given an account of the process described by Mr. Williams, which, from its extent, 300 persons being employed in it, must have been carried on for profit, and of course would be conducted in the most economical manner. "A piece of ground, nearly level, containing about four acres, was divided into square plats, from four to five feet wide, which were surrounded by little mounds of earth, four inches high. In these enclosures, previously filled with dry straw, or sugar-cane haum, were placed as many broad, shallow, unglazed earthen pans, containing unboiled pump water, as they could hold. The air was generally very still, when much ice was formed; wind prevented its formation altogether. In the morning, between five and six o'clock, at which time alone, Mr. Williams made his observations, a thermometer, with its bulb naked, placed on the straw, amidst the freezing vessels, was never found by him lower than 35°; and he has observed ice, when a thermometer so placed was 42°. Another thermometer, suspended five feet and a half above the ground, was commonly 4° higher than that among the pans. It is possible, therefore, that Mr. Williams may have seen ice, a little before sun-rise, when the temperature of the air was 46°. But granting this were the fact, it would not hence follow, that the ice was formed, while the air was colder about sun-rise than at any other time, I know, from my own observations, that this is not always the case in England; and similar exceptions may occur in Bengal."

The formation of ice in the circumstances above specified is ascribed by Sir R. Baker wholly, and by Mr. Williams in great measure, to cold produced by evaporation; and this opinion has been adopted by Bishop Watlon, Thompson, Young, Davy, and Leslie. Dr. Wells, however, is of opinion, that they have not fully considered the subject, alleging several reasons against it. He conceives, agreeably to his sentiments respecting the formation of dew (see Dew), that the formation of ice in Bengal depends upon the radiation of heat to the heavens. This cause, he says, not only exists, but exists in a degree sufficient for the production of the effect which it attributes to it. To this purpose he observes, that according to Mr. Leslie (on Heat, p. 80.) the power of water to radiate heat exceeds, perhaps, that of
all other subfancies. Ice, he adds, is chiefly formed in Bengal during the clearest and calmest nights; and on such nights the greatest cold, from radiation, is perceived on the surface of the earth. Moreover, the cold that produces this effect in Bengal appears, in its greatest degree, like cold from radiation in other subfancies, on those still and serene nights, during which little dew is deposited by the atmosphere. He further adds, that clouds and wind prevent the formation of ice in Bengal; and that the same states of the atmosphere either prevent, or considerably diminish, the occurrence of cold from the radiation of heat at night by bodies on the ground. From experiments, in procuring ice in the manner of Barker and Williams, Dr. Wells found reason for inferring, that water may freeze at nights, in air of a temperature higher than 32\(^\circ\), not only without any lobs of weight from evaporation, but with a gain of weight from an opposite procfs: and he concludes in general, that the formation of ice in Bengal, in the circumstances described by Barker and Williams, must be attributed, in by far the greater measure, if not altogether, to a lobs of heat, which the water suffers by its own radiation, while situated in such a manner, that it can receive little heat from other bodies, either by radiation or conduction.

Our author, in the course of his experiments, found, that evaporation from water of 32\(^\circ\) produces very little cold, even in the daytime: and he thinks it much more probable, that on a clear and calm night, though in a dry winter of Bengal, water at the temperature of 32\(^\circ\) will acquire warmth from the formation of dew upon it, than that it will become cold from evaporation.

ICHNEUMON. Add—The characters are, mouth with jaws, tongue; antennæ with more than thirty joints; abdomen in most species foot-tailed; piercing exerted, with a cylindric-bivalve sheath. The animals of this genus deposit their eggs in the bodies of other living insects, and generally in those of caterpillars. Here they hatch, and the young larve, resembling small white maggots, nourish themselves with the juices of the unfortunate animal, and at length the young brood of ichneumon larve creep out by perforating the skin in various places, and each spinning itself up in a small oval folken cafe, changes into chrysalis, the whole number forming a group on the thrivelled body of the caterpillar which had afforded them nourishment, and, after a certain period, emerge in the state of complete ichneumons. The principal species are, glemerator, puperum, ovularum, ramidulus, luteus. See Vespa, and Aasp.

ICTUS SOLARIS, A Stroke of the Sun, denotes the effect of a too violent influence of the fun upon the head. It is ranked by Dr. Cullen as a variety of apoplexy, under the name of “Carus ab inflatione.”

IDA. Add—The summit of Ida is denominated Gargarus; and it affords a level surface, of no great extent, but of an oblong form, with a rudely-built wall around it, in which are small blocks of marble. This inclosure, it is conjectured, may have been a Greek church, or perhaps only a sheep-pen, united for the protection of the flocks in the summer months.

IDOCRASE. See Vesuvian.

IDOLATRY, col. 5. l. 15 from the bottom, for even r. ever.

JEDBURGH. In 1811, the burgh and parish contained 669 houses, and 4454 persons; viz. 1957 males, and 2497 females: 399 families being employed in agriculture, and 405 in trade and manufactures.

JEFFERSON. (See J.ass.)—Alfo, a county of the Misissippi, containing 4301 inhabitants, of whom 1792 were in 1810.—Alfo, a township of Clarke county, in the Indiana territory.

JEFFERSON, in Kentucky, l. 3, r. 11,611; l. 4, r. 3746; l. 7.—It contains, together with Louisville, 6111 inhabitants, the slaves in the county being 2080, and in the town 256; l. 9, r. 7309 inhabitants, of whom 783 are slaves; l. 14, r. 1971; r. 11 towns with 17,260 inhabitants, of whom 6001 are slaves; l. 14, after Steubenville, add—Alfo, a town of Adams' county, in Ohio, having 404 inhabitants.—Alfo, a town of Fayette county, in Ohio, having 327 perfoins.—Alfo, a township of Madison county, in Ohio, having 246 inhabitants.—Alfo, a township of Montgomery county, in Ohio, having 1343 inhabitants.—Alfo, a township of Mifkingham county, in Ohio, having 562 perfoins.—Alfo, a township of Preble county, in Ohio, having 385 inhabitants.—Alfo, a township of Ross county, in Ohio, having 1456 inhabitants.—Alfo, a township of Scioto county, in Ohio, with 258 perfoins.—Alfo, a township of Geinger county, in Ohio, containing 168 inhabitants,—Alfo, a town in Maine, in Lincoln county, having 1205 inhabitants.—Alfo, a township of New Hampshire, containing 11,581 inhabitants, including 3532 slaves; l. 17, for Granite r. Coos, Cottam's co. d. r. 1971; l. 19, after Scottville, add—Alfo, a county, containing 161 inhabitants.—Alfo, a township of Greene county, in Pennsylvania, having 1124 inhabitants.—Alfo, a county of New York, containing 15,140 inhabitants.

JERICO, l. 4. r. 1185.

JERSEY, New, after the table, add—By the census of 1810, the whole number of its inhabitants is stated to be 245,562, and that of slaves 10,851. See each county, and the United States.

JESSAMINE, l. 2, r. 8219 and 2466.

JET. See Mineralogy, Addenda.

JEWS, col. 16, l. 9 from the bottom, r. 110,000.

JINIAL, denotes a large mullet, fixed on a trivet, iced in Indian forts, and fired with great precision.

ILCHESTER, l. 2. r. 1811—83—

ILEUM. See Intestine.

ILLFRACOMBE, l. 4th, r. 434 and 1934.

IILLINOIS. Add—The Illinois territory, now one of the United States, contains two counties, viz. St. Clair and Randolph: the former comprehending nine townships, and the latter four; and the number of inhabitants in the whole territory is stated, by the census of 1810, to be 12,282 perfoins, of whom 108 were slaves. See United States.

ILLORI, a town of Mingrelia, on the left bank of the Enguri, farrowed by a wall.

ILMINTER. By the return in 1811, the parish contained 364 houses, and 2160 persons; viz. 1022 males, and 1138 females: 121 families being employed in agriculture, and 231 in trade, manufactures, and handcraft.

ILSLEY, l. 2, and Eail and Welf IlIlley were returned to parliament, in 1811, as containing 179 houses, and 996 perfoins.

INCUBATION, dele the account of the figures. INDEPENDENCE, in Geography, a town of Sussex county, in New Jersey, containing 1234 inhabitants. INDIANA. After the table, add—According to the census of 1810, Indiana is divided into five counties, viz. Dearborn, having 7310 inhabitants; Clark, with 5670; Harrison in two divisions, having in one 2338, and in the other 1257 inhabitants; and Knox in two cantons, one having 4057, and the other 3848. See United States. INDIANA, in Pennsylvania. Add—Indiana contains nine townships, and 6214 inhabitants. Alto, a township of Alleghany county, in Pennsylvania, containing 692 inhabitants.

INDICATOR, Honey-guide, in Ornithology, a peculiar genus formed of the Cucullus Indicator; the characters of which are, beak long, conic, dilated at the base, narrow towards the tip, the upper mandible bent and carinated, the lower one recurved at the tip; nofrills slightly covered with feathers, feet simple, with two toes before and two behind. The external hinder toe longest, armed with a stout claw. See Cucullus, and for Dr. Sparrman's account of it, Phil. Trans. vol. lxi. p. 38.

INDIGO, Chemical Properties of. The indigo of commerce is exceedingly impure, and seldom contains more than half its weight of real indigo. Thus, Bergmann could only obtain 47 per cent. of real indigo from the purest specimen he could procure; and more lately Chevreul from the belt guatamina could only obtain 45 per cent. The following analysis of Chevreul will give some idea of the substances with which the indigo of commerce is adulterated.

The principal properties of indigo have been already detailed. The effects of nitric acid upon indigo, however, as ascertained by Mr. Hatchett, have been omitted, and are so interesting that they deserve to be mentioned.

Nitric acid acts on indigo with great violence, so as even to set fire to it when concentrated, as was long ago observed by Woulfe. When the acid is dilute, the action is less violent. Mr. Hatchett, however, found, that when diluted with an equal quantity of water, the action of the acid was still so violent as to require further dilution. When the effervescence had nearly subsided, the liquid was placed on a sand-bath for some days, and evaporated to dryness. Water poured upon this residuum diffused a considerable portion of it, and formed a beautiful deep yellow solution of an intense bitter taste. This solution contains only a very small portion of oxalic acid; but with a solution of sodium it forms a copious yellow insoluble precipitate, and hence contains a portion of artificial tannin; with ammonia, crystalline precipitate, consisting of bitter principle combined with ammonia.

When four parts of nitric acid are poured upon one part of indigo, the pigment soon loses its colour, and is dissolved. The solution becomes yellow, and a thin layer of a resinous-like substance appears on the surface. This substance becomes solid on cooling if the processes be now stopped. If it be removed, and the solution be evaporated to the constancy of honey, redissolved in hot water and filtered, the potash throws down yellow spicular crystals, consisting of bitter principle combined with potash. These crystals have the property of detonating with a purple light when wrapped up in a paper, and firing with a hammer; the retn by treating it with nitric acid may be converted into the same bitter principle. If the processes be stopped sooner than the point above-mentioned yellow crystals are obtained, which on sublimation become white, and appear to possess the properties of benzoic acid. Thus it appears, that by treating indigo with nitric acid, it is converted into tannin, oxalic acid, benzoic acid, and bitter principles.

INDRA, col. 2, l. 32 and 33; read thus, without a break, and omitting INDRA Malva. Malva, the hereditary possession, &c.

INDUSTRY, in Geography, a township of America, in Maine, county of Somerfield, having 562 inhabitants.

INFLAMMATION of the Breast. See Breast, Inflammation of, in the Addenda.

INGA, in Botany, an American name, recorded by Meargeaven, and adopted by Plumer. It was funk in Mimoso by Linnæus; but Humboldt and Bonpland having separated from thee the original genus of Plumer, have retained the appellation he had chosen, and they are followed by Wildenow, as well as by Brown and Alton in Hort. Kew. If any barbarous name be tolerated, and they can hardly be all expunged, the present is excepcionable. —Plum. Gen. 13. t. 198. Wild. S. & Pl. v. 4. 1804. Ait. Hort. Kew. v. 5. 451. —Clafis and ordre, Polygama Monoeia; rather Monadelphica Polyspondia. Nat. Ord. Lumenca, Linn. Leguminosae, Juss. Eff. Ch. Calyx five-toothed. Corolla tubular, five-toothed. Stamens united into a cylindrical tube. Legume of one cell. Seeds imbedded in pulpy tunics. Some flowers without a pithil.

Obf. If Mimoso be divided at all, the present numerous genera may commodiously be separated from it, though the infraclasses, and structure of the flowers, come, in many instances, very close to Acacia; see that article, as well as Mimoso and Desmanthus. From the lat., Inga is truly distinct, in having monadelphous indefinitely numerous flowers, no neuters, though many males, flowers, and in every instance a very different fruit. The greater size of the leaflets is characteristic of Inga, and they are, for the most part, differently compounded from those of the other genera. Wildenow enumerates fifty-eight species, some of them truly superb in their flowers. We shall give examples of this writer's fix sections. The leaves of this whole genus are compound; none of them fentive.

of Coromandel, for the sake of its sweet pulpy red fruit, which is six inches long, wholesome, though rather inipid. Flowers small, white.

Seet. 2. Leaves three yokes. Five species.

Native of Martinico. Leaflets an inch long, oblique. Flowers purplish.

Seet. 3. Leaves pinnate; common stalk winged. Thorns none. Twelve species.

I. vera. Common Inga. Willd. n. 17. Ait. n. 3. (Mimofa Inga; Linn. Sp. Pl. 1498. Inga flore albo imbrati, frutico dulei; Plum. 1c. 14. t. 25. Arbor. Merian. Surin. t. 51.)—Leaflets about five pair, ovato-oblong; pointed, smooth, with a gland between each pair. Corolla hairy. Legume furrowed, downy. Native of South America and the West Indies. where the legumes are esteemed for their agreeable sweetmeats.

I. fafua. Statey Inga. Willd. n. 25. (Mimofa fafua; Jacq. Fragm. t. 10.)—Leaflets about four pair, ovate, pointed; hairy beneath; with a flanked gland between each pair. Corolla hairy. Legume hairy, compressed, twisted.—Native of the Caraccas. We have from Dr. Maeter a fine dried specimen, such as that from which Jacquin’s plate is taken. This is a truly magnificent plant, whose copious large tawny flowers, with long crimson flaments, make a splendid appearance. The leaflets are from two to five inches long. Legume broad, flat, but containing a sweet pulp, with large oval seeds.

Seet. 4. Leaves pinnate; common stalk simple. Thorns none. Ten species.

I. nodosa. Knobbed Inga. Willd. n. 29. Ait. n. 6. (Mimofa nodosa; Linn. Sp. Pl. 1498. Phaefalus arbores, &c.; Pluk. Phyt. t. 211. f. 5.)—Leaflets two pair, ovato-oblong, smooth, unequally divided by the rib; the lower, ones smallest, with a gland between. Found in Ceylon and Cochinchina. It appears to have been raised in the English and Dutch flotts, but not preferred. The leaflets are from one to two inches long, their two sides very unequal.

Seet. 5. Leaves conjoint, pinnate. Nine species.

I. purpurea. Purple Inga, or Soldier-bush. Willd. n. 42. Ait. n. 8. (Mimofa purpurea; Linn. Sp. Pl. 1500. Andr. Repol. t. 372. Acacia fruticenses, &c.; Plum. 1c. 6. t. 10. f. 1, the Linnaean characters misapplied.)—Leaflets four pair, obvate, obtuse; unequal at the base. Footstalks without glands. Heads of flowers flaked.—Native of the West Indies. The leaflets are half an inch long, smooth. Flowers copious, very conspicuous for their long taffels of crimson flaments.

Seet. 6. Leaves doubly pinnate. Eleven species; some thorny.

I. Saman. Great Downy-leaved Inga. Willd. n. 49. (Mimofa Saman; Jacq. Fragm. t. 9.)—Thorns none. Leaves with six pair of primary divisions; leaflets five or six pair, elliptic-ovate, obtuse; terminal ones unequalized; all downy beneath as well as their flalls. Native of the Caraccas. One of the largest and stoutest trees of the Mimofa tribe. Leaves two feet, or more, in extent, with a depressed gland at every subdivision. Legume flat, seven or eight inches long.

INGATESTONE, I. 5. r. 98 and 640.

INSTITUTE, NATIONAL, &c. col. 2, after line 6, add—By a royal edict, passed the 26th of March, 1816, the first class resumes the name of the Royal Academy of Sciences, preferring the organization and distribution in fections.

INVERARY, col. 2, l. 8 and 7 from bottom, r. 103 and 111.

INVERKEITHING. Add—The burgh and parish of Inverkeithing, by the last returns in 1811, contained 581 houses, and 2400 persons.

INVERNESS, col. 2, l. 7, 8, 9, r. The burgh and parish was returned, under the act of 1811, as containing 1672 houses, and 10,757 inhabitants.

INVERNESS-SHIRE, l. 10 and 11, r. comprehended, in the year 1811, 78,336 persons, occupying 14,466 houses; 35,722 being males, and 42,614 females.

INVERURY. In 1811, the burgh and parish contained 205 houses, and 907 persons; 453 being males, and 454 females.

INULIN, in Chemiſtry, a name given by Dr. Thomson to a substance extracted from Roea, from the Inula heurum, or Elecampane. This substance is extracted by boiling the roots in water, and putting by the decoction to cool, when the inulin is deposited in the form of a white powder. Inulin resembles flarch in its appearance, and some of its properties. It is principally distinguished from flarch by separating from water after boiling in the form of a white powder. Inulin has been found by Dr. John in the roots of several other plants.

IOANNA. Add—In 1809, this island was visited by the favages of Madagacar, called Malagacars, who laid siege to the principal town, and destroyed the crops, and thus reduced the inhabitants to the most deplorable state, so that nearly 200 women and children perished of hunger, and numbers of the latter were actually eaten by their parents, so that these favages have nearly desolatod the Comoros islands. The once happy and flourishing island of Ioanna, with its 570 towns and villages, so enchantingly described by Sir William Jones, is now reduced to two walled towns, and a population of 3000 souls.

IOANNINA, a city of Albania, the capital of Ali’s dominions, situated on the western banks of a lake of the same name, at about two miles from its easter extremity. In its utmost length, it may be, perhaps, about two and a half miles, and in breadth nearly a mile. Near the lake it stands on a flat, but the northern and western parts are built on slopes of rising and uneven ground. A triangular peninsula juts into the lake, and contains the residence of the pacha, being defended by a fortitation at each angle. The entrance into these forts is over a draw-bridge. There is one street which runs nearly the whole length of the town, and another that intersects it at right angles, extending to the fortresses; these are the principal streets. Many of the houses are large and well built, containing a court-yard, and having warehouses or flables on the ground, and the apartments of the family above. A flight of wooden steps and a gallery connect the under and upper parts of the houses. Although gloomy in appearance, with small windows latticed with crofs bars of wood, the yard is furnished with orange and lemon trees; and the best houses communicate with a garden, and the galleries are sufficiently spacious to allow scope for walking in rainy weather. The bazaar, or principal street, inhabited by tradesmen, has a flowy appearance; the bizzalfeen, or covered bazaar, is of considerable size, and would put one in mind of Exeter Change in London. Befide the palace of the pacha, and two houses allotted to the sons of Ali, there is another summer residence of the vizier’s in the suburbs, at the N.W. end of the town. Beyond the pavilion,
See particularly this and it the inhabitants.

besides the common symptoms of ophthalmia, there are changes which occur at the very commencement that indicate the seat of the inflammation. The pupil is contracted, the motions of the iris are less free, and the pupillary opening loses the bright black colour which it naturally posseffes. The colour of the iris is next oberved to alter: this happens first in the exter circle, which gets of a darker hue; and afterwards in the greater, which grows green if it has been greyish or blue, and reddish if it has been brown or black. The iris afterwards swells and projects towards the cornea; and the margin of the pupil loses its sharply defined edge, and is turned back towards the posterior chamber. The redness accompanying these changes is by no means considerable, and is at first confined to the sclerotic coat, in which a number of very minute rose-coloured vesicles are seen running in bright lines towards the cornea. The pupil, at the same time, loses its circular form, becomes somewhat irregular, and presents a greyish appearance. Examined with a magnifying glass, this appearance is seen to be produced by a fluctuation very like a cobweb, occupying the pupil, and which is soon afterwards distinguished to consist of a delicate flake of coagulable lymph. Into this, the processes or dentations of the margin of the pupil seem to shoot, and it is afterwards found, that at these points adenitie are apt to be established, in consequence of which vision is rendered more indistinct, and only one fide or parts of objects can be discerned.

The effusion of lymph into the pupil continues to increase; it is likewise poured into the posterior chamber, and adhesions between the iris and capsule of the lens are formed. The quantity of lymph effused is sometimes so great, as to fall in a currled form from the pupil to the lower part of the anterior chamber. The pupil, the size of which is considerably diminished, now derives a greyish-white colour from that of the lymph by which it is filled; the morbid sensibility to light, which prevailed at the commencement of the inflammation, is diminished; the powers of vision become gradually more and more limited; and, at length, merely the perception of light remains.

By this time, the redness of the eye has increased, and partly arises from vesicles which are now developed in the conjunctiva. The redness is deepest all around the cornea; and the periphery of the eye-ball it fadens. The cornea loses somewhat of its peculiar brilliancy; and lymph now appears as to be effused into the substance of the iris; for, while it projects more and more towards the cornea, its fibres are collected into vessels, and its surface exhibits a puckered or plaited appearance. A yellowish-red tubercle then forms on some part of its surface; it is at first small, but enlarges and projects forwards, and, according to Schmidt, is distinctly seen to be an abscess, which finally bursts, and discharges its contents into the anterior chamber. At this period of the disease, a small quantity of blood is sometimes extravasated into the anterior chamber. The inflammatory symptoms now abate, and, as the diseafe subsides, both the pus and blood in the anterior chamber are absorbed. The threds of the cyst of the abscess, which were floating in the aqueous humour, in a few days disappear. The anterior chamber regains its transparence; the iris remains permanently expanded; its puckered appearance continues, the pupil is closed, and the power of vision is entirely loft. When the termination is somewhat more favourable, the pupil is not entirely closed, and the iris retains some degree of motion. The piece of coagulable lymph which occupies the pupil is reduced to the flate of a thin membrane, which is opaque towards its centre, but somewhat transparent at the edges; the margin of the iris is only adherent

Vol. XXXIX.
at some points to this membrane; and vision is impaired, but not destroyed.

Sometimes the inflammation of the iris extends to other textures of the eye. When the cornea is attacked, it becomes cloudy and thickened; and the iris projecting, the two inflamed textures come into contact, and adhere before any visible effusion of lymph takes place. Should the inflammation spread more deeply, and attack the membranes of the lens, and of the vitreous humour, the choroid coat, &c. then the violent symptoms of deep-seated inflammation of the eye take place. Even if the form of the organ is preserved, vision is totally destroyed; but often the eye suppurates, bursts, and almost entirely disappears.

In the Syphilitic Iritis, a pale redness all round the cornea is the first symptom which is perceived. It is at first seated in the fcelerotic coat alone; but the conjunctiva very soon shares in it, and afterwards becomes even redder than the preceding membrane. However few the vessels may be elsewhere, there is always a broad zone of them all round the cornea, a zone formed at this place, not only by the vasa net-work in the conjunctiva, but by the ciliary vessels on the external surface of the sclerotic. The redness has a peculiar tint; for instead of being bright red, it is brownish, something like the colour of cinnamon. The whole cornea becomes uniformly hazy. The pupil also becomes contracted, and the iris limited in its motions, as in common iritis; but the pupil does not prefer its natural situation. It is removed in a direction upwards and inwards towards the root of the nose, and is irregular. At the same time, the iris loses its natural colour, and projects forwards.

Towards evening, there is always an aggravation of the symptoms; the intolerance of light and painful sensibility of the whole eye increasing, and a gust of tears following every change of light and temperature. At length, a regular nightly pain sets in, of an extremely feverish kind, but strictly limited to that part of the cranium which is immediately above the eye-brow. It usually begins between six and seven in the evening, gradually increases, reaches its utmost height about midnight, and then diminishes till about four or five in the morning, when it ceases. After every such attack of pain, the pupil is found more contracted, drawn farther upwards and inwards, the iris more altered both in colour and form, the quantity of lymph increafed, and consequently vision more impeded.

Peculiar appearances then take place in the iris; for, either on its papillary or ciliary margin, or on both, one or more reddish-brown tubercles arise, which have a pensive look. Their growth is pretty rapid. Lardy-looking ulcer sometimes appear on the cornea and white of the eye, or on the eyelids. Even when syphilitic iritis terminates in the most favourable manner, the eye for a long time afterwards is peculiarly sensitive to the influence of cold and moisture. On every exposure to these, the organ becomes morbidly sensitive to light, of a reddish colour, and discharges tears. Indeed, frequently for more than a year afterwards, on every sudden change of temperature, a pale violet-coloured zone appears around the cornea, but goes off when the eye has remained for some time exposed to an equal temperature.

In the iritis which appears in conjunction with the eruptions supposed to be connected with the abuse of mercury, the inflammation seems less active than in the other kinds. The pupil is not much contracted, and lymph is less apt to be effused. A vehicle full of yellow matter sometimes rises on the iris, without any other alteration on this membrane than that of colour, the pupil remaining almost unchanged. By the use of proper remedies, this vehicle, even when it seems quite ready to burst, can generally be made to disappear in a few days, without any rupture taking place. The blood-vessels of the conjunctiva are large and dilated, without being varicose; they have a more vivid colour than in the iritis of arthritic persons, and run quite to the edge of the cornea.

The treatment of iritis is conducted on the same principles as that of inflammation in general, with one difference, which is deduced from the important fact so well explained by Dr. Farre and Mr. Travers, viz. that in iritis, the free exhibition of mercury is the most effectual means of preventing the effusion of coagulating lymph, and promoting its absorption after it has taken place, from which effusion the thickening and adhesions of the iris, the formation of opacities in the pupil, and other mischiefous and disturbing effects upon vision, are principally derived. According to Mr. Travers, indeed, whatever may be the cause of iritis, mercury is the grand remedy for resisting the progress and confessions of the effusion of lymph in the eye. According to professor Schmidt, of Vienna, general bleeding is necessary only where there is a great degree of symptomatic inflammatory fever. Hence, it is principally in the idiopathic iritis that large bleedings from the arm are requisite. In the syphilitic species, he says, it is never necessary to open a vein. In the arthritic, it is sometimes attended with benefit; but in patients of this description, a small bleeding, repeated next day if necessary, is found to answer much better than a large bleeding at once, even though the constitutional disturbance be considerable. In the rheumatic iritis, it is also sometimes highly beneficial to bleed from the arm. Local bleeding, by means of leeches to the forehead, produces the most decided benefit in all the varieties of iritis.

Purgatives, given so as to act copiously, professor Schmidt describes as being useful only in the idiopathic iritis; and as for cold local application, he tells us that they are in all cafes quite useless.

In the idiopathic iritis, he recommends us to take sixteen or twenty ounces of blood from the arm; and to repeat the bleeding if circumstances should require it. Six or eight leeches are to be applied to the eye-brow or temple. A smart purgative should then be given. The application of leeches, but in smaller number, should be continued every day, or every other day, until an abatement of the inflammation has evidently taken place. In the fifth stage of the process, blisters to the temple, or behind the ears, have little or no effect; though sometimes a large one on the nape of the neck seems to be of service. According to Schmidt, the only topical treatment which is admissible is the fomentation of the eye with water made hot as the patient can bear it, which sometimes procures a mitigation of the violence of the pain. Care, however, must be taken to dry the eye-lids and circumference of the orbit well after using this application.

When the disease passes into its second stage, or that in which the effusion of coagulating lymph commences, mercury is to be given with the views already mentioned. Two grains of the submuriate of mercury, and half a grain of opium, made into a pill, are to be given every evening and morning; or common mercurial fictions may be employed. Externally, professor Beer applies a solution of the oxymuriate of mercury in water, to which mucilage and a considerable quantity of the vinum opii have been added. When this collyrium looses its effect, or the eye cannot bear any fluid application, which is sometimes the case, then he infers daily between the eye-lids a small quantity of a salve composed of two draams of fresh butter, six grains of red precipitate, and eight grains of extract of opium. According to
to the fame eminent oculist, frictions once a day over the eye-brow with mercurial ointment, opium being added to it, very much contribute to the aborption of the lymph effused in the posterior chamber.

It is seldom necessary to continue many days the exhibition of mercury; for such is the efficiency of this mineral in producing a removal of the lymph, and clearing away all opacities about the pupil, that in less than eight or ten days these objects are generally effected, and the medicine then may be omitted.

The form of iritis, usually named syphilis,t, is unquestionably one of those diseases which does not require more mercury for its cure than the common idiopathic iritis; and although it was supposed by professor Schmidt that it could not be radically cured without removing the constitutional disease, modern experience fully proves, that it may often be entirely and permanently relieved by freely exhibiting mercury for only a few days. This is another fact tending to confirm the opinions which have recently been examined and promulgated with so much ability by several of our army surgeons, in relation to the curability of all the forms of syphilis without mercury. For, even in the syphilitic iritis, we are not to imagine that the complaint is flopped and cured by a few grains of calomel, on the principle of eradicating a specific disease: the thing is more rationally explained by the peculiar efficacy of the medicine in producing an aborption of the lymph, which thickens the iris, obliterates the pupil, and even serves for the formation of preternatural adhesions, and new opaque membranes destructive of vision. Besides the use of mercury, however, other means are advisable. When there is fever in the eye with violent head-ache, three or four leeches should be applied on the eye-brow, and a mild purgative administered. The nightly attacks of pain, which are so invariably followed by an aggravation of all the symptoms, are most effectually prevented by rubbing into the part just over the eye-brow a small quantity of mercurial ointment with opium, a short time before the pain is expected to begin, and then covering the eye with a folded piece of warm linen. Generally speaking, calomel given in small doses two or three times a day, is the best preparation of mercury for internal exhibition.

The iritis which accompanies cutaneous eruptions was thought by Schmidt to be the most easy of cure; local bleedings are said to be in this case strikingly beneficial. According to some writers, when the eruptions have arisen from the previous use of mercury, calomel has not the least effect on the accompanying iritis. But at the London Infirmary for diseases of the eye, this form of the disease, though originally it may have been caused by the effects of a mercurial course, is said to be benefited as much as the other varieties of iritis by the exhibition of mercury; a circumstance which no mode of reasoning would ever have led us to anticipate. If, however, it be an unequivocal fact, the voice of experience must direct us in practice, and we must be silent on things which we cannot explain.

The best account of iritis is contained in professor Schmidt's valuable work, entitled "Ueber Nachthar und Iritis nach Staar-Operationen," 4to. Wien. 1801. Additional information is also published in Beer's "Lehre von den Augenkrankheiten," b. i. p. 450. Wien. 1813. Saunders on Diseases of the Eyes, edit. 3. by Dr. Farre; B. Travers, in "Surgical Essays," part I. Carnichael in "Observations on the Symptoms and Specific Diffections of Venereal Diseases," 8vo. 1818. The Quarterly Journal of Foreign Medicine, No. 1, contains a well-written analysis of professor Schmidt's work on Iritis; and at the same time that we acknowledge our obligations to that periodical publication for every thing which is valuable in this article, we cannot refrain from expressing our warmest wishes for the success of a journal, the principal object of which is to make us acquainted with the contents of all the best modern books which appear on the subject of medical science in different parts of the continent.

IRON, in Chemistry. According to the recent determination of Dr. Thomson, the black or protoxyd of iron is a compound of

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>100.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iron</td>
<td>Oxygen</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>28.5</td>
</tr>
</tbody>
</table>

Hence the weight of the atom of iron will be 35. The red or peroxyd of iron, according to the same chemist, is a compound of

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>100.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iron</td>
<td>Oxygen</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>42.5</td>
</tr>
</tbody>
</table>

Or it is composed of 4 atoms iron + 1; atoms oxygen, or, to get rid of fractions, of 2 atoms iron + 3 atoms oxygen, on which latter supposition the weight of an atom of peroxyd will be 100.

KERKUK, or Kerko, the largest town in the lower Kurdistan, in N. lat. 35° 29', 39 furnungs from Bagdad, and 41 from Mafuf, on the road from one place to the other. It was formerly a military station, called by Strabo, Demetrias; and by Ptolemy, Corcora. Its population is estimated at 18,000 houfes, Turks, Armenians, Nettlorians, Kurds: this estimate, however, is supposed to exceed the truth by 5000. The city is defended by a mud wall, has two gates, seven mosques, fourteen coffee-houfes, one hoummon, one caravansera, one Armenian church, and twelve pieces of uifeles artillery mounted on the battlements. In the suburbs, are five mosques, nine small caravanseras, thirteen coffee-houfes, three convents, and three Catholic churches. Near it is a number of naphtha pits, which afford an abundant supply of that commodity.

KERMANSHAM, one of the five districts of the province of Irak in Perfo; the capital of this extensive and fruitful district of the same name, and the residence of Mahomet Ali Meerza, the king's eldest son, and the most able and warlike of all the princes of Persia. It is a flourishing town, containing about 12,000 houfes, at the extremity of a fine plain, through the centre of which runs the Karafu. It is adorned with many gardens, and fourteen humming or public halls, four mosques, and yields a revenue of 15,000 tomans a year.

KERRIA, in Botany, so named after Mr. William Kerr, a gardener, who has introduced the shrub in question, with many other Chinese plants, into the English gardens.—De Candolle Tr. of Linn. Soc. v. 12. 156.—Clas and order, 

Corchorus, n. 12.—A correct examination of the genere has authorized the learned professor De Candolle to consider this favourite plant as a new genus, though the precise nature of its feed-veilis is not known.

KEW, l. 4 and 5, r. 1811—73—560.

KEYNSHAM, l. 4 and 5, r. 1811; the parish comprised of 313 houfes, and contained 1748 inhabitants.

KHERAS, col. 2, l. 3, r. (See Khiva.)

KHOELE, a town of Persia, in the province of Azerbaijan, 22 furnungs from Tebris. This town is the capital of a rich and extensive diocese, and the emporium of a confiderable trade carried on between Turkey and Persia. It is said to contain a population of 25,000 houfes, and is situated on a plain, famous for a battle fought, in 1514, between Shah Ismael and Selim I., in which 30,000 Persians encountered 300,000 Turks. There is no town in Persia better built or more beautiful than Khoie; the walls are in good repair; the streets are regular, shaded with avenues of trees; and the ceilings of many of the houfes are painted with extraordinary tafle.

KHONsar, a town of Persia, in the province of Irak, situated at the base of two ranges of mountains, running parallel with each other, and so close that the houfes occupy the bottom and also the declivity of the hills to some height. The town, placed in a beautiful and romantic situation, and formed of houfes and gardens, connected by means of its plantations, is about five miles in length, and about one-fourth of a mile in breadth. It contains 2500 families under a chief named Ali Shah, and yields an annual revenue of 5000 tomans, exclusive of the fadrus, which generally consists of dried fruits and a kind of cotton chintz. Although they have no corn in the valley, fruit is so abundant, that the inhabitants procure for it every article which they can want or desire. Of their apples, they make a kind of cyder, but it will not keep above a month. The women are celebrated for their beauty and vivacity.

KHORASSAN. Add.—Khorassan is a level country, interperfed with sandy deserts, and irregular ridges of lofty mountains; the climate is accordingly various; in some parts temperate, but in others very cold; and the "had-e-fum," which blows in the deserts for 40 days in the year, proves inftan-
infrantaneously fatal to all who are exposed to it. This province was once populous and flourishing, and adorned with many princely cities. The soil is generally excellent, and produces wine, fruit, corn, rice, and silk in abundance, and of the beet quality; but from the success of its commerce and agriculture, it has been changed into solitary deserts. At present the power of the king of Persia extends only over the cities of Methed, Nilapour, Turfih and Tabas. The southern parts, including Herat, are in possession of the Afghans, and some wandering tribes of Patans and Ymuucks; and those to the E. and N. belong to the Lubeck Tartars and Turks. Khorasan is separated from Cabul by the mountains of Bampian and Goor. Its rivers are, the Oxus, the Tadzhik or ancient Oros, the Heriroid, the Murghah or ancient Margus, the Ester or ancient Siderius, from which the province of Aftabad derives its name, and which runs into the Caspian sea. The provinces of Irak and Khorasan are separated by a deep ravine, which interdicts the road leading from Tehran to Methed, 22 furlongs E. of the former place. The districts in this direction are, Sumnum, Damgan, and Billan. The present capital of the Persian division of Khorasan is Methed. That part of Khorasan which extends from the lat. 32° 30' to 34° 40', from 56° to 62° E. long., comprehends the following towns and districts, viz.: Pulhing, Zuzaan, Turfih, Turbat, Jam, Kohlafian, Nilapour, and Sarukhs. McKinner's Persia.

KIBBAN, termed Medan from its mines, a town of the pachalik of Diarbekr, larger and more populous than Argurna Madan; it is situated at the base of a high mountain, and on the verge of a chasm, through which a torrent forces its way to the Euphrates, distant about 1 ½ mile from the town.

KIDDERMINSTER, l. 5 and 6, r. 1811-13, 348-828.

KIDWELLY, l. 5, r. 1811-329-1441; l. 10, add—The vicinity is rich in coals and iron-ore, and some iron and tin manufactories have long been carried on here; l. 11, r. condition; l. 13, add—Its markets are held on Tuesday and Friday, and it has three fairs in the year.

KIGES, a town of Ohio, in Gallia county, having 387 inhabitants.

KILBACHAN. Add—By the parliamentary returns of 1811, the parish contained 360 houses, and 3509 inhabitants.

KILBIRNIE, for Renfrewshire, r. shire of Ayr. In 1811, the parish contained 180 houses, and 1088 persons; viz. 509 males, and 579 females.

KILBRIE. Add—in 1811, the town and parish contained 517 houses, and 2926 persons.

KILBRIDE, W'ldl. In 1811, the parish contained 183 houses, and 1015 persons; viz. 462 males, and 553 females; 76 families being employed in agriculture, and 108 in trade and manufactures.

KILKENNY, in America, l. 1, for Grafton r. Coos; l. 2, r. 28.

KILLBUSH, a township of Stark county, in Ohio, having 332 inhabitants.

KILLEARN, for KILLEAM, l. 1, and l. 3, add—In 1811, the parish contained 157 houses, and 997 persons.

KILLINGLY, l. ult. r. 2512.

KILLINGWORTH, l. ult. r. 2244.

KILMARNOCK, l. ult. r. In 1811, the town and parish contained 912 houses, and 10,148 inhabitants, of whom 1363 families were employed in trade and manufactures.
houses, and 13,779 persons; and Mull, 3010 houses, and 16,834 persons.

KIRCALDY, col. 2, l. 25, r. In 1811, the number of inhabitants in the burgh and parish was 3747, occupying 581 houses, of whom 405 families were employed in trade and manufactures, and 56 in agriculture: the number of houses in the whole district was 4899, and of inhabitants 31,958.

KIRKBY-LOSDALE, l. 5, r. In the year 1811, the town contained 271 houses, and 1368 persons.

KIRKBY-Moorfield, l. 6, r. 1811—319—1673.

KIRKSTAPP. Add—By the return of 1811, the township contained 250 houses, and 1235 persons.

KIRKCUDBRIGHT, l. wh. r. In 1811, the number of houses in the burgh and parish was 392, and of inhabitants 2763.

KIRKCUDBRIGHTSHIRE, col. 2, l. 8, r. 1811—33,684 persons; 15,788 being males, and 17,894 females: the number of houses being 6223.

KIRKHAM, l. 6, r. 1811—424—2214.

KIRKHAM, a township of Apeonde's hundred, in Lancashire, part of Kirkham parish, containing, in 1811, 444 houses, and 2214 persons; viz. 1039 males, 1175 females.

KIRKINTULLOCH, l. penult. r. In 1811, the number of houses was 605, and of persons 3740; of whom 573 families were employed in trade and manufacture.

KIRK-OSWALD. At the end, add—In 1811, the number of houses in this township was 116, and of inhabitants 636.

KIRKWALL. Add—The burgh and parish of Kirkwall contained, in 1811, 287 houses, and 1715 persons.

KIRKMINSHA. Add—See KIRKMINSHAW.

KIRKMIERUIR, l. 12 and 13—1811, the town and parish were returned as containing 955 houses, and 4791 persons.

KIRTON, l. 6, r. In 1811, it contained 307 houses, and 1531 persons.

KIRTON Lindsey, l. 5, r. 1811—258—1152.

KITTERY, l. 3, r. 2019.

KIZIL-OZAN. Add—This river, called the Golden Stream, is the natural boundary of Irak and Azerbijan, and, according to Renell, the Gozan of Scripture.

KNARESBOROUGH, col. 4, l. 15, r. The population of the borough and township, as returned to parliament in 1811, was 4234, occupying 888 houses.

KNEE, in the Manse, add—Broken knees very much depreciate the value of a horse; and therefore various methods have been proposed for repairing and correcting this injury. Mr. Teplin recommends, first of all, to wash the injured parts well with a sponge and warm water, so as thoroughly to cleanse them from gravel or sand; and then plentifully embrocating them with camphorated lead-water, and bandaging them over a pledow of towmoilleden with the fame, repeating the operation once or twice, if necessary. This treatment should be continued, that a crust or cicatrix may be formed, which will render unctuous or greasy applications unnecessary. But if the laceration be considerable, suppurating will ensue, and should be encouraged by a common poultice, and the cure completed by digestive ointments. Mr. Lawrence propoves to make the hair grow after such accidents, by binding a piece of wet-leat on the part after the wound is healed; and he also mentions a contrivance by which the knees of a valuable horse may be preserved from this accident. (See Hose.) He advises to wash the wounded clean with a linen rag and warm soap-fuds, and having wiped the parts dry to apply brandy. Friar's balfam (compound tincture of benzoin) will, he fays, heal broken knees very speedily. A kind of hofe, or boots, is used to defend the legs of race-horses in travelling; and some kind of guard, fastened above and below the knee, would be very useful to poll-horses. For broken knees, Mr. Ryding recommends a mixture of 1 dr. of caoutchouc in fine powder with 1 oz. of olive-oil, which should be applied occasionally with the hand to the wounded part. This, he fays, by its gently stimulating power, will brace the parts, promote the fore, and facilitate the growth of hair.

KNIGHTIA, in Botany, fo named by Sir Joseph Banks and Mr. Brown, in honour of Thomas Andrew Knight, Esq., the able president of the Horticultural Society, well known by his numerous writings on vegetable physiology.—Br. Tr. of Linn. Soc. v. 10. 193.—Clafs and order, Tetrandria Monogyna. Nat. Ord. Protales, Juff. Br.

1. K. excelsa. Br. as above, t. 2.—Found by Sir J. Banks, in New Zealand. A large tree, often eighty feet high. Leaves scattered, flaked, elliptic-lanceolate, ferrated, five or six inches long; sown beneath. Flowers red, in dense lateral clusters, with red flacts. This genus comes very near Aulet's and Schrebner's Rihopalus, (see that article,) differing only in having four seeds winged at the apex, instead of two winged all round.

KNOWLTON, l. 2, r. 2064 inhabitants, including 17 slaves in 1810.

KNUTSFORD, l. 5 from the bottom, r. In 1811 there were in the township of Nether Knutsford 448 houses and 2114 persons, and in Over Knutsford 49 houses and 243 persons, of whom in the former township 276 and in the latter 37 were employed in trade, manufacture and handicraft.

KOM, l. 4, add—It is said to have been built in the year 203 of the Hegira, from the ruins of seven towns, which had composed a small sovereignty under Abdalrahman, an Arabian prince—r. 19, after khan, add—It was taken by the Afghans, when they invaded Persia in 1722, and completely destroyed. Part of it has been since rebuilt, but it still appears like a vaft ruin.

KORASAN, or Khorassan. Add—See Khorassan.

KORNA. See Shat-ul-Arab.

KOUOMISS, an intoxicating drink, prepared by the Tartars from mare's milk. See Milk.

KRISSHNA, l. 21 and 24 from the bottom, for Gopia r. Gopia; l. 18, for Tafuda r. Yafuda.

KROOK. See REGAN.

KUFA, a kind of boat in use on the Euphrates and Tigris; it is perfectly round, made of wicker-work, covered with bitumen, and generally about seven feet in diameter.

KUFR, in Geography, a town of Persia, in the pachalic of Bagdad, between Bagdad and Kerkook, containing about 2000 inhabitants.

KURPI-ALTUN. See ALTUN-Kupri.

KUROBARTARA, l. 18 from the bottom, for beautiful r. bountiful.

KYANITE. See Mineralogy, Addenda.

1. K. calycina.
1. K. calcina. Roxb. t. 215.—Outer calyx four-leaved, longer than the corolla.—Native of the banks of rivulets, in Coromandel and Hindoostan, flowering in the cool season. A tree, with long-stalked, roundish, mealy, slightly threelobed leaves. Flowers small, white, in terminal panicles.

2. K. fraterna. Roxb. t. 216.—Outer calyx six-leaved, shorter than the corolla.—Native of the Cirrar mountains, flowering in the rainy season. A larger tree than the foregoing. Flowers more conspicuous. Leaves whiter underneath.

LABORATORY. Woulfe’s Apparatus, Plate V. Chemistry.

LAC, in Coinage. See Lack and Rupee.

LACK, in Geography, l. 2, r. 165.

LACKAWANACT, a township of Mercer county, in Pennsylvania, having 379 inhabitants.

LACTATES, in Chemistry. See Lactic Acid.

LACTIC Acid. The description of this acid has been omitted, we shall therefore introduce a brief account of it here.

The lactic acid was first obtained by Scheele from four whey. He considered it as analogous to the acetic acid. Bouillon Lagrange afterwards instituted a series of experiments upon it, from which he drew the conclusion that it is merely acetic acid, contaminated with some fatty and animal matter. Four years afterwards, Thenard advanced a similar opinion. Both these chemists, however, had obtained the acid which they examined by distillation, though Scheele had expressly stated that lactic acid, when distilled, was converted into acetic acid. The existence of lactic acid, therefore, was by no means disproved by their experiments. Soon afterwards, Berzelius took up the subject, and in an elaborate set of experiments proved that Scheele’s original opinion was correct, and thus fully established the peculiar nature of lactic acid.

Berzelius obtained the lactic acid by the following complicated process. The extract obtained by evaporating whey to dryness was dissolved in alcohol, and mixed with alcohol holding \( \frac{1}{3} \) th of its weight of concentrated sulphuric acid in solution, till there was an excess of sulphuric acid present. Sulphate of potash was precipitated. To get rid of the other acids, it was digested over carbonate of lead till the liquid acquired a fetid odor. By this means, the sulphuric acid, the phosphoric acid, and most of the muriatic acid, were separated; but the lactic acid forming a soluble compound with lead remained in solution. A current of sulphured hydrogen gas being passed through the liquid threw down the lead. The liquid was digested over quick-lime till all the animal matter was separated. It now contained only lactic acid, muriatic acid, and lime. A portion of it was freed from lime by means of oxalic acid. This portion was then saturated with carbonate of silver; by means of this solution, the remainder of the liquid was freed from muriatic acid. Finally, the lime was thrown down by means of oxalic acid, so that nothing remained but lactic acid dissolved in water. To get rid of a small portion of oxalate of lime which it held in solution, it was evaporated to dryness, and redissolved in water.

Lactic acid thus obtained has a brownish-yellow colour, and a sharp four table, which is much weakened by diluting the acid with water. While cold it has no smell, but when heated it acquires a sharp four odour, not unlike that of sublimed oxalic acid. It does not crystallize, but when evaporated to dryness forms a smooth varnish, which gradually attracts moisture from the air. It dissolves readily in alcohol. When heated it boils, emits a four smell, and leaves a bulky charcoal, not easily burnt. When distilled it gives out empyreumatic oil, water, acetic acid, carbolic acid, and inflammable gas.

Lactates.—All the lactates are more or less soluble in water, and hardly any of them can be made to crysurilize. The lactate of potash and lactate of soda form a light yellow transparent gummy mass, which cannot be easily made hard. The lactate of ammonia has some tendency to crysurilize. It forms a gummy mass, which acquires in the air an excess of acidity. When heated, most of the ammonia is driven off. The lactates of barytes, lime, and magnesia, are divided by alcohol into superficilates of those earths which are soluble in alcohol, and into sulflates which are insoluble. The metallic lactates do not possess remarkable properties. There are three lactates of lead; the superficilate which does not crysurilize, the lactate which exists in grey crysurilize grains, and the sulflurate which is insoluble. The lactate of zinc crysurilizes.

Dr. Thomson estimates the weight of the atom of lactic acid from Berzelius’s experiments at 57.5.

Such are the chief properties of lactic acid and its compounds. We have entered further into the description than we should otherwise have done, on account of the importance of the subject,—the lactic acid existing both in a simple and combined state in most of the animal fluids. See Blood, and Fluids, Animal.

LACTODORUM, in Ancient Geography. See Towercester.

LACTUCARIUM, a name given by Dr. Duncan to the insipid juice of the lactuca salvia, or common lettuce, and which has been found beneficial in various disorders, especially consumption, as an anodyne, where opium disagreed and could not be taken.

LADY-BIRD. See Coccinella.

LAFOURCHE, in Geography, a county of the territory of
of Orleans, containing in its interior, and in the parish of Assumption, 4467 inhabitants.

   —Native of Cuba. A tender annual, of little beauty. Herb downy, very soft. Leaves stalked, ovate, toothed; the lower ones opposite. Flowers terminal, white.

LAHORE, l. 10, for Schanguiro r. Shah Jehan.

LAKE, a town of Champaign county, in Ohio, containing 450 inhabitants.

LAKSHMI, col. 3, l. 4, for deities r. deity's wives.

LALESTON, Higher and Lower, in Geography, form a parish of Newcalle hundred in Glamorganshire. The Higher in 1811 contained 34 houses, and 177 persons; 81 being males, and 76 females; and the Lower contained 62 houses, and 271 persons; 111 being males, and 160 females.

LAMBERTH, 1. 25, r. 1811-17261; l. 24, r. 410,644, and 4491; l. 27, r. 338.

LAMBOURN, l. 13 and 14, r. In the year 1811, the population of the parish, with its dependent hamlets, viz. Blagrove and Halley, Ealbury and Bockhampton and Upper Lambourn, was 2674 persons, and the number of houes 527.

LAMP, Aphlogistic. Sir Humphrey Davy, during his researches on flame with the view to the construction of his safety-lamp for coal-mines (see Wire-Gauze), observed, that a fine platinum wire heated red hot and held in the vapour of ether would continue ignited. Soon after this curious fact was made known, Mr. Ellis of Bath thought of extending the principle, and found that a coil of fine platinum wire, flung into the wick of a common spirit-lamp (being previously heated), might be kept red hot for any length of time. The lamp thus constructed received the apppellations of aphlogistic lamp, lamp without flame, &c.

The platinum wire for this experiment should not exceed 1/5th part of an inch in diameter. About twelve coils of this (the coil being about 3/4ths of an inch in diameter, and as close together as possible without touching) are to be placed upon the wick of a common spirit-lamp, in such a manner that half be on the wick and half above it; the lamp is then to be lighted, and when the wire has become red hot the flame is to be blown out; the wire will then remain red hot for any length of time required, and in a dark room, if properly constructed, will emit a considerable light. Instead of alcohol, ether may be employed, or a similar effect may be produced by flicking the ignited wire into a piece of camphor.

LAMP, Safety, for coal mines. See Wire-Gauze.

LAMPIER, l. 2, r. 2301.

LAMPIE Acid, in Chemistry. The name recently given by Mr. Daniell to an acid generated by the combustion of alcohol, &c. by the aphlogistic lamp.

Sir Humphry Davy observed, during the combustion of ether in the manner above described, the formation of a peculiar acid pungent vapour, which he considered as a new product. Mr. Faraday soon afterwards described some of the properties of this acid, and more recently Mr. Daniell has given us a more full description. Mr. Daniell prepared it for his experiments by burning the aphlogistic lamp under an alembic head, and collecting the products; but we understand it may be formed much more readily by paffing the vapour of ether through a tube containing platinum wire. The lampic acid, when pure as possible, is a colourless fluid, of an intense yellow and pungent odour. Its vapour when heated is extremely irritating and disagreeable, and produces an oppression on the chest, something like that produced by chlorine. It reddens vegetable blues, and decomposes all the earthy and alkaline carbonates. Its fp. gr. when rectified as highly as possible, according to Mr. Daniell, is 1.015.

The Lamps of Potash and Soda are delequent fats, and do not readily crystallize. The lampate of ammonia is volatile, and easily decomposed. The lampate of barites readily crystallizes in colourless transparent needles. The lampates of lime and magnesia are delequent.

The lampic acid has the property, according to Mr. Daniell, of reducing many of the metallic oxys; this is particularly the case with the oxys of gold and mercury. When warm nitrate of mercury, according to Mr. Daniell, is mixed with lampic acid, a metallic flower takes place, and brilliant globules of mercury soon accumulate at the bottom of the vessel.

Mr. Daniell estimates, from his experiments, the weight of the atom of lampic acid at about 64, and considers it as composed of 1 atom hydrogen + 1 atom carbon + 1 atom water. How far these determinations are to be depended upon we cannot say, though we think it probable that they are incorrect.

LANARK, l. ult. r. 1811-1677-858.

LANARKSHIRE, l. 13, r. according to the parliamentary returns in 1811, the population of the county consists of 191,752 persons, occupying 32,040 houses; the males are 88,688, and the females 103,064: the families employed in trade, manufactures, and handicraft, are 27,672, and those employed in agriculture 5387.

LANCASHIRE, l. 21, r. 1811-144,283-828,309; l. 22, r. 114,522; l. 23, r. 23,305. The number of males was 394,104, and that of the females was 434,205.

LANCASTER. This county contains several villages and parishes, which, by the prevalence of its manufactures, are become populous, but which our limits will not allow us to mention.

Afton-under-Lyme (omitted in its proper place) deferves a particular notice as a parish in the hundred of Salford, which in 1811 contained 1042 houses, and 19,052 persons, viz. 9146 males, and 9966 females; 213 families being employed in agriculture, and 2737 in trade, manufactures, or handicraft.

Afton-in-Mankesfield is also a township in the hundred of Wel Darby and parish of Winwick, which contains 864 houses, and 1747 persons; viz. 2332 males, and 2405 females: 163 families being employed in agriculture, and 726 in trade, manufactures, &c.

LANCASTER, col. 4, l. 26 from bottom, r. 1811; l. 25, r. 1694 and 9247.

LANCASTER, in America, l. 5, r. 3927-44. Col. 2, l. 5, r. 5592 inhabitants, of whom 3112 were slaves in 1810; l. 7, r. 6318; l. 8, r. 1646; l. 18, add—by the census of 1810, 4545 inhabitants, including 700 slaves; l. 41, add—Alfio, a township of the same county, containing 928 inhabitants:—l. 43, r. 1694; l. 44, for Grafton r. Coos; l. 47, r. 1810, and 717.

LANDAFF, l. 2, r. 650.

LANDGRIVE, a town of Bennington county, in Vermont, having 299 inhabitants.

X LANDSCAPE,
LANDSCAPE, l. pednul., r. wherein. Col. 2, l. 6 from bottom, r. aims.
LANESHOROUGH, l. 3, r. 1502.
LANGAYA, a genus of serpents, the characters of which are, that it has abdominal plates, caudal rings, and terminal scales. Of this genus there is only one species, differing from all the rest of the serpent tribe in having the upper part of the body marked into complete rings, or circular divisions, resembling those on the body of the amphipus bana, while the extreme or terminal part is covered with small scales, as in the genus anquis. This species is called Langaya nafauta, or large-snouted Langaya, has 184 abdominal scales, and 42 caudal rings: it is a native of Madagascar, and was first described by M. Brugiure of the Royal Society of Montpellier. The natives of Madagascar are much afraid of this serpent, as they conceive it to be very poisonous.
LANGDON, l. 3, r. 632.
LANGHOLM, l. 5, r. 1811, 2636 perfons, occupying 522 houses.
LANGPORT, col. 2, l. 3, r. 1811—112; l. 4, r. 861.
LANTWIT, MAJOR, a parish of Cowbridge hundred, in the county of Glamorgan, containing, in 1811, 179 houses, and 786 perfons; viz. 357 males, and 429 females.
LANTWIT, LOOEY, a parish near Neath, which, in 1811, contained 116 houses, and 564 perfons; viz. 265 males, and 299 females.
LAR, l. 6, add—It still contains about 12,000 inhabitants, celebrated for the manufacture of muffets and cotton cloth. It has very handsome buildings, and particularly a bazaar, that is reckoned the noblest structure in Perfa. N. lat. 37° 30'. E. long. 52° 45'. See Tarem.
LARISTAN, l. 1, after Perfa, add—extending along the Northern shore of the gulf from E. long. 55° to 58°.
LARUS, col. 3, r. RIBBUNDUS.
LASCAR, a term in India, denoting a camp-follower, but applied to native sailors and artillerymen.
LASCO, JOHN. Add—A brief account has already been given of this famous reformer under ALASCO.
LASSUS. See ORLANDO.
LATIMORE, in Geography, a township of Adams' county, in Pennsylvania, having 666 inhabitants.
LAUD, l. 16 from bottom, r. Stanford.
LAVENHAM, at the clofe, r. 1811—308, and 1711.
LAUGHTER, l. 15, add—See LUNGS.
LAVINGTON, Ethl, l. 11, r. 1811: l. 12, r. 899—1843, l. 16, for Whorlton r. Potter and Canungra. l. 17, r. 1811—1781; l. 18, r. 582.
LAUNCESTON, col. 2, l. 4 and 3 from the end, r. 1811—1758, and 262.
LAUREAT, POET, l. 5, add—in anciently conferring degrees in grammar, which included rhetoric and verfification, at our universities, particularly at Oxford, a wreath of laurel was presented to the new graduate, who was afterwards usually styled " Poeta Laureatus." Thes scholastic laureations seem to have given rife to the appellation:—l. 19, after Edw. IV. infect—who appointed John Kay poet laureat, and who, according to Warton, was the king's first poet under this appellation. The only composition he has transmitted to posterity is a Profe English translation of a Latin history of the siege of Rhodes. In the dedication, addressed to king Edward, or rather in the title, he styles himself by bumble poet laureate. The fame appellation occurs under, &c. At the clofe, add—Warton's Hift. of English Poetry, vol. i, p. 128.
LAUROPHYLUS, in Botany, an exceptionable compound name.—Thumb. Prodr. pref. n. 16. Willd.
I. L. capensis. Thumb. Prodr. 31. Willd. n. 1. Ait. n. 1.—Found at the Cape of Good Hope. A tree, with round, brown, fhiming branches; alternate, oblong, fer- rated, smooth, coriaceous leaves; and minute flowers, in terminal panicles.
LAUSANNE, in Geography, a township of Northampton county, in Pennsylvania, having 157 inhabitants.
LAWSVILLE, a township of Luzerne county, in Pennsylvania, having 169 inhabitants.
LEAD, in Chemistry. According to the most recent determinations, maffic, or the prototest of lead, is a compound of 100 lead + 7.692 oxygen; and the brown or ferous, of 100 lead + 15.384 oxygen. Hence the weight of the atom of lead will be 130, oxygen being 16. From these data, the composition of all the other compounds of lead can be easily estimated. See Atomic Theory.
What is usually called minimum, or red-lead, is a combination of these two oxides, or of 2 atoms lead + 3 atoms oxygen.
Red-lead does not appear capable of combining with acids, at least no fact of which it forms a constituent is at present known.
LEAD, page 16, c. 2, l. 3, after gallic, read acid.
LEAD-ORES. See LEAD, and MINERALOGY, Addenda.
LEATHERHEAD. In 1811 the parish contained 312 houses, and 1209 perfons; viz. 580 males, and 629 females: 75 families being employed in agriculture, and 103 in trade, manufactures, and handicraft.
LEBANON, in America, l. 3, r. 1810; l. 4, r. 1938; l. 8, r. 2580; l. 11, 1810: l. 12, r. 1808. Col. 2, l. 3, containing 1434 inhabitants.—Also, a township in the same county, containing 2473 inhabitants.—Also, a town of Hunterdon county, in New Jersey, containing 2409 inhabitants.
Eff. Ch. Calyx in five deep acute segments, with rounded finches. Stamens all connected. Legume cylindrical, with many seeds.
Thumberg and Willdenow describe three species with simple, and five with ternate, leaves, all shrubs, found at the Cape of Good Hope. Three are in Hort. Kew. L. contamina, fericus, and cyrofolius, all previously referred to Sparium; see that article.
LECANORA, Ach. Syn. 146. " Lichenogr. 77. l. 7. f. 3—7;" a new genus, containing 139 species, of the Lichen tribe, being the crustaceous species of Parmelia; see that article.
LECHLADLE, l. 16 from bottom, r. 1811; l. 15, r. 993; l. ultl. r. 195.
LECIDEA, in Botany, Ach. Syn. 11. " Lichenogr. 32. t. 2. f. 1—7." A genus of Lichenes, chiefly the tuber- culatus of Linnæus, whose shields have no border from the substance of the frond or clyft, 153 species are now described, whose fronds are various.
LEDIBURY, col. 2, l. 17, r. 1811—3126; l. 18, r. 604.
LEDYARD, col. 2, l. 39, r. Ochotokl.
LEE, in Virginia, l. 6, r. 4954 inhabitants, of whom 336 were slaves in 1810; l. 16, r. 1329; l. 12, r. 1356.
LEE, a long measure in China, rather more than one-third of a mile.
LEEDS, col. 2, l. 25, r. 1811, the town and liberty contained.
LEP

contained, &c.; l. 26, r. 12,249 and 62,534; l. 27, r. 11,739 families were flated, &c.

Leeds, in America, l. ult. r. Kennebeck for Cumberland; after county, add—containing 1273 inhabitants.

LEEKE, l. 17, r. 1811—832; l. 8, r. 3792.

LEELITE. See Mineralogy, Addenda.

LEGEND, col. 2, l. 34, r. Sybaris. Col. 3, l. 36, for sound r. secret ; l. 8 from bottom, r. Coningham.

LEH, in Geography, add—Allo, a township containing 1188 inhabitants.

LEICESTER. At the close, r. 1811, 4609 houses, 23,466 inhabitants.

LEICESTERSHIRE, col. 3, l. 24, r. 1811—150—419; add—of whom 10,501 were males, and 12,345 females; 17,027 families were employed in trade and manufactures, and 11,700 in agriculture. The number of houses was 30,019.

LEIGH, West. In 1811, this township contained 341 houses, and 1960 persons; viz. 927 males, and 1033 females.

LEIGHTON-BUZZARD, l. 5, r. 1811—408 houses, 2114 inhabitants; of whom 187 families were employed in trade and manufacture, and 283 in agriculture.

LEITH. At the end, add—By the parliamentary return of 1811, North Leith had 1085 houses, and 4875 inhabitants; and South Leith had 838 houses, (if not a mistake in the number,) and 15,488 inhabitants.

LEMINF, or LIMINGTQ, l. 2, add—containing 1774 inhabitants.

LEMINF-PRORS, a parish of Warwickshire, in the hundred of Knightlow and Kenilworth division, contained, in 1811, 125 houses, and 543 persons; viz. 275 males, and 268 females. But since that period, it has been much returned to as a watering-place refembling Cheltenham; and the number of private houses, baths, hotels, and public buildings, for the accommodation and amusement of its visitors, has been very much augmented, and is every year increasing.

LEMNIAN EARTH. See Phragide.

LEMON, a township of Ohio, in Butler county, having 1308 inhabitants.

LEMPSTER, col. 3, r. 1810 and 8r.

LEMUR, col. 3, l. 17 from bottom, r. Macaco.

LENIOR, or LERQNE, l. 3, r. 5572, of whom 2449 were slaves in 1810.

LENOX, l. ult. r. 1310.

LENS, Cryphaline of the Eye, Chemical Properties of. See EYE.

LEOMINTH, col. 3, l. 19, r. the population of the borough and parish, &c.; l. 1811—3238; l. 20, r. 730.

LEOMINESTER, in America, l. 5, r. 1584.

LEONINE, l. 12, after Leonis, add—A French monk of St. Victor, at Marseilles, about the year 1135; l. 14, after III. — But rhymes in Latin verbs were in use much earlier. See Warton's Hist. of Poetry, vol. i. diff. ii. At the close, add—See Rhyme.

Four Weft Indian species are described, small plants, each with a thick, solitary, roundish leaf, and one or two clusters of minute flowers.

L. crista, Wildenow's only species, from the East Indies, bears aggregate, sessile, fleshy balls of flowers, chiefly about the crown of the root. The numerous flesms are decumbent, eighteen to twenty inches long, leafy, square. Leaves linsple, oblong, rough-edged. Mr. Brown has corrected the character, as above, from various Chinese and tropical species, in Mr. Banks's herbarium.

LEPIDOLITE. See Lepidolite, and Mineralogy, Addenda.

LEPSIA. Add.—It is now called Lipso.

LERIA, l. 2, after Strabo, add—This little island has three harbours, and is paid to produce abundance of the wood of aloes, so much esteemed in Turkey as a perfume; though others have doubted this fact, on account of the high price of this wood at Constantinople. In this island is a monastery, and it has a town called Lera.

LERWICK. At the close, r. 1811—1049; add—

the number of houses was 252.

LESQGEAN, one of the small islands of the Daghelia, consisting of a stupendous range of mountains, very long but narrow, and forming the whole N.E. frontier of Georgia. The Lefigi or Lefighans, who inhabit this country, are a wild and savage banditti, divided into different tribes and speaking a different dialect. Their houses are situated on the loftiest mountains, and on the most tremendous precipices: they are connected by stone or wooden bridges, and roads carried through rocks; and they are supplied with water by pipes or canals cut out of the rocks. The soil is scanty, and in order to furnish them with the means of subsistence, the surface is increased to the summits of the elevated ground by graduated terraces, the intermediate space being filled up with rubbish, and covered with earth. These people are the bravest, as well as the most turbulent, of all the nations of Mount Caucasus, exciting terror in their neighbours, laying waste their cottages, and carrying away the inhabitants into servitude. They have long preferred their liberty and independence, and resisted their country inaccessible to any foreign invaders. Most of them are Mahometans; and the few tribes that continue in ignorance, never change the object of their veneration, which is either the sun, moon, or stars; or indeed any thing that has made an impression on their minds. They hire themselves to fight the battles of their neighbours, at the price of twelve rubles the campaign, which is to cease at the end of three months from the appointed day. They often take different fides, not caring against whom they fight; and thus it often happens, that the Lefighan falls by the sword of his brother or most intimate friend. They are lightly drest, after the manner of the Tartars, and armed with a gun, pistols, dagger, and sable. Their women surpass in symmetry and beauty all the females of Mount Caucasus, and fetch the largest prices in the markets of Constantinople. M'Kinze's Persian.

LESSERTIA, in Botany, named in honour of the late Mr. Stephen Deleffert, to whose mother Roufseau's celebrated Letters on Botany were addrefized, and who, like all his family, was no less endeared, to those who knew him, by personal worth than by talents.—"De Cand. Alfragal.

3 X 2

37."
LEX

L. annua, (Colut.-a herbacea; Linn. Sp. Pl. 1045.), and L. perennans, (C. perennans; Jacq. H. Vind. v. 3. t. 3.), see Colutea, n. 11 and 12; with L. diffusa, (Galega dubia; Jacq. l.c. Rar. t. 176;) are the only species in Hort. Kew. all natives of the Cape of Good Hope, composing a very natural genus.

LEWIS, in Geography, a township of Gallia county, in Ohio, having 591 inhabitants.

LETTERKENNY, l. 2, r. 1549.

LEVER, col. 2, l. 3, dele (See Plate Surgery.)

LEYVERT, l. 4, r. 769.

LEVES. At the close, r. The population of the rape of Lewes was flated in the parliamentary return of 1811, to be 18,659 persons, occupying 2932 houses.

LewIS XVI. col. 15, r. 44, r. the fon, Lewis XVII., died very miserably June 8th, 1795, and his father, Maria Theresa Charlotte, was delivered up in exchange for deputies, December 26th, 1795. The queen was brought to the scaffold on October 16th, 1793; and Elizabeth, the king’s sister, May 12, 1794. Col. 11, l. 2, add—Lewis XVIII., on whom the crown devolved after the death of Lewis XVI. and his son Lewis XVII., retired, during the subséquent period of the Revolution, (which feé,) first to Petersburg, and was allowed a procéllion by the emporor of Ruffia, April 3d, 1798; he afterwards fought an army in this country, and landed at Yarmouth, under the title of the Count de Lille, October 6th, 1807; and being recalled to the throne of France, made his public entry into London from Hartwell, where he had reféed, April 21st, 1814; and having failea from Dover April 23d, made his entry into Paris May 3d, 1814; but quitted this city again in confection of the landing of Buonaparte in France, March 21st, 1815. After the battle of Waterloo, he returned to Paris, and refumed the government, July 8th, 1815.

Lewis, in Geography, a county of New York, containing 6433 inhabitants, of whom 4 were slaves in 1810.—Alfo, a township of Ohio, in Clermont county, having 993 inhabitants.—Alfo, a county of Kentucky, containing 2337 people.

LEWISBURG, a town of Kentucky, in Mason county, having 19 inhabitants.

LEWISHAM. In 1811, the parish contained 1105 houses, and 6625 persons; 2923 being males, and 3702 females.

LEWISIA, in Botany, in memory of Meriwether Lewis, eq. late governor of Upper Louifiiana, the discoverer of several new American plants.—Pursh 368.—Clafs and order, Polyandria Monogynia. Nat. Ord.....

1. L. rediviva. Pursh n. 1.—On the banks of Clark’s river, perennial, flowering in July. Leaves radical, linear, rather fuculent. Stalk radical, bearing one or two hand- fome white flowers, whole calyx is elegantly veined with red. Pursh.

LEWISTOWN, l. 3, r. 1028; l. results, r. 474.

LEXIS WACEIN, a township of Wayne county, in Pennsylvania, containing 165 inhabitants.

LEXINGTON, l. 2, add—containing 6641 inhabitants, of whom 1711 were slaves in 1810; l. 19, after univerty, add—or college, a Lancasterian school, and other wel- regulated seminaries; l. 22, r. in 1810, was 4326, of whom 1509 were slaves. In 1817, it amounted to 6000, though in 1773 it was merely a hunting camp; l. 28, after Georgia, add—in Oglethorpe county, having 113 inhabitants; l. 34, add—in 1810, the inhabitants were 1052.

LEYDEN, l. ult. r. 1009.

LEYLAND, a township of Leyland hundred, in Lancashire, which, in 1811, contained 459 houses, and 2646 persons; 1263 being males, and 1383 females; 97 families employed in agriculture, and 391 in trade, manufactures, and handicraft.

LIBEL, col. 4, l. 30, dele pilory.

LIBERTY, l. 12, r. 6228 inhabitants, of whom 4808 were slaves in 1810. At the close—Alfo, a township of Butler county, in Ohio, containing 1790 inhabitants.—Alfo, a township of Ohio, in Delaware county, containing 206 inhabitants.—Alfo, a township of Highland county, in Ohio, having 1120 inhabitants.—Alfo, a township of Ohio, in Trumbull county, having 473 inhabitants.

LICHEN ISLANDICUS, Chemical Composition of. This has been submitted to a rigorous and curious analysis by Berzelius. Our limits will not permit us to enter into the details, but the following are the results:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syrup</td>
<td>3.6</td>
</tr>
<tr>
<td>Bitartrate of potash, with some tartrate of lime</td>
<td>1.9</td>
</tr>
<tr>
<td>Phosphate of Lime</td>
<td></td>
</tr>
<tr>
<td>Bitter principle</td>
<td>3.0</td>
</tr>
<tr>
<td>Green wax</td>
<td>1.6</td>
</tr>
<tr>
<td>Gum</td>
<td>3.7</td>
</tr>
<tr>
<td>Extractive colouring matter</td>
<td>7.0</td>
</tr>
<tr>
<td>Starch</td>
<td>4.6</td>
</tr>
<tr>
<td>Starchy insoluble matter</td>
<td>36.6</td>
</tr>
</tbody>
</table>

We presume in the above analysis the excess of weight (if not an error) was owing to water.

This indefatigable chemist afterwards examined other species of lichen, such as the L. barbatus, L. sylvaticus, and the L. fraxinosus. He found them all characterized by the presence of a species of thclic which poffedles several peculiar properties.

LICHIIFIELD, l. 4, r. 1811—1010 houses, 5022 inhabitants, 509 families employed, &c.

LICK, a township of Ohio, in Ross county, having 334 inhabitants.

LICKING. Add—Alfo, a county of Ohio, containing 7 townships, and 3852 inhabitants.—Alfo, a township of the said county, having 632 inhabitants.—Alfo, a township of Ohio, in Muskingum county, containing 7956 inhabitants.

LIEOU-KIEOU, or LOO-CHOO, or Great LOO-CHOO, l. 2, after number, add—or rather innumerable. At the close, add—The belt maps are wrong in the situation of Loo-choo. They place its town between 25° 45’ and 27° 53’ N. lat. and between 128° 5’ and 129° 6’ E. long. The island is also made to extend about 130 miles from N. to S. with an uniform breadth of about 30 miles. Its true direction is nearly N.E. by N. and S.W. by S.; its length is only 36 miles, and its breadth about 11. The longitude of the western extremity is 120° 34’ E., and of its eastern 128° 16’. The latitude of the S. point is 26° 43’ N., and of the N. point 26° 52’ N. See an interesting account of these islands in Capt. Hall’s Voyage to Loo-choo, or Edinburgh Rev. No. 58. p. 460, &c.
LIME, in Chemistry. Lime, according to the recent determination of Dr. Thomson, is a compound of 100 calcium + 38.09 oxygen; hence the weight of the atom of calcium will be 26.25, and of lime 36.25. We expect that the weight of the atom of lime will be hereafter proved to be 37.5. See Atomic Theory.

The salt of lime, commonly known by the name of oxymuriate of lime, and employed for bleaching, has been recently demonstrated by Dr. Thomson to be a real chlorite of lime, and not a chlorite of calcium; that is to say, it is a compound of chlorite and lime. (See Bleaching, Chlorine, and Oxy-Muriatic Acid.) Dr. Thomson has also rendered it probable, that barytes, frontonian, potash, and soda, as well as many of the metallic oxides, likewise unite with chloride and form chlorites of the respective bales.

LIMERICK, in America, l. 4, r. 177; l. 5, r. 1282.

LIMINGTON, Add.—with 1774 inhabitants.

LINCOLD, col. 6, l. 4, and from bottom, r. 1811—1813—8861.

LINCOLD, in America, l. 1, 3, after Warren, Add.—The number of inhabitants, in 1810, was 42,992; l. 22, r. 16359—2489. Col. 21, l. 3, r. 4555; l. 4, 2212; l. 5, r. 8676—2341; l. 11, r. 109; l. 13, r. 221; l. 15, r. 713. Add—Alfo, a county of West Tennessee, containing 6104 inhabitants, of whom 720 are slaves.

LIMONSHIRE, l. 8, r. 1811—46,368—237,891; l. 9, r. 117,022 males, 120,869 females, 13,184 families; l. 11, r. 29,881.

LINCOLD TOWN, Add.—Alfo, a town of Georgia, in Lincoln county.

LINCOLDVILLE, Add.—It contains 1013 inhabitants.

LIME, in Fortification. Add.—See Field-Fortification.

LINGA, col. 2, l. 2, for fire r. fine.

LINLITHGOW, l. 11, r. 1811—4022—535; the country part having 229 houfes, and 1465 perfons; and the town part having 306 houfes, and 2557 perfons.

LINLITHGOWSHIRE, col. 2, l. 15, r. 1811—19,451, occupying 3098 houfes; the number of males is 8874, and that of females 10,577; of these 1560 families are employed in trade and manufactures, and 1132 in agriculture. Col. 4, l. 18, after town, Add.—The number of houfes in the parish is 352, and of perfons 2704.

LINNÆUS, col. 5, l. 24, r. journal. Col. 8, l. 19, r. Caper. Col. 11, l. 12, r. Oeland. Col. 15, l. 7, r. Ham-malney.

LINOZOSTIS, Add.—See Mercurlinis.

LIQUIDS, Expancion of. See Expansion and Heat, LISBON, in America, l. 3, r. 1128. Add—Alfo, a town of Maine, in the county of Lincoln, having 1614 inhabitants.

LISKEARD, l. 32, r. in the year 1811, the borough and parish were returned to parliament as containing 523 houfes, and 2884 perfons; the borough having 361 houfes, and 1975 perfons.

LISMORE. At the clofe, Add.—By the returns of 1811, the parish of Lifmore, in the diocf of Lorn, contains 252 houfes, and 1323 perfons.

township contained 266 houses, and 1442 inhabitants. Col. 2, l. 5, for Friday r. Saturday. Add—It has six fairs in the year.

Llandrinod. Add—In 1811, the parish was returned as containing 32 houses, and 171 inhabitants.

Llan-elly, l. 3, r. 1811; l. 4, r. 862, and 1891; l. 16, add—This is one of the most thriving places in South Wales. It abounds with excellent coals and iron-ore, extensive iron-works, and also lead and copper ores.

Llan-gadog vawr, l. ult. r. 1811—1964; and add—378 houses.

Llangollen, l. 4, r. 1811; l. 5, add—theope of the parish, comprehending three townships, amounted to 612, and the inhabitants to 2897.

Llannerch y medd, l. 3, add—the part of the parish of Amlech contains, by the returns of 1811, 920 houses, and 4210 inhabitants.

Llan rhaiadar, col. 2, l. 6 and 7, r. 1811—1974; add—414 houses.

Llanrwst, near the clove, r. 1811—2502, and 452 houses.

Llanstephan, col. 2, l. ult. r. 1811—927—221.

Llantrissent, l. ult. r. 1811—246—2122.

Llanvyllin, of Llanyllin, l. ult. r. 1811; the parish of Llanvyllin contained 291 houses, and 1508 inhabitants.

Llanydloes. Add—By the return of 1811, the parish contained 470 houses, and 2386 inhabitants.

Llapharne, l. ult. r. 1561; and add—the number of houses was 283.

Loche. See corbit.

Llockerbie. In 1811, the whole parish of Drydale contained 369 houses, and 1893 persons; 504 being males, and 902 females.

Logan, l. 2, r. 11591, including 2285 slaves in 1810.

Lonchurus for lonchurus.

London, in Geography, a town of Rockingham county, in New Hampshire, having 1492 inhabitants.

London Britain, a township of Cheltenham county, in Pennsylvania, having 404 inhabitants.

Londonderry, in America, l. 5, r. 2765; l. 16, add—containing, in 1810, 637 inhabitants.—Also, three townships in Pennsylvania, one in Dauphin county, having 2411 inhabitants; date the rest of the article, and add—the second in Cheltenham county, having 1164 inhabitants; and another in Bedford county, having 486 inhabitants.

Londongrove, l. 2, r. 983.

Long Meadow, l. ult. r. 1026.

Long Sweep, a township of Mercer county, in Pennsylvania, having 908 inhabitants.

Longtown. In 1811 this township contained 173 houses, and 1579 persons; viz. 744 males, and 835 females: 169 families being employed in agriculture, and 417 in trade, manufactures, and handicraft.

Longtown, a township of Ewesley hundred, in the parish of Clodock, and county of Hereford, which, by the returns of 1811, contained 164 houses, and 844 persons; viz. 423 males, and 421 females: 124 families being employed in agriculture, and 40 in trade, &c.

Lo-e-choo. See lie-ou-keod.

Loe, Eas., l. 14, r. 1811—128—608.

Loe, Ws. l. 13 and 14, r. 1811—92—433.

Lostwithiel, col. 2, l. 17 and 18, r. 1811; for town r. borough and parish—132 houses, 825 inhabitants.

MADDERING, an operation performed in Calico-Printing; which fee.
MADDOX, l. 32, dele to that of St. Asaph; and for and from thence to r. that of Worcester.
MADELEY, l. 9.—In 1811, the parish contained 1026 houses, and 5076 persons; viz. 2502 males, and 2574 females: 18 families being employed in agriculture, and 747 in trade, manufactures, or handicraft.
MADISON, l. 4, r. 8381 inhabitants, of whom 3970 were slaves in 1810; l. 7, r. 11,587—3000. At the end, add—Alfo, a township of Maine, in Somerset county, having 686 inhabitants.—Alfo, a county of New York, containing 25144 inhabitants, of whom 35 were slaves in 1810.—Alfo, a township of Ohio, in Guernsey county, having 1449 inhabitants.—Another in Highland county, with 430 persons.—Another in Knox county, with 138 persons.—Alfo, a county of Ohio, containing six townships, and 1623 inhabitants.—Alfo, a township of Montgomery county, with 426 persons.—Another of Muskingum county, with 426 persons.—Another of Pickaway county, with 406 persons.—Another of Butler county, with 1228 persons.—Another of Columbian county, with 739 persons.—Another of Gallia county, having 170 inhabitants.—Another of Scioto county, with 307 persons.—Alfo, a town of Georgia, in Morgan county, having 124 inhabitants.—Alfo, a county of the Muscogee territory, having 4899 inhabitants, of whom 948 were slaves in 1810.—Alfo, a township of Clarke county, in the Indiana territory.

MADRID,
MADRID, in America. At the close, add—The district, by the census of 1810, contains 2103 inhabitants, of whom 287 were slaves.

MAD-RIVER, a township of Champaign county, in Ohio, having 1008 inhabitants.

MAGIC, Superstitious, infect—has been suppos'd to consist in l. 2, infect after its—suppos'd; l. 7, del. half.

MAGIC SQUARE, col. 5, l. 18 from bottom, del. and. MAGNESIA, in Chemistry. According to the latest determinations, the weight of the atom of magnesia is 25, that of oxygen being 16; from this, the composition of its salts can be easily ascertained. See Atomic Theory.

Separation of Magnesia from Lime.—We may take the opportunity of mentioning here an ingenious method of effecting this difficult chemical problem lately proposed by Mr. R. Phillips, and originally suggested, we believe, by Mr. T. Cooper. The two earths are to be reduced to the state of sulphate, and then well washed with a saturated solution of sulphate of lime, which readily diffolves, and thus separates the sulphate of magnesia, but which, from its being already saturated, can take up no more sulphate of lime.

MAGNESIAN LIME-STONE. See MINERALOGY, Addenda.

MAGNESITE. See MINERALOGY, Addenda.

MAGNESIUM, in Chemistry, the metallic balls of magnesia. See Magnesia.

MAGNOTS. At the end, add—See Maine.

MAHBBING, a township of Northumberland county, in Pennsylvania, having 629 inhabitants.

MAHIM, for 17 miles N. of Bombay r. 7 miles N. of Bombay fort.

MAHONING. Add—In Indiana county, having 532 inhabitants.—Also, a township of Mercer county, in the same state, having 1216 inhabitants.

MAHONTOGO, Lower and Upper, two townships of Berks county, in Pennsylvania; the former having 637, and the latter 439 persons.—Also, a township of Northumberland county, having 1608 inhabitants.

MAID, or Maiden. See Virgin.

Maid, in Ichthyology. See Skate.

MAIDENHEAD, in America, l. 4, r. 1810—1086.

MAIDSTONE, col. 3, l. 21, &c. r. 1811—9443; viz. 4412 males, and 5031 females: of whom 942 families are employed in trade and manufactures, and 437 in agriculture. The number of houes is 1706.

MAIDSTONE, in America, l. 2, r. 177.

MAIN, a district of the Morea, including that part of the country anciently called Laconia, that lies between the gulf of Melene and Gythium, bounded on the N. by the highest range of Taygetus, from which a chain of rugged mountains descends to Cape Matapan, the southern termination of the country. It is watered by Pamfus, now the Fornetas, the broadest river of the Peloponnesus. The plains round Calamata, a town towards the N.W., are fertile and well cultivated, abounding with the cactus, a prickly pear, the white mulberry affording food for great numbers of fik worms, and various fruit-trees. The town is built on a plan that is well adapted for defending the inhabitants against the attacks of the pirates that infest the coast. The government of the Main, in 1705, refembled that of the Scottish islands in former time. Over each district presided a capitan, whose residence was a fortified tower. Each chief, besides his own domain, received a tithe from the produce of the land of his retainers; and the different chiefs were independent of each other. Because the Mainots were reluctant to submit to the chararach, or poll-tax, they had been repeatedly attacked by the Turks, but without success; when an enemy appeared, the coast was immediately deserted, and the inhabitants retired to the strong holds of Taygetus. Expert also in the use of the rifle, besides the advantages of their situation, they have been able to defy the Turkish forces. Some of the chiefs were found by Mr. Morritt to be tolerably vered in Roman literature, and some capable of reading Herodotus and Xenophon. The laws of hospitality were observed amongst them with the strictest punctiliousness, and letters of recommendation secured to travellers a friendly reception. The religion of the Mainots is that of the Greek church, with all its munimony. Their women were never clad nor enlaved, and therefore neither corrupted nor ignorant. They distinguished themselves by attention to domestic management, and the education of their children. Infanies of conjugal infidelity were rare. In case of necessity, it is said that the Mainots can bring 12,000 men into the field. See Walpole's Memoirs on Turkey, &c. 1817.

MAINE, at the close, add—See United States.

MAINOTS. See Maine.

MAKEFIELD del.: add—See Wakefield.

MAKONGO, one of the states of Loango in Africa, of which Malemba is the port. The king of Makongo, or Malemba, refides inland at a town called Chingale, the Kinkale of the charts.

MALABAR, l. 11, add—The Malabar language prevails on the western coast of Cape Comorin, extending over Travancore and Malabar, formerly named Kerala, as far N. as Nilisuran. See Toolava.

This appears to us a very natural and well-defined genus, though hitherto confounded with Cheiranthus. The three species in Hort. Kew. are,

1. M. maritima. See Cheiranthus, n. 143; a pretty annual, frequently and easily cultivated.

2. M. africana. (Hepheris africana; Willd. Sp. Pl. v. 3. 532. Leucojum gallicum, folio halimi; Bocc. Sic. 77. f. 42, f. 1.)

3. M. littorea. See Cheiranthus, n. 21. (Leucojum marium minus; Cluf. Hilj. v. 1. 298, f. 2.)

MALDEN, col. 2, l. 12, r. 1811; l. 13, r. 250—259.

MALDEN, l. 4, r. 1384.

MALEMB, or Malemba. Add—See Makongo.

MALIC Acid, in Chemistry. See SORBIC Acid.

MALKOHA. See PHENOCHEUS.

MALLENDERS, a cutaneous disease, commonly confined to draught-horses: it is an inflammation of the skin below the hock, producing cracks which discharge a fetid matter. For the cure of this disorder, owing to the want of cleanliness and friction, the hair should be clipped, and the parts well washed with soft-soap and water; and Mr. White recommends the following ointment: viz. a composition of 2 oz. of wax ointment, 1 oz. of olive-oil, oil of turpentine and camphor, of each 1 dr., and 2 drs. of acetate water of litharge. Mr. Ryding recommends a mixture of 1 oz. of strong quicksilver ointment, and 10 grs. of muriated quicksilver.
silver in fine powder. When this disease occurs above the knee, it is called tallowing.

MALLING, West, l. 6 and 7 from the bottom, r. 1811—1154—223. Add. —In 1811, the number of houfes in East Malling was 217, and of inhabitants 1256.

Malmesbury, vol. 2, l. 34; r. 1811; l. 35; 237—1154.

Malpas. In 1811, the township contained 103 houfes, and 938 perfons; vin. 478 males, and 460 females.

Malta, a town of the district of Maine, in the county of Kennebeck, having 468 inhabitants.

Måvern, Great, l. 22 from the bottom, r. 1811—1205 inhabitants, occupying 204 houfes.

Mammon, St. r. S. Mamot.

Mammalia. Delte the account of the plates.

The name of mammoh has been given to two very different animals, whose remains are found in a foillil rate; the firft, which has been before ages called fo by the Ruffians and Siberians, occurs abundantly on the north part of the ancient continent. It is a species of elephant, the ivory of which is fo well preferred as to become an article of commerce. This animal, according to the refearches of Cuvier, is a different species of elephant from that of India or Africa, resembling the former moft. The American mammoh, as it has been called, belongs not only to a species different from the European mammoh, but from the Indian or African elephant, and from the form of its teeth must be even clofl as a different genus; he has given it the name of maitodon. See Mastodon, Addenda.

Of the Ruffian maitodon very erroneous accounts have been published, particularly refpefwng its fize. An animal of this kind having been difcovered preferred entire in the ice, by a Tungufian fisherman in Siberia, was afterwards defcribed by Mr. Adams; but, according to Cuvier, the great fize attributed to it by that gentleman does not accord with the actual admeafurement of the bones, the hea1d, weighing, according to this account, four hundred pounds, which brings it nearly to the known fize of the foillil elephant.

The moft remarkable fact defcribed by Mr. Adams is, that the animal was covered with two kinds of hair; the one red, which was both of a finer and cofer fort; the other was long, black, and bright. This hair was very abundant. The fact proves two things of importance in the natural history of the mammoh, namely, that it was a different species from living elephants, and that it was sufficiently covered to enable it to live in cold climates. It is a commonly received tradition in Siberia, that these animals are frequently found entire in the ground, from whence the name of mammoh is derived, which signifies an animal that lives in the earth. According to Cuvier, thefe facts prove that the foillil elephant perifhing by a fudden revolution of the globe that defroyed the whole species, and which froze the individuals that were then in the northern regions: nor can any reafl be advanced why these remains should not continue preferred in the eternal ice of thofe countries, till difcovered by accident, or the hands of man. Thofe which were overthrown and buried in moft southern climates are more decomposed, and their bones have become more or lefs friable; but this decomposition is the only change which they have undergone; they are neither broken nor rolled, and it may be clearly perceived that they perifhed where their bones are now found. Many bones of the fame species of mammoh, or foillil elephant, have been difcovered in different parts of England. We have fed a tooth, one of the molares of these animals, found near Whithby in Yorkshire, which measured fourteen inches round.

Vol. XXXIX.

The greaftest number of the teeth of the mammoh that have been examined refemble at firft light thofe of the Indian elephant; but, according to Cuvier, the fcx, and the variety, on more attentive obervation, will be found somewhat different. In the living species of elephants, the fize of the teeth varies with the fcx, the color, and the varieties; and as they continue to grow during the life of the animal, age determines their dimensions more than any other caufe. The fusks of the African elephant are larger than thofe of the Indian; they are harder, and preferve their whitefnes better. According to Poennant, Mofambique furnifhes fusks of living elephants ten feet in length, which are the largest that are known. The degree of curvature in the fusks differs as much as the fize; some occasionally occur in a fpiral form, and fome in that of the letter S. We are uneafily acquainted with the differences that might exift in the curvature of the fusks of the mammoh occafioned by difference of sex or other caufes. Many of the fusks have the common degree of curvature, but others have much more curvature than occurs in any living elephants, approaching to a femicircle or half an ellipse divided through its tranverfe axis. Some fusks of the mammoh are formed fpiral, like what fometimes occur among living elephants. The height of the mammoh did not greatly exceed that which the Indian elephants can attain. It is neverfey certain from its remains, that the mammoh differed as much from the Indian elephant as the afs differs from the horfe.

The bones of the mammoh, or foillil elephant, are generally found in alluvial foil, near the surface of the ground. They are seldom isolated, but generally mixed with bones of other quadrupeds of known genera; as the rhinoceros, the ox, the horfe, and the antelope; and are often accompanied with the remains of marine animals, fuch as shells, parts of which are attached to the bones. Cuvier fates that he has in his pofeflion a jaw-bone covered with millepores and oylers.

The beds which cover the bones of the foillil elephant have feldom any great depth, and are scarcely ever comafoned of ilone. They are rarely petrified, and only one or two infallances are quoted where they were incurred with a fkeletal ilone. Often they are only accompanied with fresh-water shells. Every thing appears, fays Cuvier, to announce that the caufe by which they were buried is one of the moft recent, that has contrived to change the furface of the globe. It was nevertheless a caufe general in its operation, for these foon bones of elephants are too numerous, and occur in countries too remote and uninhabited to allow us to fuppofe that they have ever been brought there by man.

The beds which contain and cover these remains fhew, that the caufe by which the animals were defroyed was water, and in many infallances the waters were the fame as thofe of the prefent day, since they contained the fame fcx of shells-fish. Thofe bones are not waterworn, and therefore have not been transplanted from a diftance.

The shells and millepores which adhere to them prove that they remained fome time covered only with water. The different fcx of maitodon, the gigantic tapir, and the foillil rhinoceros, lived in the fame countries as the foillil elephant, fince their bones are found in the fame beds and preferved in the fame flate. Every thing therefore leads us to conclude that the mammoh, or foillil elephant, is an extinct fcx, though it differs fes from exiling fcxes than the other remains of quadrupeds that are found in the fame fracutions. In a former part of this work, under the article Megatherium, the difcovery of the foillil elephant described by Mr. Adams is more particularly given; but the animal is erroneously fuppofed to belong to another species.
MAN

species than the elephant, and the tusks are called horns. (See Mastodon, Megalonyx, and Megasaurium, Addenda.) According to Pallas, there is scarcely a river from the Don or the Tanais to Tchutkoins in the banks of which the bones of the mammoth are not abundant, and two ilands of great size near the mouth of the Indigefika. The bones and bones have been generally found in alluvial soil over the chalk formation; but in Dr. Bakewell's Introduction to Geology, it is given of an entire skeleton having been found in a cavern in the mountain lime-stone near Wirksworth, in Derbyshire, in 1663. Its skull was so large that it is flatted to have held four bufenels of corn.

MANCHA, La, l. 1 and 2, r. bounded on the N. by New Caflile; dele north of.

MANCHESTER, l. 10, add—In 1811, the number of houses in Manchester and Salford was 16,533, and that of the inhabitants 98,573; 44,332 being males, and 54,241 females; of whom 15,639 families were employed in trade and manufactures, and 47 in agriculture. l. 15, r. the whole population of which, including Manchester, was 135,449.

Manchester, in America, l. 4, r. 1137; l. 7, r. 1502; l. 9, r. 1579; l. 10, r. 978; add—Allo, a town of Hillisborough, in New Hampshire, containing 615 inhabitants.

MANÈGE, or MANÈGE, denotes an academy, riding-school, or other place for learning to ride, and for breaking horses to their various motions and actions. Allo, the exercise itself, or the art of riding, which teaches at the same time to form the horfeman and the horfe.

MANÈ-SHEET, in the Manège, a covering for the upper part of a horfes head, extending round his neck, with holes for the ears to pass through, and joining to the halter upon the fore-part of the head, and likewise to the curingale, or long girth, upon the horfes back.

MÂNANESE, in Chémistri. The specific gravity of manganese, according to Dr. John, is 8.013. A good deal of confusion still exists respecting the oxyds of this metal. According to Dr. John, there are three oxyds; the green, the brown, and the black. According to Berzelius, there are but two, namely, the olive or protosyd, which combines with acids, and forms the common falt of manganese, and the black or protosyd, which is found native. From the experiments of Dr. John and Berzelius, Dr. Thomson fixes the weight of the atom of manganese at 35, and of course that of its protosyd at 45; from which data, if correct, the composition of its falt may be estimated. The following erratum exists in this article in the Cyclopaedia. Col. 3, l. 16, for malats r. metals; also in the same paragraph, 9, at the end of the fentence respecting iron, add—Berzelius has lately shewn, that manganese is a constituent of cast iron.

MÂNGE, a cutaneous diseafe, incident to many domestic quadrupeds, and attended with an eruption and lofs of hair. Its caufe, according to Mr. Ryding, are, sudden changes of temperature, hot fables, bad diet, and want of cleanlines. It is also communicated by infection, as when a found horfe rubs himfelf againft a flall, in which a mangy horfe

had been kept. Its fymptoms are, lofs of flefh, without any apparent caufe, a flaring of the coat, and afterwards eruptions, difcharging a thick yellowish matter, which forms a kind of feur that peals off, and a falling off of the hair. The disorder, though partial at first, soon spreads all over the body, and is attended with an itching, which caufes the horfe to rub againft every thing that comes in his way. It is said, that if the horfes rub their tails, an ointment composed of 1 lb. of prepared hog's-lard, ½ lb. of sulphur, 3 oz. of white helbore in fine powder, and olive-oil in fufficient quantity, rubbed over the affected parts, and repeated after an interval of three days, will after two or three applications complete a cure. Some fay, that if the animal's strength will allow it, the cure fhould be commenced with bleudings, and a ball formed of powdered nitre, powdered robin, and caftile foam, of each ½ oz., 1 drachm of camphor in powder, and honey 2. should be given in the evening. Attention fhould be paid to diet, exercise, and good grooming; the bowels fhould be kept in a proper flate with mashes, in which 1 oz. of nitre is dilufed; the affected part fhould be well washed with a strong folution of loft-foap, and afterwards rubbed morning and evening with an ointment composed of 4 oz. of flowers of sulphur, 3 oz. of hog's-lard, and 2 oz. of quickfine ointment. The ointment may be continued every other day, until the difeafe is removed. Two or three doses of mild phlyce are recommended, and then a ball made of t. Ethiopa's mineral, crude antimony in powder, and cream of tartar, of each ½ oz., and honey 2. should be given every night for a month.

In a flight cafe, strong tobacco infufion with one-third part of filce urine, ufed for washing the affected parts, will be fufficient; but as an efficacious unguent, the following is recommended; viz. ½ lb. of quickfine ointment, 4 oz. of finely powdered brim Stone, 2 oz. of black foap, 15 oz. of crude faf ammoniac, and oil of bays and turpentine q. s.; or tar, gun-powder finely pulverized, black foap, and oil of turpentine, of each about equal quantities; the fores may be washed twice a day with a lotion composed of 4 oz. of muricated mercury (fubsinate) in powder, diluted in 1 pint of boiling water; or muricated mercury, muricated ammoniac (crude faf ammoniac), of each from two to three drachms, and three half pints of boiling water.

MANHEIM, l. 3, r. 1282; l. 5, r. 2207; add—Allo, a township in Berks county, having 1354 inhabitants.

MÂNINGTREE, l. 18, r. 1811; l. 19, r. 1075—217.

MÂNNA, Chemical Properties of. Manna differs from fugar in several remarkable particulars. It diffolves very readily and abundantly in alcohol, and crystallizes on cooling. Nitric acid converts it partly into oxalic, and partly into fufulphuric acid. It does not ferment like fugar, and of course yields no alcohol. The common manna of the fllops, according to Fourcroy and Vauquelin, confits of four different ingredients. Pure manna conftituting about three-fourths of the whole—a little common fugar—a yellow matter with a naufeous odour, to which the purgative qualities of manna are chiefly owing—and a little mucilage, convertible into fufulphuric acid. Manna seems to be formed during the fermentation of many juices, such as the juices of the onion, melon, &c.

MÂNNINGTON. Add—containing, in 1810, 1664 inhabitants.

MÂNTUA,
MANTUA, a township of Ohio, in Portage county, containing 2,425 inhabitants.

MARAZION, l. 15 and 13 from bottom, r. 1811—184—1022.

MARBLEHEAD, l. 4, r. 5900.

MARECHAUSSÉS, denoted, under the French monarchy, several small bodies of troops, composed of officers and soldiers who had been in service, that continued stationary in the principal towns, for the purpose of aiding the civil magistrature. That in Paris consisted of three companies; viz. the company belonging to the "Lieutenant criminel de Robe au Coutre," or to that particular court of judicature, which was fortified by the provost de la Marechaussee, and which Charles IX. attached to the gendarmerie; the independent company of mounted police, called "Guet à Cheval;" and the company of the police or foot patrols, called "Guet à Pied," which was again subdivided into two companies, in order that one might do the duty of the quays. These companies were under the immediate direction of the secretary of state for the interior department of Paris.

MARGARIC ACID, in Chemistry. This acid exists in the form of pearly scales; hence the name. It was first described by Chevreul, who obtained it by digesting a foap made of hog's-lard and potash in water. Part of the margarate of potash was dissolved, while another part was deposited in the form of pearl-coloured scales. The potash was afterwards removed by muriatic acid, and thus the margaric acid obtained in a state of purity. Margaric acid is pearl-white. It is talc-like, and emits a smell something like white wax. It melts at a temperature of 134°, and crystallizes on cooling into beautiful brilliant white needles. It is insoluble in water, but very soluble in alcohol. It reddens vegetable blues very readily, and combines with all the bases, especially with the alkalies and alkaline earths, forming salts, or rather foaps. Dr. Thomson, from the experiments of Chevreul, fixes the weight of the atom of this acid at 320.

MARLBOROUGH, in America, l. 4, add—containing 4996 inhabitants, of whom 1709 were slaves in 1810; l. 7, r. 16745; l. 12, r. 1810—145-14; l. 14, r. 1112. Col. 2, l. 1, r. three l. 2, after Pennsylvania, place one in Montgomery county, having 672 inhabitants; and E. and W. Marlborough, in Chester county; the former having 1046, and the latter 917 inhabitants.—Allo, a town of Hartford county, in Connecticut, having 720 inhabitants.—Allo, a township of Delaware county, in Ohio, containing 177 inhabitants: l. 5, r. 1832.

MARLOW, Great, col. 2, l. 16 and 17, r. 1811—225—1166 persons; add— and its borough to contain 468 houses, and 2799 inhabitants; l. 20, add—in a parish of the same name, which contains 140 houses, and 730 inhabitants.

MARLOW, in America, l. 2, r. 564.

MARPLE, a township of Delaware county, in Pennsylvania, having 649 inhabitants.

MARSELESS, The, or Marrelles Hymn, a national march, adopted by the French during the course of the Revolution, and regularly played in their armies when they went to battle. It was frequently accompanied, or rather succeeded by the "ça ira," a lively tune; the former being calculated for slow or ordinary time, and the latter for quick movements. Both are now proscribed.

MARSHFIELD, l. 25, r. 1811—272; l. 26, r. 1415.

MARSHFIELD, in America, l. 4, r. 1364; l. 6, r. 513.

MARSHPEE, l. 3, r. 139.

MARTHELLO, or Morello, Tanger, denoting small cabbages erected for the defence of a coal; such are those of Lord Mary Martel, of the town of Jersey, Halifax, in Nova Scotia, &c. Grose defines the term mortelio, from morta, whence morta or mortar, which formerly signified a cale. Others derive it from the Italian "fouare in campana a martello," to found the alarm bell, which, in some parts of Italy, is struck by hammers. In old French, the word signifying the same thing, (now marcello,) was marcel, and marcel en tete was the adage for the humour of annoyance or alarm.

MARTOCK, l. 2, r. 1623.

MARI—Add—This was the ancient capital of the province of Margiana, founded by Alexander the Great, and afterwards embellished by Antiochus Nicator, who called it Antiochia. It was one of the four imperial cities of Khorasan; its fruits were finer than those of any other place, and the walls were on all sides surrounded with flatly palaces, groves, and gardens. It was taken and pillaged by the Ulbecks about 25 years ago; since which time, it has gradually declined, and the population is now reduced to 3000 souls, under the government of Hyder Shah of Bokhara. The revenues of the khan are 20 mounds of grain, and 60,000 rupees annually. It is 88 furlongs from hence to Herat. Delo the next article.

MARY, queen of Scotland, l. 2, infer (or 7th), Col. 2, l. 29, after their own, add—This article, says Mr. Chalmers, "ubi infra" denuded the Scottish queen, who was heir-prefumptive to the crown of England, of all future pretensions to the crown. The fluctuation, he says, ought to have been, not in all times coming, as expressed in the article, but during the life of Elizabeth. Considering, moreover, the defective powers of the French negotiators to treat of a matter of that importance, in addition to the wordings of the clause, these circumstances created an imperceptible objection to the ratification of such a treaty; which treaty was never ratified by the Scottish queen, or by any person under her authority. Col. 4, l. 8, for Her r. Darnley l. 20.—We know for certain, says Mr. Chalmers, that the king was murdered by Murray's faction, and that Morton, Bothwell, and Maitland, were the eminent characters who were attained by parliament for the deed, though many inferior persons and some of the innocent, were tried and punished for the same crime. But the queen, he says, as she was not one of that faction, was not guilty; and every attempt of Robertson and Laing to establish her privity to this transgression has failed. Col. 6, l. 28, after employers, add—Queen Elizabeth, it has been said, wished to have had Mary put to death privately by poison or by asphyxiation, and actually suggested and expressed her wishes to this purpose, and she thus acted suitably to the declaration made by her on Palm-funday 1572; viz. "that the queen of Scots' head should never be quiet."

At length, when her dark hints or more explicit instructions, communicated to Paulet and Drury her keepers, had failed of producing effect, preparations, &c. l. 29, after publicly, add—but the privy-councillors differed in their opinion
opinion concerning the law by which she should be tried, whether it should be the statute of treasons, (25 Edw. III.) or a late act of the 27th of Elizabeth, which had been made for this special occasion. However, the last opinion prevailed. At the close, add—Chalmers's Life of Mary, Queen of Scots, vol. 1. 4to. 1818.

MARY, St. col. 2, l. 8, r. 12,794; l. 9, 6000; l. 13, add—in the county of Camden, which see.

MARYLAND. Add—See United States.

MARYPORT, col. 2, l. 5 and 6, r. 1811—322—312. 313—314.

MASHAM, l. 7, r. 1811—213—1014.

MASOLES, the name of a militia in Croatia, which is bound to march to the frontiers whenever there appears the least symptom of hostile disposition on the part of the Turks. The private soldiers have lands allotted to them, which they cultivate for their own use, but receive no pay from the public. The officers are paid.

MASON, l. 7, r. 1077.

MASSACHUSETTS. Add—See United States.

MASTODON, in Natural History, a large quadruped, whose bones are found in a fossil state. It was for a long time confounded by naturalists with the mammoth or woolly elephant. (See Mammoth, Addenda.) Cuvier has ascertained, that the mastodon is not only a distinct animal from the mammoth and the living species of elephants, but that it must be classed as a new genus. Five species of this genus have been at present discovered.

The great mastodon, or the animal of the Ohio, the bones of which have been found in the greatest abundance near the Ohio river, in the province of Kentucky, in North America, bears a considerable degree of resemblance to the elephant in its tusks and general osteology, the form of the grinders excepted. It had probably a trunk, but this part being more perishable than the bones has not been discovered. Cuvier concludes from its general structure, that it could not have fed itself without the aid of a trunk. Its height did not surpass that of the largest elephant, but its body was longer, and its members were somewhat thicker; its belly was less extended than that of the elephant. Notwithstanding the general resemblance, the structure of the grinders is so different, as to entitle us to class it as a different genus. It fed itself nearly in the same way as the hippopotamus and the wild boar, on the roots and pulpy parts of vegetables; and this kind of food would naturally lead it to moist and marshy ground; but it was not made for swimming, or living under water, like the hippopotamus, but was really a land animal. Its bones are more common in North America than elsewhere, and are more fresh and better preserved than any other known fossil bones. Yet there is not the least reason to believe, according to Cuvier, that there are any living mastodonts either in America or elsewhere. The most celebrated place where the remains of the mastodon occur is called Big-bone Lick, on the south-east of the Ohio, five miles from the river, and thirty-six miles below the entrance of the Kentucky river, and nearly opposite the great Miami. The place where they occur is a flat marsh surrounded by hills. The bottom of the marsh is a black and fetid mud. The bones are found in the mud and on the borders of the marsh at about four feet below the surface, but they occur also in various parts of North America in marshy situations. In 1825, many bones of these animals were found in the county of Wythe, in Virginia, about five feet under the earth, upon a bed of limestone. One of the teeth weighed seventeen pounds. But renders this discovery the more remarkable is, that a mass of half-ground branches, roots, and leaves, inclosed in a kind of sack, supposed to be the aliment, was found in the midst of these bones, so as to leave no doubt that these were sublimacies that the animal had devoured. Among the vegetable matter in this sack were distinguished the remains of some plants known in Virginia. The bones of the great mastodon may be said to be common in North America; two nearly entire skeletons were collected by Mr. Peale; one of the largest is preserved in the Museum of Natural History at Philadelphia, the smaller was exhibited in London a few years since. These bones are scarce in other parts of the world; but wherever they have been found, it is at no great depth under the soil, and yet they are but little decomposed. They are not rounded by attrition, and offer proofs that they have not been removed from the places where the animals died. The skeletons found near the river called the great Oafages were nearly in a vertical portion, as if the animals had simply sunk into the mud and been buried there. According to a letter from Mr. Smith Barton, professor at the university of Pennsylvania, to M. Cuvier, "An intelligent traveller had seen near that river thousands of these bones, and had collected seventeen tusk, some of which were six feet in length, and a foot in diameter; but the greater part of these bones was much decomposed." Mr. Barton sent a grinder to M. Cuvier, so that no doubt can be entertained that the bones belonged to the mastodon. No remains of marine shells have been discovered with the bones of the mastodon, as is the case with those of the mammoth. Mr. Barton thinks, that the salt water of the marshes where they are found has contributed to the preservation of the bones. He states also two instances which appear to prove that from time to time the soft part or flesh of these animals has been dug up; a circumstance which, from the heat of the climate, is much more astonishing than what is stated of the flesh of the mammoth and rhinoceros being found in Siberia. (See Mammoth.) The Indians, who discovered five skeletons in 1762, relate, that one of the heads had a long nose above the mouth; Mr. Barton supposes that this was in fact the trunk. Kalm, in speaking of a great skeleton discovered by the savages in a marsh in the Illinois country, says, that the form of its beak was still discoverable, though half decomposed; it is probable that this was the root of the trunk.

Some doubts exist whether the mastodon be really an extinct genus, and whether it may not be found living well of the Mississippi. The Indians of Virginia, according to Mr. Jefferson, say, that a troop of these formidable beasts destroyed the deer, buffaloes, and other animals created for their use; when the great man above destroyed them all with his thunder, except the largest male, which presenting its head to the thunder-bolts threw them off as they fell, but being at last wounded in the side, it fled towards the lakes, where it lives to this day.

The skeleton of the great mastodon exhibited in England was near eleven feet high. From the size of detached bones, Cuvier conjectures that the animal never exceeded twelve French feet, but its body was much longer in proportion than that of the elephant.

The form of the crown of the molars or grinders is nearly rectangular. The sublunacy of the teeth is of two kinds only, the inner or office part, and the outer or enamel, which is very thick, and has no kind of cement or cortical. This very important difference joined with the form brings this animal nearer to the hippopotamus and the pig, than to the purely herbaceous animals like the elephant.

The crown of the grinders is divided by deep open furrows into a certain number of transverse ridges, and these ridges...
ridges are again divided into two large irregular pyramidal oblique points, a little rounded. The crown therefore is fluted with these pyramidal points disposed in pairs; it is however very different from the teeth of carnivorous animals, which have only one principal longitudinal furrow, divided into finer indentations, like a few. The teeth of the elephant have on the crown several little transverse walls, divided into a number of small tubercles, and these grow flat early, whereas the tubercles or cones on the tooth of the mastodon being much larger, the crown remains long mamillated. It was this circumstance of the grinders being fluted with points that gave rise to the opinion of the mastodon being carnivorous.

The number of grinders, according to Cuvier, are six on each side, three above and three below.

The structure of the jaws indicates that the mastodon had tufts like the elephant or mors. The number of tufts which occur with the teeth further confirms this opinion. A skull was found by Mr. Peale which proves this fact, being furnished with alveoles. The curvature of the different tufts varies as much as in those of the elephant; but Mr. Cuvier thinks there is no ground for believing with Mr. Peale, that the tufts turned downwards. The head of the mastodon being of vast size, and rendered exceedingly heavy by the teeth and tufts, which carried the centre of gravity far from the point of support, the neck was therefore necessarily short, like that of the elephant; so that without a trunk it could not have reached the ground with its mouth. Its tufts would also have deprived it of the power of eating on the ground; it is therefore certain that it must have had a trunk like that of an elephant.

From the remains of the mastodon, it appears there were five species, all of which are believed to be extinct,

1. The great mastodon that we have been describing.
2. The mastodon with narrow grinders. The remains of this species have been dug up at Semorre, and many other places in Europe, and also in America.
3. The little mastodon with small grinders. This species is much less than the preceding, and was found in Saxony.
4. Mastodon of the Cordilleras. This species was discovered in South America by Humboldt. Its grinders are square, and it appears to have been equal in size to the great mastodon.
5. Humboldtian mastodon. This, which is the smallest species of the genus, was found in America by Humboldt. These five species may be considered as forming a distinct and hitherto unknown genus.

The following are the dimensions of the skeleton of the great mastodon found by Mr. Peale, and placed in the Museum of Natural History in Philadelphia.

MATHIOLA, or Mathiola, in Botany, Brown in Art. Hort. Kew. v. 4. 119. See our former article. Mr. Brown has redorsed this meritorious name, to degitate a new genus of his own, extracted from the more hoary kinds of Cheiranthus, (see that article,) n. 16, 17, 20, 23, 31, 28, and 15. We allow a difference of habit, but fearfully perceive a sufficient character.

MATLOCK, l. 14, r. 1811—523—2497.

Vol. XXIII.

MAURICE, l. 4, add—The town contains 2085 inhabitants.

MAURY, a county of West Tennessee, containing 10,530 inhabitants, of whom 2626 were slaves in 1810.

MAWS, St. In 1811, the parish of St. Jufl contained 272 houses, and 1630 persons; viz. 751 males, and 888 females: 72 families being employed in agriculture, and 99 in trade, manufactures, and handicraft.

MAYOMBA, or MAZUMBA, Cape, a cape on the coast of Africa, in S. lat. 3° 34'. E. long. 11° 13' 30'.

MEAD, a township of Crawford county, in Pennsylvania, containing 786 inhabitants.

MEADVILLE, l. 5, after houses, add—457 inhabitants.

MECKLEBURG, l. 2, r. 18, 453 inhabitants, of whom 16,264 were slaves in 1810; l. 6 and 7; r. 14, 272—3494.

MECONIC ACID, in Chemisty. See Morphia, and Opium.

MECRAN, or Mekran. At the end, Kidge or Kej, add—The population of Mekran is formed of many different tribes and independent chiefs, of which the Balouches are the most numerous; a middle-sized race of men, spare, muscular, and active, and armed with a match-lock, sword, shield, and dagger. The common language of the country is a corrupt Persian, mixed with Scindi, and the Balouches in general are of the Soonee perfumation. Those of the central territories reside mostly in towns; those of the lower countries are scattered over the plains, in hamlets of eight or ten huts, built of branches of palm, and covered with mats. The Balouches take, in general, but one wife, and their chiefs four; they are said to have great influence in the disputes of their tribes. The women of Mekran are allowed to appear indifferently in public. Mekran was formerly under the dominion of Nafier Khan, the chief of Kela; but since his death, in 1795, the authority of his son has ceased, and of the dominions of his father he only retains posseession of the fort of Kej. The whole force of the country, it is thought, may amount to about 25,000 men, whom it would be impossible to collect or to induce to concur in action. The revenues of this country are trifling.

MEDFIELD, l. 39, r. 786.

MEDFORD, l. 6, r. 1443.

MEDICAL ELECTRICITY. Since our remarks on medical electricity (see Medical Electriciy) were written, a method has been announced, in some degree new, of exhibiting this remedy, which we shall very briefly notice here. This consists in employing a jar coated on the outside with paper tinfoil, and instead of a costing on the inside, having only a spiral coil of wire in contact with its surface. On making the experiment, we find the shock is modified and softened by this contrivance. It appears, therefore, much better adapted for administering what is commonly called vibratory shocks (that is to say, small shocks in very quick succession,) than the jar commonly used for the purpose. We omitted to mention that this method of exhibiting electricity (called vibratory) is commonly practiced by electricians, chiefly from its requiring
requiring a very small apparatus, and from its being at the same time equal, or nearly so, in effect to a large current of fluid produced from a very powerful machine.

MEDOMAN, in Geography, a town of America, in Maine, and county of Lincoln, having 121 inhabitants.

MEDULLIN, in Chemistry, a name given by Dr. John to the pith of the sunflower, the *strogylo vulgaris*, &c. and which, according to him, is distinguished by the following properties. It is insoluble in water, alcohol, ether, and oils. It has neither taste nor smell. It is soluble in nitric acid; but instead of forming fulfure acid, furnishes a quantity of oxalic acid. Its structure is peculiar, and when burnt it leaves a charcoal having a metallic bronze-like appearance.

MEDWAY, in America, l. 4, r. 1213.

MEERSCHAUM. See MEERSCHAUM, and Mineralogy, Addenda.

MEGALONIX, in Natural History, an extinct species of quadruped, about the size of an ox, whose remains were first discovered in Virginia. It was suppos'd by Mr. Jeffereon to be allied to the lion, and hence received its name. According to Cuvier, however, the megalonix and megarhizium are nearly allied, and may be considered as belonging to the same genus, which may be placed between the floth and the ant-eaters, but nearer to the former than the latter. The remains of these animals have hitherto been found only in America, where floths and ant-eaters are present. See MEGATHERIUM, Addenda.

MEGATHERIUM. (See MEGATHERIUM.) The animal described in the former part of that article, whose remains were found in Siberia, and noticed by Mr. Adams, was not the megarhizium of Cuvier, but the foifil or extinct elephant. (See Mammoth, Addenda.) The megarhizium was of the size of the rhinoceros; its foifil remains have hitherto been found only in South America. The first and most complete skeleton was sent from Buenos Ayres in the year 1789. It was found in digging in alluvial soil, on the banks of the river Lauzen, a league S.E. of the village of that name, and three leagues W.S.W. of Buenos Ayres. A second skeleton was sent from Lima to Madrid in the year 1795; and a third was found in Paraguay. This animal differs from the megalonix chiefly in magnitude, being much larger. See Cuvier's description in the latter part of the article MEGATHERIUM.

MEGIDDO, or MEGIDO, in Scripture Geography, a city of Manaffeh (Joel xvi. 11. Judg. i. 27.), famous for the defeat of King Josiah. (2 Kings xxii. 29, 30.) Herodotus, speaking of this victory, says, Necho obtained it at Magdolob, dib. ii. cap. 159.

MEIGS, in Geography, a township of Adams' county, in Ohio, having 835 inhabitants.

MEKRAN. See MEKRAN.

MELDRUM. In 1811, the parish of Old Meldrum contained 411 houses, and 1635 per sons; viz. 736 males, and 919 females: 345 families being employed in agriculture, and 86 in trade, manufacturers, and handicraft.

MELFORD, Long, l. 5 and 6, r. 1811—415—2068—951—1117.

MELLIT, in Farrowy, a dry flat growing upon the heels of the foot of a horse, which is cured by a mixture of half a pound of common honey, and a quarter of a pound of black soap, with four or five spoonsful of vinegar, half an ounce of finely powdered alum, and two spoonsful of fine flour, applied to the affected part, after removing the hair, like a plaster, and suffered to remain five days. If the cure be not completed, the leg, foot, and fore, should be washed, and the same application repeated.

MELMOTH, col. 2, l. 20 and 21, r. thus—The author of 'The Pursuits of Literature' says, "Mr. Melmoth is a happy, &c.

MELROSE, l. 12. In 1811, this parish contained 538 houses, and 3132 persons; viz. 1531 males, and 1601 females: 239 families employed in agriculture, and 251 in trade, &c.

MELTON-MOWBRAY, l. 24 and 25, r. 1811—451—2115.

MENALLEN, a township of Fayette county, in Pennsylvania, having 1228 inhabitants.

MENANGEEBOW, for MENANGEBOW.

MENDHAM. Add—containing 1277 inhabitants.

MERA, l. 14 from bottom, after Linga, add a comma.

MERCER, after acres, add—16 townships, 8277 inhabitants; l. 6, 11,587 inhabitants, of whom 3000 were slaves in 1810.—Alfo, a township of Mercer county, having 262 inhabitants.—Alfo, a township of Butler county, in Pennsylvania, having 888 inhabitants.—Alfo, a township of Maine, in Somerset county, having 562 inhabitants.

MERCURY, p. 12, col. 2, l. 12 from bottom, for Todd r. Thomon.

Mercury. This metal boils, according to Crichton, at 65°; according to Heinrich at 69°. These differences respecting the boiling point of this metal, as well as those mentioned in the original article, probably arise in part from the mode in which the thermometers employed were graduated. See further on this subject under Heat.

There are but two oxides of mercury known, and not three, as stated in the Cyclopaedia, the black or protosyl, and the red or peroxyl; the first of which, according to Dr. Thomson's recent determinations, is a compound of 100 mercury + 4 oxygen; and the second, 100 mercury + 8 oxygen. Hence the weight of an atom of this metal will be 250, and from this the composition of its salts may be deduced. (See Atomic Theory.) What has been said in our original article respecting calomel and corryswe sublimates, formerly termed suburate and oxyurate of mercury, is now to be understood, according to the present views of their composition, as applicable to the protochloride and perchloride of mercury. See further on this subject under Chlorine.

MERDIN, l. 7. Its inhabitants amount to nearly 11,000 souls; l. 9, add—there number is supposed to be 1500, having several churches, and a synagogue; and besides here are 200 Jews, and also Turks, Arabs, and Kurds. At the end, add—it is 46 furlongs from Diarbekr. It is the frontier of the pachale of Bagdad, towards Conabantinople, and under the government of a Musulleeam, appointed by the pacha.

MEREDITH, l. 4, r. containing 1940 inhabitants.

MERIDEN, a town of New Haven county, in Connecticut, having 1249 inhabitants.

MERION, l. 3, r. 1156—1835.

MERIONETHSHIRE, col. 5, l. 37 and 38, r. 1811—6022—50924—145086—16616—3619—1270.

MERRIMACK, l. 3, r. 1048.

MERTHYR-TYDVIL, col. 2, l. 30, add—in its five hamlets, by the parliamentary returns of 1811, is rated to amount to 11,104 persons, occupying 2264 houses.

MERTON, l. 4, r. 1811: l. 5, r. 135—905.

MERU-SHAH-JEHAN. See MURU.

MESCHID, Meschid, or Mifched, l. 1, infer—the capital of the Persian division of the province of Khoraffan, situated about two furlongs from the ruins of the ancient city of Tous, and celebrated for a very superb sepulchre, containing the relics of Imam Reza, and those of the caliph Haroun ul Rufchid. This city, though a great part of it
MIC

it is in ruins, has a population of 50,000 souls. The bazaar is well supplied with fruits and provisions, from the fertile plain on which it is situated. It is surrounded by a strong wall, three forfings in circumference, and the great bazaar is three miles in length. The city is governed by one of the king's sons, and the district belonging to it yields a revenue of 50,000 tomus. It carries on a considerable trade with Bokhara, Bulkh, Candahar, Yezd, and Herat. Velvets of the finest quality are manufactured here; and its fur peltries are much esteemed.

MESHEE. See Meschino.

MESHEE All. See Meshef.

METALL, in Geography, a town of Franklin county, in Pennsylvania, having 1236 inhabitants.

METALS, in the Materia Medica, col. 2, l. 24, for Todd r. Thompson.

METEOR, an iron. See MINERALK, Addenda.

METHERVAN, in Geography, a town of Essex county, in Massachusetts, containing 1181 inhabitants.

METEWOLD, col. 2, l. 4, r. 1811—942—174.

METROXYLON, in Botany, a name given by Rottboll, in the Copenhagen Traductions, to the true Sago Palm, described from Dr. König's manuscripts, by Mr. Charles König, in Ann. of Bot. v. 1. 195. t. 4. This genus appears to differ from Gerten's Sagus, (see that article,) in having a corolla; which is monopetalous and three-cleft. See Sago.

MEXICO, coll. 15, l. 21 from bottom, add—The industrious researches of the ingenious and philosophical traveller M. Humboldt have established the remarkable fact, that in the whole of the New Continent, there is nothing which indicates the existence of alphabetical writing, nor any very near approach to it. Although the use of hieroglyphic paintings was common among the Toltecs, Aztecs, and other tribes, which, since the seventh century, have appeared successively on the elevated plain of Anchua, Humboldt suggests, that the progressive perfection of symbolical writing, and the facility with which objects were painted, prevented the introduction of letters. It is alleged, that they have done so for a much longer time with the Chinese.

MIAMI, a town of Clermont county, in Ohio, containing 1670 inhabitants.—Alfo, a town of Greene county, in Ohio, having 794 inhabitants.—Alfo, a town of Hamilton county, in Ohio, having 455 inhabitants.—Alfo, a town of Ohio, containing 6 townships, and 3941 inhabitants.

MICHIGAN. Add.—The territory of Michigan includes four districts, viz. Detroit, Erie, Huron, and Michilimackinac, and by the census of 1810, 4702 inhabitants, of whom 24 were slaves.

MICKLEHAM, col. 2, l. 1, r. 1811; l. 2, 416 persons, occupying 54 houses; l. 3, 190—226.

Mr. Pursh speaks of Arenaria saxifragula as probably belonging to this genus, but we know not whether he intends the plant of Limeux, or of Jacq. Aufr. t. 182; see Engl. Bot. l. 1744.

MIDDLEBOROUGH, l. 3, r. 4400.

MIDDLEBURY, l. 6, r. 2188; add.—Alfo, a town of New Haven, in Connecticut, having 847 inhabitants.

MIDDLEFIELD, l. 3, r. 822.

MIDDLESEX, col. 2, l. 4, r. 1811—130,613 houses, 953,776 inhabitants; viz. 434,613 males, and 518,663 females; of whom 135,308 families are employed in trade and manufactures, and 4988 in agriculture.

MIDDLESEX, in America, l. 5, r. 44; l. 6, r. 52,789. Col. 2, l. 9, r. 8—20,723; l. 10, r. 57 were in 1810; l. 14, r. 20,383; add—Alfo, a township of Chittenden county, in Vermont, having 401 inhabitants.—Alfo, a township of Butler county, in Pennsylvania, containing 568 persons.

MILDETTON, l. 3, r. 541; l. 8, after houses, add—2014 inhabitants.

MIDDLETOWN, l. 3, r. 3368 inhabitants.—Alfo, a township of Columbus, in Ohio, having 579 inhabitants.

MIDDLETON, col. 2, l. 23, r. 1811; l. 24, r. 442 persons, occupying 805 houses.

MIDDLETOWN, l. 3, add—containing 439 inhabitants; l. 4, add—having 1207 inhabitants; l. 7, r. 976; l. 17, r. 3849; l. 23, add—containing 948 inhabitants; l. 34, after Cumberland, add—having 2351, and the third in Bucks county, having 1462 inhabitants.

MIDDLEWICH, col. 2, l. 10, r. 1811; l. 11, 279—1232.

MIDHURST, l. 8, r. In 1811, the borough and parish contained 1256 persons, occupying 166 houses; 66 families being employed in agriculture, 127 in trade and manufactures.

MIEMITE. See Mineralogy, Addenda.

MIFLIN, l. 4, r. nine; l. 9, r. this county contains 12,132. Add—Alfo, a township in Allegheny county, in Pennsylvania, containing 637 inhabitants.—Alfo, a township of Rens county, in Ohio, with 445 inhabitants.

MILBORNE PORT, coll. 2, l. 7, r. 1811, l. 8, r. population of this borough and parish amounted to 1000 persons, occupying 224 houses; 474 being males, and 526 females; of whom 132 families were employed in trade, and 78 in agriculture.

MILDENHALL, l. 25, r. 1811; l. 26, r. 2493, occupying 355 houses; 1187 being males, and 1306 females;—278—11.

MILFORD, col. 3, l. 39, 40, r. 1811—1961, the number of houses being 352.

MILFORD, in America, l. 2, containing 2095 inhabitants; l. 3, 973; l. 11, containing 2033 inhabitants; l. 18, and 2674 inhabitants.—Alfo, a town of Hillyborough county, in New Hampshire, containing 1117 inhabitants.—Alfo, a township of Wayne, in Pennsylvania, having 87 persons.—Alfo, a township of Somerset county, in the same state, with
MIL

with 1180 inhabitants.—Also, a township of Butler county, in Ohio, having 1037 inhabitants.

MILFORD, New, a town of Litchfield county, in Connecticut, having 3337 persons.—Also, a township of Luzerne county, in Pennsylvania, having 178 inhabitants.

MILK, col. 5, l. 29 from bottom, for oxifying r. offlifying.

After the observations on curd, add—\textit{Curd} has many of the properties of coagulated albumen. It is white and solid, and when all the moisture is squeezed out, it has a good deal of brittleness. It is precipitated by acids, and the precipitate consists of the curd combined with the acid employed. If this precipitate be digested with carbonate of lime or barytes in water, the acid combines with the earth, remains undissolved, and leaves the curd in solution. The aqueous solution of curd thus obtained is yellowish, and resembles a solution of gum. When the solution is boiled in an open vessel, it becomes covered with a white pellicle, precisely as milk does, and acquires the smell of boiled milk. The membrane is almost insoluble in water, and appears to be produced by the action of the air on the diffused curd. With the mineral acids, curd forms the same compounds as albumen and fibrin do; but the neutral compounds are less soluble. A great excess of acetic acid is required to diffuse curd, and the neutral compound of curd and this acid appear insoluble. According to the analysis of Gay Lussac and Thenard, curd is composed of

MINERAL CAOUTCHOUC. See Mineralogy, \textit{Addenda}.

MINERALOGY, according to the most eminent mineralogists of the French school, comprises the study of all inorganic substances that exist naturally in the earth, or on its surface. According to this comprehensive definition, water, air, and all ponderable elementary matter, may be classified with minerals. The German mineralogists use the term \textit{mineral} in a more restricted sense. See \textit{Mineralogy}, where is given a history of the progress of this science, and an outline of the systems of Werner and Haüy. For a more full account of the external characters of minerals and of the system of classification introduced by Werner, see \textit{Oryctognosy}; and for the leading principles of crystallography, on which the system of Haüy is formed, see \textit{Crystallography}, \textit{Addenda}. Under the article \textit{Systems of Mineralogy}, we have given a summary view of the chemical system of mineralogy recently attempted to be introduced by the distinguished Swedish philosopher Berzelius.

Mineralogy has scarcely been cultivated as a regular science in Europe longer than fifty years, and in England it has not excited much attention until the present century; since which time our acquaintance with the mineral kingdom has been rapidly extending. We propose in the present article to describe those minerals which have been recently discovered, or whose characters have been more accurately known since the articles were written in which they were described. Many minerals having received several different names, we have also deemed it expedient to give an alphabetical list of all the known species of minerals, with references to the particular name under which each is described. This will, we trust, in a considerable degree, remedy the inconvenience resulting from the use of multiplication of names; an evil which, in this department of science, tends greatly to retard the progress of useful knowledge. To Werner, we are indebted for the first precise definition of the external characters of minerals; but unfortunately both he and the mineralogists of the Freyberg school have introduced such a multiplicity of divisions, subdivisions, and minute distinctions into the science, with so many quaint terms to express what was before perfectly definite in the language of common life, that the description of the most intelligible properties is often rendered harsh and obscure to the student. This is greatly to be regretted, as it prevents many from cultivating mineralogy, deterred by a parade of frivolous distinctions which affright them in limine. The
MINERALOGY.

The characters of minerals, arranged according to the Wernerian method, are enumerated under the article Oryctognosy; but a selection of the most important ones, with a further definition of some of them, appears necessary to render more complete this department of our work, and to enable the general reader to understand the descriptive language used by mineralogists. The characters of minerals are either physical or chemical. Physical characters are those properties which can be discovered without decomposing or changing the nature of minerals; under this term we comprise the external characters of Werner, and also some of those properties which are elicited by the action of other bodies on the mineral examined, such as magnetism and electricity.

Chemical characters in mineralogy are those properties which are most easily discovered by the action of heat, of acids, and of various re-agents. It is in this limited sense that these characters are underfoot by the mineralogist.

A complete analysis of minerals belongs to chemistry.

In our enumeration of physical characters, we shall commence with those which depend on the action of light; namely, colour, transparency, lustre, and refraction.

Colour is regarded by the German mineralogists as an important character, and it is that which first arrests the attention of the observer; but in earthy minerals, the colours of the same species are often so various, that this character loses much of its value as applied to them. The colours of minerals, as far as they have been chemically examined, are principally owing to metallic oxides and inflammable matter: the earths, the acids, and the alkalies, in a flature of purity, are white or colourless. The colour of earthy minerals may, therefore, be regarded for the most part as arising from accidental admixtures with unimportant ingredients. But in the inflammable minerals and metallic ores, and in a few of the earthy minerals, the colouring matter is as important as the other parts, and generally more so; hence in the latter, the colour varies but little in each species, and is a character of importance precisely in proportion to its simplicity. For an enumeration of the different varieties of each colour, and the minerals in which they are most characteristic, and for change of colour, see Oryctognosy.

Transparency, in its different degrees, from perfect transparency, demi-transparency, translucence, and opacity, are terms perfectly intelligible to every reader. When the cloudiness in semi-transparent minerals increases, so that the outline of objects can scarcely be seen, translucent commences, as in common chalcedony.

Double Refraction, or Duplicating, is the property which some transparent minerals possess of presenting a double image of an object when seen through them in particular directions, of which calcareous sparry, an Iceland crystall, offers a remarkable example. See CRYSTAL OF ICELAND.

Opalescence, a term not unfrequently applied to some minerals, is thus defined by Mr. Jameson: "Some minerals, when held in a particular direction, reflect from some fingle spots in their interior a coloured shining lustre; this is what is understood by opalescence: it is distinguished into simple and stellular; in the latter, the lustre diverges in fixed rays in the form of a star, as in the star-sapphire."

Lustre.—The lustre of a mineral produced by the reflection of light is of different kinds, and is called metallic, semi-metallic, adamantine, pearly, refrinous, and vitreous. Perfectly opaque minerals, as the metals, and most of the metallic sulphures, reflect the light wholly from the surface without undergoing any refraction, and exhibit the metallic lustre of various degrees of intensity; and the lustre is increased, and the colour is unchanged, when a scratch is made in them with a knife or file. Minerals having a semi-metallic lustre yield a lighter colour, or have their lustre destroyed when scratched. The adamantine lustre is exhibited by minerals which are translucent, and possess great refractive power; the lustre is reflected from the interior of the mass with great vivacity, and is produced both by reflected and refracted light. Examples, the diamond, sulphur, and the native salts of lead. In these minerals, though the lustre is increased by polishing, yet its particular character is lost distinct, owing to the increased reflection of unrefracted light from the surface.

The pearly or nacreous lustre is well exhibited in some kinds of zeolite, and in kyanite. When it proceeds from fibrous minerals, as in satar spar and fibrous gypsum, it is sometimes called a silky or fatdy lustre.

The refringent lustre is well represented by that of pitch: it exibits in pitch-flake and refrinous flints.

The vitreous lustre is perfectly represented in rock crystal.

Each of these kinds of lustre may vary in degree from the most splendid, which can be seen at a great distance, to shining, glittering, or glimmering. When entirely defective, a mineral is called dull.

The break implies the colour or lustre which a mineral exhibits when scratched with a knife or file: the colour is the same as that of the mineral when pulverized.

Salping is a character that occurs in some soft minerals, which leave a mark when drawn on the surface of other bodies, or on the fingers, as plumbago, chalk, and reddle.

The above are the principal characters depending on the action of light.

Phosphorescence.—Certain minerals give out light when rubbed against each other, as quartz; or when scratched with a knife, as dolomite. Other minerals give out light, when thrown on hot coals, or heated iron, as fluor spar; and certain minerals emit light when exposed to the action of the blow-pipe.

Hardness and Solidity.—Solids are the only bodies to which the terms hard or soft can properly be applied. In common language, hardness and frangibility are often confounded. A stone that endures many heavy blows before it breaks, is considered as harder than another which requires fewer blows for its fracture; but the property which different minerals have of resisting the point of a knife or file of hardened steel, or the effect produced when a mineral is rubbed on other minerals, or scratched by them, is the most unexceptionable test of their hardness. Thus some minerals scratch crystallized quartz, a stone easily recognized, and whose hardness in that state is always the same; other minerals scratch steel, glas, fluor spar, &c. This method is precise, and gives the real hardness of the parts; whereas striking fire with steel, which is often mentioned as a character, is a vague test, subject to variation from the form of the mineral, the sharpness of its edges, &c.; and soft minerals not unfrequently contain minute grains of harder ones, which will give sparks with steel.

As a knife is the most convenient and portable instrument for determining the hardness of most minerals, except gems, the following judicious observations on the use of it, by Mr. Aikin, are deserving the attention of the student. In fibrous minerals, a scratch directed across the fibres will always indicate a lower degree of hardness than the true one; for the fibrous structure presenting an alternation of ridges and furrows, the knife glances across the intervals, thus interrupting the uniformity of the stroke, and producing a succession of small blows, which rather break down than divide the

fuminits
fissures of the ridges. The hardness should, therefore, be tried by a scratch parallel to the direction of the fibres, or, still better, on the surface of the transverse fracture. Another precaution is always to select a second undecomposed specimen to make a trial of the hardness, this character being affected sooner than any other by the spontaneous alteration of a mineral. In examining the relative degree of hardness of two minerals, by trying which will scratch the other, it is necessary to be aware that the solid angles and edges of the primitive forms are very feeblyHarder than those of the derivative forms, or than the angles or edges produced by casual fractures, either of crystals or massive varieties of the same species. This fact has been long known to diamond-cutters, who always distinguish between the hard and soft points of the gem, that is, between the solid angles belonging to the primitive octahedron, and those belonging to any of its modifications, the latter being easily worn down by cutting or rubbing them with the former.

The whole range of hardness obtained by the use of the knife may be thus called. When a mineral does not yield to the point of a knife, it may be called very hard, as quartz and flint. When it yields with great difficulty, it may be called hard, as feldspar. When a mineral yields more readily than the former, it may be called semi-hard, as hornblende and flour fpar. When it is easily scratched with a knife, it is called soft, as calcareous fpar and barytes. And when it yields to the nail, very soft, as gypsum and chalk.

Tenacity.—By this property is understood the relative mobility of the particles of minerals, and the different degrees of coherency. In some metallic minerals, particularly native gold and silver, the particles, though they cohere with great force, are capable of a considerable degree of motion, and may be cut with a knife or extended with a hammer. Such minerals are called malleable. When a mineral may be cut into fragile fragments, or coarse grains, adhering to the knife, it is called fêêlîle, as in plumbago and soap-stone. When on cutting a mineral with a knife, the particles part off with a grating noise, it is said to be brittle. All hard minerals, and the greater number of semi-hard minerals, are brittle, as quartz and flour fpar.

Frangibility.—By this property is understood the resistance which minerals oppose to the stroke of a hammer before they are broken into fragments. The degrees of frangibility depend partly on the cohesion of the particles, and partly on the structure of the mineral. Frangibility must not be confounded with hardness; many soft minerals are more intran-
gible than hard ones. Quartz is much harder than horn-
blende, but may be broken with greater facility. The brit-
tle minerals are the most fragile, whilst those which yield to the knife and are fêêlîle are generally very tough; and the malleable minerals, such as native gold, can scarcely be said to be fragile.

A mineral is more easily fragile by a sharp blow from a small hammer, than by a heavier blow from a large hammer; hence this property appears to depend much on elas-
ticity. Some earthy minerals, as beryl, flint, and topaz, are more fragile when first obtained from their native beds, than when they have been exposed for some time to the atmosphere, owing to their containing a portion of moisture which is afterwards evaporated. The degrees of frangibility, from very difficulty fragile to very easily fragile, are enumerated under Quâlities.

Some earthy minerals, and all malleable minerals, bend without breaking, or are flexible; and some minerals are both flexible and elastic, as mica.

Stressure of Minerals.—This is the internal arrangement of the particles of a mineral. The three great divisions of struc-
ture are, the perfectly crystalline, imperfectly crystalline, and the promiscuous structure. The perfectly crystalline structure is described under the article Crystal; and the Wernerian def-
cription of crystalline forms will be treated of in the follow-
ing section. For the imperfectly crystalline and promiscuous structure, see Structure of Minerals, where these impor-
tant characters are described. The structure of minerals is ascertained by the number of joints, or determinate direc-
tions in which a mineral can be split, or exhibits distinct lamine. This is called the cleavage by the German mineralogists.

When a mineral splits in one direction, it is said to have a single cleavage, as in mica. The cleavage may be double, as in felspar; triple, as in calcareous fpar; quadruple, as in fluor fpar; or six-fold, as in blende and rock-cystal.

The Wernerian fylem takes no measure of the angles under which the planes or lamine of a mineral meet, except as being rectangular, equiangular, or oblique. But the angular measurement of the inclination of the planes forms the basis of Haüy’s fylem of crystallography. (See Crystal and Goniometer.) According to Werner, the two-fold cleavage is described either as rectangular, (examples, felspar and hyacinth,) or oblique, as in hornblende.

In the triple cleavage, the lamine may intersect each other rectangularly, as in lead-glance or galena; or the cleavage may be oblique, but equiangular, as in calcareous fpar; or oblique and at unequal angles, as in heavy fpar; or may be partly rectangular and partly oblique, as in feldspar.

The four-fold cleavage may either be equiangular and oblique, as in flour fpar and the diamond, or three cleavages may be equiangular and oblique in the common axis of the crystal, and intersected by a fourth, which is at right angles with the axis, as in beryl.

In the six-fold cleavage, all the lamine may meet under equal oblique angles, as in rock-cystal, or three of the cleavages may form equal and oblique angles in a common axis, and be obliquely intersected by three others, which also intersect the axis in an oblique direction.

Fracture.—This property is carefully distinguished from the structure by Haüy. The fracture is the casual division of the whole into fragments, and depends much on the kind of fstroke by which it is produced, whereas the structure exils in the mineral before it is broken. Fracture is either conchoidal, which is composed of convex or concave elevations or depressions more or less regular. When regular they have smooth concentric ridges, as in many shells; hence the name is derived. The conchoidal fracture is distin-
guished according to the magnitude of the elevations and depressions, into large conchoidal, as in obsidian or flint, and small conchoidal, as in pitch-stone. It is further distin-
guished into deep or flat conchoidal, and into perfect con-
choidal and imperfect conchoidal. The conchoidal fracture is characteristic of brittle minerals, which have some degree of lustre and transparency. The uneven fracture presents elevations which are commonly irregular and angular. This fracture is most frequent in metallic minerals, and in opaque minerals which have some lustre; it passes into small and imperfect conchoidal, and also into earthy.

The even fracture is that kind of surface which fows the fewest inequalities, and the inequalities are flat and never sharply defined. It passes into large conchoidal and splintery.

The splintery fracture, improperly so called, denotes a nearly flat surface, on which are numerous small wedge-shaped scales, adhering by their thick end.

The earthy fracture is peculiar to opaque earthy minerals,
MINERALOGY.

The crystalline form of minerals is called by Mr. Jameston the regular external shape. When a mineral occurs crystallized in a simple form which has received a name in geometry, as the cube, the rhombohedron, the octahedron, etc., it is easy to give an idea of it by referring it to that form; but when a crystal presents a great number of unequal planes, or is very complicated, the description becomes difficult without a drawing or model. Mr. Werner has, however, considerably facilitated the mode of describing crystals by considering them as modifications of certain simple forms; and this mode, though not strictly scientific, is found most convenient in practice.

The simple forms, or what he calls the fundamental forms, are, the cube (fig. 1.); the rhombohedron (fig. 2.); the prism, which may have three, four, or a greater number of sides (figs. 3, 4, 5, &c.);* the pyramid, which may have three, four, five, or eight triangular planes (fig. 6.); the table, which has two equal and parallel planes, which are very large compared with the thickness of the table, and is bounded by an indeterminate number of sides (figs. 7 and 8.).

The three following forms are very rare. The isohedron, having twenty equilateral planes (fig. 9.); the dodecahedron, having twelve pentagonal faces (fig. 10.); and the hexahedron, which has two curved faces (fig. 11.).

Mr. Aikin is of opinion, that the number of simple forms, or models, to which almost all crystals can be referred, may be reduced to four. The prism, the rhombohedron, the tetrahedron (fig. 12.), the regular tetrahedron (fig. 13.), and the double pyramid formed by two equal and similar pyramids joined together by a common base. The pyramid, like the prism, may have a greater or smaller number of sides, and the edges of the bafe of each pyramid may be in the same plane, as in fig. 14., or fall on one another, as in fig. 15.

These forms, or models, it must be carefully noticed, have no connection with the true primitive forms of crysvals (see Crystallography, Addenda), but are merely adopted as convenient types for the description of crystals. The changes which these forms are supposed to undergo by truncation and bevelling may take place either on the edges or fold angles of the crystal. As the prism and the cube are the most common forms of crystals, we shall proceed to describe them modified by these changes. The prism, as we have before observed, may have several sides, and may be triangular, or rectangular, as in fig. 3.; oblique, as in fig. 4.; or polygonal and equiangular, as in fig. 5. The sides are technically called the lateral planes, they are parallel to and surrounding an imaginary axis. The bafe at each extremity of the prism are called the terminal baces. The lateral edges are formed by the junction of two contiguous sides or planes, and the terminal edges are formed by the junction of the lateral planes with the bafe or terminal planes, and the fold angles are formed at the point of junction of the terminal planes with the lateral planes. The cube may also be described as a short rectangular four-sided prism. When a fold angle is removed and one plane is formed in its place, as in Plate VII. fig. 16., the cube is said to be truncated on the angles. When planes are formed on the edges of a crytai, as in fig. 17., it is described as truncated on the edges; and when two planes are formed on an edge of the crvystal, as in fig. 18., it is said to be bevelled on the edges. Fig. 19. is a three-sided prism bevelled on its lateral edges. When the fold angles of a crystal, or the terminal planes, appear cut off by three or more planes converging to a point, the crystal is said to be acuminate: in fig. 20. each angle of the cube is acuminate by three small planes set on the lateral planes; and in fig. 21. each angle is acuminate by planes set on the lateral edges. Fig. 22. according
MINERALOGY.

to the Wernerian method, is a four-sided prism, acuminate at each extremity by four planes set on the lateral planes. Fig. 23 is a four-sided prism acuminate by four planes set on the lateral edges. In the second instance, the acuminating planes are rhomboidal; in the first instance, triangular. Fig. 24 is the equatorial six-sided prism, acuminate at each extremity by six planes set on the lateral planes. Fig. 25 is a similar prism acuminate by three planes at each extremity set on the alternate lateral planes; and Fig. 26 is also a similar fix-sided prism acuminate by three planes at each extremity, set on the alternate lateral edges. The planes at the opposite extremities in Figs. 25 and 26 are set in different planes or edges, and are what the Germans call unformable.

The octahedron, or double four-sided pyramid (Fig. 27), is a common form of crystals: it is frequently truncated or bevelled. Fig. 28 represents the octahedron bevelled at each of the angles. Fig. 29 is a double eight-sided pyramid acuminate by four planes at each extremity, set on the alternate lateral edges of the pyramid, thus forming a crystal with twenty-four faces, a form common in the leucite. The table may be bevelled on the surrounding edges, as in Fig. 30; but in this figure, the Wernerian mineralogists call the surrounding fides the terminal planes, and the larger fides the lateral planes, a deviation for which there does not appear any sufficient reason, and which is liable to introduce confusion into the description of crystals. Some of the forms here referred to, particularly Figs. 23 and 24, may be more simply described as four-sided and six-sided prisms, terminated at each extremity by four-sided or fix-sided pyramids. The edges of a crystal may sometimes be doubly bevelled, or may be bevelled, and the edge of the bevelment truncated. Such modifications are better described as replacements of the edges by three, four, or more small planes or secondary faces. A very long prism is called a capillary crystal, if the diameter be too small to render the faces distinct. A very short prism, in which the length is very small in proportion to the thicknesses, may be regarded as a tabular crystal. Most crystals may be very intelligibly described by alluming the fundamental forms of Werner variably modified. We are not, however, to suppose, that Werner himself intended to convey the idea that nature first made crystals complete, and then cut away the angles and edges; he only exprests, by the terms truncation and bevelment, the appearance the crystal presents to the eye. The primitive forms, or the true fundamental forms of crystals, as given by Haly, are enumerated under the article Crystal; but Plate VII. Crystallization, compries these forms, and also those of the integrant molecule. The primitive forms are, the paralleloipiped, including the cube and rhomb (Figs. 1 and 2), and the rectangular-table (Figs. 7 and 8), the octahedron (Fig. 27), the tetrahedron (Fig. 13), the hexagonal prism (Fig. 3), the rhomboidal dodecahedron (Fig. 12), and the dodecahedron with triangular faces (Fig. 14). The integrant molecules are, the tetrahedron (Fig. 13), the three-sided prism, and the cube (Fig. 1).

In nature, we rarely find crystals entirely perfect and symmetrical. If, says Mr. Aitken, the student will imagine that the real crystals of minerals, such as nature presents them, are formed with the precision that characterizes the models of the crystallographer, he will in general find himself much mistaken. By far the greater number of crystals are either muddled in other fabrics, from which it is difficult to disengage them without much injury, or inhre by one extremity in amorphous or uncryallized matter of the same nature with themselves. Hence it is, that few prisms occur both terminations of which are entire. Not unfrequently also crystals, by being formed in narrow clefs, are compelled, or in other ways variously mutilated, and thus perplex even the most skilful mineralogist. Their minutenees too, when the parts are much complicated, is frequently such as to elude the keenest eye and the most adroit use of the goniometer.

It is often by no means easy to distinguish genuine from spurious crystals. The latter are generally suppos'd to have been formed in cavities occasioned by the decomposition of real crystals. These are called casts. Spurious or suppoticitious crystals are either casts or incrustations; the latter occurs when a mineral is deposited over a pre-existing crystal and affirms its figure. The crystal either remains forming a nucleus, or it disappears, and the suppotitious crystal is hollow.

In the Wernerian crytography, the magnitude of crystals and their mode of aggregation are minutely enumerated. (See OBSCTOOGNOSY.) In the last edition of Mr. Jameson's external characters, he defines the sopiform or factories aggregation as "composed of a number of thin prismatic crystals, diverging from their point of attachment, and forming a kind of fasciculus or bundle; example, zeolite." The manipulor, or sheaf-like, consist of a number of crystals that diverge towards both ends and are narrower in the middle, thus resembling a sheaf; examples; zeolite and prehnite.

Scalarwise is when many cubical crystals are arranged like the ribs of a flair; example, cubes of connois silver ore.

The surface of crystals is either smooth or streaked, the streaks sometimes crofs longitudinally and sometimes transversely. These streaks are deciding of notice, as they frequently serve to indicate the structure of crystals. See Crystallography, Addenda.

Electricity is a character peculiar to a small number of cristallized minerals, that exhibit the positive and negative electricity at their extremities on being heated. This property was first discovered in the tourmaline. (See TOURMALINE.) The points which exhibit electricity are called the electric poles. In order to distinguish these poles from each other, the following simple apparatus is employed. (See Crystallography, Plate IV. Fig. 92 A.) It consists of a needle of copper or silver, having at each end two small balls a, b; this needle, like the common compass-needle, is moveable upon a pivot, having a very fine point, and at the bottom a fand or foot. The needle and item are influated by placing the foot on a plate of wax or rfin. To use the apparatus, we place one finger on the item, and present near to the needle a flick of sealing-wax, made electrical by rubbing, then withdraw the finger, and afterwards the flick of sealing-wax, and the needle will be positively electrified; and when a crystal electrified by heat, and held by a pair of small pincers in an influated handle, as at B, is brought so that the positive or negative pole may approach one of the balls a, a, b, it will be attracted or repelled. The electricity of the needle will be perceived a quarter of an hour, or longer, and may be rendered more or less strong by varying the distance at which the flick of sealing-wax is held. It may be proper to observe that many minerals become electric by friction.

Magnetcism is a character which occurs principally in ores of iron, or in minerals that contain a portion of iron, or iron in a state of black oxyd.

The above are the most important physical characters, comprising those which are called the external characters by Werner, and those to which he restricts the term physical.

Specific Gravity, or weight, is one of the most important.
MINERALOGY.

important characters of minerals, and is obtained accurately by weighing them in the hydrometric balance. (See Hydrostatics.) For most practical purposes, a pair of common gold scales that will turn freely with the tenth part of a grain is sufficiently accurate. The mineral may first be weighed, and the weight be noted, and then it must be suspended by a fine thread, and weighed again in rain or river water, about the temperature of 60°. The original weight of the mineral divided by the difference of the weight will give its specific gravity, or the weight compared with that of water. The heaviest bodies are the metallic, and the metallic ores, which range from about five times the weight of water to seventeen; the latter is the specific gravity of native platina. The heaviest earthy minerals are the barytic and ilronotic earths, and the gems; these range from 3.5 to 4.5. The other solid earthy minerals range from 2. to 3.5, and some few solid minerals are lighter than water, as rock-cork.

The feel, whether unctuous, or smooth or dry, meagre or harsh, is a character which serves to distinguish particular minerals. The odour and taste are also characters of particular minerals; some yielding a peculiar odour naturally, as petroleum, or when rubbed, as tallow-tone; and others, as the haline, affect the taste. Adhesion to the tongue is also a character possessed by minerals which absorb water. The coldness and found of minerals are also given as characters by Werner, but they are of little practical value.

Friable minerals are either loose, as when the particles have no perceptible cohesion, or are slightly cohering. The particles are in some instances scarcely discernible, and are called dusty particles, as in coal-buff crust; in other instances, the particles are large and scaly.

The fluid minerals are few in number, and are characterized by their fluidity, transparency, and lustre.

The remaining characters are purely chemical, except the action of water, and of the atmosphere, which is in some instances chemical, and in others mechanical. Water unites with many of the clays, and renders them plastic; other minerals, as fuller's-earth, fall to pieces in water, without being disintegrated, or even rendered plastic. In some cases, minerals absorb water, which alters their transparency and colour. Saline minerals chemically combine with water, and are disintegrated. To the absorption of water, is owing the property of adhering, when applied to the tongue before noticed. The action of the atmosphere on minerals is principally effected either by the abstraction or absorption of moisture, and the oxidation of minerals when exposed to the air is for the most part owing to the moisture which it contains.

The chemical characters of minerals are those which the mineralogist can ascertain by the action of acids, or of heat as applied by the blow-pipe, either simply or aided by re-agents. The action of acids is of great use in ascertaining many essential characters of minerals. For this purpose, the muriatic or the nitric acids of moderate strength are most convenient; but it requires some precautions in the management to render it efficient. The best and clearest directions for this purpose which we have seen are those given by Mr. Aikin.

"Few persons," he says, "are able at first to produce a continued stream of air through the blow-pipe, and the attempt often occasions a good deal of fatigue. I shall make no apology, therefore, for treating this matter somewhat in detail. The first thing to be done is to acquire the habit of breathing easily and without fatigue through the nostrils alone; then to do the same while the mouth is filled and the cheeks inflated with air, the tongue being at the same time slightly raised to the roof of the mouth, in order to obstruct the communication between the mouth and the throat. When this has been acquired, the blow-pipe may be put into the mouth, and the confined air expelled through the pipe by means of the muscles of the cheeks. As soon as the air is nearly exhausted, the expiration from the lungs, instead of being made through the nostrils, is to be forced into the cavity of the mouth; the communication is then instantly to be shut again by the tongue, and the remainder of the expiration is to be expelled through the nostrils. The second, and all subsequent supplies of air to the blow-pipe, are to be introduced in the same manner as the first. Thus, with a little practice, the power may be obtained of keeping up a continued blast for a quarter of an hour, or longer, without inconvenience."

"Much depends on the size of the external aperture of the blow-pipe. If so large that the mouth requires very frequent replenishing, the flame will be wavering, and the operator will soon be out of breath; if, on the other hand, the aperture be too small, the muscles of the cheeks must be strongly contracted, in order to produce a sufficient current, and pain and great fatigue of the part will soon be the consequence. An aperture about the size of the smallest pin-hole will generally be found the most convenient, though for particular purposes one somewhat larger or a little smaller may be required."

"Several varieties of form have been recommended for the blow-pipe: they all have their advantages and disadvantages. Upon the whole, it appears desirable that there should be an expansion of the tube somewhere between the two extremities, both for the sake of collecting and retaining the condensed moisture of the breath, and for producing a regulated preface, and therefore a regular blast. The nozzle also should be tipped with a movable piece for the convenience of giving at least three different sizes of aperture. These conditions being obtained, other circumstances are of small importance, provided neither the bulk nor weight of the instrument be troublesome."

"The fuel for this little reverberatory furnace (as the blow-pipe apparatus may, without impropriety, be denominated) is oil, tallow, or wax, kept in combustion by means of a wick. The oil is the worst, the tallow is better, and the wax is best, not only as being cleaner, and free from any offensive smell, but also as affording a greater heat. The management of the wick too is a matter of some nicety. It should neither be too high nor suffused too low, and should be a little bent at its summit from the blast of the pipe. All casual currents and drafts of wind ought to be carefully avoided, as rendering the flame unsteady, and very materially impairing its strength. The above conditions being duly complied with, the flame, while acted on by the pipe, will evidently consist of two parts, an outer and inner; the latter will be of a light-blue colour, converging to a point at the distance of about an inch from the nozzle; the former will be of a yellowish-white colour, and will converge.
MINERALOGY.

The most intense heat is just at the point of the blue flame. The white flame consists of matter in a state of full combustion, and calcines or oxygenates substances imdered in it; the blue flame consists of matter in a state of imperfect combustion, and therefore partly deoxygenates metallic oxides which are placed in contact with it.

The supports of the various substances while undergoing the action of the blow-pipe come next to be considered. Of supports there are two kinds, combustible and incombustible. The combustible support (used chiefly for metallic ores) is charcoal. The charcoal-grained and foundd pieces are to be selected for this purpose; and even the best often split and become gritty after being used for a short time. This will not unfrequently happen in the middle of an experiment, when the melted globule sinks into the cracks, is lost, and the experiment must be begun again. Instead of sticks of charcoal, some persons recommend that the charcoal, after being finely pulverised, should be moistened with a solution of gum tragacanth, and moulded into a convenient form; a plan that well deserves to be fairly tried. Perhaps simply moistening the charcoal-powder, and then submitting it to the action of a very strong screw is, might be still better. The incombustible supports are metal, glases, and earth, in the use of all which one general caution may be given,—to make them as little bulky as possible. The support always absorbs more or less of the heat, and in many cases, especially when metallic spoons are employed, entirely prevents the flame from producing its due effect. The bell metallic support is plaita, because it is infufible, and transmits heat to a less distance and more slowly than other metals. A pair of flender forceps of brafs, pointed with platina, is the best possible support for non-metallic minerals that are not very fusible. For the fusible earthy minerals, and for the infufible ones when fluxes are used, leaf-platina will be found the most convenient; it may be folded like paper into any definable form, and the refult of the experiment may be obtained simply by unfolding the leaf in which it was wrapped up. Glases supports are flender tubes or rods of this substance. If the mineral to be examined is of a longith or fibrous shape, one end may be cemented to the top of the glases rod by heating it, and in this state it may be further examined with great convenience. Earthen supports are used only for extemporary copulation; they are bell made of bone ash, and must of necessity be of a certain bulk, in order to absorb the lime, and other impurities, which it is the object of this procés to separate from the fine metal. With regard to the magnitude of the specimens required for examination, no very precise rule can be given; the most fusible, such as some of the metallic ores, may be as large as a small pea, while the more refractory of the earthy minerals should scarcely exceed the bulk of a pin’s head.

The heat that is first applied to investigate the properties of mineral substances should be very slow, not exceeding that which exists on the outside, even of the yellow flame; at this temperature, the phosphorescence is best elicited, and decapitation for the moss part takes place, the fusible inflammables begin to melt, and the metallic and moist other mineral faults lose their water of crystallization. The yellow flame will raise a substance to a tolerably full red heat, by which the following effects are produced. Many changes of colour take place, all the yellow ores of iron become red, and the peach-bloom tinge of flowers of cobalt becomes blue; certain earthy minerals lose their water of crystallization or of composition, and exfoliate, as gypsum, or throw up coarse and irregular ramifications, as prehnite and meotelophy. At this temperature, also, carbonate of fronton begins to tinge the flame with its peculiar crimson colour, and muriate of copper with its bright green colour. The roasting of all the metallic ores is best carried on at this heat; sulphur and arsenic are drawn off, and exhibit their characteristic colours; grey antimony melts; native bismuth runs out from the matrix, through which it is disseminated; and pearl-piar and phathoe iron blacken and become magnetic. In the still higher degree of heat produced at the point of the interior blue flame, although some minerals still continue perfectly refractory, and undergo but little change of any kind, yet the greater part is very sensibly altered. Some, as pearl-piar, enlarge very considerably in bulk at the first impression of the heat, but are with difficulty afterwards brought to a state of fusion. Others become covered with a superficial glazing, and the sharp edges and angles become glossy and rounded off. Others, confiding really, though not visibly, of an intermixture of two substances differing in fusibility, undergo the proccss of fritting, in which refractory grains are dispersed through a vitreous mass. In others, a complete fusion takes place, and produces a pongy opaque fenumitricous mass called a flag, or an opaque glass called an enamel, or a more or less transparent or true glases, which latter may vary in texture from compact to porous and pongy or intumescent.

In examining the habits of the earthy minerals with the blow-pipe, no fluxes are required; whereas to moll of the metallic ores, fluxes will be found at almost all times a very useful and often a necessary addition. The ores of the difficulty reducible metals, such as manganese, cobalt, chrome, and titanium, are characterised by the colour which their oxyds give to glases; in all these cases, therefore, vitreous fluxes must be largely made use of, both to disolve the earthy matter with which the oxyds are generally mixed very intimately, and to furnish a body with little or no colour of its own, which may receive and sufficiently dilute the inherent colour of the oxyd. I say sufficiently dilute, because the colour of molt oxyds is excessively intense, and most persons in their first experiments of this kind, are very apt to obtain ambiguous results in consequence of using too large a proportion of oxyd, that the glases, whether blue, red, or green, appears quite black. With regard to fluxes, the following will, I believe, be found amply sufficient. Where the object is not only to disolve the oxyd, but at the same time to retain it at a high state of oxidation, the flux employed should be such as will not or will only slowly change into a mixture of this with a glases of borax, or, will better, nitrous borax formed by dissolving common borax in hot water, neutralizing its excess of alkali by nitric acid, then evaporating the whole to dryness, and half-half molten it in a platina crucible. For an active, and at the same time non-alkaline flux, boracic acid may be used, or neutral borate of soda; and where a slight excess of alkali is required, or at least does no harm, common borax by itself, or mixed with a little cream of tartar, when a strong reducing flux is wanted, may be had recourse to. For coloured glases, the proper support is leaf-platina; but for reductions, charcoal. In the latter case, the ore previously roasted, if it contain either sulphur or arsenic, is to be pulverised and accurately mixed with the flux; a drop of water being then added to make it cohesive, it is to be formed into a ball, and deposited in a shallow hole in the charcoal, being also covered by a piece of charcoal, if a high degree of heat is wanted. The easily reducible metals, however, may be treated with less ceremony; a bit of the ore being placed on the charcoal, and covered with glases of borax, will, in the space of a few seconds, be melted by the blow-pipe, and converted
converted into a metallic globule, imbedded in a vitreous scoria.

"In all cases where a metallic globule is obtained, it should be separated from the adhering scoria, and examined as to its malleability and other external characters; being then placed a second time on the charcoal, but without flux, it is to be brought to a state of gentle ebullition, during which the surface being oxygenated, will exhale a heavy vapour that condescends on the blow-pipe, or falls down on the charcoal in form of a powder, or of spicular crystals, from the colour and other characters of which the nature of the metal may probably be ascertained. If any suspension is entertained of a portion of silver or of gold being mixed with the oxydable metal, the button must be placed on an earthen support, and there brought to a full melting heat; by degrees the oxydable metal will become fecularized, and will entirely sink into the support, leaving on the surface a bright bead of fine metal, if such was contained in the alloy; but the proportion of this last being generally very small, and the entire mass of the alloy often not exceeding a large shot, it is not unfrequently necessary to have recourse to the magnifying glafs, to be fully convinced of the presence or absence of fine metal." Aikin's Manual of Mineralogy.

The above directions will be found of the greatest Use, and are sufficiently ample to make any additional remarks unnecessary. Some German mineralogists have, indeed, arranged under nearly one hundred heads, the different changes produced on minerals by the action of the blow-pipe, and have given elaborate explanations of words known with sufficient accuracy by almost every child of seven years of age. This we regard not as smoothing the paths of science, but as blocking them up with rubbish to impede the progress of the student.

In the mineralogy of Hauy, he has introduced very judiciously what he denominates the definite characters of minerals, noting the particular characters which serve to distinguish one mineral species from another, to which it has the greatest general resemblance.

New species of minerals have been discovered almost every year since the commencement of the present century, and the great number of these discoveries have been made in the mines of Sweden. Few, however, of the newly discovered minerals possess properties that entitle them to much notice, and it is highly probable, that as the science of mineralogy advances to perfection, many of these supposed new species will be discovered to be only various species of species that have been long known.

Actinolite, or Albitolite. Fr. actinit. See Strahlstein.

Actinote, Amphibole. See Strahlstein.

Adamantine Spar, or Common Cerundum; Corindon harnophane, Hauy. See Adamantine Spar.

Adhesive Slate, a species of polishing flake, or pefler scibile. See Polishing Slate, Addenda.

Adularia. (See Felspar, Addenda.) This variety of felspar was formerly confounded with glaify felspar. (See Glassy Felspar, Addenda.) Adularia occurs in veins of granite in Bumshire, in the Isle of Arran, and other parts of Scotland. Rolled pieces of adularia having a most beautiful pearly light are found in the island of Ceylon.

Agalmatolite, or Figure-Stone; Beldstein, Werner; Talc graphique, Hauy. A mineral which may be regarded as an indurated flatale, or rather, according to Jamelton, as intermediate between flatale and nephrile jade. It occurs massive; the fracture is splintery, or imperfectly flat; the colours are greenish-grey, apple-green, or yellowish-brown, and sometimes flesh-red and rose-red. It is transfluent, unctuous to the touch, and yields with ease to the knife, owing to which property it is carved with facility into different figures by the Chinese, and into pagodas, cups, and snuff-boxes. The specific gravity is from 2.6 to 2.8. According to Klapproth, the conlent parts of agalmatolite are,

According to Aikin, this mineral occurs at Glyder Bach, Caernarvonshire.

Agaric Mineral, or Rock Milk; Chaux carbonatie Joumgiens, Hauy. See Agaric Mineral.

Agate. (See Agate.) The agate is not a simple mineral, but is composed of various fioiceous fragments arranged in concentric lamelle, exhibiting, when cut and polished, zones and angular lines, like fortifications. There is also a kind of agate-breccia, in which angular fragments are cemented by quartz or chalcedony. Agates appear to be formed by fioiceous infiltration in the cavities of bafalitic rocks, the formation commencing from the surface, and the cavity gradually filling by successive depositions on the sides, until the whole forms one solid nodule. According to the direction of the lines or the structure of agates, they are designated ribbon or striped agate, fortification agate, landscape agate, brecciated agate, tabular agate, jasper agate, spotted agate, banded agate, flar agate, marked with radiated spots; petrafiction agate, fofill-hills and zoophytes are sometimes penetrated or filled with agate. In the variety called moja agate, nodules of chalcedony inclufo minute arborizations refembling mofs, some of which are fupposed by mineralogists to be branches of mofs suddenly inclufo and preserved in fioiceous matter.

Alabaster, Calcareous, or Calcifer Alabaster, Gypseous Alabaster, See Alabaster and Gypsum.

Alalite, Diopside, and Maffite, a mineral allied to augit; first found in the Alp of La Maffia, near the town of Ala, from whence the names alalite and maffite are derived. See Diopsie, Addenda.

Alallane, Cerium allanite, Fr. an ore of the newly-discovered metal cerium, first analyzed by Mr. Allan, and hence called allanite. Its colour is a brownish-black; it occurs diffemated and crystalized in rhomboidal prisms, the angles of which measure 117° and 63°. The internal lustrer is shining, and refno-metallic. It is opaque, and yields a greenish-grey streak. It Scratches glass, is brittle and easily fragrable. Before the blow-pipe it froths, and melts into a brown flag. It gelatinizes in nitric acid. The specific gravity is from 3.5 to 4. The conlent parts are:

It occurs in granite in West Greenland.

Allochroite,
MINERALOGY.

_Allochrocte, idem, Haüy; spintery garnet of Karhen._ It is classed with the garnet family by Werner, but is regarded as a distinct species. It occurs massive; the fracture is uneven, paffing into conchoidal. Its colours are greenish and yellowish-grey; it is translucent on the edges; internally it has a glinting silicious lustre. It gives sparks with file. The specific gravity is 3-5. It has hitherto been found only in an iron-mine at Dramman, in Norway. It is less hard and lighter than common garnet. According to Vaquélin, the constituent parts are,

_Amalgane, regards as a variety of garnet._ See Amalgedin; but for granite r. garnet.

_Alum-Earth, Alum-Slate, Common and Goffy, Alum-Stone._ See Alum, Ores of.

_Alumine, Sub sulphate of Alumine; Reine boronée, Werner; Alumine pur, Haüy._ This mineral has a bow-white colour, verging on yellowish-white. It occurs in reniform pieces, it has no lustre, the fracture is earthy, and the confidences between friable and solid. It is opaque, foils flowing, affords a glinting flake, and adheres freely to the tongue. It feels fine, but meagre. The specific gravity is 1.66. A variety of the same mineral substance occurs at Newhaven in Suffolk, filling up fissures in chalk. This variety is white, yields to the nail, and adheres strongly to the tongue. The constituent parts of the foreign aluminate are,

_Anastase, or Octahedrite, Titane anatase, Haüy._ See Titanium.

_Andalasite, Feldspath aphyre, Haüy, is of a flesh-red colour, sometimes inclining to pearl grey; it occurs massive or crystallized in rectangular four-sided prisms, with the terminal edges and angles sometimes truncated. The structure is imperfectly lamellar, with a double rectangular cleavage, parallel with the lateral planes of the prism. It is translucent; it scratches quartz with ease, but is rather easily fragible. The specific gravity is 3.16. Before the blow-pipe it becomes white, but is insuflicient. According to Vaquélin, the constituent parts are,

<table>

It occurs in veins in granite, gneifs, and mica-flats, along with felspar, quartz, mica, and chlorite. It was first found in the province of Andalasie. It has since been found in Aberdeenhire. The crystals are generally middle-sized or small, and occur imbedded. It is distinguished from felspar by its greater hardness, weight, and insufliciency; and from corundum by its double rectangular cleavage, and its inferior specific gravity.

_Amblydrite, or Anhydrous Gyphrum, a species of gypsum which contains scarcely a trace of water in its composition, and is much harder than common gypsum; the latter (see...
MINERALOGY.

(see Gypsum) contains 22 per cent. of water, and some varieties 38 per cent. There are five varieties of anhydrite: compact, fibrous, radiated, sparry, and feebly.

**Compact Anhydrite.**—Its colours are various shades of white, inclining to small blue, bluish-grey, and is also red and brownish-red. It occurs massive, contorted, and reniform. The contorted variety, from its resemblances to the convolutions of the invertebrata, was called tripe-stone, or pierre de tripes. Compact anhydrite is more or less translucent, and is usually a spheny fracture, pitting into even or conchoidal. The fragments are sharp-edged: it is difficulty frangible. Specific gravity from 2.8 to 2.9.

According to Klaproth, the constituent parts are:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Specific Gravity</th>

</tr>
<tr>
<td>Water</td>
<td>1.75</td>
</tr>
</tbody>
</table>

Fibrous Anhydrite is of a red colour: it occurs massive, and has a delicately fine and parallel fibrous structure. Radiated anhydrite has a blue or greyish-blue colour, and is sometimes spotted with red: it occurs massive. The structure is radiated, the surface splintery and pearly: it is translucent and rather hard. Its specific gravity and constituent parts are the same as the former variety.

**Sparry Anhydrite, or Cube-Spar; Chaux sulphate laminaire, Haüy.**—The prevailing colour is white, inclining to blue-grey, pale yellow, and red. It is more or less transparent, the lustrous spheny and pearly: it refracts doubly. It is crystallized in rectangular four-sided prisms, and in six or eight sided prisms. It also occurs massive. It has a foliated structure, and a cleavage parallel with the sides of a rectangular prism, which is its primitive form. It etches carboeaceous spar, but is easily frangible. Its specific gravity is 2.9. Before the blow-pipe, it becomes glazed over with a white friable enamel, but does not melt and exfoliate like gypsum. It is met with in the salt-mines in the Tyrol, and in Switzerland, and also in the gypsum of Nottinghamshire. Sealy anhydrite is generally white, inclining to blue or grey: it occurs massive, has a confused foliated structure, and a splenetic and pearly lustrum. It is translucent on the edges, is easily frangible, and is soft. Specific gravity 2.9. According to Klaproth, the constituent parts are:

It occurs in the salt-mines of Hall in the Tyrol.

**Anthophylite.** Its colour is between dark yellowish-grey and olive-brown: it occurs massive and crystallized in reed-shaped crystals, which appear to be four-sided prisms longitudinally flecked. The lustrous is shining and pearly, approaching to metallic. The structure is radiated. It has a two-fold cleavage parallel with the sides of a rectangular prism. It is more or less translucent, yields to the knife, but etch thick glases with difficulty. It is intubable before the blow-pipe. Its specific gravity is 3.2. The constituent parts are:

**Arsenic Oxide, and Arsenical Pyrites, or Marcasite.** See Arsenic, Ores of.

**Asbestos, Common and Flexible.** (see Amiantus and Asbestos.) Asbestos ligniform, or wood asbestos. Its colour is

Vol. XXXIX.
MINERALOGY.

It occurs in common basalt, in wacke, and in lava; also in some kinds of porphyry. It decomposes more slowly than basalt; hence, according to professor Jamefon, we frequently find crystals of basaltic hornblende dispersed through clay formed by the decomposition of basaltic rocks. See Hornblende, Addenda.

Basanite, black flinty flake. See Slate.

Bergmanitite, a mineral which occurs massive with grey and red quartz at Freidichswarm, in Norway, and is classed with scapolite in the seltar family in Jamefon's Mineralogy. Its colours are greenish and greyish-white, or yellowish-grey and muddy flesh-red. It is extremely glithening, with a lustre between pearly and resinous. The structure is delicately fibrous, curved, or diverging. It is faintly translucent on the edges, and feringas felpar. It melts before the blow-pipe without intumeoicing into a white enamel.

Beryl. (See Beryl and Emerald.) In Weis's collection at Vienna, there are two crystals of beryl in a group croosing each other, which are a foot and a half in length, and one foot in diameter. It has been found in alluvial foil, in the upper part of Aberdinehire, and in the county of Wicklow, in Ireland, imbedded in granite.

Bildstein. See Alabamatite.

Bismuth, Native. See Bismuth-Ore.

Bismuth, Glance, or Sulphurated Bismuth. See Bismuth-Ore.

Bismuth-Ore, Plumbago cupriferus, has a steel-grey colour, with a pale copper-red tarnish. It occurs diffuminated and crystallized in oblique four or fixed acicular prisms, longitudinally streaked. The crystals are frequently adhering together, and are sometimes curved, and divided by cros rents. The lustre is metallic. The crofs fracture is fine grained and uneven. It yields easily to the knife. The specific gravity is 6.2. Before the blow-pipe, it melts into a steel-grey globule; by continuing the heat, it is partly volatilized, and deposits in the charcoal a yellow powder, after which there remains a red globule, containing a grain of cupiferous metallic lead, which communicates a blueish green colour to borax. According to John, the constituent parts are,

This is a very scarce ore of bismuth.

Bismuthic Silver-Ore. See Silver-Ore.

Bitumen,
MINERALOGY.

BITUMEN, Liquid, Tenacious, Solid, Compact, and Elastic. See Bitumen.

Bituminous Mark-Slate occurs in beds in the lower stratified lime-stone in various parts of Europe. It has a dark-brown or blackish-grey colour, a glimmering lustre, a flat structure, and is soft, meagre, opaque, and fettish. It frequently contains ores of copper. It is remarkable for the number of petrified fish which occur in it. It also contains fossil remains of shells, corals, and of cryptogamous fresh-water plants. In many of its characters, it appears to resemble the alum- shale of Whitby. It is a frequent mineral in Saxony, Thuringia, Franconia, Bohemia, Bavaria, and in Switzerland.

Bituminous Wood, a variety of brown-coal or wood-coal, in which the fibres of the wood are distinguishable. See Coal and Wood-Coal.

Black Coal. See Coal.

Black Chalk, or Drawing-Slate, Ampelisographica, Fr. occurs in beds, in rocks of the slate formation. It has a blueish or greyish-black colour, a flat structure, an earthy crass fracture, is dull, meagre to the touch, and leaves a distinct mark on paper. It is fettish, and becomes gelatinous in the breeze. The specific gravity is 2.11. According to Wregleb, its constituent parts are,

- Silex 64
- Alumine 11
- Carbon 7
- Water 3

It is found at Morilla in Spain, in Brittany, in Germany, and in Italy. It is cut into square pencils, and used for drawing; it is also ground and used in painting. Those varieties which have the darkest colour and the finest earthy texture are to be preferred. The pencils become hard, unless kept in a moist place.

Black Jack, a provincial name for blende.

Blende, Black, Brown, and Yellow, various sulphurets of zinc. See Zinc-Ores.

Bog Iron-Ores. (See Iron-Ores.) Werner supposes bog-iron, whether in meadows, swamps, or marshes, to be formed by water impregnated with vegetable acid, dissolving part of the iron in the rocks over which it flows, which, being poured into hollows, becomes flagrant, and evaporates. Thus successive depositions are formed, which are at first yellowish earthy, and of little confluence. This is morafa-ore. In course of time, it becomes harder, and the colour passes to brown, forming swamp-ore. After the swamp is dried up, the ore becomes much harder, and passes into meadow-ore, which is covered with soil and vegetation.

Bole. See Bole.

Bolognese Spar, or Radiated Heavy Spar. See Heavy Spar, Addenda.

Boracic Acid, Native or Saffoline, is found in saline inclusions on the borders of hot springs, near Saffo, in the territory of Florence. It has a greyish or yellowish-white colour; it occurs in thin crusts or minute nearly scales; it is soft and friable, and is feebly translucent. To the touch, it is slightly bitter, and acidulous. It melts easily before the blow-pipe into a transparent globule. According to Klaproth, the constituent parts are,

- Boracic acid 86
- Ferruginous sulphate of magnesia 11
- Sulphate of lime 3

Boracite, Magnesio boraté, Haüy. (See Boracite.) Vaquelin found no lime in this mineral, and supposes it to be a simple bole of magnesia. Boracite is remarkable for its electric properties when heated. The form is generally that of the cube, and those angles which are diagonally opposite are, one positive, and the other negative, forming eight electric poles.

Bozюryolite occurs in mammillary or botryoidal concretions, in a bed of gneis, near Arendal in Norway, associated with quartz, fuchor, calcareous spar, and iron pyrites. Its colours are, pearl-grey, greyish or reddish-white, and pale rose-red. The colours are concentric stripes. It has a delicately fibrous stellar structure, and sometimes a sphynter fracture. It has a pearly glimmering lustre internally, is translucent on the edges. According to Klaproth, the specific gravity is 2.88; and the constituent parts are,

- Silex 36.0
- Lime 39.5
- Boracic acid 13.5
- Oxid of iron 1.0
- Water 6.5

Earthy botryolite occurs with the above, which has a snow-white colour, and an earthy fracture.

Bovey Coal. Bituminous wood coal, found at Bovey Heathfield, Devonshire. See Coal.

Bromellite, Diallage metalloside, Haüy. A mineral nearly allied to Labrador hornblend or hornfels. It has a yellowish-brown or pinchbeck-yellow colour, and a femetmetal lustre; it occurs massive, and coarsely disseminated; it has a foliated and fibrous structure, with a distinct single cleavage. It is opaque. The specific gravity is 3.2. According to Klaproth, the constituent parts are,

- Silex 60.0
- Magnesia 27.5
- Iron 10.5
- Water 0.5

It occurs in silex at Glentilt, in Perthshire, and at the Lizard, in Cornwall, intermixed with jade in serpentine.

Brown Spar, Pearl Spar, or Dolomite Spar; Chaux carbonatée ferre manganesefere, Haüy; Bitter Spatth, Werner. Its prevailing colours are, milk-white, greyish-white, yellowish-grey, and pearl-grey; it also occurs red, brown, yellow, and black. It occurs both massive and crystallized in oblique rhomboids, and in compressed hexahedrons. The joints are parallel to the faces of an oblique rhomboid, the alternate angles of which measure 106° 18′ and 73° 45′. The faces of the rhomb are sometimes convex or concave; it occurs also in lenticular forms. The lustre is shining, and between vitreous and pearly; it is more or less translucent. It yields to the knife, but is harder than calcareous spar. Its specific gravity is from 2.18 to 2.88. It hardens and becomes an opaque brownish-black before the blow-pipe. It diffuses slowly in cold muriatic acid, but with considerable effervescence in hot acid. According to Klaproth, the constituent parts are,

4 A 2 The
MINERALOGY.

The proportion of manganese and iron is sometimes much greater, and there are several intermediate varieties, which it is difficult to determine whether they are to be classed with brown spar or spar iron-ore. Brown spar occurs in veins along with galena and other ores of lead, in the mines of Cumberland and Northumberland. Fibrous brown spar, both massive and in balls, occurs in veins in Lower Hungary. Columnar brown spar has a splendent lustre and a foliated structure, but no distinct cleavage can be observed in it. The fragments are wedge-shaped. It has been found at Geriford in Saxony, and Guanaxto in Mexico. The name brown spar was given to this species because it changes its colour, on exposure to the air, from a light to a dark brown, bordering on black.

BUTTERMILK, Silver. See Silver-Ores.

BYSOLITE, a name given by Sauvage to a variety of asbestiform actinolite, which occurs in minute acicular diverging crystals, which are elastic. See Actinolite.

CACHOLONG, Quartz agate cacholong, Haüy, is by some mineralogists considered as a variety of milk-white chalcedony, by others as a kind of common opal. Cacholong is distinguished by its milk-white colour, its refringent lustre, its even fracture, and its want of translucency, except at the edges. It sometimes adheres when applied to the tongue. This mineral accompanies flints and chalcedony, and, according to Brougnart, even pitchstone is sometimes coated with it; hence it is supposed to be the result of alteration in these minerals, produced by an unknown caufe, as it is observed passing into them by almost imperceptible gradations. The true cacholongs, which have given the name to this variety, are found near the banks of the river Cach, in Bucharis; they are spread over the fields, but are not rounded; on the contrary, they form tables composed of alternate layers of cacholong and chaledony. Cacholongs are sometimes cut and employed in jewellery.

CALAMINE. See Zinc-Ores.

CALCAREOUS SPAR, crystallized carbonate of lime. See Lime-stone.

CALC-SINTER. See Stalactic fibrous Lime-stone, in the article Lime-stone.

CALC.TUFF, or Tuffaceous Lime-stone, a light porous lime-stone, formed by the deposition of calcareous matter, in calcareous springs, or near lakes or rivers. It frequently enclaves the remains of animals or vegetables which have been encased and imbedded in it by successive depositions. See Tuff.

CALP, a name given by Kirwan to a dark ferruginous lime-stone, agreeing in many of its characters with the English lias. See Lias, Addenda.

CANDLE COAL. Bituminous coal, so called on account of the great light which it affords in burning. See Coal.

CAT’S-EYE, Quartz agate chatoyant, Haüy; by some mineralogists called fialfe opal. It appears to be a variety of agate occurring like the latter mineral in trap rocks, but remarkable for reflecting a peculiar play of colour, resembling that of the eye of a cat, whence its name; it is used in jewellery, and is generally cut into ring stones. Cat’s-eye occurs massive and in loose angular and rounded pieces; its colours are various, inclining most frequently to yellowish and greenish-grey, and sometimes to brown-red and greenish-black. It exhibits a beautiful opalescence when cut in a spherical form, which proceeds from the fibrous structure, and sometimes from the intermixture of amianthus. It is translucent in different degrees; it has a thinning vitreous-refrangible lustre, a small conchoidal fracture; it scratches quartz. Cat’s-eye becomes opaque and spotted by exposure to the

blow-pipe. Its specific gravity is 2.64. According to Klaproth, its constituent parts are,

</tbody>
</table>

Cat’s-eye occurs in the Harz, in Hanover, in trap, with amianthus, aethal, axinite, and calcareous spar. It is brought from Ceylon, Malabar, Sumatra, Peria, and Arabia.

CELESTINE, sulphate of bismuth. See Zephyrian.

CERIUM, or Cerite, Cerium oxyde filicifer, Haüy, an ore of the newly discovered metal cerium. (See Cerium.) The colour is between rose-red and flesh-red, and also reddish-brown; when pulverized it is grey; it occurs both massive and disseminated. The fracture is splintery, the lustre glimmering and refractive. Opalite (Jamefon), transparent (Atkin). It scratches glass with difficulty; it is brittle and easily frangible. Specific gravity 4.6 to 4.9.

Infusible before the blow-pipe, but changes from grey to yellow. According to Klaproth, the constituent parts are,

88.25

Cerium occurs in a bed of copper pyrites, situated in gneiss, near Riddarhytta, in Vemmland, Sweden.

CEYLONITE, Pleonaste, Haüy, is classified with the ruby family by Werner: its colours are a muddy dark-blue and greyish-black, which approaches to iron-black: it occurs in grains and in small crystals, either perfect octahedrons or truncated on the edges, or with the angles acuminate by four planes, which are set on the lateral planes, also in rhombohedral dodecahedrons. The crystals are smooth and splendent: it is translucent on the edges. The fracture is flat conchoidal: it scratches quartz. Before the blow-pipe, it is infusible. The specific gravity of ceylanite is 3.8. According to Berzelius, the constituent parts are,

This mineral was first found in the island of Ceylon, where it occurs in the sands of rivers with tourmaline, zircon, fahalite, and iron-land. It occurs in lava from Vevuvias, with olivine, augit, and mica. It occurs also in balfat, near Anderach, on the Rhine.

CHABASITE and Chabasite. See Zeolite.

CHALCEDONY. See Chalcedony and Quartz.

CHALK. See Chalk and Geography, Addenda.

CHERT, a variety of hornstone: it differs from flint principally by being more opaque, and having less lustre; it occurs in nodules and mafles in the sand under the chalk formation, and in beds in some mountain lime-stone.

CHIANTOLITE, or Hollow Spar, occurs crystallized in slender rhombohedral prisms, the edges of which are sometimes

rounded,
rounded; sometimes four prisms are arranged in the form of a cross. The prisms appear composed of two distinct substances, as if they had once been hollow, and the hollows filled up with clay-flake, nearly similar to what the crystals are imbedded in. The exterior part of the prism is of a greyish-white or reddish colour, and varies in thickness, in some specimens being a mere film; within this, is a dark-blue or black prism, exactly parallel to that by which it is inclosed. Frequently from each angle of the interior prism a black line or thread proceeds, inclining the corresponding angle of the white prism, and often terminated by a small black prism. The white part exhibits a lamellar structure, parallel with the lateral planes of the prism; it has a slight glistering lustre, is translucent, and feretishes glafs. The specific gravity is 2.9. Before the blow-pipe, it fuses into a whitish fcoria; the black part affords a black glafs. This mineral occurs in acicular crystals in some beds of dark flake in the mountain Skiddaw, Cumberland. The largest crystals are found in clay-flake, near St. Brieux, in Brittany. Some mineralogists consider chlortophile as the same fubstance as andalusite; others clasf it with common feldspar, and fome regard it as a distinct species.

Chlorite, Tale chlorite, Haiyi. This mineral is nearly allied to talc and mica. The prevailing colour is various shades of green, hence it derives its name from the Greek 

Chlorite Slate has a greyish or darkish-green colour; it occurs in beds in clay-flake, sometimes associated with tale-flake, into which it passes. It has a glistering refiuous lustre, a flaty structure, inclining to fclay. On minute examination, it appears composed of small scales of chlorite clefely adhering. Chlorite-flake forms beds in mountains of clay-flake in various parts of the Grampian-hills. It passes into hornblende-flake and clay-flake. The specific gravity is 3.03.

Chlorophane, a variety of fluor spar from Siberia, which gives out a beautiful apple-green light when placed on a heated iron. Pallad mentions a pale-violet blue variety spotted with green, which becomes phosphorescent when held in the hand, and gives out a pale-whitifh light; in boiling water, it emits a green light, and at a higher temperature a blue light. See Flufor Spar.

Chromate of Iren, Fer chromacie, Fr. has a pitch-black colour, with somewhat of an olive tinge superficially. It occurs massive and difteminated, and also cryftrallized in octahedrons. It has a fhining lustre, between refinous and metallic. The fracture is uneven, or imperfectly small conchoidal, and fometimes imperfectly lamellar. It feretishes glafs, is opaque. The colour of the flake is ah-grey or brownifh. The specific gravity is 4.03. It is rarely magnetic, is infusible, but tinges borax of a beautiful green colour. According to Vauquelin, the conftituent parts are,

According to Haiyi, the fcaly particles are regular hexagonal prisms when viewed with the microscope.

Common Chlorite is a leek or dark-green colour, intermixed with black. It occurs in rocks of various kinds, in beds and veins, either alone, or with quartz, magnetic iron-flone, iron-pyrites, hornblende, fclay-flate, and other minerals. It is amorphous, has a glistering lustre, an earthy fracture, and a fine granular, laminated, or fcaly structure. Common chlorite is soft, opaque, and greasy. Its specific gravity is 2.8. It occurs in various parts of Scotland, and in Cornwall, Cumberland, and all alpine parts of England.

Foliated Chlorite: Tale chlorite, Haiyi.—Its colour is leek-green; it occurs crystallized in six-sided tables, curiously aggregated in cylindrical or conical forms. The crystals are longitudinally streaked. The lustre is refluous, either glistering or fming. The structure is curvedly lamellar, with a fingle cleavage. It is opaque or translucent at the edges; it is soft, fectile, and rather greasy. The specific gravity is 2.8. According to Lampadius, the conftituent parts are,

Foliated Chlorite is found in various parts of the continent of Europe, and on the island of Jena, one of the Hebrides.

Chlorite Slate has a greyish or darkish-green colour; it occurs in beds in clay-flake, sometimes associated with tale-flake, into which it passes. It has a glistering refluous lustre, a flaty structure, inclining to fclay. On minute examination, it appears composed of small scales of chlorite closely adhering. Chlorite-flake forms beds in mountains of clay-flake in various parts of the Grampian-hills. It passes into hornblende-flake and clay-flake. The specific gravity is 3.03.

Chlorophane, a variety of fluor spar from Siberia, which gives out a beautiful apple-green light when placed on a heated iron. Pallad mentions a pale-violet blue variety spotted with green, which becomes phosphorescent when held in the hand, and gives out a pale-whitifh light; in boiling water, it emits a green light, and at a higher temperature a blue light. See Flufor Spar.

Chromate of Iron, Fer chromacie, Fr. has a pitch-black colour, with somewhat of an olive tinge superficially. It occurs massive and difteminated, and also cryftrallized in octahedrons. It has a fhining lustre, between refinous and metallic. The fracture is uneven, or imperfectly small conchooidal, and fometimes imperfectly lamellar. It feretishes glafs, is opaque. The colour of the flake is ah-grey or brownifh. The specific gravity is 4.03. It is rarely magnetic, is infusible, but tinges borax of a beautiful green colour. Chromate of iron occurs in beds and veins, and in imbedded mafles, in ferpentine and tale-flake. It has been found at Portfoy, in Bamshire, and is faid to occur in confeiderable quantities in the Shetland iflands. It occurs in the vicinity of Nantes, and in the department of Van. The greatest quantity has hitherto been found in ferpentine, in the Bare-hills near Baltimore. The chronic acid
acids obtained from this mineral when combined with lead forms a beautiful yellow pigment, and is now an article of commerce.

Chromate of Lead. red lead-ore. See Lead-Ores.
Chrysocolla. Earthly Malachite. Criore malachite cry-
facolite, Fr. See Copper-Ore.
Chrysolite. Peridot chrysolite, Fr. (See Chrysolite.)
This gem is the finest of the precious stones; its colour change by heat. It is brought to Europe from the shores of the Jefeon.

Chrysoprase. Apple-green chalcedony coloured by the oxyd of nickel. (See Chrysoprase.) It has hitherto been found only in the vicinity of the towns of Glafiendorf, Grochau, and Kofenutz, in Lower Silefia. It is not as common as chaledony. It is used in jewellery.

Cimolite. See Cimolite.

Cinnabar. Mercure sulphure. Haüy. (See Mercury-
Ores.) Besides the localities of cinnabar there enumerated, various mines of cinnabar occur in New Spain. In the kingdom of New Granada, cinnabar is found in three different places in veins, and also in alluvial foil, mixed with gold. In Peru, cinnabar occurs in various parts, particularly near the town of Huancavelicha, at the height of twelve thousand feet above the level of the sea. Cinnabar is found in veins near to Sillacara, interfacing alpine lime-robe; these veins, according to Humboldt, at present furnish all the mercury of Peru.

Cinnamon-stone. This gem was originally found in the lands of rivers in Ceylon. It has been cliffed with hyacinth, but is a variety of garnet. Its colours are, hya-
cinth-red inclining to orange-yellow. It is found in blunted-
angular or in roundish pieces. It has a shining vitreous luflre approaching to splendifer. The fracture is flat and small conchoïdal. It is transparent or semi-transparent, but generally full of cracks. It feraches quartz with difficulty. When cut it feels rather greasy. The specific gravity is 3.6. According to Klaproth, the constituent parts are,

Silex - - - - 38.80
Alumine - - - - 21.25
Lime - - - - 31.25
Oxyd of iron - - - - 6.50

97.80

Before the blow-pipe, it fuses into a blackish enamel. When free from flaws it is of considerable value.

Clay Iron-robe, Argillaceous Iron stone: For oxyde maf-
iffs, Haüy. (See Iron-Ores.) The name has been inapprop-
riately given to this species of iron-robe, as it frequently contains liacerly any alumine or clay in its composition.
The following analysis of Decotels, given in the Ann. de
Chemin for 1812, No. 251, will show how greatly this species of ore varies in its composition.

From Blancheland.

In these specimens, the iron was in the flate of carbonate;
in others, it exists in the flate of oxyd. According to Mr. Jamefon, it would appear that the carbonated iron-robe by decomposition lose their carbonic acid, and are in time converted into the oxydated varieties. In those common clay iron-robe which have a yellow or brown freak, the iron is in the flate of hydrate; in those having a red freak in the oxydated flate, and in most of the varieties having a grey freak, the iron is carbonated. When the carbonated varie-
ties begin to decay they become soft, and assume a liver or reddish-brown colour. This species of iron-robe, besides occurring in numerous thin flata alternating with coal-shale and sand-robe in the coal formation, occurs in kidney-shaped and rounded nodules. The greattst repository of this ore in Great Britain is in the coal basin extending from Pem-
brokeshire into Glamorganshire, on the borders of the Britol Channel.

Clay-slate, Argillaceous Schubus. See Slate.

Clay-stone is nearly connected with basaltic and por-
phyritic rocks of the trap formation. It forms the basis of clay porphyrtes. The colours of clay-stone are blueifh and yellowifh-grey or yellowifh-white, lavender-blue and brownifh-red. It is sometimes spotted and striped. It has a fine earthy fracture, sometimes inclining to flaty or con-
choïdal. The fragments are angular and rather blunt-
edged. It is opaque, yields to the knife, and is rather easily frangible. The specific gravity is 2.2. It occurs in various parts of Scotland, in North Wales, and in Shrop-
shire.

Clinz-stone, Phonolite, Porphyry-flust, Feldspath compate
stones, Fr. has most frequently a greenifh-grey colour. It occurs in beds of considerable magnitude in rocks of the trap formation. (See Trap.) The principal fracture is flaty, with a fealy aspect and a glintening pearly luflre. The croz fracture is splintery and faintly glimmering. It occurs columnar and tabular, is tranfluent on the edges, and easily frangible. The thin tables yield a metallic found when fluck. The specific gravity is 2.8. It melts before the blow-pipe into a grey-coloured glafs. According to Kla-
proth, the constituent parts are,

Silex - - - - 57.25
Alumine - - - - 23.50

Cornelian. See Chalcedony and Agate.

Corundum, Coriand, Fr. The French mineralogists chiefly as varieties of corundum the oriental ruby, the sapphire, and emery. (See these articles.) Though they are principally composed of alumine, they are, excepting the diamond, the hardest of mineral substances, and nearly the heaviest of earthy minerals, the specific gravity being from 3.87 to 4.28.

Common corundum, or adamantine spher, has a greenish-white colour: it is sometimes pearl-grey, brown, or red. It is translucent and sometimes nearly transparent, and is doubly refracting. It has a distinct lamellar structure, and splits into rhombooids, the angles of which are 86° 38’ and 93° 2’.

(See Adamantine Spar.) This mineral is found imbedded in granite, like felspar, in various parts of India, and also in North America, and imbedded in micasous schist in Italy.

Cross-stone, Hartnaton, Haüy. See Zeolite.

Cryolite, Alumine fluite, Fr. This mineral has hitherto been found only in West Greenland. It occurs in two thin layers in gneiss. Its name is derived from the Greek word denoting ice, because this mineral melts almost like ice at a low heat. Its colours are pale greyish-white, snow-white, and yellowish-brown. It occurs massive and disseminated. It has a shining or glinting vitreous lustre, inclining to pearly, and is translucent. The structure is imperfectly lamellar, with joints in three directions parallel to the faces of a rectangular parallelopiped. It is softer than fluor spar, and is easily fusible. The specific gravity is 2.9. It becomes more translucent in water, but does not melt. Before the blow-pipe it first melts, then hardens, and assumes the appearance of a flag. According to Klaproth, the constituent parts are,

- Alumine - - - 24
- Soda - - - 36
- Fluoric acid and water - - - 40

According to Vauquelin,

- Alumine - - - 21
- Soda - - - 32
- Fluoric acid and water - - - 47

Crysoberyl, Cynophane, Haüy. See Crysoberyl.

Cuprous Arseniate of Iron, Martial Arseniate of Copper. See Copper-ores.

Cyanite, or Kyaneite; Sapphir, Sauffure; Dorthene, Haüy. See Kyante, Addenda.

Datolite, (See Datholite,) is composed of boracic acid, united with lime and silex. It occurs massive and crystallized in oblique four-sided prisms, generally truncated on the edges and angles. The primitive form of the crystal is fluted by HANSF in to be an oblique four-sided prism, with angles of 77° 30’ and 102° 30’. It gelatinizes with acids. In the flame of a candle it becomes opaque and friable. Before the blow-pipe it turns to semi-melt, and then melts into a globule of a pale rosh-colour.

Diallage, Smaragd of Sauffure; Diallage vert, Haüy. Its colours are grawa-green and apple-green; it occurs massive and disseminated. The lustré is shining, glinting, and pearly; it is translucent on the edges. Diallage has a lamellar structure, with a two-fold nearly rectangular cleavage, only one of which is distinct. It is rarely so hard as glass. The specific gravity is 3. Before the blow-pipe, it melts into a grey or greenish enamel. According to Vauquelin, the constituent parts are,

- Silex - - - 50.0
- Magnesia - - - 6.0
- Alumine - - - 11.0
- Lime - - - 13.0
- Chrome - - - 7.0
- Copper - - - 1.5

Diallage is found in Corfica with sauffurit, and on Mont Blanc in Switzerland; also in Carithia and Transylvania. The mixture of diallage and sauffurit is named Gabbro by the Italians, Euphotide by the French, and Verde de Corfica duro by artists. When cut and polished it has a beautiful appearance, and is made into various articles of ornament.

Diallage Metalloid. See Bronzite, Hyperstene, and Schiller Spar, Addenda.

Diamond, Diamant. (See Diamond.) In addition to the characters of the diamond given under that article, it may be proper to state, that besides the colours there enumerated, the diamond occurs sometimes blue, red, brown, yellow, and green, with the following transitions. The only variety of blue is indigo-blue, which appears to pass into red. Of red, the varieties are rote-red and cherry-red. From the latter colour it passes into olive-brown, and yellowish-brown, ochre-yellow, orange-yellow, wine-yellow, and
and sulphur-yellow; further into fikín-green, asparagus-green, pillachio-green, leek-green, and mountain-green, which latter paltes into greenish-grey and greenish-white.

The olive-brown paltes into blackish-brown, pitch-black, and greyish-black.

Besides occurring crystallized, the diamond is also found in rolled pieces and grains. The crystallizations of the diamond, besides the octahedron and its varieties, are, the perfect tetrahedron; the tetrahedron with truncated angles, or with the angles acuminated by three planes, set on the lateral planes; segments of the tetrahedron, either detached or united, forming twin crystals; the rhomboidal dodecahedron, with convex planes or faces; the fame figure somewhat elongated; the dodecahedron, with the planes divided diagonally; an acute double fixed-pyramid, with the lateral planes set on each other, and the apex acuminated by fix planes set on the lateral planes; a flat double three-sided pyramid, with convex planes set laterally on each other, and the angles of the common base acuminated by four planes set on the lateral planes; a flat double three-sided pyramid, on which the lateral planes of the one are set on the lateral edges of the other, and the angles of the common base truncated; a fix-fixed table, with oblique terminal plates; and lattly, the diamond has been found in a cubic form, either perfect or with the edges truncated, or variously modified.

The surface of the octahedron is either smooth or firereaked; the external luflre of the natural diamond is adamantine, and alternates from splendid to glimmering; internally it is highly fplendent. It is feldom completely transparent. The black diamonds are nearly opaque. The diamond has a four-fold equiangular cleavage parallel with the planes of the octahedron in this direction; it is rather easily fragile. The diamond feratches all other minerals. Its specific gravity is flated by Mr. Lowry at 3.488. The diamond, besides its other localities, is found in the district of Serro Dofria, in Brazil: it was flrst discovered there about the middle of the last century, in gullies of torrents, and the beds of rivers, where gold is also obtained, but for a very considerable time, the diamonds being unknown, were difregarded and thrown away. Diamonds occur also in other parts of Brazil, in the rivers Giquitig. 

Diaspore is regarded as a variety of wavelitic. (See Wavelite.) It occurs in curved lamellar concretions easily separable from each other; it has a grey colour, a shining pearly luflre, the angular pieces cut glafs. It flies before the blow-pipe, but is infufible. Its specific gravity is 3.43.

According to Vaquelin, the constituent parts are,

This mineral has hitherto been found only in the rock named zircon sienite. (See Zircon Sienite.) It is claffed by Mr. Jamefon in the felpspar family; but is placed by Werner between jasper and cat’s-eye.

Electrum, an argentiferous gold-ore, or native alloy. Its colour is a pale brass-yellow. It is not soluble either in nitrous or nitro-muriatic acid. It contains, according to Klaproth,

It occurs at Schlangenberg, in Siberia.

Emerald, Emeraldus vertus, Haüy. See Emerald.

Faffe emeralds are sometimes offered for sale, which are either green flour fpar, green quartz, or prafes. The emerald of Brafl is sometimes the green tourmaline. The true emerald is harder than quartz. The beryl and the emerald have both the same primitive form of the crystal or the hexagonal prism. The terminal planes of the emerald are rough, those of the beryl smooth. The emerald agrees in chemical composition with the beryl, both containing from thirteen to fourteen parts of the newly-discovered earth glaucine; but the colouring matter of the emerald chrome is wanting in the beryl. See Geo.

Emery, Corindon granulatâ, Haüy. (See Emery.) This mineral owes its hardness to an intermixture of blue corundum. See Adamantine Spar, and Corundum, Addenda.

Epidote. (See Pizaxite, and Thallite. Under the latter article, for Arundel in Norway, &c.) Epidote occurs at the Malvern-hills in Worceftershire, at Wallow Cragg near Keswick in Cumberland, and near Marazzion in Cornwall.

Episom Salt, Native, or sulphate of magnesia, occurs as efflorescence at Hurlet near Paisley, and sometimes is found efflorescent on old walls, and on the surface of different rocks, particularly pygmm, sand-flone, clay, and compact lime-flone.

Euclare. See Euclare.

Fainlerz, Werner; grey copper ore. See Copper.

Ores. Vol. XXXIX.

Felspar. (See Felspar.) The name of this mineral appears to be derived from the Saxon term fell, a mountain, still used in the northern counties of England; hence felpspar, in its original signification, denoted mountain fpar. In the mineralogical systems of Werner and Mr. Jamefon, the felpspar family comprizes various species of minerals, which are supposed to be nearly allied to felpspar. The felpspar species is also divided into adularia, glaffy felpspar, Labrador felpspar, common felpspar, disinte grated felpspar, and compact felpspar.

Adularia. (See Felspar.)—The forms of crystallis of adularia are the fame as those of common felpspar. It poifles double refraction. It melts before the blow-pipe into a transparent white glafs. Adularia occurs in veins in granite and gneifs, in various parts of Aberdeenhine and Bamshire, in the 7ile of Arran, and in the granite of Switzerland, France, and Germany. The largest and most beautiful cryfals are found in the mountain of Stélia, a part of St. Gothard. Rolled pieces having a beautiful pearly light are collected in the island of Ceylon. The variety which exhibits a fhong pearly light is cut in a semi-lobular form, and is called under the name of morn-ßtone, and is usually worn as a ring-ßtone.

Gffluffy Felpspar occurs always cryfllized in broad rectangular four-fided prisms, bevelled on the extremities. These cryfals are very much cracked, and always imbedded. It is transparent, and has a fpleffent vitreous luflre internally. Its other characters agree with adularia. It occurs in pitch-ftone and trap in various parts of Scotland.

Labrador Felpspar. See Felspar.

Common Felpspar occurs variously cryfllized. Haüy enumerates more than twenty of its secondary forms; several of them are represented Plate I, figs. 8, 9, 10, 11, 12, &c. Cryfllallography. The primitive form is an oblique-angled parallelopiped. The structure is perfectly lamellar, with a double, very distinct, rectangular cleavage, and an oblique indiffident cleavage intersecting the two former. The four rectangular planes have pfpentent faces; the faces of the oblique cleavage are dull. This remarkable character is peculiar to felpspar, and may very frequently be observed in the rhomboidal fragments of this mineral. Felpspar has been frequently analyzed with different results. According to Berzuchus, the most probable composition of common felpspar, fo far as we can calculate it from the many analyses of which we are in possession, is, that the alumine bears the fame proportion to the potash as in alum, and that the silica contains three times the oxygen of the base. The following is therefore a comparison between the calculated and experimental results, according to the principles of Berzuchus’s new system of mineralogy. See Syslem of Mineralogy.

The lime and protoxyd of iron are regarded as accidental admixtures. Felpspar is one of the principal constituent ingredients of many of the rocks called primary, in many of the trap rocks, and many of the lighter-coloured lavas. It forms an essential constituent part of granite, gneifs, sienite, greenstone, and forms the base of many porphyries, and the rock called white-flone. (See White-Stone.) In green-flone, the felpspar is often tinged of a green colour, from the admixture of hornblende or augit. In many of the porphyries, it exists in a compact state, or as compact felpspar. The colours of compact felpspar are various shades of white, grey, green, or red. The
lamellar structure is nearly lost in many of the compact felspars, particularly in those varieties which have little luftre. When it contains crystals of quartz or felspar, it constitutes a felspar porphyry. It forms extensive beds in many alpine districts. It is distinguished from hornstone by its inferior hardness, fusibility, and its frequent intermixture with hornblende or mica.

Disintegrated Felspar has generally a greyish-white colour. It occurs mafive and in imbedded crystals which have the same form as common felspar. It is glimmering, glimmering, and dull and soft and felctile. In some instances, it appears to be felspar in a decomposing slate; in others, to be a softer kind of felspar in an unaltered slate.

Fibrolite, a mineral which occurs with corundum; it has a white or grey colour, is crystallized in rhomboidal prisms, the angle of whose planes are 80° and 100°. It has a fibrous structure, and an uneven cross fracture. Internally it is glimmering. Fibrolite is harder than quartz. Its specific gravity is 3.21. According to Chenevix, the constituent parts are:

| Alumine | - | - | 58.25 |
| Silex   | - | - | 38.00 |
| Iron and loxa | - | - | 3.75 |

100

Figure-Stone. Agalmetolite, or biildteen.
Fish-Eye-Stone, or ichthyophthalmithe.
Flint. See Flint.
Float-Stone, Quaer melinite, Haüy; sometimes called swimming quartz. Its colours are yellowish-white and grey. It is dull, earthy, and friable, absorbs water and becomes translucent. Its specific gravity is less than water, being from 0.448 to 0.793. The constituent parts are:

| Silex | - | - | 91 to 98 |
| Water | - | - | 6 |
| Carbonate of lime | - | - | 2 |
| Oxyd of iron and alumine | - | - | 2 |

It is found at St. Oien, in the vicinity of Paris, along with felspar, and sometimes contains the same petrifactions as those found in flint. Flint is sometimes found in the centre of float-stone, and paffes into it by gradation. Float-stone may therefore be considered as a porous flate of flint.

Flos Ferri, Coralboild Aragonite, occurs in snow-white dendritical branches, either smooth or incrusted with points. It is found in the mines at Dufton Fell, Westmoreland, and is fupposed by count Bouron to be formed by sublimation.

Fluor Spar, Fluor, Werner; Chaux flaitées, Fr. See Felspar.

Foliated Granular Lime-Stone. The name given by Mr. Jamefon to crystaline primitive lime-stone, called by the French chaux carbonatée fraucaire. See Lime-Stone, and Lime-stone, Addenda.

Fossil-Copal, or Highgate Refin, a refracous substance found in perforating the bed of London clay at Highgate. It appears to be a true vegetable gum or resin, partly changed by remaining in the earth. It gives out a refracous aromatic odour when heated, and melts into a limpid fluid. It takes fire when applied to the flame of a candle, and burns away entirely before the blow-pipe. The colour of fossil-copal is a yellowish-brown; it has a refraous luftre, is brittle, and yields easily to the knife. The specific gravity is 1.046.

Fullers-Earth, Argile fontairée, French. See Fullers-Earth.

Gadolinite. See Gadolinite.

Galema, or Sulphure of Lead, Lead Glance; Plumb sulphure, Haüy. See Lead.

Garnet, Grenat, French. (See Garnet, Precious, and Garnet, Common.) The garnet family of Werner and pro-fessor Jameson, in their mineralogical systems, comprises the following minerals, supposd to have an alliance with garnet: leucite, velufian, grossular, melatine, allochroite, garnet, granite, pyrope, and cinnabar-stone. (See these articles in the preceding volumes, and in the Addenda.) In the British Museum, these minerals are chaffed together under the name of garnet substances, whereby the confusion of making the same word represent both the genus and species is avoided.

Glance-Coal, Anthracite. The coal which has a splendid luftre, and burns without flame. (See Coal.) It is principally composed of carbon, and paffes into graphite, or black-lead. Werner divides glance-coal into three sub-species; conchoidal glance-coal, flaty glance-coal, and columnar glance-coal. See Coal.

Glauber Salt, Native Glauberite; Soda sulphate, Fr. occurs as a mealy efflorescence in the neighbourhood of some salt lakes, and occasionally encrusting sand-stone and marl-flate. It is sometimes flatactitic, botryoidal, or crystallized in acicular crystals. According to Reufs, the glauber flat of Eger, in Bohemia, contains

| Sulphate of soda | - | - | 67 |
| Carbonate of soda | - | - | 16 |
| Muriate of soda | - | - | 11 |
| Carbonate of lime | - | - | 5 |

99

Glassy Felspar. See Felspar, Addenda.

Glassy Tremolite. See Tremolite.

Gold. (See Gold.) In addition to the localities of gold given under that article, we may state that native gold is found in some of the stream works of Cornwall, and, like the stream tin which accompanies it, is doublets once a part of the metallic veins that have been destroyed by the natural disintegration of the rocks which these once interfected. We have seen globules of native gold the size of a pea in a matrix of quartz, in the poffefion of the Rev. Mr. Hennor, of Plymouth.

Native gold was found in alluvial foil in various parts of Scotland, and was once extensively worked at the leadhills. In the time of queen Elizabeth, it is said that three hundred men were employed in searching for it, and that in the course of a few summer's a quantity was collected equal to 100,000l. sterling. Gold was obtained a few years since in a ferruginous land in Ireland, near Arklow, in the county of Wicklow. One mass of pure gold weighing twenty-two ounces was found, which was the largest piece hitherto discovered in Europe. The total amount of gold exported to Europe annually from the Spanish and Portuguese colonies in America is stated by Humboldt at 45,580 pounds troy, of which 25,000 pounds weight comes from the Spanish colonies; the remainder from the Portuguese, principally from the Brazil, where it is collected by washing the sands of rivers and alluvial deposits. Gold is found almost every where along the foot of these immense mountains which run in a chain nearly parallel with the coast, from 5° to 35° of south latitude. Many of the silver-ores in America are also rich in gold. (See Silver.)
MINERALOGY.

SILVER. For a more particular account of these repositories of the precious metals, we must refer our readers to the various works of M. Humboldt, to whom we are indebted for almost all the correct information we have respecting the European colonies in South America. The quantity of gold and silver imported from these colonies between the years 1802 and 1805, is stated at one hundred and sixty-fix millions in pounds sterling; an amount some-what exceeding that of the present national debt of England!!

Grammatite, Tremolite. See Tremolite.
Granular Lime-stone, flinty marble; Chaux carbonatée fluorscribe. See LIME-STONE, and LIME-STONE, Addenda.
Graphic Gold and Graphic Tellurium. See Tellurium.

Graphite. Plumbago or black-lead, (see Plumbago,) has an iron-grey colour, and a glimmering or glistening metallic lustre. It is fettile, and when fresh cut has a lead-grey colour: it is uncouth to the touch, yields to the nail, and leaves a distinct lead-grey mark on paper. Before the blow-pipe it gradually burns away, leaving a portion of red oxvd of iron. According to Berthollet, the constituent parts are,

<table>
<thead>

</tbody>
</table>

The graphite of Borrowdale occurs with ochreous and unctuous clay; it is found in nodules and maffes of various sizes. The bed in which it is found lies in a rock of grey porphyrite felspar, which has been improperly called grey wacke. Three beds of scaly graphite have lately been discovered in a rock of mica-slate or gneiss, near Buxey, in Inverness-shire.

Green Earth, Chlorite zérophrique, French. This mineral, though made a distinct species by Werner, appears to be but earthy chlorite (see Chlorite): it generally occurs in cavities or encrusted agates in amygdaledol. It is of various shades of green, is soft and fettile, and adheres slightly to the tongue. The specific gravity is 2.5. Before the blow-pipe, it is converted into a black flag. It is used as a green colour in water-painting. When lightly burned, it affords a beautiful and durable brown.

Grenatite, Staurosite, Haïy; the fassaule of some mineralogists. (See Staurolith.) This mineral is called in the garnet family by Werner; but it varies from garnet in the form of its crystal, which is an oblique four-sided prism, truncated on the acute lateral edges. Sometimes it is bevelled on the extremities by two planes cut on the lateral edges, and the edge of the bevelment is truncated. The crystals sometimes interlace each other, forming a croft; hence it has been called croft-stone by some mineralogists: but it is a very distinct species from the harmotome, or croft-stone, which is a member of the zeolite family. (See Zeolite.) The colour of grenatite is dark reddish-brown. It is infusible before the blow-pipe. The above characters distinguish it from precious garnet. It occurs imbedded in mica-slate, and in talc, generally accompanied with kyanite and precious garnet.

Grey Antimony-Ore. (See Antimony-Ores.) Grey antimony occurs in some of the mines in Cornwall in considerable quantities, particularly at St. Stephen's, Padlehead, and Huel bays. It is found also at Glenedenning, in Dum-frieshire.

Grey Cobalt-Ore. (See Cobalt-Ore.) This mineral is found at Herland and Doktooth mines, and in some other veins, in Cornwall.

Grey Mangansc-Orce. See Manganese.
Gypsum, felenite; Chaux fulfate, Haïy. See Gypsum.
Harmotome, Croft-stone. See Zeolite.

Haïyne, Latialite, Haïy. A mineral claffed by the German mineralogists with the azure-stone, or lapis lazuli family. It was first discovered in the volcanic rocks of Albano and Frafcati, and called initialite, from ancient Latium, and was afterwards discovered in the bafaltic rock of Andernach, and has been called Haïyne, in honour of the celebrated mineralogist Haïy. Haïyne has a sky-blue colour, passing into pale Berlin-blue and bluein-green. It occurs in imbedded grains, and crytallized in minute splendent rhomboidal dodecahedrons. The fracture is conchoidal, passing into uneven; it has a vitreous lustre, is transparent or semi-transparent, ferstches glafs, and is infusible before the blow-pipe. When pulverized, it gelatinizes with muriotic acid, giving out an odour of sulphuric hydrogen. The specific gravity is from 3.1 to 3.3. According to Vauquelin, the constituent parts are,

<table>

95.0

It has by some mineralogists been claffed with saphirin, and described under the name of saphirin. It was arranged by Cordier with fpinel.

Heavy Spar, Sulphate of Baryste, Baro-Selenite. This mineral exceeds in weight all other purely earthy minerals, its specific gravity being from 4.3 to 4.49. It occurs both maifive and crytallized in many metallic veins. Its colours are various shades of white, yellow, red, green, grey, and blue. Crytallized heavy spar is transparent or tranflucent, and refracts doubly; it has a distinct lamellar structure, and splits into a right-rhomboidal prism, which is its primitive form; the angles of the rhomb are 78.3° and 101.90. The joint parallel to the base of the rhomb is the most distinct. The lustre is shining, between vitreous and piffinous: it yields readily to the knife. Before the blow-pipe it decrepitates violently, and then melts into a hard white enamele. A piece exposed to the blow-pipe, and laid on the tongue, gives the flavour of sulphuric hydrogen. The powder of some varieties of heavy spar, when calcined, absorbs light, and emits it again in the dark. Sulphate of frontian (see Strontian) is the only earthly mineral with which heavy spar can probably be confounded. White lead-ore may be distinguished from heavy spar, as it is softer, and yields a metallic globule before the blow-pipe. Pure heavy spar consists of

100

Mr. Jameson makes the following varieties of heavy spar, which he clasifies as sub species: earthy heavy spar, compact heavy spar, granular heavy spar, lamellar heavy spar, radiated heavy spar, fibrous heavy spar, and prismatic heavy spar; and he divides lamellar heavy spar into three kinds, straight lamellar heavy spar, curved lamellar heavy spar, and disintegrated lamellar heavy spar.
**MINERALOGY.**

*Earthy Heavy Spar* occurs sometimes loose, and sometimes cohering in the drusy cavities in veins; it is composed of dull or glimmering dusty particles, which feel meagre.

*Compact Heavy Spar* occurs massive, effaced, reniform, semi-globular; it has a coarse earthy fracture, and is sometimes imperfectly foliated; it has a glimmering lustre, is slightly translucent, soft, and easily frangible. It is often marked with dendritic delineations. According to Weilrumb, it contains:

In Derbyshire, this mineral is called *crack* by the miners.

*Granular Heavy Spar* occurs massive; the structure is finely granular; the structure of the grains is lamellar. This mineral nearly resembles granular lime-stone, but is much heavier, and does not effervesce with acids.

*Lamellar, or Crystalized Heavy Spar* occurs in the following secondary forms. 1. A rectangular four-sided table, either perfect, or with the terminal planes bevelled, and sometimes the angles of the bevelment are truncated. 2. An oblique four-sided table, perfect, or with the angles or edges truncated. 3. A long horizontal table, either perfect or variously bevelled. 4. Eight eight-sided tables, either perfect, bevelled, or truncated. Curved lamellar heavy spar occurs in distinct concretions, which have a curved lamellar structure.

*Fibrous Heavy Spar* has a chefsuant-brown colour. It occurs in reniform or botryoidal masses, and has a plamose or diverging fibrous structure.

*Radiated Heavy Spar, or Bolognese Spar.*—Its colours are, smoke-grey, ash-grey, or yellowish-white. It occurs in roundish collected pieces, which are always covered with marl or clay. The structure is lamellar in one direction, and in the longitudinal fracture radiated: it is translucent. It is remarkably phosphorescent after being heated and exposed when cool to the light, and carried into a dark room. It was first found at Monte Paterno, near Bologna. Its constituent parts are:

*Columnar Heavy Spar:* Baryte sulphaté bacillaire, Haüy.

—Its colours are, yellowish, greyish, and greenish-white. It occurs crystallized in acicular oblique four-sided prisms, laterally aggregated into columns; the lustre is shining and pearly: it is translucent, and has a lamellar structure.

*Prismatic Heavy Spar* is heavy spar crystallized in four-sided or six-sided prisms, variously acuminate and modified by bevelments and truncations.

*Hepatite, Baryte sulphaté fétide,* Haüy, may be clasped as a variety of heavy spar, which poissified the property of yielding a fetid sulphureous odour when heated or rubbed. It occurs in globular masses, from an inch to a foot in diameter; these masses have a curved lamellar structure. According to John, the constituent parts are:

*Hepatite occurs at Buxton, in Derbyshire.*

*Heliotrope, Quaars agate penduli,* Haüy.

*Hematite, Black and Brown:* For oxyde hematite, Haüy.

*Hematite, Red:* For dolerite concretions, Haüy. See *Iron-Ores.*

*Hepatic Pyrites, or Lower Pyrites.* See *Pyrites.*

*Hematite.* See *Heavy Spar, Addenda.*

*Highgate-Resin.* See *Fossil-Copal, Addenda.*

*Hollow Spar.* See *Chalcedony, Addenda.*

*Honey-Stone.* See *Malachite.*

*Horn-stone,* a mineral nearly allied in composition to flint, but has a more earthy texture; it received its name from the supposed resemblance to horn. A more opaque variety of flint, which occurs along with silt and chalcedonic flint in the sand strata below chalk, is called chert. (See *Chert, Addenda.*) This is a kind of horn-stone. Horn-stone is the *petro-fissé* of some mineralogists, and under that name is often confounded with compact selloar. Indurated flake, which contains a large portion of filex in its composition, is sometimes called *hornstone flake.* Saffure, under the names of palioperite and neoptere, appears to include both the splinterly horn-stone and flinty flake of Werner. Werner divides horn-stone into three sub-species, splinterly horn-stone, conchoideal horn-stone, and wood-stone.

*Splinterly Horn-stone* occurs of various shades of grey, red, and green. It is generally massive, but sometimes found in large balls, and sometimes lenticular, or in the form of crysall, in the cavities where crysall have once occurred, and hence called suppositititious crysall. The lustre is dull, the fracture splinterly; it is more or less translucent, is somewhat less hard than quartz. It is infusible before the blowpipe, which distinguishes it from compact selloar. The latter mineral is not so hard as horn-stone, and has more lustre. Horn-stone paves into compact selloar, quartz, common jasper, and chalcedonic flint. In the latter substance, it is frequently difficult to determine which of these it should be placed. It forms the bals of horn-stone porphyry.

*Conchoideal Horn-stone* is glimmering or glittering, with a vitreous lustre; it has a more or less perfect and flat conchoideal fracture. It is harder and less translucent than splinterly horn-stone. It occurs massive, globular, and sometimes forms suppositories crysall. It is found in veins and beds. Chert appears to belong to this sub-species.
MINERALOGY.

Wood-flone, Quarz agathe xylolide, Haüy, is generally various shades of grey, frequently striped or clouded. It occurs rounded, and in the shape of the trunks, branches, or roots of trees; it is generally translucent at the edges, with little or no lustre. The crosf fracture is imperfectly conchoidal, the longitudinal splintery and fibrous. Wood-flone is properly wood fiilicified, in which the greater part of the vegetable matter has disappeared, and siliceous matter has occupied the place, preferring the form and texture of wood. Some wood is petrified with opal, forming wood opal; and sometimes the mineral matter of petrified wood is quartz, or calcareous earth.

Hornblende, Amphibole, Haüy. The description of this mineral, so important in geology, was omitted in the proper place, and is given here. Hornblende may be divided into common hornblende, bafaltic hornblende, and hornblende slate. Haüy, under the term amphibole, classes actinolite with hornblende. (See Actinolite.) Hornblende generally occurs of various shades of dark green passing into black; sometimes common hornblende occurs of various shades of brown. Hornblende has a lamellar structure longitudinally, with a two-fold oblique angular cleavage, parallel to the planes of a rhomboid prism, the alternate angles of which are 124°55' and 56°55'. This is the form of the primitive crystal, and distinguishes it from epidote, which cleaves at an angle of 114°30' and 65°30'; and augit or pyroxene, which cleaves at an angle of 92° and 88°. The crosf fracture of hornblende is coarse-grained, uneven; it melts easily before the blow-pipe into a greyish-black coloured glass. These characters, together with the cleavage, serve to distinguish hornblende from augit or epidote; its inferior hardness distinguishes it from fchorl.

Common Hornblende occurs both massive, disseminated, and crystallized; the crystals are oblique four-sided prisms, aggregated or long flatish prisms, intersecting each other, or confusedly radiated. The structure is lamellar or banded. The crystals are long and deeply streaked longitudinally. The lustre is shining and pearly. The black-coloured varieties are opaque; the green generally translucent at the edges. It yields pretty easily to the knife, leaving a greenish-grey streak. It is very tough, and becomes indented by the stroke of a hammer. The specific gravity is from 3.26 to 3.28. According to Klaproth, the constituent parts are,

This mineral occurs forming beds in mountains, or is disseminated, as a constituent part of many compound rocks. It occurs occasionally in granite, gneisf, mica-flate, and slate, and is an effential part of fienite and green-flone. It forms a constituent part of many bafaltic and volcanic rocks, but has frequently been confounded with augit. (See Volcanic Products.) Hornblende occurs abundantly in various parts of Scotland and in England, particularly at the Malvern-hills in Worcestershire, and at Charwood forest in Leicestershire, and in Devonshire, Cornwall, and Cumberland.

Bafaltic Hornblende, Amphibole schorbiq bafaltique, Fr.

It occurs imbedded in bafalt, as at Arthur's seat, near Edinburgh, and in various parts of Scotland. It is frequently found in lava, particularly in the lava of Vefuvius. It was formerly confounded with schorl, until Werner pointed out its characters.

Hornblende-Slate occurs in beds in granite, gneisf, and mica-flate; in the latter rocks, it is often much intermixed with mica, and sometimes contains garnets, as is the case near Tyndrum in Perthshire. Its colour is greenish-black. It has in the mass a flaty structure, and is internally laminar or fibrous, and has a glintening or velvet-like lustre. No very well characterized beds of hornblende-slate occur in England.

Horn-Mercury, Mercure muriaté, Haüy. See Mercury-Ores.

Horn-Silver, Argent muriaté, Haüy. See Silver-Ores.

Humite occurs at mount Somia near Naples, in a granular topaz rock, intermixed with brown and olive-green mica and white Haüyne. Its colour is reddish-brown; it occurs crytatallized in octahedrons, which are always more or less truncated and bevelled; the planes are frequently transversely streaked; it has a shining lustre, and is transparent; it fractures quartz with difficulty. This mineral was named humite in honour of Sir Abraham Hume, by the count de Bourron, who has given the preceding characters of it in his Catalogue Mineralogique.

Hyacinth, Zircon hyacinth. See Zircon.

Hyalite, Muller glafs, Werner; Quarz concretion, Haüy. (See Hyalite.) The specific gravity of this mineral is given in the last edition of professor Jansen's Mineralogy at 2.47, from Karlsen. Its constituent parts are given by Bucholz as under:

HYDROPHANE. See Opal, Addenda.

HYPERSTENE, Labrador Hornblende; Diallage metallic, Haüy. Its colours are, dark-greyish, brownish, or greenish-black, with generally a pseudo-metallic lustre, reflecting a copper-red, a pinchbeck-brown, or a gold-yellow light. It occurs both massive and disseminated; it has a lamellar structure and a two-fold cleavage, the planes forming angles of 100° and of 80°. It is opaque, and yields a greenish-white streak. It is harder than common hornblende. Its specific gravity is 3.38. Before the blow-pipe it blackens, but is infusible. According to Klaproth, the constituent parts are,

Until very recently, this mineral had only been found on the coast of Labrador, where it forms a constituent part of a rock composed of Labrador felspar, and sometimes containing common hornblende and magnetic iron-oxide. It has been lately discovered by Dr. Macculloch in Sicenite, at Lock Scawig in Sky, also near Portroy, and is supposed to exist in many rocks which have hitherto been designated green-oxides.

IETHYLOPHTHALMITE, Apophylite, Haüy. See ZEOLITE.

IODCHAS, Vesuvian. See Vesuvian.

INDIANITE, a mineral brought from the Carnatic, of which we have the following account by its discoverer the count de Bournon. Its colours are white and grey, its lustre shining; it has a lamellar structure, is translucent inclining to transparent; it fractures glaas, but is less hard than felspar; it occurs massive, and is associated with hornblende. Its specific gravity is 2.74. According to Chevénix, the constituent parts are,

INDICOLITE, Indigo blue, tourmaline. See Tourmaline.

IOOLITE, Diopside, occurs principally crystallized, in small equiangular and equilateral fix-sided prisms, which have rough surfaces. The colour is violet-blue, or dull prussian blue, but when viewed by transmitted light at right angles to the axis of the prism is a brownish-yellow. The structure is indifferently lamellar, with joints passing through the axis at right angles to the lateral faces of the prism. The fracture is uneven, pitting into conchoidal. It paltes from translucent to opaque. Iolite fractures quartz. Its specific gravity is 2.5. It is not affected by acids. Before the blow-pipe, it melts with difficulty into a greenish-grey enamel. This mineral occurs at Cape de Gage, in Spain; it is found imbedded in fragments of gneists and compact felspar, contained in what is supposed by Cordier to be a volcanic tufo, which contains, besides blocks of scoria, obsidian and basalt. Iolite has also been found in trap at Arendal in Norway.

IRIDÉUM, Naïve, has a pale red or grey colour; it occurs in flat irregular, in alluvial, or in South America. It has a shining metallic lustre, a lamellar structure, is brittle and harder than platinum. Its specific gravity is 19.5. It is proved by Dr. Wollaston to be an alloy of Iridium and Osium; which see.

IRON-CLAY is of a reddish or brownish-red; it occurs massive and fuculent, as the bafes of some amygaloids which form beds in basaltic rocks. It is intermediate between basalt and watke, having less hardness than the former, and more than the latter. It is also more easily frangible than either basalt or watke.

IRON-FIINT is generally of a brown or brownish-red colour; it is opaque and hard, and has an imperfeet conchoidal fracture. It occurs massive in rounded pieces, and crystallized in small equiangular fix-sided prisms. Its specific gravity is from 2.5 to 2.8. It is infusible. This mineral appears to be quartz rendered opaque by a chemical combination with iron. According to Bucholz, the constituent parts are,

Pebbles of iron-fiint are used at Worcester for burning the gilding in china. They have sometimes been found in considerable quantities in the ploughed fields near Ashby-de-la-Zouch in Leicestershire.

IRON-MICA. Micaceous iron glance, or iron-ore. See IRON-ORES.

IRON, Naïve. See IRON-ORES.

IRON, Naïve and Meteoric, Fer naïve meteorique, Haüy, is the iron which has been observed in various places to fall from the atmosphere. See STONE, Meteoric, Falling Stone, and Meteoric Iron, Addenda.

IRON-ORE and Iron-Stones. (See IRON.) We shall here enumerate the different species of iron-ore, with the names given to them by the French and German mineralogists.

Iron Pyrites, Common; Fe sulphuré, Haüy; Gemmeiner schmelzfliks, Werner. Capillarity Pyrites, Fer sulphuré capillaire, Haüy; Haarkies, Werner. Cellular Pyrites, Zellkies, Werner. Radiated Pyrites, Fer sulphuré radie, Haüy; Strahltkies, Werner. Hepatic, or Liver Pyrites, La pyrite hepatische, Brochant; Leberkies, Werner. Magnetic Pyrites, Fer sulphuré magnetise, ou magnétique, Haüy; Magnetkies, Werner. Fohlated Magnetic Pyrites, Blatlicher magnetkies, Werner. For an account of these species, see PYRITES, and IRON-ORE.

IRON-STONE, Magnetic, Common, Fer oxydatile, Haüy; Gemmeiner
MINERALOGY.

Gemeiner magnetit, Werner. This ore is highly magnetic with polarity. According to Berzelius, it contains

Peroxyd of iron - - 71.86
Protoxyd of iron - - 28.14

It occurs in various parts of the world, chiefly in primitive mountains; it is found at St. Jull in Cornwall, and Tavistock in Devonshire.

Iron-fond, or Sandy Magnetic Iron-fond, Fer oxydul titanifer, Haüy, (see Iron-ore,) occurs in volcanic and basaltic rocks, forming a component part of many black lavas, and in the sands of rivers. According to Cordier, its constituent parts are,

Iron-fond, Teneriffe.
Oxyd of iron - - 79.2
Oxyd of titanium - - 14.8
Oxyd of chrome, a trace - - 1.6
Oxyd of manganese - - 0.8
Silex and alumine - - 96.4

According to Thompson,

River Dee, Aberdeenshire.
Oxyd of iron - - 85.3
Oxyd of titanium - - 9.5
Articul - - 1.0
Silex and alumine - - 1.5
97.3

Earthly Magnetic Iron-fond; Fer oxydul fuliginanis, Haüy; Oxydrige magnetitbenz, Werner.—The colour is blueish-black; it is opaque, soft, feitle, and easily frangible. It appears to be common magnetic iron-fond in a state of decomposition. Common magnetic iron-fond and iron-fond are distinguished from iron-glance by the colour of the streak, which is black; but that of iron-glance is red. According to Mr. Jameson, Werner was the first who observed that magnetic iron-fond does not possess the magnetic property when at a depth in the earth, but it acquires it after exposure to the atmosphere.

Specular Iron-ore, or Common Iron Glance; Fer ocellat, Haüy; Eisenglanz, Werner.—This ore, according to different analyses, appears to contain about 90 per cent. of oxyd of iron. See Iron-ores.

Salty Red Iron-ore, or Iron Froth; Fer ocellat rouge luisant, Haüy; Rotter eisernahn. Ochre Red Iron-fond; Fer oxydul rouge graﬃer; Ochrer rotheisenbenz, Werner.

Compaq Red Iron-fond; Fer ocellat specular, Haüy; Dickher rotheisenbenz, Werner.

Red Hematite, or Fibrous Red Iron-fond; Fer ocellat concretionis, Haüy; Rotther glasfop, Werner. See Iron-ores.

—Brown iron-fond is distinguished from red iron-fond by its red streak and inferior specific gravity: it also contains more water, the brown iron-fond being an hydrate. This ore, according to professor Jameson, makes but indifferent cast-iron, but affords good malleable iron and excellent steel. See Iron-ore.

Compaq Black Iron-fond; Dickher sowerzeissenbenz, Black hematie; Mine de fer noir compacts, Fr.; Schwarzer glasfop, Werner.—When melted with borax before the blow-pipes, it yields a violet-blue glas; hence it is conjectured to contain much manganese.

Sparry Iron-fond; Chaus carbonaté ferrifereauer man- gane, Haüy.

Columnar Clay Iron-fond; Fer argileux basaltique, Fr.

Lenticular Iron-fond; Fer oxydul brun granuleux ou lenticalaire, Fr. (See Iron-ore.)—The following analysis of this ore is given by Daubrueil, Journal des Mines, 1816.

Peroxyd of iron - - 73
Water - - - 14
Silex - - - 9
Peroxyd of manganese - - 1
Lofs - - - 3

100

Reniform Clay Iron-fond; Fer oxydul geodi que, Haüy.—The constituent parts of this ore are stated by Daubrueil.

Peroxyd of iron - - 76
Water - - - 13
Silex - - - 7
Oxyd of manganese 2 a trace
Alumine - - - 1

97 99

See Iron-ore.

Pee-ore, or Pifform Iron-ore; Fer oxydul globusiforme, Haüy; Bobnere, Werner. See Iron-ore.

Picky Iron-ore; Fer oxydul pyrinte.—The pitchy iron described under the article Iron-ores appears to be a phosh- phate of iron: later mineralogists describe it as an oxyd and sulphate of iron. It is a rare ore, having been found only in one mine near Freyberg, and in the district of Pilfs in Upper Silefia. Its colour is greyish-black, passing into dark liver-brown. It is said to occur forming crusts. It has a splendent or shining refrinons lunte. The fracture is imperfectly conchoideal; it is composed of granular dilincent concretions: it is translucent on the edges: the streak is lemon-yellow: it is soft. When placed in water, it becomes semitransparent and vitreus. According to Klaproth, its constituent parts are,

Oxyd of iron - - - 67
Sulphuric acid - - - 8
Water - - - 20

95

Blue Iron-ore; Blue Iron Earth; Fer phophaté terreux, Haüy.
MINERALOGY.

Häuly. (See Iron-ore.) According to Klaproth, this ore contains,

| Oxid of iron | - | - | 47·50 |
| Phosphoric acid | - | - | 32·0 |
| Water | - | - | 20 |
| **Total** | | | **99·5** |

**Chromate of Iron.** See Chrome, and Chromate of Iron, Addenda.

**Cuba Ore.** See Ores of Iron.

**Muriate of Iron, Native, or Pyrolusite, Fer muriaté, Fr.** has a liver-brown colour, inclining to pichachio-green. It occurs crystallized in short six-sided prisms. The terminal planes of the crystals are shining and pearly, the lateral planes, when clear, are shining and vitreous. It has a felicated structure and four-fold cleavage, the most distinct of which is parallel with the terminal planes. It is translucent on the edges, and yields a brownish-white streak. Its specific gravity is 3·08. It is insoluble in water, but soluble in muriatic acid, except a small residuum of silicious earth. Before the blow-pipe, it gives out copious fumes of oxy-muriatic acid. This is a very rare ore of iron.

The following table of the annual quantity of iron raised and smelted in different parts of Europe, is extracted from the second edition of Jamefon's Mineralogy, vol. ii. p. 314.

The United States of America, without including Louisiana and the Indiana territory, are said to yield 480,000 quintals, and, according to Dr. Bruce, the value of the iron and manufactured articles of iron in the United States is from twelve to fifteen millions of dollars. The annual importation, including bar-iron and every article of iron or steel, is estimated at four millions.

**Iridium,** an alloy of iridium with osmium. See Osmium, Addenda.

**Iserine.** See Titanium.

**Jade, Jade-Nephrite, Fr.** See Nephrite, Addenda.

**Jasper.** (See Jasper.) In that article it is stated, that common Jasper is exclusively found in veins: this is not strictly correct, for Jasper occurs in irregular beds and masses in the argillaceous schistus, which covers the granite of the Grampian-lills in Kincardineshire. Jasper occurs in some of the beds of manganite near Exeter.

**Jenite.** See Yenite.

**Jet Pitch-coal, Joyet, Fr.** has a black colour, and yields a brownish-black streak. It occurs massive, and in the shape of branches. Jet has a ligneous structure. The fracture is large and perfect conchoidal, with a shining refrinoous lustre. It becomes electric by friction, and burns with a greenish flame and bituminous odour. Jet, according to the experiments of Dr. Macculloch, contains vegetable extract on distillation; but when heated under compression, it is converted into true mineral coal. For some account of the localities of jet, see Jet.

**KaoLin.** See Porcelain Earth, Addenda.

**Kyanite, or Cyanite. Diphacten, Häuly; Sapphir, Sapphire, Saffire.** Its colours are bluish, or grey sky-blue, and pale blueish-green. The white varieties are partially shaded with blue. It occurs crystallized and massive. The form of the crystals are an oblique four-sided prism, with two opposite broad, and two opposite narrow planes. This is the primitive crystal. It occurs also truncated on the two opposite acute lateral edges, forming an hexahedral prism; sometimes all the lateral edges are truncated; and sometimes two prisms are joined by their broader lateral planes, forming a twin crystal. The narrow lateral planes are longitudinally streaked. The lustre is shining and pearly, and that of the broad planes is sometimes splendent. Kyanite has a lamellar structure, with a cleavage parallel to the planes of an oblique tetrahedral prism; that parallel with the broad lateral planes is the most distinct. The fracture of amorphous kyanite is more or less curved lamellar, passing into bladed. It is translucent or transparent; it scratches glass, and is easily fragrable. The specific gravity is 3·47 to 3·51. Some of the crystals becomes positively electric, others negative; hence the name of thene was given to it by Häuly, on account of its double electrical powers. It is infusible before the blow-pipe. According to Klaproth, its constituent parts are,

It occurs in primitive mountains, in mica-flate, talc-flate, and white-fole. It has been found at Boharn, in Bamfie and Bambour, Aberdeenshire. In India it is cut and polished, and sold as an inferior kind of faphphire. Sometimes crystals of kyanite may be seen joined and intermixed with grenolite, (see Grenolite,) which hews the near alliance of these minerals, which have also nearly the fame chemical composition.

**Labrador Peltsparr.** See Felixpar.
**Labrador Hornblende.** See Hyperstene, Addenda.
**Lapis-Lazuli.** See Lazuli.
**Lattialite.** See Häuly, Addenda.
**Laumonite.** See Zeolite.
**Lazmestone.** See Lazuli.
**Lazulite.** See Lazuli.

**Lead-Ores.** (See Lead, where eleven species of lead-ore are described.) The antimonial lead-ore is called the triple sulphuret of lead. Four other species of lead-ores have since been described; cobaltic lead-ore, native mummite, arsenate of lead, and muriate of lead.

**Cobaltic Lead-ore** is a fresh lead-grey colour, and a shining metallic lustre. It occurs minutely diffaminated,
and in extremely minute crystals, aggregated like moss; it is opaque, soft, and feeble. Before the blow-pipe it splits into small pieces, and communicates a small blue colour to borax.

Native Minium; Plomb oxydé rouge, Haüy.—It has a scarlet-red colour. It occurs massive and pulverulent; when examined with a lens, it exhibits a crystalline structure, like galena, in which it is generally found. Before the blow-pipe, on charcoal it is first converted into litharge, and then into metallic lead. This mineral is probably produced by the decomposition of galena, which it ferrets. It has been found at Graffington, and other parts of Craven, in Yorkshire.

Muriate of Lead, or Corneous Lead-Ore.—Its colours are greyish or yellowish-white, paffing into wine-yellow. It occurs crystallized in cuboidal prisms, either simple, or terminated by tetrahedral pyramids, or bevelled on the edges. It exhibits a lamellar structure, with joints in three directions parallel to the faces of a cuboidal prism; the cross fracture is conchoidal; it has a splendid adamantine lustre; is more or less transparent. It is very soft and fragile. On exposure to the blow-pipe, on charcoal it melts into an orange-coloured globule, and appears reticular externally, and of a white colour when solid; if melted again, it becomes white; and on increase of the heat the acid flies off, and minute globules of lead remain. According to Klaproth, its constituent parts are,

This ore occurs in considerable quantities in some of the mines in Craven, in Yorkshire, and is infested as a rich ore of lead.

Conchoidal Phosphat of Lead contains a small portion of arsenic and muriatic acid. It differs from green lead-ores, described under the article Lead-Ores. When crystallized, the planes of the crystals are generally convex. It occurs also talcitic, reniform, and botryoidal. The colour is orange-yellow, passing into lemon-yellow and red; the fracture is conchoidal; it is translucent; internally the lute is shining and refrinous. Its specific gravity is 7.26. According to Langier, its constituent parts are,

**Lepidolite. (See Lepidolite.)** When that article was written, it was supposed that this mineral was exclusively found on Mount Hradisco, in Moravia. Lepidolite has since been discovered in Saxony, Sweden, Norway, France, the Island of Elba, and in several parts of Scotland, particularly in lime-stone, near Dalmally, in a flint-quadry at Ballachulish, at the head of Loch Fyne, and at Glenfiddich in Perthshire.

**Lecite, Amphigene, Haüy. See Lecite.**

**Limestone, or Tenite. See Yenite.**

**Lithomarge, Friable. (See Lithomarge.)** This variety is characterized by its sable particles foiling, and low degree of coherence. According to Klaproth, it contains

**Lithomarge, Indurated; Argil lithomarge, Haüy. (See Lithomarge.)** This variety occurs in veins in porphyry, gneifs, grey wacke, and serpentine, and in druffy cavities in basaltic rocks. It is intermediate between flåtite and variegated clay, and appears sometimes to laps into mear-cham.

**Lydi-an-Stone. See Flinty Slate, and Horn-stone, Addenda.**

**Lythrodens, a mineral discovered in Norway, which appears allied to chalolite, and was called lythrodens by Karlen, because when frill broken it appears as if spotted with coagulated blood. Its colour is aurora-red, passing into brownish-red or brown; it is occasionally marked with cream-yellow and greenish spots. It occurs massive and disseminated; it has an imperfect foliated structure. The lustre of the surface is resinous and glimmering. The cross fracture is splintery and dull; it is feebly translucent on the edges; it is hard. The specific gravity is 2.5. According to John, the constituent parts are,

Other analyses give a small portion of sulphur and magnesia.

**Magnesian Lime-stone, or Compact Dolomite, has generally a yellowish-brown or yellowish-grey colour, a granular structure, a glimmering or brightening lustre, and diffuses fadowly in acids; these characters distinguish it from common lime-stone. The specific gravity is about 2.8. It contains fewer petrifactions than most common lime-stones. It occurs in regular strata on the eastern side of England from Nottinghamshire to Sunderland. It occurs also in amorphous mafes, and variety contorted beds, and also forming a kind of lime-stone breccia in the red marle. According to Tennant, its constituent parts are,

**Magneite, Magnesia carbonatæ, Haüy.** It occurs in amorphous mafes and tumberous fongiform. The fracture is fplintery and large, and flat conchoidal. It is opaque, earthy. The colour is yellowish-grey or white, with spots and dendritic delineations of blackish-brown. Magnefite yields to the nail externally, but internally it is harder than calcareous spar; it feels somewhat meagre, adheres to the tongue, and absorbs from nine to ten per cent. of water when immersed in it, and becomes semi-transparent on the edges. It is feebly soluble with effervescence in concentrated muriatic acid. Before the blow-pipe it is infusible, but becomes sufficiently hard to scratch glass. Its specific gravity is 2.88. According to Bucholz, the constituent parts are,

According to Thomson,
MINERALOGY.

It is found in serpentine in Moravia, along with mearschaum and earthy talc. It is distinguished from mearschaum by its colour, external shape, fracture, meagre feel, and weight.

Magnetite. See Copper-Ores.

Manganese-Ores. See Manganese and Wadd.

Marl. See Marle.

Mearschaum. (See Mearschaum.) This mineral, of which an account is given under the article, appears to be hydrate of magnesia combined with flex; it is flated by Mr. Jameloff to be fusible on the edges into a white enamel. It occurs in veins in the terpentine of Corawall. In Natalia it occurs in beds under the soil, and from 60 to 700 men are employed in digging it. When first raifed, it is soft and greasy, and lathers with water like soap; hence it is used by the Tartars for washing. Mearschaum is extensively manufactured in Turkey into tobacco-pipes, which are boiled in oil or wax; afterwards they are baked and then polished.

Mieonite. See Melonite.

Melanite, Gneis, Haüy. See Garnet.

Melilite and Mellilite, Honey-Stone. See Mellilite.

Menachanite. See Titanium.

Menilite, Quartz, fulgurante brunone, Haüy. See Menilite.

Mercury-Ores. See Mercury, and Cinnabar, Addenda.

Mesoxy. See Zerolite.

Meteor, Native Iron; Fer natif meteorique, Haüy. The colour is pale lead-grey, which inclines to silver-white, like alabaster; it is generally covered with a thin brown crust of oyxid of iron; it occurs in racemose or globular masses, and also minutely disseminated in meteoric flones. (See Stone, Meteoric.) The external surface is smooth and glimmering; the internal glimmering or glutining with a metallic lustre: it yields a splendid irteak, and is malleable and flexible, but not elastic. The specific gravity of meteoric iron is from 6.48 to 7.57; it is magnetic. According to Mr. Howard, the constituent parts are,

Iron - - 96.5 - - 96.75
Nickel - - 3.5 - - 3.25

All the meteoric iron which has yet been examined contains a portion of nickel; the latter metal is also found in most of the meteoric flones. The phenomena attending the deficient of meteoric iron are precisely similar to those which accompany the fall of meteoric flones. In most instances, loud detonations and brilliant light or fire-balls have preceded the fall. These fire-balls appear to be the metallic or mineral matter in a state of vivid ignition. Pliny mentions the fall of a mass of sponge iron from the atmosphere in Lucania fifty-six years before the Christian era. Avicenna mentions a mass of iron weighing fifty pounds, which fell from the air near Luriga; and Avemroes says, a mass of iron weighing one hundred pounds fell at Cordova in Spain. In the year 1164, a shower of iron fell in Minia. (Georg. Fabri. Rer. Miniae, lib. i. p. 32.) In the year 1552 fire-dome or masses of iron fell near Milkos, in Tranfylvania. And among numerous other instances in the year 1751, a fire-ball bursted with a loud explosion in the bithorpe of Agram, in Croatia: two masses of iron fell from it; one of which weighed seventy-two pounds, sunk a considerable depth into the earth; and the other, which was sixteen pounds, fell on the surface of a meadow, at the distance of 2000 paces from the former; the larger is still preserved in the Imperial cabinet of Vienna.

Numerous masses of native iron occur in various parts of the world, which agree in external appearance and chemical composition with those whose deposit from the air is well attested. Prof. Pallas discovered a mass of native iron, weighing about 1600 pounds, on the surface of a hill between Krafnojark and Abakunus, in Siberia. It is considered as a holy relic by the natives, who believe that it fell from heaven.

Several masses of native iron have been met with in Mexico; and many years since, a mass of native iron, calculated to weigh about thirty tons, was discovered in the district of St. Jago del Ouro, in South America. It lies in the middle of a great plain, where no rock or mountain is within an hundred miles of it. According to Howard, it consists of 90 parts of iron, and 10 of nickel. Similar masses have been found in Africa, North America, and the East Indies.

Mica. See Mica.

Mieenite, Granular, is a variety of magnesian lime-dome, first found at Mieno in Tuscany: it has a light green or greenish-white colour; it occurs massive and crystallized, in small flat double three-sided pyramids, in which the lateral planes of one pyramid are set on the lateral edges of the other; the crystals are often joined by the edges, or interfet each other. It is translucent, and has internally a splendent and pearly lustre. The fracture is curvedly lamellar. Its specific gravity is 2.88: it dissolves slowly in acids. The constituent parts are,

Carbonate of lime - - - - 53
Carbonate of magnesia - - - - 42
Carbonate of iron and manganese - - - 98

Pristinatic Mieenite occurs in low, small, three-sided pyramids, deeply truncated on the edges; it appears to contain less magnesia than the preceding.

Milk Quartz, or Roche Quartz. See Quartz.

Mineral Caoutchouc, or Elastic Bitumen. (See Bitu-
men.) This singular mineral has been hitherto only found in the Odin mine, near Cockleton in Derbyshire. According to the analysis of Klaproth, it contains in 100 grains,

Cubic Inches.
Carbonated hydrogen 38
Carbonic acid - - - 4

Grains.
Bituminous oil - - - 75
Acid water - - - 1.50
Carbon - - - 6.23
Lime - - - 1.50
Silica - - - 1.75
Sulphate of lime - - - 3.50
Alumine - - - 2.25

Mineral Oil. See Petroleum.

Mineral Pitch, Earthly, or Maltha. See Bitumen.

Mineral Pitch, Slaggy, or Alphaltum. See Bitumen.

Mispigel, Arsenical Pyrites. See Arsenic, and Py-
rites.

Molydendrum, or Sulphuret of Molybdena; Molybdene sul-
phurate, Haüy; is of a bright lead-grey colour. It occurs massive, disseminated in plates, and crystallized. The form of the crystals is a regular four-sided table, or a very short four-

C 2 fided
MINERALOGY.

Molybdenum, terminated by two low six-sided pyramids. The lutre is metallic and blinding. The structure is lamellar, with a single cleavage parallel with the lateral planes of the table. It is brittle and somewhat flexible, but not elastic. Molybdena is unctuous to the touch, and leaves a mark on paper like plumbago, but on white porcelain it makes a greenish mark. Its specific gravity is from 4.5 to 4.7. Before the blow-pipe it gives off a sulphureous odour, and when urged by the utmost force, it yields a white vapour, and a pale blue flame; in carbonate of soda, it is soluble with violent effervescence. The characters here given, particularly its mark on china, serve to distinguish molybdena from graphite and plumbago. (See Molybdeneum, and Sulphur.) According to Buchholz, its constituent parts are.

Molybdenum - - 60
Sulphur - - 40

100

This mineral occurs in some parts of Scotland, and in granite at Coldbeek-fell in Cumberland. It is found also at Huel-Gorland, Cornwall.

Molybdene Ochre is a yellow colour, passing into yellowish-green; it is friable and dull, and occurs incrusting molybdena, on which it is doublefles formed by the decomposition of the latter mineral.

Moon-stone, a variety of adularia. See Adularia, and Felspar.

Moras-Ore. See Bog Iron-Ore.

Mountain Cork, or Mountain Leather; Aphelle truffe, Haüy; it is sometimes called mountain felt and mountain pader. It occurs in thin flexible plates like leather, or in thicker and less flexible pieces like cork-wood. The colours are yellowish and greyish-white; it yields to the nail, is meagre to the touch, and floats as to swim on water. The structure is finely and promiscuously fibrous. According to Bergmann, its constituent parts are,

<table>

100

This mineral occurs in some parts of Scotland, and in granite at Coldbeek-fell in Cumberland. It is found also at Huel-Gorland, Cornwall.

Nephrite, or Jade; Jade nephrite, Haüy. The colour is leek-green, passing to greyish-green; it occurs massive. The fracture is uneven and pimplery, with a glimmering and somewhat greasy lustre; it is translucent. Nephrite yields to the knife, but fuses glass; it has a greasy feel, is very tough. The specific gravity is from 2.9 to 3. Before the blow-pipe, it melts into a white enamel. According to Kallner, its constituent parts are,

<table>

</tbody>
</table>

99.30

Nephrite occurs in granite veins in the Alps in Saxony; the most beautiful varieties are from Perithia and Egypt. In Turkey it is cut into handles for flabards and daggers. It was formerly believed that this stone had the property of relieving nephritic complaints; hence it has been called nephritic stone. A flaky kind of nephrite is used by the inhabitants of New Zealand for hatchets, and hence has been called axe-flone. Nephrite is nearly allied to serpentine and flecitite; there is also a kind of nephrite which is more nearly allied to felspar, and is called by Mr. Jameson with the felspar family; it is called fassurite, after the celebrated geologist Saffure, by whom it was first discovered. See Saussurite, Addenda.

Nickel-Ores are, native nickel, copper nickel, and nickel ochre.

Native Nickel has only been found hitherto in the Adolphius mine at Johanngeorgenstadt in Saxony, and at Joachimsthal in Bohemia. Its colour is bronze-yellow, but is frequently tarnished greenish-grey, or fleck or lead-grey, and occasionally invested with a crust of brown iron-flone. It occurs in capillary crystals, which are either promiscuously or ecopiformly aggregated. Internally the flute is splendent and metallic, externally shining or splendent when unattainted.
untarnished. The cross fracture is even palling into flat conchoidal; it is easily frangible, and rather hard; it is more or less flexible and elastic. Before the blow-pipe, on charcoal it melts into a metallic globule, without any smell of arsenic or sulphur, which serves to distinguish it from capillary pyrites. Native nickel contains the metal nickel with a minute portion of cobalt. See Nickel.

Copper Nickel, Nickel arsenical, Haüy, has a copper or crimson colour, of different degrees of intensity, and often tarnished grey or black. It occurs massive and disintegrated, and sometimes reticulated, botryoidal, or dendritic, and very rarely crystallized in six-sided tables; it has a shining metallic lustre. The fracture is imperfectly conchoidal, palling into granular and uneven. It is usually compact, but sometimes occurs in granular distinct concretions. It yields with difficulty to the knife, and is difficultly frangible. Its specific gravity is from 6.67 to 7.5. Before the blow-pipe it gives out an arsénilic vapour, and then fusés with difficulty into a dark scoria, mixed with metallic grains: it is fusible in nitric acid, forming a dark green liquor, from which can be precipitated with alkali a dark green precipitate, which distinguishes it from copper; the precipitate of the latter is a dark brown. This ore is a compound of nickel and arsenic; it occurs in small quantities in the lead-mines of Lead-hills and Wanlockhead, in Scotland, and in various parts of the continent of Europe, generally in veins in primitive mountains; it nearly resembles native copper, but may be distinguished by its brittleness.

Black Nickel-Ore has a greyish or brownish-black colour; it occurs massive, disintegrated, and in crusts; it is dull, has an earthy fracture, but becomes refractory and shining in the fumes; it foils slightly. In nitric acid it forms an apple-green solution, which fuses a precipitate of white arsenic. It is rather a rare mineral, and is found in veins with other ores of nickel, and is supposed to be formed by the decomposition of copper nickel.

Nickel Ocher, Nickel oxyde, Haüy, has an apple-green colour, but on exposure to the air becomes greenish-white; it is generally found as a thin coat or crust, and seldom massive or disseminated; it is in loose powder or friable, meagre to the touch, and brittle. It is infusible before the blow-pipe, but with borax it forms a red colour; in cold nitric acid it remains infusible. This ore occurs at Lead-hills and Wanlockhead, in Scotland, and in Saxony and France.

Nigrite. See Titanuim.

Nitre, Native, Potas; nitrate, Fr. occurs in flakes, crusts, and capillary crystals on the surface of the ground. In many countries, it appears to form at certain seasons of the year. It abounds in many of the plains of Spain, Hungary, the Ukraine and Podolia, and on the walls and floors of chalk caves in France. It is very abundant in India, Egypt, and in some parts of North and South America. See Potash, Nitre of.

Obsidian, or Volcanic Glass; Lava vitreuse obisienne, Haüy. (See Obsidianus Lapis.) This mineral bears so close a resemblance to dark-green bottle-glass as scarcely to be distinguished from it. Its most common colours are dark-grey or greenish, or brownish-black; it has a vitreous and shining or fusible lustre; the fracture is large and perfectly conchoidal. It dissolves from transparent to nearly opaque, according to the intensity of the colour; it scratches glass, but is easily frangible. The specific gravity varies from 2.34 to 2.38. The black obsidian of Iceland is said to melt into a pale ash-grey vesicular glass on charcoal; that of Spanish America lost its black colour when exposed to heat, became white, spongy, and fibrous, and increased to seven or eight times its original bulk; hence it appears that some gaseous fluid climate escapes. Humboldt conjectures, that the gas evolved during the volcanic fusion of obsidian in the interior of the earth, may give rise to the earthquakes that agitate the Cordilleras. According to Abhiguard, the constituent parts of obsidian are given as under:

<table>

</tr>
</tbody>
</table>

Some analyses give 1.6 lime, and only 5 of potash and soda.

Obsidian is found in a great many volcanic countries, and also in various parts of the world, where no volcanic fires have existed since the history of man. For a long period it was contended by Werner and his followers, that this mineral was of aqueous origin, but the appearance of obsidian, and the situations in which it occurs, offer decisive proofs of its formation by fire. The mountain de la Cafagna, in Lipari, according to Spallanzani, is wholly composed of it, which appears to have flowed in feebler currents, like streams of water falling with a rapid descent and suddenly frozen. The obsidian is sometimes compact and sometimes porous and spongy. On the south side of the Peak of Teneriffe, there is a stream of obsidian several miles in length. In the island of Feeric, a current of lava intermixed with obsidian may be traced to the very crater of a volcano.

Obsidian behaves like lava suddenly cooled; it is well known, since the experiments of Mr. Keir, Mr. Watt, and Sir James Hall, that lava or basalt cooled suddenly forms black glass; and we have a specimen of lava from Vulcainia, which flowed in the year 1818, one part of which is compact black lava, the other is a vitreous substance passing from pitch-flake to obsidian. See Volcanic Products.

Octahedrite, Anatase. See titanium.

Olivine. (See Olivine.) This mineral forms a constituent part of many lavas, and is of frequent occurrence in basaltic rocks. When crystallized, it is in broad rectangular four-sided prisms, which are imbedded, and so easily broken, that it is difficult to ascertain their form; the structure of the crystals is imperfectly lamellar, in a direction parallel with the planes of the prism. Werner considers olivine as a distinct species from chrysolite (see Chrysolite), with which it is closely mingled by many mineralogists. The colour, lustre, and fracture of olivine and chrysolite, are not precisely the same; olivine is also softer and more fragile than chrysolite. Chrysolite is more transparent, and has a greater specific gravity, being from 3.4 to 3.54; that of olivine is 3.22 to 3.26. Olivine is often much intermixed with augite; it has generally a paler colour and greater transparency than the latter mineral. Olivine is subject to decomposition, and when this commences it exhibits on the surface iridescent colours, but afterwards falls into an earth resembling iron ochre.
MINERALOGY.

**Opal, Quartz отfinita opalina, Haüy.** (See Gem.) This mineral is divided into seven sub-species by Mr. Jameron.

Precious Opal has frequently a milk-white colour inclining to blue, and displays brilliant and changeable reflections of green, blue, yellow, and red. It is translucent or semi-transparent, and when placed between the eye and the light exhibits a beautiful yellow or blue colour. It occurs in veins in clay-porphyr, either massive, disseminated, or in plates; it has a shining or splendid vitreous lustre, a perfect conchoidal fracture, scratches glass, and is easily frangible. Some varieties adhere to the tongue. Precious opal becomes white and opaque before the blow-pipe, but is infusible. The specific gravity is 2.110. According to Klaproth, the constituent parts are,

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Silex</td>

<td>98.75</td>
</tr>
<tr>
<td>Water</td>
<td>-</td>
<td>-</td>
<td>93.50</td>
</tr>
</tbody>
</table>

Hence it appears, that the precious opal is properly a hydrate of pure siliceous earth. This mineral, on account of its beauty, is employed in jewellery, and is held in great estimation. Jewels of opal must be kept with care, as they are easily scratched, and are apt to crack on sudden changes of temperature. Precious opal is found more abundantly at Cafchau, in Upper Hungary, than in any other known situation. It occurs there in clay-porphyr, and mines of it have been worked for a long period; towards the end of the fourteenth century, about 300 men were employed in these mines. Precious opal is sometimes sparingly found in the bafaltic rocks, in the north of Ireland, and in the Faroe islands. The finer varieties of opal are named oriental opal. Taverner, however, informs us, that no precious opal is found in the earth, and those which are found are oriental are brought from Hungary. Those varieties of opal that adhere to the tongue are less translucent than the others, and more dull; but when immersed in water, they become nearly transparent, and acquire a beautiful play of colours. These opals have received various names, as the oculus mundi, hydrophane or changeable opal. They are much prized by collectors. To preserve their beauty, the water in which they are immersed should be perfectly pure, and they should be taken out as soon as they have acquired their full transparency. If these precautions are neglected, the pores become filled with earthy particles deposited from the water, and the hydrophane will remain more or less opaque.

Common Opal differs from precious opal, principally by its inferior lustre and transparency, and the greater variety of its colours, which are either milk-white, grey, yellowish-white, yellow, red, or green. The famous specimen never shews more than one colour by reflected light, but the milk-white variety, when held opposite the light, transmits a wine-yellow colour. Common opal occurs massive, disseminated, and in sharp angular pieces. Internally the lustre is shining, splendid, and vitreous; the fracture is conchoidal; it scratches glass, and is easily frangible. Before the blow-pipe it is infusible. The specific gravity is 2.01 to 2.14. According to Klaproth, its constituent parts are,
MINERALS.

It appears to be common or semi-opal rendered opaque by the great intermixture of oxied of iron.

Oriental Amethyst, Sapphire, Ruby, Topaz, and Emerald, names given by jewellers to varieties of the sapphire. The blue sapphire is the true or oriental sapphire; the violet-blue is the oriental amethyst; the red sapphire, the oriental ruby; the yellow sapphire, the oriental topaz; and the green sapphire, the oriental emerald. See Sapphire, &c.

Opalite, Red, or Realgar, Sulphure of Arsine; Arsine sulphure rouge, Fr. (See Arsenic.) According to Klaproth, the composition of this ore is,

Osmium occurs as a native alloy of the metal so called with iridium; it is found in grains along with platina in alluvial soil in South America. The grains have a pale steel-grey colour, a metallic lustre, and lamellar structure; it is harder than platina, and brittle. The specific gravity is 19.5. By fusion with nitre, it acquires a dark-black colour, but regains its lustre and colour by heating with charcoal.

Palladium is a native alloy of the metal palladium, with a minute portion of platina and iridium; it occurs in grains along with grains of platina in the alluvial gold districts in Brazil. Its colour is pale-steel grey, falling into silver-white; the structure of the grains is divergingly fibrous, the lustre metallic. The specific gravity is 12.4-14.8. Lowery. Palladium is infusible; but on the addition of sulphur, it melts with ease by continuance of the heat, the sulphur is diffused, and a globule of metallic palladium remains. With nitric acid, it forms a deep-red solution.

Paranthine. See Scapolite.

Pearl-Spar. (See Brown Spar, Addenda.) The name pearl-spar has been given to those varieties of this mineral which in colour and lustre have a strong resemblance to pearl, but it often occurs brown, black, and of various colours.

Pearl-Stone, Lave vitreux perlée, Haüy. (See Pearl-Stone.) This mineral is regarded by many mineralogists as a volcanic production; it is frequently intermixed with obsidian, and hence is claffed by them as a variety of the latter mineral. It occurs in basic and porphyritic rocks, in large and somewhat angular concretions, which are composed of smaller rounded concretions, and those of others still smaller. The surface of the concretions is smooth, shining, and pearly. The colour is grey, passing into pearl-grey and greyish-black. It is translucent on the edges; it scarcely scratches glass, is easily frangible, and is fusible with intumescence before the blow-pipe into a white foppy glass. This mineral has been found near Sandy Bræ, in Ireland, in the island of Iceland, and in Mexico; it was first discovered in Hungary, where it occurs in large beds. It is claffed by Mr. J. B. Werner with obsidian, pitch-stone, and pumice, as forming a member of the pitch-stone family.

Pea-Stone, Péfolite, Fr. This mineral is composed of carbonate of lime, slightly coloured yellowish-white or brown by the oxide of iron; it is properly a calcareous tufa, containing rounded globules, varying in size, from a pea to a hazel-nut; these consist of concentric lamelle, and often contain in the centre a minute fragment of quartz, felspar, or granite, and sometimes, but rarely, a double six-sided pyramid of rock-cystal; but in some instances, the centre of the globule is hollow. Pea-stone occurs in great masses in the vicinity of the hot springs at Carlsbad, in Bohemia; its formation we conceive to be analogous to that of rose-stone, and to be the result of crystallization; the particles included having diffused the calcareous matter to crystallize round them, in the same manner as a thread or fragment of a stone in a saline solution, generally disperses the crystals to shoot round them.

Perovskite, the name given to a new mineral found at Erby, near Abo, in Finland. The following imperfect account is the only one we have of its character. It has a green colour; its form is an octahedron, with a cleavage in three directions; it is harder than foppy spar. The specific gravity is 4.11. Before the blow-pipe, it melts into a mass with a pearly-white lustre. Its constituent parts are given as under:

Peridot Chrysolite. See Chrysolite and Olivine.

Petaite, a mineral recently discovered in Sweden; externally, it nearly resembles some varieties of quartz, but the cleavage is two-fold, parallel to the sides of a rhomboidal prism; two of the planes are fplendent, and two dull. The planes meet at angles of 100° and 80°, forming a four-sided prism with a rhomboidal base. Its colour is white with a flight tint of pink; it scratches glass, but yields with difficulty to the knife. When exposed to the flame of a blow-pipe it remains for some time infusible, but by continued heat it exhibits a glazed surface, which, on examination with a lens, appears full of minute bubbles. When triturated, the powder has the whitens of snow; it is partially soluble in highly concentrated nitric acid, losing its colour, and changing to a dingy hue; the acid at the same time becomes clouded. The prulated alkali threw down a green precipitate, and the solution assumed an amethystine colour, which afterwards changed to brown. The constituent parts of this mineral are flated to be,

And this alkali proves to be the oxied of a new metal. The new alkali has been called lithia and lithion; it has a greater capacity of saturating acids than any other alkali, and forms a class of salts that are remarkably deliquescent. With alcohol, lithion yields a rofe-coloured flame, like that communicated by ilrotian. The metal of lithion bears a strong resemblance to fodium. The alkali found in petaite contains 84.84 oxygen, united to a metallic base.

Petroleum, Liquid Bitumen, or Mineral Oil. (See Bitumen.)
Bitumen. It is essentially composed of carbon and hydrogen, containing less carbon than the solid bitumens, or than any kind of mineral coal. In Piedmont, Peru, Japan, and other countries, it is used in lamps, in place of oil, for lighting streets and public buildings; it is also mixed with earth, and burned for warming rooms. In Asia, numerous mines are worked for mineral oil or petroleum, the shafts are sunk through coal strata to the coal from whence the oil issues; it is intermixed with water, and is separated by decantation.

Pharmacolite, Arseniate of Lime, Chaux arsenictée, Haüy. Its colours are snow-white and milk-white, sometimes inclining to reddish or yellowish-white. It occurs in small reniform botryoidal and globular masses; sometimes it incrusts other minerals, or is crystallized in small diverging capillary crystals. Externally, it has a silky glimmering lustre; internally, it is shining or glistening. The structure is delicately radiated, either straight, diverging, or fanned, and sometimes fibrous. It yields to the nail, and is easily frangible. The specific gravity is 2.5. According to Klaproth, the constituent parts are,

There is an earthy variety of pharmacolite, which occurs in thin crulfs, and is dull and opaque. Pharmacolite is found in veins in granite, with ores of cobalt and native arsenic.

Phosphate of Copper, Cuivre phosphatée, Haüy. Under the ores of copper, one species of this mineral is described, which was the only one then known. Mr. Jameon makes three sub-species of phosphate of copper; foliated phosphate of copper, fibrous phosphate of copper, and compact phosphate of copper.

Foliated Phosphate of Copper, Cuivre phosphatée rhomboïdale, Haüy, has a greyish-black colour externally, but internally it is emerald-green, verdigris-green, and leek and olive-green. It occurs crystallized in octahedrons, which are sometimes lengthened or cuneiform; also in rhomboheds with small curvilinear faces; the edges and angles are sometimes truncated. The structure is lamellar, the lustre shining, between vitreous and pearly; it is transluclent. This ore is insoluble in water, but dissolves without effervescence in nitric acid. Before the blow-pipe, it fuses into a brownish globule, which spreads on the surface of the charcoal by a continuance of the heat, and acquires a reddish-grey metallic lustre. The globule on cooling crystallizes into three-sided and six-sided facets. According to Bucholz, it is a compound of copper and phosphoric acid. It has been found in the neighbourhood of Neufotl in Hungary, and at Virenberg, near Rheinbrechenbach, on the Rhine; at the latter place it occurs with fibrous phosphate of copper; the latter mineral is found massive, botryoidal, and in crulfs; it has a diversely fibrous or radiated structure.

Compact Phosphate of Copper, Cuivre phosphatée compacte, Haüy, has the same localities as the foliated sub-species; it occurs massive, reniform, botryoidal, and incrusting; it has a flat conchoidal fracture; a fibrous fracture may sometimes be observed. It contains near 1.81 parts of phosphoric acid united with 68 of copper.

Phosphate of Manganese. See Manganese-ores.

Phosphosphate, Common, and Phosphorite, Earthly. These minerals have been classified by mineralogists as varieties of apatite; but Mr. Jameon makes phosphorite a distinct species, which he divides into two sub-species.

Common Phosphate, Maffre Apatite, Aikin; Chaux phosphatée terreuse, Haüy; has generally a yellowish, greenish, or reddish-white colour; it occurs massive, foliated, reniform, and incrusting, also crystallized in six-sided tables; it is opaque, soft, and easily frangible. The specific gravity is 2.81. When rubbed in an iron mortar, or laid on hot coals, it emits a greenish light. According to Pelletier, its constituent parts are,

<p>| | | |</p>

In part of Extremadura in Spain near Lagonfan, it forms whole beds that alternate with limestone and quartz.

Earthly Phosphorite consists of dull earthy particles, loosely cohering, and appears to be the preceding mineral in a decomposing state, intermixed with earthy matter. We think the characters and constituent parts of these minerals entitle them to be classed merely as varieties of apatite. The multiplication of species, where no sufficient specific difference exists, tends to retard the progress of useful knowledge, and ought not to be unnecessarily introduced.

Phosphorite, Phosphate of manganese. See Manganese.

Pirrolite, a mineral described by Hanfmann. It is principally composed of the carbonate of magnesia. According to the description of Mr. Jameon, (Mineralogy, vol. ii. p. 537.) its colours are leek-green, mountain-green, or straw-yellow. It occurs massive; internally it is dull or glimmering and pearly. The fracture is long, splintery, which passes by gradation to flat conchoidal. In some instances, it throws a delicate concentric fibrous structure. It sometimes occurs in concretions which are either concealed or have undulating lamelle. It is translucent on the edges, and is rather hard, and difficultly frangible. It feels meagre, and is insalubrious. The specific gravity is 2.53. It appears to be allied to fergusonite and talc.

Pilite. This mineral is nearly allied to mica. It occurs crystallized in regular six-sided prisms, which, according to Haüy, is the primitive form. The prisms are sometimes truncated on the edges and angles. Massive varieties of pilite also occur in thick and straight lamellar concretions. (See Pi·nite.) This mineral is found in the granite veins at St. Michael's Mount, Cornwall, and in some parts of Scotland in porphyry.

Pistacite, or Epidote. See Pistacite, and Epidote, Addenda.

Pitch-coal, or Jet. See Jet.
MINERALOGY.

Pitch-ore, or Pitch-blende, an ore of Uranium. See Uranium, and Pitch-ore.

Pitch-stone, Rutilite, and Petro-files rutilite, Fr. This mineral is named from the striking resemblance which some varieties have in colour and lustre to pitch. Its prevailing colours are dark-green, from which it passes into black, grey, and blue, to brown and red. It is feebly translucent, and has a glinting or shining vitreo-luminous lustre. It occurs mafive in veins and beds of considerable magnitude. Pitch-stone is sometimes columnar, and sometimes in thick and wedge-shaped concretions, or in somewhat globular or curved lamellar distinct concretions, and sometimes it has a flat structure. The fracture is more or less perfectly conchoidal, or passing into splintery. The fragments are angular and sharp-edged. It feraches glasfs, is rather easily frangible, and is fusible into a grey fpongy enamel. Some varieties of this mineral, however, fuse with great difficulty by the blow-pipe. The specific gravity of pitch-stone is about 2.3. According to Klaproth, its constituent parts are,

Pitch-stone of Meiffon.

Pitch-stone is found in various parts of Scotland, and in the islands of Rum, Egg, and Arran. It bears a near resemblance to obsidian, or volcanic glasfs, into which it appears to pass, and also into pearl-stone. It is regarded by many geologists as a volcanic product. Like bafalt, it intersects rocks of different formations, from granite to fand-stone, and is intimately associated with bafaltic rocks.

Plasma has generally a dullish-green colour, with yellowish or whitish dots, a glinting lustre, a conchoidal fracture, is translucent, and rather harder than quartz. It consists of about ninety-seven parts of silex, and appears to be a properly green variety of frit. It was confidered by the Romans as a gem, and figures were engraved upon it. Most of the specimens in collections were found in the ruins of Rome.

Platina. See Platinum.

Pleonaste. See Ceylanite, Addenda.

Plumbago. Graphite or black-lead. See Plumbago, and Graphite.

Porcelain-clay. (See Porcelain.) The porcelain-clay of Cornwall occurs in beds of considerable thicknesses in the parish of St. Stephen's. According to Wedgwood, it consists of fifty parts alumine, and forty of silex. Porcelain clay originates from the decomposition of granitic rocks, abounding in felspar, and frequently contains portions of quartz and mica. The absence of iron in porcelain-clay is what constitutes one of its most essential properties; that of remaining white after burning. The Kaolin or Chinese porcelain-clay contains a much larger portion of silex than of alumine.

Porcellanite, or Porcelain Jasper. (See Jasper.) It appears to be formed accidentally by fires in coal-mines, which have indurated and femitrivulled beds of coal-thole or slate-clay.

Pot-stone, Lapis ollaris; Tale ollaire, Haïy. (See Vol. XXXIX.)

Pot-stone. This mineral appears to be indurated talc, passing into serpentine; with the latter rock, it is frequently associated. It has a curved and undulating-lamellar structure, passing into flaky. It is very soft, lecithic, and greasy to the feel, is translucent on the edges, and affords a white-coloured streak. It is fusible before the blow-pipe. The analysis of this mineral given by Tromsdorf is,

<table>

Near Inverary there is a quarry of talcous flake, some of which appears to pass into pot-stone, and can be turned in the lathe; of this stone, Inverary Castle is built. Pot-stone was extensively used in Upper Egypt for culinary vessels. They were found to reflect the action of fire, and did not communicate any taste to the food boiled in them. Quarries of pot-stone were worked on the banks of the lake of Como from the beginning of the Christian era to the year 1618, when the mountain fell down on the 25th of August, and destroyed the neighbouring town of Pienas. This town had annually raised stone from these quarries to the value of 60,000 ducats. Pot-stone is also used for lining ovens and furnaces, and is remarkably durable.

Fraske. Quarz kyanit vers obfuir, Haïy, is translucent green quartz, the green colour being derived from an intimate intermixture of quartz and actinolite. See Quartz, and Plaissis.

Precious Garnet. See Garnet.

Prehnite. (See Prehnite.) This mineral is divided into two sub-species by Mr. Jamefon; foliated prehnite and fibrous prehnite. The prevailing colours are, green, greenish-white, and yellowish-white. It occurs both mafive and crystallized in oblique four-sided tables, or in fix or eight-sided tables; also in four-sided and fix-sided prisms. The crystals are generally attached by their lateral plains, and form diverging groups. The cleavage is single, parallel to the short diagonal of a rhomboidal prism, the planes of which are inclined at angles of 103° and 77°. The lustre is shining and pearly; it is translucent or transparent, feraches glasfs with difficulty, and intumecees before the blow-pipe. Prehnite was discovered by Mr. Bakewell in a rock bafaltic amygdaloid, near Berkley in Gloucestershire, accompanied with green earth and mafive lamellar prehnite, or kenhphite. This is the only English locality of these minerals at present known. It was first brought from the Cape of Good Hope.

Fibrous Prehnite has a delicate fibrous structure, either straight, diverging, or cellullar. According to Langier, its constituent parts are,

<table>

Both sub-species of prehnite bear a near resemblance to zeolites, but they do not gelatinize with acids, and they become electric by heating.

Pumice. See Pumicestone, and Volcanic Products.

Pycnite Schorlic, or Schorlaceous Beryl. (See 4 D Pycnite.)
MINERALOGY.

PYCnite.) The crystals of this mineral are long hexahedral prisms, and are deeply streaked longitudinally. They have a cleavage at right angles to the axis of the prism. Pycnite is now considered by Haüy as a variety of the topaz.

PYRITES. See PYRITES.

PYROPE. This mineral is now regarded by Haüy as a variety of the precious garnet, with an accidental portion of magnefia derived from the rock in which it is imbedded.

PYROPHYSALITE. See PYROPHYSALITE.

PYROMALITE. Native muriate of iron. See IRON-Ores, Addenda.

PYROXENE, Augit. See PYROXENE and AUGIT, Addenda.

QUartz, Quarz hyalin, Fr. See QUartz.

Common Quartz, Rock Cristal, Amethyst, and Caïrgorm Stone, or Clove-brown Quartz, Aventurine Quartz, and Rose or Mild Quartz, are essentially the same mineral substance or pure crystals, varying only in transparence or colour, owing probably to a very slight admixture of the other earths or metallic oys, an admixture which may be regarded as accidental, and which is scarcely appreciable by chemical analysis. According to Buchholz, rock-crystal is composed of 99.5% of silica. It is probable, however, that many minerals, which have hitherto been classed with quartz from bearing in many characters a close resemblance to it, may contain other ingredients besides silica in such proportions as to constitute them distinct species. This opinion is rendered more probable by the recent discovery of a mineral in Sweden, called petalite, which might easily be mistaken for a variety of quartz, but which contains a considerable portion of alumine, and two parts in the hundred of an alkali hercophore unknown. See PETALITE, Addenda, and Rock-Crystal.

QUICKSILVER. See MERCURY, Ores of.

REALGAR. See ARSENIC-Ores, and REALGAR.

RED Antimony-Ores. (See ANTIMONY-Ores, and RED Antimony.) A variety of red antimony-ore, called tiderore, is described by Mr. Jarmaston as occurring in delicate flexible leaves, which are opaque and friable, foil strongly, and swim on water. Tiderore contains a portion of silver.

RED Cobalt-Ore. (See COBALT-Ores.) This species of ore is divided by Mr. Jarmaston into three sub-species, earthy red cobalt-ore or cobalt ochre, flag red cobalt ochre, and radiated red cobalt-ore or cobalt bloom; Cobalt arseniate aciculare, Haüy. The analysis of this ore by Buchholz gives

<table>

This ore has been found at Alva, in Stirlingshire, and at Tyndrum; also in lime-stone in Liliithgowshire, and at the Dolcoath mine in Cornwall. Slaggy red cobalt ochre has a muddy crimson-red colour, or dark hyacinth-red, which passes into chefneut-brown. It occurs in thin cruits, and sometimes reniform. It has a shining and reflexive lustre, a conchoidal fracture, and is translucent, soft, and brittle.

RED Lead-ore, or Chromate of Lead. See LEAD-Ores.

RED Manganeis-ore. See MANGANESE.

RED Silver-ore, or Ruby Silver, where read—before the blow-pipe on charcoal.

REDDLE, Red Chalk, or Red Ochre. See REDDLE.

RETIASPHALTUM. See RETIASPHALTUM.

REFUSEITE, the name given to a salt which occurs in the country round Sodlitz, and at Pirl near Brux. It forms a mealy efflorescence, and is also crystallized in flat six-sided prisms and in acicular crystals. According to Reufs, it consists of

| Sulphate of soda | 66.04 |
| Sulphate of magnesia | 31.35 |
| Muriate of magnesia | 2.10 |
| Sulphate of lime | 0.42 |

100

RHOMB Spar. See BROW Spar, Addenda.

ROCK Butter. (See ROCK Butter.) This mineral appears to be a sub-sulphate of alumine. It oozes from aluminous rocks.

ROCK Cork; Aâpletre, Haüy. See ROCK Cork.

ROCK-CRYSTAL. (See QUARTZ.) This is the purest variety of quartz. Very large and brilliant rock-crytals occur in many parts of Scotland. The smoke-grey or clove-brown crystals are called caïrgorm, from a place in the upper part of Aberdeen, where they occur in alluvial soil along with beryl and topaz. The largest rock-crytals hitherto found come from the island of Madagascar. Faujas St. Fond mentions a crystal imported from thence into France, which weighed upwards of one hundred and fifty pounds. Very brilliant groups of rock-cystal occur in Dauphiny. Vases of rock-crystal were highly prized by the ancients. A vase, broke by the emperor Nero in a fit of despair, was estimated at 15,000 livres. Different colours may be communicated to rock-crytals artificially, by heating them and plunging them into different-cooured solutions.

ROCK-SALT. (See ROCK-SALT.) According to the analysis of Dr. Henry, the rock-salt of Cheshire contains, in 1000 parts,

| Muriate of soda | 93.9 |
| Sulphate of lime | 6.1 |
| Muriate of magnesia | 0.7 |
| Muriate of lime | 0.7 |
| Infusible matter | 10 |

1000

ROCK-WOOD, or Ligniform Aâphlus. See ASBESTUS.

ROE-STONE, or Oolite; Chaus carbonate globuliform, Haüy. See ROE-STONE.

ROSE Quartz, or Milk Quartz. See QUARTZ.

ROBELETTE, called Red School, a variety of tourmaline. See ROBELETTE, and TOURMALINE.

RUBY, Oriental, or Red Saphire. See GEMS, and SAPPHIRE.

RUBY Spinelle. (See GEMS and RUBY.) The spinel ruby is the common ruby of the jewellers. It differs from the oriental ruby in the form of its crystallization, and contains a portion of magnesia and chromic acid. The former is nearly unmixed alumine. When these two gems are cut, it is, however, difficult to distinguish them. The oriental ruby is harder than spinel. Though the prevailing colour of the common ruby or spinel is red, yet it is sometimes blue-green or yellowish-brown. The carmine-red is called the spinel ruby; the cochenile ruby is called the balas ruby, from Balaschan, the Indian name of Pegu, where it is found. The specific gravity varies from 3.50 to 3.53; that of oriental ruby from 3.97 to 4.28. The latter is a true sapphire.

RUTILE,
MINERALOGY.

RUTILE, or Sphene; Titane oxide, Haüy. (See Rutile.)

This mineral, which appears to be an analysis of a pure oxyd of titanium, (see Titanium) is of a dark blood-red colour, or light-red and brownish-red. It occurs massive, disintegrated, membranous, and in crystals. The crystals are rectangular four-sided prisms, oblique four-sided prisms, and also fix and eight-sided prisms. The crystals are small and often capillary. It occurs imbedded in drusy cavities, in granite, fennite, gneifs, mica-flate, chlorite-flate and hornblende-flate, and in lime-flone. It has been found in the granite of Cairngorm, the lime-flone of Kanneich, and at Craig Cailleach, near Killin, imbedded in quartz, also near Bedgalliet, in Caernarvonshire.

RUTILE, Titane silice calcaire, or Sphene. See Rutile and Sphene.

SAHLITE. (See Sahlite.) Pyroxene laminaire gris verdâtre, Haüy. According to Bourron, the primitive form of fahlite is a rectangular four-sided prism, having rectangular bases, which are inclined on the two opposite fides of the prism, so as to form angles of 103°, 15°, and 73°, 45°, 

hence he considers it as a distinct species from augite. According to Jamefon, the cleavages of fahlite are five-fold, one parallel with the terminal planes, two with the lateral planes, and two with the diagonals of the prism; the three first are made with great facility. The cros fracture of fahlite is uneven and dull; that of augite, though uneven, generally inclines to conchoidal, and has a considerable degree of luster.

SAL AMMONIAC, Native; Ammoniaque muriatée, Haüy. (See Sal Ammoniac.) This salt is divided into two sub-species by Werner, valcanic fahl ammoniac and conchoidal fahl ammoniac. The former occurs in fissures, or coating volcanic rocks, and also in the vicinity of burning beds of coal. The latter occurs with sulphur, in indurated clay, or clay-flate, in Bucharia. According to Klaproth, it contains 250 of sulphate of ammonia, with 97.50 of the muriate.

SAPPANCE, Kymanite; Diopside, Haüy. See Sappace, and Kyanite, Addenda.

SAPPHIRE, Telcete, and Caridon byalina, Haüy. The common forms of the crystals of sapphire are the perfect fix-sided pyramid and fix-sided prism, or the double fix-sided pyramid. These forms are frequently modified by truncations on the angles and extremities. (See Gems, Sapphine, and Ruby, Addenda.) The red sapphire is the oriental ruby; it differs a little from the blue sapphire in its constituent parts, which, according to Che nevix, are,

<table>

</table>

Sapphire occurs in alluvial soil along with pyrope, zircon, and iron-flone, at Podfeclitz and Trzibith, in Bohemia; in the shafts of the stream Ruot, near Expaill, in France; also at Brendole, in the Vicentine, and in Portugal.

SARCOLITE, Red Zeolite. See Sarcolite and Zeolite.

SARDE, Sardoine, a reddish-brown cornelian, which appears of a deep blood-red when held between the eye and the light.

SARDONIX is a cornelian composed of white and red layers.

SASSOLIN, Native Boracic Acid. See Sassolin.

SATIN-SPAR, Chaux carbonatée fibreuse conjointe, Haüy. See Sattin-Spar.

SAUSSURITE, Felspath Tenace, Haüy; a mineral so called after the older Sauvur. It was confidered by him as nearly allied to nephrite or jade, (see Nephrite, Addenda,) but is now placed with the fispur family. It occurs massive, disintegrated, and in rolled pieces, in various parts of Switzerland and Norway, Finland, Italy, France, and Savoy, and it forms a confinuent part of the well-known rock in Corfica, called the Verde di Corfica, which is composed of diastyle and saussurite. It occurs with diastyle metalloide near the Lizard Point, in Cornwall. The colours are white-grey and green, of various tints; green or yellowish, or greenish-white, are the most prevailing colours. Internally the luster is dull or faintly glimmering.

The fracture is splintery; but according to Mr. Jamefon, an imperfectly foliated fracture may be discovered with a double rectangular cleavage. It is faintly transparent on the edges, is extremely tough, and so hard, as to scratch glass; the feel is somewhat unctuous. The specific gravity of saussurite is 3.20 to 3.31. According to Sauur, the constituent parts are,

</table>

Before the blow-pipe, saussurite melts on the edges and angles; but according to Mr. Jamefon is not entirely fusible.

SCAPOLITE, Paranthine, Haüy. (See Scapolite.)

This mineral has been divided by Mr. Jamefon into three sub-species; radiated scapolite, foliated scapolite, and compact scapolite. Foliated scapolite has a three-fold and rather oblique-angular cleavage; the cros fracture is small and fine-grained, uneven or small conchoidal. This mineral, besides occurring with the other sub-species in Scandinavia, is found along with scapol in granitic mafses that are imbedded in compact fispur, or white-flone, on the north-western ac tivity of the Saxon Erzgebirge. Compact green scapolite is the wernerite of Haüy. It occurs both mafive and crys tallized in rectangular four-sided prisms, acuminated by four planes set on the lateral edges. Compact red scapolite occurs along with the green sub-species, but is of a blood-red colour. All the varieties of scapolite decay very readily on exposure to the air.

SCHORL, Tourmaline noir, Haüy. (See Schorl.) The constituent parts of schorl, as stated by Klaproth, vary considerably.
conferably from the analysis of Gerhard, which we have
given, and are,

|        |       |       |    |     
|--------|-------|-------|----|-----
| Silex  | 36.75 |       |    |     
| Alumine| 34.50 |       |    |     
| Magnesia| 0.25 |       |    |     
| Oxid of iron with a trace of manganese | 21 |       |    |     

According to Gerhard,

|        |       |       |    |     
|--------|-------|-------|----|-----
| Silex  | 36.50 |       |    |     
| Alumine| 31.0  |       |    |     
| Magnesia| 1.25 |       |    |     
| Oxid of iron with a trace of manganese | 23.50 |       |    |     

The crysals of School are longitudinally fretted, and have externally a shining lustre. It occurs in the granite rocks of Cornwall, and intermixed with quartz, when it forms a compound rock, known to Cornish miners by the name of cockle. Very magnificent crysals of School have recently been discovered near Bovey Heathfield, in Devonshire. See Tourmaline.

**Schiller-Spar**, Diagglication metalloide, Haey, occurs most frequently in lamatine disseminated in serpentine, and is regarded by some mineralogists as crysallized serpentine. The colours are, olive-green, pincheke-brown, and yellowish-brown. The lustre of the principal fracture is splendent and pseudo-metallic; the cross fracture is dull and glimmering. The cleavage is distinct in the direction of the laminate. According to Bournon, the primitive form is a acetangular four-sided prism, in which the baxes are let on the broadest lateral planes, forming with them angles of 87° and 95°. The prism is diabolic both in the direction of the lateral and terminal planes, but molt easily parallel with the latter. Schiller-spar is translucent in thin laminate; it yields a greenish-grey f rack, is seftile, and softer than hornblende.

**Schloraceous Beryl.** See Pycnite.

**Selenite, or Crystalized Gypsum.** See Gypsum.

**Serpentine, Noble and Common.** See Serpentine.

**Shale, Coal-Shale and Bituminous Shale.** A name given to the argillaceous strata which accompany coal. These consist of clay more or less indurated and flaty, and intermixed with a portion of carbonaceous or bituminous matter.

**Siderite,** a name given by some mineralogists to Rubellite; which fee.

**Silver-ore.** (See Silver.) A species of native silver occurs in Norway, which contains 28 parts in the 100 of gold, and is called auriferous native silver. On account of the gold, its specific gravity is greater than native silver. Its other characters, except the colour, (which inclines to brafs-yellow,) agree with native silver; which fee, under Silver-Ores.

An ore of silver containing bismuth has been found in one mine on the Schappbach, in the Black Forest. It is called bismuthic silver. It is a pale lead-grey, is soft, seftile, and eaily fragrable. Before the blow-pipe metallic globules ooze out, which, on the addition of borax, unite in one metallic button, which is brittle, and of a tin-white colour. It contains 27 parts of lead, 33 of bismuth, and 15 of ful-

**Cornes Silver-Ore, or Horn Silver.** is divided by Mr. Jamefon, in the last edition of his Mineralogy, into four sub-species; conchoidal, radiated, common, and earthly cornes silver-ore.

**Conchoidal cornes Silver-Ore.—** Its colours are greyish or greenish-white. It occurs massive in compact lime-stone, at Guantahoygo in Peru; it has an adamantine lustre, and is the purest kind of cornes silver known, containing

</tr>
</tbody>
</table>

The radiated cornes Silver-Ore has a dark-green colours, and, like the preceding, has hitherto been found only in South America.

**Common cornes Silver-Ore,** (see Silver-Ores,) has been found in some of the mises in Cornwall, particularly at Huel-Mexico, and in a mine near Peranzabula, on the north-eall of Cornwall. In the analysis of this ore, we have stated the constituent parts at 68 of silver, and 28 of muratic acid; but 6 parts of the latter are oxygen.

**Earthly cornes Silver-Ore** is very soft, and almost friable. This mineral is an intermixture of cornes silver-ore and alumine.

**Earthly Silver-Flake** appears to be a decomposing phosphuret of silver. It has a blueish-black colour, and varies from friable to solid; it is dull or glimmering, but yields a metallic f rack; it occurs with other ores of silver in veins.

Under the localities of silver in England, in the article Silver-Ores, for Benallen r. Beeralten, Devonshire. One of the richest repositories of silver is the Weal Duchy Mine, on the banks of the Tamar, above Plymouth. Silver-ores occur there in regular veins, but are also disseminated in nodules, through the rock itself, which is kilas or clay-flate. The ores are, native capillary silver in considerable branches, vitreous silver-ore, black silver, and ruby silver-ore. Under the article Silver, we have given the annual quantity of gold and silver obtained in Europe, South America, and part of Asia, as given by Humboldt, in killogrammes, which reduced to the value of the pound sterling is as under:

<p>| | |</p>

</table>

Total annual value 10,368,109.; a sum not equal to the payment of one-half of the interest of the national debt of Great Britain !

**Slate, or Slate-Clay, Werner.** See Slate.

**Slate-Spar, Chaus carbonaticus nacré, Fr.** (See Slate-Spar.) Though this is made a distinct species of the limestone family by some mineralogists, it is composed of carbonat of lime with an admixture of about three or four parts in the hundred of manganese or iron with water, to which probably its nacy lustre may be owing. It occurs in some parts of Cornwall, and in Scotland.

**Slikensides, a name given by the Derbyshire miners to galena or lead-glance, when it forms a smooth polished surface or lining to veins.**

**Smargadite, green diagglication; Diagglication vertue, Haey.** See Diagglication.

**Soap-Stone,** a variety of fléetite, is found in Cornwall, and
and extensively used in the porcelain manufacture at Worcester. It has a milk-white or greenish-grey colour, mottled with a muddy-purple; it is veryunctuous to the touch, yields to the nail, and falls to pieces in hot water. Before the blow-pipe, it is friable into a somewhat translucent enamel. According to the analysis of Klaproth, it contains

\[
\begin{align*}
\text{Silex} & \quad - & 45.00 \\
\text{Alumine} & \quad - & 9.23 \\
\text{Magnesia} & \quad - & 24.75 \\

\text{Water} & \quad - & 18.00 \\
\end{align*}
\]

Under the article Steatite, it is stated to differ from common silexite by the absence of alumine; it should have been by the excess of alumine. Some varieties of silexite scarcely contain a trace of the latter earth.

**Soda.** *Native,* or *Natron.* See *Natron, Addenda.*

Sodalite. (See *Sodalite.*) This mineral is claffed by Mr. Jameson with the felspar family, on account of its external character; it differs from felspar in the proportions of its constituent parts, and foda supplies the place of potash, which is a constituent of molten felspars.

**Somatic,** or *Nepheline.* See *Somatic and Nepheline, Addenda.*

**Specular Iron-Ores.** See *Iron.*

*Spheine.* See *Spheine, Rutile,* and *Titanium.*

Spinel. See *Gem, Rutile,* and *Spinel.*

Spodumene. (See *Spodumene.*) According to D'Andrade, this mineral before the blow-pipe first separates into gold-coloured scales, and then into a kind of powder or ash. It is recently found to contain 8 per cent. of the new alkali lithia.

*Staurolite,* or *Granite.* See *Staurolite and Granite, Addenda.*

Staurotide, the name given by Haüy to staurolite.

**Steatite.** See *Steatite and Soap-stone, Addenda.*

*Stilbite.* See *Zolite.*

Striped Jasper. See *Jasper.*

MINGRELLA, l. 12, after gem, add—a kind of pafe made of. At the close, add—According to Reineggs, it contains four millions of founs, and annually exports 12,000 faves.

MINKALLI, an African term, denoting a quantity of gold, nearly equal to 10s. fering.

MINOT, in *Geography,* a town of America, in the district of Maine, and county of Cumberland, having 2020 inhabitants.

MIRRIN, r. *Wolein.*

*MODBURY,* l. 33, r. 1811—1890—863 males; l. 34, 1027 females, 190 families, and 156.

*MOFFAT,* col. 2, l. 13, r. 1811; l. 14, r. 1824 persons, occupying 334 houses; 850 being males, and 974 females.

MOGO, l. 2, after gulf, add—which has one of the most fecure roadsteads in the gulf, formed by Cape Bollana to the E. and the point improperly called Certes to the W. and capable of holding the largest fleets.

MOHOCKS, a denomination given to a mob of disorderly people, who traversed the streets of London at night,
night, and amused themselves with wounding and disfiguring the men, and indecently exposing the women, in the year 1711. A reward of 100l. was offered by royal proclamation for apprehending any one of them.

MOLD, l. 6, r. 1811, the parish, &c. 5083 persons, occupying 1026 houses; 2457 being males, and 2618 females: of whom 217 families are employed in trade and manufactures, and 180 in agriculture.

MOLE. See NUVES.

MOLLA, in Botany, Ait. Hort. Kew. v. 2. 62. See POLYCARPS and HAGEA.

MOLTON, South, col. 2, l. 15, r. 1811—520—2739.

MOLTON, North, an adjoining parish, containing 329 houses, and 1526 inhabitants.

MOLYBDENA. See MINERALOGY, Addenda.

MOLYBDENUM, in Chemistry. The specific gravity of this metal, according to Hjelm, is 7,400; but according to Bucholz, who, from the greater heat he employed, obtained it in a more compact state, it is as high as 8.611. According to the experiments of this latter chemist, there are three oxides of this metal, the brown protoxid, the blue or molydbus acid, and the white or molybde acid. Dr. Thomson, from the experiments of Bucholz, deduces the weight of the atom of this metal to be 60.

MONAHAN, or MONAGHAN. Add—containing 725 inhabitants.

MONEY. See POLITICAL ECONOMY.

MONFALOUT, r. See Manfalout.

MONKTON, l. 2, r. 1248.

MONMOUTH, l. 3, r. even for fix; l. 4, r. 22,150

—1501. —Alfo, a town of the district of Maine, in the county of Kennebeck, containing 1262 inhabitants.

MONMOUTH, col. 3, l. 37, r. 1811; l. 38, r. 3553. Add—The number of houses is 661; that of males 1630, and of females 1873, of whom 375 families are employed in trade and manufactures, and 116 in agriculture.

MONMOUTHSHIRE, l. 10. In 1811, the county was returned as containing 11,766 houses, and 62,127 persons; 30,087 males, and 31,140 females; 5815 employed in agriculture, and 4812 in trade, manufactures, and handicraft.

MONONGALIA, l. 2, r. 12,703 persons, of whom 351 were slaves in 1810.

MONOPTERUS, in Ichthyology, a genus of fishes of the order Apodes; the characters of which are, that the body is anguilliform, the nostrils placed between the eyes, and the fin caudal. The only animal of this genus hitherto discovered is the M. javanicus, blackish, with a very shapely pointed tail. It is a native of the Indian seas, and is very common about the coasts of Java, where it is considered as excellent food.

MONROE. Add—containing 5444 inhabitants, of whom 476 were slaves in 1810.

MONSON. Add—containing 1674 inhabitants.

MONTAGUE, l. 4, r. 934.

MONTAGUE. See MOUNTAGUE.

MONTENEGRINS, so called from the Monte Negro, or Black mountain, near Cantaro, have been reckoned amongst the most daring inhabitants of Dalmatia; which see. The whole amount of these, who are scattered over mountains, has been estimated at about 60,000. All profess the Greek religion, but with several remains of superstition. The Morlacs, and other inland tribes of Dalmatia, are honest and sincere barbarians, and the dregs of their vaivodes somewhat resembles the Hungarian. The general peace of Europe has restored tranquillity and present security to them.

MONTGOMERY, in America, l. 3, r. 2954, of whom 747 were slaves in 1810; l. 6, r. 41,214, of whom 712 were slaves; l. 10, r. 237; l. 12, r. 595; l. 14, r. 30; l. 15, r. 29,703; l. 16, add—containing 580 inhabitants; l. 17; having 2693 inhabitants; l. 18, r. 8430; l. 19, r. 1696 slaves; l. 21, r. 8499 inhabitants, of whom 1099 were slaves; l. 24, r. 17,980—7572; l. 25, r. 8026 inhabitants, of whom 2629 are slaves; l. 29, r. 12,650 inhabitants, of whom 1691 are slaves. Add—Alfo, a town of Somerset county, in New Jersey, having 2282 inhabitants.

—Alfo, a township of Franklin county, in Ohio, having 556 inhabitants. —Alfo, a county of Ohio, containing 7 townships, and 7722 inhabitants.

MONTGOMERY, in Wales, col. 2, l. 35, r. 1811; l. 36, the borough and—932—442 males, and 490 females.

MONTGOMERYSHIRE, col. 6, l. ult. r. 1811—

51,031—25,373—26,558. Col. 7, l. 1, r. 3164 families; l. 3, r. 6309.

MONTICELLO, a town of Georgia, in Randolph county, having 89 inhabitants.

MONTIQUE, a town of Sussex county, in New Jersey, containing 661 inhabitants.

MONTROSE. In 1811 the burgh and parish contained 1064 houses, and 8953 persons; viz. 3837 males, and 5118 females: 170 families being employed in agriculture, and 1520 in trade, manufactures, and handicraft.

MONTVILLE, l. 3, r. 2187—Alfo, a town in Maine, in Lincoln county, with 864 inhabitants.

—MONTVILLE Plantation, a township of the fame, having 130 inhabitants.

MOON, a township of Alleghany county, in Pennsylvania, having 1622 inhabitants.

—MOON, Half, a township in Centre county, in Pennsylvania, having 560 inhabitants.

MOON, First and Second, two townships of Beaver county, in the same state, the former having 1035, and the latter 1245 inhabitants.

MOONBEE, an Indian term signifying a letter-writer or secretary, and applied by Europeans to the native who instructs them in the Perian language.

MOONSTERLING, in Geography, a township of Kentucky, in Montgomery county, with 325 persons, of whom 76 were slaves in 1810.

MOORE, a township of Northampton county, in Pennsylvania, having 1108 inhabitants.

MOOSH, the ancient Moxene, called also Daran, a town of Armenia, occupying a small eminence, walled by the Ephraites, over which is a bridge of fifteen arches, badly built and thinly inhabited; but the adjoining country is fertile and populous. The natives of this district, which is one of the Turkish pashalics of Armenia, are a degenerate race, and paid to amount to 80,000 souls; 12,000 of whom are Yezedis. Considerable quantities of tobacco and manna are exported from hence.

MORAYSHIRE, col. 4, l. 32, r. 1811—6208—

28,188; viz. 12,401 males, and 15,787 females; l. 32, r. 2635 families; l. 34, r. 1886.

MORELAND, l. 2, having 400—the other having 1692 inhabitants.

MORETON-HAMPSTEAD. In 1811 this parish contained 337 houses, and 1653 persons; viz. 770 males, and 885
MOU

883 females; 263 families being employed in agriculture, and 43 in trade, manufactures, &c.

Moreton in the Marsh. In 1811 this parish contained 194 houses, and 928 persons; viz. 457 males, and 471 females: 60 families being employed in agriculture, and 91 in trade, manufactures, &c.

Moreton, a town of Chittenden county, in Vermont, having 405 inhabitants.

Morgan, a town of Orleans county, in Vermont, having 135 inhabitants.—Alfo, a township of Greene county, in Pennsylvania, having 1621 inhabitants.—Alfo, a township of Knox county, in Ohio, having 388 inhabitants.

—Alfo, a county of Georgia, having 2294 inhabitants.

Moriah Plantation, a township of Maine, in the county of Hancock, having 224 inhabitants.

MOROKINNEC, r. Morokinnee or Morotinnee, a place of Klaproth to an acid, principle obtained from a film exudation from the morus alba, collected by Dr. Thompson in Sicily. This exudation contained the acid in question in combination with lime. When separated, it was found to puzzle the following properties:—It exists in the form of needle-like crystals, having the taste of succinic acid. It is not altered by exposure to the air. It dissolves readily in water and alcohol, and does not, like the moroxylate of lime, precipitate the metallic solutions. It is volatile, and may be sublimed without change; hence this is probably the bell mode of obtaining it in a state of purity. The moroxylates are little known, and do not appear to puzzle remarkable properties.

Morpeth. In 1811 the borough contained 464 houses, and 3244 persons; viz. 1470 males, and 1774 females: 77 families being employed in agriculture, and 529 in trade, manufactures, or handicraft.

Morphia, the name which has been given to an alkaline principle existing in opium; the description of which, and of the other principles existing with it, will be found under opium. See Opium.

Morris, 1. 3, for five r. ten. Col. 2. 16, r. 21, 828—856 were slaves in 1810.—Alfo, a township of Washington county, in Pennsylvania, having 1679 inhabitants.—Alfo, a township of Greene county, having 944 inhabitants.

Morristown, 1. 4, r. and in 1810, 3753 inhabitants, 214 being slaves.—Alfo, a town of Orleans county, in Vermont, having 550 inhabitants.

Morrisville, 1. 2, r. Bucks; add—having 961 inhabitants.

Mortlake. In 1811 the parish contained 346 houses, and 2021 persons; viz. 832 males, and 1189 females.

Mosul, 1. 2, after Nineveh, add—though others think that the village of Nuni, on the opposite bank of the Tigris, presents the position of this ancient city. It is situated in the pachalic of Bagdad; delv. in the province of Dabekir, situated.—1. 12, infer—The inhabitants are said to amount to 35,000 souls.

Mucacilla, r. Rubecula.

Mother-Kill. Add—containing 7445 inhabitants.

Moultonborough. Add—It contained, by the census of 1810, 994 persons.

Mount Holly, 1. 3, r. 922.

Mount Jef, after Lancaster r. county, having 1551; at the close, add—having 656 inhabitants.

Mount Pleasant, 1. 4, add—having 1105 persons.—Alfo, a township of Wayne county, having 522 persons.—Alfo, a township of Washington county, having 1165 inhabitants.

—Alfo, a township of the same county, in Wellmoreland county, having 1788 inhabitants.—Alfo, a township of Jefferson county, in Ohio, with 846 persons.

Mount Takour, a town of Rutland county, in Vermont, containing 209 inhabitants.

Mount Vernon. Add—containing 1098 inhabitants.—Alfo, a town of Hillborough county, in New Hampshire, containing 762 persons.

Mount Montague. Add—See Montague.

MOUNTAIN CORK. See Mineralogy, Addenda.

Mountains, col. 7, under Ireland, instead of l. 3, infer—Sleibh Donard, a mountain in the county of Down—2500. Col. 13, l. 10, r. Varenus.

Mumbo-Jumbo, a kind of bugbear dressed in a maskerade habit, formed of the bark of trees, and suspended upon a tree at the entrance of the Mandingo towns in Africa. It is much employed by the pagan natives in keeping their women in subjection; for as the Kadirs, or infidels, are not restricted in the number of their wives, every one of them as many as he can conveniently maintain; and as it frequently happens that the ladies disagree, family quarrels sometimes arise to such a height, that the authority of a husband can no longer preserve peace in his household. In such cafes, the interposition of Mumbo-Jumbo is called for, and is always decisive. This strange minister of justice, who is supposed to be either the husband himself, or some person instructed by him, disguised in the above-mentioned dress, and armed with the red of public authority, announces his coming, when called for, by loud and dismal screams in the woods near the town. He begins the pantomime at the approach of night, and as soon as it is dark enters the town, and proceeds to the bentang (a kind of stage erected in every town, answering the purpose of a town-hall), at which all the inhabitants immediately assemble. Every married female, not knowing for whom the visit is intended, is alarmed, but when summoned mull appear; and the ceremony commences with fongs and dances, which continue till midnight, about which time Mumbo fixes the victim, whose unfortunate victim being thereupon immediately fized, is stripped naked, tied to a poll, and severely flogged with Mumbo's rod, amidst the fhouls and derision of the whole assembly; and it is remarkable, that the rest of the women are the loudest in their exclamations on this occasion against their unhappy filler. Day-light terminates this indecent and unmanly revel.

Muni, col. 2, l. 3 from bottom, for many-mothered, for r. many-mothered ion.

Muræna, col. 5, r. Myrus.

Muriate of Ammonia. See Sal Ammoniac.

Muriatic Acid. Muriates, in Chemistry. See Chlorine.

Musci, col. 8, l. 18, r. shrinks; l. 7 from bottom, r. exuval.

Muskingsum, l. 5, add—This county has 11 towns-ship, and 16,076 inhabitants.

Mussophaga, Plantain-Eater, in Ornithology, a genus of birds of the Picæ or order; the characters of which are, bill flout, triangular; the upper mandible elevated at the base, above the front; both mandibles dentated at the edges; nostrils in the middle of the bill; tongue entire, thickish; feet with three toes before and one behind. This genus is conflatuted by the blackish-violet plantain-eater, with crimson crown and quill-feathers, and a white stripe beneath the eyes. The bird, which is highly elegant, is
of African origin, and is found in the province of Acre in Guinea, and is said to live principally on the fruit of the mufa or plantain-tree. Dr. Shaw, in the Museum Leveiri-
num, has described this bird as a species of cuckoo, under the name of Cuculus regius; but in his Zoology it is a distinct genus.

MUSTELA, col. 3, under B. r. BARBARA, Guiana weasel; l. 3, r. Guiana.

MUSTELIA, in Botany, in memory of Mr. Muffel, who wrote, in Phil. Trans. v. 63, some “New Observations upon Vegetation.”—Sprengel Tr. of Linn. Soc. v. 6. 152.

—This plant is said to differ from Eupatorium, (see that article,) in having five minute scales accompanying the brily feed-crown. How far such exist in any Eupa-
torium, or not, and whether they ought to make a generic distinction, merits inquiry.

MYLOCARYUM, from μυλος, a mill, and καρυς, a nut, alluding to the four spreading wings of the feed.—Wild. Enum. 454. Pursh 363. (Walkeriana; Frazer's Cat.)—Cháis and order, Decandria Monogynia. Nat. Ord. Erica, Juft.

MYOXUS. At the close, add—Dr. Shaw enumerates some other species, such as the Chryfrus, or gilt-tailed D., the M. guerhucus, or guerlinguet, and the African, or earles Dormouse.

MYRIANDRUS. Add.—According to Xenophon, it was a Phoenician city, a mart-town, and many merchant-
ships lay at anchor before it.

MYRICIN, in Chemistry, a name given by Dr. John to the substance that remains after bees' wax, or the wax of the myrica cordifolia, has been heated with alcohol. This sub-
stance is insoluble in water, ether, and alcohol, both hot and cold. It is soluble in the fixed and volatile oils, and does not precipitate from the former of these. It melts between 100° and 140°, and is somewhat glutinous, but of the con-

MYTHOLOGY of the Hindoo, l. 26 from bottom, for flowers r. flores.

N.

NACHITOCHES, l. 2, after Orleans, add—and in the territory of Orleans; its inhabitants in 1810 being 2870.

NACOGDOCHES, a small town of Louisiana, situated in N. lat. 31° 27', W. long. 24° 17', on the Arroyo de la Nana, in a beautiful, healthy, well-watered country. This small town, and a few farms in the vicinity, are hitherto the only improvement made by the Spanish emigrants after the revolution of 98 years. A tribe of Indians, called Nadacos, refides about 30 miles N. of Nacogdoches, upon the headwater of the Angelina, where they were found near a century ago by the French and Spaniards. The Nadacos are a poor inoffensive race, in peace with all their neighbours, both white and black.

NAGA, a name of the Hindoo mythological serpent, otherwife called Sisra; which fee.

NAGANTEKA, in Hindoo Mythology, is a name of the hypogriff Garuda, the vehicle of the god Vishnu. It means the destroyer of serpents. Another of its names is Superna; which fee.

NAIRTI, is one of the eight regents of the winds, or points of the heavens. He rules the south-west quarter, and is subordinate to Indra, regent of the firmament. (See INTRA.) These rulers of the cardinal and intermediate points are sometimes called Marut (which fee). See also VIRUPAKSHA, meaning with a disagreeable countenance.

Another of his names is Karbara. He has a fakir or con-
fornf alligned him, usuall named Nirriti; which fee.

NAIRN, i. alt. for 632 r. 613.

NAIRNSHIRE, col. 2, l. 45, number of houses was 1746, and the inhabitants, 6.

NAKAL, one of the champions of the Hindoo heroic poem, entitled the Mahabarata (which fee). As that poem is supposed to be allegorical, and to represent the conflicts between man’s virtues and vices, Nakal, one of the five fons of Pandu, is said to be a personification of temperance, and is made the twin-brother of Sahadeva, or chaffy. Other commentators make them to represent beauty and wisdom. Their mother was Maderi, a wife of Pandus which fee.

NAKSHATRA, in Astronomy, is the name given by the Hindoos to the mansions which they allign to the moon. They seem to be the same, though not exactly coinciding, with the lunar fages of the Arabians, which they call mansil. The “Nakshatras, or asterisms, marking the moon’s path,” are twenty-four or twenty-eight in number. A
table of them is given in the ninth volume of the Arabic Religions, by Mr. Colebrooke, the president of the Arabic Society. See also the second volume of the same work, together with the Indian zodiac, accompanied by an effay on its antiquity, by Mr. W. Jones.

The Hindoos ascribe the invention of their solar and lunar
NAR

Lunar zodiacs to Daksha, who is mythologically represented as a son of Brahma, and they then give a free rein to their poetical imaginations, representing the Nakhatras as the daughters of Daksha.

NALA, in Hindu Romances, is a perlonage of considerable importance, though described as an ape. Others begat by the divine architect Pīṣakārma (which see); and he is said in the Ramayana to have been the builder of Rama's bridge, usually called Adam's bridge, from the continent to the island of Ceylon, or Lanka. See Ceylon and Lanka.

NAMUKI, is the name of a friend and companion of Indra, the regent of the firmament.

NANCÉMOND. See Nansemond.

NANDANA, the name of the garden, or city, affigined by Hindoo fabulists for the delightful residence of their demigod Indra, the regent of the firmament. (See Indra.) There are four cities or gardens of this name, and three of them are sometimes said to belong to Ganeta, or Patacar. One of them is called Swa-nandana-puri, the self-delighting city; nandana meaning delightful or happy.

NANDI, in Hindu Mythology, is the name of the bull on which the god Siva rides. The bull, with the Hindoos, is the symbol of divine justice, as it is also of generation or protection. See Siva.

NANSEMOND, l. 14, r. 10,324—4462.

NANTICOKE, l. 12, r. 2843 inhabitants, including 192 slaves in 1810.

NANTMILL for Nantrill, l. 2, add—the former contains 1544, and the latter 1188 inhabitants.

NANTUCKET, l. 13, r. 6807.

NARAKA, one of the receptacles for sinners, or hells of the Hindoos. Of these, they have at least seventy-one; and their names are given in the Inl. of Menu, c. *, v. 88, 89, 90.

NARAMEDEHA, a term in the Sanskrit language signifying the sacrifice of a man. It cannot be doubted that human sacrifices were formerly offered by some tribes of Hindoos, although it is said, and may be reasonably believed, that in these days the practice is wholly discontinued. (See Rarskia.) To the godfess Parvati, or Bhavani, the consort of Siva, under her name of Kali, or the black goddess, these offerings, it would appear, were usually, if not always, made. The rules and regulations for this horrid sacrifice are laid down in a chapter, emphatically called the fanguiary chapter of the Kalika-Purana, which has been translated by Mr. Blaquiere, and published in the fifth volume of the Asiatic Researches, art. xxiii. No religious rite can be more minutely ordered and detailed.

Although it must appear evident, that human sacrifices were formerly legal and practifed among Hindoos, they are most pointedly prohibited in very ancient, as well as in more modern books: such prohibition is, indeed, a farther, and of itself sufficient proof of the existence of the practice. In the Brahma Purana, (see Purana) every Naramedha, or man-sacrifice, is emphatically forbidden; and in the fifth book of the Sri-Bhagavat, (see that article,) fr W. Jones has pointed out the following emphatical words: "Whatever men in this world sacrifice human victims, and whatever women eat the flesh of male cattle, those men and those women shall the animals hereplain torment in the mansions of Yama, (see Yama,) and, like slaughtering giants, having cleared their limbs with axes, shall quaff their blood." Asiatic Researches, vol. iii.

In the first Veda an emblematical or vicarié sacrifice is ordained, in which men and animals are the victims, but are released after certain ceremonies.

Vol. XXXIX.

NARA-SINGHA, in Mythology, is the designation of the fourth avatara or incarnation of the Hindoo deity Vishnu. It means literally man-lion, such being the form in which this defecit is related to have taken place.

Sir W. Jones furnished that this avatara, and the following of Yamana, (see Vamanavarata,) were allegorical references to the two presumptuous monarchs Nimrod and Belus, under the names of Hiranyakasipu and Beli, the former name meaning with a golden axe, or, according to other authorities, clad in gold. Hind. Panth. Af. Ref.

The three avatara, or defecits of Vishnu on earth, that preceded that which is the subject of this article, were the Matasya or fish, the Kuruma or tortoise, and the Varaha or the boar; under each of which words, having the common denomination of avatara prefixed, some account of them will be respectively found. A list of the ten grand defecits, or dyaavatara, will be found under the article VISHNU. This is sometimes written Nri Sinha.

NARASINHI, or Narshini, or Nris@di, is the name given to the Hindoo goddess Lakhmi, who became thus incarnated to accompany her lord Vishnu in his avatara or defecit of Narasingha, as sufficiently explained under that article, and the others thence referred to.

NARAYANA, is a personification of rather a bold and apparently reprehensible nature. "The waters are called nara, because they were the first production of Nara, or the Spirit of God; and since they were his first aya, or place of motion, he is thence named Narayana, or moving on the waters." Inf. of Menu, c. *, v. 10. See Menu.

On the whole, Narayana seems to refer in character more to Vishnu than to any other of the Hindoo deities.

NARAYANI, a name and form of the Hindoo goddesses Lakhmi. In this character, she is considered as the Sakti or comfort of Narayana; which see, and Matri.

NARBETH, l. 9, r. 388.

NAREDA, or Narada, in Hindu Mythology, a personage among the Hindoos, deemed the mythological offering of Brahma and Saraswati. In the popular histories of Krihna, Nareda is represented as his humble friend, on whom he paffes many jocose and whimsical jokes, metamorphosing him into a woman, &c. But in more serious books, his character is more corresponding with the magnificence of his origin. He is represented as a wise legislator, great in arms, arts, and eloquence; and, indeed, of such historical celebrity, that his actions are the subject of a Purana, named after him; some account of which is given under Purana. He was also an astronomer, and an excellent musician. Hence Saraswati, the patroness of science and harmony, is said to have been his mother. He further invented the vina, a sort of lute, which Sir W. Jones remarks as a singular fact, is otherwise called ksetrapa, having the fame meaning as tftudo and Nareda being also a frequent meffenger of the gods, to one another, or to favoured mortals. His character is highly admired, and is a favorite poet of Homer or Mercury.

NAS, l. 2, r. 7268—2897.

NASTICK, in Philosophy, the name of a sceptical sect of Hindoos. The word in the Sanskrit tongue means negative, and is intended to designate thofe who do not believe the Veda. Individuals of more orthodox sects call the Nasticks, materialists and atheists.

NASTURTIUM, in Botany, (see our former article,) is now adopted to designate the Water-cress and its allies, separated by Mr. Brown from Stracophum, (see that article,) sect. 2.—Br. in Ait. Hort. Kew. v. 4. 109.—Class and

Eff. Ch. Pod nearly cylindrical; valves concave, without rich or keel. Cotyledons accumbent. Calyx spreading.

N. affinale, (Silwybr. Nafurtium; Linn. &c.), with fylwybris, terrepsi, amphibium, pyrenicum, and fylwybris, are the species mentioned in Hort. Kew. We have already described all but pyrenicum, which is a well-known species.

NATICK, l. ult. r. in 1810, contained 766.

NATRON. See Mineralogy, Addenda.

NATUNZ, in Geography, a town of Peria, in the province of Trak, 63 miles from Ipahan, and 43 from Cahani, situated on a very delightful spot, in a valley surrounded by high and rugged mountains; and famous for the salubrity of its climate, pears, peaches, and handmome females. It has a fort in the centre of the valley, an excellent warm bath, and an old mosque, with a very handmome mineral, said to have been built 300 years ago.

NAVY. Add—having 56 inhabitants.

NEAKIA, l. 10 from bottom, after villages, add—Dr. Clarke (in vol. vi. of his Travels) states the whole population of the island, including women, at 18,000 persons, about 3000 of whom are Latins, and the rest Greeks.

NAZARETH, col. 2, l. 34, add—Lower Nazareth is a township containing 758, and Upper Nazareth is a township in the same county and state, containing 535 inhabitants.

NEATH, col. 2, l. 5, r. Saturday for Thursday; l. 6, add—It has three fours; l. 12, r. was for is.

NECYDALIS, Minor, add—in fields and about hedges in the summer months. Cerelea, add—in woods during the summer months.

NEEDHAM, l. 7, r. 1097.

NEIFF, or Meshed Ali, a holy city, being the supposed burying-place of the caliph Ali, a town of the pachylo of Bagdad, nine furlongs from Hilleh, and four miles from Kafa, situated on a hill, at the bottom of which is an artificial lake. It was founded by Alexander the Great, and bore the name of Alexandria, which was afterwards changed into that of Hira, when it became the residence of a dynasty of Arabian princes, who fought under the Parthian banners against the emperors of Rome. Neiff is not so large as Kerbela, but better built, and defended by a good wall, deep ditch, and lofty towers, lately renewed, under the apprehension of an attack from the Wahabees, who extend their ravages to the gates of the town. The tomb and mosque of Ali occupy an ample space in the middle of the city, and form a handufome structure, within a high wall, which an infidel subjects himself to death for attempting to pass. The governor of Meshed Ali is a Turk, but the population, not easily intimidated on account of the constant influx of pilgrims, is like that of Kerbela, chiefly composed of Persian fanatics. The relics of almost all persons of rank are transported from the most remote parts of Peria to be interred either here, or at Kerbela, Kazamem, Koom, or Meshed in Khoraflan.

NELSON, l. 2, r. 13,257—2908. Add—Alfo, a county of Virginia, containing 9684 inhabitants, of whom 4678 were slaves in 1810.

NEMESIA, in Botany, a name borrowed by Venentat from Dioecories, who is faid to have applied it to fome kind of Antirrhinum, we know not in what part of his writings. The present genus is nearly allied to Antirrhinum—Venentat, Mufalifi. 41. Ait. Hort. Kew. v. 4. 16.—Clafs and order, Didynamia Anglopermia. Nat. Ord. Peresonate, Linn. Scrophularia, Julif.

Eff. Ch. Calyx in five deep segments. Corolla spurred at the bafe; throat clofed by the palate. Capsule compreffed, of two cells, and two boat-like valves; partition linear, covered with hairs.

2. N. icornis. Horned Nemedia. Ait. n. 2. See Antirrhinum, n. 24. (Linaria; Burm. Afr. 211. t. 75. f. 3.)—Leaves lanceolate, with tooth-like ferratures. Clufter terminal, rather lax.—From the fame country. Annual. The specific name applies to the calyptra.

3. N. feta. Fettid Nemedia. Vent. n. 1. t. 41.—Leaves linear-lanceolate; upper ones entire. Cluthers terminal, defne. Stem shrubby.—From the Cape. Flowers white, marked with red; palate yellow.

NEPANESE, in Geography, a township of Lycoming county, in Pennfylvania, having 298 inhabitants.

NEPER, col. 1, l. 22 from bottom, for Neper’s rods r. Neper’s bones.

NEPHELINE, or Somicite. See Mineralogy, Addenda.

NEPHRIT. See Mineralogy, Addenda.

NERANTEKA, in Hindo Mythology, is the name of a malignant demon, mentioned often in their heroic poems, flan by Krihu, and by other divine warriors. The name generally means deftroyer of men.

NERKA, one of the many halls of the Hindous. See NARAKA.

NEROS, in Chronology, an ancient Chaldean period of 600 years, and equal to the Sofos of 60 years multiplied by 10.

NESENPACK, in Geography, a township of Luzerne county, containing 450 inhabitants.

NESHANSACK, a township of Mercer county, in Pennsylvania, having 700 inhabitants.

NETCHEZ, or weftern branch of the Sabine, a river of Louifiana, formed from the united streams of the Angelina, Atouquea, Nena, and the Attaoecito. The Netchez, though not fo long as the Sabine, exceeds it as to quantity of water. The lands watered by this river, and its tributaries, are of superior quality to the country on the Sabine; but fertile compared with thofe on the margin of many rivers in Louifiana.

NETTING. Add.—The netting is ufed in different parts of a ship; thus, the boarding-netting is thrown over the fides, to prevent the enemies boarding. Bow-fprit-netting is fntened near the outer end of the bow-fprit, to the man-ropes or horfes, to flow away the fore-topmaft-flay-fail and jib. Breaff-work quarter and main nettings are ufed to keep the hammocks in the fiamons. Head-netting is fntened to the horfes in the head and upper rail, to prevent the men from flipping overboard. Quarter-deck netting is fuaped under the officers’ heads, to prevent any thing falling thereon. Top-netting is fntened to the rail, fhrouds, and top, to preferve the men from falling.

NEWARK, in America, l. 2, add—having 88 inhabitants; l. 12, add—and in 1810 contained 8008 inhabitants, of whom 360 were slaves.

NEW BRAINTREE, l. 2, after Worcefter, infer—Massachus-
NEW

—Massachusetts; l. 5, add—in 1810 contained 912 inhabitants.

NEWBURY, or Newberry, l. 2, add—It contained, in 1810, 13,063 persons, of whom 4066 were females; l. 3, r. 1709; l. 10, r. 1303; l. 13, r. 5176.

NEWBURY Port, l. 4, r. 7634.

NEW CANAAN, a town of Fairfield county, in Connecticut, containing 1599 persons.

NEWCASTLE, l. 5, r. 9 hundreds, and 24,429; l. 6, r. 1087; l. 16, add—It contained 2340 inhabitants, including 174 slaves; l. 19, r. 592; l. 26, r. 1232. At the close, add—Alfo, a township of Muskingum county, in Ohio, having 370 persons.

NEWCASTLE-in-Emlyn, col. 2, l. 2, for Saturday r. Friday. Add—A few miles below the town is a beautiful salmon- leap.

NEW CHESTER. Add—containing 895 inhabitants.

NEW DURHAM, a town of Strafford county, in New Hampshire, having 888 inhabitants.

NEW FAIRFIELD, a town of Connecticut, in the county of Fairfield, containing 772 inhabitants.

NEWFIELD, l. 3, r. 1376.

NEW LEBANON, a town of Maine, in the county of York, with 815 inhabitants.

NEW GRANTHAM. Add—containing 864 inhabitants.

NEW HAMPSHIRE. Add—See United States.

NEW HAMPTON, l. 4, add—and contains 1293 inhabitants.

NEW HARTFORD. Add—containing 1507 inhabitants.

NEW HAVEN, in America, l. 4, r. 18; l. 5, r. 1810; containing 37,064 persons. For other particulars, besides those which have been mentioned, see New Haven, and United States.

NEWINGTON, l. 3, r. 508.

NEWINGTON, Stock, a village of the county of Middlesex, in the Pinbury division of Offullstone hundred, and parish of St. Mary’s. In 1811 the parish contained 342 houses, and 2149 persons; viz. 895 males, and 1254 females.

NEW KENT, l. 3, r. 6478 inhabitants, of whom 3745 were slaves in 1810.

NEW L.Sc. Add—containing 780 inhabitants.

NEW LONDON, l. 4, r. 14; l. 6, r. 1810—34,707—77; l. 14, r. 3283; l. 26, r. 692. At the close, add—Alfo, a township of Pennsylvania, in Chester county, containing 1018 persons.

NEW MARKET, in America, l. 3, r. 1061. Col. 2, l. 1, add—Alfo, a township of Highland county, in Ohio, containing 978 inhabitants.

NEW MILFORD, l. 7, add—In 1810, the inhabitants were 3237. At the close, add—it has 797 inhabitants.

NEWPORT, in Cornwall. In 1811, the parish of St. Stephen’s contained 159 houses, and 896 persons; viz. 433 males, and 463 females.

NEWPORT, col. 1, l. 4, r. 1427; l. 7, r. 16329; l. 19, r. 7907. Col. 2, l. 9, add—containing 566 inhabitants. Add—Alfo, a township of Washington county, in Ohio, having 243 inhabitants.

NEWRY, a township of the district of Maine, in the county of Oxford, having 202 inhabitants.

NEWTON, l. 3, r. 1709; l. 5, add—Alfo, a township in Bucks county, having 902 inhabitants:—l. 8, r. 4543; add—Alfo, a township of Delaware county, in Pennsylvania, containing 601 inhabitants. —Alfo, a township of Cumberland county, in the same state, having 1312 inhabitants.—Alfo, a township of Miami county, in Ohio, having 556 inhabitants. —Alfo, a township of Muskingum county, in Ohio, having 802 inhabitants.—Alfo, a township of Trumbull county, in Ohio, having 490 inhabitants.

NIGER. Add—It has been supposed that the Niger terminates in the Nile; but this hypothesis, though maintained by several modern travellers, viz. Hornemann, Jackson, &c. is the most unfounded of any, and the least consistent with acknowledged facts. The supposition adopted by Mr. Park is, that the Niger terminates in the river Congo, or, as it is sometimes called, the Zaire; which see. Another supposition, respecting the termination of the Niger, is that of a German geographer, Mr. Reichard, published in the "Ephemerides Geographiques," in August 1808, who represents the Niger, after reaching Wangara, as seeking a direction towards the south, and being joined by other rivers from that part of Africa, taking a great turn from thence towards the south-west, and pursuing its course until it approaches the north-eastern extremity of the gulf of Guinea, whence it divides and discharges itself by different channels into the Atlantic; after having formed a great Delta, of which the Rio del Rey constitutes the efluary of the Rio Formoso, and Benin river the western branch, Vol. XXV.

NEWTON-NOTTAGE, a parish formed by the hamlets of Newton and Nottage, situated in the county of Glamorgan, near the Bristol Channel. In 1811, the former hamlet, at a small distance from Pyle, that lies in the road between Cowbridge and Neath, contained 55 houses, and 254 persons; viz. 117 males, and 137 females: and the latter contained 43 houses, and 217 persons; viz. 107 males, and 110 females.

NEWTOWN, l. 3, containing 2834; l. 14, having 1551 inhabitants; l. 17, and 2082 persons; l. 25, add—See Newton; l. 27, add—See also Newton.

NEW VINEYARD, l. 1, for Kennebeck r. Somerfield. Add—containing 484 inhabitants.

NEW YORK. See New York.

NIAGARA. See Niagara.

NICHOLAS, l. 2, r. 4898 inhabitants, 509 being females.

NICKEL, in Chemistry. The weight of an atom of this metal, according to the recent determinations of Dr. Thomson, is 33.75, from which date the composition of its salts may be easily ascertained. See Atomic Theory.

At the end of the article in the Cyclopaedia, add—from the experiments of Tuppini, it appears that preparations of nickel poiffees poisonous properties.

Nickel-Ore. See Mineralogy, Addenda.

NICOTIN, in Chemistry, the name which has been given to a peculiar principle in the leaves of the Nicotiana latifolia, or tobacco, and to which that plant owes its peculiar properties. This substance was obtained by Vanquelin from the juice, by a process sufficiently complicated. When pure it is colourless. It has an acrid taste, and the peculiar smell which distinguishes tobacco. It occasions violent feverishness. It is soluble both in alcohol and water; it fels colourles, and distilled by the peculiar taste and smell of nicotin. It is precipitated from its solutions by tincture of nutgalls. It is volatile, and some-what reembles in short the volatile oils in its properties. It poiffees poisonous properties. See further in the Annales de Chemie, lxx. 139.

NILA, in Mythology, is one of the many names of the Hindoo goddes Parvati. The word means blue or dark-azure, and is one of the Sanskrit names for the Nile, as is also Kali.

NILAKANT'HNA, a name of the god Siva, meaning blue-throated, similar to Shitakantha, or Shitakouatha, under which word some account is given of the origin, &c. of the appellation.

NILE, in Geography, a town of Ohio, in the county of Scioto, having 396 inhabitants.

NIMMISHITHAN, a township of Ohio, in Stark county, having 385 inhabitants.

NIobe, in Ancient Mythology, was, according to the historians who acquire in the authority of Diodorus Siculus and Apollodorus, the daughter of Tantalus, and sister of Pelops. Pelops removing from Phrygia, carried his father with him to that part of Greece which afterwards took his name; and for the security of his new dominions, married her to Amphion, a prince eminently powerful and eloquent, who fortified Thebes with walls. Niobe became, in consequence of that marriage, the mother of a numerous progeny; and was thus led to dispute Latona, who in revenge induced Apollo and Diana to put all her children to death, in the manner related by Ovid and Plutarch. This episode, as it is said by some writers, contains a history no less true than tragic. The city of Thebes was defeated by a pestilence, which destroyed all Niobe's children; and as contagious diftemper has been attributed to the immediate heat of the sun, it was reported that Apollo flew them with his darts. Niobe, after the death of her children, and husband, who, overpowered with grief, destroyed himself, returned to Lydia, and ended her days near mount Sipylys, upon which she was seen, according to Pausanias, a rock that, viewed at a distance, resembled a woman in deep melancholy and despair. Sophocles, in his Antigone, says, that this princess was not at first transformed into a stone; but that the gods, at her request, granted her that favour afterwards. The same poet, in his Electra, says, that Niobe sheds tears in a tomb of stone.

NIPPER, in Rope-making, is formed of two flued plates, through which the yarn passes from the tar-kettle, which are so adjusted by weights and a lever, that the yarn receives no more than is required, and what is squeezed out drops into a trough and returns into the kettle.

NIRRITI, is the name of a Hindoo deity, comfort or fakiti of Nirrit or Nairit. (See the latter article.) She shares with her husband the regency of the south-west quarter of the heavens.

NISHAPOUR, anciently the greatest and richest city of Khorasan in Persia, and one of the four royal cities of the province, is seated on a plain, formerly irrigated by about 12,000 aqueducts, which have fallen into decay. It is said to have been founded by Taimuras, and destroyed by Alexander the Great. After the lapse of many years, it was rebuilt by Sapor I., and his flatae was feen in it till the Arabs destroyed it. This city was taken in the 54th year of the Hegira by the Tartars, who completely ruined it, that when the original inhabitants returned to take possession of it, they could not distinguish their own houses. After having regained its former splendour, it was again taken and pillaged by the Tartars under Gengis Khan; so that the present inhabitants do not exceed the number of 15,000. The ruins of the city are nearly ten furfungs in circumference. It is at present subject to the dominion of the king of Persia, and has nine disritcts dependent upon it, each of which has about ten walled villages. The fruits are abundant and delicious.

NITRE, Native. See Mineralogy, Addenda.

NITRIC ACID, NITRATES, &c. in Chemistry. The correct proportions in which azote and oxygen combine, will be found in the tables appended to Atomic Theory, to which therefore we refer our readers. We shall only state here the composition of nitric acid, which is 5 atoms oxygen + 1 atom azote; hence the weight of its atom is 67.5, from which datum the composition of the nitrates can be accurately determined.

Ten species are described, all shrubs, natives of hills at the Cape of Good Hope. Leaves scattered, doubly pinnatifid, thorned; the upper ones, in fix of the species, divided into florets. Flowers white. Petals free, capitate, bracteate, purplish.—Four species are mentioned in Hort. Kew.

1. N. Sceptrum. (Protea Sceptrum; Linn. Suppl. 116. Spar. Stockh. Trans. for 1777. 53; not 55. t. 1.)—Upper leaves obviate or lanceolate, flatish; simple at the edges. Corolla silky, with clove hairs.

3. N. siccata, and 4. N. crithmifolia, the latter P. Lagopus; Andr. Repof. t. 243, have all the leaves doubly pinnatifid.

NOBLEBOROUGH, l. 3, r. 1206.

NOCK, the foremost upper corner of a boom; and of flay fails cut with a square tack.

NOCKAMIXON, l. 2, r. 1327.

NOCTURN, Littering, the divine office of the night, as distinguished from that of the day. The latter consisted of the seven canonical hours, the former of three nocturns, each consisting of several psalms, lections; &c.; and it was heretofore customary to interrupt the sleep three different times for the performance of them.

NOOTH'S Apparatus. See Laboratory.

NORFOLK, col. 2, l. 15, add.—By the parliamentary returns in 1811, this county contained 33 hundreds, 3 boroughs, viz. King's Lynn, Thetford, and Great Yarmouth, and one city, viz. Norwich; 51,774 houses, occupied by 291,999 persons; 138,089 being males, and 153,910 females; of whom 31,454 families are employed in agriculture, and 23,082 in trade and manufactures.

NORFOLK, in America, l. 4, r. 22; l. 6, r. 31,245; l. 8, r. 18,679—5647; l. 4 from bottom, r. 1441.

NORMAN. Add.—Alto, a square and oak, or short carling, fixed through the head of the rudder of East India ships, to prevent the loss of the rudder, in case of its being unhinged. Alto, a short wooden bar with a head, used in one of the holes of the windlass when there is little strain on the cable.

NORRIDGEWOCK, l. 2, add—and county of Somerset: l. 3, r. 880.

NORTH BEAVER. See Beaver.
NOR

North-We] Fort, a hundred of Suffolk county, in the state of Delaware, containing 3203 persons, of whom 382 were slaves in 1810.

North-West Paffe, l. 15, after Labrador coast, add—nor of the Cortecares of Portugal in 1500, nor of the Cartiers and others from France in 1508 and 1534; nor of Gomez, &c. from Spain in 1524; &c.; nor of sir Hugh Willoughby in 1533, of Richard Chancellor and Steven Burrough in 1555 and 1556. 1. 19, such as Edward Fenton in 1577, Arthur Pet and Charles Jenkinson in 1580, sir Humphry Gilbert in 1584, John Davis in 1585, 1586, and 1587, Cornelis Cornelison, Brands Yibrants, and William Barentz of the United Provinces, in 1594, of Barentz in 1599 and 1596, William Adams in 1596, George Weymouth in 1602, James Hall in 1605–6–7, John Knight in 1606, Henry Hudson in 1607–8–9–10, sir Thomas Bat- lion in 1612, James Hall in 1612, Gibbons in 1614, Robert Blyt in 1615, Blyt and William Baffin in 1616, Jens Mank, a Dane, in 1619. 1. 41, and, after the failure of Samuel Hearne in 1760, 1770, Confiantine John Shipps (lord Mulgrave) in 1772, captain Cook, &c. Col. 2, l. 39 add—our limits will not allow us to continue the voyages of captain (now admiral) Lowenorn, lieutenant Egede, and lieutenant Roth, Danes, in 1786 and 1787, nor the travels of Alexander Mackenzie in 1789, nor those of Charles Duncan in 1790 and 1791, nor the discoveries made by the Russians on the northern coast of Siberia during the 18th century, nor the voyages for farther discovery, undertaken in the early part of the 19th century by lieutenant Kotzebue 1815 to 1818, of John Rofs, David Buchan, William Edward Parry, and John Franklin in 1818. Add to the references—Barrow's Chronological History of Voyages into the Arctic Regions, &c. 8vo, London, 1818.

Nux Vomica, Chemical Properties of. MM. Pelletier and Caventou, in analyzing the nux vomica and St. Ignatius's bean, observed a new vegetable alkaline substance, having the following properties.

It is slightly soluble in water, very soluble in alcohol, refines the colour of turnsole after it has been reddened with an acid, does not reddem turmeric, combines with acids which it fatuates, and forms with them crystallizable salts. The discoverers have suggeted the name Vanguin for this substance, in honour of the celebrated chemist Vau-
quelin, who is said to have first discovered the alkaline properties of a substance obtained by him from the daphne alpina.

Nycteriurn, in Botany, a genus entirely artificial, made by Ventenat in Hort. Mdmart. 85, out of such species of Solanum, (see that article,) as have irregular flowers.—Sims in Curt. Mag. 1801.—M. Dunal has very judiciously, as we presume to think, kept Solanum entire.
OIL

OAKHAD, in America, 1. 3, r. 848.

OBSIDIAN. See Mineralogy, Addenda.

OCATAHOOTA, in Geography, a parish of New Orleans, in Louisiana, resembling in its soil and produce Oachitita; which see.

Ed. Ch. Lip articulated with a kind of claw which bears the petals. Anther a moveable deciduous lid. Males of pollen eight.

We know not of how many species this genus is composed. One only occurs in Hort. Kew.

OGHAM, col. 3. l. 35, for Diflfrt. r. Diflfrb, and for bifidktb r. bifidkltb.

OGLETHORPE, l. 3, containing, with its town Lexington, 17,297 inhabitants, of whom the slaves in the county are 38,235, and in the town 1,133.

OHIO, l. 8, add—Bradbury, in his “Travels,” estimates the area of the Ohio state at 38,460 square miles, and its population at 230,760 souls; so that by this statement there was, in 1810, only one inhabitant in one and a half square mile, and allowing 640 acres to the square mile, one inhabitant in every 600 acres. At the close, add—For a later and more correct account of the number of counties and amount of population in this state, see United States. Col. 5. l. 3 from bottom, add—This river derives its waters from an area of 198,464 square miles, four times the extent of England and Wales, the surface of which is supposed to be 49,450 square miles, and comprehended between the parallels of 35 and 43 degrees of latitude.

Ohio, county of Virginia, l. 4, r. 8175 inhabitants, of whom 446 were slaves in 1810; l. 6, r. 3682; l. 7, r. 497. —Add—Alfo, a township of Alleghany county, in Pennsylvania, having 832 inhabitants. —Alfo, a township of Beaver county, in Pennsylvania, having 1124 inhabitants. —Alfo, a township of Ohio, in the county of Clermont, having 1803 inhabitants. —Alfo, a town of Gallia county, in Ohio, having 350 perfons. —Alfo, a township of Knox county, in Indiana territory.

OIL of Caraway, l. 1, for Carua r. Carum.

OPA

Oil Creek. Add—Alfo, a township of Crawford county, in Pennsylvania, having 340 inhabitants.

OLEA, l. 4 from bottom, for Calyx r. Corolla.

OLEFIANT GAS, Chemical Composition of. See Atomic Theory and Carbon.

OLEIC Acid, in Chemistry, obtained by Chevreul from a soap made by digging hog's-lard in potash ley. When this soap is put into water, a portion was deposited in pearl-coloured scales, which was the margoiate of potasb. (See MARGARITE AcID.) Another portion, confuting of the oleate of potash, mixed with some margoiate of potash, remained in solution. These two were then separated, and the oleic acid obtained in a state of purity. Oleic acid when pure is an oily fluid, without taste or smell. But most commonly it has a rancid odour, and a yellow or brown colour, somewhat resembling olive-oil. Its specific gravity is .909. Sometimes it remains liquid at 35°, though other varieties of it congeal at 43°, or even higher. When congealed it crystalizes in needles. It reddens litmus with great energy. It is insoluble in water, but very soluble in alcohol. It combines readily with the alkalies and earths, forming fatis, or rather foaps, none of which poofes very remarkable properties. Dr. Thomson, from Chevreul's ex- periments, estimates the weight of its atom at 360. It may be obtained from mofl other animal fats as well as hog's-lard.

OLEY, in Geography, a township of Berks county, in Pennsylvania, having 1284 inhabitants.

OLIVINE. See OLIVINE, and Mineralogy, Addenda.

O'M, col. 5. l. 31, for researches r. researchers; l. 42, r. monofyllabic; l. 4 from bottom, dele of, and r. one of their. Col. 6. l. 24, r. composed of a, &c.

ONELEG, in geography, a township of Ohio, in Tus- caraw, having 610 inhabitants.

ONDANDO, l. 16, r. 25,987, of whom, in 1810, 50 were slaves.

ONSLOW, l. 3, r. 6669—2299.

ONTARIO, l. 3, number of inhabitants in 1810 was 43,032, of whom 212 were slaves.

OPETHUS, Touraco, in Ornithology, a genus of birds of the order of Pice; the characters of which are, beak short, convex above, rather bent, compressed laterally, and denticulated from the middle to the tip; nostrils covered with short silky feathers; feet simple, with two toes before and two behind. One species of this genus is known, which is a native of Africa, and one of the most beautiful of the birds that are found in that quarter of the globe. It feeds on fruits, is easily tamed, and capable, as it is said, of turning its exterior hinder toe either backwards or forwards. This is the Cuculus Parra of the Linnan fyltem. Shaw.

OPAL. See Mineralogy, Addenda.

OPELOSUS,
OPELOUSAS, in Geography, a county and parish of the territory of Orleans, containing, in 1810, 5048 inhabitants. This territory presents a great variety of soil, or, if we except the sugarcane and orange-tree, the cultivation of most valuable vegetables has succeeded. Cotton, indigo, and tobacco, have been and the former now is the staple commodity of the country; to which we may add, cattle, hides, leather, sheese, beef, and pork.

OPHIDIUM, l. 25; add—See Dr. Broussonet's description of this fish in the Phil. Trans. vol. lxi.

OPIUM, Chemical Properties of. M. Derose in, 1803, published an analysis of opium, in which he announced the existence of a peculiar crystallizable substance to which that drug owes its narcotic properties, whence it was named the Narcotic Principle (which see). Soon afterwards, M. Serttiner published an analysis of the same substance, but the results of the two chemists were so different, as to render both doubtful. This latter chemist, however, purified the subject, and at length succeeded in separating a peculiar substance from opium, which he denominated morphia. It is to this principle that opium owes its narcotic properties; and the narcotic principle of Serttiner, according to Serttiner, is a compound of morphia, and a peculiar acid called the meconic, which opium contains. This latter circumstance, however, has been since called in question by Robiquet.

According to Serttiner, morphia occurs in opium combined with meconic acid. There are different methods of separating morphia from opium. Serttiner effected it by adding acetic acid, and thus forming an impure acetate of morphia. The acetic acid was then separated by ammonia, and the morphia thus obtained purified by means of alcohol. Others, after separating the extraneous matter as much as possible, add at once to the watery solution of opium pure ammonia, to precipitate the morphia, which is to be purified as before.

Morphia thus obtained is crystallized in the form of double four-sided pyramids, whose bases are squares or rectangles, and sometimes of four-sided prisms with trapezoidal bases. It diffuses in eighty-two times its weight of boiling water, and the solution on cooling deposits regular colourless transparent crystals. It is soluble in thirty-six times its weight of boiling alcohol, in forty-two times its weight of cold alcohol, and in eight times its weight of fulphoric ether. All these solutions change the infusion of Brail wood to violet, and the tincture of rhubarb to brown, thus denoting different alkaline properties. They have a bitter and peculiar astringent taste; and the faturated solutions, when rubbed upon the skin, leave a red mark. It acts with great energy on the animal economy. Half a grain being swallowed by a young man of seventeen, produced a flushing in the face and an augmentation of the mucular energy; another half grain being swallowed half an hour afterwards, occasioned a dull pain in the head, giddiness, stupor, and nausea. A third half grain aggravated the symptoms so much, that Serttiner became alarmed, and made his patient swallow a quantity of vinegar. But the symptoms were rather aggravated and continued all night, though they were removed next morning by the use of magnesia.

Morphia readily combines with the different acids, neutralizes them, and thus forms salts of the properties of which the following is a brief summary. The carbonate of morphia crystallizes in short prisms. The acetate of morphia crystallizes, but is very soluble in water. The sulphate of morphia is likewise very soluble. The muriate of morphia assumes a plumose appearance, and is much less soluble than any of the other salts of morphia. The nitrate of morphia crystallizes in prisms.

Dr. Thomton estimates the weight of the atom of morphia, from the experiments of Choulant, at 82.5; but this probably differs considerably from the truth.

Meconic Acid.—This acid may be obtained from the infusion after the morphia has been separated by ammonia as above-mentioned, by adding muriate of barytes as long as any precipitate falls, which is meconium of barytes. To obtain the meconic acid from this salt, M. Choulant triturated it in a mortar with its own weight of glasse boracic acid. This mixture being put into a small glass flask exposed gradually to heat in a sand-bath, the meconic acid sublimed in the flake of fine white fcles or plates.

Meconic acid thus obtained has a strong four taste, which leaves behind it an impression of bitterness. It is readily soluble in water, alcohol, and ether. It redens the greater number of vegetable blues, and changes the solution of iron to a cherry-red colour; when these solutions are heated, the iron is precipitated in the flake of protoxyd. This acid unites with the different bales forming meconiates. The meconiate of potash crystallizes in four-sided tables, and is soluble in twice its weight of water. The meconiate of soda crystallizes in soft prisms, and is soluble in five times its weight of water. It seems to efflorecce. The meconiate of ammonia crystallizes in star-form needles, which when sublimed lose their water of crystallization, and assume the form of flakes. The meconiate of lime crystallizes in prisms, and is soluble in eight times its weight of water. Dr. Thomton estimates the weight of the atoms of this acid, from the experiments of Choulant, at 27.5; but this can only be considered as an approximation.

Such is a brief account of the principles which chemists have lately detected in opium, and which, from the importance of the subject, we have thought proper to infer here.

ORANGE, l. 2, r. 23,247. Col. 2, l. 4. r. 1686; l. 7, r. 229; l. 11, r. 764; l. 13, r. 34,347; l. 14, r. 566; l. 22. The number of inhabitants in 1810 was 226,66, including 48 slaves; l. 27, r. 12,523 inhabitants, of whom 6516 were slaves in 1810.

ORANGEBURG, l. 6, r. 13,229—5564.

ORES, Chemical Analysis of. See Analysis.

ORFA, in Geography, the present name of the ancient Edessa (which see), from which the pachalic of Orfa derives its appellation. This pachalic is almost entirely encircled by the windings of the Euphrates and the river Khabour, and occupies a considerable portion of the most barren part of Meopotamia. In the early ages of the Roman empire, this division of Meopotamia bore the name of Orthoeone. It had subsisted 843 years as an independent kingdom, when it was reduced under the form of a province by Caracalla, who led Abgarus, the last of its kings, in chains
chains to Rome. The city of this name, after the expulsion of the princes of Ophirhoe, became a Roman colony, and was regarded as one of the bulwarks of Mepotamia against the Parthians and Persians. It was the residence of the Coutneys, counts of Edessa, and fell, together with the adjoining territory, into the hands of Zangi and Sallahadeen. In the thirteenth century it was sacked by the Moguls, and by Timur in the 824th year of the Hegira. It is now subject to the grand geignor, and the residence of a pacha of two tails. It is situated in a barren country, 232 miles from Diarbakr, surrounded by a stone-wall, defended by a citadel, and a broad deep ditch. The houses are well built, and the inhabitants, composed of Turks, Arabs, Armenians, Jews, and Nefiorians, amount to about 20,000 souls. The chief ornaments of the city are, a magnificent mosque, consecrated to Abraham, and the cathedral of the Armenians, now fallen to decay. On an adjoining mountain are the ruins of a building, called the palace of Nimrood, and several extraordinary subterraneous apartments, apparently very ancient. McKinnier’s Peria.

ORFORD, L 4, r. 1265.

ORGAN, col. 8, l. 12 from bottom, r. thoroughly repaired.

ORLAND. Add.—It contains 480 inhabitants.

ORLANDO. See Lassus.

ORLEANS, l. 4, r. 23; l. 10, r. 5830; l. ult. and in 1810 of 1248 persons.

ORLEANS, New, l. 3, infert 105 miles, &c.; l. 3, add—or, by the statement of Mr. Darby, N. lat. 28° 57’ W. long. 90° 8’. At the close, add—By the census of 1810, it is stated as comprising the following counties; viz.

Orleans, German Coafl, Acadia, La Fourche, Iberville, Point Couppee, Concordia, Ouachatta, Rapides, Nertchitoches, Opelousas, and Arkanfas, which include a number of parishes, and a population of 75,536 souls. The city and suburbs of New Orleans contained 175,247, and its preceding 73,740: the number of slaves in the former is stated at 5961, in the latter at 4863. Since the census of 1810, there has been a rapid increase of population. Mr. Darby, in his "Description of Louisiana," published in 1816, states that 1800 may be added for the annual increase, so that the present population may be estimated at more than 23,242 persons. No city perhaps on the globe, he says, presents a greater contrast of national manners, language, and complexion, than New Orleans. The proportion between the whites and men of mixed cast or black is nearly equal. Among the whites, the French are hitherto most numerous and wealthy; next to these are the Anglo-Americans; and lastly, the natives of the British islands. Here are but few Spaniards and Portuguese, some Indians, and dispersed individuals of all the nations of Europe. For a further account, see United States.

OSAGES. Add.—See Wasame.

OSMAZONE, in Chemistry. See Blood and Fluids, Animal.

OSRINGTON, l. ult. r. 1341.

OSNABURG, a township of Ohio, in Stark county, having 301 inhabitants.

OSSIPPEE, l. 2, r. Strafford; l. 4. r. 1205. Ossipee Gorge, a township of the same state and county, having 157 persons.

OFAHEITE, l. 6 from the end, add.—From a survey made by captain Wilson in this voyage, he estimates the whole number as not exceeding 16,550 persons; and Turnbull, in his "Voyage round the World," performed from 1820 to 1824, says, that they cannot now be estimated at more than 5000.

OTALGIA, derived from otis, the ear, and akos, pain, signifies the disororder, which, in plain English, is generally called the ear-ache. The pain may be confined to one ear, or affect both these organs with different degrees of severity. It may be either of a burning, shooting, prickking, piercing, throbbing, or gnawing description; or it may consist of an unpleasant sensation of whispering in the ear, of a ringing of bells (see Tinnitus Aurium), a continual humming noise, &c.; the complaint in such instances usually depending upon irritation of the nerves of the organ.

According to the nature and situation of the disease, the pain may affect either the outer part of the ear, the meatus auditorius externus, the cheeks and temples, or the internal parts of the organ, the cavity of the tympanum, the labyrinth, and the auditory nerve itself. Otalgia is divided into several species, which are determined by the nature of their particular cause. Callen mentions five varieties of the disorder; viz. the otalgia inflammatoria, catarrhalis, purulentula, melatística, (a cæa which the modern doctrines in pathology hardly allow us to admit,) and the otalgia a corporibus alienis intrafu.

The inflammatory form of the complaint, when seated in the external parts, is indicated by the common symptoms of inflammation, as heat, swelling, and redness, extending over the lobe of the ear, and the adjoining part of the cheek, attended with a diminution in the diameter of the meatus auditorius, and a consequent dulness in the power of hearing. But when the inflammation is seated in the internal ear, it is accompanied with acute fever, excruciating pain in the deeper part of the organ, exquisite sensibility to the slightest noise, intolerance of sounds, redreelves, sometimes a great deal of delirium, convulsions, &c., coldness of the extremities, and, according to the accounts of several respectable writers, the disease may even have a fatal termination.

The otalgia catarrhalis is preceded by the usual symptoms of a cold, which is very frequently the consequence of an exposure of the head to a current of wind, or of the feet to damp, at a period when they are much heated. This ear-ache is commonly characterized by much milder symptoms than other varieties of the complaint; the swelling of the parts about the ear is not considerable; the nafs discharges a very small quantity of mucus; the patient is troubled with cough and tooth-ache; and not unfrequently an enlargement
enlargement of the neighbouring glands is conjoined with the cutaneous swelling of the face.

The inflammatory otalgia sometimes terminates in the formation of an abscse, which may be superficial, being then sufficiently manifest from the presence of the ordinary symptoms of a cutaneous collection of matter. In this case, the fever and pain abate as soon as the abscess is opened, or has spontaneously burst, and the pus has been discharged. In other examples, the matter forms more deeply in the cavity of the tympanum, and it either makes its way outward by ulceration of the membrana tympani, or, in a more favourable way, through the Eustachian tube. When the abscess occupies a full deeper situation, that is to say, when the matter collects in the labyrinth, a necrosis of the bones often follows, the abscess either discharging itself into the cavity of the tympanum, or becoming diffused under the pericranium.

The otalgia cariosa may originate from a caries, or rather a necrosis of the temporal bone, or, sympathetically, from a caries of one of the teeth. As the communicating branches of the facial nerve are affected, we see why paralysis of the muscles of the face is a frequent concomitant of this species of otalgia.

The abscess from extraneous substanaces in the ear, as malleus of hardened cerumen, infects, the lodgment of any small body, like a pea, &c. may be suspected from the account which the patient will give of his case; but it may be clearly ascertained by examining the state of the meatus auditorius in a strong light, and by the use of a probe. An obstruction or compcrflion of the Eustachian tube may also become a cause of otalgia, as Callisen affects, by confining fluids in the tympanum.

From what has been stated, it is obvious that although otalgia may indeed sometimes be an idiopathic disorder, it is more commonly really symptomatic, in which latter circumstance it necessarily requires for its relief the same means which are proper for the cure of the primary disease, of which it is merely the effect.

In otalgia, the prognosis generally differs according to the seat of the disease, its nature and violence, and the case or difficulty of removing the cause. The following circumstances relative to the prognosis seem to deserve remark.

Young persons usually suffer much more severely from ear-ache than older subjects, and experience more serious degrees of indisposition from the complaint. The internal inflammatory otalgia which produces suppuration affects the trunks of the auditory nerve itself, and discharges its matter within the cranium, may destroy the patient in a few days, if we are to credit the observations of Callisten. A subsidence of the inflammation, as indicated by a remission of the fever and pain, and a speedy evacuation of the matter by the rupture of the abscess, are events which augur a favourable termination of the disorder. When suppuration has occurred in the cavity of the ear, and the abscesses uncomplicated with any curious affection has burst and discharged itself through the meatus auditorius externus, the disorder may prove no more dangerous than any other simple abscesses. For the most part, after every severe attack of otalgia a degree of deafness remains, and this happens with still greater certainty when the case has been attended with suppuration.

The treatment of the various forms of ear-ache must of course depend upon the nature of the causes of the disorder. In general, however, if inflammation exit in the organ, it is to be opposed by the active employment of antiphlogistic remedies, especially topical bleeding with leeches, venesection, gentle purgatives, and anodyne fomentations. When

Vol. XXXIX.

matter is collected, the bursting of the abscesses should be accelerated by emollient applications, or an opening should be made with a lancet. In such circumstances, the ear should be frequently cleansed by means of injections, which, generally speaking, ought to be of a simple unirritating kind. Foreign bodies must be extracted. A morbid sensibility in the nerves of the ear must be lefened by suitable internal and external remedies, the use of opium, anodyne fomentations, the exhibition of conium or framonium, the introduction of a droph of soft cotton into the meatus auditoriius, dip in a mixture of olive-oil and laudanum, or the tinctura camphora, a perpetual blister in the vicinity of the ear, &c.

OTIS, in Geography, a town of Berkshire county, in Maffachuetts, containing 1111 inhabitants.

OTSEGO, l. 6, r. 38,802 inhabitants, of whom 74 are natives.

OUACHITA, a county and parish of the terity of Orleans, which, in 1810, contained 1077 inhabitants. The fpecies of this territory are, cotton, tobacco, lumber, and peltries. Ouachita river is not navigable in autumn, when the waters are low, for any vessels above the fize of canoes.

OXGEN Gas, in Chemistry. According to the most recent determinations, the specific gravity of this gas is 1.111; and 100 cubic inches of it, at a mean temperature and pressure, will weigh 33.888 grains. See Atomic Theory.

OXGENIZED Acids. M. Thenard has recently been enabled to combine oxygen with acids almost to an unlimited extent, chiefly by means of the peroxys of barium. His general method was, to diffuse the peroxys in the acid intended to be oxygenized, and afterwards to separate the barytes by means of sulphuric acid; the oxygen was thus transferred from the peroxys of barium to the acid, and by repeating the operation he found that additional doses could be added. In this way, he oxygenized the nitric, muriatic, phosphoric, and other acids, and by taking advantage of its other properties, the muriatic acid in particular was oxygenized, even so far as to contain 64 atoms of
of oxygen to 1 of muriatic acid. These oxygenized acids combine with the different bases, and neutralize them; but they are by no means permanent, readily giving off their superfluous oxygen upon the application of heat, &c. The oxygenized muriatic acid also is decomposed by the oxyd of silver, chloride of silver is formed, and the oxygen is set at liberty.

By similar methods, M. Thenard has been able to combine additional doses of oxygen with many of the metallic oxys. See Annales de Chimie et Physique, vols. viii. and ix.

PAINT, in Geography, a township of Fayette county, in Ohio, having 534 persons.—Alfo, a township of Highland county, in Ohio, with 775 inhabitants.

PAINTING in Enamel. Of all the various mediums of painting none is so durable as enamel, since time, which destroys all other things, alters neither its beauty nor its brilliancy; and that this great advantage may not be too easily attained, it may be said, also, that no other method of painting unites in itself so many difficulties in the execution.

Enamel painting differs from every other kind of painting, in employing, as a vehicle for the colours, glafs or some vitreous body, to hold the parts together, and fix them to the ground on which they are laid. This being mixed with the colours, and fused or melted by means of heat, becomes fluid; and having incorporated with the colours, joins them together with a hard shining mass. This vitreous body, called flux, is to an enamel picture what oil, gum, or varnish, is in the other modes of painting, as by its means the work acquires its full degree of brilliancy and depth. See Flux.

The quality of the flux is an object of the greatest consideration to the enamel painter; when it is easily fusible, it is called soft; and when it requires a greater degree of heat, it is called hard; these terms are applied as well to the enamel grounds, and the other vitreous substances employed, as to the fluxes. It is essential that the fluxes compounded with the different colours should be of the same degree of hardness, or nearly so; as otherwise tone, from being too soft, would be destroyed by the fire; while others, from having the contrary defect, would not be fixed to the plate, nor acquire their proper colour. It is necessary too, that the plate or enamel ground on which the picture is painted should be harder than the colours; for if they both melted with the same degree of heat, they would necessarily run together, and render the work indistinguishable.

The ground-work of the enamel plate is metal. Gold and copper are those chiefly employed. For small plates, where great neatness and delicacy are necessary, gold is preferable, on account of its not blifling round the edges in the fire, as is the case with copper; for large plates, copper is preferred, not only on account of the difference of expense between it and gold, but because it is found from experience to be better; gold being a much softer metal than copper, the plate, if of any size, is not found to retain its original form, in passing through the fire, so well, when made of it, as when it has copper for its base. The form of the enamel plate is slightly convex; if it were made quite flat, in passing through the fire repeatedly it would become concave. It is on this account that gold is not proper for large plates, being heavier as well as softer than copper; its own weight added to that of the enamel would naturally tend, while in a state of fusion, to sink them in the middle, and render the surface warped and uneven, unless they experienced resistance from the back, which would most probably occasion the defraction of the whole.

When platina was first discovered, it was imagined, from its great difficulty of fusion, that it would be of essential service in the making of enamel plates, but it was found to be useless for that purpose; as, although a plate made of it passed through the fire with its form unaltered in the slightest degree, there was found wanting that union between the enamel and the metal on which it is laid, that is so necessary to ensure its safety, since a slight shock was sufficient to separate them and leave the platina quite free from the enamel. With gold and copper it is quite different, it is hardly possible to free the gold entirely from the enamel, and so it is its adhesion to the copper, that if broken it invariably brings a lamn of the copper with it. The mode of preparing the enamel plate for painting is exactly similar to that for watch and clock dialling (see ENAMELLING), with this exception, that over the enamel is passed a softer body, a flux for the purpose of incorporating with the colours laid on; this flux should agree with every colour used.

The colours used in enamel painting are all prepared from metals, earths, or other mineral bodies, mixed and melted with certain proportions of flux, which, when fused, discover the colours, and fix them to the plate. The colours of the enamel painter are few, and his palette, when compared to that of other artists, is of the most discouraging description, many of them appearing very different before and after passing the fire. This is indeed one of his greatest difficulties, and one which requires the greatest practice to overcome.
overcome. It is true he may lessen it by having by his side a plate on which he has made trial of his colours, and by which he has ascertained their positive colour, and what their various combinations can produce; but it is also necessary that he should have in his mind’s eye the effect which the fire will give, and calculate the depth and brilliancy of his work; without this, he will be ever in danger of using one tint for another, and continually subject himself to disappointment.

It is of the greatest importance that the colours should all agree. This will entirely depend on the properties of the fluxes made use of. It would be very desirable that all the colours should be fluxed with the same materials; but as this cannot be, care should be taken that they are not of discordant principles. This disagreement manifests itself by some of the colours destroying the others when mixed, or by occasioning a bubbling of the tint in the fire, and a roughness on the surface when cold.

Some writers on the subject have considered it necessary, that to paint in enamel two sets of colours should be made use of; one hard, for the beginning of the picture; the other soft, for the later paintings. This idea could only have originated with a person totally unacquainted with the principles of the art, as if it were not more necessary to have the full power of the colours at the finishing than at the beginning of the work: the softness or hardness of the colour depending on the greater or less degree of flux mixed with it, it is evident that in proportion to the quantity of glairy matter mixed, so will the strength of the colour be diminished. It is much better to continue the old mode of using the same colours from first to last, more freely and in greater body in the beginning, and more thinly towards the finish.

It has been said, that the French painters in enamel have discovered the mode of making the colours appear the same before as after palling the fire. If this were really the case, the advantage is not so great as at first sight it seems to be. The disadvantage is not so much the different appearance of the colour, as the want of its proper depth. This is not to be overcome but by the admission of a greater evil. To bear a colour out, an oil must be used, which will not evaporate, and the confluence of this would be, that on its application to the fire corrosion would take place, and the picture must undergo an operation which would much reduce its power before it would be fit for again proceeding with. It is towards the finish of the picture that the enamel painter’s greatest difficulties begin; for such is the nature of his colours, that the parts he touches, when it is not necessary to cover the whole, whether he heightens the lights or deepens the shades, appear the same, and much lighter than the general tint. This is an operation which renders great practice and great caution equally necessary.

The principal colours whose tints are most altered by the fire are the reds, and as they are essential in the painting of the flefs, their alteration necessarily affects the whole; as the same colour which after fire becomes a bright carnmine, is before that operation of a dirty-brownish hue: this inconvenience may be lessened by exposing the colour to a slight heat, by which it will acquire somewhat of its right tint. Some painters for this purpose have mixed a portion of carnime, or some other colour which is destroyed by fire, with their rose-colours or reds, to render them when painted with the same in appearance as after they are fired: this, to say the least of it, is a very fallacious mode of proceeding, and one which an artist’s practice would soon teach him to despise.

The colours used in enamel are few and simple, and from them the different tints should be made by the artist himself, (and not by the colour-maker, as used to be the case,) in the same manner as in any other way of painting. They are, white, yellows, rose-colours or reds, browns, blues, and blacks. The white is prepared from tin; the yellows from silver, antimony, and from some ochres; the rose-colours from gold; the blues from cobalt; and the browns and blacks from iron. A red may be prepared from iron, and a green from copper, but these will not agree with the other colours. A green cobalt has been lately found in some parts of Germany, from which a green may be made, as also one from the chrome; but neither is found to be in any respect better than that which may be made from blue and yellow, and it is therefore unnecessary to encumber the palette with them. No colour should be admitted till, from repeated experiment, it has been found to agree with every other in every possible combination.

The oils employed are essential, and they are such as on application to the fire evaporate with a slight degree of heat; for this purpose, the oil of Ipske lavender is the best. The oil of amber is used to keep the colours moist for the day’s use, as it does not evaporate before exposure to heat. A thick oil of turpentine is likewise used for the purpose of binding the colours together, and making them work more pleasantly; this however must be done with the greatest caution, as if used too freely it will not escape in the fire, and will occasion corrosion.

The last process which the enamel picture undergoes is that of palling the fire; this is done after every painting, and is very often necessary; as without it the artist cannot tell the real state of his work. The fire for this purpose is of the same utility to the enamel painter, as a proof of his plate is to the engraver; it fliows him what he has accomplished, and points out to him what remains to be done. The last time of palling through the fire is, as may naturally be supposed, a moment of great anxiety to the artist, as he may, in an infall, witness the destruction of his picture, and see the labour of months rendered unavailing, by the enamel ground opening and shrinking a crack across his work. This accident may sometimes be repaired, but never without great labour. The mode of firing the picture is exactly similar to that used in the making of the clock plates. See Enamelling.

The history of enamel painting is involved in the greatest obscurity; of its antiquity we have ample testimony in the account which Diodorus Siculus gives of the painted walls executed by the command of Semiramis, in her city of Babylon. At this time, enamel painting had attained the highest eminence to which any art can aspire; when it was made the engine of policy, and the instrument of religion; when it was employed to commemorate the heroic deeds of the living, and celebrate the virtues of the dead. How long it retained this elevation we know not, but it is probable it was esteemed while Babylon remained, and, like that majestic city, was overwhelmed with such entire ruin, as fearfully to leave a wreck behind.

The coloured heads which enrobe the mummies, and the painted idols of the Egyptians, prove that this art was not unknown to that extraordinary people; although nothing which exactly deserves the name of painting has descended to us.

To the Greeks it was known, as is evident from their painted vases, which although generally executed in one or two colours, yet furnish some inludes in which, departing from this simplicity, they have displayed a variety of colours with great success.
PAINTING IN ENAMEL.

By the Romans, if this art were not unknown to them, which, considering their intimate knowledge of the acquisitions of the Greeks, is not probable, it was at least unpractised; sculpture with them seems to have superseded painting in the decoration of their vases, the embellishing of their sarcophagi, and other ornamental purposes.

Some ornaments which have reached our time indicate that the Saxons were not unacquainted with the art of enamel; and in the tomb of Edward the Confessor are many specimens of coloured glaft. Other monuments of a subsequent period prove, that the art regularly descended, although with varied success, at different intervals; but in the tomb of Edward III. John of Eltham, and some others of that period in Westminster abbey, are striking instances of the art of enamelling. On the monument of the king, the coats of arms are enamelled in their proper colours on thick plates of copper; and the armour of the warrior is curiously ornamented with an enamelled pattern of blue, white, and gold.

These remarks may be said more properly to relate to the practice of enamelling than to the art of enamel painting, which are only mentioned here to prove that it was never entirely lost sight of; although it was long after that it became enamel painting, as that term is now understood.

In the sixteenth century, ornamental works of considerable dimensions were executed: every one conversant with the arts must be acquainted with the painted dishes called Raffaelle ware, copied from the designs of that immortal painter and his disciple Julio Romano: these are, strictly speaking, legitimate enamel pictures, executed on a ground prepared as it is at present, and differing only in the shape. They are generally painted in two colours.

Enamel painting seems long to have remained in this state, and there are but few examples where a variety of colours was used until the time of Petiot, who died in the latter end of the seventeenth century. He is the first painter in enamel of whom any particular mention is made: he was in this country in the reign of Charles I. His pictures are of a small size, not exceeding two or three inches; they are very highly and beautifully finished, but certainly not deferving the distinguishing commendation bestowed on them by Pilkington; who says, that if they were magnified to the size of life, the pictures of Vandyck would suffer by the comparison. His best pictures were copied from that master, and are of a small size: his portrait of lady Southampton, a whole length after Vandyck, in the duke of Devonshire's collection, the largest picture he ever painted, is certainly not among his best. His works have too much that particoloured appearance, for which enamel painting has by persons of true taste been justly cenasured. The reputation of Petiot was no doubt owing to the novelty of his pursuit, as he has since been much surpassed. His son practised the same art when his father quitted this country, and his pictures are now generally taken for those of his father.

No farther mention is made of enamel painting until the reign of queen Anne, when Boit, who polished very little ability, appeared: he did not practise long in this country. He had the honour, however, of instructing Zincke, who far surpassed not only his master but Petiot. Although his pictures are not so highly finished, his best works have less of that particoloured effect, and consequently more the appearance of nature, than those of his great predececor. Petiot's best works were copied from Vandyck, those of Zincke from Kneller. Meyer, who chiefly painted in water-colours, commenced enamel painting on the decline of Zincke; as he applied but little to this branch of art, he could not be expected greatly to excel: his principal work, the portrait of the marquis of Granby, in the king's collection, though poffessed of considerable ability and sweetness in the execution, has too many of the defects of early enamels, and by no means conveys an idea of the style of the great original from which it is copied, for John Reynolds. The best pictures of Meyer are inferior to those of Zincke. Spencer's pictures, as far as they go, are very beautiful both in colour and execution; but he, as well as all other enamel painters, confined his efforts to a very small scale, and either did not wish or thought it impossible to obtain depth and richness; his pictures, therefore, are little more than beginnings. The other professors of this art, of this period, were Hone, who afterwards became a portrait-painter in oil, Spicer, Burch, and Craft. Craft is only mentioned here to caution future enamel painters against an error into which he fell,—of painting on an enamel ground without the addition of a flux. The flux being hotter than the enamel incorporates more readily with the colours, and gives that melting softness to the tints so peculiar to enamel painting. By omitting this, he deprived himself of one of his greatest advantages; and the consequence is, that instead of great delicacy and finishing, his pictures appear hard, crude, and inharmonious.

Stubbs, an animal painter in oil, a comparative anatimist, and eminent as either, was also a painter in enamel. Unfortunately he took up this branch of art on too confined a principle, considering rather its durability than that excellence which alone can render durability truly estimable. His pictures are painted on plates made of Wedgwood's ware, and he prided himself on being the maker of his colours, which are, however, of the most ordinary kind. Now, although it is desirable that the artist should know how to make his own colours, it is equally certain, that if he can get them made for him, it is much better to do so than to employ his own time in preparing the means, when it should be directed to the accomplishment of the end. Neither the material on which he worked, nor the colours with which he painted, were calculated to bear more than two or three fires, consequently great perfection could not be expected; and although they might tolerably well answer his purpose for the painting of animals, it is certain that his pictures in oil are in every respect superior to those he executed in enamel.

We have now brought enamel painting down to our own time, when such great improvements have been made by the exertions of a living artist, Bone, as to render it an era in the art; that he is living, must be our apology for not entering into a full diffusion of his merits; but it must be said, that by his endeavours, aided by the liberal encouragement of that true lover and magnificent patron of the arts of his country, the Prince Regent, from a mere mechanical labour, enamel painting has become a highly useful branch of a liberal art; no longer confined to things merely ornamental, no longer differing from every other mode of painting, as much in its effect as process, it now assumes the appearance of highly-finished oil-painting, with the advantage of perpetual durability. As enamel painting from its nature must be always copied, the style of the original should be scrupulously observed, as to convey an instantaneous recollection of the painter. In this respect, the works of Bone are pre-eminent; whether the severity of Leonardo, the purity of Raphael, the glow of Titian, or the splendour of Rubens, is enthralled to his pencil, each is alike successfully portrayed. To the admirers of that ornament of our country and of the arts, Reynolds, this must appear in its full force; and it must afford them great pleasure.
pleasure to find, that such close imperishable copies of the rare and justly valued pictures of this great master can thus be transmitted to posterity.

Of the advantages of enamel painting, it would be superfluous to speak, they are so obvious as to occur to the most superficial observer. Its unalterable durability is alone sufficient to counterbalance every disadvantage to which it is subject: to paint for eternity is the peculiar province of the enamel painter. To him the hyperbolical compliment which Pope paid to Jarvis is justly due:—

"Beauty, frail flow'r, which every fen/en fears,
Blooms in his colours for a thousand years."

How often have we mingled pity with our admiration of the fine works of the great masters, colourists in particular, when we have observed the dreadful ravages of time on their pictures. By enamel painting this disadvantage is removed; by means of this art, posterity will become acquainted with the real merits of their predecessors; and those works which must of necessity decay, will be preserved in all their original splendours. How invaluable at present would the portraits of the illustrious characters of Greece and Rome appear! Had enamel painting then been known as it is practiced at present, we should not now have to seek their imperfect remembrances in bulbs and gems.

Thus has this art, sometimes shining forth in full splendour, sometimes nearly merged in obscurity, survived the lapse of ages, and descended to the nineteenth century, whose enlightened policy and liberal patronage will never allow it to be again disregarded; but will employ the talents of the enamel painter in the way in which they can be best employed, by preferring for futurity the portraits of our illustrious ancestors, whose deeds have conferred an honour on their country; and in handing down to posterity the remembrances of our great contemporaries, and in perpetuating the best efforts of native genius. See ENAMELLING.

Painting of Clocks and Watches. See the preceding article, and ENAMELLING.

PALAVER, an African term denoting a court of justice, or a public meeting of any kind.

PALERMO, in Geography, a town of America, in Maine, and county of Lincoln, having 761 inhabitants.

PALLADIUM, in Chemistry. According to the recent determinations of Dr. Thomson, the weight of the atom of this metal is 75, oxygen being 16; though this, perhaps, is not to be depended on, but as an approximation.

PALLADIUM. See MINERALOGY, Addenda.

PALMA, Giacopo, in Biography, called the Younger, to distinguish him from his great uncle, has been styled by Lanzi, "the last painter of the good and the first of the bad epochs of the art of Venice." He was born in 1544, the son of Antonio Palma, an obscure painter, who first taught him the little he knew, and encouraged him to study the works of others, particularly those of Tintoretto and Titian. At the age of fifteen, he obtained the patronage of the duke of Urbino, who sent him to Rome, and maintained him there for eight years, during which time he employed himself in copying the works of M. Angelo, of Raphael, and above all, of Polidoro, and was employed by the pope to adorn one of the rooms of the Vatican.

On his return to Venice he found but little employment, Tintoretto and Paolo Veronese occupying the places of renown, and being engaged in all the public works. Their disadventure with a celebrated architect and sculptor, named Vittoria, furnishd Palma with a patron, who endeavored to lower the esteem of his enemies, used his utmost efforts to establish the rival painter, affixed him with his advice, and found him employment. Their united endeavors failed however of success, and Palma was obliged to contend to hold the third rank in the art till their deaths left him without a rival. He had, in the mean time, painted in competition with them both, and produced very excellent works.

When he was left alone and was much employed, he relaxed from the care and diligence he had formerly used, and his works became flight in execution, so much so that Cefare d'Arpino, remarking upon the lightness of the style in which he painted, observed, that he meant to make some play at Venice, to learn of him to make such admirable sketches. When price and time, however, were left to his own discretion, in which he did not abound, he produced some works worthy of his former fame; such as the altar-piece at the church of S. Cofma and Damiano; the celebrated naval battle of Francesco Bembo, in the public palace; the Saint Apolonia at Cremona, &c. The compositions of the younger Palma are more distinguishing for their copiousness than the judgment with which they are conducted, and his design is more bold than correct. His colouring is more vivid than true, but is deftively admired for his richnefs, lustre, and freshness.

PALMER, in Geography, l. 4, r. 1114.

PALMYRA, a township of Maine, in the county of Somerset, having 117 inhabitants.—Alto, a township of Wayne county, in Pennsylvania, having 336 inhabitants.—Alto, a township of Knox county, in the Indiana territory.

PALOMINO Y VELASCO, Don Antonio, in Biography, a Spanish painter, born in Valencia, in 1633. He studied at Cordova in grammar, philosophy, theology, and jurisprudence; the elements of his art he acquired of Don Juan de Valdes Seal, and to acquaint himself with the styles of the different schools, he went to Madrid in 1678. Here he painted the gallery del Cienzo, and pleaded the king and the minister, and in 1688 he was made painter to the king. He was overwhelmed with commissions, for many of which he made only the designs; but whatever was begun and terminated by himself in fresco, or in oil, poffefes invention, defign, and colour, in the effential, and taste and science in the ornamental parts. His style was certainly more adapted to the demands of the epoch in which he lived, than to those of the preceding one, and probably would not have obtained from Murillo the praise lavished on it by Luca Jordano.

Palomino may be considered as the Vafari of Spain, as copious, as cedulous, and as negligent of dates, too garulous for energy, and too indefinite for the delineation of character, but eminently useful with the emendations of modern and more accurate biographers.

His literary work is divided into three parts, theoretical, practical, and biographical. The two first bear one title, viz. "El mufico Pictorico y efcula optic." The third part, distinguished by that of "El Parnaso Espanol Pintoresco lubreida," &c. Madrid, 1754, though perhaps only intended as an appendix to the two former, is by far the most important and interesting.

PALOU, or PALO, L. 446, add—pachalic of Erzeroum, situated on the edge of a mountain and the banks of the Euphrates; the population amounts to about 8000 souls, Turks, Armenians, and Kurds: the river here is very rapid, and from the bad construction of the bridges made of wood, whole caravans have been swept away before the melting of the snow. The district of Polo is four days' journey in length and two in breadth.

PANDEANS,
PANDEANS, a title given to itinerant companies of Italian musicians, who perform on the Syrinx or Pan's pipes of different pitches with their mouths, and accompany themselves on different instruments with their hands and feet.

The lowest seat of reeds (the septem differentia vocum of Virgil) is called the contra basso, or double-basso; the next fagotto, or bassoon; the third, feptenary, is the tenor or second treble; and the fourth, or highest range of pipes, the first treble: so that in the aggregate there is a complete scale of four octaves, and they never play in lefs than three or four parts. The instruments with which they accompany themselves with their hands are the cymbals, the triangles, the double drum beat at both ends, the mezza luna, a Turkish instrument, and the tambour de basque.

The reeds or pipes are fastened under the chin of the performer, and the lip of the player runs from one to the other with seeming facility, without moving the instrument by manual affinence. (Et sapra calamos uno percurrere tabro, Lucretius.) The music which these people perform is very gay and pleasing. One of the company with whom we conversed told us that they were Milanese peasants and villagers, not allowed to stroll into great cities: which accounts for our never having heard them in their own country, nor any of our friends who have made the tour of Italy, and remained there some years.

The nfe which these ingenious people have made of Pan's pipes, by playing in troops and in different parts, is beating the ancients at their own weapons. The Grecian shepherds of Theocritus, and the Roman of Virgil, contend in dialogue, but never perform in parts.

It will be observed, that some of the performers, particularly the first treble, have more than seven pipes, which enables them to extend the melody beyond the septenary.

PARK, MUNGO, in Biography, a celebrated traveller, was the son of a farmer on the banks of the Yarrow, near the town of Selkirk, in Scotland, and born on the 10th of September 1771. After having received the first rudiments of education in his father's family, he was removed to a grammar-school at Selkirk, where he remained for a considerable number of years, and where he was distinguished by his application and improvement. At this early period, though he was sedate, studious, and thoughtful, he manifested traces of that ardent and adventurous disposition which formed his distinguishing character in future life. Preferring the medical to the ecclesiastical profession, for which he was originally designed, he was bound apprentice, at the age of 15, to Mr. Anderfon, a reputeable surgeon at Selkirk; and after refiding with him for three years, he removed in 1789 to Edinburgh, where he attended the usual medical lectures during three successive sessions. In this situation he distinguished himself among his fellow-students, by ardour and alacrity in the prosecution of his studies, and by particular attention, during his summer vacations, to botanical pursuits, in which he was assisted by his brother-in-law Mr. James Dickfon. Upon his removal to London, this eminent botanist introduced him to Sir Joseph Banks, by whose recommendation he was appointed assistant-surgeon to the Worcester East Indian. In 1792 he failed for Bexcenol, and having availed himself of the opportunities for scientific researches, which this voyage afforded him, the result of his inquiries and observations was communicated, after his return, to the Linnaean Society, and published in the third volume of their Transactions. Some years prior to this period, a society had been formed with a view of promoting discoveries in the interior parts of Africa, of which we have already given a brief account under the article African Association; and several persons had been employed in accomplishing the laudable purposes for which this society was established. Among these, we may reckon Mr. Ledyard and Lucas, major Houghton, and Mr. Hornemann, who fell sacrifice either to the severity of the climate, the fatigue of the service, or the violence of the natives. The Society, though disposed to afford liberal encouragement to any person who was qualified for this undertaking, and who had at the same time resolution sufficient to engage in it, with the prospects which past experience presented to view, found themselves at a loss for a person in every respect fit for this hazardous mission. At this interesting period Mr. Park returned from India, and no person could have been better qualified for such an arduous office. Sir Joseph Banks, the distinguished patron of genius and science, had been his friend, and with him Mr. Park was in habits of frequent and intimate intercourse. Thus circumstanced he offered his services, and they were accepted. Having received his final instructions from the Society, he set sail from Portsmouth on the 22d of May 1795, and on the 21st of June landed at Jillifree, a small town near the mouth of the river Gambia, whence he proceeded to Pifania, where he was hospitably received by Dr. Laidley, to whom he had letters of recommendation. For an account of his progress, see the articles Africa and African Association. Upon his return, he was received with cordial congratulation, both by his friends and the gentlemen of the African Association; and he was allowed to publish an account of his travels for his own benefit. In the mean while, Mr. Bryan Edwards, secretary of the Association, printed and distributed among the subscribers an abstract of the Travels from Mr. Park's papers. To this abstract was annexed an important Memoir by major Rennell, confiding of geographical illustrations of Park's journey; and this, by Mr. R's permission, formed a valuable appendage to the fourth edition of the Travels. In the spring of 1798, government having it in contemplation to obtain a complete survey of New Holland, applied to Mr. Park for this purpose; but the proposed plan was never executed. The remainder of this year was spent by Mr. Park in visiting his friends in Scotland, and arranging the materials of his Travels. Towards the close of this year he returned to London, and devoted the principal part of his time to the correction of his MSS., which he committed to the press in the spring of the year 1799. The work, as soon as it was published, commanded an extensive and rapid sale, both on account of the interesting information which it contained, and the general elegance of its composition. An abstract of Mr. Park's discoveries, with
with regard to the earlier course and magnitude of the Niger, the large and populous towns and villages that occupy the interior parts of Africa, the discriminating character of the negroes, contrasted against that of the Moors, and the civilization of the inhabitants of the interior, beyond the influence of the slave-trade, compared with that of those who are situated near the coast, and a variety of other particulars relating to the soil and productions of the country, and the manners and habits of its inhabitants, has been already given under the articles Africa, Morocco, Niger, &c. so that we need not here enlarge. The curiosity of the public was amply gratified, and the name and work of Mr. Park became singularly popular, though neither the one nor the other altogether escaped censure. The slave-trade was at this time a subject of general reprobation, and attempts were repeatedly renewed for the abolition of it. It was, therefore, natural to imagine, that in a work of this kind, the author would have availed himself of the opportunities which his narrative afforded him, of expressing his decided disapprobation of this nefarious species of commerce; more especially as it was well known to many of Mr. Park's intimate and confidential friends, that in conversation he had frequently declared his abhorrence of slavery and the slave-trade. Nor was it sufficient to allege, as some of his advocates have done, that he considered the abolition of the slave-trade as a measure of state policy; and that it would be improper for him to give an opinion on a subject which was at this time under the deliberation of the legislature. This neutrality on his part, to say the least of it, led persons, who did not know his real sentiments, to reckon him among those who were hostile to the abolition; and his authority was triumphantly appealed to by the advocates of the slave-trade. Whilf he seems to have studiously avoided giving an opinion on the pernicious influence of this trade, he states facts which have been cited and strongly urged in favour of its abolition. In order to account for this kind of incon sistency without impeaching his integrity, we should recollect how he was circumstanced whilst he was preparing and publishing his narrative. "He was then," says a candid biographer, "a young man, inexperienced in literary composition, and in a great measure dependent, as to the prospects of his future life, upon the success of his intended publication. His friend and adviser, Mr. Bryan Edwards," (a West India planter, and a systematic advocate of the slave-trade in the House of Commons,) "was a man of letters and of the world, who held a distinguished place in society, and was besides a leading member of the African Association, to which Park owed every thing, and with which his fate and fortunes were still intimately connected. It is difficult to estimate the degree of authority which a person poising these advantages, and of a strong and decisive character, must necessarily have had over the mind of a young man, in the situation which has now been described. Suggestions coming from such a quarter must have been almost equivalent to commands; and instead of severely animadverting on the extent of Park's compliances, we ought, perhaps, rather to be surprized, that more was not yielded to an influence which must have been nearly unlimited." Mr. Park is known to have regretted that some parts of his publication, relating to the slave-trade, had been misunder-stood, and applied in a sense which it was not intended they should have been. The writer of this sketch of his life knew, from personal intercourse, that he lamented any ful-\fision of his integrity should attach to this part of his pub-\lication; and we can well imagine, that he did not perceive the bias of his mind, or the caucuses that produced it, which were apparent to every one besides himself. Such a bias would naturally result from the assiaince afford d by Mr. Edwards in the composition of Mr. Park's work, and from the influence attending the connection that subsisted between them. How far Mr. Edwards's influence might extend, it is difficult to say; but of this we are certain, that it was not such as to affect the authenticity of the work itself, or the literary reputation of Mr. Park; we regret, however, that in deference to Mr. Edwards's judgment or authority, Mr. Park should admit into his narrative some reflections pertaining to the slave-trade, which should have given occa-\sion for concluding that he was friendly to its continuance, or that he should have omitted any favourable opportunity that occurred for expressing in an explicit manner his real sentiments concerning it. But it is now needless to pursue this kind of discussion. The narration of Mr. Park, written as we have reason to believe by himself, entitled him to respect as an author; but he has other more unequivocal claims to grateful and honourable remembrance, as a person who hazarded much in making geographical discoveries, and who maintained in traversing unknown countries, and in very trying situations, a degree of firmness and self-possession that has seldom or ever been surpassed.

After the publication of his Travels, he returned to Scotland in the summer of 1799; and on the 2d of August in that year, he married a daughter of Mr. Anderson of Sel-kirk, with whom he had served his apprenticeship. In the month of October 1801, he settled at Peebles, with a full purpose of pursing his medical profession; but as he de-\voted much of his time and attention to the poor, the profits of his business were inconsiderable; nor could he forbear wishing for a change of situation that would be more advantageous. His views, however, were directed towards a second African mission. A prospect of this kind was pre-\\nted to him by a letter from Sir Joseph Banks, soon after the signature of the preliminaries of peace with France, in Octo-\ber 1801; but it was not till the autumn of the year 1803, that a specific proposal was made to him for this purpose. Pre-\\viously disposed to accept it, he did not long hesitate in announcing his purpose; and, accordingly he took leave of his friends, and left Scotland in December 1803, confi-\dently expecting that he should soon embark for the coast of Africa. A variety of circumstances occurred which threatened the total failure of the expedition; however, a course of time all difficulties were obviated; the objects and plan of the undertaking were settled to the satisfaction of Mr. Park, and he received a commission from government in January 1805, for conducting and executing it. To himself was granted a brevet commissio of a captain in Africa; and to his friend Mr. Alexander Ander-\\fon a similar commissio of lieutenant; and Mr. Scott was ap-\\pointed to attend him as a draughtman. He was empowered to enroll at Goree any number of the garrison that would be necessary for his purpose, not exceeding 45, with such bounties as would induce them cheerfully to accompany him. From Goree he was directed to proceed up the river Gambia, and thence, crossing over to the Senegal, to march by such routes as he should find most eligible to the banks of the Niger. The great object of his journey was to pur-\\se the course of the river as far as it could be traced; to es-\tablish a communication and intercourse with the different nations on the banks; to obtain all the knowledge in his power respecting them; and to ascertain various points which he had stated in his Memoir. Mr. Park was em-\\powered to draw for any sum which he might want, not ex-ceeding 5000l.

When the preparations for the expedition were completed, Meffrs. Park, Anderson, and Scott, proceeded to Port-

mouth,
PARK.

mouth, and being there joined by four or five artificers from the dock-yards appointed for the service, they set sail on the 28th of January 1805, and on the 28th of March arrived at Goree. On the 27th of April 1805, Mr. Park took his departure from Kayee, a small town on the Gambia, a little below Piania, having previously engaged a Mandingo priest, named Ilacco, who was also a travelling merchant, and much accustomed to long inland journeys to serve as a guide to his caravan. On the 15th of May, he arrived at Madina, the capital of the kingdom of Woolli, and on the 14th he reached Kuffia, on the banks of the Gambia, where the river is about 100 yards broad, and has a regular tide. On the 18th, he crossed the river Nerito, 60 feet broad four feet deep, flowing at the rate of two miles an hour, and with a heat at two o'clock of 94 Fahrenheit, and arrived at Jallacotta, the first town of Tenda, at fun-fet. On the 26th reached Tendico or Tambeco, a village belonging to Jallacotta, lat. 15° 53', half a mile from which is a pretty large town, called Bady. May 21st at eight, halted at Jeningalla, near Buutra or Katabtada. On the 24th, flopped at Mansafara, which consists of three towns, contiguous to each other, and distant from the village of Nutakorra, on the north bank of the Gambia, eight miles due south. Next day entered the Tenda or Samakara wilderments, and halted at Sootectabba, lat. 13° 31' 33'; after leaving this place, crossed the first range of hills, which afforded a beautiful route and prospect. On the 26th reached Bee creek, lat. 13° 52' 43'', W. long. 10° 59', where men and beasts were attacked by an immense number of bees, who seemed for a time to have completely terminated their journey. Arrived at Sibikillin, after travelling four miles, on the 27th; and on the 28th, arrived at Badoo, a small town, consisting of about 400 huts, near which is another town of the same name; but the two towns are distinguished by the names of Sanfanding and Sanfsaha, at each of which custom is demanded of all carriages or caravans, lat. 13° 32'. From Badoo proceeded to Tumacunba, about four miles east of it, and about four miles distant from the river Gambia, south of Badoo: leaving Tumacunba on the 30th, entered the woods, and at dark arrived at Tabba Goo, which was left at day-break the 31st of May, and halted during the heat of the day at a small village, called Mambari. On the 1st of June, arrived at Jufunda, a considerable trading town, containing about 2000 persons, who trade on credit, and are called "Jull," by way of distinction from the Sante, who trade with his own capital. At this place, lat. 13° 32'', they were exorbitantly taxed by Manfa Kuffan, who is reckoned one of the most avaricious chiefs on the road. On the 4th of June, arrived at Banferle, a Mahometan town, whose chief, Fodi Brahima, was one of the most friendly men they met with, lat. 13° 35'. The kingdom of Dentla is famous for its iron; and the flux used for smelting it is the ashes of the bark of the kino-tree. On the 7th of June, in prosecution of their journey, crossed the bed of a stream that runs towards the Falme river, called Sumako, on account of the vast herds of elephants which wash themselves in it during the rains. At noon of the 8th, reached Madina, and halted by the side of the Falme river; in the evening went to Sattadoo, one mile east of the river. On the 10th reached a small town called Shondo at sun-set; here they were alarmed by a tornado, which was the commencement of the rainy season, and extremely pernicious to the attendants on the expedition.

In the vicinity of this town are some gold-mines, which were inspected, and which afforded occasion for witnessing the expeditions mode practised by the female na-
31st, they halted at Sobec, a town, the walled part of which serves as a citadel. On the 2d of August, they halted at Bandalung; and on the 3d, at Bandaloo; and on the 4th reached Kooolkor, a town partly walled, but having the greater part of its huts without the walls. On the 6th, they reached Ganifarra, a small beggarly village. On the 9th, they crossed the Ba Wouli, a very deep river, flowing at the rate of four or five miles per hour. They purfued their route, until on the 13th, thofe of them who furvived reached Koomikoom, where they halted; lat. 13° 16' 29". On the 15th, they reached Doombila, where Mr. Park met with an old friend, Karfa Taura, a worthy negro whom he had known, and whose kindnels he had experienced in his former travels. From Doombila, they proceeded on the 18th to Toniba, and from thence they affended the mountains fouth of it, till having attained the fummit of the ridge which separates the Niger from the remote branches of the Senegal. Mr. Park had the fatisfaction of once more feeing the Niger rolling its immense flood along the plains. But this fatisfaction was accompanied by the mortifying reflection, that three-fourths of the foldiers had died on their march, and that in their weakly state, they had no carpenters to build the boats in which they propofed to prosecute their discoveries. It was, however, a pleafing confideration, that in conducting a party of Europeans, with immense baggage, through an extent of more than 500 miles, he had always been abfe to preferve the moft friendly terms with the natives; and hence he was warranted to infer, that with common prudence, any quantity of merchandise may be transported from the Gambia to the Niger, without danger of being robbed by the natives; and that this journey may be performed in the dry feafon, with a probability of not lofling more than three or at moft four out of fifty. But Mr. Park was unfortunate in undertaking fuch a journey with the prospect of the rainy feafon, and the event proved, that this feafon fell in before his journey to the Niger was more than half completed. The effect produced on the health of the foldiers by a violent rain, preceded and accompanied by tornadoes, on the 18th of June, was almoft infamite; twelve of them at once were dangerously ill, and from this time, the great mortality commenced, which was ultimately fatal to the expedition. When he reached the Niger at Bamkakoo, where the river begins to be navigable, on the 19th of August, there remained out of thirty-four foldiers and four carpenters, who left the Gambia, only six foldiers and one carpenter, and the principal perfons who comphed the expedition, besides Mr. Park himfelf, were three, viz. Mr. Anderson, Mr. Scott, and lieutenant Martyn, who were more or lefs affected by the diffeafe of the climate; the two former very ferioufly, fo that Mr. Scott was left behind at Koomikoom, and died without reaching the Niger. Mr. Park had been ftrongly afected, and it is wonderfule, that the anxiety and fatigue which he muft have experienced did not break down both his fpirits and his strength. Having arrived at the Niger, Mr. Park, and the few companions that remained, embarked in a canoe on the 22d of August, and were borne away by the current at the rate of about five knots per hour. The river is at the point of embarkation an English mile broad, and at the rapids, of which there are three principal ones, it spreads out to nearly twice that breadth. On the 23d, they arrived at Marraboo, where they were joined by three foldiers who came by land. Ifacoo was immediately dispatched to Sego, the capital of Bambara, to negotiate with Manfong, the sovereign, for a free paffage through his dominions, and whilst Mr. Park waited for his return, he was feized with the dyfentery, that threatened the termination of all his projects. But by the aid of medicine and the advantage of a good conftitution, he was soon refored to health. Many difculties and delays occurred in the negociation, which was conducted on the part of Mr. Park with fingular judgment, and addrefs; but at length, after many unfavourable rumours, which kept his mind in a flate of diftreffing fufpenfe, Manfong defeuted a messenger to conduct him towards Sego. Under his eftort, he left Koolkorro (N. lat. 12° 52') on the 13th of September, and enjoyed the beautiful views which his voyage afforded him; "the river," as he fays, "being sometimtes as smooth as a mirror, at other times ruffled with a gentle breeze, but at all times sweeping us along at the rate of fix or seven miles per hour." On the 14th, they departed from Deena, where they had lodged, and arrived at Yaminna, (lat. 13° 15') where they halted on the 15th; and on the 16th reached Samee (lat. 13° 17'). A depufation of Manfong's friends visited Mr. Park, in order to hear from himself a fatement of his views and purpofes in the voyage he was under-taking. His fatement was fatisfactory to the grandees that had executed this commiffion, and Mr. Park was afured of permiffion to pursue his voyage, and of protection from Manfong as far as his power extended. The king and his courtiers were much gratified by the preffents which they received on the occafion. Accordingly, on the 26th of September, Mr. Park proceeded from Samee to Sanfanding which is here. He intended to provide a proper veffel for his further navigation down the Niger; but it was with difficulty that he procured from Manfong and his fon, in return for the preffents he had given them, two decayed canoes, which merely afforded him materials for conftucting with his own hands, and some affifiance from one of the surviving foldiers, a flat-bottomed boat, to which he gave the founding title of His Majesty's Schooner, the Juliba. In the meanwhile, Mr. Park was informed of the death of Mr. Scott, and he had now occafion to lament the losf of his friend Mr. Anderson, who died, after a lingering attack of four months, on the 26th of October. The fenfibility he expreffed on this occafion did honour to his feelings, and yet considering his preffent perilous fSituation, and the dreary and difcouraging prospects which prefented themfelves with regard to the projects of his undertaking, he muft pollfs a very high degree of equanimity, firmness, and felf-poffeffion. On the 16th of November, the Schooner having been completed, and every thing in Mr. Park's power to command being ready for the voyage, he clofes his journal; and in the courfe of the fucceeding days, previous to his embarkation, which was on the 19th, he wrote feveral letters to his friends and kindred in England and Scotland. In these letters, we discover traces of that deliberate and inflexible resolution, without effort or offender, which proved a differing feature of his character. From this period, we have no strictly authentic information concerning Mr. Park, on the progres and termination of his expedition. In the courfe of the year 1806, conjectures and reports agitated the public mind; and the agitation was aggravated, by intelligence communicated by the native traders from the interior of Africa to the British settlements on the coast; whence it was concluded, that Mr. Park and his companions were killed. In confequence of these unfatisfactory and alarming rumours, lieutenant colonel Maxwell, then governor of Senegal, obtained permiffion from government to engage a proper perfon to investigate and afcertain the truth of these rumours.
rumours. Accordingly, he engaged Ifsaco, Mr. Park's guide, to conduct this business. In January 1810, Ifsaco left Senegal, and returned on the 1st of September, 1811, fully confirming the reports of Mr. Park's death. His journal, including another from Amadi Fatouma, the guide who had accompanied Park from Sanfanding down the Niger, was delivered to the governor, and transmitted by him, after having been translated from Arabic to English, to the secretary of state for the colonial department. From Amadi Fatouma's journal we learn, that the conductors of the expedition went from Sanfanding to Silla, where Mr. Park had ended his first voyage; and that from thence, Mr. Park, Martyn, three other white men, three slaves, and Amadi, as guide and interpreter, nine in number, proceeded in a canoe to Jimma; and as they paddled Sibby, or Dibbe, they were attacked by an armed force in three canoes, which they repulsed. Again at Rakbara, or Kabra, they repelled another assault, and in passing Tomboctoo, they refilled another similar attack, escaping by force and by the slaughter of many of the natives. As they advanced, the number of hostile canoes increased, till at length it amounted to 60, and in self-defence they killed a very considerable number of perons; their own number being now reduced by the death of one of the white men to eight. At length having paddled Kasso and Gournon, and having supplied themselves with provisions, they entered the country of Haoufia. The king of the country having received information from the chief of Yaour, a village in this district, that the white men had departed without giving them any presents, sent an army to a village called Bouffa, near the side of the river, which was posted on the top of a rock that traversed the river, in which rock there was a large cleft or opening, that admitted the water to pass in a strong current; and when Mr. Park arrived at this opening and attempted to pass, he was attacked with lances, pikes, arrows, and stones; against which he for some time resolutely defended himself, till at length, overpowered by numbers and fatigue, and unable to keep up the canoe against the current, Mr. Park laid hold of one of the white men and jumped into the water; Mr. Martyn did the same, and they were drowned in the stream in attempting to escape. One slave was left, and they took him and the canoe, and carried them to the king. Amadi, after having been kept in prison for three months, was released; and obtained information from the surviving slave, concerning the manner in which Mr. Park and his companions had died. Nothing was left in the canoe but a ford-belt, of which the king had made a girdle for his horse; and this belt Ifsaco afterwards recovered. Amadi, according to Ifsaco's report, was a good upright man, and delivered the above account to him on oath, nor could he have any interest in deceiving him. From circumstances it is concluded, that Mr. Park died four months after his departure from Sanfanding.

On Mr. Park's disposition and character it is needless to enlarge, after the details of the principal transactions and events of his life given in this article and the article Africa. In private life his conduct was exemplary, as a son, a husband, and a father. As to his person, he was about six feet high, and well proportioned. His whole aspect was interesting, and his corporeal frame robust and active, and fit for great exertion, and for enduring severe hardships. His family consisted of three sons and one daughter, who with their mother survived to lament the loss of him. See the second volume of his Travels, a new edition of which was published in 1816, 2vols. For some other particulars, we refer to the articles Africa, Niger, and Zaïre.

PATMOS, l. 14, add—Such is the account given by Sonnini; but Dr. Clarke (Travels, vol. ii.) informs us, that he visited the library, which is a small oblong chamber, with a vaulted stone roof, and found it to be nearly filled with books of all sizes in a most neglected state; some lying upon the floor, a prey to the damp and worms; others standing confusely on the shelves, which were printed volumes, some of which were well bound, and in good condition; but neither of the superiors of this college was able to read. At the extremity of the chamber he found a heap of Greek MSS., some of which were of the highest antiquity; amongst other specimens of Grecian calligraphy, the author found a copy of the 24 first dialogues of Plato, written upon vellum, in the same exquisite character, which remained in the hands of his friend professor Peron until his death. But it is now, with the other MSS. from Patmos, &c. in the Bodleian library at Oxford.

PEDAL HARP. The machinery of this instrument was invented by M. Simon at Brussis, about the year 1760, and was soon adopted in France. In the eighth volume of the folio Encyclopdia, printed in 1765, it is said, that the "foundations of the pedal harp are more sweet and melodious than those
the centre of oscillation, and the vibrations in both positions will be performed in equal times. As the distance of the centre of oscillation from the point of suspension depends on the figure of the body employed, if the arrangement of its particles be changed, the place of the centre of oscillation will also suffer a change. Suppose then a body to be furnished with a point of suspension, and another point on which it may vibrate, to be fixed as nearly as can be estimated in the centre of oscillation, and in a line with the point of suspension and centre of gravity. If the vibrations in each position should not be equal in equal times, they may be readily made so by shifting a moveable weight, with which the body is to be furnished, in a line between the centres of suspension and oscillation; when the distance between the two points about which the vibrations were performed being measured, the length of a simple pendulum, and the time of its vibration, will at once be known, uninfluenced by any irregularity of density or figure. This principle being adopted for the construction of the pendulum, the next object of importance is to select a mode of suspension equally free from objection. For this purpose a knife-edge was preferred, and the grounds of preference are briefly stated. The pendulum is formed of a bar of plate brass, an inch and a half wide and one-eighth of an inch thick. Through this bar two triangular holes are made, at the distance of 39 inches each from the other, to admit the knife-edges. Four strong knees of hammered brass, of the fame width as the bar, six inches long, and three-quarters of an inch thick, are firmly screwed by pairs to each end of the bar, in such a manner, that when the knife-edges are passed through the triangular apertures, their backs may bear steadily against the perfectly plane surfaces of the brass knees, which are formed as nearly as possible at right angles to the bar, which is cut of such a length, that its ends may be short of the extremities of the knee-pieces about two inches. Two slips of deal 17 inches long, and of the same thickness as the bar, are inserted in the spaces thus left between the knee-pieces, and are firmly secured there by pins and screws. These slips of deal are only half the width of the bar; they are flained black, and in the extremity of each a small whale-bone point is inserted, for the purpose of indicating the extent of the arc of vibration. A cylindrical weight of brass, in diameter three inches and a half, and an inch and a quarter thick, and weighing about 2 lbs. 7 oz., has a rectangular opening in the direction of its diameter, to admit the knife-piece of one end of the pendulum. This weight being passed on the pendulum, is so thoroughly secured there by means of a conical pin fitting an opening made through the weight and knee-pieces, as to render any change of position impossible. A second weight of about seven ounces and a half is made to slide on the bar near the knife-edge at the opposite end; and this weight may be fixed at any distance on the bar by two screws with which it is furnished. A third weight, or slider of four ounces, is moveable along the bar, and is capable of nice adjustment by means of a screw fixed to a clamp, which clamp is included in the weight. This slider is designed to move near the centre of the bar; and it has an opening, through which may be seen divisions, each equal to one-twentieth of an inch, engraved on the bar; and a line is drawn on the edge of the opening to serve as an index for determining the distance of the slider from the middle of the bar. The knife-edges are made of that kind of steel prepared in India, and called wootz. Their form is triangular, and their length an inch and three-quarters. They were ground on a plane tool, so as to ensure their having a perfectly straight edge. They were then carefully finished on a plane green
höne, giving them such an inclination as to make the angle on which the vibrations are performed about 120 degrees.

Before the knife-edges were hardened, each was tapped half-way through, near the extremities, to receive two feathers, which being pasted through the knee-pieces, drew the knife-edges into close contact with them; the surfaces of both having been previously ground together to guard against any flaw which might injure their figure. For the description of the support and other apparatus of this pendulum, illustrated by drawings, and the method of determining the experiments, and certain other observations, our limits require us to refer to the Phil. Trans. for the year 1818, pt. 1.

From his experiments and observations, captain Kater concludes, that the length of the pendulum vibrating seconds in vacuo at the level of the sea, measured at the temperature of 62° of Fahrenheit, appears to be

- By Mr. G. Shuckburgh’s flandard 3013860
- By general Roy’s scale 3013717
- By Bird’s parliamentary flandard 3013842

The latitude of the place of observation being 51° 31’ 8034 north.

PENKIRIDGE. In 1811 this township contained 106 houses, and 293 persons; viz. 438 males, and 485 females.

PENN’S, l. 2, r. 3798. Add—Alto, a township of Northumberland county, having 2072 inhabitants.

PEN’S Neck, l. 2, add—Upper Penn’s Neck contains 1658, and the lower 1163 inhabitants.

PENNSBOROUGH, EAST. Add—-containing 3265 persons.

PENNSBOROUGH, West. Add—It contains 1264 persons.

PENNSYLVANIA, l. 7, add—By the census of 1810, the number of counties is 43; the five following counties having been added; viz. Cambria, Indiana, Clearfield, Jefferson, Tioga, Potter, McKean, and the city and county of Philadelphia being separated. The number of inhabitants is stated to be 810991, including 795 towns. See each county, and United States.

PENOBSCOT, l. 5, r. 1302.

PEORIA, a township of St. Clair, in the Illinois territory, having 93 inhabitants.

PÉPERELL, l. 4, r. 1333.

PEQUANOCK. Add—containing 3853 inhabitants.

PERCHLORIC ACID, in Chemisty. See CHLORINE.

PERGASITE. See MINERALOGY, Addenda.

PERICARDIUM, Liquor of, Chemical Composition of. See Fluids, Animal.

PERTH-AMBOY, l. 11, r. 815 inhabitants.

PERTHSHIRE. In 1811 this thire contained (exclusive of the town) 21894 houses, and 116975 persons; viz. 55177 males, and 61799 females: 8500 families being employed in agriculture, and 9602 in trade, manufactures, or handicraft.

Vol. XXVII.

PERU, in America. Add—Alto, a town of Berkshire county, in Massachussetts, containing 912 persons.—Alto, a township of Bennington county, in Vermont, having 239 inhabitants.

PERUVIAN BANK, Chemical Properties of. See CINCHONA.

PETALITE. See MINERALOGY, Addenda.

PETERSBOROUGH, in America, l. 3, r. 1537.

PETERSBURGH, a town of Huntingdon county, in Pennsylvania, having 194 inhabitants. Col. 2, l. 19, for Albert r. Elbert. At the close, add—It contains, together with the county and Elberton-town, 12356 inhabitants; the flames of the county being 4291, those of the town 225, and those of Elberton 59.

PETERSHAM, l. 6, r. 1450.

PETROLEUM. See MINERALOGY, Addenda.

PHÆNICOPHEUS, MALAOKA, in Ornithology, a genus of birds of the order Picæ: the characters of which are, beak strong and slightly incurved; feet simple, two toes pointing forwards, and two backwards, the outer toe the longest; head naked round the eyes and warted. This genus is readily distinguished from Cutucus by the naked and papillated space that surrounds the eyes, and from Polophius by the structure of the hinder toes; the head is somewhat square, and very thick; the wings rather short, and the tail remarkably long. Shaw.

PHANAGORIA for PHANAGORA.

PHARMACOPEIA EQUINA, a dispensatory adapted to the purposes of veterinary practitioners, and designed more especially to comprehend those drugs and medicines which pertain to the diseases of the horse. Such a pharmacopeia is a desideratum in veterinary science. The drugs and preparations that are chiefly used are described, as far as our limits would allow, under their several titles on the disorders to which they are appropriated. The form under which they are most commonly administered is that of balls, under which many of them are recited, and the general method of preparing them described. Veterinary writers have arranged these balls under several denominations, founded on the medical purposes for which they are administered. Accordingly we have alteratives, purging, diuretics, cordial, astringent, refortificatory, and diaphoretic; for the preparation of which a variety of forms have been given by modern practitioners.

For alteratives balls we have the following instructions:

Mr. J. Lawrence directs flowers of sulphur and cream of tartar, of each ½ oz.; 1 dr. of canella alba in powder, and treacle q.v., half of which ball should be given twice a day on an empty stomach:—or, flowers of sulphur, cream of tartar, gum guaiacum and turmeric, of each 2 drs., and 1 dr. of canella alba, may be made into one or two balls with treacle, and given as above:—or, prepared antimony and gum guaiacum, of each 3 to 4 drs. prepared with treacle, may be given every day:—or, antimonial Ethiops, from 4 to 6 drs. made into a ball with treacle, may be administered every night for a fortnight, and discontinuing it for a week, resumed for another fortnight; which is said to have great effect in the farcy, the mange, and oblitinate dry coughs in horses. Mr. R. Lawrence recommends a ball made of 1 dr. of tartarised antimony, 1 0z. of liquorice-powder, and ½ oz. of Venice turpentine, given
given every other night for four or five nights, for horses affected with greafe. Mr. White directs a composition of 6 oz. of levigated antimony, 8 oz. of flowers of sulphur, mixed with treacle, to be made into 8 balls:—or, 4 oz. of powdered rosin, 3 oz. of nitre, 1 oz. of tartarified antimony, mixed with treacle, and divided into 8 balls:—or, 2 oz. of unwhashed calx of antimony, 2 drs. of calomel, and 4 oz. of powdered aniseeds, mixed with treacle, and divided into 8 dozes:—or, ½ dr. of calomel, 1 dr. of aloe, 2 drs. of Caltife opop, 30 drops of oil of juniper, and ½ oz. of powdered aniseeds, made into a ball with syrup, which serves for one dose, and which Mr. W. calls the "mercurial" alternative. Mr. Taplin recommends levigated antimony, flowers of sulphur, and nitre, of each 3 oz., 10 oz. of Caltife opop, 3 drs. of oil of juniper, formed into a mafs with honey q.f., and divided into 12 balls, and one to be given every morning for three or more weeks, in cases of greafe, after purging with a common ball:—or, milk of sulphur, prepared antimony, cream of tartar, chinarbar of antimony, of each 5 oz., 4 oz. of Ethiop's mineral, and honey q.f., and the mafs divided into 12 balls, one of which should be given every morning, for a month, in the farcy.

Purging balls are prepared, according to the directions of Mr. Taplin, of 1 oz. of fococotane aloe, 2 drs. of rhubarb, jalap, and cream of tartar, of each 1 dr., 2 scrupules of ginger, oil of cloves and oil of aniseed, of each 20 drops, and fyrup of buckthorn q.f. Mr. White orders 5 drs. of fococotane aloe, 2 drs. of prepared natron, 1 dr. of aromatic powder, 10 drops of oil of caraway, with fyrup q.f.:—or, 7 drs. of fococotane aloe, ½ oz. of Caltife opop, 1 dr. of ginger, and 10 drops of oil of caraway, with fyrup q.f. — or, 1 oz. of fococotane aloe, 2 drs. of prepared natron, 1 dr. of aromatic powder, 10 drops of oil of aniseeds, and fyrup q.f. Mr. White affirms us, that the second of his compositions is generally sufficient for strong horses, and that he has never had occasion for a more active purge than the laft. Mr. Ryding directs 6 drs. of Barbadoes aloe, 1 scruple of ginger, and soft-fop fop q.f.:—or, ½ oz. of Barbadoes aloe, 1 dr. of calomel, and miuelage of gun arabic q.f. The ffirf he calls a mild purging ball, and the latter the mercurial purging ball. Mr. J. Lawrence directs 2 or 3 balls to be made of the following ingredients:—wax, from 12 to 14 drs. of fococotane aloe, from 1 to 2 oz. of cream of tartar, a tea-spoonfull of powdered ginger, a table-spoonfull of olive-oil, and fyrup of buckthorn or treacle, q.f. Mr. R. Lawrence, for the fame purpofe, orders 9 drs. of Barbadoes aloe, and 1 dr. of ginger, to be formed into a ball with fyrup or treacle.

Diuretic balls are prepared by Mr. R. Lawrence of ¼ oz. of Venice turpentine, 2 drs. of tartarified antimony, and 1 oz. of liquorice-powder, with treacle. By Mr. White, they are made to contain of 4 oz. of Caltife opop, and powdered rosin and nitre, of each 2 oz., ½ oz. of oil of juniper, linseed-powder, and fyrup q.f. This mafs for strong horses is divided into 6 balls, but for weak ones into 8:—or, the fame balls may be prepared of 4 oz. of Caltife opop, 2 oz. of Venice turpentine, and powdered aniseeds, and treacle, q.f. to 28 to form 6 balls:—or, balls from 1 to ¼ oz. of each prepared, according to Mr. Ryding's directions, of yellow rosin, Caltife opop, and Venice turpentine, of each 1 lb. diffolved slowly over the fire and formed into a mafs. These balls, he fays, are excellent diuretics, and may be given in grifes, fwellled legs, greafe, or in difeafes of the eye, &c.

Cordial balls are prepared by the fame of 2 oz. of grains of paradise, finely powdered, ginger and canella afo, of each ½ oz., aniseeds and caraway-seeds, of each 1½ oz., 2 oz. of liquorice-powder, and honey q.f.; to be given occasionally. By Mr. White, these balls are prepared by making a mafs with treacle of cammin-feeds, aniseeds, caraway-seeds, of each 4 oz., and 2 oz. of ginger; and they are given in the quantity of about 2 oz.:—or, they may be made of aniseeds, caraway-seeds, moift fennel-feeds, or liquorice-powder, of each 4 oz., ginger and cuffia, of each ½ oz., made into a mafs with honey, and given in a dofe of about 2 oz.

Astringent balls are prepared by Mr. Taplin's directions of 6 drs. of diafocodium, gum arabic, prepared chalk, and Armenian bote, of each ½ oz., 1 dr. of ginger, 40 drops of oil of aniseed, with fyrup q.f.; they are given in cafes of laxness or fcooring, and repeated every 6, 8, or 12 hours, as the cafe may require. For this purpofe balls may be prepared of rhubarb, and compound powder of gum tragacanth, of each ½ oz., columbo and ginger, of each 1 dr., 15 grs. of opium, 6 drs. of orange-peel, and fyrup of poppies; the ball to be repeated in 12, 18, or 24 hours:—or, 1 oz. of mithridate, Armenian bote, gum arabic, and prepared chalk, of each ¼ oz., 2 drs. of ginger, and fyrup of poppies, may form a ball.

Reforative ball is formed, according to Mr. Ryding, of ¼ lb. of Peruvian bark, 2 oz. of grains of paradife, gigant, and columbo, of each 3 oz., and honey q.f.; the mafs is to be divided into 16 balls, and one to be given every morning in cafes of indigefion or lofs of appetite. Mr. Taplin directs a ball for this purpofe to be made of 4 oz. of Peruvian bote, 2 oz. of mithridite (or diafocodium), canella alba, snake-root, and camomile, of each, in powder, 1 oz., or formed into a mafs with honey q.f., and divided into 6 balls, one to be given night and morning:—or, ½ oz. of Venice treacle, 6 drs. of Peruvian bark, columbo, and camomile, of each 2 drs., 25 drops of oil of caraway, and honey q.f.

Diafoparetic balls are prepared, according to Mr. White's directions, of 1 dr. of opium, 2 drs. of camphor, 3 drs. of tartarified antimony, ¼ oz. of powdered aniseeds, and fyrup q.f.

PHNIS, l. 9, infert—it is at the town of Serpafa that it becomes navigable, and after collecting the freams of the plain of Minerea, it enters the Black sea. It pursues a courfe of 500 miles, 40 of which are navigable for large vessels. At its discharge into the sea, it has a small woody island in the midst of the channel.

PHASMA, in Entomology, a genus of inferfa formed from some of the Limane Mantes, and differing from that genus in having all the legs equally formed for walking, and without the falciform joint that dilinquare the fore-legs in mantes. The characters are, head large, antenne filiform, eyes small, rounded; femmata three, between the eyes; wings four, membranaceous; the upper pair abbreviated, the lower pleated; and feet formed for walking. They feed entirely on vegetable food. The most remarkable is the P. gigas or M. gigas of Linnæus. It is a native of the island of Ambona. Another extraordinary species is the P. dilatatum, decribed in the 4th volume of the Transactions of the Limane Society. Some of this genus, as well as thofe of the antics, have their upper wings refembling the leaves of trees; nature having thus provided for their fecurity against the attacks of birds, and as well as for the more ready attainment of their prey. The female of the P. fucifolium has no under wings.

PHILADELPHIA, l. 6, r. 19; l. 7, r. contained, in 1810, 574,88 inhabitants. Add—Allo, the metropolis of Pennsylvania, and now a distinct county, containing 14 wards, and, by the census of 1810, 53,722 inhabitants.

PHILADELPHIA Stores, l. 3, after city, add—in Allo.

PHIJLIPS
PHILIPSBURG, a town of York county, in Maine, with 1427 inhabitants.

PHILOSTROPHE, l. 23 from the end, r. should not encourage.

PHOCA, l. 4, r. fix (or four, Shaw.)

PHOSPHATE of Copper, in Mineralogy. See Mineralogy, Addenda.

PHOSPHORITE. See Mineralogy, Addenda.

PHOSPHORUS. Phosphoric Acid, Phosphates, &c. in Chemistry. According to the most recent determination of Dr. Thomson, the weight of the atom of phosphorus is 15, that of phosporous acid 25, and that of phosphoric acid 35. A good deal of doubt, however, still hangs over this principle and its compounds. The hypophosphorous acid, discovered by Dulong, and which is formed when phosphuret of barytes is dissolved in water, appears to contain less oxygen than either the phosphorous or phosphoric acid, and was formerly considered as the protoxyd or first compound of phosphorus and oxygen. Dr. T., however, is lately disposed to consider the hypophosphorous acid as a compound of 2 atoms phosphorus + 1 atom oxygen; but this is by no means ascertained. We may also observe, that all the boil analyses of the phosphates shew that the weight of the atom of phosphoric acid lies between 40 and 45.

We may mention here, that Dulong has observed an acid formed during the flow combustion of phosphorus, composed, as he supposes, of 1 atom phosphorous acid + 1 atom phosphoric acid, and which he has named phosphatic acid.

PHYRGIA Minor, l. 6, r. N.W.; l. 26, r. Alexandria-Troas. Col. 3, l. 8, r. Podarces.

PICÉ. At the clofe, add—See Aves, Classification, and Natural History.

PICROLITE. See Mineralogy, Addenda.

PICRÔMEL, in Chemistry. See Bile.

PIGMÉNTS. Add—The refults of Sir Humphry Davy's late experiments on the colours used by the ancients as pigments are as follow. The red colours which they employed he found to be red-lead, vermilion, and iron ochre. The yellows were yellow ochres, in some cafes mixed with chalk, in others with red-lead. The ancients likewise used orpiment and maffeot as yellow paints. The blue was a pounded glafs, composed of soda, silica, lime, and oxyd of copper. Indigo was likewise employed by the ancients, and they coloured blue glafs with cobalt. The greens were compounds containing copper; sometimes the carbonate mixed with chalk; sometimes with blue glafs. In some cafes, they confifted of the green-earth of Verona. Verdigris was likewise used by the ancients. The purple colour found in the baths of Titus, was an animal or vegetable matter combined with alumina. The blacks were charcoal; the brown ochres; the whites chalk or clay. White-lead was likewise known to the ancient painters.

PILKINGTON, l. 1, after Lancashire, add—in the hundred of Salford, and parish of Redwick, containing 7353 persons, occupying 1196 houses, of whom 123 are employed in trade and manufactures, and 166 in agriculture.

PILLORY. This kind of punishment is now abolished in England.

PITCH-STONE. See Mineralogy, Addenda.

PITT, in America, l. 2, add—of whom 3389 were slaves in 1810.

PITTSTOWN. Add, at the clofe—containing 694 persons.

PITTSYLVANIA, l. 2, add—of whom 6312 were slaves.
POINTE, in Geography, a township of Northumberland county, in Pennsylvania, having 431 perfons.

POINTE COUPÉ, a county and parish of New Orleans, containing 4539 perfons.

POIRET, See PIKNIOPHILS.

POISON, col. 3 l. 15 from bottom, for versus r. 

POLAND, col. 9 l. 31, add—From a statistical account of Poland, published at Warsaw, it appears, that this kingdom in its present state contains 1291 square miles, of which 15 is a degree), 481 towns, 22,604 villages, and a population of 2,732,324 perfons, of whom 219,244 are Jews.

POLAND, in America, col. 2 l. 2, r. 850. Add—Also, a township of the county of Tribull, in Ohio, with 827 inhabitants.

POLARIETY of Light. See Light.

POLARIZATION, in Optics, a term which has been lately applied to that change which takes place in the direction of rays that pass through certain crystals, and which derives this appellation from its analogy to magnetic phenomena. It was first suggested by the modifications of light discovered by M. Malus (see Light), and has since been investigated with equal ingenuity and diligence by Dr. Brewster. For his numerous communications on this subject to the Royal Society, he was honoured with the Copley medal.

POLASKI, in Geography, a county, containing 2091 inhabitants, of whom 228 were slaves in 1810.

POLE, l. 2, add—the fourth son of the countess of Salisbury, who was cruelly and unjustly beheaded by Henry VIII., and whose father, the duke of Florence, was drowned in a butt of maltmuy by his son.

POLOPHILUS, COUCAL, in Ornithology, a genus of birds of the order Picz; the characters of which are, beak strong, slightly incurved, nostrils straight, elongated, feet simple, two toes pointing forward, the exterior being the largest, two toes turning backwards, the interior furnished with a very long claw. The COUCALs, so first called by Vaillant, form a most beautiful tribe of birds. They reside in woods, feed on insects and fruits, and construct their nests in trees, and (contrary to the manners of cuckoos) bring up their young, from which circumstance their generic name is derived. Shaw.

POLYPHERUS, in Ichthyology, a genus of the abdominal fishes; the character of which is, that the gill-membrane is fingle-rayed, and the dorsal fins numerous. This fish constitutes a new and remarkable genus, and was first scientifically described by M. E. Geoffroy, who considered it as forming a connecting link between the oolous and the carinogamous fishes. It seems most nearly allied to the genus Etox. It is known to the Egyptians by the name of Bichir, among whom it is rare, and fupposed in general to inhabit the depths of the Nile among the soft mud. Its flesh is white and favoury, though it is hardly possible to open its skin with a knife, and therefore the fish is firly boiled, and its skin drawn off whole. Its specific name is "Niloticus," and it is characterized as the green P., with the abdomen spotted with black. Shaw.

PONT-VOLANT, dele the description, and let the reference remain.

PORANTHERA, in Botany, from ποράς, a pore, and ανθον, an anther.—Rudge Tr. of Linn. Soc. v. 10. 302.

EFF. Ch. Involucrum of eight leaves, many-flowered. Perianth none. Petals five. Anthers of four cells, each with a terminal orifice. Capsules three, with numerous seeds.

P. ericifolia. Rudge as above, t. 22. f. 2.—Native of New South Wales. Dr. White. A very extraordinary little plant. Stem branched, round, leavy, four to six inches high. Leaves scattered, numerous, linear, glaucous. Flowers corymbose, minute, white. The dried specimens resembile some small kind of Loftidium.

PORCELAIN, col. 24 l. 31, r. in a melted state.

PORCELAIN Jasper. See Mineralogy, Addenda.

PORCELIA, in Botany, so called by Ruiz and Pavon, in honour of Don Antonio Porcel, a Spaniard, whom they celebrate, in the highest terms, as a promoter of botanical pursuits. Our reasons for adopting this name, in preference to any other, for the genus we are about to describe, may be found under the article Asiminux. That we presume to confer the Asiminaux and Porceliaux of De Candolle as one and the same genus, may require a still further apology, and we shall presently give it, as far as we are able.—"Ruiz et Pavon Fl. Peruv. v. 1. 144. Prodr. 84. to 16. Dunal Anonac. 85," De Cand. Syll. v. 1. 482. "Perf. Syst. v. 2. 98." Purba 478. (Asim. ; Adans. Fam. v. 2. 367. Dunal Anonac. 81. De Cand. Syll. v. 1. 478. Orchidisparum; Mich. Boc. Amer. v. 1. 329. Anonace spec. Linn. Juff. Gen. Willd. Ait. &c.—Clas and order, Polyandria Polygynea. Nat. Ord. Contrauan. Linn. Anona, Juff. Anonaceae, De Cand.

Gen. Ch. Col. Perianth inferior, of one leaf, in three deep, equal, ovate, concave, permanent segments. Cor. Petals fix, unequal, in two rows, sefifile, ovate-oblong, spreading, coriaceous; the three innermost either larger or smaller than the rest. Stam. Filaments scarcely any; anthers very numerous, nearly sefifile on the convex receptacle, oblong, curving at each side. Pet. Germens from three to fix, ovate-oblong, sefifile; styles none; stigmas obtuse. Pet. Berries as many as the germens, sefifile, crowned, ovate or nearly cylindrical, more or less succulent, of one cell. Seeds numerous, elliptic-oblong, ranged transversely in a single or double row, inserted into the inner margin.

A shrubby or arboreous genus, with oblong, undivided, deciduous leaves, and axillary, nearly solitary flowers, either sefifile or filiiform, in some infumata excided before the foliage. All the species are natives of the cooler parts of America. The able professor De Candolle separates Asiminaux of Adanson from Porceliaux of the Fl. Peruvi., the latter having its three inner petals rather the large, the fruit more cylindrical and coriaceous, the seeds in a double row. In Asiminaux the three outer petals are much the largest, and the fruit more oval. But the seeds are likewise in a double row in one species at least of this genus, the tribola, as De Candolle, on the authority of Ehret, admits; and the comparative size of the inner and outer petals, different in different species of Asiminaux, can hardly be much relied on, nor is this admitted by De Candolle among his most efficient characters. p. 465. The more or less cylindrical or ovate form of the fruit will not, surely, be inlined on; nor can that of the original Porcelia differ essentially in substance from the others, being like them succulent and edible.

1. P. nitidifolia. Shining-leaved Porcelia. Fl. Peruvi. v. 1. 144. De Cand. n. 1.—Leaves ovato-lanceolate, pointed, smooth on both sides. Flower-flanks aggregate. Inner petals rather the large.—Native of moun-
tainous woods in Peru. A tall and very handomene tree, forty eills in height, with greyish, rugged, minutely dotted branches. Leaves alternate, on short stalks, oblong-lanceolate, rounded at the base, entire, veiny on both sides, shining above. Stalks axillary, several together, drooping, thickened upwards, each bearing on one or more yellowish-white flowers, about an inch in diameter. Berries cylindrical, tumid, rather coriaceous, but juicy and eatable, each marked externally with a longitudinal seam. Seeds oblong-kidney-shaped, compressed, in two rows. The leaves afford a yellow dye.

2. P. parviflora. Small-flowered Porcelain. Pursh n. 2. (Aimina parviflora; De Cand. Syst. v. i. 478. "Dunal Anonac. 82. t. 9." Orchidocarpum parviflorum; Mich. Boreol.-Amer. v. i. 320.)—Leaves obovate-egg-shaped, pointed, clothed with rusty down beneath, as well as the young branches. Flowers sessile. Outer petals long, scarcely twice the length of the calyx.—In shady woods, near rivers and lakes, from Virginia to Georgia, flowering in April and May. A low shrub, sometimes not above two feet high when in full fruit. Flowers small, dark purple. Pursh. Branches smooth, slightly rugose, when young leafy, and covered with reddish pubescence. Leaves on very short stalks; acute at the base; ribbed and downy beneath; smooth and green above. Flowers nearly or quite sefle, coming before the leaves, from the axillary fears of last year's foliage. Their flalks, if any, as well as the outsides of the calyx and corolla, are clothed with reddish down. Berries two or three from each flower, aggregate, ovate, smooth, rather flaky, "the size of a plum." De Candolle.

3. P. triloba. Three-leaved Porcelain. Pursh n. 1. (Aimina triloba; De Cand. Syst. v. i. 479. "Dunal Anonac. 83." Annona triloba; Linnae. Sp. Pl. 758. Willd. Sp. Pl. v. 2. 1267. Ait. Hort. Kew. v. 3. 335. A. foliis lanceolatis, fructibus triphillis; Mill. 1c. v. 1. 23. t. 35. A. fructu lutefcente heri, fierunt arieti referent; Catacb. Carol. v. i. 85. Trew Ehret t. 1. 7. Duhum. Arb. v. 1. 51. t. 19. 20. Orchidocarpum arctiniunum; Mich. Boreal.-Amer. v. I. 329.)—Leaves elliptic-oblong, pointed at each end, nearly smooth as well as the young branches. Flowers on stalks. Outer petals roundish-ovate, four times the length of the calyx.—On the overflowed banks of rivers, from Pennsylvania to Florida, flowering in March and April. A small tree. Flowers dark brown. Fruit large, eatable. Pursh. This species, introduced by the celebrated Peter Collinson, is still met with in several curious gardens, like thofe of Kew, Sion-house, &c. where it produces in the spring large inodorous flowers, an inch and a half broad, with wrinkled dark-brown petals, as represented by Miller. Catacby and Ehret make them of a pale yellow-green. The leaves, which come forth as the flowers begin to fall, are five or six inches long, and an inch and a half or two inches broad, on short stalks. The flower-flasts are solitary and single-flowered, from one to two inches long, downy with purplish hairs. Berries ovate, yellow, two or three inches long, not perfect in England, eatable, though reported by some persons to have an unpleasant smell. Seeds eight or ten, large, brown, rugose, in a double row, as represented by Ehret. Miller's figure exhibits a single row only. One or two berries only appear to be perfect from each flower.

4. P. pygmaea. Dwarf Porcelain. Pursh n. 3. (Aimina pygmaea; De Cand. Syst. v. i. 479. "Dunal Anonac. 84. t. 10." Orchidocarpum pygmaeum; Mich. Boreol.-Amer. v. i. 335. Annona pygmaea; Bartr. Trav. t. 1. Willd. Sp. Pl. v. 2. 1268.)—Leaves oblong-lanceolate, obtuse; wedge-shaped at the base; smooth, as well as the young branches. Outer petals larger, obovate-oblong, greatly exceeding the calyx.—In the sandy fields of Georgia and Florida. The whole shrub not above a foot high. Flowers the size of Anona fipunamata. Pursh. This is smooth in every part, with very long leaves, and short, single-flowered, solitary, bracteate flower-flasts. Flowers white; their inner petals smallest, elliptical and obtuse. De Candolle. Pursh, by a faulty punctation, makes the inner petals longest.

5. P. grandiflora. Large-flowered Porcelain. Pursh n. 4. (Aimina grandiflora; De Cand. Syst. v. i. 480. "Dunal Anonac. 84. t. 11." Orchidocarpum grandiflorum; Mich. Boreal.-Amer. v. i. 330. "Anona grandiflora; Bart. Trav. t. 2." A. obovata; Willd. Sp. Pl. v. 2. 1269.)—Leaves obovate-egg-shaped, obtuse; clothed beneath with rusty down, as well as the young branches. Flowers sessile. Outer petals obvate, many times larger than the calyx.—In fandy shady woods, of which there are several kinds, in Georgia and Florida, flowering in May. A small shrub. Flowers very large in proportion, white. Pursh. Older branches smooth, as well as the upper surface of the leaves. Inner petals linear-oblong. Berries smooth, oblong-ovate. De Candolle.

PORTER, in Geography, a small township of the district of Maine, in the county of Oxford, having 292 persons.

PORTLAND, New, a township of Maine, in the county of Somerset, having 421 inhabitants.

PORTSBOROUGH. In 1811, the parth of St. Cuthbert's contained 1958 houes, and 38,673 persons; viz. 16,873 males, and 21,800 females: 210 families being employed in agriculture, and 3342 in trade, manufactures, or handicraft.

PORTSMOUTH, col. 5, 1 oz, for tons r. cwt.

POTASSIUM, Potash, in Chemistry. The most recent determinations make the weight of the atom of potashium to be 35, and that of potash of course to be 60. Potashium, when heated in oxygen gas, combines with a larger quantity of oxygen than exists in potash, and thus forms a compound of a yellow colour. When put into water it effervesces, giving off oxygen gas. Phosphorus, sulphur, and carbon, are acidified when brought in contact with it. Hydrogen, when heated with it, is slowly and without combustion converted into water. It decomposes ammonia, converting it into water and azotic gas.

POTT, Percival, col. 2., 1726, for 1726 r. 1736.

POTZDAM. Add.—Potzdam contains (the military not included) 115,426 souls.

POULTICE, in Farriery, is compounded of various ingredients, according to the purposes of its application. Some of the most approved, founded in modern veterinary science, are the following:—The common poultice consists of ½ peck of bran and water, q. f. boiled for ten minutes, and then thickened with linseed-meal, having the addition of 3 oz. of hog's-lard: or, ½ peck of fine pollard, 2½ lbs. of linseed-meal, and boiling water, q. f. adding 2 oz. of hog's-lard. Fermenting poultice is obtained by boiling a quantity of brewer's wort, and throwing into it as much oatmeal as will thicken it; adding, lastly, a tea-cupful of yeast: this is adapted to putrid ulcers, or mortified parts. Satureine poultice is had by adding to the common poultice 3 drs. or ½ oz. of extract of lead, and mixing them well together: or, 1 oz. of acetate of ceruse, (fugar of lead,) 3 quarts of boiling water, with the addition of bran and linseed-meal, q. f. A suppulsive poultice may be made by stirring a sufficient quantity of common turpentine into fome
some of the common poultice. An anodyne poultice may be prepared in the same way, by adding a sufficient quantity of tincture of opium.

POWATAN, l. i. r. 8073 inhabitants, of whom 5291 were slaves in 1810.

POYANG, l. 2, add—According to a statement in "Ellis's Journal of an Embassy to China," (vol. ii.), this lake is very inferior in extent to the Tung-ch'ing-ho, in Ho-guang, the one being 180 lees, and the other 800 acres; the lake being rather more than one-third of a mile, wide.

POWDER-CHEST. 1. peri. for fixed r. fired.

PRAIRIE, or MEADOW, a term used in North-West America, to denote a tract of land divided of timber. In travelling W. from the Alleghanies, such tracts occur more frequently, and are of greater extent as we approach the Mississippis. When we proceed to the distance of 2 or 300 miles to the west of that river, the whole country is of this description, which continues to the rocky mountains westward, and from the head waters of the Mississippis to the gulf of Mexico, an extent of territory which probably equals in area the whole empire of China.

PREBBLE, in Geography, a county of Ohio, containing 7 townships, and 8304 inhabitants.

PREHNITE. See MINERALOGY, Addenda.

PRICE. See Political Economy.

PRINCE EDWARD, l. 2, after inhabitants, add—of whom 6996 were slaves in 1810.

PRINCE George, l. 3, inferf—for of whom 4486 were slaves in 1810.

PRINCE George, l. 5, inferf—for of whom 9189 were slaves in 1810.

PRINCE William, l. 3, add—for of whom 2220 were slaves in 1810.

PRINCESS Anne, l. 4, inferf—for of whom 3926 were slaves in 1810.

PRINTING, CALICO, is the art of imparting various colours to plain calicoes, in any form, or according to any pattern that may be desired, by means of certain coloured mordants previously applied to the cloth. This art has sometimes been denominated TOPICAL dying, and the various branches of it are calculated to attune those who may have the opportunity of witnessing the different processes, without being acquainted with the nature of chemical mordants, and their several uses in the arts.

The art of calico-printing is of great antiquity. Homer speaks of the variegated cloths of Sidon, as having a very splendid appearance; and Pliny describes the Egyptians as accustomed to prepare parti-coloured linens, and observes that these colours were produced after a manner corresponding with our method of topical dying. He says the Egyptians began by painting or drawing on white cloths, (doublestifns linen or cotton,) with certain drugs, which in themselves possessed no colour, but had the property of attracting or absorbing colouring matters. After which, these cloths were immersed in a heated dying liquor; and though they were colourless before, and though this dying liquor was of one uniform colour, yet when the cloths were taken out of it soon after, they were found to be wonderfully tinged of different colours, according to the different natures of the several drugs, which had been applied to their different parts; and these colours, so wonderfully produced from a tincture of only one colour, could not afterwards be discharge by washing; and he considers it as admirable, that the dyeing liquor, which, if cloths of different colours had been put into it, would have confounded them all, should thus produce, and permanently fix several colours, being itself only of one colour. Play, lib. xxxv. cap. 2. vol. XXXIX.

This account contains so plain a description of one of the branches of calico-printing, that no one who is conversant with the present practices can entertain any doubt but that the ancient Egyptians were acquainted with many of the principles of this very curious art. Our readers, who are desirous of further investigating this interesting subject, will find abundant and satisfactory information by consulting the following works: viz. Pliny's "Natural History," the 26th volume of "Recueil des Lettres Edifiantes, &c." Strabo, lib. xv.; Delaval's "Experimental Inquiry into the Cause of Change of Colours, in opaque and coloured Bodies," Berthollet's "Elements of the Art of Dyeing," vol. i. p. 10; Beckman's "History of Inventions," in vol. 8vo.; Mr. Parkes's "Chemical Essays," vol. ii. p. 67, &c.; and Dr. Bancroft "On Permanent Colours." In the above works, abundant testimonies will be found to shew that printed calicoes were not unknown to the ancients; and we have good reason also to suppose that the colours which they imparted to their cloths possessed a considerable degree of permanency, as we know that iron and alum were both employed by them as mordants. It is likewise well known that several ancient nations were acquainted with fodia, madder, tin, the juice of the buccinum, cochineal (or an insect similar to it), the celebrated Tyrian purple, and other materials, sufficient in the whole to enable them to give a great variety of colours and tints to their several productions.

Our object, however, in this communication, is to give a succinct account of the art of calico-printing as it is conducted at present, and we do not know that we can do better than to copy the greater part of the detail which has been given by Mr. Parkes in his "Essay on Calico-Printing," in the second volume of his "Chemical Essays," and which he has very politely allowed us to make use of in any way we think proper.

From this essay it appears, that calico-printing, as an art, is but of modern date in this country, though it has been practised in India, and other parts of the East, from time immemorial. From various accounts it appears, that formerly in India the cotton cloths when brought from the weavers, partly bleached, were worn next to the skin by the dyer and by all his family, during the space of eight or ten days, after which they underwent several macerations in water, with goat's dung, and were afterwards submitted to frequent washings, and at frequent dryings in the rays of an intense fun-shine. Afterwards they were soaked for a time in the mixture of the alriment fruit of the yellow myrobalans, and of curdled buffalo's milk. When thoroughly impregnated therewith, they were fuzed, dried by exposure to the sun, and then, by pressure and friction, they were made smooth enough for being drawn upon by the pencil with the different mordants.

The first of these mordants was an iron liquor, made by dissolving iron in a mixture of four palm-wine and of water in which rice had been boiled. This liquor was applied to the figures or spots intended to become black, and afterwards the aluminous mordant was applied, commonly by children, with the pencil, to the parts intended to be made red. The pieces were then exposed to the hottest fun-shine, that the parts to which the mordants had been applied might be dried as much as possible; and then they were thoroughly soaked in pits of water, to cleanse them from the superfluous mordants, as well as from the buffalo's milk, &c.; and lastly, they were dyed in water, with certain roots answeringly nearly in their effects to those of madder.

It was in this way the manufacture of printed cottons...

4 H
was conducted by the Indians in former times. The following is an account of the modern Indian practice, in one particular branch of their manufacture, which Mr. Parkes says he procured from a gentleman who had spent some time in India, and who had taken pains to inquire into their manipulations.

This process relates to the method of printing the fine cotton chintz counterpanes, which the natives call pallam-poor, and which are manufactured at Madras. These are woven in one piece, from two to four yards square, and are printed, or rather painted, with various designs, and in various colours. Their method is to draw a pattern first on sheets of paper sewn together, of the size of the intended pallam-poors; and then to prick out the same in the paper with a sharp instrument. This done, the paper pattern is smoothly fixed upon the cloth, which is previously dampened, and a small mullin bag containing some kind of black powder is rubbed over the whole, in order to pass a part of the powder through the pin-holes, and completely mark out the pattern.

The pattern being thus sketched upon the cloth, the paper is removed; and when the outline of the various figures is drawn with a pencil, the piece is considered to be ready for receiving the colours. One is then laid on with a brush made with a tough root of a particular kind of tree, or with the husk of the cocoa-nut; and when this is dry, the piece of cotton is given to a woman to wear, or to use in the family, till it be very much dirtied; in order that it might necessarily undergo a thorough washing, which is thought requisite to prove the goodness and permanency of the colour. Another colour is then laid on in the same manner, and the piece is again submitted to the same trial of wearing and washing. The Asiatics may not be aware of it; but doubtless the long exposure to the air in these cases is the important point, as it is well known that the atmosphere is a prime agent in rendering many colours permanent, which, under a different treatment, would be heavy and fugitive. This is repeated for every colour that is employed; and when any of these colours is found to be deteriorated by this treatment, it is printed afresh; and so are all the rest, till the workman is satisfied that all the colours are actually permanent.

This tedious process is adopted, however, only when the manufacturer means to warrant the article; but in all cases, even in those pieces which will not bear washing, the colours are laid on by a brush, as before mentioned.

Whether they are all sublimate colours which are thus applied, or whether they use any species of mordants in their fall work, we are unquestioned, as the artificers of India observe great secrecy, and are extremely jealous on this subject.

Such are the facts which we have been able to collect respecting the progress of calico-printing from the earliest ages; and also of the present state of the art among the Asiatics. The more difficult part now remains, viz. to give a brief detail of the most important processes of our own artificers. This, however, we shall endeavour to do with the utmost plainness, and shall not fail to suggest any improvement that may have occurred to us during our inquiries respecting this very intereting and varied branch of manufacture.

We have not been able to ascertain when calico-printing was introduced into this country, though there are various reasons for believing that it is an art, among us at least, but of modern date.

As the whole of this ingenious business, as it is now conducted, depends upon the proper application of a few compounds called mordants, it will be necessary, in the first place, to explain their nature and use. In doing this, one or two preliminary remarks will afford us.

The colouring substances chiefly employed in this art are divided into two classes, viz. sublimate and adjutine. A sublimate colour is one which is capable of itself of producing a permanent dye on wool or woollen cloth; such is the juice of the buccinum, used by the ancients for producing the imperial purple; such are also the woad and indigo employed by the moderns for producing a permanent blue; and we may add the metallic solutions, particularly those of iron, cobalt, gold, platinas, and silver, which give various colours, according to the processes by which they are prepared.

It has been proposed to employ this valuable permanent colour for pencilling on fine muslins. In time of peace it might readily be procured in sufficient quantities, and would prove an important addition to the resources of the British calico-printer.

Dr. Bancroft tells us, that the first mention of indigo, as known in England, is in the Act of the 23rd of Queen Elizabeth, chap. 9, where it is called Anck, or Blue Ind. Bancroft on Permanent Colours, p. 138.

By adjutine colours are meant all those which are incapable of giving permanent dyes without the aid of certain intermedia, which form as it were a bond of union between them and the substances intended to be dyed.

These intermedia are what are known by the term mordants, and are used for this purpose in very considerable quantities by the calico-printer of the present day.

Several expedients of this kind were employed by the ancients to produce fall, or more properly, permanent colours, and this appears from the testimony of Aristotle and Pliny. The chief articles in use at present are, the acet of iron, the acetate of alumine, and the various solutions of tin, all of which should be very carefully and correctly prepared.

We have already given some account of chemical mordants in vol. xxiv. part 1, under the article Mordants; which see.

When piece-goods are designed to be dyed of one uniform adjunctive colour, they are first immersed in a solution of one of these mordants, then hung up to dry, and to afford the oxygen of the atmosphere. When sufficiently exposed to the air, they are wafted or dunged, to remove the superfluous mordant; that is to say, that part of it which is not chemically combined with the cloth; and the goods are then submitted to a bath of that particular kind of colouring matter which is to be imparted to them.

The dung of the cow is used in such large quantities by the calico-printer, that it has become an article of great expense. The proportion that is employed is usually about one bushel to one hundred gallons of water, though frequently a larger proportion would be more effectual. The brightness of the colours, and the purity of the whites, are always dependent upon the quantity of dung employed.

Whenever it is meant that the colour should be partially inflected, the mordant is applied to those particular parts only; so that, when the piece is immersed in the colouring bath, no other place will receive the permanent stain. If a sufficient number of colouring substances should ever be discovered, that have no affinity for anything but the chemical mordants, the busines of calico-printing would be rendered much more easy and simple than it is at present. For though the whole texture of the cloth will be coloured,
PRINTING ON CALICO.

yet having in it self no affinity with the vegetable with which the decoration is impregnated, the whole of the colouring matter will be easily removed by exposure to the air, and the ground of the piece relored to its original whiteness; whereas parts to which the mordant was applied, will retain and fix the colours in a way which will be more fully explained hereafter.

Formerly all calico-printers were bleachers; but in the neighbourhood of London these are separate and distinct trades, and the printer either purchases bleached goods for printing on his own private account, or receives the cloth from his customers in a white state; and, when printed, he returns the identical pieces, and is paid so much per yard, according to the number of colours, for printing them.

In our opinion every printer should bleach his own goods, for it is impolitable always to rely with confidence on the care of those who bleach for hire; and every printer knows that good bleaching is absolutely a necessary preliminary in the production of good printing. Indeed, this is now pretty generally acknowledged in the north of England; for most of the opulent houses in Lancashire and in Scotland, which produce fine work, are bleachers as well as printers.

Oxymuriate of lime is the agent generally employed in bleaching; but it appears to us that some other article might be introduced with advantage. For, as the goods are washed in diluted sulphuric acid when they are taken from the oxymuriate of lime, a sulphate of lime is always formed, which becomes fixed in the fabric, and, acting as a mordant when the pieces come into the madder-copper, occasions an indelible stain, which in very fine goods often impairs their beauty. If oxymuriate of soda were employed, the sulphuric acid would form a soluble salt with the soda, easily removable by washing.

No people have taken more pains to excel in bleaching than the Irish, and their credit is established accordingly. The German linen, we believe, is generally better than theirs; but the Irish has always the preference in foreign markets, owing to their superiority in bleaching and finishing.

A very minute account of the various procéeds in bleaching has been explained given in our 4th vol. part ii. under the article Bleaching; which see.

By whatever means the bleaching is performed, the printer commences his part of the business in the following manner.

The goods are first dressed by fingeing off the whole of the nap which is attached to them. This is effected by the following contrivance:—Ten pieces are generally wired together, and wound upon a roller, from whence they are passed over a hot iron, nearly in the form of half a cylinder, and received upon another roller; from thence they are returned to the iron, which is still kept red, or nearly at a white heat. The use of repeating this process is to remove the nap more effectually than it would be done by passing it only once over.

The next operation is that of steeping, which consists merely in soaking the pieces for twenty-four hours in a vessel of weak alkaline ley, at a temperature of about 100°. These operations of fingeing and steeping are going on at one and the same time, which effectually prevent any accident that might otherwise arise from the effects of the hot iron.

The goods are then boiled or else bowked in a solution of potash (some workmen prefer to have this alkali in a pure caustic state); they are then well cleaned by thorough washing in wash-wheels, or in blocks, to ensure their being entirely divested of the alkali. The intention of this treating them with potash, is to remove any grease or impurity that may be attached to them, which would otherwise endanger the evenness and uniformity of the colours. This process is called slopping.

By some observant calico-printers it has been imagined, that the rendering of the ley caustic is apt to impair the beauty of the cloth; and we doubt not but that this has often been the case. Under the eye of the maller, however, we are sure that it might be employed with advantage and safety.

It may be remarked, that in weaving calicoes the workman generally greases the reeds, in order to make them move easier. Tallow is also employed for dressing the warp, and this has a baneful effect on all goods which are designed for printing. Wherever this grease is in the cloth, it becomes fixed by the operation of fingeing; and if it be not taken out before bleaching, it will not come out afterwards by the usual process of slopping and fouring; for, when the pieces are submitted to a blue vat to be dyed of a uniform self-colour, all those greasy places will be found to have taken the dye in a very imperfect manner. If the calico-manufacturers themselves would make a point of preparing the oeligious matter for the weavers, and would furnish them with nothing but pure vegetable oils, such as those of rape, linseed, &c., it is very likely that these inconveniences would not occur; for the flain from vegetable is not so indelible as that from animal oil. To cleanse such goods, various expedients have been adopted, but we apprehend nothing but a solution of caustic alkali can be depended upon. To prove the effect of any method which may be tried, it is a good way to run the pieces through water, and then to pass them from the water to gradually over a roller, as to give the superintendant an opportunity of examining every inch of the surface; and if any part remains greasy, it will be seen at once, for that part will continue dry, while all the rest of the cloth is wet.

There is another way in which the goodnecess of bleaching might be proved. Let a few of the suspected pieces be run once or twice through a madder-copper, at the temperature of about 180°. This will inevitably mark any part that may be imperfectly bleached; whereas, if the operation has been properly performed, they will come out so little flained, that an intelligent workman, who has been used to a madder-copper, will at once be satisfied that they contain no impurity that can form a permanent mordant.

The next process is one with diluted sulphuric acid. A quantity of soft water having been poured into a leaden vessel, oil of vitriol is gradually added to it, in the proportion of about twenty pounds of oil of vitriol to every hundred gallons of water, which by weight is in the proportion of about one to forty.

When this mixture has been well stirred, it is ready for use. Sometimes it is employed in this state, at others it is heated to 90° or upwards of Fahrenheit, according to the nature of the work to be done, and the goods are immerged in it. They are not suffered to lie in this solution, but are wound by means of a winch over a wooden cylinder, that every part of the cloth may be immersed in the fluid, and exposed alternately to the action of the atmosphere.

This operation is generally continued for about twenty minutes, and is designed to remove any iron-moulds or other flains which the cloth may have acquired. It has also the effect of neutralizing any portion of potash that may have been left in contact with the cloth. The process is called souring.

After this operation it is necessary to wash the goods thoroughly, that no part of the acid may be left in them to injure their texture, and this is best effected by means of the
the waft-wheel. The calicoes are then to be regularly and thoroughly dried, which finishes these preliminary operations, known in the trade by the term preparation; so that those cloths which have passed through these manipulations are said to have undergone a preparation. Besides the uses already mentioned, there is another advantage attending these processes, viz. that the cloth which has undergone this preparation will bleach sooner, the colours will be brighter, and the whites more delicate, than they would have been had they not gone through these previous operations.

The next process is that of calendering. Here the goods are passed through a set of rollers, which gives them a gloss, and the appearance of their having been ironed. They are now fit for printing. For copper-plate printing, or cylinder work, the process of calendering is omitted.

In printing fast colours, the artist usually proceeds in this way: he lays the piece of calico, which has been already smoothed by calendering, upon a strong thick table, which is previously covered with a woollen cloth. He then proceeds to apply one or more mordants, as the cafe may require, for fixing the intended colours. These mordants are applied by means of wooden blocks, with the patterns formed upon them. These blocks were formerly chosen of holly, and the cutting them was a separate branch of the bufinefs, and was called black-cutting. Of late years, however, a considerable improvement has been made in this part of the bufinefs by the introduction of brass or copper; that is, the pattern, instead of being actually cut in the wood, is now formed by means of slender pieces of one of these metals being firmly fixed to the block, fo as to produce the pattern intended. This alteration was occasioned by the pernicious nature of wood, on account of which every printer incurred great and unnecessary expense. The pattern when thus fixed with copper, is not only more lasting, but it has also the advantage of giving greater sharpness and beauty to the impression. When it was customary to use wooden blocks, the patterns were not encaflhed in the wood, but the wood was cut away in such a manner as to leave the pattern in relief. It will be obvious that this must always be the cafe in black-printing.

When the mordant is ready, it is mixed up either with flour-paste, or with a thick aqueous solution of gum arabic, gum fenegal, or gum tragacanth, and is then spread upon a piece of superfine woollen cloth, strained tight upon a hoop. This is placed within another hoop, covered either with sheep-slin or oil-cloth. These hoops are both so broad as to give to each of them the appearance of a tambarine. That which is covered with the woollen cloth is called a fieve, the other a cafe. The fieve within its cafe is now placed in a small tub of gum-water, and is ready for use.

Flour is an article of considerable consumption with the printers for making paste. Some houses buy twenty barrels of American flour at once. Should it be muddy or four from keeping, it is of little consequence for their use; but they are careful to buy none but such as has been made with found wheat, for if unformed it will be of no value for their purposes.

Gum tragacanth is much dearer than the other gums mentioned above; but notwithstanding this, it must be had for some styles of work, as no other will answer for any of those cloths or mordants which are prepared with nitrious acid. A solution of gum fenegal would be coagulated in an infblent by any of those preparations. Of late years, an article called British gum has also been much in use for the same purpose; so much so that the making of it has become a distinct trade. It is merely common pitch pul-

verized, and then calcined till it attunes a cinnamon-brown colour.

When the apparatus is thus prepared, the mordant is applied by a bruth to the surface of the fieve. This is called nering.

It should have been remarked, that when a colourless mordant, like the acetate of alumine, is employed, the workman generally mixes a little of the decoction of Brazil wood, or of any other fugitive dye, with it. This is called-lightening and is for the purpofe of making the pattern more obvious to the workman, that he may fee its progres, and the efficacy of the materials, as he proceeds in printing. The manipulation may be thus described.

Taking the block containing the pattern in one hand, the workman applies it gently to the surface of the fieve, fo that a sufficient quantity of the thickened mordant may adhere to the figures. When the block is thus charged, he applies it to the calico, and gives it a blow with a small mallet, either slightly or otherwise, according to the nature of the pattern.

This alternate application of the block to the fieve and to the calico, is continued till the workman has gone over the whole piece. In this way, several different mordants are sometimes applied to the fame piece of goods. This is chiefly always necessary, when the finished piece is intended to contain a variety of colours, the different colours requiring different mordants to fix them and render them permanent.

The calico is now removed to a room called the fieve, where a certain degree of heat is given to it by means of flues, which go round the room on the infide, near the floor. In this room, it is generally continued for at least twenty-four hours. This is when common red-liquor has alone been printed; but if citric acid or long muriate of tin has been employed, lefts time is sufficient, and for the latter seldom more than half an hour is allowed. The inten-

<insert next sentence here>tion of this is to evaporate the acids used in the preparation of the mordants, and which might otherwise injure the texture, and also to fix the bafe more surely within the fibres of the cloth.

In this operation, an attention to temperature is of the utmost importance. In general the room is kept at about 90°; but an intelligent calico-printer varies this according to the nature of the work under operation. If iron-liquor has been employed in printing the goods, it is an excellent practice to keep them for several days exposed to the atmo-

<insert next sentence here>sphere, after their removal from the fieve, as the blacks, pompadours, olives, and indeed every other colour prepared with that metal, will increase in intensity; the goods will clean better in the dung-vessels, as will be explained hereafter, and the colours will rife higher and brighter when they come into the copper of bark or madder. The iron in an acceous solution is in the state of the black oxyd; but by expofore to the air it acquires a further dofe of oxygen, and the more nearly it is made to approach to the state of the red or peroxyd, the more fit it becomes for a mordant in dyeing. It may be worth an experiment to discover whether the colours containing iron would not be better if they were suffered to be only a very fhort time in the fieve, but were hung up instead for several days, exposed to a current of air at the temperature of the atmo-

<insert next sentence here>sphere; as the iron would thus acquire the oxygen flower, and consequently would be fixed more firmly within the cloth.

When the pieces have been properly fieved, they are passed, by means of a winch, through water at various temperatures, with a little cow-dung mixed in it. This part
PRINTING ON CALICO.

part of the business was formerly conducted in a very uncleanly and negligent way; but of late years some printers have incurred a considerable expense in the construction of their dunging machines, with cocks for hot and cold water attached to them, and thermometers to regulate the temperature. Those erected by Mr. Wright, a very ingenious calico-printer, at Strines, near Dilye, are the most complete of any we have yet seen.

The intention of the dung is to absorb and remove that portion of the mordant which is not actually combined with the cloth, and which otherwise might stain the white or unprinted parts.

We suppose the dung of the cow is serviceable in another way besides that of cleaning, though the printer may not be aware of the nature of its operation. To clean calicases by immersion in a dung-veil, may appear to be a strange phrase; but as this is the technical language of the trade, no other could be employed with propriety. It is acknowledged that madder, cochineal, and other dyes, produce much better colours on woollen than on cotton cloths, owing to the former being of animal, and the latter of vegetable origin. We premise, therefore, that the dung imparts an animal matter to the fibres of the cotton, and that this animal matter acts as an additional mordant, and thus more powerfully attracts the colouring particles of the dye, than the mordants alone would be capable of doing. Berthollet, who analysed the dung of the cow, found in it a substance partaking of the nature of bile.

If a piece of calico, prepared with the extract of alum, be divided into two parts, and the superfusor mordant removed from one of them by cow-dung and water, and from the other by water only, though both fluids were at the same temperature, it will be found, on passing the two portions through a decoction of weld or quercitron bark, that the yellow will be much more intense and bright in that which had been submitted to the action of the cow-dung. This is a satisfactory and decisive experiment.

The process of dunging is an operation that varies in time from five to forty minutes, according to the flax of work. The pieces are then taken to the river or wheel, to be more effectually washed; after this they are passed through tepid water, in order that the workman may be assured that every impurity is removed.

His next care is to provide a copper boiler of pure cold water, in which a sufficient quantity of madder is put, and a fire lighted underneath it. The calicases, printed and rinsed as above, are now put into this boiler, and from the time they are immersed, the workman never ceases to turn the winch, so as to pass every part of the goods repeatedly through the liquor, till the whole acquires a boiling heat. Indeed, this operation is sometimes continued for ten or fifteen minutes after the bath of madder actually boils, when the pieces are taken out and washed.

Madder is one of the most valuable drugs we have, for a variety of purposes in dyeing and calico-printing; as it is the agent by which the blue and most permanent blacks are produced, also the finest purples, and every shade of red from a pale pink to a crimson. But perhaps it may not be generally known that this article improves by age. If a quantity of madder-roots be ground, and then packed tight in a cach, so as to exclude the air, and are kept thus for six months, they will then dye a much better colour, and go much further than they otherwise would have done, had the roots been used as soon as they were ground.

This process, which is called muddering, has the effect of imparting all the requisite colours to the goods, by means of one operation, which may be thus explained. While one mordant precipitates the colouring matter of the madder to a red, another precipitates a different portion of it to a purple, another precipitates it to a black colour, and so of every possible shade, from a lilac to a black, and from a pink to a deep red.

If a portion of weld or bark be added to the madder, every shade from a brown to an orange may be produced; whereas, if weld or bark alone be employed, all colours between a dark olive and a bright lemon can be imparted to the cloth. These changes are all occasioned by the play of chemical affinities, and are due to the improved state of chemical knowledge.

Here it may be worth remarking, that whenever it is of consequence to produce the finest yellows or more delicate lemon colour, it is necessary to dry the pieces in the open air, as the flose would not fail to injure such colours; for flose-drying has always a tendency to convert a yellow to an orange. It is also necessary to be equally careful in the operation of dunging the mordants for these pale yellows, for, should this be done at a higher temperature than 96° or 100°, their beauty will certainly be impaired. There is another advantage in this, viz. by dunging at this low temperature, the dyeing may be completed even at 110° or thereabouts, which will give a much livelier colour than where a higher temperature has been employed.

The mordants generally used in calico-printing are acetas of iron for browns, blacks, lilacs, &c. and acetate of alum for all the different shades of reds and yellows.

Formerly the acetate of iron was made by digesting old iron hoops in four beer, or in very weak vinegar; but of late years it has chiefly been made with the pyroligneous acid, [if wood be submitted to an intense heat, when inclosed in an iron veifel of any kind with a proper aperture to allow the vapour to pass, this vapour on being condensed forms the acid in question, and is now known to be a kind of impure vinegar. The wood in this case is converted into charcoal, of which a great deal is prepared by this process, particularly for the formation of gunpowder,] the oleaginous impurities of which tend, in some cases, to improve the mordant.

Blacks are also produced by the nitrate of iron [nitrate of iron was not applied to calico-printing until within the last fifty years. This discovery formed an important era in the trade, as it afforded the manufacturer the means of varying his dyles of work in a multiplicity of ways and forms, which, till then, were entirely unknown,] and gallic acid; the mixture is called chemical black. This nitrate of iron is made by dissolving metallic iron in a peculiar kind of aquafortis. Common aquafortis will not answer for this purpose; for, though it may dissolve the iron with rapidity, part of the metal is apt very soon to precipitate; which not only weakens the colour, but leaves the remainder so acidulous, that there is always a danger of such a preparation injuring the texture of the cloth.

It is, however, necessary to remark, that the black which is formed by this solution of iron, is produced in a different way from blacks in general; for, when common iron-liquor is used for this purpose, it is first printed on the calico: and when it has been sufficiently oxidized by exposure to the air, the goods are boiled in a decoction of madder, which renders such parts as had been printed with the acetate of iron an intense black. But the black from nitrate of iron and galls is applied at once to the cloth, and is not afterwards raised by dyeing.

The calico-printer by using a black ready formed is thus enabled to mix it with other colours, in cafes where by dyeing alone it could not be produced, as in conjunction with yellows and olives, raised by weld or quercitron bark.
The acetate of alumine is prepared by a mixture of the sulphate of alumine with acetate of lead, both in a state of solution; so that, on the theory of double decomposition, sulphate of lead is formed, which precipitates, while the acetate of alumine remains in solution.

Since the demand for this article has been increased on account of the extension of the printing trade, it has been prepared from the pyroligneous acid by means of lime and alum. The following is the method:

The pyroligneous acid is first passed through a full, to dilute it of a portion of the tar which is always dissolved in it; it is then saturated with lime or whiting; and lastly, the acetate of lime thus formed is decomposed by a heated solution of sulphate of alumine. The result of this double decomposition is sulphate of lime, which precipitates, and acetate of alumine, which is drawn from the sediment of the calcareous sulphate, and preferred for use.

And here it may be necessary to caution the manufacturer against a misfortune that may befall him if he be not conversant with the chemical nature of the sublimates he employs.

Magnesian lime-stone abounds in Derbyshire, and in some of the adjacent counties; and should a maker of acetate of alumine employ such lime in his processes, the article which it would produce would in all probability be entirely unfit for the use of the calico-printer. But we must be more explicit.

In employing the common lime in conjunction with alum, a sulphate of lime will be formed, as mentioned above, and this being nearly an insoluble salt, will precipitate. But here, sulphate of magnesia would also be formed, which being a soluble salt, would remain in solution, and increase the specific gravity of the liquor, a circumstance which would be very apt to occasion the deception which we are anxious should be avoided. If magnesian lime-stone be employed, the liquor will appear good by the hydrometer; but, as it will contain more Epson salt than acetate of alumine, it will be unfit for every purpose for which it was intended.

While speaking of acetate of alumine, we cannot avoid remarking that the processes which have just been described for making this mordant, and which is followed invariably by many of the manufacturers in the North, is extremely improper, on account of the lime which is employed in it, be the lime ever so good, as that earth is very prejudicial to every species of red dye. The true way of making it, though more expensive, is that which was originally pointed out by Berthollet, and which consists in decomposing sulphate of alumine by means of faccharum faturni, or acetate of lead.

In reverting to the remaining processes of the print-work, it must be noticed, that when the goods have passed through the weld or madder-copper, they are usually carried to a boiler containing wheat-bran and water, in which they are winched for a considerable time, for the purpose of freeing the white grounds from the stain which they had acquired from the madder or the weld. This process always impairs, in some measure, the intensity of the colours; [branning has also the effect of giving a pink hue to all madder reds. But it is not generally known what a peculiar richnecf may be imparted to madder-colours, by raising them with a mixture of bran and madder; that is, by mixing a portion of bran with the madder in the first instance. Mr. Parkes tells us, that he has sometimes produced colours in this way which whole brilliancy has astonished him. The operation of the bran in producing this effect will be explained hereafter;] but it is a necessary operation, as there is no other mode so convenient for removing the stain which is always given to the white part of a print by the madder, the bark, or the weld, which has been used in dyeing it.

It frequently is the case, however, that goods will not bear to be sufficiently branned to clear the whites entirely by that one operation; [the temperature at which the operation of branning is performed, is very important. If bark yellows are dyed at 100°F, it is customary to brann such goods at 115° or 120°, as it is a principle always to brann at a higher temperature than the goods are dyed at. Madder-work must be brann'd at a boiling heat] such goods, therefore, are partially cleaned in the branning-copper, and are then laid on the grafs for some days, till they become perfectly clean.

But within a few years a new method has been introduced, which consists in immersing the pieces for a certain time in a very weak solution of one of the bleaching salts, such as oxymuriate of potash, soda, or magnesia. [A Scotch house of great consequence had practised this method a considerable time; and in the year 1812, a person visited Lancashire for the purpose of instructing the English printers in the method.] This simple process, which effects in a few minutes what would require more than as many days in grafs-bleaching, is now much practised, and promises very soon to supercede crofting entirely. This is a most important improvement, as some of the large printers formerly required as much land to spread out their goods upon, as would make a farm of a very considerable size.

Besides the kinds of calico-printing already mentioned, there are others which it will be proper to notice in this place. Of these, what is called after-work, is now done in considerable quantities. It is conducted in the following manner:

A certain preparation of copper, mixed either with flour-paste, with gum, or with pipe-clay and gum, is printed on the calico, in any shape or of any pattern that may be desired. [The sulphate, the nitrate, the muriate, and the acetate of copper, have all been employed for preparing the after-paste; but the sulphate is the best for the purpose; unless a very concentrated solution of the four salts were prepared by successively dissolving each of them in pure water.] When this is sufficiently dry, the goods are repeatedly dipped in the blue vat till they have acquired that depth of tint which may be required; and then, when they are washed, and passed through dilute sulphuric acid, those parts which had been printed with the preparation of copper, are found to be a good white; the preparation having effectually refiled the operation of the indigo, [the art of making an indigo-vat confists in forming such a mixture of lime and sulphate of iron as shall most effectually deoxydize the indigo; as indigo has no affinity for cloth in its natural or oxygenized state. Hence, those parts of a piece which are printed with a solution of copper will never be dyed blue in one of those vats; because the deoxydized indigo becomes oxygenated the moment it touches the copper, which parts with its oxygen to the indigo, and occasions it to become insoluble, and consequently incapable of forming a dye. Thus, while sulphate of iron has the power of deoxydizing indigo, sulphate of copper, or any other salt of that metal, is incapable of retaining its oxygen, whenever it comes in contact with that singular substance in a state of deoxydization; and it is a curious instance of the different degrees of intensity by which oxygen is held by the different metals,] though all the other parts of the cloth have received a permanent dye. The various deep blue calickees with white spots or white figures, which are now so common, are generally done in this way; and by a familiar management with infrequent dyeing in madder, weld, or bark,
PRINTING ON CALICO.

bark, figures in red or yellow are exhibited upon a blue ground.

In some particular styles of work, the operation of certain colours is resorted to by means of hopping out with wax; but this is too expensive a method to be adopted often in these times, when it is the object of every manufacturer to finish his prints at the least possible expense. In printing those flk handkerchiefs called Bandanas, a procés called waxing is still followed. It consists in making a preparation of tallow and rosin very liquid by heat, and in printing it in that fluid with a block upon the filk. When such goods are passed through the blue vat, those parts which are covered with the tallow and rosin are preferred from the action of the indigo, and remain white, while all the rest is dyed a fast blue. The method afterwards taken to discharge a part of this blue, and produce yellow, orange, &c. will be mentioned hereafter. Formerly this mode was very generally practised, and wax [in the East Indies wax is still used for preferring the whites in calico-printing] was confused in very large quantities by this procés. [A very singular-looking sub stance was discovered a few years ago near Stockport, which being hawked about from one to another as an undescribed sub stance, created considerable inter est in that neighbourhood. Every body supposing it to be a natural production, specimens of it were sent to a variety of per sons into various parts of the kingdom, for their opinion and analysis, and among others a portion was sent to Mr. Parkes. However, after every one had been bulky engaged in examination and conjecture respecting this unknown substance, it was announced, that some seventy or eighty years before a calico-work had had its spot on the article was found, and that this was nothing more than a large heap of the refuse compound of flour, wax, and gum, above-men tioned.

The reader will perceive that these shafts are employed for the purpose of preferring certain parts of a piece white, and of giving other varieties to those goods in which blue is the predominant colour; but if the ground is to be white, and the piece is only to have one small object [a technical term, belonging to this branch of manufacture] in indigo blue, such as a single sprig, then a different manage ment is necessary, and the colour is imparted by a procés which is called pencil-blue.

Here the indigo is deoxygenized by means of sliver, which is a fulphenuret of arsenic; and formerly, whatever ob jects were done with it were put in by means of a pencil: hence its name, pencil-blue. Pencil-blue is composed of the following ingredients, viz. Ten ounces of indigo finely ground in water; twenty ounces of quick-lime in lumps; the same quantity of potash of commerce, or the impure subcarbonate of this alkali; and ten ounces of orpiment. These proportions require one gallon of water, and the whole is to be thickened with gum tangelo.] See Colour.

Another kind of procés remains to be noticed, called chemical discharge-work. Here the cloth is first dyed of some uniform colour, by means of a mixture of iron liquor, and some one or more of the common vegetable dyeing sub stances; and calicoes thus prepared are laid to be dyed of full-colours. They are then washed and dried; and when properly pressed or calendered, they are fit for receiving any pattern whatever, according to the artist's taste or design.

This is generally effected by means of the mineral acids, which are previously composed for the purpose, by dissolving the iron which is contained in the dye, and which is always used in such quantity as to cover, or at least to diffuse in a great measure, the other colour or colours which had been employed with it, and at the same time to act as a mordant in beautifying and fixing the colours.

Thus a piece treated with a decoction of Brazil-wood, and dyed black by being padded [by the term padding is understood the operation of pasting the pieces from a roller through a trough containing a solution of iron, or any other mordant. Blotching is another term used in calico-printing, and is synonymous with padding] with iron-liquor, if, when dried, it be printed with a peculiar solution of tin, the fur rowing portion of the dye will be dissolved, and the printed part will instantly be converted from a deep black to a brilliant crilmom.

In the same way an olive-coloured calico, dyed in a solution of iron and a decoction of weld, will as quickly be changed to a bright pale yellow; and the various drabs and slates of every shade which have iron in their composition, will undergo as sudden a change by the same treatment; though the colour of the figures produced on them will depend on the materials with which the cloths were originally dyed. Now the deep gold colours, or torgnent buffs, are produced by iron only, namely, by a peculiar preparation of tin, be discharged; and such parts of the cloth as have been treated with this metallic solution will be restored to their pristine white ness.

By similar management, calicoes dyed of a light blue in the indigo-vat, then run through sumach and copperas, and finished in a bath of quercitron bark and alum, may have figures of a bright green imparted to them. Here the green is originally formed by means of the indigo-vat and the bark, though it is enveloped by the iron of the copperas, which overcomes the other colours, till the solution of tin is applied, which removes the iron from those particular parts, and gives a brilliancy to the remaining colours which they would not otherwise have possessed; the tin being a powerful mordant for the bark, by which the yellow of the green is produced.

Again, a good self-colour may be given to calicoes, merely by dyeing them in sumach and copperas, and then running them through an alkaline solution of anatto; and here the figures produced by the application of a colourless solution of tin will be of a bright orange. But it is needless to enumerate more in fluences, as the workman accustomed to a dye-house will have little difficulty in varying these in a thousand ways, when he becomes acquainted with the nature of the solution of tin which he employs.

The whole of this, however, refers to that branch of discharge-work only, where all the purposes are attained by dissolving the iron which makes a part of the colour that is intended to be discharged; whereas, the finer and more expensive work is done in a different way, and by a procés which it will be necessary for us presently to describe.

In the mean time it may be proper to remark, that there is an objection to the particular kind of chemical discharge-work of which we have been speaking, namely, that it is not perfectly fall; that is, the goods produced in this way will not bear such frequent washing, as those which are done by the bath of madder or bark.

It is certainly an object of great national importance to give a permanency to the calico-printing of the country; to this end great improvements have lately been made in the method of grinding madder-roots, by separating the inferior parts, and dividing the whole into two or three different qualities. Thus the printer is enabled to apply the finest, which in this way is made equal to Dutch crop-madder,
PRINTING ON CALICO.

madder, to his best work, and the other is laid by for inferior purposes;] and a great deal of very excellent printing is now done in various parts of the kingdom, especially the best chintz-work and other furniture patterns. But, in what is called fast-work, there is a great variety of qualities, and some of it little devolves the name of permanent.

The mention of permanent colours reminds us of a very valuable green which was invented a few years ago by a Mr. Illet of London, and which devolves to be noticed by us. This colour, which was secured to him by his majesty's letters patent, was produced by printing ground indigo, mixed with a peculiar kind of solution of tin, and in then fastening the indigo within the fibres of the calico by means of that proccee, which is well known to printers by the technical designation of china-blue dipping. [China-blue is produced thus: Indigo ground fine, and then thickened, is printed upon the cloth, and afterwards it is dissolved, and chemically united to the fabric, by alternate immersion in a solution of sulphate of iron and in lime-water. A description of this proccee has already been given very much in detail, in our eleventh volume, part ii., under the article DIPPING, in Calico-Printing.] After this the goods are to be dyed in a copper of bark or weld, which converts the blue to a green, and the whites are to be cleansed by croft-bleaching, &c.

Upon this ingenious proccee, Mr. Parkes has the following observation. "Having," says he, "formed a very high opinion of this invention, I procured several interviews with Mr. Illet, soon after he obtained the patent, and from him was fully informed of the whole proccee. — This I have since repeated for the purpose of verifying the detail in all its branches; and I am satisfied that it is one of the most beautiful and permanent colours that has ever been fixed upon cotton."

There is, however, another mode of producing very beautiful blues which has been much practiced lately, and therefore devolves notice. This consists in printing some solution of iron, and then paffing the goods through a very dilute and neutral solution of prussiate of potash. The prussian blue which is thus formed upon the cloth may be rendered tolerably permanent by a variety of expedients, and this by means of any of the yellow dyes may afterwards be formed to any shade of green or of olive.

In returning from these digressions we must not forget to revert to that other kind of discharge-work which we have engaged to describe, and which we will now attempt as concisely as is consistent with perplicity and correctness.

Here, the agent which is employed is the citric acid, and this is used in various Ilates of concentration according to the purpose to which it is to be applied, and the strength of the ground intended to be discharged. It is chiefly employed for the production of white figures upon self-coloured grounds produced by madder and fundry other dyes. For this intention the acid, in whatever Ilate of concentration it may be, is mixed with either gum or with palse, [when citric acid is used for refil-work, it is always mixed with gum fennegal and pipe-clay. The clay gives it a greater body, and likewise acts mechanically as a refiller.] to a proper consistency for the block, the plate, or the cylinder, and from thence it is transferred to the piece; and wherever it attaches, the mordant, whether iron or alumine, is discharged, and a delicate white arises in its stead. [It should be understood, that the discharge is printed upon the mordants before the goods are dyed. In using citric acid for this purpose, a portion of one of the mineral acids is sometimes mixed with it.]

The acid here referred to is produced from the juice of limes or lemons, and formerly it was not employed by the calico-printer until it was reduced to the utmost point of concentration, and appeared in a crystalline form. Even then, it was not thought sufficiently pure, but was dissolved again, and redisolved and recrystallized, till it became as white and pellucid as any other pure salt in a crystallized state, and was then generally sold for 36s. the pound, at which high price it could only be employed on the best styles of work. Now, however, it is oftener used in the brown, or bistre state of crystallization; and some of the larger printers purchase lime juice, and concentrate it themselves; and in many cafes, they use it largely both for discharge and refill work, without ever crystallizing it at all.

More on this subject may be seen in Mr. Parkes's Essay on Citric Acid, in vol. iii. of the Chemical Essay, page 1—118.

This mention of discharge-work by citric acid, [Mr. Thomson, who has a print-work near Clitheroe, has taken out a patent for discharging the Turkey-red dye by means of the citric and oxymuriatic acids; and the work executed in this way has a very pleasing effect.] reminds us of another species of discharge, which is employed by the printers of Bandana handkerchiefs, and which we are under the promise of noticing before we conclude this memoir.

The agent which these printers employ is the nitrates, and sometimes the nitro-muriatic acid. It is used for the purpose of putting yellow figures upon blue silk handkerchiefs. The following is the proccee which is principally adopted.

Acqua-fortis, or nitro-muriatic acid, of such a strength as is suitable for the kind of blue which is intended to be discharged, is mixed either with gum tragacanth, or with flour, to a proper consistence, and in this form it is printed on the silk, by means of a common block, on which the intended pattern is cut. The consequence of this is, that wherever the acid attaches, there the original colour is discharged, and a yellow dye is produced in its place. The pieces are then tinned, by paffing them over a vessel containing boiling water, which gives brilliancy to the colour and finishes the operation.

If a stronger dye than the usual yellow, or even a deep orange be desired, all that is necessary is to immerse the goods, for a moment, in lime-water, or in a solution of lime and potash; and by varying the proportions of these ingredients a great variety of shades may be produced.

Recollecting, however, that this is a paper professedly on calico-printing, we must not deviate too far from the path we have prescribed; otherwise, there are many proccees in the printing of silks which are curious and interelating, on which we might copiously expatiage. The Bandana handkerchiefs which are printed upon cotton in imitation of India goods, are produced by a very different proccee, and which we have already described under the article Discharging of Colour, in vol. xi. part ii.

Having been speaking of yellows, it may be worth mentioning, that there is a mode of producing yellows on calico which is not very frequently practiced, and yet has a very good effect. The proccee is as follows:

A strong decoction of bark, thickened with gum tragacanth, is to be mixed with a portion of very pure muriate of tin, and this, when printed with the usual management, will produce a colour of great brilliancy and durability. We mention this the rather, because very many pleasing effects may be obtained by this method which cannot be produced in the usual way, by means of the acetate of alumine, and any of the yellow dyes that may be employed with it.

There is one very important advantage which this mode possezes,
PRINTING ON CALICO.

Upon those parts of the calico which still remain white, any of the above mordants may be printed, according to the effect designed to be produced, after which all the preceding managements are to be repeated, except that instead of boiling in a decoction of madder, they are to be immersed for about half an hour, more or less, in a warm decoction of querciton bark, the Quercus nigra of Linneus; a most important dye-wood, introduced by Dr. Bancroft, and which is found to give out a much brighter colour to tepid water, than it does when treated with boiling water, or with water nearly approaching to that temperature.

The effect produced upon these prints by an immersion in a lukewarm decoction of this American bark, will be quite different from that produced by the madder: upon those parts of the cloth where the mordants have been printed which before produced a black, a dark olive only will be apparent, and instead of pompadours will be drabs, and instead of reds we shall have yellows, which will vary in intensity according to the strength of the aluminous mordant.

Again, a further variety may be given to these prints, if the yellow mordant, or acetate of alumine, be applied to any of the colours which have already been dyed with madder; but this must be done before the pieces are immersed in the decoction of bark. This application will convert the reds and pinks into different shades of oranges, and the lilacs into cinnamon colours. By means of these different processes an endless variety may be given to the goods, and a calico-printer of taste will never be at a loss how to produce a pleasing effect, whatever may be the patterns which he has to imprint upon the cloth. This second immersion in the dyeing vessel will, however, give a yellow tinge to the remainder of the whites, but a short exposure on the grafts will obliterate it.

When chintz furniture-prints are designed to have as much variety of colouring as possible, a part of the remaining white is often coloured blue or green, or of any shade between those colours, by a still different process. This is done with what is called pencil-blue, which is a preparation that has already been described. The blue is given by putting in the prepared indigo with a pencil; and the green is produced by pencilling some of the same colour over certain parts of the pattern which has already been dyed yellow. When these colours have been imparted, the printing is said to be finished, and the pieces are hung up to dry for at least twenty-four hours, after which they are rinsed thoroughly in cold water; and when they have been dried with care, they are properly calendered and put up for sale.

Nothing now remains but to notice an improvement which has been made of late years by the introduction of cylinder-printings, and which has the advantage of superior accuracy and neatness, as well as of great expedition.

The machines which effect this are rather complicated and expensive; but they are so contrived that the cylinders on which the patterns are engraved, furnish themselves with colour during their revolutions; are kept clean by a steel knife, or dao as it is called, passing over their surfaces the moment they have charged themselves with the thickened colour; and they have such a pressure given to them, either by means of screws or levers, which can be tightened or slackened at pleasure, that the whole surface can be made to deposit its colouring matter with the greatest certainty and exactness on the cloth, while this rolls over it in succession, from one end of the piece to the other.

These cylinders, which are made of copper, are from eighteen to forty-two inches in length, according to the width of the calico to be printed, and three and a half to five
five inches in diameter; and these maffy rollers have the patterns encahnted upon their surfaces, in the same way as a pattern is cut upon a flat plate of copper, that is intended to be employed in copper-plate printing. As these cylinders are made with plates of copper hammered into a circular form and joined by brazing, great los has sometimes been sustained by the engraving giving way upon the brazed joint. To obviate this, a patent has been lately obtained for boring the copper cylinder from the solid metal in the modern way of boring cannon.

Many of these machines are now contrived so as to carry two of these cylinders, each of which has a trough of colour attached to it, by which means two different colours may be printed on the same calico, at one and the same time.

Mr. Adam Parkin of Manchester has lately invented a machine capable of printing at one time, by means of one cylinder and two surface-rollers, or by two of the former and one of the latter, three different colours.

These machines have not only the excellence of printing more correctly than can possibly be done by means of the block, but the saving of time and labour which they afford is great indeed. A piece of calico which would take a man and a boy three hours to print with one colour, or fix hours to finish with two colours, may by this means be done in three minutes, or three minutes and a half, and then much more completely than could ever have been imagined before the introduction of this invention.

Besides these cylinders there are others which are called surface-machines, which contain cylinders of wood, and which have the pattern formed upon their surfaces in relief, exactly similar to the blocks already described. These are employed in particular styles of work, especially in light ground-work, and for certain kinds of refit and discharge work.

In light work, the white grounds are apt to be foiled by the cylinders; hence surface-machines were contrived, and these are not liable to the same objection. Cylinder-machines are more commonly employed in those styles which are full of colour and leave but little white.

It must be obvious to every one who is acquainted with the subject, what an amazing facility these machines have afforded to the production of printed calicouces; and also what an advantage they give to the British printer in foreign markets.

But we cannot conclude without expressing our fears, that even these facilities may eventually be the means of doing a serious injury to the trade, and of destroying that confidence in the goodness of British prints, which has hitherto been generally felt in every market on the continent, and also in every part of the New World, wherever they have been introduced. We refer to that mode of printing which has lately been adopted, and which consists in precipitating the colouring matter from logwood, and from other fugitive dyes, and in printing these on the cloth, without any mordant or previous preparation whatsoever. Thousands of pieces of this sort have been finished at the low rate of one penny the yard, including every expense of colour, paste, and printing. These articles, it will scarcely be credited, are dried up immediately from the printing-machines, and are shipped abroad, without even being washed off.

To wash off is a technical phrase. It means the foaking and rinsing the pieces in water, in order to dissolve and remove whatever gum or paste had been employed with the colours in printing them.

Such goods, wherever they go, must produce great dissatisfaction; for they will neither endure the rays of the sun nor moisture. The first shower of rain to which they may be exposed, will not fail to wash out the pattern, and reduce them to a worse state than of plain white calicouces.

In the reign of queen Elizabeth, an act was passed to restrain the use of logwood in dyeing, on account of the fugitive nature of its colour; and if this degrading kind of printing be continued, the interference of the legislature will again become necessary, or the foreign trade will, from this cause alone, be entirely lost to the country.

PRINTING, CYLINDER. See the preceding article.

PRINTING ON PORCELAIN. The art of printing, particularly as it applies to books, has, from its incalculable benefits and vast importance, excited at once the profound admiration and gratitude of the world; and this inestimable discovery has been claimed by several individuals, alike anxious for the honour of giving to mankind at large the advantage of a rapid and economical diffusion of delight and instruction. The first idea of types was very probably given by the Roman potter, who were in the habit of stamping their names in raised characters on their vases, &c. The letters on this plan were, in fact, models of the types used by the first printers; and it appears singular that the idea of adapting such models by the medium of ink, to the common purpose of multiplying words and sentences, should not have come into use until about the year 1422.

It will appear, on consideration, still more singular, that after the introduction of engraving on wood and copper, (which was in use at the same time with letter-press printing,) the art of transferring impressions of ornamental designs, from the copper-plate to the surface of porcelain or pottery, was not discovered till about the year 1769.

The Royal Porcelain Works in Worcester, belonging to Messrs. Flight, Barr, and Barr, are the only establishment that claims the honour of inventing this admirable and ingenious process. We can find no mention of this art in the annals of this or any other country prior to this period. It was practiced with great success for many years in the works alluded to; and besides the demand for home consumption, large quantities were exported to Holland. In the year 1788, his present majesty Geo. III., and his royal conrant the queen, with the princes royal, the princes Augusta, and the princes Elizabeth, visited the Worcester Porcelain Works, and particularly noticed this ingenious branch of the art of decoration. The royal party were much gratified by the compliment paid them, in the striking off impressions from two copper-plates with the likenesses of the king and queen, which had previously been engraved by direction of the proprietors, in order to exemplify the nature of the operation. The secret of the printing was, about the year 1781, conveyed from the works at Worcester into the potteries of Staffordshire, and has proved of infinite service in extending this branch of national commerce, and affording employment to the numerous population in that part of the country. The common British blue and white printed earthen-ware is now held in high esteem in foreign countries, from its cleanly and neat appearance, besides its being in general use at home. This art is certainly well confined, as in the present day, to the inferior fabrics, such as earthen-ware, as the material on which the print is made is reasonable, and can be rendered at a price which suits the convenience of the consumer for all common purposes. The method, as invented and adopted by the original proprietors of the Worcester Porcelain Works, is as follows:—The engraved copper-plate having
first been warmed on the iron, is prepared to receive the colour, which, being previously mixed with oils of a proper consistence, is then rubbed into the engraved lines, and the superfluous quantity of colour is carefully cleaned from the surface of the plate. The paper, which is very thin, and manufactured for the purpose, is then laid on the plate, and delivered to the pressman, who places it on a plank covered with warm flannel, and being fixed between two iron cylinders, it is drawn through by turning a wheel, exactly on the plan practiced in taking off copper-plate prints. The paper bearing the clear-coloured impression is now removed from the copper-plate and delivered to the printer, who fixes the piece of porcelain in a vise, to keep it steady; and the printed paper is then rubbed with a wooden tool, covered with flannel, till the impression is completely transferred to the surface of the biscuit, or unglazed porcelain. The operation of rubbing on the impression being completed, the porcelain, with the paper left on the surface, is thrown into a tub of cold water, and in a short time the paper delivers itself, and leaves the print. The ware is now placed out to dry, and is afterwards carried to the kiln, where the impressions are burnt in. It is then dipped in the liquid vitreous substance called the glaze, is burnt a second time, and the colour, which is the oxide of cobalt, (and most generally used,) comes out a neat blue, perfectly secured under the glaze.

An improved method of printing, comparatively of very recent invention, was introduced under the direction of the late Martin Barr, Esq., and is now carried on in the Porcelain Works at Worcester, and is much admired for the excellence of the engravings, and the great beauty of the impressions. On this plan, the printing-press and iron are not necessary, as the engraved plate is charged with a prepared oil by the printer, who cleans the surface of the engraving with the hand; and instead of paper, a bat of glutinous consistence is cut out and laid on the copper-plate, and so ductile as to adapt itself to the form of any vessel intended to be printed; and by the simple preface of a flattened leathern ball with the hand, produces a perfect impression of the subject in oil on the smooth face of the bat. The ware being rubbed dry and clean, the bat is now gently pressed with the leathern ball on the glazed surface of the porcellain, and when removed the impression appears complete, but only in oil. The colour, in form of a powder, is then lightly moved over the oil impression with a piece of carded cotton, and the print completely cleared of all that is superfluous. The porcelain is afterwards carried to the enamellers, who finish the design by adding some decorations in gold; and it is then passed through the enamelling kiln, where the oil is evaporated by the fire, and the colour, which is always a mineral preparation, unites firmly with the glaze, and becomes perfectly durable as the tints laid on with the camel's-hair pencils by the painters. The great advantage of this plan is, that the engraving can be executed much finer for the smooth surface of the glazed porcelain, than for the coarser blue and white prints, (which are laid on the rough unglazed surfaces,) as the glaze is capable of receiving the finest touch the artist can put into his engraved plate. Messrs. Flight, Barr, and Barr, the proprietors of these works, have in consequence introduced beautiful engravings of figures from the antique, besides designs in landscapes, flowers, shells, &c. which reflect no small degree of credit on this branch of the art of printing. Considerable quantities have been exported to the East and West Indies; and where economy is the object of the consumer, this style of decoration suits very well, however deficient in richness of effect and elegance, to the more elaborate production of enamelled designs, executed in these interesting and highly respectable works.

PROFUVIUM, l. 2, for veneeris r. venteris.

PROJECTION of the Sphere, Orthographic. Prob. I. l. 8, for C. and F. G., r. I. C.

PROMEROPS, in Ornithology, a genus of birds of the order Picae; the characters of which are, habit as in the genus Upupa; feet formed for walking; tail lengthened, and in molt species cecamed. Dr. Shaw enumerates and describes the following species: viz. Corvus, or blue P. with black bill and legs; the Upupa indica, or blue promerops of Latham; a native of India: Cafer, or brown P., tufted beneath, with rufsetent breast, and very long tail; the Upupa P. or Cafer P. of Latham, and the Upupa P. or Merops cafer of Linnaeus: a native of Africa, and common about the Cape of Good Hope: Striatus, or brown P. beneath white, with black undulations and very long tail; the Upupa papuensis, or New Guinea brown P. of Latham; native of New Guinea, inhabiting large woods: Superbus, or black P. with violet and green glofs, filiated golden shining scapular feathers, and very long tail; the Upupa superba and great P. of Latham; a magnificent species, exceeding all the rest in the splendour and elegance of its plumage; a native of New Guinea: Paradisfeus, or chefnut P., the Upupa paradisa of Linnaeus and Latham, and crested P. of the latter: Mexicanus, or grey P., with green and purple glofs, bluefe wings, yellowf belly, and very long tail; Upupa mexicana, or Mexican P. of Latham; a native of Mexico, frequenting mountainous regions, and feeding on various kinds of insects: Aurantius, or orange-coloured P., with tail of moderate length and even at the P. of Latham; the Upupa aurantia, or orange P. of Latham; native of Guiana, frequenting the small islands in the mouth of the river Berbice; Fernandez describes the suppos'd female of this species under the name of Cochtiulf: Erythrocynthos, or black P. with green and purple glofs, red bill and legs, and long tail with the feathers spotted with white near the tip; the Upupa erythrocynthos, or red-billed P. of Latham; an highly elegant species, an inhabitant of Africa.

PROPERTY, LITERARY. (See Literary Property.)

The statute of literary property has been considerably improved since the article on this subject appeared in the body of this work. By the act of 54 Geo. III. c. 156. an absolute term of twenty-eight years copyright has been vested in the author of every book that shall be published after the palling of that act, and in his assigns, and if the author shall survive that period, the copyright is also secured to him for his life. On books that were published before this statute was made, the second contingent term of fourteen years granted by the former acts on this subject, was made absolute in such authors as were then alive, and a life interest was also added if they survived this extension. On this last subject, the court of King's Bench has decided in a recent case, that if the book had become the property of the public at the time the act passed, which was on the 20th July 1814, the benefit granted by the act to the authors of books published before that time, were not meant by the legislature to apply in such instances.

The same act continued the obligation of delivering eleven copies of every book, and of its maps, plates, &c. to the eleven libraries therein mentioned, being the British Museum, Sion College, the Bodleian Library at Oxford, the Public Library at Cambridge, the Library of the Faculty of Advocates at Edinburgh, the Libraries of the four universities of Scotland, Trinity College Library, and the King's Inns Library.
PUR

Library at Dublin. This delivery has been felt to be a severe burthen, and several petitions have been presented to parliament by authors as well as publishers of books to be relieved from it. These petitions were in the sessions of 1818 referred to a committee of the House of Commons, which examined many witnesses on the subject, and made a report to the House of the following import:

That it is the opinion of this committee, that it is desirable that so much of the copyright act as requires the gratuitous delivery of eleven copies should be repealed, except in so far as relates to the British Museum, and that it is desirable that a fixed allowance should be granted in lieu thereof, to such of the other public libraries as may be thought expedient.

That if it should not be thought expedient by the House to comply with the above recommendation, it is desirable that the number of libraries entitled to claim such delivery, should be restricted to the British Museum, and the libraries of Oxford, Cambridge, Edinburgh, and Dublin universities.

That all books of prints, wherein the letter-press shall not exceed a certain very small proportion to each plate, shall be exempted from delivery except to the Museum, with an exception of all books of mathematics.

That all books in respect of which claim to copyright shall be expressly and effectually abandoned, shall also be exempted.

That the obligation imposed on printers to retain one copy of each work printed by them shall cease, and the copy of the Museum be made evidence in lieu of it.

PURANA, col. 3, l. 6, for Varishta r. Varishtta.
PURPURIC ACID, in Chemiftry. The name of an acid principle recently discovered by Dr. Prout; produced by the action of nitric acid upon the lithic or uric acid. The beautiful purple substance produced by the action of the nitric acid and heat upon lithic acid, has been long known to chemists. This purple substance is a compound of the acid in question and of ammonia. This acid, which may be likewise formed from the lithic acid by chlorine and iodine, possesses the remarkable property of forming beautiful purple compounds with the alkalies and alkaline earths. Hence the name of purpuric acid has been adopted by Dr. Prout, which was suggested by Dr. Wallaston.

Purpuric acid may be separated from the purpurate of ammonia above-mentioned, by the sulphuric or muriatic acids. It usually exists in the form of a light yellow or cream-coloured powder. It is exceedingly insoluble in water, and consequently possesses no taste, nor affeets litmus paper, though it readily decomposes the alkaline carbonates by the assistance of heat. It is soluble in the strong mineral acids and in alkaline solutions, but not in dilute acids in general. It is insoluble in alcohol. When exposed to the air it assumes a purple colour, probably by attracting ammonia. Submitted to heat it is decomposed, and yields carbonate of ammonia, pruffic acid, and a little fluid of an oily appearance.

The alkaline purpurates, as before observed, all form solutions of a beautiful purple colour. They are capable of crystallizing, and their crystals possess some remarkable properties. The purpurate of ammonia crystallizes in quadrangular prisms, which when viewed by transmitted light appear of a deep garnet-red, but by reflected light two of the opposite surfaces appear of a beautiful green, while the other two retain their natural red colour. This curious property seems to be possessed by the other alkaline purpurates. The metallic purpurates are in general remarkable for their solubility, and the beauty of their colours. The purpurate of zinc is of a beautiful golden-yellow, the purpurate of tin of a pearly-white. The other purpurates are all more or less of a red colour.

Dr. Prout thinks it probable, that this acid forms the basis of many animal and vegetable colours. The pink colour of the sediment in the urine of fever seems to be owing to the purpurate of ammonia. Dr. Prout also thinks, that some of its salts might be used as paints, and also for dying, as they appear to possess strong affinities, especially for animal substances. See Philosophical Transactions for 1818.

QUARANTINE, that space of time (usually forty days, as the term manifestly implies) which vessels and persons are restricted from having intercourse with other vessels or persons, or with the shore, on their arrival from places subject to the plague or other infectious disease or deltempor, or having held communication with ships coming from such places, or on board of which any infectious disease shall have appeared during the voyage.

The public health is a matter of the highest importance, and whoever is sensible of the havoc which the plague and other infectious diseases formerly made in this country, (see Plague,) and considers the prevalence of such diseases in some parts of the globe, how easily they are communicated, and how long the poisonous contagion lies dormant without losing its malignity, will readily avert to the strong necessity that exists for rigorous precautions being adopted, to prevent its introduction into these kingdoms.

Of such common concern, indeed, is the health of large and trading communities, that the chief magistrates (says Blackstone) have the guardianship of the public health, and are empowered to issue such ordinances as may be deemed necessary, either to prevent the introduction of infection from neighbouring or remote countries, or for separating those actually infected by removal, or by cutting off communication with their abode.

In this country, a Board of Health has been instituted, to inquire into the nature of the infection of the plague, and the mode to counteract its effects; and public ordinances have been made from time to time upon this subject; formerly by proclamation, but latterly by parliament. And such has been the anxious solicitude to frame the laws and orders to obtain the ends desired, that they have at various times undergone laborious revision, and such further regulations and amendments have been introduced as by experience were found to be necessary. Nor has the care and anxiety of the British government flagged here, for their consuls and public functionaries abroad are instructed to convey, with the utmost promptness, intelligence of the appearance of any epidemic deltempor in the places where they reside, or in such as are in their vicinity. Government is thereby enabled to issue necessary directions, for subjecting ships and persons arriving from thence, to a more rigid examination and seclusion than might otherwise have been adopted. Governors and commanders have similar local powers and injunctions, and are empowered to make such orders, either to regulate or entirely cut off communication with suspected places and vessels as they shall deem necessary. In sea-ports, vessels and their cargoes and crews are subjected, on arrival, to examination; where the two former are aired and purified for a necessary time, and the latter retained a certain number of days, in which time, it is supposed, any infectious disease they might retain, would make its appearance.

In inland places, restrictions are likewise imposed for similar purposes, and intercourse thereby cut off by proper means, (usually a cordon of troops drawn round the infected place,) which taking possession of the roads, rivers, and watercourses, effectually prevents infected persons entering the place, as well as others from escaping.

All these measures, though they may appear arbitrary, are founded upon sound policy; and however irksome they may be found by those who are subjected to their operation, yet if they reflect for a moment what dread is created at the very apprehension of approaching persons afflicted with diseases of an infectious or putrid nature, or having even the possibility of harbouring contagion; and what dreadful and painful consequences are known to follow from an unguarded or indifferent exposure, in such cases they will refrain from halfly rushing into society, without submitting to such salutary precautions which are so absolutely necessary, or at least to satisfactorily to their fellow-citizens. No doubt the time is tedious, and the places appointed may be but little calculated to afford comfort to or reconcile "les detenus;" but when they reflect that thousands may be swept away in a few days, by the introduction of such a malady, it is hoped they will submit with less impatience.

One thing which makes the necessity less apparent is, that from the length of time since England has been afflicted with such a calamity, and from theucceds of the measures that have long been adopted to prevent its introduction, persons in general have no actual knowledge, and full less fear of its dreadful effects, and they perceive with indifference, as it were, an object at a distance, which on nearer approach would almost paralyse their senses.

That persons and commerce may be as little impeded as the nature of circumstances will admit, a certificate is always obtained by persons coming from places where any of these distempering maladies are of frequent occurrence; by this means, the general safety is more strongly secured, as well as less impediment given to the trader and the traveller; because when it declares the country free from any infectious disease or deltempor, no further detention is generally required, than is necessary to transmit the safe to the consideration of those who are intrusted with the general safety. If on the contrary the certificate states, that an infectious deltempor does prevail at such place at the time of their departure, or if no certificate is brought, the examinations are more minute, and the purifications are of longer duration.

It is not intended in this article to say anything of the nature of infectious diseases; they will be found in the previous work under the heads Epidemical Diseafes, Plague, Yellow
QUARANTINE.

Yellow Fever, Contagion, &c. to which the reader is respectfully referred. A succinct account only will follow of such enactments and orders as have been made with the view of securing the performance of quarantine, and that the necessity and value of these regulations may be more generally known.

Much pains and inquiry have been instituted for considering the most effectual means for preventing the introduction, and of the speedy most necessary to be adopted, in case of the sudden appearance of the plague, both with regard to the treatment of the persons and their houses, as well as their dealings and communication with each other; whereby such instructions can on any emergency be immediately issued, as must check the extension and deprive the malady of half its inveteracy and of half its terrors.

Besides this, so much more air has been admitted to large and manufacturing towns than formerly, so much more cleanliness secured by underground drainage, as well as among the lower classes, that in addition to their better condition generally, in point of food, and the treatment of febrile complaints being better understood, its recurrence or virulence may be considerably lessened. Apprehensions and false alarms will, at times no doubt, be created among weak and credulous persons, and it will be most judicious in the local magistracy, immediately to infuse (rigid inquiry into the rumour, and either to take prompt measures to contrariety and thereby prevent unnecessary alarm, or to adopt such speedy steps as will secure those deemed infected from having intercourse with others who are in health, until his majesty's privy council can illude such directions as the case may require, which they are specially authorised to do by 45 Geo. III. ch. 10. sect. 12. So much is the privy council on the alert in this respect, that it directed, and deemed prudent for the safety of the community, to have three vessels funk a few years ago, having cargoes of skins from Mogadore on board, under very strong suspicion of their harbouring the plague.

It will not here be necessary to make an enumeration of the many acts that have been passed respecting quarantine, since they were all repealed, (except so much of the 39 & 40 Geo. III. c. 80. as repealed the former acts,) by the 45 Geo. III. which passed 12th March 1805, and which embodies many of the former provisions and amendments.

Three other acts have passed subsequently, (46 Geo. III. c. 98. 50 Geo. III. c. 20. and 51 Geo. III. c. 45.) making further provision and amendments; and several general orders in council have been published in the London Gazette, by authority of, and in furtherance of those laws; and which have equal force with the laws themselves. Indeed but for the levying of duties, and the infliction of pecuniary penalties and capital punishments, it is conceived acts of parliament would have been unnecessary, for by the common law the king is invested with the care of the public health, and his edict mutt of necessity have been binding on the subjects residing in or trading to this country. But to return: the 45 Geo. III. c. 10. in the first place, declares what ships, persons, and goods, are liable to the performance of quarantine. They are,

1. All ships and vessels (including his majesty's ships of war) arriving from or having touched at any place, from whence his majesty shall declare it probable the plague or other infectious disease or diarrhoea may be brought, and all persons, goods, wares or merchandize, packets, packages, baggage, wearing apparel, books, letters, or any other articles whatsoever on board the same. By 5 Geo. III. c. 25. sect. 3.

Letters are to be given to the superintendent, who is to dispatch the same in the usual manner, after due precaution.

2. All ships, vessels, and boats, receiving any person, goods, wares or merchandize, packets, packages, &c. out of such ships, whether they came or were put on board the same, either before or after the arrival of such ships at any port in Great Britain, or on the islands of Guernsey, Jersey, Alderney, Sark, or Man, and whether they were bound to Great Britain or not. They are likewise deemed to be liable from the time of the vessels leaving such infected place, or from the time when such person or goods went or were received on board such vessel. (Act, sect. 10.)

3. Ships and vessels importing certain goods, more especially liable to retain infection, (to be set forth in any order in council,) and which may be carried from infected places into other countries, and from thence imported into Great Britain, are liable to all such regulations and restrictions as are made concerning quarantine. (Act, sect. 11.) For the goods, see Clafs 1 and 2.

4. Ships and vessels coming from any place in Europe, without the freights of Gibraltar or America, (where there is not a regular establishment of quarantine,) having on board any goods enumerated in the first class, the produce of Turkey, or Africa within the freights, or West Barbary, and all ships and boats receiving such goods out of such ships, are, together with all persons, (and pilots,) goods, &c. to perform quarantine, as ships coming from the Mediterranean with clean bills of health (which is fifteen days). Order in council, 5th April 1805, sect. 5.

5. But by order of the prince regent in council, 26th April 1817, ships which have failed from ports deemed liable to infection, to others which are not liable to infection, and afterwards arriving here, shall not be liable to perform quarantine, if they come in ballast, or with a cargo taken in at the last-mentioned port, if the master shall make oath that all the goods of the first and second classes were landed or otherwise discharged at the latter port forty days at least before her arrival in Great Britain, and that no plague, &c. existed on board at any time from the commencement of the outward voyage to the termination of the homeward one; and provided also, that the goods taken on board at the port not liable to infection are not the growth, &c. of any country declared liable to infection; or if any goods of Clafs 1, taken in at a place not deemed liable, shall be the produce of any country deemed liable, then on proof according to the 43d section of order in council of 5th April 1805, that such goods have performed quarantine at one of the foreign Lazzaret.

6. Ships and vessels arriving from any place whatever, under any alarming or suspicious circumstances as to infection, are liable to such regulations and restrictions as are made by any order of his majesty (Act, sect. 11.); or by any three of the lords of the council, in case of any unforeseen emergency on any ship arriving with any infectious disease on board, or if any infectious dilatation has appeared in the course of the voyage, although she shall not have come from any place from whence his majesty has declared it probable the plague, &c. may be brought. (Act, sect. 12.) And all such ships and boats, and all persons, (including pilots,) goods, wares, &c. whether imported or put on board such ships, boats, &c. as well as on board the receiving ship, shall be obliged to perform quarantine in such places and manner, and for such time, as shall be directed by his majesty's order in council, published in the London Gazette, and that until they have performed and been duly discharged from quarantine, they shall not come or be brought.
brought on shore, or go and be put on board any other ship, &c. in order to go on shore, though such ship may not be bound to Great Britain, unless by directions and permission of his majesty in council. And all ships and boats, perfons, pilots, masters or commanders, goods, wares or merchandise, coming from such restricted or any infected place, shall be subject to all the rules, regulations, and provisions of the act, and any order in council, and to all pains and penalties, &c. of that act for any breach or disobedience to it, or of any order in council made under its authority. Sect. 15. of the act.

By 46 Geo. III. c. 98. his majesty, or any of the lords of the council, as often as they shall apprehend that the yellow fever, or other highly infectious distemper, prevails in America, or the West Indies, may require every vessel coming from or having touched at those places, to come to anchor at certain places to be appointed by the commissioners of the customs, for the purpose of having the state of health of the crew ascertained before the shall be permitted to enter any port in Great Britain; but the ship shall not be deemed liable to quarantine, unless it shall be afterwards specially ordered under that restraint. Sect. 6.

Shortly after the passing of the act the 45 Geo. III., and under its immediate authority, an order in council was issued, dated 5th April 1805, which declared what places his majesty judged it probable the plague, or other infectious distemper or disease, may be brought from. They are by vessels coming from or through the Mediterranean, or from the West Barbary on the Atlantic ocean, and also by the importation of certain goods being the growth or produce of Turkey, or Africa within the straits of Gibraltar or West Barbary, from any port in Europe without the straits, or on the coast of America. And by further order, dated 7th November 1805, it was declared, that an infectious distemper might be brought by vessels coming from or having touched at any port in the states of Pennsylvania or New York, but this order has since been annulled.

The Goods deemed most liable to retain infection are set forth in three tables, by sect. 33, 35, and 38 of the order in council, and are as follow:

Class I.—Apparel; artificial flowers; boll, or any article made thereof; beads, bracelets, or necklaces, in strings; beds, bed-ticks; books; brooms; brushes; bedkettles; camblet; canvas; carumen wool; carpets; cordage not tarred; cotton wool, yarn, or thread; all articles wholly made of or mixed with cotton, silk, wool, thread, or yarn; down; feathers; flax; furriers' wales; goats' hair; gold or silver in thread, cotton, hair, silk, or wool, or any other fibulation herebefore enumerated; grogram; hats, caps, or bonnets of straw, chip, cane or any other material; hemp; hoop; horns and horn tips; hair of all sorts; leather; linen; liquor of any kind, in bottles or flasks; saddles, bridles, or harness; maps; mappletre: mats and matting; mohair yarn; nets, new or old; paper; packthread; parchment; pelts; plating of bait, chip, cane, straw, or horse-hair; quills; rags; sail and sail-cloth; silk; vin. crapes and tiffanies, huilks and knubs, raw silk, thrown or organzine silk, waife silk, wrought silk; flks, hides, and fur-s, and parts or pieces of skull, hides, and fur-s, whether undressed, or in part or wholly tanned, tawed, or dressed; sponges; straw; or any article made or mixed with straw; stockings; thread; tow; vellum; whiffs; wool, whether raw or anywise wrought; yarn of all sorts.

Class II.—Senna; jalap; gum arabic; gum tragacanth; myrrh; opium; scammony; antimony; cantharides; alum; juniper-berries; pomegranates, flowers and seeds; fel nitre; fal ammoniac; madder; sumach; galls; tobacco; coffee; wood in rapsings; cork.

Class III.—Grain; pufle; and other seeds in bulk; grain; lignum, and other seeds in facks or, and or, and or bagels of rufl mat; dried fruits in baskets, or packages made of articles enumerated in the first clas, or in packages of wood and oil in barrels.

Where vessels are to perform quarantine depends upon circumstances; for if the plague, &c. appears on board any ship within the straits of Gibraltar, the is to go to one of the foreign lazarets (at Malta, Ancona, Venice, Melilla, Leghorn, Trinelle, Genoa, or Marseille); but if it appears without the straits, then she is to go to the harbour of St. Helen's-Tean and North Withal, (two of the islands, one of which is the Scilly islands,) or such places as his majesty shall appoint. (Sect. 13. of the act.) And immediate intelligence shall be given to the commissioners of the customs, and to the privy council, so that measures may be taken for the comfort and support of the crew and passengers, and such precautions used as the case may require; and the ship is to remain there, and none of the crew or passengers are to go on shore, or have any communication with any other vessel; and any person who shall not act conformable hereto, or any directions of the privy council, are to suffer death without benefit of clergy. If the vessel cannot make those islands or other places appointed, or shall be forced by itselfs of weather to go up either of the Channels, she shall not enter any port in Great Britain, or the islands of Guernsey, Jersey, &c, but shall remain in some open road till the master receives direction from the privy council. Sect. 13. of the act.

The next regulation is, that ships not having the plague actually on board, (except king's ships, &c.) coming from or through the Mediterranean, or West Barbary, without clean bills of health, bound to the western ports of Great Britain, may perform quarantine at Stangate Creek, and no where else. (Order, sect. 4.) But by order 15th July 1813, ships not having the plague actually on board, (except king's ships, &c.) coming from or through the Mediterranean, or West Barbary, without clean bills of health, bound to the western ports of Great Britain, may perform quarantine at Milford Haven.

The 46 Geo. III. c. 98. sect. 7. authorizes his majesty or the privy council to prohibit (by proclamation or publication in the Gazette) any perfons, ships, or boats from going within the limits of any station which may be affigned for the performance of quarantine by ships without clean bills of health, under the penalty of 500l. By orders in council, dated 21st July 1806, and 5th September 1811, it was ordered, that no ship or boat (except quarantine and custom-house boats) should go, but on cafes of emergency, within the place at the Motherbank set out with yellow buoys for ships not having clean bills of health; and that ships with clean bills of health ordered to go within the compas of the yellow buoys, but separate from his majesty's ships and ships without clean bills.

The two west buoys are placed to the eastward of Wooton Creek, and the two north ones near the Isle of Wight, with another buoy midway between them, and a red buoy as a mark for a burying-place.

By sect. 2. of the order of 5th April 1805, ships (king's ships as well as others) with clean bills of health, Bound to London, Rochefelt, Pa-verham, or any creeks or places belonging to or within any or either of the above ports, are to perform quar-}
[Note.—In the case of ships coming from Turkey, and
obliged to perform quarantine before their entry into the port
of London, it is usual for the consignee to fend down perfonns
at his own expence to pack and take care of the goods; and
where a consignee had omitted to do so, and the goods were
damaged by being sent loose to shore, it was held that he
had no right to call upon the master for a compensation.

Guildhall, M. T. 1789.]

Ships bound to Leigh, and the ports
and creeks extending from thence
to, and including Berwick,

bound to Carhile, and the ports
and creeks extending from thence
to, and including Beaumaris and the
Isle of Man,

bound to Sandwich and Covens,
and the ports inclusive,

bound to Poole and Selby, and
the ports inclusive,

bound to Bridgewater and Swan-
sea, and the ports inclusive,

bound to St. Ives and Aberyst-
with, and the ports inclusive,

bound to Jersey, Guernsey,
Sark, or Man, or any part of them,

bound to Leeds, and all the ports
or creeks extending from thence
along the eastern coast of Scotland,
as far as including Aberdeen, -

bound to Glasgow, and all the ports
or creeks extending along the
western coast of Scotland, as far as
and including Wigtoun,

bound to Inverness, and all the
northern coast of Scotland, as far as
and including Stornaway,

bound to Dunfries and Kirk-
cudbright, and all the ports and
creeks on the south-west coast of
Scotland,

bound to any port or place on the
coasts of England and Scot-
land, not within any of the before-
mentioned limits,

Vessels liable to quarantine, and having a clean bill of health
on board, which are bound to any of the above ports, and
have passed the place appointed to perform quarantine, either
from the master's ignorance of being liable, or by force of
weather, or other unavoidable circumstance, may, on proof on
oath that it was unintentional, and not with the view of avoid-
ing the regulations of quarantine, repair (and shall be com-
pelled to go) to any other place at the discretion of the
quarantine of the place, to which the ship is bound; and

she is bound; and

Vessels not bound to this country are not to touch at or
attempt to enter any port in Great Britain, or the islands
belonging thereto, although they may be ports appointed
for performing quarantine (except for orders, or in con-
sequence of fires of weather, or loss or damage at sea); and
then the masters are to answer the preliminary questions, and
to conform to all such directions, as they shall receive, as
well with respect to their continuance at such ports, and depart-
ing and repairing to any other place, as to all other regu-
lations, &c. touching quarantine; and if they do not
comply, they may be compelled to put to sea; to aid which,
the commander, or other officer of his majesty's ships
of war, may be called in. Order, sect. 7, and 45 Geo. III.
c. 10. sect. 19.

Vessels performing quarantine is as follows:

Ships having the plague on board, and arriving under
any alarming or fulpicious circumstances, the time is left
to the discretion of the privy council. 45 Geo. III. sect. 12
and 13.

Ships coming from or through the Mediterranean or
West Barbary with clean bills of health, having on
board goods of Clas I. and II., fifteen days. Order,
sect. 12.

Ships arriving without clean bills of health, thirty days.
Order, sect. 37-40.

Ships arriving from places in Europe without
the freights, or on the continent of America, where there is not
a quarantine establishment, bringing goods of the 1st,
the produce of Turkey, or Africa within the
freights, or West Barbary, to perform quarantine for
fifteen days. Order, sect. 5.

Vessels bringing touched, i. e. suspected bills, to perform
quarantine for twenty days. Order, sect. 41.

The time for passengers and the crews of vessels
performing quarantine is to be governed by the nature of the
cargoes of the respective vessels, and whether they come with or
without bills of health.
QUARANTINE.

The duration for goods performing quarantine to be as follows:—

Goods of the 1st Clafs, coming without clean bills of health, forty days at the lazaret. Order, feft. 33.

Goods of the 2d Clafs, coming without clean bills of health, thirty days. Order, feft. 33.

Goods remaining after those of the 1st and 2d Clafs are removed to a floating or land-lazaret, are to perform quarantine for thirty days, and are to be afterwards fumigated. Order, feft. 37.

Goods arriving from or through the Mediterranean, or Wefl Barbary on the Atlantic ocean, in ships not having the plague on board, without clean bills of health, to be removed to the floating lazaret at Stangate Creek, and perform quarantine for thirty days. Order, feft. 14. and 40.

Goods coming from thofe places with clean bills of health are to be aired one week in the fame ship; except goods of Clafs I. and II., which are to be removed to the lazaret, and be aired for fifteen days. Order, feft. 13.

Goods coming in ships with fupfected bills of health to be treated as ships coming without bills of health, except that they are to perform ten days' quaranfine. Order, feft. 41.

Dried fruits having been shifted from baskets and packages made of articles in Clafs I., or confidered fupfetfible, if all the perfon's on board are in health may be delivered in twenty days. Order, feft. 38.

Dried fruits in wood, may be delivered in ten days. Order, feft. 38.

Oil in barrels, the bungs being tarred, and the barrels brushed and dipped in sea-water, may be delivered in ten days. Order, feft. 38.

Grain, pulse, and feed in bulk, or in facks, or casks, or mats, when shifted, and packed through a fieve, may be delivered in ten days. Order, feft. 38.

And the packages, when made of fupfetfible articles, are to be fent to the lazaret to perform quarantine, according to the nature of them, or be defroyed at the option of the owner. Sect. 38.

Formerly the 32d claufe in the order in council required "the production of a declaration on oath for goods of the 1st Clafs," when brought from places without the freights of Gibraltar, or on the continent of America, &c. to affure their growth, and that they were not the produce of Turkey, &c., but that claufe has been fupplanted by order of 8th Aug. 1810; and they may be admitted without performing quarantine, on the matter making oath that no infeftious disorder prevailed at the place from whence they failed, or on oath of the importer that they are not the produce of Turkey, or of any place in Africa within the freights, or Wefl Barbary: but whenever that declaration is produced, the oath of the matter or of the importer is not required. Order in Council, 27th Oct. 1818.

Veffels having performed quarantine at any of the foreign lazares, and producing proper documents to prove that fact, are not required to do fo again; nevertheless, fuch part of the cargo as confifts of articles in Clafs I. are to be taken out and perform quarantine in the usual manner for fifteen days (Order, feft. 43.) But no goods are to be landed or removed therefore until the matter has given notice to the quarantine superintendent, or officer of customs, in order to be laid before the privy council. Landing or removing them, before directions are given, or contrary thereto, subjects the matter to the penalty of 200l. 45 Geo. III. feft. 22.

Having thus flated what ships and goods are liable and required to perform quarantine, and the time for which they are to perform it, we shall proceed to state the manner of doing it, which is to be by opening and airing in the manner directed by order in council (Act, feft. 29.), according to the nature of the goods, and the articles of which the packages are made.

Goods of the 1st Clafs, unaccompanied with a clean bill of health, undergo two performances, one probationary, the other of longer time and greater precaution. The hatches of the veflel are firft to be opened, and as many of the bales as can be ranged upon the deck are to be taken from the hold, (as foon as the pilot and paflengers are removed,) and the ends opened, and the contents handled by the failors, under directions of a quarantine guardian for fix days; and after this, any further parcels are only required to be opened and aired for three days, unlefs any fupficious circumftances afire, and then the time may be extended to four, fix, or eight days, fo as to complete in the whole twenty-one days, or even a longer time if neceffary, and then they are to be conveyed to the lazaret. Order, feft. 32.

In the second performance, or expurgation at the lazaret, all bales of cotton are to be opened from one end to the other, and fo much removed as admit the handling and removing the remainder. Rags, raw wool, goats' wool, Carnen wool, and hair, are to be taken out and ranged in heaps of four feet high, and often rummaged. Bales of filk to be opened on one fide, from end to end, the cords laced, and the filk aired for twenty days; then the other side to be opened in like manner for five days more. Cottons, yarn, thread, fluffs, and linen, are to be piled in rows or pyramids, and turned every four days, and completely spread out and fuspended on cords for feveral days. Paper, books, parchment, sponges, and lockings, are to be un-packed and feparated, fo as to admit thorough airing. Feathers, fwab-hats, artificial flowers, coral beads in furnishings, and brushes, fpread out in the fame manner. Carpets, furs, hides, and skins to be unbale, and each piece spread and fuspended on cords in the open air, and frequently turned; and all goods packed with fraw, cotton, or articles flated in Clafs I., shall be entirely taken out of the fame, opened, and handled, and carefully aired, as well as all other goods in that clafs, for which no directions are given. Order, feft. 34.

Goods of the 2d Clafs, unaccompanied with clean bills of health, though lefs liable to infeflion, are to be carried to the lazaret, and be un-packed, opened, and aired as much as poifible; and by moving them as much as practicable from time to time, fo as to admit free ventilation for thirty days. Order, feft. 35 and 36.

Goods not mentioned in thefe claffes, and remaining on board the importing ship, are to perform quarantine for thirty days, by being frequently swept and shifted, fo as to admit free ventilation; at the end of which time, if all the perfon's on board, and those employed in the expurgation on shore, are well, the ship, goods, crew, and paflengers, are to be fumigated and discharged. Order, feft. 37.

There are other regulations and enactments on this fubjeft which it is neceffary to notice, and though they relate to the firft arrival of the ships, and take effed from that time, yet being rather regulations to affure the nature of the voyages, and the fate of the crews, and the goods con- poled in the cargo, than any part of the performance of quarantine, this is conceived a proper place to introduce them.

It is manifeft, that without the earliest information of the arrival of veflels from countries inflected with the plague, &c. and of the kind of goods of which their cargoes are composed, many of the above-mentioned falutary regulations would be ufeless, either by perfon's quitting veflels imme-

Vol. XXXIX.
diately on their arrival, or from having intercourse with other ships, or with the shore, or by breaking bulk and sending goods into the common stock of the country. To this end, the law has imposed the necessity of the masters of ships liable to quarantine shewing proper signals by day and night, by which the quarantine officer and others are apprized of their arrival; and to prevent any abuse herein, for the purpose of covering any smuggling transactions, persons exhibiting them, when not liable to quarantine, are liable to 200l. penalty by 45 Geo. III. c. 10. fect. 15. And as persons, especially passengers, may innocently render themselves liable to those penalties, as well as those statutes which affect their lives, it is necessary they should be set out for their information. The severity that has been annexed to the violation of the quarantine regulations is a sufficient proof how irksome the constraint is, and how regardlefs persons are to the general safety of others, for nothing short of imposing the penalty of death, on a violation of some of the enactments, has been found sufficient to impose respect to the law on this subject.

By 45 Geo. III. c. 10. fect. 14. ships subject to quarantine are required at all times, when they meet any other ship at sea, or shall be within four leagues of the British or Irish coasts, or the islands of Guernsey, Jersey, Alderney, Sark, or Man, to have a signal hoistedit, to denote that they are so liable, which they are to keep hoisted so long as they remain in sight of such ship, or are within such limits of the coast, until they shall have arrived at their quarantine port, and been legally discharged. The signals are to be, by day, a large yellow flag at the main-head; for which purpose, every ship leaving Great Britain for the Mediterranean, or West Barbary, or any place suspected or liable to have the plague, &c. shall be provided with one or more quarantine signal-flags and lanterns, and proper materials and instruments for fumigation and infection, and shall keep them on board, to be used upon the ship’s return (Order, fect. 45.); and if coming without clean bills of health, then with the addition of a large black spot in the centre: and by night a lantern with a light therein, also at the main-head; on failure whereof, the master is subject to a penalty of 200l. (45 Geo. III. c. 10. fect. 14.) Ships actually having the plague on board are to hoist a signal flag of yellow and black, borne quarterly, of eight breadth of bunting at the main-topmasts-head; and in the night two lanterns, one over the other, to be kept up when in sight of any other ship, or within four leagues of the coasts or islands, and until arrived at the proper quarantine port, and legally discharged from quarantine, upon penalty of 200l. 46 Geo. III. c. 98. fect. 1.

Masters of ships are also further required by fect. 16. of the act of the 45 Geo. III. to give the pilot who shall go on board a written paper containing a true account of the place at which they have touched or loaded on the homeward voyage, and any neglect or refusal, or any false representation, or willful omission therein, subjects them to the penalty of 200l. And by the 46 Geo. III. c. 98. fect. 2. masters of ships that are not liable to quarantine in respect of the place from whence they come, are also to give a true account of all the different articles of their cargoes, under the penalty of 200l. And if by proclamation or order in council, ships are liable, as coming from any place mentioned in any order in council, or by reason of bringing any goods mentioned in such order, the pilot is to give the master notice of being liable, so that he may hoist the proper signal, under the penalties of 50l. and 100l. by the 45 Geo. III. c. 10. fect. 16. and 46 Geo. III. c. 98. fect. 2.

Pilots, not conducting ships to the proper places, (except prevented by fref of weather, adverse winds, or other accidents,) to forfeit 100l. (45 Geo. III. c. 10. fect. 17.;) and not requiring such paper, 100l. by 46 Geo. III. c. 98. fect. 2.

Masters knowing any place from which they came, or at which they touched, to be infected with the plague, or any infectious disease, or having any person on board infected with it, and who shall refuse or neglect to disclose the same when examined by the superintendent of quarantine, or officer of customs, and omitting to hoist the proper signals, shall be guilty of felony, and suffer death. 45 Geo. III. c. 10. fect. 19.

Masters of vessels ordered to perform quarantine are to deliver to the officer of customs, or quarantine superintendent at the quarantine station, (and which they are required to demand,) their bills of health, manifest, log-book, and journal, under penalty of 100l. 45 Geo. III. c. 10. fect. 20.

Masters of ships liable to quarantine, although the plague, &c. shall not have then appeared, who shall quit the ship, or suffer any feaman or passenger to quit the same, till they have performed quarantine, (unless by licence or order in council,) shall forfeit 500l. And if any person coming in, (or any pilot or other person who may go on board, whether before or after her arrival at any port in Great Britain,) shall afterwards quit her before the shall be regularly discharged, all perons (by necessary force) may compel such person to return on board: and every person for quitting such ship shall forfeit 200l. and be imprisoned six months. 45 Geo. III. c. 10. fect. 21.

Such of the passengers and crew of ships not furnished with clean bills of health as are the defiers of performing quarantine in a separate vessel, (to be hired at their own expense,) may, if the superintendent and medical attant of the place consent thereto, do so, and may quit the ship before the hatches are opened and go on board such ship, (a guardian being there placed at their expense,) for thirty days (Order, fect. 28.); but their baggage, apparel, and books, for which they have not immediate occasion, shall be sent to a floating lazaret to be aired, and before any passengers or crew shall be discharged, they, their clothes, and effects, shall be fumigated (Order, fect. 31.) but passengers and the crews continuing on board the ship in which they arrived are to remain under quarantine till the ship be discharged. Order, fect. 28.

Pilots may quit the ship and be removed to the hospital ship, after the quarantine guardians are placed on board, provided they come from ships having no suspicious sicknotes on board; but if otherwise, they are to be sent to the pest-house, or other place appointed for perons so affected, and they are to continue under quarantine until the probationary airing of the goods is finished, when, if they continue well, they are to be fumigated and discharged. But such pilots are not to have communication with any other person, except under the regulations usual in like cases. Order, fect. 37.

If any pestilential accident occurs among the ship’s crew or passengers during the probationary airing, (at whatever stage it may happen,) the quarantine of the crew, passengers, and pilot, (if any shall have been on board,) and the goods, is to recommence, and the sick are to be sent to the hospital, or pest, or place provided for perons so afflicted, the external guard to be doubled, and notice immediately given to the privy council. Order, fect. 29.

If any peron falls ill, and a medical man is on board, he shall confer with the medical man who comes alongside, the latter keeping ten feet to windward; but if no medical man
QUARANTINE.

man is on board, and it is necessary to visit the sick, the visit shall be made at the ship's boat by the medical attendant in his own boat, keeping to windward ten feet; and if medical aid cannot be administered on board, the sick is to be carried to the pell or hospital ship. Order, sect. 23.

Perfons under circumstances to induce a suspicion of having any pestilential disorder, to be removed to the pell or hospital ship; but if it is not infectious, they may be removed to a more commodious apartment in the lazaret, there to complete the remainder of their quarantine. Order, sect. 24.

If any pestilential disorder shall actually discover itself in any ship or lazaret, the person is to be removed with all possible care and dispatch, under the special directions of the superintendent or medical attendant, to the pell-house, and a proper attendant is to be assigned to him, and he shall be visited at a due distance; but if a nearer approach is necessary, some person is to be specially appointed for that purpose. Order, sect. 25.

Passengers and crews may have the assistance of any medical person they may choose from the shore; but if any persons communicate by contact with the sick, they shall perform the like quarantine as the sick. Order, sect. 26.

Perfons liable to perform quarantine, and others having had intercourse with them (whether in ships or lazarets), are to be subject to the orders of the superintendent or officer of customs, who are required to enforce obedience to all such orders, and to call in others to their assistance; and they may compel all such persons to repair to the lazaret or ship, and cause all goods liable to quarantine to be conveyed there also; and persons refusing to go, or, who being there, shall escape, shall be compelled by force to return; and persons refusing or neglecting to return, and persons escaping, shall suffer death without benefit of clergy. (45 Geo. III. c. 10, sect. 23.) And may be feized by any constable, headborough, tythingman, or peace officer, or any other person, and be carried before a magistrate or justice of the peace, or such justice may issue his warrant for their apprehension and conveyance to their ship, or to any ship performing quarantine, or to any lazaret from which they have escaped, or for confining them in safe custody (but not in a public gaol) under such restrictions, as to having communication with other persons, as the justice may think proper, (calling to his aid medical advice) until they can be safely removed to some place appointed for quarantine, or until directions can be obtained from the privy council. 45 Geo. III. c. 10, sect. 24.

Perfons not infected with the plague, &c., entering the lazaret whilst any person is performing quarantine, are to perform it also, and are not to return without licence or order in council; and, if they shall actually escape before it has been fully performed, they shall suffer death, without benefit of clergy. 45 Geo. III. f. 27.

Perfons on board ship, or in a lazaret, may have communication with others by letter, to be collected by a boat, which is to go round at a fixed hour daily, and they are to be dipped in vinegar and put into the fumigating-box, and the covers shut open (Order, sect. 16.); but letters to perfons on board are to be taken by the quarantine superintendent only, and no conference is to be had by perfons not under quarantine with perfons who are under quarantine (except by permission of or in the presence of the quarantine superintendent or his attitant), nor from any ship, unless the superintendent's boat be present, and then at the distance observed by the superintendent. And to prevent improper or clandestine communication, there is to be a watch and row-guard at all the quarantine stations; and the boats belonging to any floating-lazaret are to be locked to the same; and the boats of the ships performing quarantine are to be taken away, and no use made of them, but for removing goods, from such ship, or upon occasions of necessity, till they are given up when the ship has done performing quarantine. Order, sect. 17.

Affluence and necessaries for ships under quarantine to be found by the superintendent and to be carried to the windward side, and delivered by means of buckets. (Order, sect. 18.) Quarantine guards are to prevent any goods being delivered from ships without clean bills of health but by an order in writing from the superintendent, such order to be entered in a book and the original returned; and nothing to be discharged from one ship under quarantine to another, nor any personal intercourse allowed. And a guardian is to go with the lighters and boats, to prevent communication during the transit of the cargo, and to take care that no remnants of cotton, or things of Class I. and II., remain in them. And before leaving off work they are to collect and deliver all such articles into the lazaret. Sect. 19 of the Order.

The duty of the quarantine superintendent and officers of the customs may partly be collected from what has gone before; but it is necessary here to observe, that they are, on a ship's arrival, to go off and put the following preliminary questions:—What is the name of the ship? Maiter? From whence? Where bound? At what port has the ship touched on the homeward voyage, or what ships spoken with? Whether the plague, or any infectious disease, exist in at the time of leaving the port the ship loaded at? What kind of goods the cargo is composed of, and of what country are they the produce? and whether the brings a bill of health?

If the ship is deemed liable to quarantine, she is then to be directed to the quarantine station, and the superintendent is to go to the windward side, (taking medical advice with him, if necessary,) and to see all the officers, crew, and other persons, quartered on the gangway, and is to put further questions to them. They are in the first instance the same as above, except more particular as to the places the vessel touched at during the whole voyage; the respective dates of her arrival at every place, and dates of her departure; the number and conditions of the crew for the voyage, whether any have a sick or died, and the nature of the disease; whether they are in the same, or in what manner, and when, and what kind of disease; whether any letters or parcels have been received out of any other ship on the passage; of what kind and where delivered, and into what vessel or boat; what pilots she has had; and any particular respecting British ships loading at the same port from whence she came; their names, where bound, &c., and what British ships were at the places at which she touched; whether any person employed in loading the cargo was taken ill, or any person employed in doing cargo was taken ill, or on arrival at the port, whether the cargo had long warehoused, or packed, handled, or brought on board by any person affected with the plague; did the touch at the ports of Rhodes, the Morca, and what part of Africa; if so, where? and had she any communication with the shore at those places, or with any ship coming from such places; if so, in what manner, and when, and whether the crew of such ship was healthy.

The answers to all these questions are to be taken in writing, and the matter to make oath to them, and is to deliver the log-book, manifest, and ship's papers, (which are to be dipped in vinegar and fumigated,) and make oath to the truth of the contents of the former, or in what particular it is not correct; and whether any particular entry
QUARANTINE.

was made soon after the fact, and if not, for what reason; and also to make oath to all the other papers. Sect. 10 of the Order.

If any suspicious circumstances appear in the answers to the above questions, or from any other circumstance, the proper officer is immediately to transmit such answers to the privy council and the commissioners of the customs, and without regard to the bill of health, whether clean or otherwise, is to order such ship to a station distant from all other vessels, and put her under special guard, the more effectually to prevent communication with her. Order, sect. 11.

Ships coming without clean bills of health are to have two quarantine guardians placed on board as soon as the examinations are ended, and they shall have arrived at her proper station. Order, sect. 15.

Guardians are to take care that, after the cargoes are discharged into the lazaret, the holds and between decks are completely swept, and the sweepings burnt. (Order, sect. 20.) And they are to search all lockers and chests, &c. of passengers and crews, so that no goods in Lift 1 and 2, or any thing liable to infection, remains undelivered, except what the superintendent or medical man declares requisite for daily use; and they are to see all such chests, clothes, and the bedding of the ship daily opened and aired. (Order, sect. 21.) They are also to make daily reports of the state of health of every person on board, and whether the regulations are regularly complied with; and, in case of any impediment, are to give notice to the master, and then to the superintendent, who shall remove the same. Order, sect. 22.

Persons landing or removing any goods, wares, or merchandize, packets, packages, baggage, wearing-apparel, books, or letters, from any ship liable to quarantine, or knowingly receiving the same, are to forfeit, for every offence, not more than 500l., nor less than 100l. And persons clandestinely conveying them (or concealing them for that purpose) from any ship actually performing quarantine, or from the lazaret, are to be adjudged guilty of felony, and suffer death without benefit of clergy. Act, sect. 31.

Officers of customs, or other persons embezelling goods, or guilty of any other breach or neglect of duty, in respect of the ships, persons, and goods performing quarantine, shall lose their office or employment, and be rendered incapable to hold the same, or receive a new grant thereof, and shall forfeit 100l. And if they shall desert their duty, or wilfully permit any ships, persons, or goods, to depart, or be conveyed out of the lazaret, ship, or other place, unless by permission under an order in council, and if they, or any person authorized to grant certificates of ships having performed quarantine, shall knowingly give a false certificate thereof, they shall suffer death without benefit of clergy; and if they shall wilfully damage any goods under their direction, they shall pay treble damages and costs of suit to the owner. 45 Geo. III. c. 10, sect. 26.

Persons forging, counterfeiting, interlining, or altering, any certificate required by this act, or any order in council touching quarantine, or procuring it to be done, or publishing it as true, shall suffer death without benefit of clergy. 45 Geo. III. c. 10, sect. 35. and 46 Geo. III. c. 98, sect. 8.

After goods have been duly opened and aired, proof thereof shall be made by the oaths of the master of the lazaret or vessel, and one of the guardians or officer of the customs, and the superintendent, shall give a certificate of such proof having been made, and such goods shall not be liable to any further restraint, either at that or any other port. 46 Geo. III. c. 98, sect. 5.

Ships and persons having performed quarantine, proof is to be made by the oath of the master, and of two other persons belonging to the ship, before the principal officer of customs or justice of peace, at the port where quarantine was performed, or, if at the islands of Guernsey, &c. before two jurats, that such ships or persons have duly performed quarantine, and that they are free from infection. And, upon producing a certificate from the superintendent to that effect, the collector or justice, &c. is required to give a certificate thereof, and therewith such ships and persons shall not be liable to farther restraint. 45 Geo. III. c. 10, sect. 28.

All forfeitures and penalties incurred against this act may be recovered in any of his majesty's courts of record, or by suit in any of his majesty's courts in the islands of Guernsey, &c. one-half to them who shall sue, and the other to his majesty, to be applied towards defraying the expenses of erecting and maintaining the lazaret. 45 Geo. III. c. 10, sect. 34.

Actions to be commenced in the name of the attorney-general, or of some officer of the customs, and the former may file proceedings if he thinks proper, as well as to the officer's share as to the king's moiety. Sect. 35 and 36.

Offences against this act, not being felony, and disobedience to any order in council, for which no specific penalty is provided, may be tried before any two justices of the peace for the county, riding, &c. where such offence happens; and if any person shall be convicted he shall be liable to fine penalty, not exceeding 50l. for any one offence, or to such imprisonment, not exceeding three months, as shall, in the discretion of the two justices, be judged proper. Such penalty to be applied as directed by sect. 34. 45 Geo. III. c. 10, sect. 38.

Offences contrary to this or any act hereafter to be passed, or of any order in council, notified by proclamation, or published in the Gazette, may be tried in any county within England or Scotland, or in the proper courts in the islands of Guernsey, &c. No attainder of felony to work corruption of blood or forfeiture of goods, &c. 45 Geo. III. c. 10, f. 39 and 42.

In any prosecution for offences against this act, or any act which may hereafter be passed, concerning quarantine, or for any breach of any order in council notified in the Gazette (which is to be a sufficient notice by 45 Geo. III. c. 10, sect. 53.), the answer to any questions or interrogatories put to the master of a ship, may be given in evidence as to the place from which such ship came, or the places at which she touched in the course of the voyage; and where any ship shall have been directed to perform quarantine, the having been so directed shall be evidence that she was liable, unless satisfactory proof shall be produced by the defendant that the ship did not come from or touch at any such place as is stated in the said answer; or that such ship, although directed to perform quarantine, was not liable. And where any ship shall have been factually been put, and shall actually be performing quarantine, such ship shall, in any prosecution, be deemed to be liable, without proving in what manner, or from what circumstances, such vessel became liable. 46 Geo. III. c. 10, sect. 40.

By the 43d section, offenders may plead the general issue, and if the plaintiff is nonsuited, or discontinues his action after the defendant has appeared, or if judgment has been given upon any verdict or demurrer against the plaintiff, the defendant may recover treble costs, and have the like remedy at law as the defendant hath in other cases.

Actions
QUARANTINE.

Actions to be brought within the space of two months after the offence is committed.

Whenever any person is charged with an offence against this or any other act, or in disobedience of any order in council concerning quarantine, and the same shall appear to any judge of the court of King's Bench by affidavit or certificate of an information being filed against such person, he may issue his warrant under his hand and seal, and cause him to be brought before him or a justice of the peace, that he be bound with two sufficient sureties to appear and answer such offence; and if such person shall refuse or neglect to become bound, he may be committed to gaol till he does give bail, or be discharged by order of the court of King's Bench. The recognizance to be returned and filed in court, and remain in force until such person is acquitted, or until he has received judgment. (Act, sect. 41.) And if he is detained for want of bail, the prosecutor may cause a copy of the indictment to be delivered to him, or the gaoler, &c., with notice thereon indorsed, that if he does not in eight days enter an appearance and a plea of demurrer, an appearance and plea of not guilty will be entered in his name; and upon affidavit being made of such notice, &c., if such person is delivered, the prosecutor may cause an appearance and plea of not guilty to be entered, and such proceedings shall be had as if the defendant had appeared and pleaded not guilty; and if upon a trial the defendant is acquitted the judge may direct his discharge. (Act, sect. 41.)

Where any examination or answer shall be taken on oath, the persons authorized to take such examinations and oath shall be deemed to have full powers to administer such oath; and if any person swear falsely, or procure others to do so, he shall be deemed guilty of perjury or falsification of perjury, 45 Geo. III. c. 10. sect. 57; and 46 Geo. III. c. 98. sect. 10.

The king may issue directions if the plague breaks out in Great Britain.—The lords of the privy council, in case any infectious disease breaks out in Great Britain, or the islands of Guernsey, &c., may make such order, and give such directions in order to cut off all communication between any person infected, and the rest of his majesty's subjects as shall appear to them expedient for that purpose. 45 Geo. III. c. 10. sect. 12.

And if it shall happen that any part of Great Britain or Ireland, or the isles of Guernsey, &c., or France, Spain, Portugal, or the Low Countries, shall be affected with the plague or other infectious disease, his majesty may by proclamation restrain all small boats, and vessels under 20 tons, from failing out of the ports of Great Britain or the islands, until bond is given by the master, with sufficient sureties for 300l., that such vessel or boat shall not go or touch at any place mentioned in such proclamation, and that the master, crew, or passengers, shall not go on board any other ship or vessel, nor receive any person on board at sea from any other ship, nor receive any goods out of any ship. And if any vessel for which such security is required, shall fail before security is given, the shall be liable to forfeiture, and the master and every mariner shall forfeit 50l. 45 Geo. III. c. 10. sect. 32.

By the 1. James I. c. 31, if any person infected with the plague, or dwelling in any infected house, be commanded by the mayor or constable, or other head officer of the town or vill, to keep his house and shall disobey it, he may be enforced by the watchmen appointed on such occasions to obey such necessary command, and if any hurt ensue the watchmen are thereby indemnified. And further, if such person goes abroad and conveys in company, if he has no plague sore upon him, he shall be punished as a vagabond by whipping, and be bound to his good behaviour. But if he has any infectious sore upon him uncured, he then shall be guilty of felony. Blackstone, vol. iv. c. 13.

Having thus far given the laws and regulations concerning this matter, we shall state the duties payable by ships performing quarantine, with the exceptions provided by the act; and also the best methods of fumigating ships and houses. It must be apparent, that the nature of the quarantine establishments and maintaining lazarets incur considerable expenses, to defray which the duties are to be applied (Act, sect. 8.); and the law 45 Geo. III. c. 10. sect. 3, declares that it is reasonable the importers should defray the same; and sect. 6, enables, that the ship-owners may recover from the Inland Board all the tonnage of their ships shall bear to the proportion of the tonnage of the ships. These duties are to be paid upon the ships clearing inwards, and to be computed according to the 25 Geo. III. c. 60. 45 Geo. III. c. 10. sect. 5. They are to be levied and recovered as duties of custom, and although not raised for the purpose of contributing to the revenue, the amount is to be carried to the consolidated fund. Sect. 7.

A Table of tonnage duties payable on ships and vessels, which ships or vessels, or the cargo of which, or any part thereof, shall have performed quarantine in Great Britain, or the isles of Guernsey, Jersey, Alderney, Sark, or Man, 45 Geo. III. c. 10. f. 5.

1. For every ship which shall have arrived from any part of Turkey, or from Africa within the frigates of Gibraltar, or in the
   West Barbary on the Atlantic Ocean, with a clean bill of health, the ton
   £ 2 0
   0 7 6

2. Do, without a clean bill of health, the ton
   £ 15 0

3. For every ship which shall have arrived from any place whatsoever, (except from any part of Turkey, &c.,) with a clean bill of health, the ton
   £ 3 0

4. Do, without a clean bill of health, the ton
   £ 10 0

5. For every ship which shall arrive with any part of the cargo consisting of goods the growth of Turkey, or any place in Africa within the frigates, or in the West Barbary, and which shall have arrived from any place whatever, the ton
   £ 7 6

6. For every ship which shall have so arrived under such circumstances as shall induce his majesty, or the lords of the council, to subject such ship to the like quarantine as ships coming from Turkey with clean bills of health, the ton
   £ 7 6

7. Ships arriving under such circumstances as shall induce his majesty to subject such ship to the like quarantine as ships coming from Turkey without clean bills of health, the ton
   £ 15 0

8. For every ship which shall enter inwards in the port of London, an additional duty of per ton
   £ 1 0

Exempted from the said Duties.

Ships of war, transports, and other vessels employed in the service ofgovernment.

Ships or vessels not bound to Great Britain or the isles, and having put in in ditrefs. (Although they should perform quarantine. Opinion of the attorney-general.)

Ships or vessels obliged to perform quarantine only on account of having goods enumerated in the tit Clafs on board,
QUARANTINE.

board, and not producing the proper declaration or document as to their growth, &c.

Ships or vessels, with a clean bill of health, in ballast, or whose cargo shall consist wholly of salt, (unless coming from Turkey, or some place in Africa within the straits of Gibraltar, or in the West Barbary.)

Ships and vessels, with their cargoes shall have performed quarantine in the foreign lazarets, and produce proper documents and vouchers attesting the same. (Or when goods, which have performed quarantine there, and been carried to other countries, are afterwards brought here. Treasury order.)

Ships and vessels rendered liable solely by reason of having received on board by force, and against the will of the master and crew, any person from a vessel coming from or having touched at an infected place. 46 Geo. III. c. 98. feet. 4.

Ships which have failed in ballast from places considered liable to infection, and which shall afterwards bring a cargo from a place not deemed liable to infection, Treasury order.

To prevent as much as possible the plea of ignorance of the laws, the order in council of 5th April 1805 directs, (feet. 44.) that the collector of the port where any vessel shall clear out for the Mediterranean or Barbary coast, or any other place respecting which an order in council is made, shall furnish the master with an abstract of the quarantine regulations, and it is to remain up during the voyage in some conspicuous part of the ship till his return, provided he returns in twelve months.

Ships of war which shall meet any vessel liable to quarantine coming to any port in Great Britain, or the islands of Guernsey, &c. are to take care to prevent the landing of any goods or persons, &c. until they shall be put under the direction of the quarantine superintendent, &c. (Sect. 45.) And the commanders of ships of war, and forts and garrisons on the sea coast, and all justices, mayors, sheriffs, bailiffs, chief magistrates, constables, headquarters and tythingmen, &c. shall be aiding and assisting to the superintendent of quarantine and his assistants, and to the officers of the customs, and in bringing such ships to places appointed for performance of quarantine, as well as in the due performance of the same. Orders, sect. 48.

The commissioners of the customs are ordered to use their utmost vigilance and care that the regulations of the acts of parliament and orders in council be duly observed (sect. 47.) and the lords of the treasury, the lord high admiral, the lord warden of the cinque ports, and the master general and principal officers of the ordinance, his majesty’s secretary at war, and the governors and commanders-in-chief of the said isles of Guernsey, &c. are to give the necessary directions herein as to them they respectively appertain. Order in council, sect. 50.

It now remains to state the best mode of fumigating vessels and apartments infected with infectious diseases, and to offer such hints as are applicable to the subject.

Odoriferous woods, gums, sweet herbs, and aromatics, have been recommended as fumigations, but with little certainty as to their effects; perfumes still less so; besides which, they rather conceal the mal-odour than correct contagion. The evaporation of common vinegar by heat is often employed as a fumigation, but it is not possessed of much power of diminishing the fetid odour of putrid air. The acetic acid or radical vinegar is better; its powers are however limited to a small space, and therefore, though it may be useful about the persons of those who attend the sick, it is inadequate to the purification of large rooms.

The stronger and better fumigations are the nitrus or marine acid, and the oxyuratic acid vapour, the former of which is made thus: half an ounce of nitre reduced to powder and nitric acid (oil of vitriol) in equal quantities, mixed in small pots, and placed in various parts of the room.

Oxyuratic acid, which is most powerful, is prepared thus:

Manganese - - - 2 parts.
Common salt - - - 4 parts.
Vitriolic acid, specific gravity 1.85 3 parts.
Water - - - 1 part.

To a small quantity of the mixture of the manganese and salt, (suppose three ounces,) the whole of the water is to be added, (half an ounce,) and to this, in a pot large enough to prevent the ebullition from flowing over, add the vitriolic acid from time to time. This will keep up for twenty-four hours a discharge of the oxygenated nitric acid, of which the smell is not unpleasant, and the vapour gives no annoyance to either the sick or the attendants.

Where houses or hospitals are highly infected with the plague, it will be necessary for them to undergo a stronger fumigation of sulphur, but that being attended with danger should only be done by persons properly acquainted with the manner of doing it; they should afterwards be white-washed, and the floors well scoured.

It may be stated once for all, that the great object of quarantine laws is the separating of those affected, or suspected to be infected with an infectious distemper, from those who are not, and nothing would be so salutary or absolutely necessary, wherever the plague breaks out, as instantly separating of the sick from those who are well; and this is best done by removing them to a proper place, rather than suffering them to remain with their family, which too frequently by that means becomes infected also.

Whatever is requisite to be done by way of fumigation will be found at large under that head; the following precautions are, however, proper to be known.

The clothes of the sick should at all times, when changed, be removed by tongs, and not by handling, and should be put into cold water and boiled for an hour, and afterwards be well washed in washing machines, and then fumigated or they may be baked in an oven; but the safer mode would be to have them destroyed, especially if not valuable.

Those who attend about the person of the sick, as well as the medical men, should remain as short a space of time as is consistent with their duty, and to avoid as much as possible all contact with his person or his bedding, clothes, &c. And they might be furnished with gloves made of oiled silk, as well as drieves made of the same article. The cup or glass out of which he drinks should be immediately plunged into water or vinegar, as well as any article he touches or uses. Whatever he leaves of his meals should be burnt or wholly destroyed. The excrementitious discharges should also be received into cold water, and instantly removed out of the room. If the sick die, he should be immediately wrapped in oiled cloth or a tarpaulin, and be speedily buried at the depth of six or seven feet; which should be performed, without bubble, in the night time, without toll of bell, to prevent the alarming of others.

With respect to the bed and bedding upon which the sick has died, it would be best to have it burnt immediately; at all events, it must on no account be used till it has been baked in an oven for twelve hours (being rolled up and removed in a cart with every possible care, that it be as little handled as possible). It should be afterwards exposed to the open air for at least fourteen days before it is again used. Furniture
QUI

Furniture consisting of chairs, bedsteads, &c., should be scoured and fumigated with sulphur and faw-dust for twenty-four hours, first removing every person out of the apartment, as no living creature can exist in the fumes for any length of time.

Houses and apartments should be fumigated in like manner, and be afterwards purified by the admission of as much air as is practicable, and also by scraping and washing the walls with lime-water, and the floors with plenty of cold water.

And lastly, we cannot inculcate too much the fact, that the belt preventive of infectious disease, and the most effectual mode of diminishing the effects of its contagion, is by the free admission of pure air, even in the room of the sick, who, to admit of its free circulation, should not have bed or window curtains, and by the greatest attention to cleanliness. By the removal of the rest of the inhabitants from the sick house to a place of observation, for the space of twenty days, and by the sick being also confined for an equal length of time, having persons appointed to prevent his escape, and to have a nurse assigned to him. Articles necessary for his support must be delivered by means of baskets or planks, as well as those received from the house, and all money received in payment to be dipped in vinegar.

Large assemblies should not be permitted to meet while towns are infected, and the theatres, churches, and markets should be closed; and if these precautions are strictly adhered to, we are confident that if the contagion cannot be wholly prevented, its spreading may be greatly confined, and its malignity considerably lessened.

QUARTZ. See QUARTZ, and MINERALOGY, Addenda.

QUASSIN, in Chemistry, the name which has been given to a bitter substance extracted from quassia. See BITTER Principles.

QUEEN Anne’s. Add—It contains 16,648 inhabitants, of whom 6,981 were negroes in 1812.

QUEMAKO, a township of Somerset county, in Pennsylvania, having 1,592 inhabitants.

QUERCITRON. See QUERCEUS Tinctoria, and PRINTING on Calico.

QUILOA. At the close, add—An island of Quiloa was visited by Capt. Beaver in 1812. He describes this island, which has been the seat of royal residence, since the foundation of the kingdom, at least 700 years, as being about six miles long and three broad; low and fertile, extending longitudinally across the mouth of a deep bay, having at either end an opening for two arms of the sea, and thus containing a peninsula which projects from the main land, forms two safe and magnificent harbours, capable of containing, in perfect security, the largest fleets. Of the splendid splendour and magnificence that subsisted when the Portuguese first visited this island, not a vestige remains. The present city, if it deserves the name, consists of a number of scattered huts from the borders of the sea to the shore. Here Capt. Beaver found the deputy of the Imam of Mufcat, who controlled the miserable Moors or Arabs who are in possession of the sea-coast, with his half a dozen of soldiers, situated in a round tower, mounting three guns, which pointed directly to the king’s house, and at the distance of a musket-shot from it. By these means, he keeps the king of the extensive kingdom of Quiloa in awe, and levies a tribute in flaxes, ivory, gold-dust, and many other articles exported from this part of the coast. The Moorish king is the only nominal sovereign both of the islands and of the shores of the continent.

QUINCUNX, l. 21, add—The notion, however prevalent, that plants thus set have greater scope than when set at the same distance without alternation, is perfectly imaginary: thus below it is evident, that the square mode becomes a quincunx when viewed angularly, and the quincunx, in like manner, becomes a square; and the distance of the plants is the same in both.

QUINTAL, col. 2, l. 3, add—The Castilian quintal is divided into 4 arrobas, or 100 lbs.; the lb. into 2 marcs, or 16 oz.; the marc into 8 drachmas, 16 adarmes, or 576 grains. The merchants commonly reckon 100 lbs. Castilian weight equal to 102 lbs. avoirdupois; but the more accurate proportion is as 123 to 125.

QUIRA, or QUIRIA, in Geography, a province of the ancient kingdom of Colchos enclosed by the end of the Muffian hills. It is a pleasant and fruitful country, and, from the ruin that still remain, we may conclude, that it was formerly flourishing and populous in an extraordinary degree. The residence of the prince of Quiria is Titi-zigh or Ighina (the ancient Pitius), situated on the shores of the Black sea, with a secure and spacious harbour. The only considerable river of Quiria is the Bos, which rises 30 versts from Titi-zigh, and after a course from E. to W. empties itself into the Black sea.

QUIRILIA, the only river of consequence in Imeritia, or, as it is now called, Iberia. It rises in the Soami ridges and being increased by the snow-streams which descend from the Georgian side of the Caucasus, enters the Phasis, in the neighbourhood of Cotaxis.
RACOON, in Geography, a township of Gallia county, in Ohio, having 295 inhabitants.

RADIATION of Heat, a property of heat or circumstance belonging to it, which has been lately investigated and successfully illustrated by professor Leflie of Edinburgh. There are two modes in which heat is discharged from bodies. A portion is communicated to the contiguous matter, and is slowly diffused through it. Another portion, when the body is placed in an aerial medium, is discharged with rapidity, darts through the air to a distance, and even at that distance, when intercepted, produces a heating effect. This forms what is called the "radiation of heat." Mr. Leflie has discovered the important fact, that different kinds of matter, at the same temperature, discharge very different quantities of heat by radiation. From a metallic surface, the quantity is comparatively small; from a vitreous surface, it is much greater; and it is still more so from a rough spongy surface.

The power of different surfaces in discharging different portions of heat, in this mode, at the same temperature, Mr. Leflie ascribes to the more or less close contact which they admit with the external air; a vitreous surface, for example, admitting of a closer proximity of the air than a metallic surface does, and thereby communicating to it, in a given time, a larger portion of heat. And on the same principle he explains the fact, that those surfaces which are most powerful in thus discharging heat, are also most powerful in arresting and absorbing it; the closer contact into which the heated air comes with the surface on which it impinges, favouring the transfer of its heat; while a surface, to which the heated air does not approach so closely, will in a great measure reflect it with little loss of heat. Hence the discharging and absorbing power are proportional to each other; while the reflecting power is the reverse.

Some important practical applications resulting from these differences are suggested by the author.

A vessel with a bright metallic surface is the best fitted to preserve liquors either long warm, or as a conservatory to keep them cool. A silver pot will emit scarcely half as much heat as one of porcelain; and even the very slightest varnishing of gold, platina, or silver, which communicates to the ware a certain metallic gloss, renders this new kind of manufacture about one-third part more retentive of heat. The addition of a covering of flannel, though indeed a flow conductor, far from checking the dissipation of heat, has directly the contrary tendency; for it prevents to the atmosphere a surface of much greater propulsive energy, which it would require a thickness of not fewer than three folds of this loose substance fully to counterbalance. The cylinder of the steam-engine is lately been most advantageously sheathed with polished copper.

The progress of cooling is yet more retarded, by surrounding the heated vessel, on all sides, at the distance of near an inch, with a cafe of planished tin; and the addition of other cafes, following at like intervals, augments continually the effect. With an obstruction of one cafe, the rate of refrigeration is three times slower, with two cafes it is five times slower, with three cafes it is seven times slower, and so forth, as expressed by the succession of the odd numbers. By multiplying the metallic cafes, therefore, and disposing them like a net at regular intervals, the innermost could be made to retain the same temperature with little variation for many hours or even days. Such an apparatus would obviously be well calculated for various culinary and domestic purposes.

In the conveyance of heat by means of steam, the surface of the conducting tubes should have a metallic lustre. On the contrary, if it be intended by that mode to warm an apartment, they should be coated on the outside with soft paint, to facilitate their discharge of heat. For the same reason, metallic pots are more easily heated on the fire, after their bottoms have become tarnished or smoked. If a bright surface of metal be slightly furrowed or divided by fine flutings, it will emit heat sensibly faster, because the prominent ridges, thus brought closer to the general atmospheric boundary, will excite the pulsations with augmented energy.

For the experiments which led to this discovery, and the conclusions deduced from it, we refer to his "Essay on Heat," and to a "Short Account of Experiments and Instruments depending on the Relations of Air to Heat and Moisture." See Heat. See also Dew, Rays of Heat, and Refrangibility of Radiant Heat.

RADNOR, in Geography, a township of Ohio, in Delaware county, having 347 persons.

RAJAFOOT, denotes literally the son of a king, and is used as the name of a warlike race of Hindoos.

RAM of M. Montgolfier. Add—See Water.

RAMA, or RAMAH. Add—This was a common name applied to many places in the Holy Land; and it is suggested (see Clarke's Travels, vol. iv. p. 432.), that the modern village of Bethor and the modern Rama are the places
places mentioned by St. Jerom, where he says, “Rama et Bethoron et relicuæ urbis nobilis a Salomone constructæ parvi villuci demonstratur.” Rama was a village in the time of Jerom, and the situation of Bethoor is distinctly marked in the Apocrypha, with reference to the plain of Rama. (I Maccab. iii. 16. 24.) (However, the prophecy of Jeremiah (xxxvi. 15.) applied by St. Matthew (ii. 17.) to the murder of the Innocents by Herod is not believed to refer to the place now mentioned, but to another Rama, noticed by Eusebius.) The origin of Rama has been ascribed to the Molems under Solomon, for it is flated to have built the town with materials from the ruins of Lydda, distant three miles from Rama. But that this is an error may be evinced by reference to the writings of St. Jerom; who speaks of its vicinity to Lydda, and calls it Arimathea, from a prevalent opinion that it was the native place of Joseph, who buried our Saviour. Jerom’s testimony, preceding the Mahometan conquest of the country, is sufficient to prove that the city existed anterior to the invasion of Palestine by the Molems. Nevertheless it is possible that Rama, from having been a small village, might have become a large town under their dominion: nor does there seem much reason to doubt, that this Rama was the village mentioned by Bethoron by St. Jerom, as the only remains of the two cities fo named, which were built by Solomon. According to Reland, the oldest writer who mentions Rama is Bernard the monk, who visited the Holy Land in the 9th century. Oriental geographers describe it as the metropolis of Palesine; and it is said that St. George, the tutelar saint of our ancestors in England, suffered martyrdom in this place; though others say, that his relics reposed in a magnificent temple at Lydda or Diopholis. Its distance from Jerusalem, usually estimated at a day’s journey, is described as equal to 36 or 37 miles by Phocas; who distinguishes Armathem, the native place of the prophet Samuel, from Ramola or Rama, with which Adrichonius seems to have confounded it; and places the church of St. George within the latter city; which position, although disputed by Reland and other authors, not only seems to coincide with the testimony given from the Alexiad of Anna Commena, but also with the evidence afforded by Bernard the monk, who mentions a monastery of St. George near Ramula. There is not a part of the Holy Land more fertile than the plain around Rama; it resemhles a continual garden; but cultivation had been neglected at the time of the arrival of Dr. Clark, the traveller now cited, owing to the dreadful plague with which the whole country had been infected. Rama and Lydda were the two first cities of the Holy Land that fell into the hands of the Christians when the army of the Crusaders arrived. Rama was then in its greatest splendour; a fenced city, abounding in all the luxuries of the East. It was exceedingly populous, and was adorned with fretted buildings, and well fortified with walls and towers. The count of Flanders having been dispatched by the princes and generals of the Christian army, with five hundred cavalry, to reconnoitre the place, and to summon the city to surrender, found the gates open, and the inhabitants, alarmed by the sudden approach of so powerful an army, had abandoned their dwellings and all their property during the preceding night. In consequence of this, a general rendezvous of the Christian forces took place in Rama, where they remained during three entire days, regaling themselves in the abundance the place afforded. During this time, Robert of Normandy was elected bishop of Rama and Lydda, to which bishopric all the revenues of the two cities and their dependencies were annexed; the whole army joining in thanksgiving to St. George the Martyr, the patron saint of Diopholis and Rama, to whom the auspicious commencement of the enterprise was attributed. Hence probably originates the peculiar consideration in which St. George was held by the inhabitants of England, during the early periods of its history.

RAMSBURY. By the returns of 1811, the parish of Ramsbury contained 396 houses, and 2025 persons; viz. 1028 males, and 1057 females: 248 families being employed in agriculture, and 85 in trade, manufactures, and handicraft.

RAMSDAL, dea.

RANDOLPH. Add—in 1810, their number was 1170; l. 3 of next article, infert—including 708 slaves.

RANDOLPH, a county of the Illinois (dele Indiana) territory, containing four townships; viz. Kalkakia, United States’ Saline, Shawanee, and the residue of Randolph county, and 12,832 inhabitants, including 168 slaves,—Also, a township of Montgomery county, in Ohio, containing 336 inhabitants.

RAPIDES. Add—This is one of the best tracts in Louisiana. No town except Alexandria, on the right bank of the Red river, has been found. (fays Mr. Darby, 1816,) in the parish of Rapides. This place is a thriving little village, and standing at the head of conjunt boat navigation, is of considerable commercial importance. The staples of the parish are, cotton, timber, beef, pork, and maize; the four first being the principal.

RATE, l. 8, for Ireland r. India; in Ireland fix, legal interest charged by all private banks, though the interest charged by the bank of Ireland for money advanced is 5 per cent.

Rate of a Ship, &c. col. 2, l. 39, add—About ten years ago, an additional lieutenant was appointed to the line of battle ships. Ships of 50 and 38 guns have four lieutenants: l. 5 from bottom, after lieutenants, infert—ships of 20 guns, and all ships upon the establishment of slopes of war, have two lieutenants. Col. 3, l. 14, add—See Ship.

Rate of Ships of War, add—By an order of council, the operation of which commenced Jan. 1, 1817, the following regulations were fixed with regard to rates in the navy; viz.

1st rate. All three deckers.

2d rate. All of 80 guns, and upwards, on two decks.

3d rate. All of 70, and under 80 guns.

4th rate. All of 50, and under 70 guns.

5th rate. All of 36, and under 50 guns.

6th rate. All of 24, and under 36 guns.

1st rate, 900, 850, and 800 men.

2d rate, 700 or 650 men.

3d rate, 650 or 600 men.

4th rate, 450 or 350 men.

5th rate, 300 or 280 men.

6th rate, 175, 145, or 125 men.

RAVA, in Geography, a town of the Persian empire, in the pachalic of Bagdad, situated between Kerkefia (the Roman Cicryfum) and Annah (the Amatho of Ammianus Marcellinus); and confiding of about 200 flame houses in the midst of extensive ruins. On the opposite side of the river are the remains of a castle, erected on the summit of a rock.

RAYUN, a town of Persia, in the province of Kerman, which, like Tchroot and Mahim, is surrounded by numerous gardens.

READING, a township of Fairfield county, in Ohio, having 780 inhabitants.

REALIZE, r. Realize. or Realize.
REV

RED ASTIMONY-OBE. See Mineralogy, Addenda.
REDSTONE. Add—the township situated in Fayette county contains 1224 inhabitants.

REEL. See Manufacture of Cotton.
REFRACTION, col. 14, l. 40, for sign r. fine.
REFRIGERATION. The following laws have been deduced by MM. Dulong and Petit from their experiments on the cooling of bodies. See Heat.

1. If the cooling of a body in a vacuum surrounded by a medium whose temperature is constant could be observed, the velocity of cooling would decrease in a geometrical progression, while its temperature would decrease in an arithmetical progression.

2. When the temperature of the medium surrounding a vacuum remains constant, the velocity of cooling for excess of temperature in arithmetical progression decreases as the terms of a geometrical progression diminished by a constant number. The ratio of this geometrical progression is the same for all bodies, and is equal to 1.0077.

3. The velocity of cooling of a body in a vacuum for a constant excess of temperature increases in a geometrical progression, the temperature of the surrounding medium increasing in an arithmetical progression. The ratio of that progression is still 1.0077 for all bodies.

4. The velocity of cooling arising from the simple contact of a gas is entirely independent of the nature of the surface of a body.

5. The velocity of cooling arising from the simple contact of a fluid varies in a geometrical progression, the excess of temperature varying at the same time in a geometrical progression. If the ratio of this second progression be 2, that of the first is 2.35, whatever may be the nature of the gas or its elasticity.

REVOLUTION, French. At the close, add—On the 4th of June 1814, the king (Louis XVIII) came to the two chambers to make a declaration of the constitutional charter; and on the occasion delivered a speech distinguished by its dignity and propriety. On the 11th of March 1815, however, Buonaparte, having escaped from Elba, landed in France, and by rapid and uninterrupted marches hastened to Paris, and resumed his power, March 22, 1815, but his fate was finally determined by the battle of Waterloo; and he made his second abdication, in favour of his son, on the 23rd of June 1815; and on the 15th of the following month, the foreign troops entered the capital. Disappointed in his views of settling either in America or in England, he surrendered himself, with a suite of forty persons, to Captain Maitland of the Belleroiphon, July 15, 1815; and at Torbay he was transferred to the Northumberland, which conveyed him to the island of St. Helena, deeded by the allied sovereigns to be the place of his future abode. Here he arrived Oct. 16, 1815. Upon his departure from Paris, Louis XVIII. was again restored and fixed by the allied powers on the throne of France.

With respect to the events that have occurred since this article was written, such as the famous battle of Waterloo (see WATERLOO), the total defeat of Buonaparte, his deposition from the government, his removal from the capital, his confinement in the island of St. Helena, the re-establishment of Louis XVIII., the withrawment of the allied troops, and the measures adopted for the secure and permanent sovereignty of France, under the present dynasty; they are so recent, and our limits are so restricted, that we must refer the reader to documents easy of access for a minute detail and more ample information.

RHEA, in Geography, a county of East Tennessee, containing 2504 inhabitants.

RHODE
RHODE ISLAND. Add—See United States.

RUMB, col. 2, l. 20 from the bottom, for right angles r. equal angles.

RICCI, Domenico, called Bruna-Verri, in Biog., an eminent painter, was born at Verona in 1494, and became a disciple of Giovanni Francesco Caroto, under whose instruction he laid the foundation of his subsequent celebrity. For further improvement he studied the works of Gorgione and Titian at Venice; and his proficiency was such, that his works have been generally admired and sought after, on account of the beauty of his colouring and the attitudes of his figures. Under the patronage of cardinal Gonzaga, by whom he was invited to Mantua, he became a competitor in the exercise of his art with two of the most celebrated masters of his time, Paolo Veronese and Paolo Farinato. In the church of St. George at Verona is a picture by Riccio, which represents the gathering of the mena in the wilderness, and which is accounted a fine composition, and distinguished by the force of its colouring. This master died in 1567, at the age of 73 years.

ROANE. Add—of whom 670 were slaves in 1810.

ROARING. A disease of horses, well known to jockeys and dealers in these animals. It takes its name from a fin-
where he had to support himself only by his own exertions. He himself embarked in trade; he educated his sons to useful trades; and he was contented at his death to leave them, instead of his original patrimony, no other inheritance than the habits of industry he had given them; the example of his own virtuous life; an hereditary detestation of tyranny and injustice; and an ardent zeal in the cause of civil and religious freedom. To him I owe it, among other inestimable blessings, that I am an Englishman. Gentlemen, this is my origin; and I trust that I need not blush to own it."

The father of Sir Samuel was an eminent jeweller, and realised a handsome fortune; his mother, whole maiden name was Garnault, was defended from a family of French refugees; and he being the youngest of nine children, of whom three only attained to maturity, was born in Frieth-street, Soho, in the city of Westminster, on the 1st of March, 1757.

In early life he manifested those powers of the understanding, and those affections of the heart, which, under proper direction and affinuous culture, augured his future advancement to eminence of station and character. "He was remarkable," says one of his biographers, "for the benevolence of his disposition, his deep and generous sensibility, his high sense of honour, the quickness of his apprehension, and the extraordinary maturity of his judgment;" combining "great vivacity and a constant flow of animal spirits, with a powerful imagination, a retentive memory, and the strongest and most durable affections;" he possessed a correct taste in literature and the fine arts, and retained throughout life a keen relish for the beauties of nature. It was his good fortune, at an early age, to form an intimacy with the Rev. Mr. Roget, a young gentleman resembling himself in taste and disposition, and afterwards his brother-in-law; to whom he was much indebted, as he himself had the modesty and gratitude to acknowledge, for giving direction to his talents, and a steady impulse to his exertions.

Thus liberally endowed by nature, and aided by the counsel of an intelligent and affectionate friend, he overcame a variety of obstacles which presented themselves in the way of his progress and advancement; and having chosen the profession of the law for the exercise of his talents, he soon exhibited those powers and that persevering application, which, without the advantages of a patrimonial estate, and an education at a public school or university, ensured his future eminence. Having enrolled his name in one of the Inns of Court, and previously acquired some notion of business in the "Six Clerks' Office," connected with the court to which he directed his views, he was called to the bar in 1783; and from the reputation he gained as an "equity draughtsman," he soon rose to the higher departments of his profession. Upon the removal of Thurlow, Scott, and Mitford, from the chancery court, Mr. R. became a leader, and was retained in almost every cause. "His indefatigable industry, his unwearied patience, his comprehensive acuteness, his deep knowledge of the law, his correct notions of the practice of the court, were all calculated to give due weight to arguments selected with skill, propounded with modesty, and enforced by a chauked eloquence."

Raised to an independence by his own exertions, it was natural for a person of his disposition to seek a domestic establishment; and accordingly in the summer of 1797, whilst he was upon a visit at the seat of the marquess of Lanfdowne, he met with a daughter of Francis Garbett, esq. of Knaill-Court, in the county of Hereford; a young lady, whose youth and beauty and other amiable qualities engaged his affection, and determined his choice; and to whom he was married in the following year. This connection opened to his views the prospect of a growing family, and of course induced him to apply to the business of his profession with additional ardour and assiduity. Accordingly when Mr. Fox and Lord Grenville assumed the reins of government in the year 1806, he was nominated solicitor-general, after some suipenfe about committing to his custody the great seal, and received the honour of knighthood.

It is recorded to the honour of Sir Samuel, as well as to that of his colleague Sir Arthur Pigott, the attorney-general, that, though the pros, according to the language of Lord Chatham, was become, during their time, a "chartered libertine," and political contention had arrived at its height, yet with a kind of triumph over all provocations which affrighted the administration of this period, no prosecution for libel occurred. Indeed, the mind of Sir Samuel was occupied about a much higher object, which was the reform of the English system of jurisprudence. His first attempt with this view was an amendment of the bankrupt laws, and though he did not succeed to the extent of his wishes, so as to render the freehold estates of persons liable to the bankrupt laws, who might die indebted, affetes for the payment of their simple-contray debts, for which he was allowed to bring a bill into the house of commons in 1807, which bill was lost on a division; he nevertheless obtained an act by means of which the debts of traders have been more effectually secured, for the benefit of the public. About this time he acted as a manager at the trial of the late vicount Melville, for high crimes and misdemeanors in his office as treasurer of the navy, which terminated in an acquittal.

On occasion of the abolition of the slave trade, which conferred immortal honor on this short-lived administration, Sir Samuel delivered a speech which made great impression on the house; and it is said that one passage of it, which he uttered with an uncommon degree of animation, was honoured by three distinct plaudits. On the dismissal of the ministry, of which he formed so distinguishing a part, he vindicated and applauded their conduct, during the year of their existence; expressing in terms of cordial approbation their decisive measures with regard to the abolition of the slave-trade, and the emancipation of Ireland, as well as their refusal to give the king a pledge not to renew the Roman Catholic question; and deploreging the return of Lord Melville to office, notwithstanding his acquittal, as no one had moved for refinding the vote against him.

The attention of Sir Samuel, both in and out of office, was much occupied concerning the state of our criminal code, and the adoption of measures for reforming it. He lamented, in common with many other enlightened patriots, that the loss of life should be annexed to a greater variety of actions in England than in any other country in the world, and that criminals of very different descriptions should be subjected, by the administration of our laws, to the same kind and degree of punishment. To rectify this anomaly in our jurisprudence appeared to Sir Samuel Romilly to be an object of great importance, in its connection, both with the equity and humanity of legislation, and the prevention of crimes. Accordingly on the 1st of May 1808, he moved for leave to bring in a bill for the repeal of certain objectionable laws; and in this bill he introduced a clause for granting compensation to persons who were unjustly accuited and tried. He soon after published a pamphlet, intitled "Observations on the Criminal Law of England, as it relates to capital Punishments, and to the Mode in which it is administered." In this pamphlet, which passed through three editions, he explained his views, and purified his refutation of the theory of Dr. Paley. "The certainty of punishment,"

ROMILLY.
ment," says this excellent writer, "is much more efficacious than any severity of example for the prevention of crimes. So evident is the truth of this maxim, that if it were possible that punishment, as the concomitant of guilt, could be reduced to an absolute certainty, a very slight penalty would be sufficient to prevent almost every species of crime, except those which arise from sudden gusts of ungovernable passion. If the restoration of the property stolen, and only a few weeks', or even a few days' imprisonment, were the unavoidable concomitance of theft, no theft would ever be committed."

Sir Samuel, having actively concurred in the abolition of the slave-trade, could not forbear expressing his indignation, when the house of commons, in the year 1814, took into consideration that article in the treaty of peace which allowed of the prosecution of the slave-trade for a period of five years, and when he found that the ministers of this country had acceded to any convention, in which this was a prominent stipulation. "If," says the biographer whose article we are citing, "the king of France has relaxed on his part, and declared the trade in human beings to be annihilated, so far as concerns his own dominions, it is to Sir Samuel Romilly, and those who supported him on this occasion, that we are to attribute the change."

The subject of this memoir soon afterwards distinguished himself by his opposition to the appointment of a new judge and tribunal for facilitating public nuisances and alleviating the labours of the lord-chancellor. This he considered and represented as an innovation, from which neither the chancellor, nor the tutors of his court, nor the public in general, would eventually derive any advantage. In a pamphlet under the title of "Objections to the Project of creating a Vice-chancellor of England," he announced to the public his opinions on this subject, "the general result of which was, that the new division of chancery into two courts, and the creation of an intermediate court of appeal between it and the house of lords, would tend greatly to enhance the expense of suits 'already grievously and oppressively high,' to multiply the business of the court, and to protract the final decision of causes." "The remedy," he adds, "my lord, which I have to propose, is a very simple one, but I am much afraid, considering the force of several expressions which I find scattered in your lordship's pamphlet, that you will think me difrepectful even in mentioning it. You have, however, really left me no choice. You have imposed upon me the necessity of being deficient in what you will think due respect, in order to avoid the reproach of being deficient in what you have made my duty. The remedy, then, my lord, seems to be, That the house of lords, like all inferior tribunals, should, when they are pressed with an unusual quantity of business, sit on a greater number of days and at unusual hours, in order to dispatch it." His letter, and as some have thought his bell speech, was delivered, at the close of the last parliament, against the "Alien-bill," and so powerful were his arguments, that, on his succedion, the amendments introduced by the lords were thrown out. In this speech, the eloquent senator details and reprobrates the measures adopted and pursued by the parliament just expiring, and he closes with the following reflection: "who our succeffors may be I know not; but God grant that this country may never see another parliament so regardless of the liberties and rights of the people, and of the principles of general justice, as this parliament has been!" However the political opinions of persons may differ, they must concur in admiring the integrity and ardour of the speaker; and considering it as the last speech which he ever delivered in the national senate, the perilof it cannot be otherwise than awful and impreffive.

Nothing ever deviated his time and talents to important and useful purposes with greater affinity and zeal than Sir Samuel Romilly. His professional practice, which was very extensive, demanded a great portion of his time and attention; and yet whenever the public interest required his attendance in the house, he never abdicated himself on account of any personal engagements. His practice and his parliamentary duties occupied the whole of the day from the morning dawn frequently till midnight; and his publications were the productions of those hours that ought to have been devoted to repose and sleep. It is not at all surprizing that talents like his, and so employed, should command general notice and respect. In a former parliament many enlightened and respectable members of the city of Bristol directed their views to him, and wished for such a representative; but other interludes prevailed against his abilities and character, and the influence of his friends. At the last general election, he was propofed as a fit representative for Westminster, his native city; and he was chosen in the most honourable manner, without trouble, expense, and solicitation, by a decided majority, and amid the applause of an immense body of electors. But a circumstance occurred which rendered the closing period of his life gloomy and disheartening, and which disappointed the expectations of his constituents. Lady Romilly, to whom he was affectionately attached, and with whom he had enjoyed a high degree of convivial felicity, had been for some time in a state of declining health, and his mind was agitated by very disquieting and depressing apprehensions on her account. During their residence at their country-house at Tanchur, in Surry, in August 1818, her complaint seems to have abated, and with the flattering hope that her convalescence would be confirmed by the mild air of the Isle of Wight, they accepted an invitation from Mr. and Mrs. Nash, to spend the remainder of the vacation at their hospitable castle at East Cowes, whither they removed in the month of September. Here lady Romilly's disorder recurred with circumstances of peculiar aggravation; and Dr. Roget, the nephew of Sir Samuel, was summoned to her relief. Her complaint, however, was irremediable; and after various fluctuations, which excited alternate hope and alarm, she died of a dropsy in the cheif, in the night of the 29th of October. During the progress of her disorder to its fatal termination, Sir Samuel's mind was kept in a state of constant suspense and anxiety, until at length his sympathy with the amiable sufferer and an apprehension of the uncertain issue of her complaint, disordered his whole frame, deprived him of sleep or scared him with frightful dreams; and it is said, that on one occasion, after having been in a state of great distress, he intimated to a friend, that he felt a burning sensation in his head; and this seems to have been the only occasion on which he made a complaint of this kind. Alarmed about himself, he fought relief, and tried a variety of medicines without any permanent effect. "He frequently expressed his surprize, that his want of sleep did not interfere with his bodily health, that his appetite and digestion continued in full vigour, that no indication of fever existed, and that he felt no uneasiness in his head. In conversing with Dr. Roget and Mr. Dumont he dwelt much on this apparent anomaly, and drew from it the most ominous prefiguration, as to the probability of its ending in infanty—an apprehension which unfortunately took deep root in his mind. Although in all other respects he was perfectly in possession of his faculties, yet on this subject his imagination
tation was certainly disordered, and we may trace, in the intensity of this dread, the incipient flame of mental derangement. A striking instance of this feeling appears in one of the entitled papers written by him about this time, in which he gave particular directions as to the management of his property, the care of his children, and the custody of his person and estate, in the event of his becoming lunatic. It may be remarked also, that the circumstance of his losing right, in a great measure, of the primary cause of his grief, and of fixing his attention so much upon his own feelings, was so opposite to his natural disposition, as in itself to constitute a strong feature of aberration." Other circumstances, which occurred on his interviews with his friends, confirm the same observation.

On the morning after lady Romilly’s death, when Dr. Roget informed him of the event, he received the intelligence with calmness and resignation, and without any effusion of grief; and prepared to quit the scene of his sorrows at the suggestion of his friends without hesitation or demur. At Marble-green, where they lodged in their way to London, we learn from Dr. Roget, who puffed the night in the same room with him, that, although he was of a general reliefs, yet, at intervals, he enjoyed tranquil sleep; nor did he betray, at any period, the smallest sign of impatience or irritability. As he approached London, however, on the following day, his agitation increased, and he once complained to his daughter that his head was disturbed. After his arrival at his own house in town, he ate his dinner with his usual appetite; he then went for Dr. Marcet, who inquired particularly concerning the state of his head, and was informed by sir Samuel, “that he had no head-ache, nor any uneasy sensation whatever in his head.” “The symptoms present were those of a high degree of nervous irritation, unaccompanied by fever or any inflammatory action; but they were of a nature to excite considerable alarm as to the state of his mind. Though he refrained from giving vent to his feelings, it was evident, from his manner and from the expressions which dropped from him, that he depair of his recovery, in spite of every endeavour to inspire him with hope and comfort.” To the use of all means that were recommended for allaying his extreme irritation he objected; alleging, “that he must necessarily pass a wretched night, and that if he were to use any medical prescription, it would only have the effect of taking away all his confidence in the powers of medicine.”

During the greater part of the night, Dr. Roget, who slept in the same room, reports that he was perfectly tranquil and apparently asleep; though in the morning sir Samuel assured him, that he had never, for an instant, dropped asleep.

The next morning the reftlessnes returned, and was attended with symptoms of fever; the tongue became white during the night, and the pulse at one time rose to 150 in a minute. Upon consulting Dr. Marcet, it was proposed, at his suggestion, to apply ice to the head, and to have recourse to cupping; but before these measures were adopted, Dr. Babington was sent for, and before he arrived the excitement had subsided, and sir Samuel was much relieved by a copious perspiration. Upon consultation it was agreed, that the measures proposed by Dr. Marcet, in existing circumstances, would not be expedient; and other medicines of an active nature were preferred. These were taken by sir Samuel without reluctance; and he continued tranquil and apparently asleep till about two o’clock. His daughter remained at the side of his bed, who observed upon his awaking, that he became restless and agitated. Upon being asked whether Dr. Roget should be called, he replied in the negative; but upon a second inquiry, he faintly assented. During the short interval of sir Romilly’s absence, a sudden paroxysm had seized him, hurried him from the bed, and armed his hand against his own life. The razor with which he had inflicted the fatal wound was in his hand when Dr. Roget entered his apartment. Before he expired, as his biographer proceeds in the relation of the melancholy catastrophe, he made signs that he wished to write, but though supplied with pen and ink, nothing intelligible could be collected from his attempts. He then defied from making them, and joining his hands, appeared, from the movements of his lips and eyes, to be absorbed in fervent prayer. It is hardly necessary to state, that the jury summoned on the coroner’s inquest brought in a verdict, “that the deceased had destroyed himself in a state of temporary mental derangement.”

Sir Samuel and his lady were interred at the same time, in the same grave, at Kailly, the seat of her ancestors, in Herefordshire. The funeral, agreeable to the instructions of his will, was private; being attended only by his nearest relations and most intimate friends. Six fans and one daughter survived to lament the irreparable loss which they sustained. The calamitous event, which thus awfully terminated the life of sir Samuel Romilly on the 2d of November, 1818, in the 62d year of his age, made a deep impression, not only in the circle of his family and friends, but through the country in general. So highly was he respected and esteemed, that, on this melancholy occasion, “the solicitors suspended their practice; the counsellor abandoned the courts; while the judge forsook the bench, after he had shed a torrent of tears!” The following singular circumstance is mentioned by his biographer, viz. that in the parish church of St. Bride, Fleet-street, there is a simple undecorated tablet placed against the wall, with an inscription on it to the memory of Mr. Isaac Romilly, F.R.S., who was the uncle of sir Samuel, and who died in 1759, of a broken heart, seven days after the deceas of a beloved wife. For the materials and authentic documents that have furnished this article, we refer to the “Annual Biography and Obituary for the Year 1819.”

ROMNEY, in Geography, a town of Grafton county, in New Hampshire, containing 765 inhabitants.

ROOFS, in Rural Economy. — Accepted of iron have lately been introduced with advantage. Mr. T. Pearfall of Bath has constructed several in the neighbourhood of Brisol and London: and on a comparison of a roof of this kind with that of timber, he observes, that the iron-roof is fixed on the walls complete for the covering; that the strength and durability of the iron must be allowed to be superior to those of wood; and that the prevention of fire should not be forgotten. By his statement, the whole expense of such a roof, erected over a brick-kiln near Brisol, 25 feet 3 inches in length, and 18 feet 6 inches in span, appears to have been 182l. 11s. 11d.

ROSAMOND, col. 2, l. 17, r. if it cannot be, &c.

ROSS, in Ohio, l. 1, r. 16. — Add—also, a township of Butler county, in Ohio, having 1321 inhabitants.

ROSSO OF Florence, in Biography, called by the French Maître Ross, was born in 1496, and without regular tuition arrived at a considerable degree of eminence in the art of painting. The works of Michael Angelo were his favourite studies, whose style he endeavoured to imitate without servilely following it. hurried away by a lively imagination and great command of the pencil, he could not attach himself to the study of nature, or the antique, so freely as they ought; hence, though his works exhibit great brilliancy of invention,
invention, grandeur in their mazes, gaiety of colour, and taste in the management of the draperies, they are frequently wild and extravagant in composition and effect.

He exhibited his talents early in life, and painted when very young a large picture of the Assumption of the Virgin for the church of La Nunciata at Florence, which was distinguished by the novelty and intrepidity of its style. He painted several other pictures there, and then went to Rome, where reputation had already forerun him. In that city, he painted an altar-piece for S. Maria della Pace, and the Decollation of St. John for the church of St. Salvatore. He remained there till it was sacked in 1527, and then fled to Votterra, where he painted a fine picture for the oratorio of St. Carlo. He went afterwards to Venice, and there painted for Arétin his celebrated picture of Mars and Venus; but not being sufficiently employed in Italy, he accepted an invitation from Francis I. of France, who then emulated the character of an encourager of art and science. By this munificent monarch, Rosso was employed both as an architect and painter, and the building and decoration of the palace of Fontainbleau were intrusted to his care, and he was gratified with a handsome pension, and lived in affluence and ease, as he was not only an able artist, but a man of literary acquirements, and of polished and agreeable manners.

The unhappy termination of the life of Rosso affords a lesson to those whose minds are inclined to indulge fanciful speculations. He had lived in friendship with one Francesco Pellegrini, a Florentine painter, who was in the habit of visiting him occasionally. Soon after one of his visits Rosso's house was robbed of a considerable sum, and he rashly suspected Pellegrini to be the thief. He accused and prosecuted him, but he having endured examination and the torture, to which he was cruelly put to extort confession without any sign of guilt, was declared innocent. As soon as he was released, the unfortunate Fontainbleau published a suit and severe impeachment of his cafe, and appealed for justice to this Rosso had nothing to plead, and to avoid the infamy and remorse to which the injustice he had been guilty of must necessarily subject him, he put an end to his existence by poison in 1541, at the age of 45. The greater part of his paintings at Fontainbleau was destroyed by his rival and successor Primaticcio, to make room for his own productions.

ROSS-SHIRE, col. 2, 1, for 15,348 r. 12,829; and after inhabitants, add—viz. 27,640 males, and 33,213 females; 7,450 families being employed in agriculture, and 2,400 in trades, manufactures, and handicraft.

ROSTRINGA. See Whales.

ROT. Dry, l. 2, add—See Boletes. Col. 7, at the close, add—Mr. Robert McC-William, in a valuable "Essay on the Origin and Generation of the Dry-Rot, with a View to its Prevention or Cure;" to which are annexed, Suggestions on the Cultivation of Forest-Tree, and an Abstract of the forest Laws, from the Reign of Canute to the Present Time," 1818, has demonstratively shown, that the common practice of felling oak in the spring is an error which ought to be avoided; and that the felling of timber is not less important as a means of preventing this disease. This ingenious author confers fungi as a proximate cause of the dry-rot; and as to the origin of fungi, he knows of no found argument against its having been created, like other vegetables, at the beginning of all things. After many investigations and researches, the cause of vitality has not been further thancertained. Dr. Darwin, in his Speculations on the Origin of Microscopic Beings, adopted the incomprehensible doctrine, that their vitality is spontaneous. Buffon, Raymer, Prielely, Ellis, Ingen-
calculation of atmospheric air, and the application of heat may be useful as an auxiliary in promoting such a circulation. He observes, that even atmospheric air itself must be applied with some discretion: for if in its passage through any part of a building which is damp and already affected it should become impregnated withnoxious gases, and be charged with any of the volatile seeds of fungi, it may do more harm than good. It is necessary, therefore, in limine, to remove the infected materials, the discovery of which requires a penetrating eye.

Water is likewise a powerful agent in preventing and remedying the ravages of the rot; and many influences have occurred that prove the antiseptic properties of water acting on wood entirely submerhed in it. But when water is applied as a substitute for air in cellars, vaults, &c. care must be taken that it does not flagmatze, but flow regularly through the drains; in which case it will carry off with it much of the carbonic acid gas, which is so essential a pabulum to fungi.

The charring of timber is of very ancient use, and against external infection is an admirable preservative; but when the principles of decomposition are within, it is of very little advantage in repainting them. Paint, when the timber is properly seasoned and dry, is likewise very beneficial. For other interesting particulars relating to this subject, we must refer to the author's Essay.

ROVING. See Manufacture of Cotton.
ROUM. For Kala r. Kela.
ROWEN. Add—of whom 3757 were slaves in 1810.
ROXBURGHSHIRE, l. 23, for 6518 r. 6423; after inhabitants, add—viz. 17,113 males, and 20,117 females; 3763 families being employed in agriculture, and 2487 in trade, manufactures, and handicraft.
RUBY, SPINEL. See Mineralogy, Addenda.
RUDGELEY. In 1811, the parish contained 453 houses, and 2213 persons; viz. 1089 males, and 1124 females; 127 families being employed in agriculture, and 277 in trade, manufactures, and handicraft.

RUMFORD, l. 1, for Cumberland r. Oxford. Add—
It has 629 inhabitants.
RUSCOMB MANOR, a township of Berks county, in Pennsylvania, having 932 inhabitants.
RUTHERFORD. Add—of whom 979 were slaves in 1810. Add—Also, a county of West Tennessee, having 10,265 inhabitants, of whom 2701 were slaves in 1810.
RUTILE. See Mineralogy, Addenda.
RUTLAND, in America, l. 7, r. 17 townships.
RYE, Chemical Composition of. This grain has been analysed by Einhoff; according to whom 100 parts of good rye-meal consist of

Vol. XXXI.

SABINE, in Geography, a river of Louisiana, being a
temporary boundary between the United States and
the Spanish internal provinces, and part of the permanent
western limits of the state of Louisiana. This river discharges itself into the gulf of Mexico, in N. lat. 29° 23' and W. long. 93° 51', or 10° 57' W. from Washington city. The depth of water at its mouth is not more than four feet on the bar in ordinary tides. This river about 12 miles from its mouth expands into a wide shallow lake, 10 or 12 miles wide and 25 long, with a bearing N.E. and S.W. At the extremity of this lake, it receives both the Sabine and Netches. A line of sea-shell banks is formed along the shore of the lake between the two rivers, and on

the point on the left shore of the Sabine, an increased mount of these shells is found, covered with dwarf trees. About 15 or 20 miles above the lake, wood presents itself in larger bodies, and the wood rives by a slow gradation; and as we advance the woods include the river on both banks, the stream becoming contracted to the width of 150 yards, and so continuing with little variation as high as the Alabama villages, where it shrinks to 70 or 80 yards in breadth, and it prefers this breadth to N. lat. 32°. The source of the Sabine has not yet been precisely ascertained; nor have any settlements of civilized people, a single family excepted, been yet made on the Sabine. The western branch of the Sabine is called Netches; which see.

SACIALCTIC Acid, in Chemistry. This acid has been recently analysed both by Gay Lussac and Thenard, and

by
by Berzelius. According to these chemists, it is composed of:

<table>
<thead>
<tr>
<th></th>
<th>Gay Lussine and Thenard.</th>
<th>Berzelius.</th>

<td>62.69</td>
</tr>
</tbody>
</table>

Which coincide nearly with 5 atoms hydrogen + 6 atoms carbon + 8 atoms oxygen; according to which, the weight of its atom will be 131.25.

SACO, in Geography, a town of Maine, in the county of York, having 2492 inhabitants.

SADDLE RIVER. Add—Alfo, a township, containing 2174 inhabitants.

SADSURY. Add—Alfo, a township of Lancaster county, in Pennsylvania, having 843 inhabitants.—Alfo, a township in Crawford county, in the same state, having 540 inhabitants.

SAHLITE. See Sahlite, and Mineralogy, Addenda.

SAL SEDATIVUS, &c. add—after Sedative SALT, under Salts.

Salem, l. 9, add—This county contains nine townships, and 12,761 inhabitants, including 29 townes in 1810; l. 24, r. 12,593; l. 52, for two r. three; l. 54, add—and a third in Mercer county, having 470 inhabitants.

Salem, New, a town of Hampshire county, in Massachusetts, containing 2107 inhabitants.

SALFORD. Add—the upper contains 838, and the lower 558 inhabitants.

SALINE, a township of Gallia county, in Ohio, having 262 inhabitants.

SALINES. Add—This town appears from the entrance into Salines bay covered with that white fog, so much dreaded, and so well known in Italy by the name of mal-aria. Whenever this phenomenon occurs, the heat upon the island is excessive. Salines, and the towns situated on the E. and N.E. coasts of the island, are subject to such dangerous temperature, that in the months of June and July, perish fall victims to the afflicting malady called by the French Coup de Soleil (a sun-stroke), if they venture out at noon without an umbrella. The great heat experienced upon the eastern coasts of Cyprus is owing to two causes: to the situation of the island with respect to the Syrian, Arabian, and Lybian deserts; and to its mountainous nature, preventing the cooler winds, the west and north-west, from the low shores to the call and north-call. See Cyprus.

SALISBURY, a township of Gallia county, in Ohio, containing 460 inhabitants.

SALIVA, Chemical Composition of. According to the experiments of Berzelius, 1000 parts of human saliva consist of:

<table>
<thead>
<tr>
<th></th>
<th>Water</th>
<th>Peculiar animal matter</th>
<th>Mucus</th>
<th>Alkaline muriates</th>

The peculiar animal matter is soluble in water, insoluble in alcohol, and is precipitated by subacetate of lead. Hence it appears to be a species of mucus. What Berzelius has termed mucus, Dr. Bottock and Dr. Thomson appear to consider as colagulated albumen.

SALMO ALPINUS. Dr. Shaw fugues that, this is the gilt char of Pennant, and the next species or Salvinus is his red char. Taimen, l. pennit. r. 33 feet. Kundsha, l. 3, r. 2 or 3. Lavaretus, add.—See Gwiniad. Dr. Shaw supposed that the gwiniad of Pennant is the S. Wartmanni. L. Leechiihys. Edentules, or tooth-leaf, olive, fawnion, with compressed yellow head, lanceolate red fins, and forked tail: a native of Surinam, where it is highly esteemed as food; r. Anamopus.

SALT, Col. 3, l. 31. r. 2. Silvery for fishes. Col. 4, l. 7, r. Silvery for fishes.

SALT, Lewis relating to, Col. 7, l. 20, add—Mr. Parkes informs us, that he has made inquiry of one of the most considerable salt-importers, who informs him, that they pay only 5. 8d. city-duty on the cargo, whether it be five tons or fifty tons of the salt imported.

SALTS, Supertartrate of Potash. Col. 1, 8, infert.—See Tartrate.

SALTS, in Chemistry. It may be proper to observe here, that a large proportion of the numbers representing the weights of the atoms of bodies given under our article Salts in the Cyclopaedia require correction; for which purpose we refer our readers to the tables appended to Atomic Theory, and to the different articles in the Addenda, where they will find the most recent determinations.

SALT-CREEK, in Geography, a township of Muskingum county, in Ohio, containing 389 inhabitants.—Alfo, a township of Pickaway county, in Ohio, containing 810 inhabitants.

SALT-LICK TOWN, l. 1, add—in the county of Pennsylvania, having 994 inhabitants.

SAM, col. 2, l. 24 from bottom, for fiction r. friction.

SAMBORNTOWN, l. 2. r. Straford.

SANDERSFIELD, a town of Berkshire county, in Massachusetts, containing 1648 inhabitants.

SANDHURST, near Baghot, in Hampshire. The royal military college, part of which is now established at Sandhurst, consists of a senior and junior department. The senior department was established at High Wycombe, in the year 1799, but has recently been removed to Farnham, in Surrey; for the purpose of instructing officers in the scientific parts of their profession, with a view of enabling them better to discharge their duty when acting in the command of their regiments, and at the same time qualify them for being employed in the quarter-master and adjutant-general's department.

No officer can be admitted into this department until he has completed the twenty-first year of his age, and actually served with his regiment as a commissioned officer for three years abroad, or four years at home. Applications for admission must be made to the governor through the colonel or commanding officer of the regiment to which the individual belongs. Every candidate, previous to admission, must undergo such examination as may be deemed requisite.

The students pay into the funds of the college such sum annually as is determined by the supreme board of commissioners. The present subscription is thirty guineas per annum. They are subject to the rules and discipline of the army, as serving with their regiments.

The studies pursued at this department are as follows:—

Mathematics in all its branches; fortification; gunnery; cañonmetation; military drawing and surveying; the recon-
noitring of ground; the disposition and movement of troops under all the various circumstances of offensive and defensive war; rules for eliminating the military resources of a country; and the German and French languages.

There are six professors in this department, viz. one mathematics, &c.; one fortification; two military drawing; one French; one German.

Public examinations on points of science are held half yearly, in presence of the collegiate board, upon which occasion one or more members of the supreme board, not being members of the collegiate board, attend. These officers who have gone through the regular course of studies, and have passed that examination by which they may be duly qualified for staff appointments, receive certificates thereof, signed by the board, and sealed with the seal of the college.

The junior department was first established at Great Marlow in 1802, (but has recently been removed to Sandhurst, near Bagshot,) to afford a provision for the sons of officers who have fallen, or been disabled, in the service of their country; and the means of education to the sons of those officers who belong to any regular regiments. It consists of four companies, of 103 cadets each. They are admitted upon three different establishments, viz.

1st, Orphan sons of officers who have fallen or been disabled in the service, are admitted free of expense, except in bringing the first suit of uniform on their admission, and keeping up their flock of linen during their residence at the college. They are provided with board, clothing, and education, by the establishment, free of charge.

2d. The sons of officers actually serving in regular regiments of the line, who pay a certain sum per annum (from 106 to 664,) according to the rank of their fathers.

3d. The sons of noblemen and gentlemen, who pay 100L per annum each.

Applications for admission must be addressed to the governor. Every candidate previous to admission must pass an examination in Latin and English grammar, and the first four rules of arithmetic. No candidate can be admitted who is under thirteen years of age, or above fifteen.

There are examinations held monthly, which are conducted by the professors of the senior department, to ascertain the progress of each cadet, previous to his removal from one class to another. There are also public half yearly examinations upon the same principle as those at the senior department, previous to the cadets receiving commissions from the college; and, according to their proficiency in the course of studies, they have certificates of qualifications to serve in the army as officers, granted to them by the board of commissioners, in whose possession the examination takes place.

The studies pursued at this department are as follows:—Mathematics; fortification; military drawing; landscape drawing; history, geography, and classics; French; German; and fencing.

There are seven masters of mathematics; four of fortification; five of military drawing; three of landscape drawing; four of history, geography, and classics; five of French; one of German; three of fencing.

Gentlemen cadets are allowed to purchase commissions at any time during their continuance at the college; but no gentleman cadet can be recommended for a commission by private interest until he has made a certain progress in his studies. See Woolwich and High Wycombe.

SANDSTONE, l. 10, r. to be visible. In other sandstones, the grains, &c.

SANDY CREEK. Add—Allo, a township of Mercer county, in Pennsylvania, containing 327 inhabitants.

SANDY LAKE, a township of Mercer county, in Pennsylvania, having 493 inhabitants.

SANGUISORBA. Add after S. officinalis.—Mr. Parkes, in his "Chemical Essays," (vol. v. p. 12.) informs us, on the authority of a Tanner, that there is more of the tanning principle in the plant called burnet than in oak-bark. His informant suggested, that it might be cultivated for cattle, which (he says) are fond of it, and ploughed up every three years in order to collect together the root for the purpose of tanning.

SANSANDING. Add—Sansanding is called Badoon, and in Park's last million to Africa is represented as a small town, consisting of 300 huts; another Badoon, N. of this, is called Sanfanba. Sansanding is said to contain 11,000 inhabitants; it has no public buildings, except the mosques, two of which, though built of mud, are not inelegant. The market-place is a large square, floored with articles of merchandise, and crowded with people. Some of the stalls contain nothing but beads; others, indigo in balls; others, wood-ashes in balls; others, Housia and Jinnie cloth. Here are also, antimony, sulphur, copper and silver rings and bracelets, amber, filks from Morocco, tobacco and salt, yellow leather, &c. &c. Park's Last Million to Africa, P. 216.

SAP, Chemical Composition of. Add—Dr. Prout has examined the sap of the common vine. He found its f. gr. did not differ from that of common water. It did not affect litmus paper, and contained no little of solid matter, that 2300 parts of it evaporated to dryness left only one part of residuum, of which about half was carbonate of lime, and the rest a peculiar vegetable matter insoluble in alcohol, with traces of an alkali.

SAPHIES, an African term which denotes certain charms or amulets, which the negroes constantly wear about them. These faphies are prayers, or rather sentences from the Koran, which the Mahometan priests write on scraps of paper, and fell to the simple natives, who regard them as polluting very extraordinary virtues. Some of the negroes wear them to guard themselves against the bite of snakes or alligators; and in this case, the saphie is commonly inclosed in a snake's or alligator's skin, and tied round the ankle. Others have recourse to them in time of war, to protect their persons against hostile weapons; but the common use to which these amulets are applied is to prevent or cure bodily diseases; to preserve from hunger and thirst, and generally to conciliate the favour of superior powers under all the circumstances and occurrences of life.

Similar charms or amulets are common in all parts of Africa, under the different denominations of dominii, grigri, fetiche, &c. &c.

SAPHIRE. See Mineralogy, Addenda.

SARASWATI, col. 2, l. 23 from bottom, for creature r. creative. Col. 3, l. 8, for Jayatri r. Gayatri. Col. 5, l. 11 from bottom, for painted r. pointed.

SARATOGA, l. ult. r. in 1810; add—of whom 107 were females.

SARKFOOT. Add.—In 1811 the parish of Graitey contained 333 houses, and 1749 persons; viz. 797 males, and 952 females.

SARS, l. 4, add—Berothus used this period, and also Nerus and Sosia (which see), in chronological calculations, and fixing the epochs of his history of Babylon. Ancient authors, however, are not agreed as to the number of years contained
SAVANNAH, I. penuit. infer—of the flames in the county being 7557, and in the town 2195.

SAUCON, Lower and Upper, two townships of Northumberland county, in Pennsylvania, the former containing 1074, and the latter 1456 inhabitants.

SAVING-BANKS, or Banks for Savings, are institutions which, under this appellation, are of recent origin, and which have been established for the purpose of ameliorating the condition of the lower classes of mankind. Many schemes, of various denominations, have been propounded with a view partly, or wholly, to this object. One of the most ancient of this kind is the institution of Male Friendly Societies, which was established about a century ago, and which, to a certain extent, counteracted the prejudice of poor-rates, and the growth of those benevolent habits of dependence which poor-rates are adapted to produce. (See Friendly Societies.) These societies, though they partake of the nature of insurances on life and property, by promising certain advantages in the event of certain accidents or contingencies, are, however, preferable to common insurance offices, inasmuch as the members infure each other, and retain all the profits in their own hands for the general advantage. In these societies, there is, also a benevolent principle that influences those who form them, and induces them to feel and express a solicitude for each other’s welfare. Nevertheless, the benefits derived from them by individual members are often distant, and in their nature uncertain; so that those who have regularly contributed to them for forty or fifty years have not received a shilling from their funds. In the year 1772, baron Maferes published “A Proposal for establishing Life Annuities in Parishes, with a View to the Benefit of the Industrious Poor;” and this was accompanied with the suggestions of some alterations by the Rev. Dr. Price. The ingenious baron recommended to the nation to obtain a law for enabling the parish-officers in England to grant, upon purchase, to the labouring inhabitants life-annuities, payable out of the parish-rates. The plan was approved by persons of the most distinguished character at that period, and a bill was brought into the house of commons by Mr. Dowdwell, under the auspices of Mr. Burke, sir George Savile, Lord John Cavendish, Mr. Dunning, Mr. Thomas Townshend, and others, for carrying it into effect. The bill was passed, but it miscarried in the house of lords at the second reading. However defirable and excellent this plan might appear in theory, it was not likely to prove effectual; because, for the purchase of the proposed annuities, a sum of money, of great amount to the purchaser, was demanded at once; and it was out of his power to procure it. A scheme somewhat resembling that of a saving-bank was published in 1797 by Mr. Bentham, in Young’s “Anals of Agriculture.” One part of his plan comprehended an institution which he denominated “A Frugality-Bank.” Into this bank he proposed to receive the deposits of the poor, not for the mere purpose of yielding an interest, and being withdrawn when wanted, but to form or purchase an annuity for old age, when the ability for earning would be destroyed or impaired. He suggested, however, that this superannuation annuity should, either wholly or in part, be converted into any other species of benefit adapted to the exigencies of the owner. E. g. It might be changed into an annuity for an exiling wife, in the event of widowhood, or into an annuity during the nonage of a certain number of children; or it might serve as a pledge for money borrowed; or part of it might be held for raising a marriage-fund; or it might be simply withdrawn. As no attempt was made for the accomplishment of Mr. Bentham’s plan of a frugality-bank, it remained without effect. It is needless to mention, or to detail, the various particulars of a plan submitted to the public by Mr. Bone in the years 1805 and 1806; as it comprehends a great number of objects which lay beyond the attainment of the poor.

It was still a matter of regret that, notwithstanding various schemes that had been suggested, no plan had been devised for securing to the labouring classes a place of safe deposit for the fruits of their industry, so as to encourage them to save, in the years of active exertion, such a portion of their gains as they might be able to spare from their present necessities, so that they might have a resource in the season of misfortune, or in the decline of life; and more especially to afford them the advantage of receiving regular interest for their small savings, on a scale advancing to a certain extent, in proportion to the amount and continuance of their deposits. Of the first establishment of an institution that may properly be called a saving-bank, we have an account in N° 84, of “The Reports of the Society for bettering the Condition of the Poor.” From this report it appears, that a female benefit-club was established on the 22d of October, 1798, at Tottenham, near London, under the patronage of a number of ladies. This institution comprehended within its general design and plan two other objects, viz. a fund for loans to prevent the use of pawnbrokers’ shops, and a “bank for the earnings of poor children.” “Children of either sex,” says Mrs. Priscilla Wakefield, an ingenious and benevolent lady, whose pen was employed in the instruction of the public, and whose heart was actuated by a generous concern for benefiting those by whom she was surrounded, “or of whatever age, whether belonging to a member or not, are permitted to lay any sum above a penny to the monthly meeting of the rewarders, to be laid up in the funds of the society; where their small earnings may accumulate in safety, until wanted for an apprentice’s fee, clothing, or rations to service, or some other important purpose.” It is added, “although the children receive no addition to the pittance they deposit in the fund, yet it answers several purposes; it stimulates them to earn and to save that which would probably be idly spent, as of too small importance for care; it often encourages their parents to lay by a little store for them, which they would not have thought of doing, had they not been invited by this opportunity of placing it in safety. It habituates the children to industry, frugality, and forethought; and by introducing them to notice, it teaches them the value of character, and of the effect of those who, by the dispensations of Providence, are placed above them; and in many instances, it may supply a resource when it is essentially requisite. The success has already exceeded expectations; above sixty children bring their little treasure monthly.” “The success of this children’s bank gave rise to a more extensive plan in the same place in 1804, called “The Charitable or Benefit Bank.” This was begun for the express purpose of providing a safe and profitable place of deposit for the savings of labourers,
labourers, servants, &c., and opened once a month for receipts and payments. The books were at first kept by a lady; six wealthy individuals were appointed to act as trustees, each of whom agreed to receive an equal part of the sums deposited, and each to be responsible to the amount of 100l. for the repayment of the principal with interest. Any sum above 1. was to be received, and, to encourage perseverance, interest at the rate of five per cent. was to be allowed for every year which should remain a year with the trustees. For every additional 100l. it was agreed that a new trustee should be chosen; and thus the loss to the trustees in fulfilling their engagement, with the fluctuation of interest, could not be considerable. The benefits of the institution were to be confined exclusively to the labouring classes; but the reference of the depositors was not restricted. One great advantage attending this plan is, that it holds out to the lower classes fixed advantages, and prefers their little property from that fluctuation of value to which the public funds are liable. This was the first distinct "Bank for Savings," publicly set on foot for the benefit of the lower classes; it was founded by Mrs. Wakefield, and remained for some time under her inspection and management. Mrs. Wakefield was succeeded in the labour of conducting it by Mrs. Powell, who has appointed a treasurer, "to whom," she says, "I account after every monthly meeting, that I may not be responsible myself for the money lodged in my hands; and I have the purchases made in the funds placed in the names of two trustees." This excellent female adds, that the benefits resulting from this institution are incalculable, as it has enabled many to save sums which have made them comfortable for life, who would otherwise have spent the money at an ale-house, or lent it to their friends. "I keep," says Mrs. Powell, "the whole of the accounts myself; and carry on the business on so easy and simple a plan, that I have nothing to relate. I merely receive and pay principal and interest the first Monday in every month, for an hour and a half. I have no allusion whatever, except that I send any money I have to the treasurer, and now and then compare his cash-book with my own. The only care I have is to keep the respective accounts correct. I have a ledger, a cash-book, an interest account, and a home book. - I call a meeting of the trustees once a year to audit my accounts, and those of the treasurer, which are the counterpart of mine." In July 1817, an act was passed for the protection and encouragement of banks for savings in England; and the several provisions and arrangements of this useful act are minutely detailed in the last edition of Mr. Roff's excellent "Tract on Saving Banks." Societies similar to those of the banks for savings have become of late years very numerous both in England and Scotland; and in England and Wales many of them have opened accounts with the bank of England under the late act of parliament.

Although some few institutions of the name and others of a similar kind had been established soon after the commencement of the present century, yet their increase was slow and inconsiderable until the year 1810; when the Rev. Mr. Henry Duncan, availing himself of one of the provisions of Mr. Bone's plan already mentioned, published an account of it, and proposed that the gentlemen of Dumfriesshire should establish banks for savings in the different parishes of the county. Whilst his zeal was applauded, his recommendation was disregarded. However he fealdly persevered, and determined to make the experiment in his own parish; and denominated his new establishment "The Parifh Bank Friendly Society of Ruthwell." He so far succeeded, that at the time of publishing the second edition of his essay, his capital amounted to a sum exceeding 1400l. About the beginning of the year 1813, a very respectable and useful society was established at Edinburgh for the protection of beggars. Mr. J. H. Forbes, an active director of this anti-mendicant society, having acquainted himself, by a perusal of the reports for bettering the condition of the poor, with the plan of the charitable bank at Tottenham, and with the regulations of the servants' fund at Bath instituted in 1808, proposed a plan and adopted regulations for the establishment of a savings' bank in the metropolis of Scotland. From the time of the publication of the first edition of the Essay on Parifh Banks, the second Report of the Edinburgh Society, and the Report of the Provident Institution at Bath, saving banks have multiplied to such a degree as to leave no room for doubt that the benefit of the system will be soon communicated to every town and village in Great Britain and Ireland. It does not appear, however, that any institution of this kind of any note was opened in London till the end of January in 1816, when the "London Savings' Bank" commenced its operation. But they are now prevalent through various parts of the city and suburbs. Of their importance and utility none can entertain any doubt; although, like other useful schemes, they may be liable to some objections. The lords' committee in their report on the poor laws, bear the following testimony in their favour. "The committee are decidedly of opinion, from every information they have received, that it is expedient to recommend the adoption of 'Provident or Saving Banks,' as likely to increase the comforts and improve the condition of the poor, and to render them less dependent on parochial relief; which, under the belt and mofit considerate administration of it, can never be so satisfactory to the person who is the object of it, or so confident with those honourable feelings of pride and independence, which are implanted in the breast of man, as that refluence which is the result of his own industry and the produce of his own exertions."

"The commons' committee also report, "that they have had no difficulty in perceiving how every extension of the poor's fund is in a perusal of the reports for bettering the condition of the poor, that it is done with the view of increasing the actual poverty of the state itself. The encouragement of frugal habits would, in any state of society, be an object of importance, but your committee are strongly impressed with the opinion, that, in the present situation of the poor of this country, it is chiefly by the gradual reformation of a feeling of reliance upon their own industry, rather than upon the parochial alleviations, that the transition to a more wholesome system can be affected."
"Your committee have the satisfaction of seeing the institutions for the secure and profitable deposit of the earnings of the industrious, which was heretofore projected, are now by the spontaneous exertions of individuals, in actual and successful operation; and from the growth of the system of saving-banks, they are inclined to expect very beneficial results, not only in affording to the industrious poor a secure deposit for their savings, but in familiarizing them with a practice, of which the advantage will be daily more apparent." Both the above cited reports are justified by ample evidence from the testimony of individuals, which is annexed to them. We shall here subjoin an extract from the third report of the "Edinburgh Society for the Suppression of Beggars," 1815. "To improve permanently, and effectually to better the condition of the poor, can be accomplished only by encouraging among them habits of industry, frugality, prudence, and foresight. The very general adoption of the plan of instituting savings' banks shews, that the genuine and enlightened principles of benevolence are beginning to be well understood, and will be zealously acted upon whenever a proper opportunity occurs; for no scheme leems better calculated for the comfort of the poor than this simple plan for enabling the poor man to lay up in the day of health for the hour of sickness. It relieves from want without checking industry;—it secures independence without inducing pride;—it removes those painful misgivings which render the approach of poverty so appalling, and often paralyze the exertions which might ward off the blow;—it leads to temperance and the restraint of all the disorderly passions, which a wasteful expenditure of money nourishes;—it produces that frugality of mind, and steadiness of conduct, which afford the least foundation for the domestic virtues in humble life. The effects of such an institution as this upon the character of the people, were it to become universal, would be almost inappreciable." But it would be endless to cite authorities for establishing a principle so universally acknowledged by all whose observation and experience render them competent judges. We are therefore the more surprized to find it asserted in the part of the Supplement to the Encyclopaedia Britannica recently published, that "taken by themselves, it is at least a doubt whether savings' banks may not produce as great a quantity of evil as good." See Annals of Banks for Savings. London. Richardson, &c. 1818.

SAYBROOK. Add. In 1810 it contained 3994 inhabitants, including 5 slaves.

SCALE of Chemical Equivalents. The description of this ingenious and useful instrument, contrived by Dr. Wolfaet, has been omitted in its proper place; but its importance demands that it should be introduced here.

The author states, that he does not offer this instrument as an attempt to correct the estimates that have been formed by others, but as "a method by which their results may be advantageously applied, in forming an easy approximation to any object of our inquiries."

"The means (to use Dr. W.'s own words) by which this is effected, may be in part understood by inspection of the plate, (Chemistry, Plate XXI., figs. 5, 6,) in which will be seen the list of substances intended to be estimated, arranged on one or other side of a scale of numbers in the order of their relative weights, and at such distances from each other, according to their weights that the series of numbers placed on a sliding scale can at pleasure be moved, so that any number, expressing the weight of a compound may be brought to correspond with the place of that compound in the adjacent column. The arrangement is then such, that the weight of any ingredient in its composition, of any re-agent to be employed, or precipitate that might be obtained in its analysis, will be found opposite to the point at which its respective name is placed.

"In order to shew more clearly the use of this scale, the plate exhibits two different situations of the slider, in one of which oxygen is 10, and other bodies are in their due proportion to it; so that carbonic acid being 27,54, and lime 35,45, carbonate of lime is placed at 63. In the second figure, the slider is represented drawn upwards, till it corresponds to muriate of soda, and accordingly the scale then shews how much of each substance contained in the table is equivalent to 100 of common salt. It shews with regard to the different views of the analysis of this salt, that it contains 46,6 dry muriatic acid and 53,4 of soda, or 35,8 soda and 13,6 oxygen; or if viewed as chloride of soda, that it contains 65,2 chloride and 39,8 soda. With respect to re-agents it may be seen, that 283 nitrate of lead containing 191 of lardth employed to separate the muriatic acid, would yield a precipitate of 237 muriate of lead, and that there would then remain in solution nearly 146 nitrate of soda. It may at the same time be seen, that the acid in this quantity of salt would serve to make 232 corrosive sublimate, containing 81,5 red oxiy of mercury, or would make 91,5 muriate of ammonia, composed of 62 muriatic gas, (or hydro-muriatic acid,) and 29,5 ammonia. The scale also shews, that for the purposes of obtaining the whole of the acid in distillation, the quantity of oil of vitriol required is nearly 84, and that the residue of this distillation would be 122 dry sulphate of soda, from which might be obtained by crystallization 277 of Glauber's salt, containing 155 water of crystallization. These and many more such facts appear at once by bare inspection, as soon as the weight of any substance intended for examination is made by motion of the slider, correctly to correspond with its place in the adjacent column.

"With respect to the method of laying down the divisions of this scale, those who are accustomed to the use of other sliding rules, and are practically acquainted with their properties, will recognize upon the slider itself the common Gunter's line of numbers (as it is termed), and will be satisfied that the results which it gives are the same that would be obtained by arithmetical computation." See Gunter's Scale.

This scale may be had at the different mathematical instrument-makers; and we need scarcely add, that the numbers laid down upon it differ a little from those recently determined by Dr. Thomson. The differences, however, are in general very trifling; but should any one prefer using the new numbers, they will find them stated in the tables appended to Atomic Theory.

SEEING, col. 3, l. 5, add—Dr. Wells, in his "Effay on Single Vision with Two Eyes," has reduced the principal opinions upon this subject into two classes. The first class comprehends those of Galen, Alhazen, Rohault, Dr. Briggs, and Sir Isaac Newton; all of whom have regarded the question as equivalent to the following one: Why should the mind be affected with only one perception from two impressions upon the external organs of sight, since either of those impressions is of itself sufficient to produce a similar perception? To this question they reply, that the two impressions are united before they are communicated to the mind, and they only differ concerning the manner in which such an union takes place. Against the opinions now stated Dr. Wells objects, that they must be considered as mere conjectures, founded upon certain suppositions changes in the brain and nerves, the existence of which, from the nature of the parts, it is impossible either to demonstrate or to refute by experiments; and that no one of them, though admitted to be true, is yet sufficient to explain the phenomena on account of which it was framed. To the second class, Dr. Wells refers the opinions of those who maintain, that an object is seen single by both eyes, because it is seen by each of them in the same external place; and who profess to point out some law, or constant rule of vision, from which this sameness of place is to be derived as a necessary consequence. This view of the question, as our author imagines, was first suggested by Aguilonius, and it has been since adopted by Dechales, Dr. Porterfield, Dr. Smith of Cambridge, and Dr. Reid of Glasgow.
Aguilonius, who has been followed in the same train of reasoning by Dechales and Dr. Porterfield, begins with defining the terms horopter and plane of the horopter. If a line be drawn through the point of the mutual intersecion of the optic axes, parallel to the interval between the eyes, this from its office is denominated the horizon; and a plane, supposed to pass through this line perpendicular to the plane of the optic axes, is called by Aguilonius the plane of the horopter. According to his statement, it is a law of our constitution, that all bodies which we see with one glance or look, whatever are their real places, appear to each eye to be situated in this plane; and upon this supposition he shows why some should be seen single with two eyes, and others double. For according to a recent opinion, which he has advanced, and which other writers on vision have not contradicted, the two lines of direction in which an object is seen with both eyes, can meet each other only in one point, and therefore all bodies which are really situated in the plane of the horopter, must necessarily appear single, as the lines of direction in which any one of them is perceived by the two eyes, coincide in that plane, and no where else; and all bodies which are not situated in the plane of the horopter must as necessarily appear double, since, in this case, the lines of their visible directions intersect each other, either before or after they pass through it. To this reasoning Dr. Wells replies, that if the visible places of all bodies were contained in the plane of the horopter, they would appear of magnitudes proportion to the angles which they subtended at the eye; e. gr. a finger held near to the face would seem as large as the part of a remote building which it might conceal from the sight. But this is contrary to experience, and therefore no reasoning that depends upon it can be admitted.
If it be asked, says Dr. Smith, why, in seeing with both eyes, we do not always see double, because of a double vision, it is sufficient to reply, that in the ordinary use of our eyes, in which the pictures of an object are constantly painted upon "corresponding places or points" of the retinas, the predominant sense of feeling has originally and constantly informed us that the object is single. What he means by "corresponding points," he thus explains: When the optic axes are parallel, or meet in a point, the two middle points of the retinas, or any points which are equally distant from them, and lie on the same sides of them, either towards the right hand or left hand, or upwards or downwards, or in any oblique direction, are called "corresponding points." Accordingly our idea of the outward place of an object is connected with both these sensations; as is manifest by its appearing in two places when its pictures are not painted upon corresponding places of the retinas; which is only a direct consequence arising from our general habit of seeing. If it be asked why, in order to produce single vision, all men agree in directing their eyes toward the object in such a manner as to receive its pictures upon corresponding points of the retinas, since custom might have connected the sensations of any other two points with the information of its unity from feeling? To this objection, suggested by Dr. Reid, the reply may be made in Dr. Smith's own words (vol. i. p. 46.): "When we view an object steadily, we have acquired a habit of directing the optic axes to the point in view; because its pictures falling upon the middle points of the retinas, are then distinct than if they fell upon any other places; and since the pictures of the whole object are equal to one another, and are both inverted with respect to the optic axes, it follows that the pictures of any collateral point are painted upon corresponding points of the retinas."
Dr. Wells is of opinion, that Dr. Smith's hypothesis for the solution of this celebrated question is liable to other objections.
SEEN.

admitting the fact

and, for instance, the information of the former seems to be uniform, or else one set of visual appearances would be associated with different reports from feeling, and no certain mark would be afforded us which of them we should trust. Feeling, as Dr. Smith allows, is not always the predominant, but sometimes the inferior sense; and its information is not constant and original, but variable and derived. When a difference occurs between the information of the two senses, it is natural to require what rule have we for determining which is most worthy of credit. But supposing that the sense of touch to have originally and constantly informed us that objects are single, it would not follow that we are hence taught to see them also single. For, since the place which an object seems to either eye to possess, manifestly depends both upon its apparent distance and its apparent direction from that eye, if visible place be, in the language of Dr. Smith, only an idea of real or tangible place, visible direction must bear the same relation to tangible direction; whence it follows, that we can never have a more accurate knowledge of the direction, in which an object may lie from any part of our bodies, by sight than by touch. Whereas the contrary is proved by facts. Moreover whatever be the direction in which an object may appear to either eye, it cannot be seen in the same plane by both, except at some point common to the two directions. Accordingly Dr. Smith says, that when an object is perceived single with both eyes, it is seen at the mutual intersection of the two visual rays; the visible direction of any object coinciding, according to him, with the visual ray, or the principal ray of the pencil which flows from it to the eye. Should we then even allow, that all we know by sight of the places of bodies has been borrowed from feeling, it will still be easy to shew, that the rule of vision for each eye, which he has derived from such experience, that of our seeing objects in the directions of their visual rays, is inconsistent with many of the phenomena of sight with two eyes; and, consequently, that he has left unremoved the chief difficulty of his subject, which was to explain the single appearance of objects to both eyes, from those laws, or rules of vision, which affect each of them singly. For it is a well-known fact, that if two bodies of the same shape, size, and colour, be placed, one in each optic axis, they appear as two bodies, provided they be at equal distances from the eyes. Agreeably to the theory of our seeing objects in the direction of their visual rays, this cannot happen, except the united body appear at the intersection of the optic axes. Dr. Smith, accordingly, maintains that it does. In the first place, Dr. Wells appeals to experiment for a direct proof that it does not; and, in the second, he observes, that, as the two bodies in the optical axes appear as one, whether they be situated within or beyond the concurrence of those lines, and as a right line joining the bodies, and extended both ways, appears at the same time to the sight as a right line, it follows, upon admitting the fact which he has denied, that all objects in the plane of the optic axes which are seen in one position and state of the eyes, however near to us, or however remote they may in reality be, must appear to be equally distant, or rather in a line drawn through the concurrence of the optic axes, parallel to the interval between the eyes, and named by opticians the horopter. Again, if a right line be made to pass through any part of the plane of the optic axes, at right angles to it, the portions above and below this plane are perceived to be in the same right line with the point which is situated in it, and the whole appears perpendicular to the plane. But the point in the plane is seen, by the left article or proposition, in the horopter; the whole, therefore, of the perpendicular line must be seen in a plane passing through the horopter at right angles to that of the optic axes; or, in other words, in the plane of the horopter, in which conveniently all bodies will have their visible places. But this was the very opinion of Agnolius, to which he was probably led by a similar train of reasoning; though, as a teacher, he might choose rather to ground it immediately upon an original law of our constitution.

Dr. Reid agrees with Dr. Smith in his general principle, but differs from him in maintaining the property to be original by which any two places in the retinas exhibit only one object, while Dr. Smith derives it altogether from custom. They differ also with respect to the meaning of a term; Dr. Smith calling corresponding points, such as have the position just mentioned, whether they represent objects single or not; whereas Dr. Reid says, that those points correspond, whatever their position may be, which represent objects single; and he appears to Dr. Wells not always to attend to the double use of the same term, when he speaks of the opinions of Dr. Smith.

Could it be shewn, says Dr. Wells, that the places of the two retinas, which represent an object single when each receives its picture, are not the centres, or such others as are similarly situated, an obvious inference would be, that the single appearance of the object is not occasioned by a property in those places,8 believed upon them for this special purpose by nature; it being reasonable to expect, that such a property should be found, if any where, in those parts of the retinas which are the most like to each other.

Anatomists have commonly taught, that the centres of the ophera, to which the cornea, the ball of the eye, and the two portions of the crystalline belong, are all placed in the same right line, hence called the optic axis, and that this being produced both ways, passes through the centres of the cornea and retina, considered as surfaces. Opticians, on their part, observe, that an object appears single to both eyes, when the axis of each is accurately directed to it; from which they infer, that the centres of the retinas agree in suggesting but one object, though each receives its picture. Again; since it is known by experience, that, while any object is seen single, to which the optic axes are turned, others at the same distance from the eyes likewise appear so; and since the pictures of these lateral objects fall upon points in the two retinas, equidistant from their centres, and both upon the same side, that is, both to the right or left of the centres, or both above or below them, opticians conclude, that every two places of the retinas, which are similarly situated with respect to the centres, must also agree in exhibiting but one object, though pictures are received by both.

But the whole of this reasoning, says Dr. Wells, is built upon a circumstance in the fabric of the eye, which has been shewn by some of the most eminent anatomists not to have place. For Varolius long ago observed, that the crystalline is not situated in the middle of the eye, but more inward; and the accurate Zinn has more lately mentioned, that if the eye be divided into a right and left half, the centre of the crystalline will be found in the inner portion. Haller confirms this fact; and Winlow's observation, that the centres of the pupil and iris do not coincide, but that the former is nearer to the node than the latter, is connected with it; since both Zinn and Haller agree, that
the centre of the pupil is placed in the axis of the crystalline, while that of the iris is evidently in the common axis of the cornea and globe. Now, a consequence of this position of the crystalline is, that, contrary to what is universally maintained, no ray of light whatsoever can pass unbent to the retina from the atmosphere, or any other medium differing in refractive power from the aqueous humour. If, then, the line joining the centres of the cornea and globe of the eye be what is called the optic axis, and if it be true, that objects appear single when we direct both these axes to them, it must be evident, to such as are acquainted with the common rules of optics, that the pictures of those objects do not fall upon the centres of the retinas, but more internally; and, therefore, that the centres and all the other points of those membranes, which by the present system are supposed to represent objects single, do in fact exhibit them double.

Admitting, however, that objects are represented single, when their pictures fall upon the centres of the retinas, or upon any other two points which are equally distant from the centres, and both upon the same side, it appears to Dr. Wells, notwithstanding, to be in violation of all analogy, to ascribe this effect, with respect to the points at least, on the right and left sides of the centres, to any peculiar property which they possess from nature. For when anatomists find, in a new species of animals, organs similar in structure to those of others they are already acquainted with, they immediately conclude, that they are also similar in regard to their use. In animals of the same species, they believe with certainty, that the organs they see in one have the same properties as the corresponding organs of another; and, if it be possible, they attribute with greater certainty the same properties to two organs of the like kind, which are found in the same individual. Such is the influence of the rule, that resemblance of property is implied by resemblance of structure. Now it is an universal fact, that if an animal be divided into a right and left half, the corresponding parts of those organs which exist in pairs are found at equal distances from the plane of partition. Thus, for instance, in respect to the eyes, the two optic nerves penetrate their outward coat at the same distance from this plane. Their muscles, blood-vessels, and every other of their component parts and appendages, are arranged in the like manner; those nearest to the dividing plane of the one organ, to the innermost of the other, the outermost to the outermost, and the intermediate to the intermediate. It is surely, therefore, natural to expect, that such parts should also be similar in their properties; and we in fact find this similarity to exist, wherever it can be clearly ascertained what the properties are. Every person, for example, admits, that the internal frractile muscle of the right eye performs the same office, with respect to that eye, as the other internal frractile muscle does with respect to the left eye. What judgment are we then to form of the opinion of Dr. Reid, which attributes the same original properties, or rather the same possession of one original property, to places in the retinas situated at unequal distances from the general plane of partition; which makes an external point in one to correspond, in use, with an internal point in the other, and this too by a principle implanted by nature? If such things exist, they may, at least, be held to stand opposed to a most extensive analogy.

To these arguments, à priori, against the opinion of Dr. Reid, Dr. Wells adds others derived from a consideration of its consequences: but all our observance to refer these to the author's own account. If objects, it may be said, appear single neither from custom, nor from any original property of the eyes, have we not an effect without a cause, and must there not be something wrong in the facts or reasoning which lead to such a conclusion? Dr. Wells replies: Since visible place contains in it both visible distance and visible direction, it is not necessary that the single appearance of an object to both eyes, should depend altogether either upon custom, or an original principle of our constitution; for its visible distance to each eye may be learned from feeling, and its visible direction be given by nature; in which case, the unity of its place to the two eyes, will be owing to neither of those causes singly, but to a combination of both; and this Dr. Wells regards as a sufficient reply.

Dr. Wells proceeds to propose and illustrate his own theory for the solution of the question, why objects are seen single with two eyes; or, in other words, why they appear in the same place to both? The visible place of an object being composed, as he conceives, of its visible distance and visible direction, it becomes necessary, for fleeing how it may appear the same to both eyes, to explain in what manner the distance and direction, which are perceived by one eye, may coincide with those which are perceived by the other. He begins with a consideration of the distance. In judging of distance by light, no person has ever observed, that while an object seemed to one of his eyes at a certain distance, it has appeared to the other to be at a different distance, and from this circumstance alone has been seen double; or, to express the same thing in another way, that while the visible appearance of an object to one eye, covered the visible appearance of the same object to the other eye, the two appearances did not seem entirely to coincide, and make one, but were seen separately by the two eyes. Hence it follows, that the difficulty in finding a true and sufficient cause for the union of the two visible places of one or two objects to two eyes, must therefore consist altogether in fleeing, in what manner the two apparent directions may coincide, conveniently with the attending phenomena.

From the time of Kepler's discovery of the law and manner of vision, there have been, says our author, only two theories offered respecting the apparent directions of objects. One is, that they are perceived in the direction of lines passing from their pictures on the retina, through the eye, to the other, that their apparent directions coincide with their visual rays. But both of these theories are inconsistent with the phenomena of single vision with two eyes. From according to neither of them can an object, placed at the concourse of the optic axes, be seen single, unless we have a most accurate knowledge of its distance; nor will either admit two objects to be seen as one, which are situated in the optic axes, whether on this side, or beyond where they meet, unless the united object be referred by sight to their very point of interfection; both of which conclusions are contradicted by experience. It is evident, therefore, that some other theory of visible direction is required, which shall not be liable to these objections.

Dr. Wells's theory is illustrated in the following propositions, which we can merely state without argumentation: 1. Objects situated in the optic axes do not appear to be in that line, but in the common axis; i.e., in a line drawn from the middle of the visual base, through the point of interfection of the optic axes, or parallel to them, if they be parallel to each other. 2. Objects, situated in the common axis, do not appear to be in that line, but in the axis of the eye, by which they are seen. 3. Objects, situated in any line drawn through the mutual intersecion of the optie
optic axes to the visual bafe, do not appear to be in that line, but in another, drawn through the same interfection, to a point in the visual bafe diftant half this bafe from the familiar extremity of the former line, towards the left, if the objects be seen by the right eye, but towards the right, if seen by the left eye. In the application of the theory which Dr. Wells has endeavoured to establish in the preceding propositions, he obferves, that, if the question be concerning an object at the concurrence of the optic axes, it is seen fingle, because its two familiar appearances, in regard to fize, shape, and colour, are seen by both eyes in one and the fame direction, or, if you will, in two directions, which coincide with each other through the whole of their extent. It therefore matters not, whether the distance be truly or falsely estimated; whether the object be thought to touch our eyes, or to be infinitely remote. And hence we have a reason, which no other theory of visible direction affords, why objects appeared fingle to the young gentleman mentioned by Mr. Cheifelden, immediately after his being condeited, and before he could have learned to judge of distance by fight.

When two familiar objects are placed in the optic axes, one in each, at equal distances from the eyes, they will appear in the fame place, and therefore one, for the fame reason that a truly fingle object, in the concurrence of the optic axes, is seen fingle. Here again, as the two visible directions coincide in every point, it is not necessary that the united appearance should be judged to be at any particular distance; that it should be referred, for instance, to the concurrence of the optic axes, where the two other theories of visible direction are obliged to place it, in opposition to the plainest observation.

Objects, any where in the horopter, will be seen fingle, because their apparent directions to the two eyes will then completely coincide. And for a contrary reason, those placed in any other part of the plane of the optic axes will appear double. To make these things evident, let a line pass through the point of interfection of the optic axes and any given object, to the visual bafe, which is to be produced, if necessary; and let it be called the line of the object’s real position. Take afterward, in the visual bafe, or its production, two points, one on each side of the line of real position, and both distant from its termination there, half the visual bafe. Lines drawn from these points, through the point of interfection of the optic axes, must confcquently contain the two visible positions of the object. But when this is ftuated in the horopter, the line of real position will coincide with the horopter, and will not therefore reach the visual bafe, unlefs at an infinite distance from the eyes. For which reafon, the two lines, containing the visible positions of the object, must fall upon the visual bafe at a like distance, and must consequently be regarded as coinciding with each other. When the object is not in the horopter, the two lines of visible direction will be found, by the fame means, not to coincide.

SEGO, col. 2, l. 13, r. Manfong; l. 17, r. Sanfanding.

SELENIUM, in Chemistry, the name of an elementary ftufaftance recently discovered by Berzelius, and confidered by him as a kind of femi-metal. This ftufaftance was ftift made for tellurium. It was obtained from a sulphuric acid manufactory at Grifiphon, where pyrites from the mines of Fahan were employed, and which of course contained the ftufaftance in queftion. It alfo efhils in the fame mines combined with copper. Selenium has the properties of a metal combined with thofe of sulphur to f0 great a degree, that it is difficult to know under which head to clasf it, and in fhort whether it might not be rather confidered as a new fpecies of sulphur. In its metallic flate it has a brilliant metallic luflre externally, with a tinge of red. The fracture is vitreous, like that of sulphur, but with a very brilliant luflre of a grey colour. It becomes hot at a temperature of 212°, and at a higher temperature it melts; and at a temperature about equal to that at which mercury boils it may be diffilied. When in a gafous flate, it is yellow, like sulphur. When diffilied in a large veftle, it is deposited in the form of flowers of a cinabary colour, but not oxydated. During its cooling, it preffures for fome time a certain degree of fluidity, fo that it may be moulded between the fingers, and drawn into threads, which are transparent, and of a ruby-red colour when held between the eye and the light; but by reflected light they exhibit a brilliant metallic luflre. It burns with an azure-blue flame when heated with a candle, and exhales a forcful odour of baffe-radiith.

Selenium combines with metals, and generally produces a reddish flame. The alloys are commonly grey, with a metallic luflre. The feheliuret of potafium diffiolves in water, without evolving any gas, and produces a red-coloured folution, which has the tafe of hydrofulphuret of potafia. When muriatic acid is poured upon this feheliuret, a feheliuretted hydrogen gas is diffengaged, which is soluble in water, and precipitates all metallic folutions, even thofe of zinc and iron. This gas has the odour of sulphuretted hydrogen gas when it is diffiited with air, but if it be breathed fels diffined it produces a painful fenfation in the nose, and a violent inflammation, ending in catarrh, which continues for a confiderable time.

Selenium combines with the alkalies both in the humid way and by fusion. Thefe combinations are red. The feheliurets of barytes and lime are also red, but they are infoluble. It alfo diffiiles in melted wax, and in the fat oils; the folutions are red, but have no hepatic odour. There efist alfo feheliuretted hydrofeleniums of the alkalies and of the earths.

Selenium diffiiles in nitric acid by the affifance of heat; the folution evaporated and fublimed yields a mass crys- talized in needles, which is a pretiy forcful acid. It has a pure acid flavour, and forms peculiar fballs with the alkalies, earths, and metallic oxdies. The felenium is fofulble in water and in alcohol: its combinations with potafia and amonia are deliquefcent; the latter is decomposed by fire, water is given out, and the felenium is reduced. The feleniates of barytes and lime are fofulble in water. The felenium acid mixed with muriatic acid is decomposed by zinc, and the felenium is precipitated in the form of a red powder; by sulphuretted hydrogen gas an orange-yellow precipitate is formed.

Such is a brief Summary of the properties of this curious ftufaftance. From the small quantities in which it has hitherto been found, we believe noperiments have been made to afcertain the weight of its atom, &c.

The country, is almost destitute of water, though a river, nearly dry, flows through the centre of the plain, is, generally speaking, barren, if we except some groves of date-trees which formerly grew in the bed of the river.**

**SIDNEY, Sir Philip, in Biography, the eldest son of Sir Henry Sidney, by a daughter of the duke of Northumberland, was born at Penhurst in Kent, in the year 1554. He was named Philip in compliment to the king of Spain, the husband of queen Mary. In very early life he manifested a sedate fludivus disposition; and he zealously improved every advantage for gaining knowledge, which he enjoyed, first at Shrewsbury school, and afterwards at Oxford, where he was entered at Christchurch college in 1569, and also at Cambridge. At the age of 18, the queen, according to the then existing custom, granted him a licence to travel abroad; and he first visited Paris, where he was introduced, by his maternal uncle, the earl of Leicester, to Sir Francis Walsingham, the English ambassador. Charles IX. who was then king of France, willing to have repose to Leicester, and probably with the peridious design of lulling into security the Protestant party in France, previously to the horrid massacre of St. Bartholomew's, appointed Sidney one of the gentlemen of his bed-chamber. When the fatal day arrived, Sidney, together with several of his countrymen, found a refuge in the house of the English ambassador. Soon afterwards he purged his tour to Germany; and at Frankfort formed an intimate acquaintance and friendship with Hubert Languet, then resident for the elector of Saxony, whose communications were singularly useful to our young traveller. After visiting Vienna, Hungary, Venice, and Padua, in company with his friend Languet, he returned through Germany and Flanders, and arrived in England in 1575, with those accomplishments, and with his moral principles in untainted purity, which rendered him the admiration and delight of his countrymen. In the following year, being only in the 22d year of his age, he was dispatched as ambassador to the court of Vienna, to concile with and congratulate the new emperor Roderick II.; and entrusted with a commission to engage the Protestant princes of Germany in a league with each other, or with England. He was also entrusted to demand the repayment of the sum advanced by Elizabeth to the elector palatine. In the discharge of these several trusts, he acquitted himself with singular reputation, and with satisfaction to all the parties concerned in the objects of his embassy. After his return, he received no other honorary recompence besides the office of cup-bearer to the queen. With a temper somewhat irascible, and a high sense of honour, blended in some degree with the spirit of chivalry, few characters in that age were so unexceptionable as that of Sidney. Of his disinterested patriotism, we have a striking instance in his renunciation addressed to queen Elizabeth on her projected marriage with the duke of Anjou; and such was the estimation in which he was held by the queen, that she did not manifest her displeasure against Sidney, though others suf-
feder for their interference. Actuated by the spirit of chivalry, he exhibited his skill in military manœuvres at a tournament held, in 1586, in honour of the queen; and in the same year, he ascertained his rank as a gentleman, against an inquest offered him at a tennis-court by Vere, earl of Oxford. In order to compose his mind, which had been thus disquieted, he retired to the house of his brother-in-law, the earl of Pembroke, at Wilton, and engaged in the composition of his well-known romance, called "Arcadia," which was not published till after his death. In 1581 his name appears as one of the knights of the shire for the county of Kent, and as one of the committee for drawing up acts, with a view to the security of the kingdom against the Pope and his adherents. His "Defence of Poetry," written about this time, contributed more to his literary reputation than Arcadia. Of this treatise, one of his biographers says, that it may be "considered as the earliest piece of criticism in the English language worthy of attention, and reckoned by some the best written of his works. In a simple and unaffected style, it displays much learning and judgment, and a true relieli of the excellencies of that art which he undertakes to patronize and illustrate." In the year 1583, he married the only daughter and heiress of Sir Francis Walsingham, a lady, as it is said, of great beauty and merit. On occasion of being nominated by the prince palatine of the Rhine his proxy at the installation of the garter in 1584, he received from the queen the honour of knighthood; an honour which he was not lavish in conferring. "When Sir Francis Drake was projecting a secret naval expedition, Sir Philip Sidney wished to join him, and with this view to equip a land and naval armament against the Spanish settlements in America; but the queen interposed, and absolutely prohibited the execution of his designs." Of his nomination as a candidate for the command of Polonia, during the death of Stephen Bathori in 1585, we shall say nothing, as one of his biographers has stated several particulars, which render the fact very improbable. In the year just mentioned, Sir Philip had a seat in the privy council; and queen Elizabeth determining to affilt the Low Countries in their revolt, on condition of their putting into her hands some cautionary towns, indulged his martial disposition by appointing him governor of Flushing. As soon as he had taken possession of his charge, he was made colonel of all the Dutch regiments, and captain of a band of English soldiers. He was soon joined by his uncle Leicestcr, as general of the auxiliaries, and Sir Philip was appointed general of the horde, under his command. It soon appeared that Leicestcr was unfit for the trufi reproached in him; his nephew was dishonoured, and endeavoured to allay the discontent which prevailed among the subordinate commanders. Sir Philip in his first exploit, which was the surprize and capture of Axell, in July 1586, without the loss of a man, was singularly successful; but in the month of September he fell in with a convoy sent by the enemy to Zutphen, and having one horse shot under him, he mounted another; and while charging the foe with great vigour, he received a musket bullet above the knee, which broke the bone and penetrated deep into the thigh. On his way from the field to Leicestcr's camp, whither he was conveyed, he found himself faint and thirsty, and called for water; but as he was preparing to drink, he observed a soldier in the agonies of a mortal wound; he renounced the draught to him, with an expression which entails permanent honour on his memory; "This man's necessity is still greater than mine!" Upon his arrival at Arnhem a mortification ensued, and on the 17th of October, after exhibiting the most unaffected piety, exemplary composure, and self-possession, he expired with tranquillity at the early age of 32 years. His death was universally regretted by his enemies as well as friends, and abroad as well as at home. The queen directed his body to be brought to London, and after lying in state, he was interred with all the solemnity of a public funeral in St. Paul's cathedral; and although no monument was erected over his remains, James, king of Scotland, composed an epitaph to celebrate his memory, and both universities furnished some collections of verses to record his fame. But his name will ever live in the records of history, as one of those who have reflected the highest honour on his country. Of his "Arcadia," we shall merely observe, that it was one of the earliest specimen of grave or heroic romance; that it was left in scattered fragments of MSS., which his editor collected and published; and from this circumstance, it was denominated "The Counteys of Pembroke's Arcadia." It became very popular, and was translated into foreign languages. Lord Orford (Horace Walpole) speaks of it very contemptuously; but Dr. Zouch has more candidly and more justly appreciated its value. Biog. Brit. Zouch's Mem. of Sir Philip Sidney. Gen. Biog.

**SIDNEY.**

Sidney, or SIDNEY, Algernon, the second son of Robert, earl of Leicestcr, by Dorothy, eldest daughter of Henry Piercy, earl of Northumberland, was born in 1621 or 1622, and carefully educated under his father's inspection. In early life he was destined to the military profession, and in 1641 he had a commission in his father's own regiment of horse, when he was appointed lord-lieutenant of Ireland. During the rebellion in that kingdom he entered immediately into active service, and had many opportunities of exhibiting his courage. In 1643, upon the commencement of the war in England between the king and parliament, he obtained permission to return. He and his brother, upon their landing, were intercepted, and placed under arrest; but as the event proved that they had been taken by their own contrivance, was much offended; and not without reason, for they both joined the parliamentary army. In 1644, the earl of Manchefter appointed Algernon to the command of a troop of horse in his own regiment; and in the following year, Fairfax promoted him to the colonelcy of a regiment of horse. Having been present in several actions, he was entrusted with the government of Chichester. In 1645 he accompanied his brother to Ireland, and was advanced to the post of lieutenant-general of the cavalry and governor of Dublin. For his services in that kingdom he received the thanks of parliament, and returning to his own country was made governor of Dover. Although he was nominated in 1648 a member of the high court of justice for the trial of the king, he was neither present when sentence was pronounced, nor did he sign the warrant for his execution. This part of his conduct, it is supposed, was owing to the particular request of his father; for it appears, from his general conduct, that his principles would not induce him to condemn this act. When he was afterwards a voluntary exile in Denmark, and charged by his father with the violation of his political sentiments, his father writes to this purpose: "It is said that the university of Copenhagen brought their album to you, desiring you to write something therein, and that you did scribere in albo the words:"

"Manus habe, nimina tyrannis,
Enfe petit placidam sub libertate quietem,"

and put your name to it; also, that a minifier, being there in company with you, said, 'I think you were none of the late king's judges, nor guilty of his death.' "Guilty!" said you; "do you call that guilt? Why, it was the just and brave act that ever was done in England, one of

4 N 2
Confidently whilest fo but and and this retired beneficial had centenarian anxious was charo-e. it finding some mention ought to others, France, time return, the king's rank. He made for his stock the reparation he might have of all this, however, he was found exasperated, and at the court. He was, in little, treated with respect and civility in various places, and particularly at Rome; and he employed his many leisure hours in making addition to the ample stock of knowledge which he had already acquired. In 1677 his father, being advanced in life, was anxious to see him, and employed his interest in obtaining the king's permission for his return, to which permission was annexed a pardon for all his past offences. When he afterwards joined in cabals against the court, he incurred the enmity of those who were disposed to take offence; and Mr. Hume has charged him with acting counter to the moral principles of gratitude and with a breach of faith: others, however, have vindicated him, alleging that unconscious of guilt he might consider the royal permission to return, after so long an absence, as a preparation of injustice rather than an act of clemency, and that personal obligation ought not to influence his public conduct, when he conceived the great interests of his country in danger. At the time of his return, parliament was urging the king to commence a war with France; but Charles, being a penitent of the French court, wished from selfish motives to avoid it; but as he was actuated by no found principles, it was apprehended that he would appear to concur with the wishes of the nation, that he might have a plea for raising supplies, for his own personal gratification, in the prosecution of his pleasures or his designs to render himself arbitrary. The English patriots were averse from war, and some of their leaders intrigued with Barillon, the French ambassador, for preventing it. In the lil of those persons in England who were at this time penitents in France, the name of Sidney appears. When this discovery was made by Sir J. Dalrymple's publication of Barillon's papers, the friends of liberty were astonished and grieved; and they hesitated in admitting this dishonourable charge. In vindication of Sidney some have suggested, that Barillon falsified his accounts of the money with which he had been entrusted; whilst others have satisfied themselves with that perusal of Sidney's honour and integrity which was founded on his general conduct, and with the assurance that he always adopted and pursued those political measures which appeared to him, all circumstances considered, most beneficial to his country. Upon his father's death, he joined the opposition party without diffidence, and offered himself for a seat in parliament; but he was twice defeated by the influence of the court. Thus exasperated, and apprehending the liberty of his country to be engaged, as well as dreading a popish successor, the ardour of his mind urged him to associate with the duke of Monmouth and his party; and in the history of the Rye-houle plot he was charged with being one of six who were promoting an insurrection. But the part which he was supposed to have taken in a conspiracy for assassinating the king was the plea for arresting him, together with Russell and several others, in June 1683. When Lord Ruffell was sacrificed, the next victim selected by the court was Sidney; and he was brought to trial for high treason, before that judge whose infamous character is indelibly recorded in the page of history, chief-justice Jeffreys. Lord Howard, who was a disgrace to the title he bore and to that rank in society with which he was connected, was the only direct evidence against him; but the law required two witnesses for conviction on a charge of treason. In order to supply this defect, the attorney-general produced some paillages from a manuscript found in the closet, in which the writer maintained the lawsuness of, refuting tyrants, and his preference of a free to an arbitrary government; and without decisive proof that they were written by him, or that they were even communicated to any living person, this kind of evidence was admitted, in defiance of law and common sense, as equivalent to the testimony of a second witness. His defence was no avail, and a servile jury pronounced him guilty. From respect to his family, the disgraceful part of his sentence was omitted, and exchanged for beheading. On the 7th of December he was executed on Tower-hill, at the age of about sixty-one years, delivering to the sheriffs a paper which proved the injustice of his condemnation, and offering a prayer for that "old cause" in which he had been from his youth engaged. This paper was afterwards printed, and made great impression on the public mind. It is given at full length in the Memoirs of his Life. He suffered with the firmness, as it is said, of an old Roman. After the revolution one of the first acts was the reversal of his attainder, and his name has been held in high esteem and veneration by all the avowed friends of free government. The following sketch of his character is given by bishop Burnet. "He was a man of most extraordinary courage, steady even to obstinacy, sincere, but of a rough and boisterous temper that could not bear contradiction. He seemed to be a Christian, but in a particular form of his own; he thought it was to be like a divine philosophy in the mind, but he was against all public worship, and every thing that looked like a church. He was stiff to all republican principles, and an enemy to every thing that looked like monarchy. He had studied the history of government in all its branches beyond any man I ever knew; and had a particular way of magnifying himself into people that would hearken to his notions, and not contradict him." Of this character, it is said, in the Notes to the Memoirs of his Life, that it was roughly and inaccurately drawn. Sidney's "Discourses on Government" were first printed in 1698, fol. reprinted in 1704 and 1751, and in 4to. 1772 at the expense of Thomas Hollis, Esq., with his letters, trial, and memoirs of his life prefixed. Lord Orrey says of them, "they are admirably written, and contain great historical knowledge, and a remarkable propriety of diction; so that his name, in my opinion, ought to be much higher established in the temple of literature than I have hitherto found it placed." Biog. Brit. Gen. Biog. Memoirs, &c. prefixed to Hollis's edition.

SIL

SID SILEN. I. 20, for facchno R. Jaccho; I. 35, for second r. fixth.  

SIFERD ROOK. See ROOD.  

SILEN, in Chemistry. From the recent experiments of Berzelius and Stromeyer, the basis of silicon does not appear to be a metal as formerly supposed, but a substance analogous to boron and carbon; hence it has been named
named silicin. Little is known, however, of the nature of this substance, except that it is dark-coloured, and will bear a considerable heat without undergoing change, and that it decomposes water, and is converted into silica when brought in contact with that fluid. It is also capable of combining with iron, and probably other metals. Dr. Thomson estimates the weight of the atom of silicin, from the experiments of Berzelius and Stromeyer above-mentioned, at 19, and of silica at 29. The same chemist also considers silicin to be an acid, and proposes for it the name of silicic acid, in which case its compounds must be denominated silicates.

SILVER, in Chemistry. Dr. Thomson, from the most recent experiments on this metal and its salts, estimates the weight of its atom at 137.5, that of oxygen being 16. See Atomic Theory.

SILVER ORE. See Silver, and Mineralogy, Addenda.

SILURES, col. 2, l. 35, r. Wilk or Ul.?

SIMIA FATTUERULS, l. 1, for tailles r. long-tailed.

SITACA. Add—twelve geographical miles below Bagdad, and nearly opposite to the embouchure of the Dealla river.

Vol. XXXIII.

SITTINGBOURNE, a town and parish of Kent, 40 miles from London, in the road to Canterbury; contained, in 1811, 230 houses, and 1362 persons; 653 being males, and 729 females.

SKIDDWAL, l. 15, after sea, add—which differs little from 3017 feet, the barometrical measurement of Mr. W. Allen, according to the method proposed by Mr. H. Englefield. (See Trans. of the Geol. Soc. vol. iv. part 2.)

SLATE-SPAR. See Mineralogy, Addenda.

SLAVE, col. 2, l. 40, for Almighty r. A mighty.

SLAVE TRADE, abolition of, col. 2, l. 12, for principled r. principled.

SLIDING-RULE. Add—Mr. Bevan has lately published in the Philosophical Magazine an ingenious modification of the sliding-rule. By the invention of the slider all the usual operations are performed, together with the extraction of the square root, and factors of any given number are found by simple inspection. At the same time, the instrument is reduced to half its usual size.

SMITH, in Geography, l. 2, add—of whom 2201 are slaves.

SNORING. Add—See LARYNX.

SNOW, col. 2, l. 3 from bottom, r. earth, and of bodies on its surface, is prevented from escaping by radiation to the heavens during still or dry nights. The cause of this additional cold is not, indeed, constantly operate; but its prevalence, during only a few hours, might effectually destroy plants, which now pass unhurt through the winter. Moreover, while low vegetable productions are prevented, by a covering of snow, from becoming colder than the atmosphere in consequence of their own radiation, the parts of trees and tall shrubs, which rise above the snow, are little affected by cold from this cause: for their outermost twigs, now that they are deliquescent of leaves, are so small, that they will very seldom become more than 2° colder than the atmosphere. The larger branches too, which, if fully exposed to the sky, would become colder than the extreme parts, are, in a great degree, sheltered by them; and, in the last place, the trunks are sheltered both by the smaller and larger parts, not to mention that the trunks must derive heat, by conduction through the roots, from the earth kept warm by the snow. In a similar way is partly to be explained, the manner in which a layer of earth or straw preserves vegetable matters in our own fields, from the injurious effects of cold in winter. It may be remarked, however, that a thick covering of snow, while it renders the surface of the earth warmer than it would otherwise be, must occasion the lower atmosphere to be colder, by preventing the radiation of the heat of the ground to the air, either by radiation or conduction. Wells's Eff. p. 258. See DEW and HEAT.

SNOWDON, l. 17, after sea, add—according to Mr. W. Allen's barometrical measurement, 3595½ feet.

SOAP-STONE. See Mineralogy, Addenda.

SODA. See Sodium. Add—under NATRON, l. 5, r. Natron, from an erroneous supposition of its being of the nature of nitre. This has been up to many times. Col. 2, l. 35, dele vegetable alkali. Col. 4, l. 35, for a further account of barilla, see CARBONATE OF SODA. Under the article LEATHER, l. 17, for a species of felt-petre r. a CARBONATE OF SODA; which see.

SODA, Sodium, in Chemistry. From the most recent and correct experiments, the weight of the atom of soda has been estimated by Dr. Thomson at 23, and consequently the weight of the atom of soda at 46, that of oxygen being 16.

SODAIC POWDERS, denote powders which are used as a substitute for soda-water. Profeur Brande, in his course of chemical lectures at the Royal Institution, took occasion to observe, that though these powders produce an effervescence when dissolved, arising from the difengagement of carbonic acid, the solution is very different from soda-water, both in its constituent parts and its properties. These powders consist of an alkaline carbonate, either of potash or soda, and a concrete acid, reduced to powder. The acid, though fold as the citric, is in reality the tartrate acid, produced from the fulbitance known as cream of tartar. When the powders are dissolved, the tartaric acid unites with the alkali, and the carboxylic acid, or fixed air, immediately escapes, occasioning a momentary effervescence. A felt is formed in the solution, called by chemists the tartrate of potash, or soda: if the former alkali has been used, and the acid is in excess, the felt formed is nearly insoluble, and has a harsher taste, and an irritating effect on the stomach. Thus, a quantity of alkaline tartrate is taken into the system, which rather tends to increase than remove obstructions, and in many instances must be highly injurious. Soda-water, if prepared in the bell manner, should contain a very small portion of carbonate of soda, which has a tendency to correct acidity on the stomach; it should contain also about eight times its own bulk of carbonic acid gas, part of which is in a state of loose combination with the water. A considerable quantity of this gas, however, appears to be united by a stronger chemical affinity, and will remain in the water for many hours after it is poured out. This gas, acting as a solvent of all the different earths, and various other substancess, gives to the soda-water a more dilute and defolvent efficiency, than is posessed by common water; and to this cause we may ascribe the good effects of soda-water in removing bile and calculous concretions. The carboxylic acid, in its concentrated state, as it exists in soda-water, is a more powerful solvent of metallic substances than is generally supposed. On which account the manufacture of soda-water, in vessels of copper, or other metals, ought carefully to be avoided, and too great caution cannot be observed by those who are in the habit of drinking.
drinking soda-water, to have it free from any metallic impregnation, or improper admixture.

SODALITE. See Mineralogy, Addenda.

SOMERSET, l. 6, r. 14725.

SOONTAARS, a wild and unlettered tribe of Hindoos, who inhabit the districts of Ramgur, the least civilized part of the Company’s possessions, and who have reduced the detection and trial of perils suspected of witchcraft to a system. For an account of their practices, we refer to the fourth volume of the Asiatic Researches, p. 343. See Benares.

SORBIC Acid, in Chemistry. This acid was so named by Mr. Donovan its discoverer, because obtained from the berries of the mortaria gigantea (formerly denominated forbus aucuparia), but now pyrus aucuparia. The juice of the ripe berries is to be strained and mixed with a filtered solution of acetic of lead. The precipitate is then to be separated by a filter, and washed in cold water. A large quantity of boiling water is then to be poured upon the filter, and allowed to pass through the precipitate into jars. After some hours this liquid becomes opaque, and deposits crystals of great lustre and beauty. These crystals are to be boiled for half an hour with 2.3 times their weight of sulphuric acid, specific gravity 1.090, supplying water as fast as it evaporates, and taking care to keep the mixture constantly stirred. While still hot a stream of sulphuretted hydrogen is to be sent through the refiuning liquid, which will precipitate the lead, and leave the forbic acid in solution in the water.

Sorbic acid thus obtained is a transparent colourless inodorous fluid, soluble in alcohol, and in any portion of water. It does not crystallize, nor is it volatile. Its taste is exceedingly acid, and it does not appear to undergo much change when kept.

The forbic of potash, soda, and ammonia, are crystallizable forms, containing an excess of acid. They are soluble in water, but not in alcohol. The forbic of barytes and lime are neutral and white insoluble powders. The forbic acid combines with lead in three proportions. The subforbic is a hard mass or a gritty powder. The forbic is a white powder, which by solution in forbic acid may be obtained crystallized in beautiful silvery crystals. The superforbic has a sweet taste, and is soluble in water. The other forbics are little known, and do not seem to be very interesting.

There appears to be a great resemblance between the forbic and malic acids. Indeed it has been alleged that they are identical. The malic acid having recently been obtained in a more pure state than formerly, has enabled chemists to investigate its properties more completely, and in this pure state it is said in no circumstance to differ from forbic acid.

SOSOS, a Chaldæan period of 60 years, which doubled gave the return of the lunar months to within the 20th part of a month. By multiplying this cycle as many times as are necessary to obtain the precise returns of the fun and moon to the same points of the heavens, astronomers found a period of 600 years, called the Neros; which fee.

SOUND, for Roberts r. Roberts.

SOUTHAMPTON, in Geography, a township of Cumberland county, in Pennsylvania, having 700 inhabitants.

SOUTH-END. In 1811, the parish of Prittlewell with Milton contained 285 houses, and 1541 persons; 759 being males, and 782 females.

SOUTHWARK, EAST, a township of Pennsylvania, in Philadelphia county, having 726 inhabitants.

SOUTHWARK Bridge, an elegant structure designed by Mr. Rennie, and forming a communication between the city of London and the borough of Southwark, in nearly a straight line between Guildhall and the Bank-side. It consists of three grand arches; the centre arch being 240 feet in span, and each of the side arches being 210 feet. The arches are composed of cast-iron, and the piers and abutments of stone. The estimate of the expense was 287,000., and that of the tolls, on the supposition that London bridge should be rebuilt, was conjectured to amount annually to 50 or 60,000. The first stone of this bridge was laid in 1815, and it was opened for passengers and carriages in February 1819.

SOWANS, a nutritious article of food prepared in Scotland from the hulls of oats, by a process not unlike that by which common flour is made. The hulls of the oat after having been separated by the sieve still retain a considerable portion of farinaceous matter. It is mixed with water, and allowed to remain till the water becomes four. The whole is then thrown upon a sieve; the milky water passes through loaded with farinaceous matter, which then falls. The four liquor is poured off, and about an equal quantity of fresh water added. This mixture when boiled forms a very nourishing article of food, and the portion of the four water which still adheres to the flax gives the whole a pleantful acidity.

SPANGLES, paillettes, are small thin round leaves of metal, pierced in the middle, which are sewed on garments, &c. as ornaments. They are prepared by first twirling wire round a rod into the form of a screw; this is then cut into small spiral rings, like those used by pin-makers in forming heads to their pins; and these rings being placed upon a smooth anvil are flattened by a small bite of the hammer, so that a small hole remains in the middle, and the ends of the wire which lie over each other are closely united. The smaller spangles were first made in the French gold and silver manufactories, and imitated in Germany, for the first time, in the beginning of the 18th century. Beckmann’s Hist. of Inventions, vol. ii.

SPARROW, in Agriculture. Add—It has been suggested, however, that the mischief done by sparrows may be fully compensated by their usefulness in destroying caterpillars; a single pair has been found to consume 40,000 in one season, in feeding their young. We may here add, that in a district in which great pains had been taken to exterminate the moles every vegetable was for a considerable time destroyed by cockchaffers, which grubs had been thus preserved by the short-lighted policy of the farmers.

SPARTA, l. 13, for country r. city.

SPARTA, col. 2, l. 3, containing 179 inhabitants.

SPAVIN. Add—In healing the blood spavin, Mr. Denny recommends repeated blistering, and afterwards a compress of folded linen, moistened in the following lotion, and confined by a long bandage: Take 4 oz. of sal ammoniac, 2 oz. of acetated cerule, 2 quarts of vinegar, and 4 oz. of water, mix them. The usual method of treating the bone spavin is by blistering and firing.

SPÉCULUM, col. 15, l. 23 from bottom, for cord r. card.

SPEECH. See LARYNX.

SPERMACETI, Chemical Properties of. See Cetic Acid.

SPERMADICTYON, in Botany, from στερμα, seed, and δικτυω, a net, because of the reticulated tunics of the seeds.—Roxb. Coromand. v. 3. 32.—Clas and order, Pentandria Monegynia. Nat. Ord. Rubiaceae, Juff.

S. fusco-velux,
1 S. *fuaveolens.* Fragrant Net-feeding.—Discovered by Mr. William Roxburgh, on the Rajamahal hills. Stem erect, shrubby, with opposite branches; downy when young. Leaves opposite, stalked, with triangular intermediate *filipus,* lanceolate, acute, entire, near a lpan long, smooth. Flowers white, an inch long, delightfully fragrant, copious, in numerous terminal tufts. A very curious and distinct genus, which we hope to see introduced from the Calcutta garden to the flowers of England.

SPHAGEBRANCHUS. See *Synebranchus.*

SPRIG, or *Spinig.*

SPRONS. Add—See *Uxahyer.*

STAMMERING. See *Larynx.*

STAPHYLINUS, 1. 15, add—The larvae are subterraneous, and much resemble the complete animals; 1. 15, add—Mr. Marshall, in his "Entomologia Britannica," enumerates no fewer than 87 British species.

**Vol. XXXIV.**

STARCH, Chemical Composition of. Starch has been analyzed by three different experimenters. The following were the results:

Berzeus employed potato starch. The other experiments were made with the starch of wheat.

Kirchhoff, a Russian chemist, found, that by boiling starch with dilute sulphuric acid it is converted into suga; and M. T. de Sauffure has recently discovered, that this change takes place spontaneously when boiled starch is exposed for a considerable length of time to the action of the air.

STATISTICS, a term applied to the topography of a country, and comprehending its population, policy, manufactures, trade, and a variety of other circumstances.

STEÅRIN, in Chemisty. A name given by Chevreul to a substance existing in animal tallow or fats. It may be separated by alcohol, or simply by pressure. Bracconet used the following method: The oil if fluid was congealed, and in this state was subjected to strong pressure between folds of blotting paper. The clain (see Elain) was imbibed by the paper while the stearin remained behind in a solid state.

Steerin thus obtained is white, brittle, and something like wax in appearance. It crystallizes in small needles. It has little or no smell. It is tasteless, and produces no effect on vegetable juices. It melts, as obtained from different fats, between 109° and 120°; that from the fat of the duck being most readily melted, and that from human fat, the least. It is soluble in water, and combines with the alkalis, forming soaps.

STEUELEN, 1. 15, add—of whom, in 1810, 87 were

Stipling, 1. 7 and 9. 9. pecks.

STIRLINGSHIRE. In 1811, this shire contained 8010 houfes, besides 55 unfinished, and 58,174 persons (including 803 local militia); 27,745 being males (militia included), and 30,429 females: 2425 families being employed in agriculture, and 5912 in trade, manufactures, and handicraft.

STIRRUP. At the close, add—The Roman manners required that young men and expert riders should be able to vault on horsecback without any assistance. (Virgil, Æneid, l. 12. 888.) In many public places, particularly highways, stones were erected, to which a rider could lead his horse, that he might mount with greater facility. Such stones Gracchus caused to be raised (Plutarch, de Vit. Gracchi); and they were to be found in many cities in the 16th century, especially near the council-house, for the convenience of the members of the council, who at that time did not ride in coaches. It was usual also to have portable stools, which were placed close to the horse when persons wished to mount: and this gave rise to the barbarous practice of making conquered generals and prisoners jump up, that the victor might more easily get on horsecback, by leaping upon their backs as upon a stool. In this ignominious manner was the emperor Valerian treated by Sapor, king of Persia. Some horses were so taught, that they kneel’d until the rider mounted; and warriors had on their spears or lances a step or projection on which they could rest the foot until they got on horsecback. (Strabo, lib. iii. Sil. Ital. lib. x.) See Anabathra and Anaboleus. The first certain account of stirrups, says Beckmann, (History of Inventions, vol. ii.) is in a book written by Mauritius, respecting the art of wars, about the end of the 6th century. Eutathius, the commentator on Homer, informs us, that in his time, i.e. the 12th century, stirrups had not become very common; but on a piece of tapestry, of the eleventh century, caused to be engraved by Montfaucon, the faddles of all the horses appear to have stirrups. However, after they became common, it was thought to be an evidence of superior dexterity to ride without them.

STOKES, in Geography, a township of Madison county, in Ohio, containing 267 inhabitants.

STONE in the Bladder. See Lithotomy, and Urinary Calculi.

STONE, Mile. See MILE-STONE.

STONES, Chemical Analysis of. See Analysis.

STONY CREEK, in Geography, a township of Somerset county, in Pennsylvania, having 943 inhabitants.

STRAFFORD, in New Hampshire, add—divided into 31 townships, &c.

STRAINING. See LUNGS.

STRAND BRIDGE. See Waterloo.

STRONTIAN, STRONTIUM, in Chemisty, the name of an elementary substance or earth, the description of which has been omitted.

Strontian is always found in nature combined with the carbonic or sulphuric acids. (See Strontianite and Celestine.) It may be obtained pure from these minerals precisely in the same manner as barytes and lime.

Strontian thus obtained is in porous masses of a greyish-white colour. Its taste is acid and alkaline, and it converts vegetable blues to green. Its fp. gr. according to Hassenfratz, is 1.647. It does not act on strong bodies as barytes, nor is it poisonous.

Sir H. Davy, led by analogy, subjected it to galvanic influence, and thus succeeded in separating its oxygen and obtaining *strontium,* the metallic basis of strontian. This metal is white, much heavier than water, and bears a close resemblance to barium in its properties: when exposed to air or thrown into water, it rapidly absorbs oxygen, and is converted into strontian.

Dr. Thomson, from the recent experiments of Stromeyer and...
and others, fixes the weight of the atom of stroniat at 65; from which the composition of its fats may be readily estimated.

The fats of stroniat require to be briefly noticed. They are in general more soluble than the fats of barytes, but less so than the fats of lime. Most of them are capable of being crystallized. They are precipitated by the sulphates, phosphates, and oxalates. Succinate of ammonia precipitates barytes, but not stroniat. When a piece of paper is dipped into a solution of a fat of stroniat, it burns with a red flame. The fats of stroniat are not precipitated by the prufiate of potash, nor are they poisonous.

Nitrates of Strontian.—This fat crystallizes in fix-sided pyramidal dodecahedrons with apexes truncated, so as to have the appearance of hexahedral plates with bevilled edges. Sometimes in eight-sided prisms. It is perfectly transparent. It has a strong pungent cooling tinge. Its fp. gr. is 3.066. It is soluble in its own weight of water at 60°, and in little more than half its weight of boiling water. It is insoluble in alcohol. It is not altered by exposure to air. It degrades in hot coals. When a crystal of nitrate of stroniat is put into thewick of a candle, it communicates a beautiful purple flame.

Muriate of Strontian.—This salt crystallizes in long slender hexagonal prisms. Its taffle is thick and penetrating. Its fp. gr. is 1.402. It is soluble in less than its weight of cold water, and in any quantity in boiling water. It is soluble in about twenty-four parts of cold alcohol. The crystals do not deliquece on exposure to the air, except in very damp weather.

Carbonate of Strontian.—This, when precipitated, is a white powder without taffle or smell, and soluble in about 1336 parts of boiling water. Its fp. gr. is about 3.66, and it is not altered by exposure to the air.

Sulphate of Strontian.—This salt is taflteless, soluble in 3840 parts of boiling water; readily soluble in sulphuric acid when allfified by heat, and poifles other properties very analogous to the sulphate of barytes.

Phosphatc of Strontian.—This salt is likewise taflteless, insoluble in water, and not altered by exposure to the air.

Acetate of Strontian.—This is soluble in little more than twice its weight both of cold and hot water. It may be crystallized, and the crystals are not altered by exposure to the air. It renders vegetable colours green.

The other fats of stroniat do not in general poifles any remarkable properties. The oxalate, tartrate, succinate, and citrate of stroniat, are all more or less soluble in water; the oxalate being the leaft soluble, and the citrate the moft. The malate of stroniat is more soluble in water than the malate of barytes.

STROUD, in Geography, a parish of Kent, part of which is included within the jurisdiction of the city of Rochester (see Rochester); and the other part, in 1811, contained 242 houses, and 1394 persons: 718 being males, and 676 females.

STYLE, in Painting, is the manner in which a painter conveys and executes the subjects he adopts; or, in other words, in which he combines the various qualities of a picture. Style is properly divisible into four distinct kinds, viz. the grand or sublime, the beautiful, the natural, and the mean. There are indeed several varieties of style which have obtained specific apppellations; but they will be found upon examination to combine, in different ways, the qualities peculiar to those above-mentioned; and are justly regarded as vicious in their nature: such are the ornamental and the artificial styles of art, which divert the attention of painters from the more pure application and exercise of their art, and lead them to adopt fictitious means of attracting attention, by contrast and affectation, by glitter, and an idle display of skill in workmanship, to the neglect of nature and just expression, and sometimes even of common sense.

The object and aim of the grand style is to captivate the imagination. It is the only proper one for the representation of grand and elevated ideas, or subjects which represent the actions of deities, or of heroes, or which relate to the higher qualities of the mind of man: the only just medium whereby the art of painting can embody such ideas as the cultivation of those qualities inspires, and by which alone it can at all pretend to rival the grandeur and effect of heroic poetry. Its characteristics are simplicity and fulness of form and colour; and it is obtained, by adopting only essential parts, avoiding those which add nothing to specific character, and fixing solely upon those general forms which particularly distinguish one race of beings, or one class of natural objects or of actions from another, giving them their greatest possible degree of elevation, even to the verge of extravagance, in undulation of line, and fulness of form. This feclusion of form and of action requires an appropriate chiaro-ocuro, arranged and combined in broad and simple masses, and painted with a ferior tone of colour; in fact, such a combination of the prime qualities of the art, as will most efficaciously unite in the production of one unmingled emotion.

The grand style does not admit attempts at illusion, or too close an imitation of natural objects; which, when carried to excess, necessarily disturbs that singleness or simplicity of effect required where the object is to produce an elevated tone of thinking. It is not dependent upon size, but may be exhibited on a small scale as effectually as on a large one; witnesses many of the beautiful bronzes and gems of the ancients, and the effect, as described by Statius, of the statue of Hercules made by Lyippus, which "though not more than a foot in height, filled the imagination in a manner equal to the Hercules Farnefo." Raphael's small picture of the vision of Ezekiel is also an efficacious influence of the truth of this assertion.

STYLE, for that word alone is adopted as signification of that mode in art, can only be acquired by those who have made themselves well acquainted with the just proportions and varieties of nature. Its aim being to represent her works with the greatest degree of sublimity commixed with truth, all attempts to produce it without real knowledge must necessarily lead to error, and a species of bombast, instead of expression, yields only deformity. Of this, the works of Gottzius, of Springer, and the Germans who followed them, are sufficient evidence. And yet such is the rarity of perfection in form among the human or the animal race of beings, that an artist whose aim is to produce grandeur of style must draw largely upon his imagination; and while he touches the verge of impossibility, will find that the difficulty he has to overcome is in uniting the principle on which he depends with propriety. Even Michael Angelo, great and glorious as he was among those who have made it their principal object, has not unfrequently allowed himself to be misled by the wish to agrandifie, and give his contours only redundancy for style; and for the sake of a flowing and varied line, has sometimes given forms of action to muscles which ought to have been represented tranquill.

Of this style, as far as relates to form, the best among the sculptures of the ancients afford the fairest examples, particularly the torso of the Belvidere, the head of Jupiter, the Laocoon, the Apollo, the figures on Monte Cavallo, &c. &c.; and it is a striking feature in the works of Phidias,
dias, though with a chastened impulse, as may be seen in the Elgin marbles. Indeed it appears to have been so perfectly understood among the artists of ancient Greece, that it spread generally in a greater or less degree through all their productions, at least in those of sculpture; and from the few remains of painting left to us, it appears not improbable that the professors of that art were no less masters of its principles. In latter times, among the moderns, the Florentine school made it their principal object of attention; and in the works of Leonardo da Vinci, Fra. Bartolomeo, and more particularly of Michael Angelo, it reached in quality nearly to a level with the tasse of those from whom it was adopted. Raphael attempted it in imitation of M. Angelo, and sometimes succeeded, but it evidently was not congenial to his feeling, which inclined to the beautiful and graceful, more than to the sublime; and hence it is that his pictures of the Godhead rarely impress us with sentiments of an exalted nature.

The beautiful style differs from the grand, in that it requires less force of contrast in form and action, and greater softness of colour and effect. Whatever is graceful and animated, void of superfluous parts, and yet essentially characteristic and pleasing in arrangement, combines to form the beautiful. Flowing lines, graceful contrasts, both in form and colour, softened lights and shades, and rich and harmonious colouring, are its principles; on them it depends, and every departure from them necessarily diminishes its quality. It is the fit medium for every subject whose character is adapted to afford pleasure.

As the grand style conflicts in an elevated view of nature, a conception of perfection almost super-human, built upon the possibilities of creative power, acting upon known and natural forms; so the beautiful also must be sought in the regions of imagination, guided by the knowledge of existing objects, and supported by selection from the varieties of nature. Therefore, in order to comprehend the character of beauty as applied to art, we must consider the perfection of that art, not as consisting in mere imitation of visible objects, but as requiring a separation and choice of parts, an ideal perfection, which, though it belongs to the works of nature in all classes of beings, yet is not to be found entire in any given object. Raphael, when he was painting his Galatea, said in a letter to his patron count Baldassare Castiglione, "that not being able to find perfect beauty upon earth, he was obliged to have recourse to ideal excellence framed in his own mind." But Zeuxis took another method to produce the constellation of perfections recognized in his Helen; viz. by selecting and combining the various beauties of the most beauteous among the virgins of Agrigentum: thus surpassing the works of nature, with materials furnished by herself.

Beauty, it will be easily conceived, is not confined to one given line, or set of lines or colours, in unison or in contact with each other. There is necessarily one general form of the male among men and animals, and one of the female; distinct in their character, and yet each having its appropriate degree of beauty: so there is also a distinction of form among different creatures of the same species. Apollo, Hercules, and a Gladiator, have each distinct qualities which must be maintained in their representatives, whilst grace and beauty are given to their forms and actions: and it would be as great an absurdity to soften each to the merely beautiful, and thus render them similar in form and character; as it is ignorable and gross to treat it to that which is characteristic alone for a graceful and agreeable effect.

Though these, which we have specified, be the distinct separations between the grand and the beautiful styles in art, yet either may be rendered more perfect by the addition of the other; and when expression is superadded, then is exhibited the most perfect display of the power of art; and it is this union of the beautiful and characteristic with the grand, which constitutes that mental and energetic application of the art of painting which elevates it above the mechanical arts, and entitles it to the highest pretensions, as it is addressed to the noblest faculties. This is that beau-ideal so much the theme of praise and exultation among the connoisseurs; so universally felt when exhibited, so little understood, and so often the foundation of the grogget follies and deceptions among both artists and amateurs. The former, pursuing the practice of it in theory, often become the dupes of their own imaginary fancies; the latter more often impose themselves upon the world as men of worth by the mere cant of its diction, and are screened from discovery by the general want of information concerning the principles and proper objects of art.

In this happy combination of beauty and grandeur the Greeks still remain unrivalled, as far as relates to sculpture, and perhaps single figures in pictures, but we have very little ground for conjecture how far they were able to conduct the principle in extended compositions in painting. Among the moderns, perhaps Parmeggiano in his latter and more perfect works, as his Moses and his Vifion of St. Jerome, has effected more than any other painter this desirable union; and most likely had he lived much longer the world would have seen the perfection of the art from his hands; more particularly if he had cultivated expression in the school of Raphael, as successfully as he had the other branches of the art in those of Correggio and M. Angelo. "The name of Correggio," says Mr. Fuseli, "is the synonyme of whatever is graceful and agreeable in painting!" to him we are principally indebted for chiaro-oscuro, and that luminous and harmonious tone of colour, which fascinates and delights the eye by its unity, blended with riches and variety. He may be regarded as the father of the beautiful in modern art, as M. Angelo is of the grand and sublime.

That kind of style which is termed natural is, as its name imports, a mere imitation of the common forms of nature, without that selection which we have pointed out as necessary to the higher styles of art. Of this we have many capital instances among the smaller antique bronzes of Fauns, Nymphs, &c. and in many of the works of Titian in his second manner. Most of the principal portrait painters have almost necessarily adopted it, though that branch of the art admits, when highly practised, of that selection of parts which constitutes the beautiful, and of being treated with dignity and even sublimity, as many of the works of Sir Joshua Reynolds, of Titian, and of Van Dyke, sufficiently prove.

In a lower degree, the Dutch and Flemish masters have most successfully wrought in this style, as Jan. Steen, Oltade, Teniers, Rembrandt, Metsu, Terburg, &c. and compensated for the want of higher qualities, by the perfection of their arrangements and execution, and the exactness of their imitations.

Of what is mean in style, it is hardly necessary to speak: examples of it may be found in all early essays; but in none more abundantly than among the works of the artists of the German and Flemish schools of the 16th century. Even in those of Albert Durer, mezzas is a never-failing alloy, amidst all the brilliancy of imagination, and activity of mind, they display; deforming actions and expressions otherwise well worthy of esteem, and extending through every part of the compositions, be it of figures, drapery, or back-ground.

Of the four species of style above enumerated, all others are
are necessarily composed; but there have been some few remarkable aberrations from the ordinary course of art, by painters of uncommon talent, which bid defiance to all classification, and stand alone in their respective spheres. Such are those of Rubens and Rembrandt, of Tintoretto and Salvador Rosa, compounds of all that elevates and graces; in which the grand and the mean, the beautiful, the natural, and the deformed, go hand in hand; the evil counterpoised by the good, and the whole rendered engaging, in spite of defects, by the skilful display of the matter hand which wielded the materials. Such examples, great though they are, ought not to serve as excuses for inattention to settled principles. Who shall say, that if Rubens had been more correct in form, his works would have been less engaging; or, that if Tintoretto had been more pure and true in expression, his productions would not have been more interesting. (See the article Picture.)

Combination, which will justify such expectations have been formed, and we have seen them in our own great sir John's productions, where fine form, rich and full-toned colour, and just chiaro-ocuro, have been blended in skillful and free execution.

**SUCCOWIA**, in Botany, in honour of professor Suckow, a learned botanist of Heidelberg.—“Moench. Meth. 265.”

Eff. Ch. Pouch nearly globular, beaked with the awl-shaped style; valves hemispherical, prickly; cells single-fed. Cotyledons folded together.

**SUFFOLK**, col. 6. 1. 13. add.—In 1811 Suffolk contained 37,227 houses, 2015 then uninhabited, and 234,211 persons; 111,988 males and 122,223 females: 26,406 families being employed in agriculture, and 15,850 in trade, manufactures, or handicraft.

**SUGAR, Chemical Composition of.** See Fermentation.

**SUGAR-Loaf, in Geography, a township of Luzerne county, in Pennsylvania, having 282 inhabitants.**

**SULLIVAN,** 1. 26, inert—including 43 slaves in 1810.

**SULPHUR, in Chemistry.** According to the most recent determinations, the weight of the atom of sulphur is 32, and of sulphuric acid 98; from which data the composition of the compounds of this substance can be accurately ascertained. See Atomic Theory.

Sulphur Island, 1. 8, add.—The sulphur is collected by a few individuals resident on the island solely for that purpose, sent to the Great Loo-choo, and thence exported to Japan and China. N. Lat. 27° 56'. E. long. 128° 11'. Ellis's Journal of an Embassy to China. 1818.

**SULPHURETTED CHYAZIC ACID.** See Cyanogen.

**SULPHURIC ACID.** It is stated in our article on this subject, that sulphuric acid cannot exist without water; and that the sulphuric acid prepared at Nordhausen from green vitriol probably differs from common sulphuric acid by containing less water. The fact is, according to Dr. Thomson, that the latter, when most concentrated, contains no water everywhere, and consequently a perfectly anhydrous sulphuric acid can exist.

**SULPHURIZED MURIATIC Acid, in Chemistry.** The substance described under this name in the Cyclopædia is a chloride of sulphur. See Chlorine. See also the original article Sulphur.

**SULTANABAD.** For Tarshish r. Turkish.

**SURABHI,** col. 2. 1. 44, for prorsis r. prefereb.**

</tbody>
</table>

The depth at which the fish in the preceding table are caught increases gradually, as well as the proportion of oxygen, from the beginning to the end of the table. The trigla lyra is always caught at a very great depth. M. Laroche found, that fishes taken at a depth greater than 150 feet, furnished at a mean about .70 oxygen, while the mean result furnished by the fish caught at lesser depths was only .20. The same law holds with respect to fresh-water fish. M. Biot's experiments were made near the Balearic islands.

**SYCAMORE, in Geography, a township of Hamilton county, in Ohio, containing 1532 inhabitants.**

**SYMPATHY.** See Mental Philosophy.
TAY

Vol. XXXV.

TAIGAREE, for Tegerly r. Tegerhy.

TALBOT. Add—of whom 478 were slaves in 1810.

TAMUL, the name of an Indian language, which is spoken in the tract extending to the south of the Telinga, as far as Cape Comorin, and from the sea to the great range of hills, including the greater part of the Barhamakal and Salem, and the country now called Coimbetore, and formerly Kangiam, along which line it is bounded to the W. by the Canara and Malabar. In the northern part of Myfore, this language is, at this day, named the Kangesa; in the central portion of Myfore it is named the Drauvader, and further N. the Arawes.

TAMWORTH, l. alt. r. Strafford county.

TANACETUM, in Gardening, col. 2, l. 22, add—Dr. Withering says, that the Finlanders obtain a green dye from this plant.

TANK, a term used in India for a pool or reservoir.

TAO-TSE, a term which denominates one of the two religious sects in China; the other being distinguished by the appellation of Fo. The sect of Tao-tse is said to have been founded about 600 years before the Christian era by Lan-Chiu in the Tcheou dynasty, and to have been more philosophical than religious. In the Koong-foo, or postures of the Tao-tse, and their supposed influences upon diseases, may be traced a practice somewhat analogous to animal magnetism. See Religion of China.

TATE, in Geography, a township of Clermont county, in Ohio, having 696 inhabitants.

TATNALL. Add—The number of inhabitants in 1810 was 2206, of whom 542 were slaves.

TAUNTON, l. 5, add—in Bristol county, containing 3907 inhabitants.

TAYLOR, Henry, l. 23, for rector r. vicar; for Rotherhithte r. Reading; l. 24, for four r. eight; for two r.

three. Col. 2. l. 9, for Discourse r. Dialogue; l. 10, r. 1817.

TAZWELL, in Geography, a county of Virginia, containing 3907 inhabitants, of whom 328 were slaves in 1810.

TCHUKOTSKIIA. Add—See ChuKotskiJa.

TEGERHY, r. Taigaree.

TELESCOPE, p. 5, col. 1, l. 9, for Plate XXIV. r. Plate XXVII. P. 25, col. 2, l. 27, for I E M r. I F M. P. 27, col. 1, l. 6, 8, 15, and 23, for 13827 r. 13-3287; l. 23, for 12.61 r. 12.17774. P. 39, col. 1, l. 15 from bottom, for convex r. concave, and let the whole sentence stand thus: viz. "To effect this improvement, the concave lens, with equal dispersive power to that of rock-crystal, must be at one side of the concave of flint, and the convex of crown glass must be at the other side." P. 55, col. 1, l. 25, for $\frac{120 \times 45^\circ}{68^{\circ} - 45^\circ}$ $\frac{120 \times 45^\circ}{68^{\circ} - 46^\circ}$

TELEFAIR, in Geography, a county of Georgia, containing the census of 1810, 744 persons, of whom 218 were slaves.

TELINGA, formerly called the Kalinga, and by the Europeans Gento, an Indian language occupying the space to the E. of the Mahatta, from near Cicaico, its northern, to within a few miles of Pulcat, its southern boundary, with the intervention of a stripe of small dimension. This space was divided into the Anda and Kalinga countries; the former S., the latter N. of the river. At the period of the Mahometan conquest, the southern part of these united provinces seems to have been known to that people by the name of Telingana, and waraikul is the capital of the whole.

TELLURIUM, in Chemistry. Add—This metal has the property of combining with hydrogen, forming a gaseous compound, to which the name of telleutsted hydrogen gas has been given. This compound was discovered by Sir H. Davy, and its properties were afterwards investigated by Berzelius.

Telleutsted hydrogen may be formed by mixing together oxyd of tellurium, potash, and charcoal, and exposing the mixture to the action of a red heat. It is then put into a retort, diluted sulphuric acid is poured on it, and the beak of the retort is plunged into a mercurial trough. A gas comes over, which may be collected in glass jars previously filled with mercury. This gas is transparent and colourless, and poffeffes the mechanical properties of common air. It has a strong peculiar smell, something like sulphuretted hydrogen. It burns with a blueflh flame, and oxyd of tellurium is deposited. It is soluble in water, and gives that liquid a claret colour. Davy was not able to determine whether it reddens vegetable blues, but in other respects it

4O2

poffeffes
poffefles the properties of an acid, combining with alkalies, and precipitating most metallic solutions like sulphurated hydrogen. Chlorine gas immediately decomposes it. The other properties of this gas have not been satisfactorily examined. From the experiments of Ritter, there appears to be a solid compound of tellurium and hydrogen.

Tellurium seems also to have the property of combining with carbon.

TEMPATION, col. 2, l. 28, r. eminence.

TERRITORY, Missouri, col. 2, l. 5, add—It was first discovered by Sebastien Cabot in 1487, and in 1512 visited by John Pontio de Leon, a Spaniard, who endeavoured to form a settlement. In 1684, M. de la Sella, a Frenchman, discovered the mouth of the Mississippi, and built Fort Louis; but being affililiated, it was again abandoned. In the year 1698, captain Ibberville failed to the Mississippi, formed a settlement, and named the country Louisiana. About twenty-two years afterwards, M. de la Suerie also failed up the Mississippi, and proceeded to the distance of 2280 miles from its mouth. In 1762 France ceded it to Spain: in 1800-181st Spain ceded it back to France; and by a treaty of April 30th, 1803, the French government sold it to the United States for the sum of fifteen millions of dollars, payable in fifteen years at the rate of one million annually.

Bradbury's Travels, p. 214.

TEST-ACT, col. 10, l. 4, for office r. offence.

TEUTATES. Add—See Druids.

TEUTHIS, Hepatus, l. penult. r. Tang.

TWEKESBURY, in Geography, a town of Hertford county, in New Jersey, containing 1598 persons, of whom 66 were slaves in 1810.

THEOPHILANTHROPISTS, a sect which sprung up, flourished, and became extinct in France during the period of the Revolution. It has been said, that the "temple of nature," opened in Margaret-Street, London, in 1776, by the lately deceased David Williams, an active member, if not the founder of the society for the relief of decayed and indigent authors, for worship on Deistical principles, suggested to the unbelievers of France the idea of a ritual and liturgy of deism, which was first carried into execution in the year 1796. The resemblance of the principles of some members of the sect to those of Robespierre, and of its ceremonies to the worship of the deities of Reaon, has led some persons to repress the Theophlan-
thropists as partisans of the tyrant, and their meetings as Jacobin clubs; but the abbe Gregoire (ubi infra) has laboured to vindicate them as a body from this charge. The first person who planned the celebration of the rites of natural religion appears to have been D'Aubermenil, a romantic enthusiast, who wished to revive a part of the doctrines of the ancient Magi. In his work intitled "Culte des Adorateurs," which is a rubric, a liturgy, and a treatise of morals, eight days are appointed for labour, and the ninth for rest; but the temples were to be con-

stantly open, and the sacred fire kept burning in them with the most religious care. The priests, whose costume was preferred, were to offer to the Deity grain and fruits of different kinds, salt and oil, and, turning to the four cardinal points, to pour libations and make apotrophe to the elements. The twelve signs of the zodiac were to be painted on the walls of the temple, (or asylum, as it was denominated,) and under each thirty butterflies, to reprent the number and shortue of our days. Sacred dances were to be performed at different periods; the elderly men leading off with the matrons, the young men and the virgins following. At funerals a libation was to be poured out to

the manes of the deceased, and the eldset of his relations was to throw water on the fire, addressing the element in a prepared formula. D'Aubermenil proposed to denominate his followers "Theanthropophiles," which appellation was afterwards changed to "Theophilanthropes." As the churches had all become national property, the Theophilanthropists applied to the civil authorities for the use of them jointly with the Catholics; and their request was granted, on condition that each party should remove the emblems and decorations of its own worship, while that of the other was performed. We shall not detain our readers with describing their ritual, the drefs of their orators, or the circumstances attending their worship, and their marriage-service, nor shall we detail their moral lefion, or give specimens of their hymns and sacred poetry. This sect did not subsist for a long time; the zeal of its partisans began to decline in the provinces; and it appears, from the registers of a society at Bourges, that their first sitting was held in the cathedral, Feb. 29, 1798; and that on the 18th of August, 1800, their number being reduced to seven or eight, they dispersed, and the Theophilanthropic church of Bourges became extinct two years and a half after its first formation. In about five years, the whole sect had quietly disappeared; the latter trace of it being that Chemin, who wrote a work defending their principles, made use of their manual as a school-book in a leminary at Paris, where he taught Latin. See Abbe Gregoire's Histoire des Septes Religionens, &c. 2 vols. 8vo. Paris.

THOMPSON'S POND, and Shaker Settlement, in Geography, a township of America, in the district of Maine, and county of Cumberland, having 191 inhabitants.

THORINA, in Chemistry. The name of an earth recently discovered in Sweden by Berzelius.

This celebrated chemist first detected thorina in the Gadolinite of Kvarvar, and afterwards in the deutoflite of cerium, and the double fluoride of cerium and yttria, both minerals found at Fahlin.

Thorina may be obtained from the minerals containing protoxyd of cerium and yttria in the following manner. Precipitate the iron by means of the ferricen of ammonia. Thorina when alone is precipitated by this salt, but this is not the case when it is mixed with the other bodies that exist in the fluixes of cerium and yttria. After the iron is removed, precipitate the cerium by means of sulphate of potash. Ammonia now precipitates the thorina mixed with yttria. Dissolve them in muriatic acid. Evaporate the solution to dryness, and pour boiling water on the residue, which will dissolve the greatest part of the yttria, but not the whole. Redissolve the residue in muriatic or nitric acid, and evaporate till it becomes as exactly neutral as possible. Then pour water upon it, and boil it for an instant, the thorina precipitates, and the solution contains a disfengaged acid. If we saturate this acid, and boil it a second time, an additional portion of thorina is precipitated.

Thorina when separated by the filter has the appearance of a gelatinous semi-transparent mass. When washed and dried it becomes white, absorbs carbonic acid, and dissolves with effervescence in acids. Though calcined it retains its white colour. After a violent heat it is diSolutely soluble in muriatic acid. The solutions in this acid are yellowish, but become colourless when diluted.

The neutral solutions of thorina have a purely astringent tafse, which is neither bitter, sweet, saline, nor metallic; a property in which it agrees with zirconia, and differs from all other earths.

Thorina is little soluble in the alkalies or alkaline earths. It
It has not yet been reduced to the metallic state. It is infusible per se before the blow-pipe, but with borax it melts into a transparent glass. It differs from alumina by its insolubility in hydrate of potash; from yttria by its perfectly alrigrate table without sweetseas; and by the property its solutions possess of being precipitated by boiling, when they do not contain too great an excess of acid. It differs from zirconia by the following properties: 1. After being heated to redness, it is still capable of being dissolved in acids. 2. Sulphate of potash does not precipitate it from its solution, while it precipitates zirconia from a solution containing even a considerable excess of acid. 3. It is precipitated by oxide of ammonia, which is not the case with zirconia. Sulphate of thorina crystallizes readily, while sulphate of zirconia, supposing it free from alkali, forms when dried a gelatinous transparent mass, without any tendency to crystallization.

Thorina combines with the different acids. The sulphate of thorina is soluble, and yields transparent crystals, which are not altered by exposure to the air, and which have a flinty tactile.

The nitrate and muriate of thorina do not crystallize. The carbonate of thorina is very readily formed, the earth having a very great affinity for this acid. None of the other salts of thorina known appear to be capable of crystallizing.

THORN, in Geography, a township of Fairfield, in Ohio, having 457 inhabitants.

THORNBURY, a township of Chester county, in Pennsylvania, having 202 inhabitants.

THORNTON, a town of Grafton county, in New Hampshire, containing 794 inhabitants.

THRIPS, col. 2, under VARIEGATA, l. 13, add.—The Thrips phylaphus has been supposed to do much injury to wheat, rye, &c. by cutting the young flowers to decay, and thus preventing the growth of the embryo grain. Some, however, have disputed this opinion, contending that the thrips does not attack itself to fuch of the cerealia as are in a perfectly healthy state, but rather to fuch as are diseased, by having the germinia covered with the dust of a very minute fungus, often growing on wheat, &c. and belonging to the genus Ascidium or Lycoperdon, and which appears in the form of a flattish, smooth, irregular exudation of a yellow colour in various parts of the plant. (See on this subject, vols. iii. iv. and v. of the Transactions of the Lin- nean Society.) The ingenious Mr. Kirby, however, feems convinced, that the thrips is in reality an insect highly injurious to corn, by deriving its nourishment from the embryo grain. Shaw's Zool. vol. vii.

TIC DOULEUXE, in Medicine, an extremely painful disease of the nerves of the face, commonly, if not exclusively, affecting some branch of the fifth pair of nerves, and most frequently the infra-orbital branch, where it passes through the foramen, so named in the check.

The complaint commences with flight and almost imperceptible attacks of pain, and generally without any warning; though some patients feel in the affected part peculiar and inexplicable sensations preceding its approach, from which they announce with horror the coming enemy; the patient at the same time enjoying a good or an indifferent state of health. The pain, however, soon becomes most acute, shooting and darting along the various ramifications of the affected nerves. It generally continues from a quarter to half a minute, and never exceeds the space of one minute. It returns at intervals more or less frequent; there being sometimes several paroxysms in a few minutes, and at other times there are intervals of from fifteen to thirty minutes, or longer. There is no determinate period; we always find the utmost irregularity even in the same patient.

The pains vary in their degree of intensity, at one time exciting the most piercing cries, and distracted writhings and motions in the miserable patient; while at another, they are more bearable. When at the aee of their violence, the parts affected are often convulsed, and sometimes various contortions and grimaces are observable. These are to be distinguished from the convulsive twitchings of the muscles, with which the diseased nerves communicate, and which are occasioned by irritation from the excessive pain; while the contortions and grimaces are voluntary, being caused by the patient's writhing and twirling from the agony of his torture, and may be prevented by a firm resolution to reft all impulse of shringking from the attack.

The pain does not always confine itself to the seat of the diseafed, but darts with the rapidity of lightning to the neighbouring parts, shooting in different directions like radii from a centre. It rarely gives warning of its approach, and often the firit sign of an attack, is the patient's startling up in a state little short of phrenzy. In this condition, some patients beat the part with violence, or forcibly rub it with some rough substance till excitation takes place; and in some instances, they have succeeded in diminishifhing the intensity of the pain. The pains are more frequent during the day than in the night, probably from there being fewer causes of irritation; and they are more frequent during conversation than in silence; and still more so, at the time of mafliciation, when the attacks often succeed each other with such rapidity as to appear like one continued paroxysm, with scarcely one interval of effafion. The eye at times is red, inflamed, and watery, as we sometimes observe in fever tooth-ach. In other cases, it is particularly dry, and in some patients a copious flow of saliva succeeds a paroxysm. In general, only one side of the face is affected with this dreadful malady. But as there are cafes recorded in which both sides suffered at the same time, we cannot lay it down as a certain characteristic of the disease. Fouquet observed at Montpellier two women who had both cheeks affected at the same time; and Pajol knew a lady, who, for several months, had the pain in one cheek, which after a while was free from pain; but the other cheek was immediately attacked in the corresponding place, the pain continuing for two months, and then refuming its former position.

When the disease continues for a great length of time with increafing violence, the patient can neither obtain rest by night nor by day. His appetite fails; and, as may be expected, there is fae degree of feverishness. But this rarely happens, and only in cafes of the utmost severity. The complaint usually terminates without any apparent cause, leaving the patient for a time to enjoy the comforts of life. But whoever has had one attack may with confiderable certainty anticipate another; and though he is to-day well, and free from all pain, to-morrow's dawn may usher in a renewal of his torment. So varied is the duration of this affection, and so limited is our knowledge of it, that we can assign no determinate or even probable period for its continuance; and unless a cure is effected it returns at intervals more or less frequent, and with increased violence, till the great final catastrophe, which, however, it does not seem to accelerate. For though Dr. Banch is said to have died of it, we can place little reliance on the report, and frequent cafes and observa- tions do not corroborate such a fuppofition.

Hartenfiiel,
Hartenbeil, Hildebrande, and Baldinger, and some other Germans, relate cases of what they call tic douleureux; which, though in some particulars, they resemble that affection, in others differ most materially. The first of these writers describes it as having been very prevalent at Saltzburgh. But the pain was periodic, recurring generally once in twenty-four hours; and sometimes, though rarely, once in twelve hours; often remaining for several hours at a time, and then suddenly departing. These, however, were obviously cases of hemiplegia; for that has, in many instances, been observed to attack the patients periodically, and to yield to bark. See HEMICRANIA.

The predisposing cause of this disease would seem to be a certain period of life, when the strength begins to fail, the functions to be impaired, and the whole corporeal frame to feel the first signs of approaching decay. We rarely find it commence before the fiftieth year, though two or three cases of an earlier date are recorded. Women do not seem to be more liable to the complaint than men; though Dr. Fothergill, having a great proportion of female patients, imagined they were more predisposed to it; as likewise did Pujiol, from their greater femininity.

The latter author (in his Essay, p. 14) says, "we generally observe in such people as are subject to tic douleureux an excess of mobility, which renders them more or less disposed to hysterical and hypochondriacal affections. Experience, however, teaches us, that people very far removed from excesses of sensibility are equally liable to the disease; that women are not more liable to it than men; and that the predisposing period of life is that when the sensibility or mobility of fibre is most defective.

The exciting causes are, cold applied to the face in a stream, whether of air or of water; particularly when the patient is fatigued by previous exhaustion. Exposure then to stormy, damp, moist, windy, and tempestuous weather, frequently excites an attack; also external injuries, as blows or contusions on the face. Paffions of the mind, as excess of anger or of grief.

The disease being once established in the system, the slightest cause in some individuals will bring on a paroxysm; such as eating, drinking, and talking, or indeed any motion of the facial muscles, or the gentlest touch with a handkerchief, or any other substance to the nose, lips, cheek, &c. of the afflicted side. Shaving is an operation most particularly disliked and dreaded by the unhappy patient; and often cannot be endured till after a considerable interval of ease. Blowing the nose is absolutely impracticable; or, if attempted, a most pungent and distracting torture attends the performance. M. Andréé, in a work entitled "Observations sur les Maladies de l'Uûrûte," mentions a very obstinate case of tic douleureux, which he attempted to cure by destroying the nerve that he supposed to be the seat of the disease. He began by laying it bare, and was astonished to find, that every time he touched the denuded nerve, he immediately excited symptoms of the disorder; the paroxysm ceasing in the usual time, and recurring whenever the nerve was touched. This fact is very clear and decisive as to the part affected by the disease, and hence we readily perceive, why the least touch or motion on the surface of the skin produces a paroxysm.

When the pain has continued with frequent accessions for a length of time, a most distressing scene is sometimes witnessed. The patient, whose health at the time is generally good, after deftitting from eating and drinking, till the kenmarks of his appetite, and the intensity of his thirst, are too irresistibly urgent to be longer unrelieved, attacks whatever food is placed before him with maniac fury and hurried precipitancy; his countenance suffused with crimson, and convulsed and contorted with pain. This horrid conflict does not last long; he soon throws down his knife and fork with desperate violence, obliged to solicit a ceasation of pain by a flate of inaction.

Treatment of Tic Douleureux.—Of the inefficacy of most medicines in the cure of this cruel disease, we have abundant and melancholy proof. Those which have been tried with no success are, opium, cicut, zinc, framonium, belladonna, argentum nitrum, and arsentic. But the influences in which a cure was effected by their use are very rare; indeed some practitioners, from painful experience, deny their efficacy altogether. All manner of topical applications, from blisters to the smoking entrails torn from living pigeons, have been in vain applied, and baths and bleeding of all sorts.

M. Waton, professor of chemistry in the central school of Vaucluse, relates two cases of tic douleureux arising from venereal causes. The first was that of an officer in the French army, aged thirty; the other that of a lady, aged forty. They were both completely cured by a course of mercury. These cases, in some respects, differed from the tic douleureux, but had its most distinguishing characteristic darting pains in the direction of the nerves. We learn nothing more from them, however, than that, where the symptoms of the tic douleureux are excited by the existence of a venereal taint in the habit, they will depart when that taint is overcome by the action of mercury; but it is found from experience, that in ordinary cases, the symptoms are not in the least relieved by the use of mercury. Recourse has next been had to electricity, to magnetism, to actual cautery, and finally, to the section of the affected nerves. Electricity sometimes produces temporary cases, but as frequently increases the pain; though Mr. Blunt, in the Medical Journal, relates the case of a lady afflicted with tic douleureux being cured by electricity. The pain was chiefly seated in the right temple, and the symptoms are so well described as not to be disputed. She was electrified twice in the day for several minutes each time; first with sparks, then with thoccks, after having previously endured a long and ineffectual course of powerful medicines. Immediately after the second application of electricity she ventured to eat, and performed that necessary operation without any inconvenience. The pains afterwards recurred very slightly; the electricity was continued; and in the course of a short time, she became entirely free from the complaint. The decided successes of this, though a solitary case, in such a dreadful disease, authorises us to hope, that future trials may be made of the application of electricity, which under the direction of an able practitioner is often a very powerful instrument in the cure of disease, and much oftener fails from want of care and affinity in the application, than from inefficiency in itself as an agent.

The mode of destroying the affected part of the nerves by cautery has been adopted by some practitioners, and failed to be attended with success. But, till more experience has better established the utility of such a cruel operation, we cannot recommend its use; it has not been had recourse to in this country; and some cases are related in which it did not succeed, and others in which deformity of the face was the consequence. M. Andréé, however, has tried it, and recommends its general use. In his work will be found an account of the method of operating.
TIN

The section of the affected nerve was thought of and tried many years ago in the cure of this disease; and of late years, from a temporary success, some practitioners have confidently asserted, that the cure was effectual and radical; but more recent experience has destroyed the validity of such assertions.

So long back as the year 1768, Veillard published a thesis, in which he decided this question in the negative. "Utrum in pertinacissimus capitis, faciisque doloribus, aliquid promesse poe festio morborum nervi quinti paris?" Now it is not likely, that he should have treated this important question superficially, but that he would rather collect all the information that at that time could be obtained upon the subject. He mentions two cases where the disease returned after the division of the nerves; and others, in which bad consequences ensued after the operation. Marechel, about the middle of last century, operated twice without success. Pujol was so convinced of its uncertainty, that he would not venture upon it. He has seen the muscles paralyzed, and the face distorted in consequence of the operation. Sabatier relates, that Rival, surgeon to the king of Poland, performed the operation with success; but the patient, after being free from the complaint for some time, was again attacked with his former pains.

Modern practice seems also to confirm our scepticism in the permanent success of dividing the nerves. We find that what was at first supposed to be the most decisive case in its favour, the operation performed, and the account of it so falsly recorded by Dr. Haigton, is now not to be relied upon. Mr. A. P. Cooper has frequently performed the operation with similar premature success, but with what permanency time only can determine.

There is a case related by Darwin, in the Zoornia, of a gentleman who first had the second branch of the fifth pair of nerves divided; then the fifth branch; and thirdly, the remaining third branch. But the patient was not yet relieved. He then had several incisions made across the side of the nose, and offa man, through the masticatory muscles to the jaw-bone, through the parotid gland. And lastly, some more twigs from the second branch of the fifth pair, passing into the cheek, and lying between the pterygoideus internus muscle, and the upper part of the lower jaw. These operations were performed by Mr. Cruikshank and Mr. Thomas. The patient, it seems, at length escaped alive and cured. Dr. Haen has divided the suborbital nerve, as have also Moreau and Guevrin, without any bad consequences. For the best method of operating, see Dr. Haigton's paper in the medical records.

It appears then, that as yet we know of no certain and radical cure for this painful affection. The section of the nerves promises the fairest; but when it is had recourse to, the patient should be warned of the possibility of the complaint returning, and not amused with the certainty of its being completely cured. Admitting, however, that the disease may return in the course of a few years, the operation is so simple, it is attended with so little inconvenience or danger, and the relief in general so complete and instantaneous, that there can be little hesitation on the part of the practitioner in recommending its being performed, when the ease of the disease is accurately ascertained.

Lentin declares, he has had the misfortune to treat, in the course of twenty-seven years, fourteen patients attacked with this painful malady, without radically curing one; and calls upon all practitioners to make public any means they may have found to succeed, either in performing a complete cure, or even a partial relief of the symptoms. The only remedies from which he experienced any good effects, were the tincture of thornapple, Datura Stramonium Linnaei, and the fulphureous baths of Meudon.

A French writer relates a method of taking nutriment for those patients who feel an appetite, but dare not indulge it, on account of the extreme pain; and that is, to suck through a small tube, as a quill, reed, &c. soup, broth, milk, or any nourishing fluid, so gently as to excite any pain.

TILE-ORE. See COPPER, and MINERALOGY, Addenda.

TIN, CRYSTALLIZED, a kind of manufacture said to have been accidentally discovered in France by M. Baget, called metallic waterings, or terre aitonique. It depends upon the action of acids, either pure or mixed together, and in different degrees of dilution, on alloys of tin. The variety of designs resembles mother-of-pearl, and reflects the light in the form of clouds. The process is this:

First, dissolve four ounces of muriate of soda in eight ounces of water, and add two ounces of nitric acid.

Second mixture; eight ounces of water, two ounces of nitric acid, and three ounces of muriatic acid.—Third mixture; eight ounces of water, two ounces of muriatic acid, and one ounce of sulphuric acid. One of these mixtures is to be poured warm upon a sheet of tinned iron, placed upon a vessel of stone-ware; it is to be poured in separate portions, until the sheet is completely watered; it is then to be plunged into water, slightly acidulated, and washed. The waterings obtained by the action of these different mixtures upon tinned iron, imitates very closely mother-of-pearl and its reflections; but the designs, although varied, are quite accidental. By heating the tinned iron to different degrees of heat, stars, fern-leaves, and other figures, are produced; and by pouring one of the above mixtures, cold, upon a plate of tinned iron, at a red heat, a beautiful granular appearance is obtained. These metallic waterings will bear the blow of a mallet, but not of a hammer; hence the invention may be used for embossed patterns, but not for those which are punched. Different colours and shades may be given by varnishes, which, when dried, are thinly polished, will set off the beauty of the waterings. When the tin is upon copper, the crystallization occurs in the form of radiations or stars. M. Lewis Felix Vallet obtained a patent for an invention of this kind, upon delivering the following specification, Feb. 5th, 1818. The procédés of giving the new ornamental surface on metals or metallic compositions, consists in employing those acids and saline compounds and substanishes which chemically act upon tin, and which, when employed in the manner to be stated presently, give to the metals or metallic compositions to which they are applied the appearance of a crystalline surface differently modified. To produce this effect, the metal or metallic composition ought to be previously tinned, or covered with a thin coat of tin. If the metal be pure tin, it requires no previous preparation. All graces remaining on the tinned surface in consequence of tinning is to be taken off with a solution of potash, soap, or any other alkaline solutions. The tin or tinned surfaces should then be washed with pure water, dried and heated to a temperature which the hand can bear. When the surface has thus been cleaned and heated, any of the acids which act upon tin, or the vapours of those acids will cause the desired appearance of crystallization; but I give the preference to the following composition, which may conveniently be laid over with a brush or a sponge. Take one part by measure of sulphuric acid, dilute it with five
five parts of water; take also one part of nitric acid, and dilute it with an equal bulk of water, and keep each of the mixtures separate. Then take ten parts of the sulphuric acid diluted in the manner before stated, and mix it with one part of the diluted nitric acid, and then apply this mixed acid to the tin, or to the tin-plates, with a pencil or sponge, as above directed, and repeat the application of the said composition for several times successively, or until the result you expect proves satisfactory. When this has been done, the crystalline surface may be covered with a varnish or japan more or less transparent or colourless, or covered, and lastly polished in the usual manner.

Mr. Shaw, of Brunswick-square, purchased this patent, and tin-plates were made under its protection, at the manufactory of Mr. Burnell, at Battersea. But the proceeds being generally known among chemists, the manufacture declined, and the patent, for which a considerable sum was paid, became of little value.

Tin-Plates. Add—The manufactory for tinning iron-plates was established at Pontypool by major John Hanbury, where he resided until his death in 1734; and the invention of the art has by some persons been erroneously ascribed to him. His monument may be seen in Trewelli church.

TOGAGA, in New York. Add—By the census of 1810, the number of its inhabitants was 7599, including 61 slaves.

Togoa, a county of Pennsylvania, including two townships, and 1687 inhabitants.—Also, a township of the said county, having 803, the other Delfer, having 884 inhabitants.

TISBURY, including the Elizabeth islands, in Duke's county, Maffachusettts, contains 1202 inhabitants.

TITANUM, Chemical Properties of, are given under钛, in Mineralogy.

TITICACA. Add—See CUSCO.

TOBACCO. l. 3; for 1560 & 1584. See Drake.

TOBAINA, a township of Cumberland county, in Pennsylvania, having 1799 inhabitants.

TOBY. Add—Also, a township of Armstrong county, in Pennsylvania, having 611 inhabitants.

TOLERATION. l. 18, add—The late abbé Gregoire, in his "Histoire des Sectes Religieuses, &c." observes, that "we must not confound civil and religious toleration. The latter supposes that truth and error are indifferent; which truth can never be, for it is only one; and this being the case religious toleration would be an affront to God, who is truth itself. Civil toleration is that which grants to every one the power of publicly exercising the mode of worship to which he is attached;—an inalienable right of every member of society, and which, incorrectly denominated toleration, ought to be called liberty of worship. It has been already observed, and cannot be too often repeated, that the only authority which the civil magistrate possesses over religious associations is to see that they neither suffer molestation nor molest one another." Col. 6. l. 13, add—and extended to Ireland by 57 Geo. III. c. 70.

Vol. XXXVI.

TOLAND. Add—Also, a town of Maffachusettts, in the county of Hampton, having 758 inhabitants.

TOOLAVA, an Indian language, which extends from Niliuram to Sedehagar, S. of Geo.—Also, the name of a country considered as a subdivision of Kéreda, which extended from Gocuro, round Cape Comorin, to the river Tumbrapuri in Tinnavelly.

TOOMBUDRA, a river of Hindooftan, which is a southern branch of the Kijbe; which see.

TOPASSES, an Indian denomination of native black Christians, the remains of the ancient Portuguese.

TOPHANIA, or TOPHANIA, the name of a woman who refided first at Palermo, and afterwards at Naples, and who rendered herself infamous by preparing and administering poison. She sold these drops which from her acquired the name of Aqua Tophania, Aqua della Topfana. It was called also Acqua di Napoli, or only Acquetta; but the distributed her preparation, by way of charity, to such wives as wished to have other husbands. From four to six drops were sufficient to destroy a man; and it has been affirmed, that the dose could be so proportioned as to operate in a certain time. As the was watched by the government, she fled to an ecclesiastical asylum; and when Keyfley was at Naples in 1730, she was then living; her life being secure under that protection. It was her practice to distribute her poison in small glass phials, upon which was this inscription, "Mamma di St. Nicholas of Bari," and ornamented with the image of that saint, whose reputation prevented its being particularly examined by the culfum-houfe officers. About the year 1769, Tophana fled from one convent to another; but she was at length seized and thrown into prison. Her imprisonment, as she was under ecclesiastical protection excited the indignation of the clergy, who endeavoured to raise an insurrection among the people; but they were appeased upon Topohana's confession, that she had poisoned all the springs in the city. Upon the rack she acknowledged her wickedness; her protectors fled, and she was strangled; and in order to ingratiate the archbishop, her body was thrown, at night, into the area of the convent from which it was taken. Her secret did not die with her; but her poison was secretly prepared and administered at Naples after her death. It was afterwards preferred, from the effects of her poison, that it was a preparation of arsenic. Keyfley. Beckmann, Hist. Invent. vol. i.

TORPEDO, a kind of destructive machine, invented by Mr. Fulton, to whom we owe the construction of the much more useful naval machine, viz. the steam-boat. Add—This submarine mine, however it may give celebrity to the ingenuity of the inventor, will, we truft, for the sake of humanity and the honour of naval conflicts, never be adopted in any civilized nation.

TORRES VEDRAS. Add—This ancient town lies about seven leagues from Lisbon, and is situated in a small plain, about three leagues from the sea, on the river Zigandra. It owes its name to the circumstance of there being the ruins of many old towers in its neighbourhood. The principal one, or castle, has been repaired, and serves as a point of defence to the works thrown up at this important post, which covers two great roads leading to Lisbon from this point, one by Mafra, the other by Euxorâ dos Cavaleiros. Although this may be a sufficient description of it in a geographical point of view, we do not think it should be omitted to be here stated, that the celebrated position occupied by the duke of Wellington to cover Lisbon in the fall of the year 1810, took its name from this town, which formed one of the principal points of the line of defence, which was carried across from the Tagus to the sea, presenting a contour of about forty miles, of such an imposing nature as to render unavailing all the efforts of an almost overwhelming French army, under one of their most distinguished marshals, to expel the Anglo-Portuguese from the
the Peninsula. This line of defence (with another about five miles in its rear), stretched from the Tagus to Alhendih to the sea where the Zigungara falls into it, being a direct line of about twenty-six miles. The whole of this most extensive, varied, and gigantic position, was selected and formed under the duke of Wellington's direction, with the most unwearied exertion by those able and scientific engineers the late sir richard Fletcher and colonel Chapman, and with the retreat of the French from before it, may be said to have commenced the series of achievements which finally ended in the triumphs of the British army in the heart of France.

TORRINGTON, l. 1., after Connecticut, add—in the county of Litchfield, containing 1586 inhabitants.

TORSK. See GAUS BROIUE.

TORTURE. At the close, add—Torture was abolished in Sweden by order of the king in 1786; in Poland, in 1776; in France by edict, Aug. 16, 1780; in Spain, Aug. 1814; and in Austria, in 1776.

TOURACO. See CCULUS and Opethius.

TOWIACHES, l. 1, infect (see PANIS); l. 5, after miles, add—N. lat. 35° 20'. W. long. 97°.

TOWNSEND, l. 1, add—in the county of Middlesex, containing 1246 inhabitants.

TOWNSHIP, Upper, Middle, and Lower, three townships of Cape county, in New Jersey; the first having 1664, the second 1106, and the third 862 inhabitants.

T. inesia. Smooth Trachymene, or Botany-hay Carrot. Rudge as above, t. 21. f. 2.—Stem nearly naked smooth. Umbels terminal. —Sent, many years since, under the above English name, from Port Jackson, by Dr. White. We have heard that the root is edible, and like a carrot. The herb is smooth, two or three feet high. Stem round, slender, alternately branched, each of the long, terminal, naked, simple branches bearing a dense, simple umbel, fearely an inch broad, of numerous, white or reddish, uniform, equal flowers. Leaves of the involucrum awl-shaped, shorter than the umbel, combined at the base. Fruit somewhat heart-shaped, broader than long, muricate all over, when quite ripe, with crowded, blunt tubercles. One seed is often abortive. The flowers are chiefly radial, flaked, smooth, terrace, with wedge-shaped, three-keft, notched segments.

T. pilosa. Hair Trachymene.—Stem leath, hairy, as well as the leaves and footstalks. Umbels lateral.—Gathered by Mr. Menzies, at King George's Sound, an the west coast of New Holland. Whole herb rough with short shaggy hairs. Umbels on stout stalks, from the fork or sides of the stem. Tubercles of the fruit acute, briskly-pointed. See Fuscaea.

TRAETH COCH, or REDWHARF in REDWARTh.

TRELECH, or TRELLEG. Add—in 1811 the town contained 23 houses, and 121 persons; viz. 58 males, and 63 females. The parish of this name, in the upper division of Ragland hundred, consists of the parish division, the town division, and the Grange division: the former contained 131 houses, and 568 persons; 225 being males, and 243 females; and the latter included 20 houses, and 134 persons; 74 being males, and 60 females.

TRENTON, l. 6, r. 3000.

TREVETHIN, a populous parish of the county of Monmouth, in the upper division of Abergavenny hundred, which, including Pont-y-pool, contained, in 1811, 466 houses, and 2423 persons; viz. 1211 males, and 1212 females: 123 families being employed in agriculture, and 280 in trade, manufactures, or handicraft.

TRICHECUS—Romare, r. Jonthone.

TRICADYLUS, a species of Braidspus; which see. See also SPATH.

TSCHUTSKI. See CHURSTSKA.

TURCOMANIA. Add—See Armenians.

TURNEF, l. 2, add—and county of Oxford, having 1129 inhabitants.

TURBSTILE, in Fortification, a kind of barrier, which consists of two or three pieces of timber, formed croisways, and making four or six rays like the spokes of a wheel; the frame is put on a post in the middle of a passage to turn horizontally, so that two of its rays always stretch across the passage, and prevent more than one person at a time from passing the same way.

TUSKARAWA, r. TESCARAWA.

TWEDDELL, John, in Biography, an accomplished scholar, whose early fate has been much lamented by all the lovers of literature and the arts, was the eldest son of Francis Tweddell, Esq. of Threepwood, in the county of Northumberland, was born on the 18th of June 1769; and after passing through the usual course of preparatory education, was entered at Trinity college, Cambridge, where he distinguished himself by such proofs of original genius as are, perhaps, without example, even in the records of that learned society. As a candidate for university honours, his "Prodolus Academicae" attired his Success to have been equally brilliant and extraordinary, and supercede the necessity of particular illustration. Mr. Tweddell was elected a fellow of Trinity college in 1792, and soon afterwards entered himself a student of Lincoln's Inn, where he kept his terms, and continued to reside until the year 1795, when he left England to commence his travels on the continent of Europe—and met with that untimely fate which has mixed his ashes with tho of the sages and philosophers of Greece. He visited Switzerland, Germany, and parts of the Russian empire, and particularly the Crimea, where his intercourse with professor Pallas was of the most intimate kind, and had so endeared him to that amiable scholar, that the admiration with which he spoke of him partook of the tenderest affection of a father. From the borders of the Euxine, where his researches were both diligent and productive, he proceeded to Constantinople; and after spending some part of the summer of 1795 under the hospitable roof of Spencer Smith, Esq. the English minister, he took his departure for the Greek islands; and having traversed the provinces of Macedonia and Thessaly, arrived at Athens; where, after a residence of several months, he reached the period of all his learned labours, on the 25th of July 1799.

Mr. Tweddell, independent of the advantages which his own merit secured for him in the countries which he visited, possessed recommendations and facilities of a superior kind for conducting his learned pursuits; and his industry keeping pace with his talents and opportunities, his collections and manuscripts are known to have been extensive and singularly valuable. Perhaps no traveller of modern times has enjoyed in an equal degree the means of investigating the antiquities of Greece.

His remains were interred in the beautiful Doric temple of Theseus at Athens; and his grave was simply a small

Vol. XXXIX.
oblong heap of earth, like those over the common graves in all our English church-yards, without a stone or inscription of any kind; and his body was carefully deposited at about three or four feet beneath the surface. The part of the temple where it has been buried is now converted into a Greek church, dedicated to St. George; but as this building is occasionally open and liable to the intrusion of animals, who sometimes seek such retreats, Dr. Clarke and his companions, in their travels to Athens, obtained leave to take up the coffin, and to have it properly covered; and a Greek epitaph, composed by Mr. Walpole in 1805, has been inscribed on a large block of Pentelician marble from the Parthenon, for recording the merits of the deceased. The completion of this business has been owing to the exertions of lord Byron, and Dr. J. F. Lee, of St. John's college, Cambridge. Clarke's Travels, vol. vi.

TWIGGS, l. 2, add—of whom 642 were slaves in 1810. TWIST, and Twisting. See MAnUFACTURE of Cotton.

V and U.

VAN

VAMANAVATARA, col. 3, l. 11, for admirer r. advicer.

VANDELLIUS, VANDEL, in Ichthyology, a genus of fishes of the order Thoracici, considered by Dr. Vandelli of Coimbra as nearly allied to the genus Trichiurus; the characters of which are, body extremely long, sword-shaped, gill-membrane five or six-rayed, and teeth subulate, those in front largest. This fish is the silverly vandel, with forked tail, which occurs, very rarely, in the Mediterranean and Atlantic seas, and sometimes near Lisbon.

VANDER WEYDE, ROGER, called Roger of Bruges, in Biography, an historical and portrait painter, was born at Bruges about the year 1455, and became the disciple of John Van Eyck, who, at a short period before his death, discovered to him the secret of painting in oil. From this time he distinguished himself by many grand compositions in a large size, and was considered as one of the first Flemish artists who improved the national taste, dividing it in some degree of the Gothic, and manifesting grace in the airs of his head, as well as correctness in his design. He painted the portraits of several princes, and of many persons of eminence, and obtained a considerable degree of fame and fortune. His paintings in the town-hall of Bruges have been much commended; one of which is formed on the subject of Trajan's justice, executed on one of his soldiers, on the complaint of a mother, whose son had been murdered by him; and that of another is Archambrant, prince of Brabant, flaying his nephew, who was his next heir, when he himself was near dying, for having ravished a maid of that country.

VAN UTRECHT, ADRIAN, was a native of Antwerp, where he was born in 1599, and learnt the art of painting; at first painting peacocks and other fowl for his amusement, in which he so much excelled that he was encouraged to prosecute this branch of his art. The subjects to which his attention was principally directed were fruit, flowers, dead game, and objects of still life; imitating and copying nature, and distinguishing by correct drawing, and the colouring of nature. He was deemed next to Snyders in that style of any of the artists in the Low Countries; and though he was very industrious, he could not execute one half of the orders which he received. His manner of pencilling was peculiarly delicate, and gives an uncommon transparency to his colours. Most of his works were engraved by the king of Spain, so that they became scarce, and they now produce very high prices. This artist died in 1651, at the age of 52 years.

VASSALBOROUGH. Add—containing 2653 inhabitants.

VATICAN. Add.—The Vatican, despoiled during the French revolution, can again boast of possessing the Apollo, the Laocoon, the Antinous, and all those fine examples of the exquisite taste and delicate sentiment of that refined people, the Greeks. The Transfiguration of Raffaelli, the St. Jerome of Domenichino, and the St. Petronilla by Guercino, since their return from Paris, have been placed in a room by themselves, but inconveniently dark.

VAUXHALL BRIDGE, a bridge over the Thames, extending from Millbank to Smith's tea-gardens, which nearly adjoin Vauxhall Gardens, and connecting the roads branching from that spot to Hyde Park Corner by a straight road and street across Tottihl-fields to Eaton-street, Pimlico, and Grosvenor-place. This bridge, constructed by Mr. J. Walker, consists of nine arches of equal span in squares of cast-iron, on piers of rudified stone, formed of fragments, united by means of Parker's cement. The total width is 809 feet, the span of the arches 78 feet, the height 29 feet, and the clear breadth of the road-way 36 feet. The embattled colt of this bridge was above 300,000l.

VELOCIPEDE, ACCELERATOR, or Swift-Walker, a machine originally invented by baron Charles de Drais, matter of the woods and forests of his royal highness the grand duke of Baden, who, in his account of its nature and properties, says, that on a well-maintained post-road, it will travel up hill as fast as an active man can walk; that on a plain, even after a heavy rain, it will move five or seven miles an hour; that, when roads are dry and firm, it runs on a plain at the rate of eight or nine miles an hour, which is equal to a horse's gallop; and that on a defective, its motion is equal to that of a horse at full speed. This machine, the theory of which is founded on the application of a wheel
wheel to the action of a man in walking, consists of two wheels, one behind the other, connected by a perch, on which is placed a faddle for the seat of the traveller. The front wheel is made to turn on a pivot, and is guided in the same manner as a Bath-chair. On a cushion in front, the fore-arm is refted, and by it doing the machine and the traveller are kept in equilibrio.

The management is as follows:—The traveller, having placed himself on the faddle, with his elbows extended, and his body a little inclined forward, must rest his arms on the cushion, and preserve his equilibrium by preffing lightly on that fide which appears to be rising. The rudder (if it may be fo called) must be held by both hands, which are not to rest on the cushion, but to extend somewhat beyond it, that they may be at full liberty, as they are no lefs effential to the conduct of the machine than the arms are to the maintenance of the balance of it, for which purpose sufficient dexterity will be foon acquired by attention and practice; then, placing lightly the feet on the ground, long but very flow steps are to be taken in a right line, at firft care being taken not to turn the toes out, the heels should come in contact with the hind wheel. Dexterity in managing the equilibrio and direction of the machine should be acquired before any attempt is made to accelerate the motion of the feet, or to keep them elevated while it is in rapid motion. This machine will run for a considerable distance while the rider is inactive, and with the fame rapidity as when his feet are in motion; and in defcent it will surpass the beft hores in a great distance, without being expofed to the risks incident to them, as it is guided by the mere gradual motion of the fiders, and may be infantly flopped by the feet. The faddle, as well as the cushion, may be railed or lowered at pleafure, fo as to fuit the height of different perfons. The inventor propofes to conftruct these machines to carry two perfonis, and to be impelled by each alternately, or by both at once; and with three or four wheels, with a feat for a lady; besides the application of a parafol or umbrella: and he also propofes to avail himfelf of a fail, with a favourable wind.

The velocipede has been introduced into this country under letters patent, by Mr. Johnfon, a coach-maker in Long Acre, by whom it has been much improved, both in lightnefs and strength.

VENICE, col. 5, l. 10 from bottom. Add—At the last cenfus, taken about the year 1815, the population was flated to be about 100,000; and it is faid to be decaifing.

VENTRILQUOUS. l. 7, add—LARYNX.

VOL. XXXVII.

VERMILION, col. 2, l. 20, add—the painter’s vermi- tion is a facultious cinabara, made by fublimating a compound of fulphur and mercury.

VERNON, in Geography, a town of Tolland county, in Connecticut, containing 827 inhabitants.

VESICULA FELLIS. See Liver for GALL-Bladder.

VESTIS ANGELICA, for Angelic.

VIENNA, in Geography, a township of Trumbull county, in Ohio, including 234 inhabitants.

VIOLIN. Add—The art of holding the bow, and of placing and moving it on the strings, is the most difficult and important to incipient practitioners on the violion, which they have to encounter; as upon that depend the force, sweet-

ness, and penetrating power of the tone. They muft pay great attention not to prefs too hard upon the string, fo as to make it curve and deviate from a right line; for then the tone would be harfth and coarse. Neither must the bow be laid too lightly on the strings, as the tone would then whifte and be too feeble. The juft point of accuracy in this particular is, to place the hair on the strings in such a manner, that every part of it is in contact with whichever may be wanted. The bow muft not act too near the bridge, nor too distant from it, as only dull and unpleafing sounds would be produced.

</tbody>
</table>

Total $151,400,000.

Their present value has not been ascertained, but it appears that the exports of their manufactures amounted in 1811 to a total of $1,553,000, including those for domestic materials at $1,321,000, and those from foreign materials at $232,000; and in 1816 to $1,755,000, including $1,415,000 of the former kind and $340,000 of the latter.

The manufactures from foreign materials were, spirits from mofl, refined sugar, chocolate, gunpowder, basts and copper, with medicines. The manufacture of wool is rapidly extending, as are also those of iron and hemp, and especially the latter, and also that of cotton. The manufac- ture of gunpowder nearly supplies the home market, which is also the cafe with regard to coarse earthen-ware, window-glass, glafs bottles, and decanters. About a million of bothels of flat are manufactured annually; and felt-petre is largely manufactured in Virginia, Kentucky, Massachusetts, East and West Tenneffee. Sugar from the maple-tree is produced in Ohio, Kentucky, Vermont, and East Tenneffee, to the amount of nearly 10 millions of pounds annually. West Tenneffee and Vermont afford abundance of good copperas: 25 millions of gallons of ardent spirits are annually distilled and confumed in the United States: 400 water and horfe mills, working 120,000 spindles, are employed in spinning cotton. The fulling-mills amount to 2000, and the number of looms exceeds 400,000, and the number of yards of cloth, manufactured from wool, cotton, and flax, is about 100 millions. They have 300 gunpowder-mills, 600 furnaces, forges, and bloomeries, and 200 paper-mills.

In the state of Vermont, the chief manufactures are those of iron, lead, pipe-clay, marble, dilliries, maple-fugar, flour, and wool. In Massachusetts, the principal manufac- tures are, duck, cotton, woollen, cut-nails (by a machine invented in Newbury port, which is capable of cutting two hundred thousand in a day), paper, cotton and wool cards,
playing-cards, shoes, silk and thread lace, wire, fluff, oil, chocolate and powder mills, iron-works, and flitting-mills, and mills for sawing timber, grinding grain, and fulling cloth, distilleries, and glafs. In Rhode island, are manufactured cotton, linen, and tow cloth, iron, rum, spirits, paper, wool and cotton cards, spermacy, sugar, machines for cutting screws, and furnaces for casting hollow ware. In Connecticut, are manufactured silk, wool, card-teeth (bent and cut by a machine to the number of 80,000 in an hour,) buttons, linen, cotton, glafs, fluff, powder, iron, paper, oil, and very superior fire-arms. In New York, are manufactured wheel-carriages of all kinds, the common manufactories, refined sugar, potters'ware, umbrellas, musical instru- ments, glafs, iron, and steam-boats. In New Jersey, are numerous tanneries, leather manufactories, iron-works, powder-mills, cotton, paper, copper-mines, lead-mines, stones, and slate quarries. In Pennsylvania, there are valuable collieries on the Lehigh river, distilleries, rope-walks, sugar-houses, hair-powder manufactories, iron foundries, shot manufactories, steam-engines, mill machinery, type-foundries, improvements in printing, and carpet manufactuary. In Delaware, there are cotton and hoeting cloth and powder manufactories, fulling, fluff, cutting, paper, grain and saw mills. In Maryland, are iron-works, collieries, grill-mills, glass- works, flax, paper-mills, and cotton. In Virginia, are lead- mines, iron-mines, copper-mines, salt collieries, and marble quarries. In Kentucky, are manufactured cotton, wire, paper, and oil. In Ohio, ship-building is carried out to a great extent. In North Carolina, the pitch-pine affords excellent pitch, tar, turpentine, and lumber; also iron-works, and a gold-mines, which has furnished the mint of the United States with a considerable quantity of virgin gold. In South Carolina, are gold, silver, lead, black-lead, copper and iron mines, and also Iullicid flones of various hues, coarse cor- nelian, variegated marble, nitrous stone and fand, red and yellow ochres, potters' clay, fullers' earth, and a number of dye-juifs, chalk, crude alum, sulphur, nitrogen, and vitriol. In Georgia, the manufactures are indigo, silk, and fago. In Louisiana, are manufactured cotton, wool, cordage, flax, and hair-powder.

But the most extraordinary, and perhaps the most impor- tant manufacture in the United States, is that of steam- boats; the first application, if not invention, of which is ascribed to Mr. Fulton. It was in the year 1807 that the first steam-boat plied between the cities of New York and Albany; but since that time this mode of navigation has been successfully used in many other rivers of the United States besides the Hudson; so that steam-boats now ascend the Mississippi and Ohio rivers, hitherto nearly unnavigable, except in the direction of their currents. The following table shews the cheapness, as well as expedition, of travelling on the great rivers of the United States, which is included.

The net amount of revenue received in 1815 was $50,926,100, being from customs $37,065,865; internal duties, $5,093,225; direct tax, $5,723,152; public lands $1,287,073; post office, &c. $2,757,282. The report of the Secretary of the Treasury for the year 1816 states, that on the 12th of Feb, 1816, the whole of the public debt, funded and floating, was $124,909,621; but on the 1st of Jan, 1817, it was $13,188,420. The Secretary, in his Report of the 3rd of December 1817, estimates the expenditure of the year 1816 at $21,946,531, and leaves a balance in the treasury of $85,796,648 on Jan. 1st, 1818.

The American capital, consisting of personal property $5,200,000,000, and of real property $5,000,000,000, amounts to $7,200,000,000; the income, $520,000,000; expenditure, $450,000,000; national debt, $500,000,000.

Bliedt observes, that the population of the whole United States has hitherto doubled itself in less than twenty-five years. The New England states, he says, of course do not retain their proportion of this increase, because large bodies of these people migrate annually to the western country, which has therefore increased much faster than the states to the southward. Kentucky, e. g. has increased 30 per cent. in ten years; Tennessee, 95; Ohio, 180; Louisiana, 150; Indiana, 800; Mississippi territory, 169; Illinois territory, 700; Missouri territory, 600; Michigan territory, 600; while of all the Atlantic states, the greatest increase is only 44 per cent.; the population growth of New York, and the rest of that of Virginia, only 20 per cent.; so that in a few years the rates will range, if the future be like the past, as to their aggregate population in the following order, viz. New York, Pennsylvania, Virginia, Kentucky, Ohio, North Carolina, Massachusetts, South Carolina, Tennessee, Maryland, Georgia, New Jersey, Connecticut, Vermont, Louisiana, New Hampshire, Indiana, Missouri, Mississipi, Illinois, Delaware, and Rhode Island.

Voltaism, l. 13.—The general conclusion deduced by Galvani from his experiments was, that the animal body possessed an inherent electricity of a specific kind, which is connected with the nervous system, and conveyed by means of the metals into the muscles, so as to throw them into convulsions. From his discoveries he formed, with a precipitance that led him into error, a theory of muscular motion, according to which the body contains an apparatus analogous to the Leyden phial, its different parts being in different states of electricity, and the metals forming a connection between them, by which the electricity is equalized. Fowler, in his "Essay on Animal Electricity," published in 1793, concludes, that the galvanic influence is not referable to electricity, becouse, for the production of the former, the presence of two different metals appears to be necessary, while electricity, as proceeding from the electrical machine, is excited by the action of an electric upon a conductor. He also endeavours to shew, fays Dr. Bollock, the ingenious historian of galvanism, that electricity and galvanism are not, in all cases, conducted by the same substances; and he also made some curious observations upon the effect of galvanism on animals not furnished with distinct limbs, such as worms of various kinds. In the same year, 1793, professor Volta's communications appeared in the Philosophical Transactions of London, who adds to his luminous account of Galvani's discovery many curious experiments and observations of his own. He attempted, and with complete success, fays Dr. Bollock, to overthrow Galvani's opinion, that the animal body bears an analogy to the Leyden phial, its different parts being in opposite states of electricity. He suggested, that for the production of the effect it was essential to have two different metals; and hence he was led to conclude, that the muscular contractions are produced by small portions of electricity that are liberated by the action of the metals upon each other. This action of the metals upon each other is described as destroying the electrical equilibrium; and by establishing a communication between them, their equilibrium is restored. This destruction of equilibrium he considers as a new law of electricity discovered by himself; and the animal is supposed to have no further concern in it, than as being a peculiarly susceptible electrometer, and affording a very delicate test of the presence of this disengaged electricity in its passage from one metal to the other. He also established another point, viz. that the nerve is the organ on which the galvanic influence immediately acts; but he found that if a part of a muscle be laid upon two different metals, and the same be made to communicate, a contraction is produced. He also confirmed the fact, previously noticed by Fowler, but by independent experiments, that fluids and worms could not be made to contract; but that many of the insects, as butterflies and beetles, were subject to the influence of the metals. For an account of Dr. Wells's experiments and observations, we refer to his paper in the Phil. Trans. for 1795. Professor Volta, prosecuting his inquiry into the nature of galvanism, was led to introduce a new principle into his theory. Having before stated that two metals were essential to the extirpation of the electric influence, he informs us, that their metallic nature may be dispensed with, provided that the substances differ in their power of conducting electricity. Accordingly he divides conductors into the two classes of dry and moist; the first including metals and charcoal; the latter, essentially containing water, holding various substances in solution. In order to form a galvanic circuit, it is necessary that a body from one of these classes be placed between two bodies from the other class; and thus the equilibrium is destroyed, which is again restored when the two are united by a conductor. (See Galvanism.) For further particulars we are under the necessity of referring to Dr. Bollock's very valuable "Account of the History and present state of galvanism," 8vo, London, 1819.

At this stage, add—It is natural to conclude, that galvanic electricity would be applicable to medical purposes. Accordingly we find, that about the year 1834, it was extensively
U R F

tensively employed, more especially in those diseases in which common electricity had been found useful. But the expectations that were formed concerning the efficacy of this powerful agent were generally disappointed. Flattering accounts, however, says Dr. Bottock, *ubi supra* of its success in different nervous disorders, in paralytic affections, in deafness, in some kinds of blindfolds, in the recovery of persons apparently drowned or suffocated, and even in hydrophobia and insanity, were published. But the credit of the proposed remedy was not permanent; and it therefore sank into disuse. Of late it has again been brought into notice by Dr. Philip of Worcester, who has made trial of it, with beneficial effect, in spasmodic asthma. Bottock's Hill.

UPPER, in Geography, a township of Scioto county, in Ohio, having 496 inhabitants.

URFE', Honore' D', count of Chateauneuf, and marquis of Vilremy, in *Biography*, was the fifth son of James D'Urfe, a noble family of Forez, originating from Swabia, and born in 1567 at Marseille, in which city he was educated, and also in the Jesuits' college at Tournon. Although he was first destined to be a knight of Malta, he was diverted from this purpose by his objection to celibacy; and he afterwards obtained a dispensation to marry the wife of his brother Anne, who was separated from her on account of impotence, and became an ecclesiastic. His view in this marriage was to secure the property of his wife, who was a rich heiress, to his own family; but as he had no children by her he was disappointed in his mercenary purpose, and the connection was unhappy. Thus frustrated in his selfish views, he retired to Piedmont, and devoted himself to letters. He was the author of several publications; but his name has been celebrated as a romance writer, on account of his *Alfred*, which was published in five separate volumes, at successive periods, and continued as a performance of general perusal for fifty years. This romance exhibits a picture of human life in its various conditions, and displays ample invention and acquaintance with men and characters under the disguise of pastoral fiction, from which, however, the author often deviates; he furnishes a history of his courtship of Diana de Chateau-Morant, his brother's wife, whom he married, and of the gallantries of the court of Henry IV. Although it was at a former period much read, it is too trifling for instruction and too tedious for amusement. It was often republished, but the best edition is said to be that of Paris in 1753, in 10 vols. 12mo. by the abbé Souchai. D'Urfe died at Villafranche in 1625. His brother Anne was also a writer, and published some poems.

WATSON, Thomas, in Biography, was born in 1590, and was editor of the second collection of Italian madrigals that appeared in England under the following title: "The First Part of Italian Madrigals Englished, not to the Sense of the original Dittie, but after the Affection of the Noate." This collection, as we are told in the title-page, includes "Two excellent Madrigalls of Master William Byrd's, composed after the Italian Vaine, at the Request of the said Thomas Watton." The poet is as much disliked for double rhymes to suit the original Italian and music of these madrigals, as his predecessor, N. Yonge, in a former publication. That madrigal, indeed, which Byrd set, first in four parts, and then in six, seems original English, and is the bell of the collection.

This sweet and merry month of May, While Nature wantons in her prime, And birds do sing, and bees do play, For pleasure of the joyful time;
I choose, the first for holy daie, And greet Eliza with a ryne; O beauteous Queen of second Troy, Take well in worth a single toy.

The editor seems to have been a man of some learning, as well as knowledge in music, as he dedicates the work, in a Latin copy of verses, to the earl of Effex, then at the summit of favour with queen Elizabeth; and addresses Luca Marenzio, from whom most of the madrigals were taken, in another.

WEARE, l. 2, r. Hillborough.
WEBB, senior, in Biography, a favourite author of English catches and glee's, and one of the most successful candidates for prizes at the catch-club during the most brilliant period of its institution in 1702. See CATCH, and CATCH-CLUB.

WEBB, Daniel, esq. author of an elegant and ingenious tract, intitled "Observations on the Correspondence between Poetry and Music," 1759, 12mo. This author had acquired considerable reputation by two former dissertations in dialogue; the first, "An Inquiry into the Beauties of Painting;" the second, "Remarks on the Beauties of Poetry;" which had rendered the public willing to receive favourably a third work from the same pen. Much learning, extensive reading, and a classical taste, were manifested in this production, "On the Correspondence between Poetry and Music." It is, however, more metaphysical and less intelligible than his former tracts. The author seems to have conceived difficulties to bring forth, and out of the reach of common language to express. He seems to concur with Rousseau, that "music cannot narrate, nor precisely express or paint any particular passion;" but it can awaken sensation and sentiments near the truth, and, with the affluence of poetry, can be pointed to a determined affection or passion. It can tooth affliction, it can supplicate, it can animate and rouse our courage, excite hilarity, and generate ideas of grace, innocence, and content, without the interpretation of poetry; but having nothing to imitate in nature, like poetry and painting, imagination must assist in finding similitudes.

The speculations of Mr. Webb are not always free from obscurity, though his language (when not deformed by his fondness for "lab") is accurate and elegant. He says, that "music cannot give pain, like poetry and painting," but extreme harsh discords allowed to be occasionally used in counterpoint, give pain to the ear, as intense as painting and poetry to the eye and the mind. The author's chief illustrations are from Milton; and the work seems more intended to show the beauties of Milton, than the analogies between poetry and music. The expression of music arises more immediately from rhythm than from the arrangement or combination of sound, and many of its imitative beauties, perhaps all, are ideal. Mr. Webb's ideas in general are delicate, refined, and beautifully expressed. But he never ventures to influence a musical composition or single passage which reminds us of practical music; and it does not clearly appear what kind of music he most approves, or indeed what it is that he honours with the name of music.

Mr. Webb was one of the first in our country who ventured to say, that counterpoint and complication of parts in dissimilar motion was an enemy to melody and expression; he quotes Algarotti's "Saggio sopra l'Opera in Musica," in confirmation of his opinions; but Roullier preceded both, in his "Lettre sur la Mus. Fran." published in 1751, when he first developed his idea of "Unité de Mélodie." Mr. Webb's observations, indeed, abound with deep reflections and belles paroles; but we have not yet discovered what benefit lyric poetry or vocal music can derive from such discussions.

WEIDEMAN, —, came to England about 1726. He was long the principal solo player, and composer, and matter for the German flute. He was a good musician, and played so well on the flute, that we remember Handel, at a rehearsal of an oratorio in Covent Garden theatre, defiring him to take a new organ just finished by the elder Byfield, that he might judge of its effects in different parts of the theatre, in which he was obeyed by Weideman with considerable abilities. But in his productions for the German flute, he never broke through the bounds of that mediocrity to which his instrument seemed confined.

WEIGEL, —, an excellent performer on the violoncello, whom we heard in 1772, at Vienna, in a grand concert given to all the first people of that imperial city, and by the best performers that could be selected. Gluck and his niece, a pupil of Mllecco, and an enchanting finger, were there, and the fuge, sometimes to her uncle's accompaniment on the harpichord only, and sometimes with more instruments, in so exquisite a manner, that we could not conceive it possible for any vocal performance to be more perfect.

Between the vocal parts of this delightful concert, some admirable quartets, by Haydn, were executed in the utmost perfection: the first violin by Startzler, who played the adagio with uncommon feeling and expression; the second violin by Ordonitz, a good performer in the emperor's band; the tenor by count Briuhl, one of the four sons of the great Saxon minifier, an admirable dilettante, and fine performer on several instruments; and the violoncello by Weigel, the subject of the present article. All the performers
formers in this concert, finding the company attentive, and in a disposition to be pleased, were animated to that true pitch of enthusiasm, with which, when musicians are themselves inflamed, they have a power of communicating to others their own order, and of setting all around in a blaze; so that the contention between the performers and listeners on this occasion was only who should please, and who applaud the most.

WEISS, SYLVIUS LEOPOLD, a famous performer on the lute, born in Silicia, travelled into Italy in 1708, in the suite of prince Alexander Sobiesky, who dying at Rome, he was obliged to make his lute bear his expences back into Germany, going first to Breslaw and afterwards to Dresden, where he was engaged in the service of the king of Poland, and became the most celebrated lutenist at that time in Europe. Germany has produced many eminent musicians of the name of Weiss; as John Adolphus Faustinus, son of Sylvis Leopold, a lutenist likewise; C. Weiss, a performer on the German flute, who visited London in 1783, an ingenious and curious man, who had improved his instrument, and had many curious peculiarities in his performance.

WELDON, JOHN, an eminent musician, was born at Chichester, learned the rudiments of music of Mr. John Porter, organist of Eton college, and afterwards received instructions from Henry Purcell. He was for some time organist of New college, Oxon. But in 1701 he was appointed a gentleman extraordinary of the Chapel royal; and in 1708 succeeded Dr. Blow as one of his majesty's organists. In 1715, upon the establishment of a second composer's place in the king's chapel, Weldon was the first who filled that situation, of which he seemed conscientiously determined to fulfill all the duties; for before he had long been in possession of this office, he gave proofs of his abilities and diligence in the composition of the common service, as well as the several anthems required by the conditions of his appointment.

He was likewise organist of St. Bride's church in Fleet-street, and of St. Martin's-in-the-Fields.

Besides many favourite songs and solo anthems of the time, Weldon composed two full anthems, which are inserted in Dr. Purcell's second volume; the first is rather too familiar and common; but the second, "Hear my crying, O God," in six parts, is a very pleasing and masterly composition; particularly the first movement. In the second movement, the words up upon are unfortunately expressed by notes that succeed each other too rapidly for their easy utterance. The passages of the third and fourth movements seem much worn by forty or fifty years use; however, the praises at the end of the last strain have a fine effect.

Six of his solo anthems were published about the year 1730; we say about that period, as musical chronology is become a very difficult study. The late Mr. Walsh, finding that old music-books were like old almanacs, ceased very early in this century to ascertain the time of their birth by dates, which have ever since been as carefully concealed as the age of antiquated virgins.

Weldon's powers of invention and of harmonical combination seem very much limited. His anthems had the advantage of being sung in the Chapel royal by a celebrated finger, Mr. Richard Elford; but now, let who will execute them, they must appear feeble and old-fashioned, unless the embellishments of George I.'s time are changed for those in present use. The truth is, that the fund of original conception or fancy, which alone can render old music valuable to the curious, long after the flyle in which it was written is become antiquated and forgotten, was never very considerable in Weldon's productions. His first anthem, "O Lord rebuke me not," remained long in favour, when well sung in our cathedrals, from its resemblance to the style of Purcell; and the natural and easy flow minuet air to "Turn thee, O Lord, and deliver my Soul," which has so much of a secular song and roundale in it, that it is remembered with pleasure by the musical part of a congregation, who are more likely to bear it in mind than more serious parts of the service.

The productions of Weldon appear skimmy after those of Crofts; and Dr. Green's after Handell's; yet Green compared with Weldon is a giant; that is, a Handel.

There is a vice of which composers of small ressources are often inadvertently guilty, for want of a sincere and judicious friend to tell them of it; and that is, eternal repetition of the same passage, a note higher or a note lower, which the Italians call rifilghe. This certainly originates in the want of ideas, and yet it may be avoided by attention, though the fleet would not fill so fast. Weldon has indulged himself in these repetitions, he has been in favor of his anthems; but in the ritornel to "Have Mercy upon me, O God," he has iterated the same poor passage a note lower seven times successively!

His song for two voices, "As I faw fair Clara walk alone," was in great favour some years ago; and his air in the Judgment of Paris, "Let Ambition fire thy Mind," is a melody so natural and pleasing, that, like an evergreen in vegetation, it will always be fresh and in season. And there is no air in greater favour than this at present, in the English opera of "Love in a Village," to the words, "Hope the Nurse of young Desire."

This composer died in 1736, and was succeeded in the King's chapel by the late Dr. Boyce.

WELLS, L. 1. r. L. and E.

WELLS, in Geography, a township of Rutland county, in Vermont, having 1940 inhabitants.

WELSH MUSIC. If incredulity could be vanquished with respect to the account which Giralddus Cambrensis gives of the state of music in Wales during the 12th century, (see GURALDES' CAMEBRESI) it would be by the Welsh MS. formerly in the possession of Richard Morris, esq., of the Tower, which contains pieces for the harp that are in full harmony or counterpoint: they are written in a peculiar notation, and supposed to be as old as the year 1100; at least, such is the known antiquity of many of the songs mentioned in the collection. But whether the tunes and their notation are coeval with the words, cannot easily be proved; nor is the counterpoint, though far from correct or elegant, of so rude a kind as to fortify such an opinion.

Some part of "this MS," according to a memorandum which we found in it, "was transcribed in the time of Charles I., by Robert ap Huw, of Bodwigen, in the Isle of Anglesea, from William Penllyn's Book." The name of William Penllyn is recorded among the successful candidates on the harp, at the eisteddfod, or feccion of the bards and minstrels, appointed in the ninth year of queen Elizabeth, at Caernows in North Wales, where he was elected one of the "chief bards and teachers of instramental song." The title given to these pieces is "Musica neu Beroraiath;" and a note in English informs us, that the manuscript contains "the music of the Britons, as fettled by a concres, or meeting of masters of music, by order of Grygyfied ap Cynan, prince of Wales, about the year 1100, with some of the most ancient pieces of the Britons, suppos'd to have been handed down to us from the British bards."

This music is written in a notation by letters of the alphabet, somewhat resembling the tablature for the lute; but
but without lines, except a single line to separate the treble from the base.

In the notation, double \textit{ff} seems the lowest note; then the first seven letters of the alphabet are written thus, \textit{g}, \textit{a}, \textit{b}, \textit{c}, \textit{d}, \textit{e}, \textit{f}; and the next septenary thus, with a dash over each letter, \textit{g}, \textit{a}, \textit{b}, \textit{c}, \textit{d}, \textit{e}. If these letters represent the same sounds as at present, we find some such chords as are admitted in modern harmony; but others frequently occur that are mere jargon.

Many of the bases, or accompaniments to the melodies, begin with the chord of C inverted, \textit{g}. These chords and melodies are lessons for young practitioners on the harp, and are said to be the exercises and trial-pieces which were required to be performed by the candidates for musical degrees, and for the silver harp. Among the first twenty-four lessons of this kind, some few are easy to decipher, as No. XI. and XVII., which we shall give here as specimens of this notation, explained in modern musical characters.

\section*{No. XI.}

\end{figure}
WELSH MUSIC.

After twenty-four lessons, or measures, as they are called, of this kind, there follow twelve variations on a ground base.

This counterpoint, however artless it may seem, is too modern for such remote antiquity as is given to it. The falso 5th, from B to E, in the first example, has not been long allowed in harmony; and the unprepared 7th, from B to A, in the second example, is a crudity that has been but very lately tolerated.

That the ancient inhabitants of Wales were great encouragers of poetry and music, cannot be disputed, as many specimens of Cambro-British verification of undoubted antiquity still subsist; and that these poems, as well as those of ancient Greece and Rome, were originally sung and accompanied with instruments, is very natural and reasonable to believe; but that a rude and uncivilized people, driven into a mountainous and barren country, without commerce or communication with the rest of Europe, should invent counterpoint, and cultivate harmony, at a period when it was unknown to the most polished and refined inhabitants of the earth, still remains a problem of difficult solution.

Dr. Burney gives a farther account of this curious MS., in speaking of national music, and the establishment of musical games or contests in Wales, before any other music seems to have been much cultivated in the rest of the isle, except the ecclesiastical or Gregorian chant, which the Britons, driven into the mountains of Wales by the Saxons, seem to have been very unwilling to receive from the Roman missionaries that were sent over to convert their conquerors. The British annals and fongs ascribe with great resentment the slaughter of the monks at Bangor, by Ethelbert, king of Kent, to the instigation of Aulfin the monk, on account of their having refused to submit to the jurisdiction of pope Gregory, and the regulations he proposed.
WELWIN, or Welwyn. In 1811, the parish contained 192 houses, and 1130 persons; viz. 567 males, and 563 females.

WEMYSS. In 1811, the parish contained 565 houses, and 3561 persons; viz. 1657 males, and 2004 females.

This parish includes Buckhaven, E. and W. Coallows, Kirkland, Methil, E. and W. Wemyss, and the rest of the parish, containing 116 males, and 117 females.

WENDLING, J. Baptist, in \textit{Biography}, an eminent performer on the German flute, in the service of the elector palatine at Mannheim in 1772.

Francis and Charles, brothers, performers on the violin, and Mademoiselle Wendling, a finger, of the same family, were all musical professors of great merit in the same service at the same period.

WENLOCK, LITTLE. In 1811, the parish contained 78 houses, and 941 inhabitants.

WENTWORTH. In 1811, this township contained 226 houses, and 1086 persons; viz. 542 males, and 544 females.

WEREMOUTH, Monk's. In 1811, this parish, comprising five townships, viz. Felwell, Hylton, Monk-Weremouth, Monk-Weremouth Shore, and Southwick, contained 832 houses, and 5044 persons; viz. 2837 males, and 2267 females. The township of Monk-Weremouth contained 210 houses, and 1091 persons; viz. 457 males, and 634 females; and that of Monk-Weremouth Shore contained 458 houses, and 4264 persons; viz. 1819 males, and 2445 females.

WESTBURY, in the county of Salop. In 1811, the township contained 112 houses, and 665 persons; viz. 348 males, and 317 females; and the parish, comprehending the chapelry of Minsterley, and the three townships of Wherwell, Welley, and Uckleton, contained 417 houses, and 2195 persons; viz. 1124 males, and 1071 females.

WESTLEY. Add—in Washington county, containing 9217 inhabitants.

WESTHaven, a town of Rutland county, in Vermont, having 679 inhabitants.

WESTMINSTER ABBEY. Its happy concert for music at the commemoration of Handel in 1784, appeared to be such as not only to overtop all the predictions of ignorance and sarcasm, but the conjectures of theory and experience. By some it was predicted that an orchestra so numerous could never be in time; but even tuning to so noble an organ was for once grand, and productive of pleasing fusions. By some it was thought that, from their number and distance, they would never play in time; which, however, they did most accurately, and without the measure being beat in the usual clumsy manner. By others it was prophesied that the band would be so loud, that whoever heard this performance would never hear again; however the found of these multiplied tones arrived as mild and benign at the ears of the audience as they could from the feeble efforts of a few violins in a common concert-room. And, lastly, that, from the immense size of the building, no single voice had the least chance of being heard by those who had places remote from the orchestra; but luckily this was so far from being true, that not a vocal breathing, however feeble by nature, or softened by art, was inaudible in any part of the wide-extended space, through which it diffused itself in all directions.

There was, doubtless, great propriety in saluting their majesties at their entrance with the Coronation Anthem, yet we could not help wishing that this performance, so different from all others, had opened with some piece in which every voice and every instrument might have been heard at the same instant; as such an effect might then have been produced as can never be obtained by gradation. Indeed the most sudden and surprising effect of this stupendous band was, perhaps, produced by simultaneous tuning; as all the stringed-instruments performed this task à double cordes, and these strings being all open, their force was more than equal to that of two fopra-strings upon two different instruments.

It is but justice to Madame Mara, in speaking of the effects of a single voice in this immense building, to record that she had not only the power of conveying to the remotest corner of this expanded structure, the softest and most artificial inflections of her sweet and brilliant voice, but of articulating every syllable of the words with such neatness, precision, and purity, that it was rendered as audible and intelligible as it could possibly have been in a small theatre by mere declamation.

The happy construction of Westminster Abbey for cherishing and preserving musical tones, by a gentle augmentation without echo or repetition, was demonstrated by no part of the commemoration performance more clearly than in that of Mifs Abrams, whose voice, though sweet, of perfect intonation, and good quality, was not regarded as theatrical, but such as the Italians denominate \textit{bella voce da camera}, yet in the solo air, which the singer with her usual taste and expression, her voice was rendered more audible in every part of that immense building, than it had ever been in any concert-room in London.

Giardini, envied of the powerful tone of Fischer's hautbois, which could even rival that of his own violin with all its force and sweetness, used to say that Fischer had an \textit{impedence of tone}, but it never produced a more full, rich, and sweet effect than in the solo parts of Handel's fourth hautbois concerto, which he performed with such taste and propriety, as must have convinced all those who heard him that his excellence was not confined to his own very original and ingenious productions. Indeed, one of the Commemoration wonders seems to have been the perfect manner with which the sweet and grateful tone of his \textit{single instrument filled} the stupendous temple of our holy religion, in the performance of this concerto.

WESTPHAL, in \textit{Biography}, an eminent music merchant of Hamburg, one of the greatest publishers in Germany during the middle of the last century.

WHERWELL, in \textit{Geography}. In 1811, Wherwell with Wellover parish, in the hundred of Wherwell, contained 113 houses, and 543 persons; viz. 277 males, and 266 females.

WHIFF. Add—See \textit{Pleuronectes Pantastus}.

WHITE, John, in \textit{Biography}, a Quaker, at whose shop in Newgate-street ladies were furnished with straw hats. This worthy man was a great collector of ancient rarities, as well as natural productions of the most curious and extraordinary kind; no one of which, however, was more remarkable than the obliging manner with which he allowed them to be viewed by his friends and examined by strangers. Among his old books and MSS. he was in possession of a very scarce and valuable music-book, which once appertained to Dr. Robert Fayrfax, an eminent English composer during the reigns of Henry VII. and Henry VIII.; it was afterwards in the possession of general Fayrfax, and upon his demise became a part of the Thoreby collection, at the sale of which it was purchased by hon. John White.
WOOD

WITTINGSTABLE, in Geography. In 1811, the parish contained 235 houses, and 1249 persons; viz. 616 males, and 633 females.

WILLIAMSBOROUGH, a township of Burlington county, in New Jersey, having 619 inhabitants.

WILTSHIRE. In 1811, this county contained 37,478 houses, and 193,828 persons; viz. 91,560 males (including the local militia 1662), and 102,268 females: 22,657 families being employed in agriculture, and 14,857 in trade, manufactures, or handicraft.

WIMBLEDON. In 1811, the parish contained 293 houses, and 1914 persons; viz. 891 males, and 1023 females.

WINDHAM, a town of Maine, in the county of Cumberland, containing 1613 inhabitants.

WINTERTON, in Lincolnshire. In 1811, the parish contained 179 houses, and 821 persons; viz. 379 males, and 442 females.

WINTERTON, in Norfolk. In 1811, the parish contained 112 houses, and 494 persons; viz. 254 males, and 240 females.

WITCHCRAFT. Add—Dr. Henry More published a curious tract, entitled "Antidotes against Atheism," in which he undertakes to prove the being of a God from the existence of witches, and the power which they possess. See his biographical article.

WITHERITE, vol. 2, p. 9, add—The known repositories of this sublimate are very limited; but it has been observed by Mr. Aikin, in great abundance, in the lower part of a lead-mine in Shropshire, where it occurs in irregular masses, which weigh from forty to two or three hundred pounds, imbedded in heavy spar. The miners call this sublimate "yellow spar;" not that it is this real colour by day-light, but its transparency is so considerable, that if a lighted candle be placed behind a mass of it, the whole will glow with a yellowish light, by which circumstance the miners distinguish it from "heavy spar." This latter from the looseness of its texture, being in large masses quite opaque. The colour of the witherite is white, with the slightest possible, if any, tinge of yellow; its fracture is hard, frirated, approaching to thirty foliated; it is for the most part massive. Mr. Aikin observed only one specimen that presented any indications of a regular crystalline form. In other particulars it agrees with the usual description of this sublimate. 100 parts of this wisterite yields,

Trans. of Geol. Soc. vol. vi. pt. 2.

WITTENA-GEMOTE, I. 14 from the bottom, r. conconatones.

WODANUM, in Chemistry, the name of a metal recently discovered by Lamпадус. This metal was obtained from a species of pyrites, named by Breihaupt Wodan-bits, or wodian pyrites, formed at Topichau, in Hungary, and which had hitherto been considered as an ore of cobalt. The specific gravity of this mineral is 5.192. Its lustre is metallic. Its colour dark tin-white, passing into grey or brown. Hitherto it has only occurred massy, and in that state it is full of cavities. Its fracture is uneven. It is brittle and easily frangible, and in hardens furpaffes fluor spar, but is inferior to apatite. This mineral contains about 20 per cent. of the new metal united with sulphur, arsenic, iron, and nickel.

Wodanium has a bronze-yellow colour similar to that of cobalt glance, and its specific gravity is 11.470. It is malleable. Its fracture is hackly; it has the hardness of fluor spar, and is strongly attracted by the magnet. It is not tarnished by exposure to the atmosphere at common temperatures, but when heated it is converted into a black oxide.

The solution of this metal in acids is colourless; or at least has only a slight wine-yellow tinge. Its hydrated carbonate is likewise white. The hydrate of it precipitated by caustic ammonia is indigo blue.

Neither the alkaline phosphates nor arseniates occasion any precipitate when dropped into a saturated solution of this metal in an acid, neither is any precipitate produced by the infusion of nut-galls. A plate of zinc throws down a black metallic powder from the solution of this metal in muriatic acid. Phosphate of potash throws down a pearl-grey precipitate, &c.

Nitric acid dissolves with facility both the metal and its oxide, and the solution yields colourless needle-form crystals, which readily dissolve in water.

Such at present is all we know of this metal, and the ore containing it. The name wodanium has been given from the old Saxon divinity, Woden.

WOOFORD, in Geography, a village in a parish of the same name, in the hundred of Beccon, and county of Ely. In 1811, the parish was returned as containing 310 houses, and 2056 inhabitants; viz. 1051 males, and 1005 females. It is situated on Epping Forest, in the vicinity of Walthamford, Wannelford, Layton, &c. which contain a considerable number of well-built houses, admirably adapted for the number-residence of the citizens of London.

WOODVILLE, in Biography. Add—Dr. Woodville, always anxious for the promotion of science, and no less disposed to serve the friends whom he esteemed, favoured the editor with several botanical articles for the Cyclopædia.

WOOLCOTT, in Geography, a township of Orleans county, in Vermont, having 124 inhabitants.

WOOLLET, William, in Biography, a very eminent engraver, was born at Maidstone, in Kent, Aug. 27, 1735, and educated in his native town. In early life he exhibited specimens of his graphic talents, which being seen by Mr. Timney, an engraver, occasioned his being taken by him as an apprentice. His advancement in his profession was very rapid, and so distinguished, that he contributed in a very high degree to the perfection of landscape-engraving. He was also singularly successful in the exercise of his art on historical subjects and portraits. So established and so permanent has been his fame, that the bel impresarios of his prints, particularly those of "Niobe" and "Phaethon," "Cebadon and Amelia," "Cymx and Alycone," "The Fifhery," "Vandyke's Portrait of Rubens," "The Death of General Wolfe," and "The Battle of the Boyne," whenever they occur in collections, are very highly appreciated.

The world was deprived of this eminent artist at the age of 50. His death, which occurred at his house in Upper Charlotte-street, Rathbone-place, May 25, 1783, was announced to the public with the following tribute of respect to his memory. "To say he was the first artist in his profession would be giving him his leaf praise, for he was a good
a good man. Naturally modest and amiable in his disposition, he never cenfured the works of others, or omitted pointing out their merits: his patience under the continual torments of a most dreadful disorder upwards of nine months was truly exemplary; and he died, as he had lived, in peace with all the world, in which he never had an enemy. He has left his family inconsolable for his death, and the public to lament the loss of a man whose works (of which his unflinching temper never boasted) are an honour to his country. An elegant monument was erected to his memory in the cloisters of Westminster-abbey. Chalmers's Gen. Biog. Diet.

WOOLWICH, col. 3, l. 11.—The cadets, who are instructed at the royal military academy, were sent for some years to the military college, then at Marlow, now at Sandhurft, as a preparatory school; but that plan, being found attended with disadvantages, was abandoned. The institutions at Woolwich and Sandhurft are now therefore entirely independent; and we may add, that they are different in their nature, and are intended for very different purposes. The institution at Woolwich is confined solely to the instruction of young gentlemen intended for the artillery and engineer service; that at Sandhurft is suplementary, and designed for the instruction of such as are destined to any other branch of the military service of Great Britain. The education at Woolwich is free of expense, except the little that is incurred by the purchase of the first uniform. The cadets at Sandhurft pay a certain sum annually, bearing an assigned proportion to the rank of their parents, and being only free, as we conceive, in cafes where the cadets are orphans, or their fathers subalterns.

WOORARA. See Ticunaë, and Vegetable Poisons, under the article Poison.

WOULFE'S APPARATUS. See Distillation and Laboratory.

WRESTLING. See PALE.

WROXETER, in Geography. In 1811, the parish contained 109 houses, and 575 persons; viz. 305 males, and 270 females.

WYMONDHAM, in Norfolk. In 1811 the parish contained 747 houses, and 3923 persons; viz. 1896 males, and 2027 females.

XANTHOSIA, in Botany, from ξάνθος, yellow, that colour being strongly communicated by the dried plant, to boiling water.—Rudge Tr. of Linn. Soc. v. 10. 301.—Clafs and order, Pentandria Digyna. Nat. Ord. Umbellatae.

1. X. pilosa. Hairy Xanthosia. Rudge as above, t. 22. f. 1.—Native of Port Jackson, New South Wales. Stem shrubby, branched, hairy. Leaves alternate, stalked, oblong, obtuse, finnated; hairy beneath. Flowers axillary, solitary, on short stalks. Bracteae two, awl-shaped, brizly, at the base of each flower-stalk. Involucrum of two obvate ribbed leaves, half way up the stalk. This plant certainly belongs to the order of Umbellatae, however different in inflorescence.

Z

ZOL

ZINJAN, in Geography, a town of Perse, in the province of Irak, distant 21 miles, and bearing about N.W. by W. of Sultanees. This is a large and prosperous town, capital of the extensive district of Khumfah, under the government of one of the king's sons. From hence to the banks of the Kizilozian, or golden stream, the distance is 71 miles over an uneven country, full of deep ravines.

ZOLLIKOFER, GEORGE JOACHIM, in Biography, an eminent German divine and popular preacher, was born at St. Gall in Switzerland, August 5th, 1730. His father, who was a practitioner in the law, much excelled for his integrity and piety, took great care of his education, and by his own counsel and example directed the course of his moral conduct; nor were any of his efforts for the proficiency of his son in knowledge and virtue unavailing. As he was intended for the clerical profession, he was removed, at an early age, from the gymnasium of his native town, first to Bremen, and afterwards to the university of Utrecht, where the theological professors were held in high estimation. Our young student, however, soon discovered that a college education was ill adapted to his aspiring mind; as, in his opinion, it was very unfavourable to all exertions of genius and originality of thought, by levelling the distinctions of nature, by restraining the intellectual capacities to a blind veneration for authorities, and preposterously misleading the judgment so as to take the means of instruction for its end. Possessing a native vigour of mind, which distinguished him through the whole course of his life, he resolved, whilst he attended the public lectures with the rest of the scholars, to cultivate his talents and to pursue his inquiries in his own way. Instead of paying implicit deference to syllables and summaries of theology, drawn up in technical and scholastic phræatology, he made scripture and reason his guide, and, as he says in a letter to a friend, "I privately applied myself to the Bible, together with a close investigation of ecclesiastical history; for I found it impossible for me to submit to the trammels of the schools, where derivative doctrines are uniformly transmitted, without examination, by the successive tutors from generation to generation, &c." In the other sciences, as well as in theology, he expres'd his dissatisfaction with the means of instruction that were then adopted and invariably practised in the public schools. "The little which I know," as this modest man was heard to say, "I was obliged to teach myself, chiefly after I arrived at years of maturity; for indeed I had but a miserable education." This is not the language of pride and pedantry; as his attention was directed to a variety of researches, which, in his youth, the state of education in Germany would furnish him with no extraordinary advantages; and as he is known to have excelled in various departments of general literature and science, besides theology. His attainments in natural history and natural philosophy were very considerable; with the histories, ancient and modern, of the several nations of the world he had cultivated an extensive acquaintance, and in the ancient and modern languages, particularly the Latin, French, and English, he was no ordinary proficient; having made the works of the best poets, orators, and philosophers, the subjects of his particular study. Of Cicero he is said to have been a great admirer; and his eloquence was formed upon the model of that of this celebrated Roman orator. "O, my beloved Zollikoffer!" says Zimmermann (on Solitude), "what delightful experiences I am constantly feeling of the truth of these lessons you delivered at Leipfic; those truly useful doctrines, which, disregarding a cold and barren theology, inculcate wise and virtuous precepts, that warm and amend the heart. On quitting your auditory, the man of business forgets his vexations, pows his anxieties into the bosom of friendship, surrenders his feelings to the charms of consolation, until his heart is dilated with new hopes and his inquietudes are so far suspended as to enable him to fulfill their return with fortitude, or to dispel them with courage. The industrious man abandons his recondite and laborious researches, escapes from the labyrinth, and finds in the innocent and simple satisfactions of his family and dependants more real content and happiness than even art and science could afford him." — "Men, in short, of every call and character, here find by degrees the mind's blest calm, and learn to put on the pure spirit of the gospel of Christ." Soon after he had finishted his academical course, he settled, as a preacher, at Murten in the Pays de Vaud; and in a little while removed to a more considerable place at Monflein in the Grisons, and afterwards to Ifenburg. But neither of these places afforded sufficient range for his talents and zeal; and therefore in the year 1758, at the age of twenty-eight, he accepted an invitation to be one of the German preachers at the church of the evangelically reformed at Leipfic. In this connection he availed himself of the opportunity which his moderate labours afforded him, of giving that perfection to his discourses which was the object of his wishes. Accordingly, the universal approbation which he received on the part of his numerous congregation from his first settlement constantly augmented from
ZOLLIKOFER.

from day to day, and adhered to him to the very last hour of his addressing them. A considerable number of young members of the univercity eagerly prefled to hear his discourses, learning from him, by example, how a subject should be studied and discussed, in order to contribute, in any remarkable degree, to the advancement of wisdom and virtue among mankind by the oratory of the pulpit.

It is therefore natural to hope, that Zollikofer's genius will continue to operate not only throughout his native country, but likewise over many provinces of Germany, by means of these his discourses, who are thus prepared for dif-feminating truth, and virtue, and happiness among their fellow-creatures to the latest posterity.

Several volumes of his excellent discourses have for some years been in the hands of the public, and are in high and deferred repute wherever the German language is understood, by all persons to whom religion and virtue are objects of ferior concern; to which the number of editions through which they have passed, and which are continually published, bear ample testimony, as well as to the taste and judgment of the times with regard to compositions of this nature. A German writer says, that "Zollikofer was one of the first pulpit orators of his time. His sermons were distinguished by clearness of ideas and warmth of feeling. In regard to form, they were the most complete productions of the kind which had appeared, at that time, in Germany. The division is copious and varied; the periods harmonious, and the whole acquires great animation from the connection of the ideas and the transitions." Of his theological creed we can form no decided opinion. His discourses are practical, and not controversial; and it must be allowed that whatever were his sentiments on disputed topics, they are adapted to in-form the understandings, to impress the heart, and to regulate the temper and conduct. Some have suspected that he belonged to the modern German school of theologians. Professor Eichhorn pronounces his eloquence in the following strain: "Zollikofer, on account of the philosophical colouring combined with popularity, which he knew how to give to his discourses, was an orator for the highest ranks. He unfolded the doctrines and principles of Christianiuty with philosophical accuracy; exhibited them in a concise and improvement of the forms, and to the proper felectiion of hymns from the modern poets, particularly Gellert, Cramer, and Klopstock. This performance appeared in the year 1766. His discourses and prayers for the use of public and family worship were published in 1777, and were followed in 1783 by his exercises of devotion and prayers for the private use of reflecting and sincere Christians. The Rev. W. Tooke, F. R. S., has done great service to the cause of rational religion, by the translation of 160 vol. 180 of Zollikofer's Sermons, and of his Devotional Exercises in 1 vol. 8vo.

Having said so much concerning the professional char-aacter and performances of Zollikofer, we cannot forbear adding a few particulars from the account that lies before us, with regard to his private and social disposition and conduct.

"In humility and retirement, he purified his path of life; never wishing to shine, his only aim was to be useful; be-cause in the exercise of that stern virtue which he taught he

found his supreme delight. The poor and delitute, espe-
cially those of his congregation, beheld in him a father and a friend; though his bounty was by no means confined to them, it also extended to those of other communions, relieving them either by his own donations or through application to others." His advice, his judgment, his intercourse with others, his admonitions, his consolation in misfortune, were at the service of all who applied for them, and he even went before their requests. Young men deficient of know-
ledge, eagerly sought his acquaintance, and all those who enjoyed that benefit have honestly confessed, that they derived from it material improvement both in heart and mind. Whatever he said was true; every word he uttered might be relied on as conveying the real sentiments of his heart; arrayed in the simple majesty of truth, he fought no other covering; and never did he commend or approve from compla-intance any thing that was contrary to the conviction of his own mind, or that he knew could not be approved upon the strictest rules of morality. His gravity was attractive and engaging, charity itself was in its imitae, his conversa-tion entertaining, often animated, his equal cheerfulness amiable and inoffensive, and his raillery, in which he very rarely indulged, the mildest possible. To a very considerable compafs of literary attainments and great brilliancy of im-
agination, were added in the character of Zollikofer, the most unassuming rectitude, the most amiable disposition, and the most profusely giving heart. The whole tenor of his life was one pure, uninterrupted, captivating harmony of virtue, and the sweet enjoyment of the felicities arising from it. Among his other satisfactions he had that of being universally esteemed, as of necessity it could not be other-
wise. That happy mixture of seriuonsness and dignity with gentleness and affability; his own strict course of virtue combined with so much indulgence and candour towards the failings of others; his heartfelt and firm conviction of the great truths he taught, which manifested itself in all his actions, in the whole tenor of his conversation as well as in his discourses from the pulpit, without entertaining the slightest intolerance towards such as differed from him in opinion, or arrogating the smallest superiority over those who polemised not the faculty of thinking for themselves, or of fully comprehending every truth; his unwaried zeal to con-
tribute to the rigorous exercise of virtue, in his demands however never disregarding the rights of humanity con-
cerning what they could or could not do in thee or the other circumstances; his impartial estimation of mankind, ju-
ly discriminating the opinions and principles upon which they acted, carefully tracing out their good qualities, and heartily rejoicing in every advantageous discovery of that nature — let the reader contemplate all this as combined in the charaeter of Zollikofer, and then pronounce, whether real undifembled veneration, the general esteem of all ranks and classes of persons must not as infalibly have attended his wisdom and virtue as the shadow follows the fulcintate. Even the wanton wit of those who, in the judgments they pass on the ministers of religion, are not ashamed to set aside the respect that is due from man to man, was awed into silence at the name of Zollikofer.

He was twice married, and in both connexions he was truly happy, though both proved children. For about a year before his death his faculties began to decline, and he wished to resign his office of preacher, and to retire to the place of his nativity in Switzerland; but at the request of his congregation, who for the sake of retaining him expressed their willingness to be satisfied with one discourse in a fort-
night, he was induced to remain in his situation. At length within a few weeks before his death he was obliged to de-
devolve the charge of preaching on another person. His last illness was very painful; but he bore it with the patience of a philosopher, and the resignation of a Christian, looking by a steady eye of faith and hope beyond the grave to a world of retribution. He obtained a release on the 22d of January 1788, and was buried on the 25th. The whole of his numerous congregation, together with some hundreds of young students of the university, and numbers of his auditors of the Lutheran communion, attended his remains to the grave, with every token of unfeigned sorrow.

THE END.

(Plate of the Horfe

IV. Stomach

Inteines

The other Plates referred to in the several articles on Comparative Anatomy, comprized in the former part of the Cyclopædia, including the articles Feathers, Fishes, Hair, Horns, Incubation, Mammalia, &c. are unavoidably omitted. Dr. Maccartney, by whom these articles were furnished, has stated, that he has found it impossible to procure, within any reasonable time, the drawings required for those Plates, in consequence of his removal from London, and of the indispensible occupations attending the laborious duties of his present professorhip in the University of Dublin; the editor has deemed it preferable, upon the whole, in this dilemma, to omit these Plates altogether, rather than to give them in an imperfect and unconnected manner; especially as he could not have given them, even in this defective state, without charging the work with a heavy additional expense, and further delaying its completion to a distant and indefinite period. He has had the least difficulty in coming to this determination, in consequence of no reference to Plates having been made in any of the articles on Comparative Anatomy, since Dr. Maccartney’s removal to Ireland deprived the editor of his affinities in this department.

ARCHITECTURE.

I. Fig. 1. Attic Bafe, Temple of Jupiter Olympia at Athens

2. Temple of Minerva Polias at Athens

MUSICAL INSTRUMENTS.

I. Ancient Musical Instruments

Fig. 1. Timbrel or Tambour de Basque

2. Cithariftria, or female Minstrel

3. Double Lituus

4. Pan playing on the Syrinx

5. A Bacchanal playing on two Flutes of the fame Pitch, *tibia pares*

6, 7. Antique Theatrical Mafques

8. A genuine ancient metallic Lituus

II. Ancient Musical Instruments and Mafks

Fig. 1. A Greek Bariton or Harp

2. Mask of the Hercules urens of Euri-pides

3. Mask of Thais from Terence’s Enunx

4. A Figure from the Herculeanum Paintings

5, 6. Lyres from Sir W. Hamilton’s Vafe.

III. Ancient Musical Instruments

Fig. 1—3. Group of Musicians performing an Epithalamium, from a Piece of Ancient Sculpture in the Ghigi Palace at Rome

4. The *Tuba*, or Trumpet of the Jubilee

5. Cupid playing on a double Flute, or *tibia pares*

6—10. From Egyptian paintings in the Tombs of the kings of Thebes

IV. Ancient Musical Instruments

Fig. 1, 2. The Teftudo, or Lyre of Amphion, front and profile

3. Lyre of Terphíchore, in the Picture of that Muse, dug out of Herculeanum

4. Flätery from the Picture of Erato, dug out of Herculeanum

5. Trigonon, or Triangular Harp

6. Abýssinian Téftudo

7. Étruscan Lyre with seven Strings

8. Lyre in an ancient Picture dug out of Herculeanum, on which Chiron is teaching young Achilles to play

9. An Egyptian Syrtrim

10. An ancient Lyre richly ornamented

V. Indian Musical Instruments

Fig. 1. From an original Indian Painting

2. The Béen, an Indian Musical Instrument

VI. Pandean Minstrels in performance at Vauxhall

VII. Welsh Harps

Single Harp
MUSICAL INSTRUMENTS.

Plate

VII. Ancient Triple Harp
Modern Triple Harp
(For Guitar, referred to this Plate, see Plates IX. XIII. & XV.)

VIII. Fig. 1—5. Origin of the Bow
IX. Russian Musical Instruments
Goudok. Rebec with three strings
Geldaika
Double Flutes of the Ancients
Rok, or Hunting Horn of Siberia
Rojoik
Balalaika, Guitar with two strings

X. Harps
Fig. 1, 2. Harp of Brian Boromh
3. Silver Prize Harp
4. Bell Harp

XI. Fig. 1. English Common Flute
2. German Flute
3. Improved Ditto, with additional keys
4, 5. Hautboys
6. B Fife
7. C Fife
8. English Flageolet
9. Gong
10. Tabour
11. Pipe

XII. Fig. 1, 2. Hunting Horns
3. Serpent
4. French Horn
5. Bugle
6. Sackbut or Trombone

XIII. Fig. 1. Arch Lute
2. Mandoline
3. Mandola

XIV. Fig. 1. Violin
2. Bow

II. Fig. 1. Common Vertical Windmill
   2. Smock Mill
   3. Internal Mechanism of a Post Windmill
   4. Dutch Windmill
   5—7. Parts of the Mechanism of a Windmill
   (The reference under "Rules for modelling the Sails of Windmills," to fig. 4, Plate II.
   WINDMILL, should be to fig. 4, Plate I.)

WINDING ENGINE.

Smeaton's Design for a Water Gin, for drawing Coals from the Pits

Fig 1. Plan
2. Elevation of the Frame on the Pit Head
3, 4. Elevations
5. Plan

WIRE-MILL.

Fig. 1—13. Machinery for Wire-Drawing

WOOLLEN MANUFACTURE.

I. Stubbins Machine, or Billy
II. Spinning Jenny
III. Shearing Machine
IV. Carding Engine
   (This Plate is not numbered)
V. Gig-Mill

WORSTED MANUFACTURE.

I. Fig. 1. Combs
   2. Supporter for Ditto
   3. Stove for heating Ditto
   4. Gilpin's Combing Machine
   5. Breaking Frame
   6. Roving Ditto
   7. Spinning Ditto

II. Fig. 1—3. Cartwright's Combing Machine

WRITING BY CIPHER.

I.—III. Characters and Examples
PLATES. VOL. V.
NATURAL HISTORY.

GENERAL SYSTEMATIC ARRANGEMENT OF THE PLATES OF NATURAL HISTORY,
INCLUDING THE THREE KINGDOMS OF NATURE, ACCORDING TO THE SYSTEM OF LINNÆUS.

* * * The Arabic Numerals on the Left, denote the Number of the Plates, according to the Systematic Arrangement of them in the Catalogue.

PLATE.

ANIMALS.

CLASS MAMMALIA.

Order I. Primates.

Genus Homo
1* Homo Sapiens, Rational Man
   (See Plate Painting)
   Anatomical Structure
   (See Plate Anatomy)
2* Varieties of Homo Sapiens, Rational Man, according to Climate
   a Americanus, American Man
   b Europæus, European
   γ Asiaticus, Asiatic, (of Palestine)
   (of China)
3 Africæ, African
   (See Painting, Plate III.)

Genus Simia.
1. Lettered Mammalia, Order I. Primates. Plate I.
   Fig. 1. Simia Satyrus, Black Oran Otan, or Outang, Homo Sylvestris, var. Pongo
   2. var. Jacca, Chefnut Otan, or Outang
   3. Simia Traglithes, (Gmel,) Satyrus indicus
      Tulippa. Chimpanzee
   4. Simia Lar, (Gmel,) Long-armed Ape
      Simia longimana, (Schreb.)
   5. Simia Inwius, Barbary Ape
   6. Simia Syloanus, Pigmy Ape

Vol. XXXIX.

Plate

1. Fig. 7. Simia Edipus, Red-tailed Ape
8. Simia Jacchus, Striated Ape

Genus Lemur.
2. Lettered Mammalia, Order Primates, Genus Lemur, Plate II.
   Fig. 1. Lemur Podis, Tarier Lemur
   2. Lemur ecaudatus, Tailles Lemur, or Maucauco
   3. Lemur murinus, Murine Lemur
   4. Lemur Catta, Ring-tailed Lemur, or Maucauco
   5. Lemur tardigradus, Loris Lemur
   6. Lemur volans, (Linn,) Flying Lemur, or Flying Colugo
* Genus Galeopithecus (Rufus) Audebert

Genus Vespertilio.
3. Lettered Mammalia, Genus Vespertilio, Plate III.
   Fig. 1. Vespertilio Vampyrus, Vampire Bat
   2. Vespertilio auritus, Long-eared Bat
   3. Vespertilio Sapsina, Cordate Bat
   4. Vespertilio leporinus, Peruvian Bat
   5. Vespertilio Spectrum, Spectre Bat

Order Brattr.

Genus Bradypus.
4. Lettered Clas Mammalia, Order Brattr, Genus Bradypus
   Fig. 1. Bradypus tridactylus, Three-toed Sloth
   2. Bradypus didactylus, Two-toed Sloth
NATURAL HISTORY.

Plate

Genus Myrmecophaga.

4. Fig. 3. Myrmecophaga didactyla, Two-toed or small Ant-Eater
4. Myrmecophaga tetradactyla, Four-toed Ant-Eater
5. Myrmecophaga jubata, Great Ant-Eater

Genus Ornithorhynchus.

Fig. 6. Ornithorhynchus paradoxus, Duck-bill Platypus anatinus, (Shaw,) Duck-billed Platypus

Genus Manis.

5. Lettered Mammalia, Quadrupeds, Genus Manis
Fig. 1. Manis pentadactyla, (Linn.) Five-toed Manis, or Short-tailed Manis
2. Manis tetradactyla, (Schreb.) Four-toed Manis, or Long-tailed Manis

Genus Dasypus.

3. Dasypus fuscidentus, Six-banded Armadillo
4. Dasypus nocomscindus, Nine-banded Armadillo
5. Dasypus duodecimcindus, (Schreb.) Twelve-banded Armadillo

Genus Rhinoceros.

Fig. 1. Rhinoceros unicornus, One-horned Rhinoceros
2. Rhinoceros bicornis, Two-horned Rhinoceros

Genus Sukotyro.

(A doubtful genus not admitted by Gmelin)

7. Lettered Quadrupeds, Genus Sukotyro
Fig. 1. Sukotyro Indicus, Sukotyro (From Nieuhoff, the Dutch traveller, and Churchill's Collection of Travels)

Genus Elephas.

Fig. 2. Elephas maximus, Elephant

Order Feræ.

Genus Trichechus.

8. Lettered Quadrupeds, Clafs Mammalia, Genus Trichechus
Fig. 1. Trichechus Rosmarinus, Arctic Walrus, or Morfe
2. Trichechus Manatus, Æ borealis, Whale-tailed Manatus

Genus Phoca.

Fig. 3. Phoca Ursina, Urnine Seal
4. Phoca groenlandica, Harp Seal
5. Phoca Vitulina, Sea Calf, or Common Seal
6. Phoca maculata, Kurile or Spotted Seal

Plate

Genus Canis.

9. Lettered Quadrupeds, Dogs, Plate II. of Order Ferae
Fig. 1. Canis familiaris, Shepherd's Dog?
2. Diugo, Australoisan, or New Holland Dog
3. Canis familiaris, var. Pomeranian Dog
4. Canis Æ pomeranus, Ditto
5. Canis var. Sibiricus, Siberian Dog
6. var. Aquaticus minor, Small Barbet, or Water Dog
7. var. Aquaticus, Great Barbet, or Water Dog

10. Lettered Quadrupeds. Plate III. Dogs, Genus XV. Canis
Fig. 1. var. brevifiliis, King Charles's Dog
2. Molosseus, Bull-dog
3. var. Ægyptius, Naked or Turkish Hound
4. fricator, Fug-dog
5. Spaniel
6. Shock
7. var. variatigratus, Small Dane
8. leoninus, Lion Dog
9. hybridus, Roquet

11. Lettered Quadrupeds, Plate V. Dogs, Genus XV. Canis
Fig. 1. var. Anglicos, Maftiff
2. Molosseus, Bull-dog
3. Great Danish, or Harlequin Dog
4. Dalmatian Dog

12. Lettered Quadrupeds, Dogs, Plate IV. of Order Ferae, Genus XV. Canis
Fig. 1. Old English, or Talbot Hound
2. Beagle
3. Harrier
4. Blood Hound

13. Lettered Quadrupeds, Dogs, Plate V. of Order Ferae, Genus XV. Canis
Fig. 1. Stag Hound
2. Fox Hound
3. Larger Terrier
4. Smooth Terrier
5. Rough Terrier

14. Lettered Quadrupeds, Order Ferae, Genus Canis
(No number on the Plate)
Fig. 1. Canis Lupus, Wolf
2. Canis Hyena, Striped Hyena
3. Canis Mefomela, Cape Jackal
4. Canis Vulpes, Common Fox
5. Canis Lagopus, Arctic Fox

Genus Felis.

15. Lettered Quadrupeds, Plate I. Genus Felis, Lions
Fig. 1. Felis Leo, Lion, Lionefs, and Young

PLATE

16. Lettered Quadrupeds, Plate II. Order 3, Genus Felis
   Fig. 1. Felis Tigris, Tiger
   2. Felis Pardus, Panther
   3. Felis Leopardus, Leopard

17. Lettered Quadrupeds, Genus Felis, Tigers, Plate II.
   Fig. 1. Felis Puma, Congouar
   2. Felis Lync. Lynx
   3. Felis Uncia, Ounce
   4. Felis Caracal, Persian Lynx
   5. Felis Onca, Jaguar
   6. Felis jubata, Hunting Leopard

18. Lettered Quadrupeds, Plate III. of Order Ferae, Genus Felis
   Fig. 1. Felis pardalis, Ocelot
   2. Felis Tigrina, Margay
   3. Felis Servalis, Serval
   4. Felis Catus, Wild Cat
   5. Felis b domesticus, Tame or domesticated
   6. Tortoiseshell Cat
   7. Felis g angorensis, Angora Cat
   8. Felis c ceruleus, Slate-coloured Cat, (Blue or Chartreux.)

Genus Viverra.

19. Lettered Quadrupeds, Order Ferae, Genus Viverra
   (No number on the Plate)
   Fig. 1. Viverra Zibetha, Zibet, or Indian Musk Weefel
   2. Viverra Fossa, Fofane
   3. Viverra Ichneumon, Ichneumon Weefel
   4. Viverra Nysa, Bushcat Weefel
   5. Viverra Civetta, Civet Weefel, or Civet-Cat, African Musk Weefel

Genus Ursus.

20. Lettered Quadrupeds, Order Ferae, Genus Ursus
    (No number on the Plate)
    Fig. 1. Ursus Lutris, Sea Otter, Greater Otter
    2. Ursus Luxa, Common Otter
    3. Ursus Foina, Martin
    4. Ursus Zibellina, Sable, or Fisher Weefel

Genus Hystrix.

21. Lettered Quadrupeds, Order Ferae, Genus Hystrix
    (No number on the Plate)
    Fig. 1. Hystrix Crivata, Common or crested Porcupine
    2. Hystrix Pheasitus, Brazilian Porcupine
    3. Hystrix Dorsata, Canadian Porcupine (white variety)

Genus Cavia.

22. Lettered Quadrupeds, Order Glires, Genus Cavia
    (No number on the Plate)
    Fig. 1. Cavia Sagu, Long-nosed Cavy
    5. Cavia Magellanica, Patagonian Cavy
    6. Cavia Paca, Spotted Cavy

Genus Castor.

23. Lettered Quadrupeds, Order Glires, Genus Castor
    (No number on the Plate)
    Fig. 1. Castor Ferox, Common Beaver

Genus Mus.

24. Lettered Quadrupeds, Order Glires, Genus Mus
    (No number on the Plate)
    Fig. 2. Mus Zibethicus, Musk Rat
    3. Mus Decumanus, Norway Rat
    4. Mus Musculus, Common Mouse
    5. Mus Cricetus, German Hamster Rat
    6. Mus Bursarius, Purse Rat or Canada Rat
    7. Mus Capenfis, Cape Mole-Rat

Genus Aecotomys.

25. Lettered Quadrupeds, Order Glires, Genus Aecotomys, &c.
    (No number on the Plate)
    Fig. 1. Aecotomys Citillus, (Schreb.) Variegated Marmot
    2. Aecotomys Emptera, Canadian Marmot

Genus Sciurus.

26. Lettered Quadrupeds, Order Glires, Genus Sciurus, &c.
    (No number on the Plate)
    Fig. 3. Sciurus Petaurista, Taquan, or Taguan flying Squirrel, Sailing Squirrel (Peru.)
    4. Sciurus Getulus, Barbary Squirrel
    5. Sciurus Vulgaris, Common Squirrel

4 X 2

NATURAL HISTORY.
3. Lettered Quadrupeds, Genus Antilope (No order or number on the Plate)

Fig. 1. Antilope Rupicapra, Chamois
2. Antilope Cervicapra, Antelope
3. Antilope pygmea, Royal Antelope, or Pigmy Antelope
4. Antilope Gymnus, Guinea Antelope
5. Antilope Gnou, Gnoo

32. Lettered Quadrupeds, Genus Capra (No order or number on the Plate)

Fig. 1. Capra Iber, Iber Goat
2. Capra Aegagrus, Mountain-cultivated Goat (Donov. Brit. Quadr.)
3. 4. Capra Aegagrus, Domesticated Goat (Donov. Brit. Quadr.)
5. Capra Aegagrus, (var. membrica) Syrian Goat
6. Capra Aegagrus, (var. angorenfs) Angora Goat

33. Lettered Quadrupeds, Ovis, Aries (No order or number on the Plate)

Aries, Ovis, Common Sheep
var. South Down Polled Sheep of the improved breeds. From the Stock of the late Duke of Bedford, Woburn

34. Lettered Quadrupeds, Genus Ovis, Sheep (No order or number on the Plate)

Aries, Ovis, Common Sheep
fig. 1. var. Norfolk Breed
2. Hereford Breed

35. Lettered Quadrupeds, Bos, Taurus (No order or number on the Plate)

Bos, Taurus, Ox
fig. 1. var. Scottith Wild Ox, the Bull
2. The Cow and Calf

36. Lettered Quadrupeds, Bos, Taurus (No order or number on the Plate)

Bos, Taurus, Common Ox
var. Long-horned or Lancashire Breed

Order Bovine.

Genus Equus.

37. Lettered Horses, Plate 1. (No order on the Plate)

Equus Caballus, Horse
fig. 1. var. Shetland Poney
2. var. English Cart Horse

38. Lettered Quadrupeds, Order VI, Belluæ, Genus 33, Equus (No number on the Plate)

Equus Caballus, Horse
var. Suffolk Agricultural Punch Horse
var. Suffolk Mare and Foal, from the Stock of the late Duke of Bedford

39. Lettered Quadrupeds, Genus Equus (No order or number on the Plate)

Equus Caballus, Horse
fig. 1. var. Race Horse, Royalist
2. var. The Hunter Skylark
NATURAL HISTORY.

Plate

Genus Hippopotamus.

40. Lettered Quadrupeds, Genus Hippopotamus (No number on the Plate)
Fig. 1. Hippopotamus amphibius, Hippopotamus

Genus Tapir.
Fig. 2. Tapir Americanus, Tapir

Genus Sus.

41. Lettered Quadrupeds, Genus Sus (No number on the Plate)
Fig. 1. Sus Scrofa, (ferus a) Wild Hog
2. Sus Babyrussa, Babyrussa
3. Sus Aethiopicus, Ethiopian Hog
4. 5. Sus Scrofa, (domesticus &c) Domesticated Hog

Order Cete.

Genus Monodon.

42. Lettered Mammalia, Order Cete, Genus Monodon, &c. (No number on the Plate)
Fig. 1. Monodon Monodon, Narwhal, or Narval (Sometimes Sea Unicorn, or One-toothed Monodon, so rarely having two teeth, that only a single example of the kind is known. Donov. Mus. Vide Donov. Brit. Quadrupeds)

Genus Baleana.
Fig. 2. Balea Myticetus, Great Mythicetus, or Common Whale
3. Balea Balo, Pike-headed Whale

Genus Physeter.

43. Lettered Mammalia, Order Cete, Genus Physeter (No number on the Plate)
Fig. 1. Physeter Macrocephalus, Blunt-headed Cachalot
2. Physeter, var. gibbosus, (Schreb.) Gibbous Cachalot

Genus Delphinus.
Fig. 3. Delphinus Phocoena, Porpoise
4. Delphinus Delphis, Dolphin

ORNITHOLOGY.

Class II. Aves.

Order Accipitres.

Genus Vultur.

44. Lettered Division I. Land Birds, Plate II.
Fig. 1. Vultur Gryphus, Megallanic Condor, or Condor

Genus Falco.
2. Falco Chrysaetos, Golden Eagle
3. Falco Gentilis, Falcon Gentil
4. Falco Subbuteo, Hobby

Plate

Genus Strix.

44. 5. Strix Bubo, Great Horned Owl, or Eagle
6. Strix Flammea, Common Owl

Order Picæ.

Genus Psittacus.

45. Lettered Division I. Land Birds, Plate I. Order Picæ
Fig. 1. Psittacus Macao, Red and blue Maccaw
2. Psittacus Alexandri, Alexandrine Parrot
3. Psittacus Aethiopicus, var. Amazon Parrot
4. Psittacus garrulus, var. Ceram Lory
5. Psittacus Moluccensis, Great red-crested Cockatoo
6. Psittacus Bankshi, Bankian Cockatoo
7. Psittacus pullarius, Ethiopian Parrot

Genus Ramphastos.

46. Lettered Division I. Land Birds, Plate II. Picæ
Fig. 1. Ramphastos Piede, Brazilian Toucan
2. Ramphastos Aracari, Green Toucan, or Aracari

Genus Bucerós.
Fig. 3. Bucerós Rhinoceros, Rhinoceros Horn-bill

Genus Buphaga.

4. Buphaga Africana, African Beef-eater

Genus Crotophaga.

Fig. 5. Crotophaga Ani, (major) greater Ani Bird

Genus Glacopós.
Fig. 6. Glacopós Cinereus, Cinereous Wattle Bird

Genus Corvus.

47. Lettered Division I. Land Birds, Picæ, Plate III.
Fig. 1. Corvus Corax, Raven
2. Corvus Pica, Magpie
3. Corvus Caryocatactes, Nut-cracker
4. Corvus glandarius, Jay
5. Corvus citrinus, Crested Jay

Genus Coracias.
Fig. 6. Coracias Garrulus, Roller, (Garrulous Roller, Donov. Brit. Birds)

Genus Oriolus.

48. Lettered Division I. Land Birds, Order II. Picæ, Plate IV.
Fig. 1. Oriolus Citrinus, Crested Oriole
2. Oriolus Balsamorhous, Baltimore Oriole
3. Oriolus Persicus, Black and Yellow Oriole
4. Neft of ditto

Genus Cuculús.

Fig. 5. Cuculus canorus, Common Cuckow
PLATE

48. Fig. 6. Cu-culus cupreus, Coppery Cuckow
    7. Cu-culus indicator, Honey-guide

GENUS GRACULA.

49. Lettered Division I. LAND BIRDS, Order II. Picse, Plate V.
    Fig. 1. Gracula Quiscalus, Purple Grakle
    2. Gracula calvus, Bald Grakle
    3. Gracula S. Laurus, Dial Grakle

GENUS PARADISEA.

Fig. 4. Paradisia Regia, King Bird of Paradise
5. Paradisia Apoda, Greater Bird of Paradise
6. Paradisia aurea, Golden Bird of Paradise

GENUS TODUS.

Fig. 7. Todus macrorhynchos, Great-billed Tody
(This genus should be placed after Sitta.)

GENUS TROGON.

50. Lettered Division I. LAND BIRDS, Order II. Picse, Plate VI.
    Fig. 1. Trogon Curucui, Red-bellied Trogon

GENUS BUCCO.

Fig. 2. Bucco Lathami, Buff-faced Barbet
3. Bucco Cayennensis, Cayenne Barbet

GENUS YIXX.

Fig. 4. Yunx Torquilla, Wryneck

GENUS PICUS.

Fig. 5. Picus pileatus, Pileated Woodpecker
6. Picus Carolinus, var. Caroline Woodpecker

GENUS SITTA.

Fig. 7. Sitta Europae, European Nuthatch

GENUS ALCEDO.

51. Lettered Division I. LAND BIRDS, Order II. Picse, Plate VII.
    Fig. 1. Alcedo cristata, Crested King’s Fisher
    2. Alcedo venerata, Venerated King’s Fisher
    3. Alcedo Alecta, Belted King’s Fisher
    4. Alcedo striata, Sacred King’s Fisher

GENUS GALBULA.

Fig. 5. Galbula paradaidea, Lath. (Alcedo paradaidea, Gmel.) Long-tailed Jacamar, Paradise Jacamar

GENUS MEROPS.

52. Lettered Division I. LAND BIRDS, Order II. Picse
    Fig. 1. Merops carunculatus, Wattled Bee-eater
    2. Merops Novae Zelandiae, New Zealand Bee-eater

GENUS UPUPA.

Fig. 3. Upupa Pomerops, Cape Hoopoe

PLATE

52. Fig. 4. Upupa Epops, Common Hoopoe
5. Upupa Erythrorynchos, Red-billed Hoopoe

GENUS CERTHIA.

53. Lettered Division I. LAND BIRDS, Order Picse, Plate IX.
    Fig. 1. Certhia parvula, Great hooked-billed Creeper
    2. Certhia obscura, Hook-billed Green Creeper
    3. Certhia coccinea, Hook-billed Red Creeper
7. Certhia c. c. c., Blue Creeper

GENUS TROCHILUS.

Fig. 5. Trochilus perula, Topaz Humming Bird
6. Trochilus furcatus, Lesser-forked Humming Bird
7. Trochilus peniculus, Crested Humming Bird
8. Trochilus auratus, Tufted-necked Humming Bird
9. Trochilus minimus, Leaf Humming Bird

ORDER ANSERES.

GENUS ANAS.

54. Lettered Division II. WATER BIRDS, Order III. Anseres, Plate I.
    Fig. 1. Anas atrata, Black Swan
    2. Anas Olor, Tame Swan
3. Anas cygnoides, Chinefe Goose
4. Anas ganseri, Spur-winged Goose

55. Lettered Division II. WATER BIRDS, Order III. Anseres, Plate II.
    Fig. 1. Anas Erythropterus, Barnacle Goose
    2. Anas Canadenfis, Canada Goose
3. Anas Speclabilis, Grey-headed Duck
4. Anas M. M., Mallard
5. Anas Barbona, Mallard
6. Anas Galericulata, Mandarine Drake

GENUS MERGS.

57. Lettered Division II. WATER BIRDS, Order III. Anseres, Plate IV.
    Fig. 1. Mergus Merganser, Goofander
    2. Mergus Eschulatus, Crested Merganser
3. Mergus albellus, Smew, or Nun
(White Smew, Donov. Brit. Birds)
5. Mergus Bovtchus, Mallard
6. Mergus Galericulatus, Mandarine Drake

GENUS ALCA.

Fig. 4. Alca antiqua, Ancient Auk
5. Alca cirrata, Tufted Auk

GENUS APTENODYTA.

Fig. 6. Aptenodyta patagonica, Patagonian Penguin
### Natural History

#### Plate 57
- Fig. 7. *Aptenodyta papua*, Papuan Penguin
- Fig. 8. *Aptenodyta minor*, Little Penguin

**Genus Procellaria.**
58. Lettered Division II. Water Birds, Order III. Anfere, Plate VI. Obs. with six Birds.
1. *Procellaria capensis*, Pink-tailed Petrel
2. *Procellaria fuliginosa*, Sooty Petrel
3. *Procellaria peliaeica*, Stormy Petrel
4. *Procellaria gigantea*, Giantic Petrel

**Genus Diomedea.**
59. Lettered Division II. Water Birds, Order III. Anfere, Plate VI. Obs. This is the Plate VI. containing five Birds, both being lettered and numbered alike.
1. *Diomedea exulans*, Labrador Petrel
2. *Diomedea irrorata*, Laysan Albatross
3. *Diomedea exulans*, Sooty Albatross
4. *Diomedea exulans*, Frigate Albatross

**Genus Pelecanus.**
60. Lettered Division II. Water Birds, Order III. Anfere, Plate VII.
1. *Pelecanus erythrophthalmus*, Red-throated Pelican
2. *Pelecanus philippensis*, Masked Pelican
3. *Pelecanus conspicillatus*, Black-faced Stork
4. *Pelecanus occidentalis*, Dalmatian Pelican
5. *Pelecanus onocrotalus*, Eastern White Stork
6. *Pelecanus onocrotalus*, Western White Stork

**Genus Phalanx.**
61. Lettered Division II. Water Birds, Order Anteres, Plate IX.
1. *Phalanx minor*, Arctic Cormorant
2. *Phalanx fimbriata*, Ivory Gull
3. *Phalanx marinus*, Black-backed Gull

**Genus Sterna.**
62. Lettered Order Grallae, Plate I.
1. *Sterna hirundo*, Common Tern
2. *Sterna dougallii*, Sabine's Gull
3. *Sterna morinata*, Black Tern
4. *Sterna sandvicensis*, Short-tailed Tern
5. *Sterna fuscata*, Bar-tailed Godwit

**Genus Rynchops.**
63. Lettered Order Grallae, Plate I.
1. *Rynchops niger*, Black Skimmer
2. *Rynchops niger*, Black Skimmer

**Genus Phoenicopterus.**
64. Lettered Order Grallae, Plate II.
1. *Phoenicopterus ruber*, Red Flamingo
2. *Phoenicopterus roseus*, Roseate Spoonbill
3. *Phoenicopterus chilensis*, Chilean Flamingo

**Genus Platalea.**
65. Lettered Order Grallae, Plate III.
1. *Platalea ajaja*, Redshank
2. *Platalea minor*, Black-winged Stilt
3. *Platalea leucorodia*, Common Stilt

**Genus Pygna.**
66. Lettered Order Grallae, Plate IV.
1. *Pygna nigricans*, Black Stork
2. *Pygna oxystomus*, Black-crowned Night Heron
3. *Pygna leptorhyncha*, Black-crowned Night Heron

**Genus Scolopax.**
67. Lettered Order Grallae, Plate V.
1. *Scolopax rusticola*, Red Grouse
2. *Scolopax caerulescens*, Blue Grouse
3. *Scolopax rusticola*, Copper Grouse
4. *Scolopax alpinus*, Alpine Grouse
5. *Scolopax alpinus*, Pin-tailed Grouse
6. *Scolopax alpinus*, Upper Grouse
7. *Scolopax alpinus*, Lower Grouse

**Genus Tringa.**
68. Lettered Order Grallae, Plate V.
1. *Tringa ochropus*, White-winged Snipe
2. *Tringa nebularia*, Common Snipe
3. *Tringa glareola*, Ruff
4. *Tringa hippotis*, Grey Plover
5. *Tringa hypoleucos*, Black-tailed Godwit

**Genus Charadrius.**
69. Lettered Order Grallae, Plate V.
1. *Charadrius hiaticula*, Avocet
2. *Charadrius alexandrinus*, Grey Plover
3. *Charadrius hiaticula*, Grey Plover
### Plate

**Genus Recurvirostra.**

68. Lettered Order Grallae, Plate VII.
Fig. 1. *Recurvirostra americana*, American Avocet

**Genus Hematopus.**

Fig. 2. *Hematopus ostralegus*, Oyster catcher (Pied Oyster Catcher, *Donov. Brit. Birds*.)

**Genus Glareola.**

Fig. 3. *Glareola austrica*, Australian Pratincole

**Genus Fulica.**

Fig. 4. *Fulica Porphyria*, Purple Gallinule
5. *Fulica crijilata*, Crested Coot

**Genus Vaginalis.**

69. Lettered Order Grallae, Plate VIII.
Fig. 1. *Vaginalis albo*, White Sheath-bill

**Genus Parra.**

Fig. 2. *Parra Jacana*, Chefmut Jacana
3. *Parra smithi*, China Jacana

**Genus Rallus.**

Fig. 4. *Rallus crex*, Land Rail
5. *Rallus variagatus*, Variegated Rail

**Genus Psophia.**

Fig. 6. *Psophia crijilata*, Gold-breasted Trumpeter

**Order Gallinæ.**

**Genus Otis.**

70. Lettered Division I. Land Birds, Order 5. Gallinæ, Plate I.
Fig. 1, 2. *Otis Tarda*, Buffard—male 1. female 2.

**Genus Struthio.**

Fig. 3. *Struthio Rhea*, American Ostrich
4. *Struthio camelus*, Callowary, or Emu

**Genus Didus.**

71. Lettered Division II. Land Birds, Order 5. Gallinæ, Plate II.
Fig. 1. *Didus Ineptus*, Hooded Dodo

**Genus Struthio.**

Fig. 2, 3. *Struthio Camelus*, Ostrich—male 2. female 3.

**Genus Pavo.**

72. Lettered Division I. Land Birds, Order Gallinæ, Plate III.
Fig. 1. *Pavo crijilatus*, Crested Peacock
2. *Pavo crijilatus* (var. *varius*), Variegated or Pied Peacock
4. *Pavo bicalcaratus*, Iris peacock

### Plate

**Genus Meleagris.**

73. Lettered Division II. Land Birds, Order 5. Gallinæ, Plate IV.
Fig. 1. *Meleagris Gallopavo*, American or Wild Turkey

**Genus Penelope.**

Fig. 2. *Penelope crijilata*, Guan

**Genus Crax.**

Fig. 3. 4. *Crax Eledon*, Curassow—male 3. female 4.
5. *Crax Pausi*, Cuhew

**Genus Phasianus.**

74. Lettered Division II. Land Birds, Order Gallinæ, Plate V.
Fig. 1, 2. *Phasianus Gallus*, Wild Cock—male 1. female 2.
3. Ditto, var. *domesticus*, domesticated varieties, Rumple's Cock
4. Ditto, Silky Cock

75. Lettered Division II. Land Birds, Order Gallinæ, Plate VI.
Fig. 11, 12. *Phasianus Gallus*, var. *domesticus*, varieties, Malay Cock—male 11. female 12.

76. Lettered Division III. Land Birds, Order Gallinæ, Plate VII.
Fig. 1. *Phasianus Calcinus*, Common Pheasant
2. *Phasianus piaius*, Gold Pheasant
3. *Phasianus Nycthemerus*, Silver Pheasant
4. *Phasianus Argus*, Argus Pheasant

**Genus Numidia.**

77. Lettered Division I. Land Birds, Order Gallinæ, Plate VIII.
Fig. 1. *Numidia meleagris*, Guinea Hen or Pintado
2. *Numidia crijilata*, Crested Pintado

**Genus Tetrao.**

Fig. 3. *Tetrao umbelius*, Ruffed or Ruff-necked Grouse
4. *Tetrao alboetus*, Pin-tailed Grouse
5. *Tetrao Camadensis*, Spotted Grouse
6. *Tetrao paradoxus*, Heteroclitus Grouse, or Paradoxical Grouse

78. Lettered Division II. Land Birds, Order Gallinæ, Plate IX.
Fig. 1. *Tetrao perdix*, Common Partridge
2. *Tetra ferrugineus*, Hackled Partridge
NATURAL HISTORY.

Plate

78. Fig. 3. *Tetrao gibraltaricus*, Gibraltar three-toed Quail
4. *Tetrao marylandicus*, Maryland Quail
5. *Tetrao viridis*, Green Quail—male
6. *Tetrao major*, Great Tinamou
7. *Tetrao variegatus*, Variegated Tinamou

ORDER PASSERES.

GENUS COLUMBA.

79. Lettered Division I. LAND BIRDS, Order Passeres, Plate II.

Fig. 1. *Columba chalcoptrix*, Bronze-winged Pigeon
2. *Columba erythrophora*, Garnet-winged Pigeon
3. *Columba macroura*, Great-tailed Pigeon
4. *Columba nicobarica*, Nicobar Pigeon
5. *Columba curvirostra*, Hook-billed Pigeon
6. *Columba capensis*, Cape Turtle, or Cape Pigeon
7. *Columba coronata*, Great-crowned Pigeon

GENUS ALAUDA.

80. Lettered Division I. LAND BIRDS, Order Passeres, Plate LXXX.

Fig. 1. *Alauda capensis*, Cape Lark

GENUS STURMUS.

Fig. 2. *Sturnus militaris*, Military Starling
3. *Sturnus nudata*, Undulated Starling

81. Lettered Division I. LAND BIRDS, Order Passeres, Plate III.

Fig. 1. *Turdus Orpheus*, Mocking Thrush
2. *Turdus Rex*, King Thrush
3. *Turdus perspicillatus*, Spectacle Thrush
4. *Turdus crassirostris*, Thick-billed Thrush
5. *Turdus cyanurus*, Blue-tailed Thrush
6. *Turdus longirostris*, Long-billed Thrush

GENUS AMPELIS.

82. Lettered Division I. LAND BIRDS, Order Passeres, Plate IV.

Fig. 1. *Amphibus carunculata*, Carunculated Chatterer
2. *Amphicus pectoralis*, Purple-breasted Chatterer
3. *Amphicus Pompadour*, Pompadour Chatterer
4. *Amphicus carnifex*, Red Chatterer

GENUS COILUS.

Fig. 5. *Colius capensis*, Cape Coly

GENUS Loxia.

83. Lettered Division I. LAND BIRDS, Order Passeres, Plate V.

Fig. 1. *Loxia lineata*, Lineated Grosbeak
2. *Loxia cucullata*, Cuffed Dominican Grosbeak
3. *Loxia philippina*, Philippine Grosbeak
4. The pendulous Nef of the Philippine Grosbeak
5. *Loxia Cardinalis*, Cardinal Grosbeak
7. *Loxia fiabilifera*, Fan-tailed Grosbeak

Vol. XXXIX.

Plate

GENUS EMBERIZA.

84. Lettered Division I. LAND BIRDS, Order Passeres, Plate VI.

Fig. 1. *Emberiza paradisiaca*, Whidaw Bird
2. *Emberiza ciris*, Painted Bunting
3. *Emberiza Regia*, Shaft-tailed Bunting
4. *Emberiza provincialis*, Multachoe Bunting
5. *Emberiza americanana*, Black-throated Bunting
6. *Emberiza bontiiana*, Ortolans Bunting

GENUS TANAGRA.

85. Lettered Division I. LAND BIRDS, Order 3. Passeres, Plate X.

Fig. 1. *Tanagra Tanae*, Paradise Tanager
2. *Tanagra capitalis*, Capital Tanager
3. *Tanagra Jacapa*, Red-breasted Tanager

GENUS FRINGILLA.

Fig. 4. *Fringilla ignita*, Fire Finch
5. *Fringilla flammea*, Crimson-crowned Finch
6. *Fringilla bengalus*, Blue-bellied Finch
7. *Fringilla Phylactes*, Parrot Finch

GENUS PHYTOTOMA.

Fig. 8. *Phytopoma rara* (Molina, Hijs. Nat. Chili) Chili Phytotoma

GENUS MUSCICAPA.

86. Lettered Division Passeres, Plate VIII.

Fig. 1. *Muscicapa bicolor*, Black and White Flycatcher
2. *Muscicapa barbata*, Whiskered Flycatcher
3. *Muscicapa tyrannus*, Forked-tailed Flycatcher
5. *Muscicapa fiabilifera*, Fan-tailed Flycatcher

GENUS MOTACILLA.

Fig. 6. *Motacilla cyanec*, Superb Wheat-ear
7. *Motacilla Madracapatena*, Pied Wagtail (Madras Pied Wagtail)

GENUS MOTACILLA.

87. Lettered Order Passeres, Plate IX.

Fig. 1. *Motacilla pileata*, Black-headed Warbler
2. *Motacilla spinicauda*, Thorn-tailed Warbler
3. *Motacilla Jaccus*, Blue-throated Warbler

GENUS PIPRA.

Fig. 4. *Pipra rupicola*, Rock Manakin
5. *Pipra fritillata*, Striped-headed Manakin
7. *Pipra punctata*, Speckled Manakin

GENUS PARUS.

88. Lettered Order Passeres, Plate XX.

Fig. 1. *Parus macrocephalus*, Great-headed Titmouse
2. *Parus crista*, Crested Titmouse
4 Y
NATURAL HISTORY.

Genus Hirundo.
88. Fig. 4. Hirundo eulelenta, Efulent Swallow
5. The efulent Nieft of this Swallow
6. Hirundo tabitica, Otaheite Swallow
7. Hirundo pelagia, Aculeated Swallow
3. Hirundo indica, Rufous-headed Swallow

Genus Caprimulgus.
80. Lettered Division Land Birds, Order Passeres, Plate LXXX.
   Fig. 4. Caprimulgus longipennis, Leona Goatfucker
5. Caprimulgus grandis, Great Goatfucker

Elementary Plates
To illustrate
The Classification of Birds.

Characters of the Feet in the different Orders and Genera.

Accipitres.
Feet formed for affhing the Mandibles in seizing and tearing the prey, being armed with strong talons.

89. Lettered Ornithology, Elementary Plate I.
The Feet in Falco (Falco Grytvasta; Golden Eagle); and Eagles, Falcons, Hawks
The Feet in Strix (Strix flammea, White Owl); Stridula, brachyotos, pafferina
(The Shrikes belong to this order)

P.I.C.E.
* Feet formed for Perching.

90. Lettered Plate IV.
The Feet in Sitta (Nuthatch) European Nuthatch

92. Lettered Plate II.
The feet in Corvus (Crow) Common Crow
Paradigea (Bird of Paradise)
The same structure prevails in the feet of the genera Buphaga, Oriolus, Coracias, Upupa, Certhia, Trochilus, &c.

** Feet formed for Climbing.

90. Lettered Elementary Plate IV.
The Feet of Picus (P. Martius, Great Black Woodpecker; P. Viridis, Green Woodpecker)
The Feet of Myzophagus (Muiophuge)
This structure is well exemplified in Ptitacus (Parrot), and Cuculus (Cuckow), which are familiar examples; and occurs in the genera Scevrops, Ramphalos, Trogon, Crotophaga, Gallula, Yunx, and Bucico.

** Feet formed for Walking.

90. Lettered Elementary Plate IV.
The Foot of Alecto (King’s-fisher)
The other genera of Pica, which have the feet formed for walking, are Momotus, Buceros, Merops, and Todus.

Anseres.
Feet formed for Swimming.

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Anas (Goose; Duck)
Alca (Auk)
Aptenodyta (Penguin)
Pelecanus (Pelican), two species
Columbus (Grebe), three species
Larus (Gull)

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Sterna (Tern)

Grallae.
Feet formed for Wading.

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Pluteiopeus (Flamingo)
89. Lettered Ornithology, Elementary Plate I.
Feet in the genus Platea (Spoonbill) P. oaja

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Ardea (Heron)

9. Lettered Ornithology, Elementary Plate I.
Feet in the genus Ardea cinerea (Grey Heron)

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Recrvirobrfrfa, (Avocet)

9. Lettered Ornithology, Elementary Plate I.
Feet in the genus Tantalus (Ibis) T. igneus, Bay Ibis

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Tringa (Phalarope) T. lobata, Scallop-toed Tringa

9. Lettered Ornithology, Elementary Plate I.
Feet in the genus Charadrius (Plover, Long-legged P.)
Hematopus (Oyster Catcher)
Glaerola (Oystercatcher) P. auftriaca

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Fulica (Gallinule)
Viginalis (Sheathbill)

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Rallus (Rail)
### Plate 91.

**Lettered Ornithology, Elementary Plate III.**

Feet in the genus *Rallus* (*Rallus gallinule*).

---

**Lettered Ornithology, Elementary Plate IV.**

Feet in the genus *Pajarra* (*Jacana*), two species.

---

**Gallinæ.**

*Form of the Feet.*

---

**Lettered Ornithology, Elementary Plate II.**

In the genus *Oeis* (*Buffard*).

*Struthio* (*Ostrich*) *S. camelus*, Common or Black Ostrich.

*Struthio catus* (*Cassowary*).

*Pavo* (*Peacock*) Common P.

*Phasianus* (*Pheasant*) Common P.

*Menura* (*Menura*)

---

**Lettered Ornithology, Elementary Plate I.**

In the genus *Tetrao* (*Grouse*), *T. Urogallus*, Great Grouse.

*T. lagopus*, Ptarmigan.

*T. tetrix*, Black Game.

---

**Passeres.**

*Structure of the Feet.*

---

**Lettered Ornithology, Elementary Plate I.**

In the genus *Colius* (*Coly*).

---

**Lettered Ornithology, Elementary Plate IV.**

In the genus *Alauda* (*Lark*), *A. arvensis*, Skylark.

*A. obsoleta*, Dusky Lark.

*Pipra* (*Manakin*)

---

**Lettered Ornithology, Elementary Plate II.**

In the genus *Parus* (*Titmouse*).

---

**Lettered Ornithology, Elementary Plate IV.**

In the genus *Turdus* (*Thrush*).

*Motacilla* (*Warbler*)

---

**Lettered Ornithology, Elementary Plate I.**

In the genus *M. Regulus* (*Gold-crested Wren*).

---

**Class Amphibia.**

**Order I. Reptiles.**

**Genus Testudo.**

*Marine Turtles.*

---

**Lettered Amphibia, Plate X.**

*Fig. 5. Telfudo mydas,* Eseulent Green Turtle.

*6. Telfudo imbriata,* Hawkbill Turtle.

---

**Land Tortoises.**

*Fig. 1. Telfudo dentulata,* Denticulated Tortoise.

*2. Telfudo emerpea,* Green Speckled Tortoise.

*3. Telfudo guttata,* Spotted Tortoise.

*4. Telfudo picta,* Painted Tortoise.

---

**Plate 94.**

**Genus Rana.**

**Fig. 1. Rana Pipa,** Surinam Toad—Female with her young swimming in cells on the back.

*2. Rana bicolor,* Two-coloured Frog.

*3. Rana paradoxa,* Paradoxical Frog, in the fifth-like former tad-pole state.

---

**Genus Lacerta.**

**Fig. 1. Lacerta Salamandra,** Salamander.

*2. Lacerta Vittata,* Forked Lizard.

*3. Lacerta Chameleon,* Chameleon.

*4. Lacerta agilis,* Green Lizard.

*5. Lacerta lennificata,* Eight-lined Lizard.

---

**Genus Draco.**

*Fig. 4. Draco volans,* Flying Dragon, (*Lacerta volans,* Flying lizard).

---

**Genus Siren.**

**Fig. 1. Siren lacertina,** Eel-shaped Siren.

*2. Siren anguina,* Anguine Siren.

---

**Genus Crotaulus.**

**Lettered Amphibia, G. Crotaulus, Plate II.**

*Fig. 1. Crotaulus horridus,* Banded Rattle-snake.

*2. Crotaulus Durissus,* Striped Rattle-snake.

---

**Genus Boa.**

**Lettered Amphibia, G. Boa, Plate V.**

*Fig. 1. Boa constrictor,* Great Boa Serpent.

*2. Boa Phrygia,* Embroidered Boa Serpent.

---

**Genus Coluber.**

**Lettered Amphibia, G. Coluber, Plate IV.**

*Fig. 1. Coluber nasicornis,* Horn-nosed Viper.

*2. Coluber crepitus,* Ceraflies Viper.

*3. Coluber naja,* Nagoo or Spectacle Viper.

---

**Genus Anguis.**

**Lettered Amphibia, G. Anguis, Plate III.**

*Fig. 1. Anguis Corallinna,* Coral Slow Worm.

*2. Anguis alter,* Black Banded Slow Worm.

*3. Anguis Jamaicensis,* Jamaica Slow Worm.

---

**Genus Amphiibina.**

**Lettered Amphibia, G. Amphiibina, Plate VII.**

*Fig. 1. Amphiibina alba,* White Amphiibina.

*2. Amphiibina fuliginosa,* Fuliginous Amphiibina.
NATURAL HISTORY.

Plate

Genus Cæcilia.

102. Fig. 3. Cæcilia tentacula, Eel-shaped Cæcilia

Genus Hydrus.

103. Lettered Amphibia, G. Hydrus
Fig. 1. Hydrus colubrinus, Colubrine Hydrus 2. Hydrus bicolor, Black-backed Hydrus

Genus Langaya.

Fig. 3. Langaya nasuta, Snouted Langaya

Genus Acrochordus.

Fig. 4. Acrochordus dubius, Doubtful Acrochordus

ICHTHYOLOGY.

Class Pisces.

Order Apodes.

Genus Muraena.

104. Lettered Apodes, Plate I.
Fig. 1. Muraena anguilla, Eel Muraena, or Common Eel

Genus Synbranchus.

Fig. 2. Synbranchus marmoratus, Marbled Synbranchus

Genus Sphagebranchus.

Fig. 3. Sphagebranchus rostratus, Snouted Sphagebranchus

Genus Gymnotus.

Fig. 4. Gymnotus electricus, Electric Gymnotus

Genus Gymnothorax.

Fig. 5. Gymnothorax muraena, Eel Gymnothorax 6. Gymnothorax catenatus, Chain Gymnothorax

Genus Stomateus.

105. Lettered Apodes, Plate II.
Fig. 1. Stomateus cinereus, Ash-coloured Stomateus 2. Stomateus niger, Black Stomateus

Genus Stylephorus.

Fig. 3. Stylephorus chordatus, Chordated Stylephorus

Genus Trichiurus.

Fig. 4. Trichiurus argentus, Silvery Trichiurus

Genus Sternoptyx.

Fig. 5. Sternoptyx diaphana, Diaphanous Sternoptyx

Genus Xiphius.

Fig. 6. Xiphius gladius, Sword-fish

Genus Anarhichas.

Fig. 7. Anarhichas lupus, Ravenous Wolf-fish

Order Jugulares.

Genus Trachinus.

106. Lettered Order Jugulares, Plate I.
Fig. 1. Trachinus major, Great Weaver 2. Trachinus draco, Small Weaver

Genus Uranoscopus.

Fig. 3. Uranoscopus sabers, Rough Stargazer

Genus Callionymus.

Fig. 4. Callionymus dracunculus, Sordid Dragonet 5. Callionymus lyra, Gemmous Dragonet

Genus Gadus.

107. Lettered Ichthyology, Order Jugulares, Plate II.
Fig. 1. Gadus morhua, Cod-fish 2. Gadus carbonarius, Coal-fish 3. Gadus minutus, Poor 4. Gadus Tau, Taw Cod-fish

Genus Blennius.

Fig. 5. Blennius maris, Ocellated Blenny

Genus Kurtus.

Fig. 6. Kurtus indicus, Indian Kurtus

Order Thoracici.

Genus Cepola.

108. Lettered Ichthyology, Order Thoracici, Plate I.
Fig. 1. Cepola Tanis, Ribband-fish

Genus Echinus.

Fig. 2. Echinus Remora, Mediterranean Sucking-fish

Genus Coryphena.

Fig. 4. Coryphena hippurus, Common Coryphene 5. Coryphena pentadactyla, Five-spotted Coryphene

Genus Gobius.

Fig. 3. Gobius minutus, Spotted Goby

Genus Cottus.

Fig. 6. Cottus grunniens, Grunting Bull-head 7. Cottus cataphractus, Mailed Bull-head

Genus Scorpena.

109. Lettered Ichthyology, Order Thoracici, Plate II.
Fig. 1. Scorpena Scrofa, Hog Sea-Scorpion 2. Scorpena horrida, Horrid Sea-Scorpion 3. Scorpena antennata, Antennated Sea-Scorpion

Genus Zeus.

Fig. 4. Zeus gallus, American Zeus 5. Zeus ciliaris, Filamentous Zeus 6. Zeus insidiosus, Infidious Zeus
NATURAL HISTORY.

Genus Pleuronectes.

110. Lettered Ichthyology, Order Thoracici, Plate III.
   Fig. 1. Pleuronectes Zebra, Zebra Sole
   2. Pleuronectes Argus, Argus Flounder
   3. Pleuronectes platessa, Plaice
   4. Pleuronectes bilineatus, Bilineated Sole

111. Lettered Ichthyology, Order Thoracici, Plate IV.
   Fig. 1. Pleuronectes punctatus, Dotted Flounder

Genus Chaetodon.

110. Lettered Ichthyology, Order Thoracici, Plate III.
   Fig. 5. Chaetodon bicolor, Two-coloured Chaetodon
   6. Chaetodon fasciatus, Banded Chaetodon

111. Lettered Ichthyology, Order Thoracici, Plate IV.
   Fig. 2. Chaetodon imperator, Imperial Chaetodon
   3. Chaetodon marginatus, Bordered Chaetodon
   4. Chaetodon arcuatus, Bowed Chaetodon
   5. Chaetodon rostratus, Snouted Chaetodon
   6. Chaetodon Tirra, Tirra Chaetodon

Genus Sparus.

112. Lettered Ichthyology, Order Thoracici, Plate VII.
   Fig. 1. Sparus falcatus, Falcated Gilthead
   2. Sparus Surinamensis, Surinam Gilthead
   3. Sparus fasciatus, Banded Gilthead
   4. Sparus caryophyllus, Golden-tailed Gilthead
   5. Sparus annularis, Annulated Gilthead
   6. Sparus mana, Cackarel

Genus Scarus.

113. Lettered Ichthyology, Order Thoracici, Plate VIII.
   Fig. 7. Scarus viridis, Green Scarus

114. Lettered Ichthyology, Order Thoracici, Plate X.
   & XI.
   1. Scarus cristatus, Large-scaled Scarus

Genus Labrus.

113. Lettered Ichthyology, Order Thoracici, Plate VIII.
   Fig. 1. Labrus micropogon, Large-scaled Wraase
   2. Labrus trichopterus, Hair-finned Wraase
   3. Labrus maleterus, Soft-finned Wraase
   4. Labrus maculatus, Spotted Wraase
   5. Labrus punctatus, Dotted Wraase
   6. Labrus melagaster, Black-bellied Wraase

Genus Sciaena.

114. Lettered Ichthyology, Order Thoracici, Plate X.
   & XI.
   Fig. 2. Sciaena diacantha, Two-spined Umber, or
   Sciaena
   3. Sciaena chirrofa, Cirrofa Sciaena
   4. Sciaena punctata, Dotted Sciaena
   5. Sciaena plumiera, Plumier's Sciaena

115. Lettered Ichthyology, Order Thoracici, Plate IX.
   Fig. 1. Perca flavescens, Brazilian Perch
   2. Perca fasciatus, Rock Perch
   3. Perca punctata, Dotted Perch
   4. Perca guttata, Gutted Perch
   5. Perca maculata, Spotted Perch
   6. Perca bimaculata, Bimaculated Perch

Genus Trachychthys.

116. Lettered Ichthyology, Order Thoracici, Plate XI.
   Fig. 4. Trachychthys australis, Australian Trachychthys

Genus Gasterosteus.

117. Lettered Ichthyology, Order Thoracici, Plate XII.
   Fig. 1. Scomber Sardus, (Scomber Scomber, Linn.)
   Common Mackarel
   2. Scomber niger, Black Mackarel
   3. Scomber saliens, Salient Mackarel
   4. Scomber ruber, Red Mackarel

118. Lettered Ichthyology, Order Thoracici, Plate XIII.
   Fig. 5. Scomber Renieri, Rotterian Mackarel
   6. Scomber aculeatus, Aculeated Mackarel

Genus Mullus.

119. Lettered Ichthyology, Order Thoracici, Plate V.
   Fig. 4. Cobitis fusilis, Great Loche

Genus Trigla.

117. Lettered Ichthyology, Order Thoracici, Plate XII.
   Fig. 5. Lonchiusus barbatus, Bearded Lonchiusus

Genus Corbina.

118. Lettered Ichthyology, Order Thoracici, Plate XIII.
   Fig. 1. Mullus surmuletus, Surmullet

Genus Lonchiusus.

119. Lettered Ichthyology, Order Thoracici, Plate V.
   Fig. 4. Cobitis fusilis, Great Loche

Genus Anableps.

118. Lettered Ichthyology, Order Thoracici, Plate XIII.
   Fig. 5. Anableps tetraphthalmus, Four-eyed Anableps

Genus Silurus.

119. Lettered Ichthyology, Order Thoracici, Plate V.
   Fig. 1. Silurus clarus, Long-bearded Silurus
NATURAL HISTORY.

Plate

Genus Platystachus.
119. Fig. 6. Platystachus anguillaris, Eel-shaped Platystachus.

Genus Loricaria.
Fig. 2. Loricaria coelalis, Ribbed Loricaria
3. Loricaria flavus, Yellow Loricaria

Genus Salmo.
120. Lettered Ichthyology, Order Abdominales, Plate III.
Fig. 1. Salmo bicmicatus, Bicmaculated Salmon
2. Salmo fisciatus, Banded Salmon
3. Salmo tumbl, Barred Salmon
4. Salmo Odor, Odoe Salmon
5. Salmo Gasteropeleus, Yellow-finned Salmon
6. Salmo Friderici, Frederician Salmon
7. Salmo rhomboeus, Rhombic Salmon

Genus Fistularia.
121. Lettered Ichthyology, Order Abdominales, Plate II.
Fig. 1. Fistularia ciminans, Chinese Tobacco-pipe Fish
2. Fistularia tabaccaria, Spotted Tobacco-pipe Fish

Genus Esox.
Fig. 3. Esox oblvs, Bony Gar Fish, or Sea Pike
4. Esox Belons, Sea Pike, or Gar Fish
5. Esox beifteps, Brasilian Pike, or Gar Fish

Genus Elops.
Fig. 6. Elop Saurus, Saury Elops

Genus Argentina.
Fig. 7. Argentina Sphyrena, European Argentine

Genus Atherina.
122. Lettered Ichthyology, Order Abdominales, Plate I.
Fig. 1. Atherina Hepsetus, Common Atherine

Genus Mugil.
Fig. 2. Mugil Tang, Tang Mullet
3. Mugil cephalus, Grey Mullet

Genus Exocet us.
Fig. 4. Exocetus coelans, Mediterraneane Flying Fish
5. Exocetus exilis, Swallow Flying Fish
6. Exocetus Mfogafier, Atlantic Flying Fish

Genus Polyneus.
123. Lettered Ichthyology, Order Abdominales, Plate IV.
Fig. 1. Polyneus paradisicus, Paradise Polyneus
2. Polyneus decadactylus, Ten-fingered Polyneus

Plate

Genus Clupea.
123. Fig. 3. Clupea Driffii, Thrilla Herring
4. Clupea nafus, Naftal Herring

Genus Cyprinus.
Fig. 5. Cyprinus culturus, Razor Carp
6. Cyprinus catus, Golden Carp, var.
7. Cyprinus phoxinus, Minnow

Order Branchiostegi.

Genus Ostracion.
124. Lettered Ichthyology, Order Branchiostegi, Genus Ostracion, Plate V.
Fig. 1. Ostracion surprisus, Eared Trunk Fish
2. Ostracion trigeter, Triangular Trunk Fish
3. Ostracion nafus, Snouted Trunk Fish
4. Ostracion bicmicatus, Bicmaculated Trunk Fish
5. Ostracion quadriconris, Four-horned Trunk Fish
6. Ostracion cornutus, Horned Trunk Fish

Genus Tetronod.
125. Lettered Ichthyology, Order Branchiostegi, Plate VI.
Fig. 1. Tetronod hifidus, Hifid Tetrodon
2. Tetronod occicus, Ocellated Tetrodon
3. Tetronod lineatus, Lincated Tetrodon
4. Tetronod caudadus, Hare Tetrodon

Genus Diodon.
Fig. 5. Diodon Hyfrix, Porcupine Diodon
6. Diodon orbicularis, Round Diodon

Genus Syngnathus.
126. Lettered Ichthyology, Order Branchiostegi, Plate VI.
Fig. 1. Syngnathus foliatus, Foliated Pipe Fish
2. Syngnathus acus, Great Pipe Fish
3. & 5. Syngnathus Hippocampus, Sea-Horse Pipe Fish

Genus Pegasus.
Fig. 4. & 4. Pegafus Draconis, Dragon Pegasus
5. & 5. Pegafus natans, Swimming Pegasus

Genus Centricus.
Fig. 6. Centricus scutatus, Mailed Centricus

Genus Balistes.
127. Lettered Ichthyology, Order Branchiostegi, Plate III.
Fig. 1. Balistes vetula, Old Wife
2. Balistes maculatus, Spotted Old Wife
3. Balistes acalus, Aculeated Old Wife
4. Balistes monocrates, One-horned Old Wife

Genus Cyclopterus.
128. Lettered Ichthyology, Order Branchiostegi, Plate IV.
Fig. 1. Cyclopterus Lumpus, Common Lump-fucker
NATURAL HISTORY.

Plate 128. Fig. 2. Cyclopterus ocellatus, Ocellated Lump-fucker
1. Cyclopterus lineatus, Lineated Lump-fucker

Genus Lophius.
Fig. 4. Lophius marmoratus, Marbled Angler
5. Lophius Hitrio, Harlequin Angler
6. Lophius rostratus, Beaked Angler
7. Lophius pisces, Painted Angler

Order Chondropterygii.
Genus Acipenser.

129. Lettered Ichthyology, Order Chondropterygii, Plate I.
Fig. 3. Acipenser Sturia, Common Sturgeon
4. Acipenser Ruthenus, Sterlet

Genus Chimaera.
Fig. 2. Chimaera monstrosa, Sea-monster
5. Chimaera eulophylica, Southern Sea-monster

Genus Pristis.
Fig. 1. Pristis antiquorum, Common Saw-fish

Genus Squalus.

130. Lettered Ichthyology, Order Chondropterygii, Plate II.
Fig. 1. Squalus glauca, Blue Shark
2. Squalus Catulus, Leifer spotted Shark
3. Squalus Squatina, Angel Shark
4. Squalus Zygana, Hammer-headed Shark
5. Squalus Zebra, Zebra Shark

Genus Spatularia.
Fig. 6. Spatularia reticulata, Reticulated Spatularia

Genus Raja.

131. Lettered Ichthyology, Order Chondropterygii, Plate VI.
Fig. 1. Raja diabolus, Demon Ray
2, 3. Raja clavata, Thorn-back
4. Raja undulata, Undulated Ray
5. Raja torpedo, Electric Ray
6. Raja rhinobatos, Long-nosed Ray

Genus Gastrobranchus.

and these, it must be allowed, were not chosen altogether with that due attention to accuracy which the intricacy of this branch of Natural History demanded. These insects were copied, we understand, from specimens in the very valuable cabinet of Mr. Francillon; but owing to the dispersion of that collection by public sale, the means of comparison has paffed away, and the death of the artist then employed, as well as of the zealous proprietor of that collection, has opposed a period to enquiry further. The far greater and more costly portion of the Francillonian Cabinet is indeed reserved, being incorporated in the princely cabinet of Alexander Mc-Levy, Esq., a cabinet to which true science is never refus'd an easy access; but the insects in question having been removed from their respective situations, in Mr. Francillon's drawers, they can be no longer recognized as the specimens from which the figures in this plate are taken; and this, in some few instances at least, it must be confessed, is requisite to enable us to speak of them with certainty. We may observe, moreover, that very few names accompany the articles represented in this Plate of Mr. Edwards; and of those few some are certainly doubtful. *Hipsa* is doubtful (a true *Hipsa* has been since given in Plate 141. fig. 8.). *Bruchus* is erroneous, and appears to be, with the exception of the antennae, *Attelabus Coryli*; (a true *Bruchus* is infected by us in Plate 141. fig. 9.) and his insect named *Attelabus*, has much the appearance of *Mylabris*, except in having pectinated instead of moniliform antennae: nevertheless this may be a *Clerus*, and allied to *Apiarius*. (See Plate 148. fig. 9.) *Lampyrus* is indifferent; *Cantharis* unintelligible. With these, and some few other exceptions, the Plate should be preferred, as it contains other insects of interest, the repetition of whose figures has been purposely avoided in selecting the materials for the rest of the Plates of Coleoptera.

We believe *Curculio*, No. 1. to be *Curculio bispinofos;* No. 2. to be *Curculio Imperialis*, the Brazilian or Diamond Beetle; No. 4. *Curculio vitatta*, of Jamaica; *Cerambyx*, No. 3. *C. Mofchatus;* No. 4. *Cerambyx marginatus;* *Nectyalis*, No. 2., *N. cerulea;* *Lampyrus*, fig. 1., *L. vulgaris*, male (having wings); No. 2. the female (being apterous, or without wings); Elater, No. 1., *E. ocellatus;* Weft Indies; No. 2. is uncertain; but is, no doubt, an Elater, placed on its back, to shew the situation of the pointed sternum in that genus, by striking which upon the breast, the insect is enabled to spring up with instantaneous velocity when laid down in that position.

176. Lettered Crustacea, Order Cancer, Plate VI.

Fig. 1. Cancer arrofor (Pagurus arrofor)

2. Cancer canaliculatus (Pagurus canaliculatus)

3. Cancer excavatus (Pagurus excavatus)

Genus Astacus.

Fig. 4. Cancer variegatus (Astacus variegatus)

Genus Squilla.

Fig. 2. Cancer digitatus (Squilla digitatus)

Genus Cancer.

177. Lettered Entomology, Order Aptera, Plate X.

Fig. 1. Monoculus quadriramus

2, 2. Monoculus polyphemus, Upper Surface and Under Surface

Genus Monoculus.

Genus Scorpius.

178. Lettered Vermes, Order Intestina, Plate I, II, III.

Fig. 1. Acantho variculatis

Genus Echinorynchus.

Fig. 2. Echinorynchus lucii

Head magnified *

2. Echinorynchus candidus

Head magnified *

3. Echinorynchus coryphæus

4. Echinorynchus linculatus

Head magnified *

5. Echinorynchus attenuatus, natural size, and magnified

6. Echinorynchus attenuatus, natural size, adhering to the skin of a fish

7. Echinorynchus alba

8. Echinorynchus brunnæa

Genus Lingulata.

9. Lingulata abrupta, Upper and Under Surface

Genus Fasciola.

Fig. 2. Fasciola binodis, the minute Figures which accompany the larger ones denote the natural size

3. Fasciola Ægææfius, Ditto
Plate 178. Fig. 4. Faschiola Scorpion, the minute Figures which accompany the larger ones denote the natural size.
5. Faschiola heteroptera, Ditto
6. Faschiola brama, Ditto

Genus Tenia.

179. Lettered Vermes, Order Intestina, Plate V.
Fig. 1. Tenia folium, grouped into folds in order to include the whole animal, which is of extreme length, within the limits of the Plate. Found in the human body.
2. The head, natural size, of a specimen twenty feet in length.
3. Head magnified.
4. Two joints retaining the external skin, and shewing the alternate disposition of the ocula along the edges of the joints as they usually appear.
5. Two joints shewing their lateral disposition when they occur on both the margins of each joint, which sometimes happens.
6. A portion of the joints of the natural size divested of the outer skin, and divesting more fully the alternate lateral ocula, together with the alimentary canals, as they communicate from one joint to the other.
7. The middle systen of vessels illustrated in another portion of four joints.
8. Another portion deprived of the outer coating, and displaying all the canals in their relative situation. Vide Carlile in Linn. Transf. vol. 2.
10. A portion of several joints exhibiting the ocula, which are disposed in a single series down the center of the joints.
11. Another portion divested of the outer coating, and displaying the stelliform vessels down the center within, and also the lateral alimentary canals. Found in the intestines of mankind.
12. Tenia canina, head, and a portion of the body, consisting of the five first joints. Found in the dog.

Genus Gordius.

180. Lettered Vermes, Genus Gordius, Plate IV.
Fig. 1. Gordius aquaticus

Genus Lumbicus.

Fig. 2, 3. Lumbicus terrestris

Genus Hirudo.

Fig. 4. Hirudo muricata
5. Hirudo geometra. The smaller figures at No. 1. denote the eggs and natural size of the animal; No. 4. magnified shews the animal affixed by the broad peduncel-like tail with the body extended horizontally; No. 3. the same contracting into an arched

Plate 180. Fig. 5. form: No 2. when most contracted, arched, and elevated, preparatory to walking, which it does somewhat in the manner of the larve of the Geometra tribe of moths, or as usually described as if measuring the ground like a pair of compasses.

Genus Planaria.

Fig. 6. Planaria crenata. No. 1, 2, 3, 4, 5, shews various positions and contractions of this animal.

Genus Siphunculus.

Fig. 7. Siphunculus nudus

Order Mollusca.

Genus Limax.

Fig. 8. Limax ater
9. Limax maximus

Genus Onchidium.

Fig. 1. Onchidium typho

Genus Laplilus.

Fig. 2. Laplilus depilans

Genus Doris.

Fig. 3. Doris argo
4. Doris radiata
5. Doris papillofa

Genus Aphrodita.

Fig. 6. Aphrodita aculeata. No. 6. *small, upper surface, right-hand figure.
No. 6. *ditto, under surface, left-hand figure.
No. 6. large size.
7. Aphrodita squamata

Genus Nais.

182. Lettered Vermes, Genus Nais, Plate V.
Fig. 1, 2, 3, 4. Nais serpentina, highly magnified, the natural size being three quarters of an inch in length, or not exceeding that of the cluster shown on the duckweed, fig. 5.
5, 6, 7, 8, 9, 10, 11. Nais vermicularis, highly magnified, natural size one-tenth of an inch.
12, 13. Nais probosidea, highly magnified, natural size three-fourths of an inch.

Genus Actinia.

183. Lettered Vermes, Genus Actinia, Plate II.
Fig. 1. Actinia dianthus
2. Actinia circus

Genus Holothuria.

184. Lettered Zoology, Clasa Vermes, Plate I. of Mol-lusca.
Fig. 1. Holothuria elegans
2. Holothuria pentactes
NATURAL HISTORY.

PLATE

184. Fig. 3, 4. Holothuria fusus
5. Holothuria penicillus
6, 7, 8. Holothuria quaumata. No. 1. upper surface; No. 2. lower surface, in a quiescent state; No. 3. with the tentacula expanded
9, 10. Holothuria inhaerens, No. 1. with tentacula expanded; No. 2. tentacula retracted

GENUS Sepia.

185. Lettered Vermes, Order Mollusca, Plate VI.

Fig. 1. Sepia octopus
2, 3. Sepia medusa. No. 1. upper surface; No. 2. under surface

GENUS Medusa.

186. Lettered Vermes, Order Mollusca, Plate IV.

Fig. 1, 2. Medusa palma, No. 1. upper surface, No. 1. under surface
3. Medusa campanula

GENUS Asterias.

187. Lettered Conchology, Vermes, Mollusca, Plate III. of Asterias.

Fig. 1. Asterias Caput medusa
2. Asterias pellinata
3. Asterias sphæralata
4. Asterias ophiura, a upper surface, b under surface

ORDER Testacea.

GENUS Chiton.

188. Lettered Conchology, Genus Chiton, Plate IX.

Fig. 1, 2. Chiton arundo
Chiton aculeatus, No. 1. upper surface, No. 2. inside
3. Chiton squamosus
4. Chiton olivaceus, No. 1. outside, No. 2. inside, small

GENUS Lepas.

189. Lettered Conchology, Genus Lepas, Plate XIII.

Fig. 1. Lepas anatifera
2. Lepas anserifera

GENUS Pholas.

190. Lettered Conchology, Genus Pholas, Plate VIII.

Fig. 1, 2, 3. Pholas dactylus, No. 1. side view; No. 2. the two lateral valves united at the hinge; No. 3. inside of one of the lateral valves
4. Pholas coarata
5, 6, 7. Pholas friaria, No. 1. the lowest figure, exhibits a side view of this shell, as composed of several valves; No. 2., the uppermost figure, shews the teflaceous valves at the top or hinge side of the shell; No. 3. the manner in which this species of Pholas buries itself into ships' bottoms or other timber

PLATE

GENUS Mya.

193. Lettered Conchology, Genus Mya, Plate XI. B.

Fig. 1. Mya truncata

GENUS Solen.

191. Lettered Conchology, Genus Solen, Plate (no number).

Fig. 1. Solen grandis, the lowest figure in the plate
2, 3. Solen radiatus, No. 1. outside, No. 2. inside, smaller shell
4. Solen frigilatus
5. Solen vagina, No. 1. outside, No. 2. of a younger shell, shewing the teeth of the hinge
6. Solen ensis

GENUS Tellina.

192. Lettered Conchology, Genus Tellina, Plate V.

Fig. 1, 1. Tellina radiata, No. 1. outside, No. 2. inside (Donov. Brit. Shells)
2, 2. Tellina lyalidus, No. 1. outside, No. 2. inside (Donov. Brit. Shells)
3, 3. Tellina fabula, one valve of this Shell is marked externally with very fine oblique subfusiform frills, the other smooth or deflective of frills (Donov. Brit. Shells)
4. Tellina bimaculata, inside and outside (Donov. Brit. Shells)

GENUS Cardium.

Fig. 5. Cardium aculeatum
6. Cardium levigatum
7. Cardium edule
8. Cardium medium

GENUS Mactra.

193. Lettered Conchology, Genus Mys, &c. Plate XI. B.

Fig. 2. Mactra radiata

GENUS Donax.

Fig. 3. Donax trunculus

GENUS Venus.

Fig. 4. Venus islandica, No. 1. outside, No. 2. inside

GENUS Chama.

Fig. 5. Chama Cap

GENUS Spondylus.

194. Lettered Conchology, Genus Spondylus, Plate XVII.

Fig. 1, 2, 3. Spondylus gardropus. Upper figure on the left hand the usual size; upper figure on the right side shews the inside of both valves; the lower figure a superb specimen, in point of magnitude, and perfection of the elongated spines. Cabinet of Alexander Melvill, Esq.
NATURAL HISTORY.

Vol. XXXIX.

GENUS ARCA.

195. Lettered Conchology, Genus Arca, Plate VIII.
Fig. 1, 2. *Arca tortuosa*, No. 1. outside, lower figure. No. 2. inside
3, 4. *Arca fimbria*, No. 1. the outside, lower figure. No. 2. inside, the upper figure
5, 6. *Arca nodulosa*, No. 1. outside, lower figure. No. 2. inside
7. *Arca nebula*

GENUS OSTREA.

Pecten, or Scallops.

196. Lettered Conchology, Genus Ostrea, Plate XII.
Fig. 1. *Ostrea Jacobea*
2. *Ostrea subfusca*
3. *Ostrea nodosa*
4. *Ostrea lineata*
5. *Ostrea obfusca*
6. *Ostrea varia*, various sizes

GENUS MYTILUS.

193. Lettered Conchology, Genus Mya, &c. Plate XI. B.
Fig. 6, 6. *Mytilus edulis*, var. purpureus, (Donov. Brit. Shells), inside and outside

GENUS PINNA.

197. Lettered Conchology, Genus Pinna, Plate VII.
Fig. 1. *Pinna nigra*, inside and outside, small size
2. *Pinna mirificata*, shewing the byfis or beard
3. *Pinna rubra*, ditto
4. *Pinna fragilis*

UNIVALVES.

GENUS ARGONAUTA.

198. Lettered Conchology, Order Univalve, Plate IV.
Fig. 1. *Argonauta argo*, Paper-fisilr Shell
2. *Argonauta vitrea*, called the Glaffy Nautilus, a shell of unusual rarity

GENUS NAUTILUS.

Fig. 3. *Nautilus Pompilius*, Great Nautilus.
4. No. 1. the largest of the ordinary size; No. 2. young; No. 3. section of the young shell, shewing the chambers and the fiphunculus

GENUS CONUS.

199. Lettered Conchology, Genus Bulla, &c. Plate XI. A.
Fig. 1. *Conus Ammiralis*, var. Banded Cedo nulli cone
2. *Conus Ammiralis*, var. Curapao Cedo nulli cone
3. *Conus Ammiralis*, var. Southern Cedo nulli cone
4. *Conus Ammiralis*, var. Senna Cedo nulli cone
5. *Conus Ammiralis*, var. Marbled Cedo nulli cone

* All these varieties are esteemed valuable: some few bear an excessive price; that known by the name of Lyonet's Shell was reputed to be worth one hundred pounds silver, or as it has been otherwise flated a much higher sum. The figure in the upper part of the plate represents the most uncommon kind of Cedo Nulli

GENUS CYPREA.

200. Lettered Conchology, Genus Cyprea, Plate XIV.
Fig. 1. 1. *Cyprea tigris*, upper and under surface
2. *Cyprea aurora*, Aurora or Orange Cowry of the South Seas
3. *Cyprea argus*
4. *Cyprea Arabica*
5. *Cyprea annulata*, upper and under surface
6. *Cyprea fuscata*
7. *Cyprea maculata*
8. *Cyprea aspera*
9. 9. *Cyprea moneta*, upper and under surface
10. 10. *Cyprea pediculus*

GENUS BULLA.

199. Lettered Conchology, Genus Bulla, &c. Plate XI. A.
Fig. 6, 6. *Bulla lignaria*, No. 1. the outside. No. 2., the lower figure, shews the mouth

GENUS VOLUTA.

201. Lettered Conchology, Genus Voluta, Plate I.
Fig. 1. *Voluta tornata*,
2. *Voluta porphyria*
3. *Voluta oliva*
4. *Voluta pallida*
5, 5. *Voluta papula*, No. 1. the back, No. 2. shews the mouth
6. *Voluta epistrophi*
7. *Voluta Athropica*
8. *Voluta indica*

GENUS BUCCINUM.

202. Lettered Conchology, Order Voluta, &c. Plate II.
Fig. 1. *Buccinum harpa*
2. *Buccinum palpum*
3. *Buccinum maculatum*
4. *Buccinum frigillatum*

GENUS STROMBUS.

Fig. 5. *Strombus chiagra*
6. *Strombus fusca*
7. *Strombus lenticulatus*
8. *Strombus uccus*

GENUS MUREX.

203. Lettered Conchology, Order Univalve, Plate III.
Fig. 1. *Murex haustellum*
2. *Murex longicuda*
3. *Murex maculatus*
4. *Murex tulipa*

GENUS TROCHUS.

Fig. 5. *Trochus niloticus*
6, 6. *Trochus perspectivus*. No. 1, right-hand figure, shews the convex surface; No. 2. left-hand, the concave surface or under side
7. *Trochus pilatus*
8. *Trochus torpius*

5 A
NATURAL HISTORY.

Genus Turbo.

199. Lettered Conchology, Genus Bulla, &c. Plate XI. A.

Fig. 7, 7. Turbo tricnecatus, (Donov. Brit. Shells) smallest figure shews the natural size
8, 8. Turbo nuciforin, (Donov. Brit. Shells) ditto

Genus Helix.

Fig. 9, 9. Helix brittany

Genus Nerita.

Fig. 10, 10, 10. Nerita carena, the figure on the left hand exhibiting the carinated umbilicus

Genus Haliotis.

204. Lettered Conchology, Genus Haliotis, Plate VI.

Fig. 1, 1. Haliotis Affinum. The lower figure shews the outside or upper surface of the shell, as the animal moves; the upper figure exhibits the hollow of the shell, when deprived of the animal
2. Haliotis tuberculata
3, 4. Haliotis spadicea, outside and inside
5. Haliotis levigata

Genus Patella.

* Shell valve within.

205. Lettered Conchology, Genus Patella, Plate (blank)

Fig. 1, 1. Patella equesris. The upper figure shews the outside of the shell, which is rugose; the lower one the inside, which is smooth, and furnished with an internal lip or valve in the hollow center
2, 2. Patella fornicata. The figure on the left hand exhibits the outside; that on the right hand the inside, with the broad inner lip or valve
3, 3. Patella striata. No. 1, the lower figure, shews the striated outer surface; No. 2, the upper figure, the concave hollow beneath, with the inner lip or valve

* * Shell at the Apex perforated.

4, 4. Patella fissura
5. Patella fissurella
6. Patella greca
7. Patella raaiata
8. Patella lobata
9. Patella nimbofa. The upper figure shews the outside surface; the lower one the hollow cavity, or inside

*** Apex of the Shell entire.

206. Lettered Conchology, Genus Patella, Plate XVI.

Fig. 1. Patella granatina. The upper figure shews the outside; the lower one the concave, or inside

Plate 206. Fig. 2, 2. Patella Auricula, two varieties. The figure in the middle of the left-hand margin shews the outer surface; the others the concavity
3. Patella vulgaris, var.
4. Patella florugra
5. Patella sagittata
6. Patella virgata
7. Patella anatina

Genus Dentalium.

207. Lettered Conchology, Genus Dentalium, Plate (blank)

Fig. 1. Dentalium elephantiurn

Genus Serpula.

Fig. 2. Serpula trigena, various examples adhering to a Pecten, (Ustrea)
3. Serpula trigena, ditto, adhering to the valve of a Mytilus
4. Serpula verrucularis, intermixed with S. triqueta
5. Serpula filiformis
6. Serpula reticulata
7. Serpula papillata
8. Serpula tortuosa
9. Serpula anguina
10. Serpula penis

Genus Teredo.

208. Lettered Conchology, Genus Teredo, Plate X.

Fig. 1. Teredo navalis, exhibiting the manner in which the timbers of ships' bottoms are sometimes perforated by this destructive creature
2. Teredo navalis, a single shell detached from the timber, is shown at the bottom of the Plate

Genus Sabella.

Fig. 3. Sabella elegans
4. Sabella alveolata

ELEMENTARY PLATES OF CONCHOLY.

Univalves.

209. Lettered Conchology, Elementary Plate I.

Fig. 1, 1, 1. The part denominated the Bafe of an univalve shell, illustrated by examples selected from different Genera, as in Dentalium, Turbo
2, 2, 2. the Apex, as in Dentalium and Patella
3, 3. the Front, as in Turbo, Buccinum
4, 4. the Back, as in Turbo, Helix
5, 5. the Sides, as in Turbo, Buccinum
6, 6, 6. the Body, as in Helix, Muræs
7. the Belly, as in Nerita
8. the Whorl, as in Turbo
9, 9, 9. the Spire, as in Turbo, Muræs
10, 10. the Sutures of the Spire or Whorl, as in Muræs, Turbo
Plate

210. Lettered Conchology, Elementary Plate II.
Fig. 11. The part denominated the Pillar or Columnella, as in Murex
12, 12, 12. the Aperture, as in Murex, Helix, Nerita
13, 13, 13. the Lip, as in Voluta
14. the Beak, as in Murex
15. the Canal, as in Murex
16, 16. the Umbilicus, as in Trochus, Nerita

211. Lettered Conchology, Elementary Plate III.
Fig. 17, 17. The part denominated the Operculum, as in Trochus, Murex
18. the Involuted Spire, as in Nautilus
19, 19, 19. the Chambers, as in Nautilus, the Chambered Patella, and the Ammonite, (found fossil)
20. the Siphunculus, as in Nautilus
21. the Epidermis, as in Turbo

Bivalves.
Fig. 22. The part denominated the Base of a Bivalve Shell, as in Venus
23. the Summit, as in Patella
24, 24. the Beak, as in Chama, (Cor.) Mytilus
25. the Sides, as in Venus

212. Lettered Conchology, Elementary Plate IV.
Fig. 26. The part denominated the Margin, or Limb, as in Tellina, (cornea)
27, 27. the Dilk, as in Venus, Tellina
29, 29. the Posterior Slope, as in Mactra, Tellina, Venus
30. the Lunule, as in Venus, Tellina, (a. & b.)
31, 31. the Cartilage, or Hinge, as in Tellina, Venus
32, 32. the Ears, as in Peiten, (Ostreæ, Limn.)
33, 33. the Ligament Perforation, (Aperture in the upper valve of the Shell through which the ligament of the animal passes, by which it adheres to extraneous substances, as in Anomia)

213. Lettered Conchology, Elementary Plate V.
Fig. 34, 34. The Length and Breadth of a Bivalve Shell, as in Solen, Mytilus
35. the Infide of a Bivalve Shell, as in Mytilus, (rugofus)
36. the Hinge, Suture, and Procefs. Denticulated future, as in Arca. Spoon-shaped procefs, as in Myia, (Pretensius, Donov. Brit. Shells)

Plate

213. Fig. 37. The part denominated the Cicatrix, Imprefion of the Spaces to which the animal-inhabitant of the Shell adheres
38, 38. the Byfius, or Beard, as in Mytilus

Multivalves.
Fig. 39, 39. The part denominated the Base of a Multivalve Shell, as in Lepas
40, 40. the Ligament, as in Lepas, (anatifera)
41, 41. the Operculum, as in Lepas, (Balanus vulgaris)

* * Vide article Conchology, which these Elementary Plates are intended to illustrate.

Order 4. Zoophytes.

Genus Tubipora.

214. Lettered Zoophytes, Genus Tubipora, Plate I.
Fig. 1. Tubipora mufica

Genus Madrepura.
* Consisting of one Star.

215. Lettered Zoophytes, Plate II.
Fig. 1. Madrepura labyrintha
2. Madrepura phrygia
3. Madrepura gyroja
4. Madrepura arvolata

*** With numerous united Stars.

216. Lettered Zoophytes, Genus Isis, Plate I.
Fig. 1. Isis Hippuris
2. Isis coccinea

Genus Antipathes.

217. Lettered Zoophytes, Genus Gorgonia, Plate II.
Fig. 1. Gorgonia lepidifera
2. Gorgonia ceratophyta
3. Gorgonia americana
4. Gorgonia eserfa
5 A 2

Genus Isis.

Genus Antipathes.

Fig. 3. Antipathes subpinnta
4. Antipathes Myriophylla

Genus Gorgonia.

Fig. 1. Gorgonia lepidifera
2. Gorgonia ceratophyta
3. Gorgonia americana
4. Gorgonia eserfa

5 A 2
NATURAL HISTORY.

Plate 218. Lettered Zoophytes, Genus Gorgonia, Plate I.
1. *Gorgonia nobilis*, Red Coral, or Noble Coral. Plate I.
2. Part of the branch of Gorgonia Nobilis magnified, and exhibiting the animals.
3. *Gorgonia umbraeolum*.
4. Portion of a branch magnified.
5. *Gorgonia reticulata*.
6. Portion of a branch magnified.

Genus Alcyonium.
Plate 219. Lettered Zoophytes, Genus Alcyonium, Plate III.
1. *Alcyonium gorgonoides*.

Genus Spongia.

Plate 220. Lettered Vermes, Order Zoophytes, Genus Flustra, Plate VIII.
1. *Flustra foliacea*.
2. *Flustra bombaycina*.
3. A portion of a branch magnified to shew the cells.
4. *Flustra carboidea*.
5. Magnified to shew the cells.

Genus Flustra.

Plate 221. Lettered Vermes, Order Zoophytes, Genus Tubularia, Plate I.
1. *Tubularia magnifica*, Magnificent Tubularia, or Animal Flower.
The figures in this Plate display the animal in its young and full-grown state, and exhibit likewise the full expansion of the tentacula.

Genus Tubularia.

Plate 222. Lettered Zoophytes, Genus Corallina, Plate VI. and VII.
1. *Corallina officinalis*.
2. One of the branches magnified.
3. *Corallina feucreata*.
4. A branch magnified.
5. *Corallina incarnata*.
7. *Corallina corniculata*.
8. A branch magnified.

Genus Sertularia.

Plate 223. Lettered Vermes, Order Zoophytes, Genus Sertularia, Plate VIII.
1. *Sertularia frutescens*.
2. A branch magnified.

Genus Gorgonia.
Plate 224. Lettered Vermes, Order Zoophytes, Genus Hydra, Plate V.
4. 5. 6. Clusters of the different species, as they live at the roots of aquatic plants immersed in water.

Genus Hydra.

Plate 225. Lettered Animalcules, Class Vermes, Plate I.
8. *Brachionus tripus*.
9. *Brachionus uncinatus*.
10. *Brachionus quadridentatus*.

Genus Brachionus.

Plate 226. Lettered Vermes Infusoria, Plate II.
1. *Vorticella polyxena*, in various figures.
2. *Vorticella polyxena*, a cluster magnified.
3. *Vorticella analectica*, the group shewing the manner in which they aggregate in clusters; and also figures of the single-headed, double-headed, and quadruple-headed, separate.
5. *Vorticella opercularia*, a group shewing the belliform animal expanded.
6. *Vorticella umbellaria*.
7. *Vorticella digitalis*.
8. *Vorticella nebulifera*.

Genus Vorticella.

Plate 227. Lettered Vermes Cercaria, Plate III.
1. *Cercaria Lomn*, in the entirely expanded position it assumes when moving, and two others.
NATURAL HISTORY.

PLATE 226. Fig. 10. Cercaria lupus
Fig. 11. Cercaria podura

GENUS KOLODA.

Fig. 12. Kolođa pyrum

GENUS PARAMECIIUM.

Fig. 13. Paramecium ossiferum
14. Paramecium chrysophila
15. Paramecium marginatum

GENUS VIBRIO.

Fig. 16. Vibrio, anguillula
17. Vibrio glutinis, the smaller figures denote the natural size
18, 19. Vibrio anser, in two positions
19. Vibrio olor
20. Vibrio lanula
21. Vibrio pasifera, variously connected

GENUS LEUCOPHRA.

Fig. 22. Leucophra cornuta

GENUS ENCHELIS.

Fig. 23. Enchelis puntilfera
24, 25. Enchelis rétigrada, two figures
25. Enchelis trunca
26. Enchelis caudata

GENUS VOLVOX.

Fig. 27. Volvox globator

Obj. All the Vermes infusoria are microscopic objects

Addenda to the Zoology.

PLATE 227. Fig. 14. a.a.a. The three masses of luminous substance, which are applied to the three last rings of the abdomen
b.b.b. The arrangement of the cellular or interstitial substance on the other abdominal rings, which give the pale color to the whole belly of the insect
15. Diffusion of the common Glow-Worm, exposing the faces of luminous matter in situ, on the last ring of the belly. a. The face on one side
16. One of the faces of the Glow-Worm taken out and very highly magnified. a. The external part of the face, composed of an interweaving of a spiral fibre. b. The luminous substance seen at one end
17. Elater noctilucus, with a portion of the shell of the thorax removed to uncover one of the organs of light, of which there are two, one being situated on each side, at the posterior part of the thorax. a. The yellow transparent spot of the thorax. b. The oval mass of luminous substance surrounded by an irradiation of the interstitial substance. c. The ends of the muscles which are on the inside of the thorax
18. The luminous apparatus of the elater noctilucus, considerably magnified. a. The radiated appearance of the interstitial substance around the oval mass of luminous substance. b. The arrangement of that substance when it passes down between the muscles. c. The ends of the muscles of the back. d. The shell of the thorax
19. Elater ignitus. a. The yellow part of the thorax. b. The small mass of luminous substance, seen on removal of the shell of the thorax

Obj. The preceding objects were those appointed by Dr. Macartney for the explanation of his article on Luminous Animals, which will be found placed under the leading article, LIGHT.

In addition to those, we have, ourselves, conceived the propriety of introducing another figure of the Nereis genus, that of Vianelli being, confessedly, very doubtful. This animal is, therefore, not merely introduced by us as a species highly phosphorescent, under certain circumstances, in common with most others of its tribe, but in order likewise to convey a more accurate idea of the Nereis genus, than the figure copied from Vianelli will afford. The species we have introduced, is the Nereis cartula of some authors, aqua marina; and is, beyond any doubt, a genuine Nereis of the Linnaean System.

The figure by Vianelli, is contained in a small tract written in the Italian language, entitled "Nuove scoperte intorno la lu
ci notturne dell' acqua marina" and which, besides being more evidently depicted from a very mutilated object, is entirely different from that included in the third volume of Amalhitates Academice, which Linnaeus himself gave very shortly afterwards as the same animal; and even this latter, like that of Vianelli, if we mistake not, must have been delineated likewise from
NATURAL HISTORY.

Illustration of the Twenty-four Linnaean Clases, according to the Number of the Stamens.

228. Lettered Botany, Plate II.

Fig. 1. Clas 1. Monandria, one flamen, as in Salicornia, Callitrichis, &c.
2. Didynamia, two flaments, as in Veronica, &c.
3. Triandria, three flaments, as in Hordeum, Agrostis, &c.
4. Tetraandria, four flaments, as in Ilex, &c.
5. Pentandria, five flaments, as in Borago, Primula, &c.
6. Hexandria, six flaments, as in Allium, Erigeron anisii, &c.
7. Heptandria, seven flaments. Trientalis, Dianthus, Resedula, Petrosaurus, Pancropa, and Jonesia are of this class.
8. Octandria, eight flaments, as in Epilobium, Oenothera, &c.
9. Enneandria, nine flaments, as in Butomus.
10. Decandria, ten flaments, as in Sedum.
11. Dodecandria, twelve flaments, as in Sempervivum; above twelve, and less than twenty flaments, as in some other genera
12. Icosandria, twenty or more flaments, as in Matthiola, Pyrus, and some other fruit-bearing plants, including Fragaria, Ribes, &c.

Plate 228. Fig. 14. Clas 14. Didynamia, flaments two long, two shorter, as in Lamiun, or dead-nettle, &c.
15. Tetradynamia, flaments four long and two shorter, as in Chenopodium, or chenopodiaceous plants, &c.
16. Monadelphia, flaments united by their filaments into a kind of tube, as in Malva.
17. Diadelphia, flaments united into two distinct parcels or sets, as in Pijum, Lathyrus, Eruca, &c.
18. Polyadelphia, flaments united into more than two distinct parcels or sets, as in Hypericum (St. John's wort).
19. Syngenia, anthers united into a cylinder, flowers compound, as in Leontodon (dandelion), &c.
20. Gynandria, flaments united with or growing out of the petals, as in Orchis (bee-flower).
21. Monoeia, flaments and pistils in separate flowers on the same plant, as in Zinnia, Belladonna, &c.
22. Dioecia, male and female flowers on different plants, as in Salix, the willow.
23. Polygamy, male or female flowers, or both, with hermaphroditic flowers on the same or on different plants, as in Valantia, Brabeium, Parietaria, &c.
24. Cryptogamia, fructification concealed, or not distinctly ascertained.

Illustration of the Linnaean Orders of Botany, as established upon the Number of the Pods.

230. Lettered Botany, Orders, Plate IV.

Fig. 1. Monogynia, one style or pistil (with five flaments), as in a mallow extensive number of plants, among which are Heliotropium, Anchusa, Borago, &c.
2. Digynia, two styles (with ten flaments), as in Chrysophyllum, Metella, Sedanthus.
3. Trigynia, three styles (with ten flaments), as in Silene, Stellaria, &c.
4. Tetragynia, four styles, with four flaments, as in Rupia, Potamogeton, Sagina, &c.; with five flaments, as Parmassia, &c.; with six flaments, as in Petunia.
5. Pentagynia, five styles (with ten flaments), as in Oxalis, Suriana, Lycopus, &c.
6. Hexagynia, six styles, as in Butomus.
7. Heptagynia, seven styles (with seven flaments), as in Sepsis.
8. Octagynia, eight styles (with eight flaments), as in Neurada and Phytolaccæ.
9. Dodecagynia, twelve styles (with twelve flaments), as in Sempervivum.
10. Polygynia, many styles, as in the 2d, 3d, and 4th order of Clas Syngenia.
11. Gymnoferma, naked seeds, as in Ajuga, Tricium, Satureja, &c.

Plate 229. Fig. 14. Clas 14. Didynamia, flaments two long, two shorter, as in Lamiun, or dead-nettle, &c.
NATURAL HISTORY.

Plate 250. Fig. 12. Angiofermis, feeds inclosed in a pericarpium or seed-vessel, as in many genera, *Anterribinum, Cybaria, &c.*

231. Lettered Botany, Orders, Plate V.

Fig. 13. Silicula, pericarpium a silicula, as in Thalospi (Shepherd's pursle), *Dryob.* &c.

14. SiliquoJa, pericarpium a silicula, as in Raphanus, *Sinapis, Brafica, &c.*

15. Polygamy Aequalis, flowers compound, all the florets hermaphrodite, as in Leontodon, *Hieracium,* &c.

16. Polygamy Superflua, florets of the disk hermaphrodite, those of the radius female, as in *Bells* (garden daily), *Tusslago, Senecio,* &c.

17. Polygamy Necessaria, flowers or florets of the disk male, those of the radius female, as in *Calendula, Chrysogonum.*

18. Polygamy Frugifera, florets of the disk hermaphrodite, those of the radius neuter, as in *Centauris, Sclerocarpus, Radbeckia.*

19. Polygamy Segregata, many partial cups contained in the common calyx, which separate and surround the floccula, as in *Echinops, Gundelia, Spharanthus,* &c.

20. Trinseia, have the polygamy or parts of fructification on three different plants, as in *Ficus, and allo Ceratonia.*

21. Felices, fructification doriforous (on the back of the leaf), as in *Alphitium, Adiantum, Trichomanes,* &c.

22. Mufci, anthers without filaments; female flowers distinct and without pistillum: seeds a naked corculum without cotyledon or tunic. With or without a calyptra or veil, as in *Brynum, Hypnum, Buxbaumia,* &c.

Obs. To the order Mufci, Gmelin and other botanists add the following (Hepatica), comprehending *Marchantia,* as the last genus of Mufci after Jungermania. Linnaeus had left it with Algae.

23. Hepatica, herbage frondoso in general, the fructification originating from what is at the same time both stem and leaf, as in *Marchantia, Jungermania,* &c.

24. Alga, root, stem, and leaf, in one, as *Ficus, Ulva, Lichen,* &c.

25. Fungi, mushrooms, as in *Agaricus, Boletus,* &c.

CLASS CRYPTOGRAMIA.

Addenda to the Mufci, in Illustration of the Fringes of Mufci.

* Furnished with single Fringes.

232. Lettered Botany, Plate Fringes of Mosses.

Fig. 1. Tetraphis. Fringe of four teeth, as in *Minium pelliculoid.* These are erect, acute, firm, polished, and permanent.

2. Olotopharum. Fringe of eight teeth, as in *Brynum albidum.* Capule without an apophysis.

3. Splachnum. Fringe of 16 teeth, dilated at the base, approaching each other in pairs.

PLATE

232. Fig. 4. Encalypta. Fringe of 16 linear upright teeth. Veil ample and bell-shaped.

7. Conoformum. Fringe of 16 tapering teeth, approaching each other in pairs, and all cohering at the points, as in *Brynum teragonum, Dickson, Grimmia conoformis, Smith Engl. Botany.*

8. Dicranum. Fringe of 16 flat, somewhat inflexed teeth, cloven half-way down.

9. Trichogonium. Fringe of 32 linear straight teeth, approaching each other in pairs, sometimes joined at the base in pairs.

11. Syntrella. In some species of *Tortula* the teeth are united into a cylinder at the base, pierced with numerous holes, upon which some recent botanists have founded this new genus.

* The following Genera are furnished with a double Fringe, some few Species of Orthotrichum and one of the Buxbaumia perhaps excepted.

Fig. 12. Orthotrichum. Capule terminal. Outer fringe of 16 teeth; inner of 8 or 16 linear ones, sometimes altogether deficient. Veil furrowed.

Obs. The fringe is sometimes variable. *Orthotrichum pulmonum* has but eight teeth in the outer fringe.

Obs. In *Buxbaumia foliosa* the outer fringe is scarcely perceptible; it is represented at fig. 16.

22. Polytrichum. Outer fringe of 32 or 64 flat inflexed teeth; inner, a transverse orbicu-
NATURAL HISTORY.

Plate lar membrane, affixed to the teeth of the outer. Veil mostly double; the outer hairy

Vide article Fringe of Moses, by Sir J. E. Smith.

CLASS CRYPTOAGAMIA.

Addenda in Illustration of the Genera of Fungi.

233. Lettered Botany, Fungi, Plate I.

Fig. 1. Genus Agaricus

234. Lettered Botany, Fungi, Plate II.

Fig. 1. Genus Merulius (eburneus)

235. Lettered Botany, Fungi, Plate I.

Fig. 2. Genus Boletus

3. Hydnium

4. Clavaeria

5. Phallus

6. Glabratus

7. Helvella

8. Peziza

22. *Papilionaceus,* as in *Pium, Colutta,* &c.

Offs. The importance of the System of Tournefort, the outline of whose classification is here laid down, will be best understood by those who are aware of the attachment of the French botanists, even of the latter times, to the method of this early author: a botanist, whose labours preceded those of Linnaeus by nearly half a century.—It has been truly observed, that Tournefort is to the French in the science of botany, the foundation-stone upon which all their systems are established. This predilection in favour of their own systems, to the exclusion of that the Swedish naturalist founded upon the sexual organs of plants, may yet have its revolution; but that in the present time is more than can be well expected. As the botanical department of this Cyclopaedia has been almost from the commencement allotted to one of the most able professors in the science, it is very far from the intention of the writer of the present article to enter into the comparative merits of the prevailing systems of this time, the Linnaean in Britain, under the auspices of its many learned advocates, and that of the French, founded on a "natural method," not very dissimilar from that of Tournefort, and as improved by Jussieu and Gartner. We only wish to offer some apology for the greater number of plates devoted to the system of the celebrated Corollifer M. Tournefort than to the sexual system of Linnaeus; the latter being a naturalist whom from adoption we may almost deem our own, and we must confes with all his imperfections our most favourite author.

The great talents of one of our ablest and most experienced botanists at this period, we are well aware have been directed to the advancement of a "natural method*;" perhaps even we might be almost justified in terming him one of the great supporters of this method, not in this country alone but throughout Europe: while the labours of Jussieu, Jaume St. Hilairre, and others, have gone far towards the formation of a method constructed upon the natural affinities of plants, and on their fruits and seeds especially; characters which, with the corolla, calyx, and other organs of the flower considered generally, it will be perceived had formed the basis of that system which was laid down by Tournefort.

After what we have advanced upon this interesting subject, it might have been thought advisable to appropriate other plates to the elucidation of what is underfoot by a natural method; but that, alas! would be impossible. Much remains undone, and it is only by a very long and arduous course of research and investigation that any system of material extent founded on that method is to be expected. "Hitherto," says M. de Candolle, one of his most popular promoters, "we have arrived only at the basis of this system, and not at the result: it exists rather in the conversations of botanists than in their books, and remains yet among the number of those opinions which Bacon calls floating." *Vide De Candolle de Taxonomie.*

Under these circumstances, the plates appropriated to the illustration of Tournefort’s arrangement of Botany will not be thought devoid of interest, and may be indeed considered of material use to the early botanist as well as general reader, in unison with those intended for the illustration of the classes and orders of Botany as laid down and established by the great Linnaeus.

VEGETABLE ANATOMY.

244. Lettered Vegetable Anatomy, Plate I.
Fig. 1—8. Dissections of the cortex or bark of various plants, of the natural size and magnified, designd to shew the structure of the layers of which they are composed, &c.

245. Lettered Vegetable Anatomy, Plate II.

Dissections explanatory of the disposition of the layers which appear internally in the stems or branches: fig. 1, 2, 3, horizontal sections; fig. 4, 5, perpendicular sections; fig. 6, 7, 8, shew the longitudinal disposition of the vessels upon stripping off the outer bark or cortex.

Fig. 9—13. Various appearances and dissections of the buds of plants. Fig. 14—17, of the flower, &c.

19. A bulbous root, shewing the exterior imbrications.
18. A horizontal section of a bulbous root, shew.

* Robert Brown, Esq., who, without rejecting the sexual organs as useful auxiliaries, regards more particularly the germination of plants, with the number and form of the Cotyledons, as essentially characteristic in a system founded on a natural classification.
NATURAL HISTORY.

Plate 245. Fig. 20. Perpendicular section of a bulbous root

MINERALOGY.

246. Inscribed Natural History, Plate I.

View of Mount Etna, from Spallanzan's Work.

This is a general view of Mount Etna, the adjacent country and the sea; and is intended to show the effects occasioned by the eruption of the volcanic matter at different times. A points out the loftiest summit of the Mount. H is Nicolosi, and marks the Mount Rosso or Red Mountain, formerly a plain, but in 1699, a new vertex opened in it, and discharged the dreadful torrents of lava which overflowed the land, till reaching the sea, it formed the promontory of lava in the sea extending as far as letter Y. G, near this new opening of Etna, is the mountain Mont Pelieri or Montpeleri.

Various other interesting spots are marked in the plate, for which consult the article Etna, Mount.

246. Inscribed Natural History, Plate II.

A View of the Crater of Mount Etna.

A A A One edge of the lava of 1797, which issued from the upper crater. B B the circumference of the crater, with its cleft C C through which the internal part is discernible. D the flat bottom of the crater. E the aperture in the bottom through which the larger column of smoke F F arose. G G is part of the edge of the crater from which its internal part is best seen. H H is the smaller column of smoke to the north-east. Vide article Mount Etna for further explanation.

247. Inscribed Natural History, Plate V.

View of Mount Vesuvius, as seen from the Bay of Naples. From an original sketch made in the year 1797, by R. Dupper, Esq.

248. Inscribed Natural History, Plate IV.

View of the Crater of Mount Vesuvius. Drawn by the same hand, and at the same time as the preceding.

MINERALOGY, Plate II.

Basalt. The Mountain of Aifa, called La Coupe, or the Col d'Aifa, near the village Entrague, in the Viverrais, above the torrent of Volant.

This plate affords an example of the formation of basaltic columns, and illustrates the hypothesis of the Huttonian system, according to which the basaltic matter has been originally of volcanic origin, and while in a state of fusible cast out of the crater of the mountain. In its progress this lava has formed a wavy channel down the mountain side. According to St. Fond, this is the most remarkable and best characterized crater in all the Viverrais. The ends of the columns may be distinctly seen before the basalt reaches the river.

GEOLGY.

250. Geology, Plate I.

Fig. 1. The upper figure in this Plate exhibits the dip, dyke, fault, fissure, trap, trouble, &c. described and referred to in the article Coal.

251. Geology, Plate II.

Fig. 1—10. Sections of various Strata.

252. Geology, Plate III.

Fig. 1. Strata: being a sketch of the arrangement of the strata through England, by Mr. R. Bakewell. Lat. 54° 35' to 54° 45'.

2. Section of the strata through part of Dorsetshire and Devonshire, by Mr. R. Bakewell.

3. Perpendicular strata.

4. Horizontal strata.

5. Inclined strata, consisting of greywacke, clay-flate, compact felspar, porphyry, felsite, trap, chink-flate and granite, valley of Long Sleddale, Wearmoreland.

6. Undulate strata: shewing the wavy structure of the beds of slate, called fillet, in Devonshire.

253. Geology, Plate IV.

Fig. 1. Metallic veins exemplified, with a "rider," &c., and also the interfection (or "cutting-off") of metallic veins.

2. Columnar and amorphous basalt, intersested by basaltic dykes.

3. Lime-flate broken and inclosed in basalt, seen in a basaltic rock on the coast of Antrim, Whinflete dykes, or basaltic veins, passing through chalk, and changing it into marble—under figure 4.

(See article Geology. Suppl. Vol. XXXIX.)

Addenda to the Geological Illustrations.

254. Plate Ichthyolite, or Ichthyological Remains.

Mineralized remains, or impressions of fishes, on black shilte stone, found at liebein, in Germany.

255. Fossils, Extraneous, Plate I.

Fig. 1. Mineralized remains of an encrinus, Encrinus liliiformis, or "stone lily," in relievo, on a flab of Stone.

2. Tranverse section of the lily-head.

3. The lily-head half broken through tranversely.

4. Bottom of the lily-head, shewing the pedestal on which it is connected to the main stem of the encrinus.

CRYSTALLOGRAPHY.

256. Lettered Crystallography, Plate I.

Fig. 1—7. Various forms of the crystals of adamantine spar.

262. Lettered Crystalization, Plate VII.

Fig. 27. The Octahedron, regularly formed.

NATURAL HISTORY.

Plate 257. Crystallography, Plate II.
Fig. 17-21. Mechanical division of an hexahedral crystal of calcareous spar, and extraction of the primitive crystal, or nucleus

Ob. Lettered fig. 17-21. Plate II. Crystallography. Described in article Crystal, Vol. 1. Part II. but erroneously referred to as fig. 1-5; Plate I.

22, 23. Mechanical division of the dog's-tooth spar, erroneously fig. 6, 7. Plate I.

Fig. 24. Rhomboids of calcareous spar, a secondary crystal, with the primitive nucleus

Plate 258. Crystallography, Plate III.
Fig. 31. The cubic nucleus of this variety is shown in the regular octahedron formed on a cube

32. The formation of the crystal by decrements

33. Decrement of the dog's-tooth spar, (the metastatic crystal of Haüy,) represented complete in Plate 257, fig. 22.

34. A secondary crystal, which is a rhomboid much more obtuse than the nucleus, is represented as surrounding the nucleus in the variety of calcareous spar, called by Haüy, squaico

The nucleus (presumed to be the primitive rhomb of carbonate of lime) progressively divided to explain its structure

The face at letter A, fig. 35, shows the same face of the rhomb as is represented in fig. 34, but symmetrically divided, and the figure shows the gradual division of the rhomb, by mechanical separation down to letter d.

Plate 259. Crystallography, Plate IV.
Fig. 36. Decrement on the angles of a crystal, shown in the regular octahedron formed on a cube

Plate 259. Crystallography, Plate IV.
Fig. 37. The arrangement of the integrant molecules on one of the triangular faces of the octahedron

Plate 258. Crystallography, Plate IV.
Fig. 38. Rhomboid crystal

39. Another example of the decrements on the angles, exemplified in the division of the rhomboid, fig. 38, which differs somewhat from that of the cube, producing a very obtuse rhomboid, encircling the nucleus; found among the secondary crystals of oligite iron ore

Further illustration of the different variations, of which the decrements of the rhomboid, both of the superior and inferior angles, are susceptible. The rhomboid is shown at fig. 47; the decrements at fig. 46, 47.

Intermediate Decrements.

Plate 259. Crystallography, Plate III.
Fig. 39. A parallelepiped undergoing a decrement, by two ranges on the angle of its base

49. A crystal, in which all the three decrements round the same solid angle are intermediate

50. Another example of intermediate decrement in one of the faces of a cubic nucleus, taking place on the angles, by the subtractions of double molecules

51. The cubic nucleus, marking the decrements parallel to the lines k, m, &c. by subtrac-
tion of double molecules, in such a manner as that three ranges be taken away in the breadth, and one in height; so that the decrements will be both intermediate and mixed

52. A polyhedral crystal of thirty faces, produced by the effusion of decrementation, before the formation of the pyramid round each face of the nucleus

53. Example of intermediate decrements on the two lateral angles of a rhomboid, (as at fig. 47.), the decrements taking place by ranges of double molecules, producing in the complete result a solid of twelve faces, disposed fix and fix towards each summit, as in one variety of calcareous sparr, or double-pointed dog's-tooth spar

Compound secondary Forms of Crystals.

Fig. 54. A secondary crystal, an icosehedron bounded by eight equilateral triangles, and twelve ifosecles triangles. Occurs in iron pyrites

55. A calcareous sparr (Analogique of Hauy), composed of twenty-four trapezoidal faces, fix of which are vertical, and twelve others disposed fix and fix. The different trapezoidal faces are shown in the figure

260. Crystallography, Plate V.

Fig. 56. The end of the regular fix-sided prism, which, for its molecule, presents us with the triangular, or three-sided prism

57. A cubic nucleus divided into its cubic molecules

59. Superior face of the second lamina, A

Ditto, further mechanical division of the integrant molecules, B

Ditto, ditto, C

58. Explanation of vacuities on the edges of a crystal, given by Hauy

60. An oblique prism with rhomboidal bases, situated that the faces A D, a d, and C D, e d, are vertical; and B D are the acute angles of the base, and that the latter proceed in an ascending direction from A to C

Intersect this prism into halves, by means of a plane passing by the diagonals, drawn from B to D, and from b to d, so that the half situated on the left remaining fixed, the other is reversed without being separated, and the figure prefixed will be as shown at fig. 61.

62. Another example of grouping, in which crystals are inserted into each other, is extremely common. This combination is illustrated by a cube, and MNr, an equilateral triangular facet, produced by a decrement of one range round the angle A

63. A second cube modified in the same manner, and affixed to the other by its correspondent facet, will afford the double crystal represented

Plate 259.

10. Pentagonal Dodecahedron

11. Lens

12. Rhomboidal Dodecahedron

13. Tetrahedron

14. Double fix-sided Pyramid
The primitive Forms of Crystals are,

Fig. 1. The Cube
2. Rhomb
7. 8. Rectangular Table
27. Octahedron
13. Tetrahedron
5. Hexagonal Prism
12. Rhomboidal Dodecahedron
14. Dodecahedron with triangular faces

The integral Molecules are,

Fig. 13. The Tetrahedron
29. Trihedron
1. Cube

Instruments employed in the Study of Crystallography and Mineralogy.

261. Fig. 91. Nicholson's instrument for determining the weight or specific gravity of solid bodies
92. B. An instrument for determining the electricity of minerals
92. A. An instrument for determining the electricity of the tourmaline
93. Goniometer for measuring the angles of crystals

(Vide Mineralogy, Appendix, Vol. XXXIX. —Vide also article Crystal, Vol. X.; and Crystallization, Supplemental Vol.)

Appendix to Geology, Mineralogy, Mining, &c.

263. Plate Mineralogy, Mining.

Fig. 1—10. Mining—construction of the shaft or passage leading to mines, mode of deflecting, manner of closing or stopping the same, &c.

253. Represented on Plate IV. Geology.

Fig. 6. Plan of a Coal Mine, and mode of ventilating

250. Mining Lamps, Plate I. Geology.

Fig. 5, 6. Sir Humphrey Davy's Wire Gauze

ERRATA

ON THE

PLATES OF NATURAL HISTORY.

Some few errors having been committed by the writing engravers in lettering the names upon the plates of Natural History, which it will be very desirable to correct, the reader is requested to observe, that wherever the names upon the plates are found at variance with those inferred in this printed index, the preference is to be invariably given to the latter; and that the names upon the plates may be corrected by a reference to this index.

The following errors occur to us in passing over the plates for the purpose of compiling the present classification.

QUADRUPEDS.

46. For Ramphastos Aracani, read R. Aracari
G. Crotophagi, r. G. Crotophaga
52. Merops Novæ Zelandiae, r. Novæ Selandiae
26. Taguan Squirrel, r. Taquan S.
29. Molpymæns, r. Mos pygmeus
31. Antelope Grimmia, r. Ant. Grimmia

BIRDS.

54. Aran Olot, r. A. Olor
56. Aran Creca, r. A. Creca
57. Manderine Drake, r. Mandarin Dr.
58. Genus Apenotydes, r. G. Apenotyda
59. Gen. Diomedia, r. Diomedæ
D. Chiororynchos, r. Chlororhynchos

PLATE

Safety Lamp, as made by Mr. Newman, Little Street, Leicester Square (See Wire Gauze)

250. Fig. 23. Dr. Clanny's Safety Lamps
4. Steam Safety Lamp

[* By attending to the above classification, the whole of those Plates of Natural History, which the proprietors have allotted to this Cyclopaedia, may be readily reduced to numerical order, and be by that means, it is presumed, more easily distinguished when required for reference than by the original plan, in which the plates of each section were lettered separately from the rest. They now follow each other, not only in numerical order throughout their whole extent, but also in the order of the Linnean System, as nearly as the number of plates appropriated to the respective Sciences would conveniently allow. The miscellaneous nature of some few plates, which it has been lately thought desirable by the proprietors to introduce, renders it impossible to place them strictly in the order of system.*]
NATURAL HISTORY.

Plate 61. For Gen. Laurus, read Gen. Larus
62. G. Phoenicopterus, r. Phoenicopterus
63. Charad. africarius, r. C. africarius
68. Pulke porphyrio, r. F. porphyrio
71. Genus Dodo (Latin name), r. G. Didus
72. Meleagris gallipavo, r. M. Gallopavo
73. Tetrao ferrugineus, r. T. ferrugineus
79. Columba Cristo, r. C. Cristo
87. Charad. africarius, r. A. Pompadora
88. R. headed Swallow, r. Rufous-headed Swallow
Acculeated Swallow, r. Aculeated Swallow

Reptiles.
101. For Anguis Coraline, read A. Corallinus
A. Jamaicens, r. A. Jamaicens
102. Amphibana fulginosa, r. A. fulginosa
103. Snowted Langay, r. Snouted L.

Fishes.
105. For Genus Stromateus, read Gen. Stromateus
Sternoptyx diaphana, r. Sternoptyx diaphana
Genus Anarhicas, r. Gen. Anarhicas
112. Sparus Surinamensis, r. S. Surinamensis
Sparus falcatus, r. S. falcatus
116. G. Scomber Mackarel, r. G. S. Mackarel
117. Ditto r. Ditto
119. Platystichus angularis, r. Platystichus angularis
120. Salmo bimaculatus, r. S. bimaculatus
S. Gaferopelecus, r. S. Gaferopelecus
121. Filitaria tabaccaria, r. F. tabaccaria
122. Genus Atherine (Latin name), r. G. Atherina
123. Clupea Trilla, r. C. Thrilla
C. Phoxinus Minnew, r. C. P. Minnow

Plate
124. For Headlines for Order Branchyosteii, read Order Branchiopterygi
126. Pegusus draco, r. P. draco
129. Headlines for Order Chondropterygi, r. O. Chondropterygi

Insects.
136. For Bostrichus pubicens, read B. pubicens
Ptinus scotias, r. P. scotius
P. affilatus, r. P. affilatus
P. faccinicornis, r. P. faccinicornis
137. Anthrenus schrophulariae, r. A. schrophulariae
138. Caffida graffa, r. C. graffa
141. Paufus fichteli, r. P. Fichteli
160. S. gigas, r. Sirex gigas
S. juveneus, r. S. juveneus
S. lobata, r. Sphex lobata
163. No. 13. Tipula ichneumonea, r. Diopis ichneumonea
164. Rhagis scolopaceae, r. Rhagio scolopaceae
168. Headlines G. Trombidium, r. G. Trombidium
12 F. aquaticum, r. 12 Trombidium aquaticum
13 F. abfargens, r. 13 Trombidium abfargens

Worms.
178. For Headlines for Vermes, Order Intestata, read Order Intestina

Shells.
192. For Tellina fabulata, read Tellina fabula
Tellina bimaculata, r. T. bimaculata
202. Headlines for Conchology, Order Volutae, r. Conchology
Genus Buccinum — Genus Strombus
226. Paramecium, r. Paramecium
Rolipoda pyrum, r. Kolpoda pyrum
ANCIENT AND MODERN ATLAS.

PLATES. VOL. VI.

ANCIENT AND MODERN ATLAS.

Plate
I. Ancient Geography—Imperium Car. Mag. ad finem seculi post Christ. VIII.
A few copies, only, of this Map were published with the parts of the Encyclopaedia. The proprietors having afterwards determined to engrave the maps on a larger scale, it was cancelled, and a Map of the World, as known to the ancients, subjoined in its stead as the first of the Ancient Atlas.

GEOGRAPHIA ANTIQUA.

Tabula
I. Orbis Veteribus Cognitus
II. Populi, Urbis, &c. in Græcia, Thræia, et Asia, quarum meminit Homerus
III. Britannia Romana, cum Hibernia et insulis adjacentibus
IV. Peloponnesus, quæ ante Apia, Pelaçia, et Argos, ante eam Romæa ditionis fuit, &c.
V. Hellas, in Græcia Propria, Thessalia et Epîrus, ante eam Romæan ditionis fuerunt
VI. Macedonîa et Thracia, antequam Romæan ditionis fuerunt
VII. Asia Peninsularis, cum Insulis adjacentibus
VIII. Ægyptus, provincia Romana Imperialis
IX. Lybia, vel Africae, ora borealis
X. Italia Regio Alpina, quæ vulgo dicitur Gallia Cisalpina
XI. Italia Media, vel Italæ propria pars borealis, ante divisionem ab Augusto factam
XII. Italia Ulterior, cujus pars Australis Magna Græcia, ob Græcorum colonias, dicta, ante divisionem ab Augusto factam
XIII. Sicilia, provincia Romanorum, cum Insulis adjacentibus
XIV. Italia in regiones undecim ab Augusto descripta, cum Insulis Corfica et Sardinia

INDEX
INDEX OF THE PLATES.

Containing a List of all the Subjects represented on the Plates, arranged in alphabetical order, and classed under the several Sciences or Departments to which they pertain; together with References to the particular Plate and Figure where each Subject is delineated.

The Roman Numerals denote the Plate; the Arabic Numerals, the Figure.

Agriculture.

Feeding Houses for Cattle, iv. 3—6. v. 1—8.
Fences, xvii.—xxii.
Flax, Implements for dreffing, &c. xxiii.
Gates, hangings and fastenings, xxxiv. 1—36.
Granary, xxxiv. 1—5.
Grafs Farm-Buildings. See Farm.
Harrow, xxvii. 6.
Sod Cutting Plough, xxvii. 7.
Graffes, xxx.
Grazing. See Grafs.
Harrow, xxvii. 1—6.
Potatoe, xxxix. 2, 3.
Halfer caft, Spring Staple for haltering, xxxvii. 4.
Hay Crib, xxvii. 8.
Sweep, xxxviii. 5.
Kentish turn-writr Plough, xxxi. 4.
Kiln, xxxvi. 1.
Coppinger's, for Malt, xxxvi. 8.
Pepper's, for ditto, xxxvi. 4—7.
Mr. Rawfon's, xxxvi. 2.
Count Rumford's, for Lime, xxxvi. 1.
for general ufe, xxxvi. 5.
Laftometer, xxxvii. 6.
Levellng Land, Mr. Charles's Machine for, xxvi. 1, 2.
Lime Kiln, xxxvi. 1.
Stone Pounding Machine, xxxvii. 7.
Malt Kiln, xxxvi. 4—8.
Mines, draining, xxxviii.
Mole catching, xxviii. xxix.
Ploughs, xxix. 1—3.
Norfolk Plough, xxxi. 3.
Ox-hoeing Machine, xxxvii. 8.
Paring Ploughs and Tools, xxxii. 1—9.
Pepper's, Mr., Malt Kiln, xxxvi. 4—7.
Pig or Swine Cafe, xxxxi. 7, 8.
Piggery at Woburn, xi.
Pile, or rammed earth buildings, implements for, xxxviii.
1—17.
Pits, draining, xxxviii.
Plough for Grafs Sod cutting, xxvii. 7.
Ploughs, Mole, xxix. 1, 2.
Paring, xxxi. 1—4.
Swing, xxx. 1—6.
Wheel, xxx. 1—5.
Ponds, Construction of, xxxix. 1.
Machine for taking off the Surplus Water, xxxix. 6.
Potatoe Harrow, xxxix. 2, 3.
Scoops, xxxix. 4, 5.

Vol. XXXIX.
INDEX OF THE PLATES.

AGRICULTURE.
Quarries, Draining, xxxviii. 1—5.
Quendon Barrow, for carrying water, xxxviii. 6, 7.
Rawson's, Mr., Kilm, xxxvi. 2.
Rogers's, Mr., Bean Cultivator, x. 3.
Rotherham Plough, xxx. 1.
Rumford's, Count, Lime Kilm, xxxvi. 1.
Slark's Potato Set Scoop, xxxix. 5.
Small's Chain Plough, xxx. 2.
Somerville's, Lord, Plough, xxx. 3.
Double Furrow ditto, xxx. 6.
Stone Lifting Machine, xxxvi. 4.
Stones, Implements for Blasting, iii. 1.
Suffolk Iron Plough, xxx. 4.
Threshing Machines. See Barns.
Water, Machine for raising, xxxvi. 5.
by Sargeant, xxxvi. 6.
Western's, Mr. C., Double Cultivator, x. 4.

ALGEBRA.
Arithmetic, Palpable
Writing, Ditto.
Neper's Bones, MISCELLANY, i. 6.

ANALYSIS.
Circle of Circles, Magic, xi. 7.
Cissoid, i. 1.
Conchoid, i. 2—7.
Construction, i. 8—20. GEOMETRY, ix. 2.
Cotesian Theorem, ii. 21, 22.
Crown, ii. 23.
Cuneus, Parabolic, xiii. 5.
Curv, ii. 18. 24—26, iv. 1—16.
Harmonic, ix. 4. No. 2—8.
Logistic, xi. 4.
Caucal, ii. 24.
Diacaual, ii. 25.
Curvature, iii. 1—13.
Cycloid, v. 1—8. See also Plate CYCLOID.
Cylinder, ii. 3. 4.
Epicycloid, v. 9—11.
Evolute, vi. 1—10.
Fluxion, vii. 1—2.
Function, Analytic, vii. 5—8. GEOMETRY, ix. 3.
Geometry, Analytic, viii. 1—10.
Gyration, ix. 1—4. No. 1.
Harmonic Curve, ix. 4. No. 2—3.
Helicoid, x. 1.
Infeclion, x. 2—7.
Istopereytry, ix. 1—17.
Lemniscate, xi. 1.
Logarithmic, Atmospheric, xi. 2.
Curve, xi. 3.
Logistic Curve, xi. 4.
Spiral, xi. 5.
Magic Circle of Circles, xi. 7.
Square of Squares, xi. 6.
Locus, xii. 1—23.
Maxima and Minima, xiii. 1, 2.
Parabolic Cuneus, xiii. 3.
Parallelogram, Analytic, xiii. 4.
Progression, xiii. 5.
Quadratic Equation, xiii. 6.

ANALYSIS.
Quadratrix, xiii. 7—9.
Quadrature, xiii. 10—20.
Ratio, xiii. 21.
Rectification, xiv. 1—5.
Sections, following, xiv. 6.
Solidity, xiv. 7—10.
Square of Squares, Magic, xi. 6.
Subtangent, xiv. 11.
Supteriories, xiv. 12—15.
Tangent, xiv. 16—21.
Tangent, Geometry, ix. 14—19.
Variation, NAVIGATION, i. ii. 8, 9.

ANATOMY.
Cranium, xix. xx.
Ear, Anatomy of, v.—vii.
Eye, Anatomy of, i.—iv.
Myology, viii.—xvi.
Myology, xvii.—xiv.
Skeleton, xvii. xviii.
Vicera, xxi.—xxiv.

ANATOMY, COMPARATIVE.
Birds, i.—iii.
Horse, i.—iv.

ARCHITECTURE.
Abacus, xxi.
Amphitheatre, ii.—v.
Annulet, xxi.
Arch, vi. 1—7.
Oblique, xxxix.
of Adrian, ix. 1.
Conilantine, x. 1.
Severus, ix. 2.
Titus, x. 2, 3.
Altaral, xxi.
Attic Bafe, i. 1, 2.
Bafe, Attic, i. 1, 2.
Doric, i. 3.
Ionic, i. 4.
Basilic, xi.
Basilica, Roman, from Vitruvius, ii.
of St. Peter's, ancient and modern, xxv.
Baths of Caracalla, xxxvi. xxxvii.
Titus, painting from, xxxv.
Bead, xxi.
Bridge, Wooden, at Walton, xxxiv.
Bridges, xxxix.—xxxv. xxxvii. xxxvii.
Cantilever, xxi.
Capital, Doric, i. 5, 6.
Egyptian, xxvi.
Ionic, i. 7.
Capitals, Corinthian and Composite, xxvii.
Caracalla, Baths of, xxxvi. xxxvii.
Circus of, xxi.
Carpentry, xxi.—xxvii. xxxvii.—xxxvii.
Geometrical principles of, xxxvii—xxxvii.
Carrara, well door of the Cathedral of, xi.
Cavetto, xxi.
Centres, lxv.—lxvii.
INDEX OF THE PLATES.

ARCHITECTURE.

Chumney, viii. & xli.
Circus of Caracalla, xii.
Composite Capitals, xxvii.
Corinthian Doric, xxvii.
Order from the Temple of Jupiter Stator, in Rome, xxix.
Corona, xxi.
Cyma, xxi.
Cymatium, xxi.
Doors, xxiii. xxiv.
Doric Base, i. 3.
Capital, i. 5. 6.
Order, xviii. a.
from the Agora, at Athens, xviii. 5.
Parthenon, xiii.
a Temple at Selinus, xv. 5.
a Temple at Delos, xv. i.
Ægina, xv. 3.
the Temple of Philip, at Delos, xv. 2.
Jupiter, at Selinus, xv. 4.
according to Sir W. Chambers, xvi.
from the Temple of Jupiter Pannellenus, in
Ægina, xvii. 4.
from the Temple of Concord, at Agrigentum, xvii. 3.
from the Temple of Minerva, at Athens, xvii. 5.
from the Temple of Theseus, at Athens, xvii. 2.
from a Pseudo-dipteral Temple, at Peræum, xvii. 1.
from the Temple of Marcellus, at Rome, xviii. 1.
from an Hexastyle Temple, at Peræum, xvii. 2.
from the Temple of Jupiter Nemæus, near
Argos, xviii. 3.
from the Temple of Juno Lucina, at Agrigentum, xviii. 4.

Echinus, xxi.
Egyptian Capitals, xxvi.
Falcia, xxi.
Fillet, xxi.
Hindoo Temple in Bahar, xx.
Hollow, xxi.
Joinery, xxiii.—xxiv.
Ionic Base, i. 4.
Capital, i. 7.
Order, from the Temple of Minerva Polias, at
Priene, xxviii.
Latopolis, Portico at, xxx.
Liftel, xxi.
Modillion, xxi.
Mouldings, xxi.
Ogee, xxi.
Pandrofus, Temple of, at Athens, xix.
Pannel, xxi.
Portico at Latopolis, xxx.
Eastern of the Parthenon, at Athens, xxxi.
Roofs, xli.—xlvi. liii. lxxii.
Scotia, xxi.
Soffit, xxi.
Talon, xxi.
Titus, Baths of, xxxv.

ARCHITECTURE.

Torus, xxi.
Trochiæ, xxi.
Tuscan Order from the Church in Covent-Garden, xiv.

ARMOUR.

Bronzes, Ancient, i.—iii.
Carthaginian Armour, iii. 11—14. 16. 18. 19.
Croupière, or Buttolph Armour, v. 2.
Danish Armour, iv. 3—4.
Egyptian Armour, ii. 1—2.
Greek Armour, ii. 3—10. 14. 18.
Henry the Eighth’s Armour, v. 1.
Norman Armour, iv. 5.
Plate Armour of Sir Thomas Beauchamp, iv. 6.
Roman Armour, iii. 12. 15. 20.
Saxon Armour, iv. i. 2.
Sword, Bras, in the British Museum, iii. 11—19.
Tilting Armour of Robert Dudley, Earl of Leicester, v. 5.
Half Habit of Prince Henry, v. 4.

ARTILLERY.

Aries, or Battering Ram, i.
Catapulta, ii.
Carriages, i.—v.

ASTRONOMY.

Aberration, i. 1. 2.
Altitude, i. 5. 6.
Parallælax of, i. 8.
Refraction of, i. 7.
Anomaly, i. 9—10.
Arc, i. 11.
Area, i. 12.
Argument, i. 13.
Armillary Sphere, iii. 14.
Ascending Nodes, xxii. 4.
Ascension, iii. 15—17.
Axis, iii. 18. 19.
Azimuth, iii. 20. 21.
Chronology, iii. 22.
Comet, iv. 23.—36.
Comets, Parabolic Orbits of 72, xxxii.
Commumation, v. 37.
Configuration, xx. 4.
Copernican Sphere, xx. 7.
System, xx, 15.
Crepusculum, v. 38—42.
Culmination, i. 3, 4. v. 43.
Day, v. 43.
Declination, v. 44. 45.
Degree, vi.—viii.
Demarcus, v. 46.
Density, ix. 60.
Depression, ix. 61. 62.
Deviation, ix. 63.
Diameter, ix. 64—66.
Dichotomy, ix. 67.
Double Star, ix. 67.
Earth, ix. 68—70. x. 71.
Eclipfareon, Ferguson’s, x. 74.
Eclipse, x. 75—77. xi. 78—89. xii. i. 90—98.
Hindoo Computation, xii. 99.

INDEX OF THE PLATES.

ASTRONOMY.

Eclipse, Mr. Pond's Machine for, xii. 100.
Eclipsis, xii. 101-103.*
Egyptian Systen, xx. 16.
Elevation, xii. 102.
Elliptic, xii. 103.
Elongation, xii. 104.
Epicycle, xii. 105.
Equal Altitude, xii. 106.
Equation of the Center, xii. 107.*
Equator, xii. 109.*
Equinox, xii. 110.
Erection, xii. 109-109. (one figure)
Excentric, xii. 110-113.
Galaxy, xii. 114, 115.
Geocentric, xii. 116.
Globe, xiv. 117-121.
Ferguson's Celestial, xv. 122.
Planetary, xv. 123.
Gravitation, xv. 124-125.
Heat, xvi. 126.
Heliocentric Latitude, xvi. 129.
Hemisphere, xvi. 129.
Horizon, xvi. 129.
Horoscopical Quadrant, xix. 8.
Hour, xvi. 142.
Jupiter, xvi. 143-146.
Satellites of, xvi. 3.
Latitude, xvi. 147.
Heliocentric, xvi. 139.
Reduction, xvi. 148. xix. 10.
Longitude, xvi. 1.
Magnitudes, proportional, of the primary Planets, ii. 10.
of the Sun, as seen from ditto, ii. 11.
Mars, xvii. 2.
Meridian Line, xvii. 3, 4.
Moon, xvii. 5-15.
Moon's Parallax, xviii. 8-14.
Nodes, xviii. 2.
Orion, Constellation of, i.
Paracentric, xviii. 3.
Parallax, xviii. 4-7.
of Altitude, i. 8.
of the Moon, xviii. 8-14.
of Venus, xviii. 15.
Particular Exports, xix. 1.
Penumbra, xix. 2, 3.
Planet, xix. 3.*-6.
Precession of the Equinoxes, xix. 7.
Prothaphelian, xix. 7.*
Ptolemaic Armillary Sphere, xx. 6.
Pythagorean System, xx. 15.
Quadrant of Altitude, xiv. 120. xix. 9.
Quadrant, Horoscopical, xix. 8.
Reduction, Latitude, xvi. 148. xix. 10.
Refraction, xix. 11.
of Altitude, i. 7.
Retrogradation of Planets, xix. 12.
the Sun, xix. 13.
Saturn's Ring, xix. 14-16.
Solar System, ii.
Sphere, Armillary, iii. 14.

ASTRONOMY.

Sphere, Copernican, xx. 7.
Ptolemaic Armillary, xx. 6.
Systen, Copernican, xx. 15.
Egyptian, xii. 16.
Ptolemaic, xii. 14.
Pythagorean, xx. 15.
Solar, ii. & xxi. 1-4.
Tychonic, xx. 17.
Times of the Planets, xxi. 2.
Trigon, xxi. 5-7.
Tropics, xvi. 140.
Tychonic System, xx. 17.
Velocities of the Planets, xxi. 4.
Venus, xxi. 8-11.
Parallax of, xvi. 15.
Ursa, Major and Minor, Constellation ii.
Whirling Table, xxi. 13-22.
Year, xxi. 12.

ASTRONOMICAL INSTRUMENTS.

Astrolabe, i. 1.
Back Staff, i. 2.
Bird's Quadrant, Graduation of, xviii. 2.
Bifecution of an Arc, xxi. 5.
Borda's Circle, ii. 4-9.
Repeating Circle, without reflection, vi.
Brewster's, Dr., Patent Telescope, xxx. 4.
Cavendish's, Mr., method of graduating Circles, xviii. 4.
Quinquagesimae, xviii. 5.
Chauhne's, due de, method of graduating Circles, xviii. 3.
Circle, Borda's, ii. 4-9.
Repeating, without reflection, vi.
Graduated, with 2 and 3 verniers, iv. 1-4.
Mayer's, ii. 1-3.
Mendoza's, iv. 5.
Ramden's, v.
Troughton's English Reflecting, iii. 1, 2.
Mural, x.
Portable, ix.
Repeating, without reflection, vii.
Wollaston's, viii.
Clavius's method of graduating a Circle, xxi. 1, 2.
Cole's Quadrant, xxiii. 2.
Mr., Equal Altitude, xvii. 3.
Crofts Staff, i. 3.

Ramden’s Astronomical Circle, v.

Portable Equatorial, xi. 2.
Equatorial Instrument, made by, Sir Geo.
Shuckburgh, xv.

Quadrant, xxiii. 5.
Refraction Apparatus, xii. 2.
Zenith Sector, xxxii. 2.

Rotative Roof, Pearson’s, xxii. 5, 6.
Smeaton’s, xxii. 1—4.

Short’s Portable Equatorial, xi. 1.
Siffon’s Equatorial Sector, xvii. 1—2.
Smeaton’s Equatorial Stand of a Telescope, xiii. 5.

Micrometer, xiii. 3.
Mr., Rotative Roof for an Observatory, xxii. 1—4.
Support for a Telescope, xxx. 8.
Star Dial, i. 6.

Graduation of Circles, xvi—xxi.

Telecope, Theory of, with respect to Aberrations, &c.

ASTRONOMICAL INSTRUMENTS.

Telecope, Dr. Herchel’s 40-feet Reflecting, xxxi.
Telecope, Reflecting, Theory of, xxvii.
 chiefly Reflecting, xxx.
Refraeting, Theory of, xxiv. xxv.
Troughton’s English Reflecting Circle, iii. 1, 2.
Mural, x.
Portable Circle, ix.
Repeating Circle, without reflection, vii. 1, 2.
Method of graduating a Circle, xix. xx.
Universal Equatorial Instrument, xiv.
Equatorial Instrument at Armagh, xvi.

Quadrant, xxi. 6.
Transit Instruments, xxxii.
Wollaston’s Circle, viii.
Zenith Micrometer, Dollond’s, xxxii. 3—6.
Sector, Graham’s, xxxiii. 1.
Ramden’s, xxxii. 2.

BASSO RELIEVO.

Altars, Pagan, iv. No. 1—5.
Carrara, Basso Relievo on a Capital in the Cathedral of,
iv. 1.
Hercules and Apollo contending for the Tripod, ii. 1.
Hindu Basso Relievo, i. 2.
Minerva subduing Hercules, ii. 2.
Sphinx, Egyptian Hieroglyphical, i. 1.
Xanthippos, Tombstone of, iii.
Zetlius, Antiope and Amphiion, Basso Relievo of, iv. 2.

BLEACHING.

Boiling Pan, &c. iv. 1—7.
Bucking, i. 1—3.
Drying, iii. 1—4.
Oxi-muriatic acid, i. 4.
Washing and Clearing, ii. 1—7.

BLOCK MACHINERY.

Boring Machine, iv. 1—4.
Cooking Engine, iii. 4—9.
Cornering Saw, iv. 5—9.
Crown Saw, ii. 1—3.
Dead Eyes, machine for making, vii. 6, 7.
Lathe, Face Turning, iii. 3—7.
Rivetting Hammer, iii. 13.
Sawing Machine, i. 1—4.
Scoring Machine, vii. 1—5.
Shaping Engine, vi. 1—5.

BOATS. See SHIPS.

CAMP.

Camaretation, v.—xxii.
Circumvallation, lines of, iv.
Encampment of a Park of Artillery, iii.
Roman Confular Camp, according to Polybius, i.
Roman Camp for Three Legions, and according to the
Hyginian system, ii.

CANALS.

Aqueduct Bridge at Kelvin, ii. 19—21.
INDEX OF THE PLATES.

CANALS.
Aqueduct, Cast Iron, Fulton's, iii. 23, 24.
Mr. Telford's, on the Shrewsbury Canal, iii. 22.
Barrow, vii. 48.
Bridges, vii. 7.
Deep Cutting, i. 6.
Embanking, i. 4, 5.
Embankment, iv. 25.
Grafting Tool, vii. 10.
Level Cutting, i. 1—3.
Lining, i. 15.
Locks, v. 36—39.
Navigator's Tools, vii. 48—52.
Pile Planks, iv. 30.
Puddling, i. 14.
Rail Ways, Iron, iv. 31—35.
Refewors, i. 16—18.
Safety Gate, iv. 26.
Scoop, vii. 52.
Shovel, vii. 51.
Swing Bridge, vii. 43—47.
Weirs, iv. 27—29.

CANDLE MAKING.
Apparatus for dipping Candles, 1.
Mould Candles, 4.
Candlesticks, 7—12.
Mould, 6.
Frame, 5.
Wick Broach, 2.
Cutter, 3.

CANNON.
Boring Cannon, Machinery for, ii. iii.
Cannon, whole length, i. 1.
Cafecible, i. 2.
Howitzers, i. 7, 10.
Mortar, i. 4, 11.
Land, i. 8.
Sea, i. 5, 6, 9.
Stone, i. 12.
Muzzle, i. 3.

CANTEENS.
Boring Machine, i. 7.
Bung Stave, i. 6.
Canteen, i. 1.
Center Bit, i. 8.
Cross Cutting Saw, i. 2, 3.
Punching the Hoops, ii. 18.
Rounding the ends of the Hoops, ii. 19.
Screw Hoop, ii. 11.
Shears, ii. 16, 17.
Slider, i. 9.
Tenenting or Rebating Saw, i. 4, 5.
Truís Hoop, ii. 12.
Turning the Chime, ii. 14.
Head, ii. 15.

CASTING.
Apparatus for Casting, 1.
Cog Wheel, method of casting, 7—10.
Lifting Screw, 5.
Loom Casting, moulds for, 11—13.

CASTING.
Open Sand Casting, 1, 2.
Ramming Tool, 4.
Sand Casting between flasks, 6.
Trowel, 3.

CHEMISTRY.
See also Furnace and Iron Manufacture.
Acid Holder, xvi. 3.
Adopter, xvi. 7.
Air Vault, xv. 1, 2.
Holder, xiv. 2.
Alcohol, iii. 10.
Alembic, iii. 10.—13.
Aludel, iii. 14.
Analysis of Organic Substances, Berzelium's Apparatus for, xxi. 4.
Antimony, iv. 15—26.
Furnaces for the reduction of, iv. 15—26.
Bell, xiv. 3.
Bended Tube, xvi. 6.
Berzelium's Apparatus for the Analysis of Organic Substances, xxi. 4.
Blast Furnace, i. vii.—x.
Works, xi. xiv.
Blowpipe, xi. 1—7.
double, xiv. 7.
Characters, Ancient Chemical, xi.
Crucible, xvi. 29, 30.
Stands, xvi. 31, 32.
Cupola Furnace, i. 1, 2.
Cupel, xvi. 33.
Dam Plate, xiii. 3.
Stone, xiii. 2.
Diffillation, vii. 1—4.
Evaporating Vessel, xvi. 23.
Eudiometer, Hope's, xxi. 1.
Pepys's improvement of Volta's, xxi. 2.
Volta's, xvi. 22.
Tubes, xvi. 18.
Furnace, Cupola, i. 1, 2.
for the reduction of Antimony, iv. 15—26.
Iron Smelting, ii. 6—9.
Blast, vii.—x.
Works, xi.—xiv.
Gas Bottle, xvi. 27.
Holder, xiv. 4.
Gaffes, Apparatus for the Absorption of, xvii. 9.
Gafometer, xiv. 1—4.
Simplified, xvii. 13, 14.
Pepys's, xvii. 15.
Glass Blower's Lamp, xiv. 5, 6.
Jar, xvi. 20.
Hamilton's Apparatus, xvi. 11.
Hope's Eudiometer, xxi. 1.
Hydraulic Bellows, xvi. 1.
Iron Retort, xvi. 35.
Iron Smelting Furnace, ii. 6—9.
Laboratory, xvi. 17.
Luflac and Thenard's Apparatus, xxi. 3.
Mattrafs, xvi. 24.
Mercurial Trough, xvi. 19.
Muffel, xvi. 28.
Nooth's Apparatus, xvi. 10, 12.
Pepys's Improvement of Volta's Eudiometer, xi. 5.
Pneumatic Trough, xvi. 16.
INDEX OF THE PLATES.

CHEMISTRY.
Proof Glasses, xvi. 25.
Pyroligneous Acid, Apparatus for the Distillation of, xx.
Receiver, xvi. 4, 5, 8.
Retort, xvi. 2.
Separatory Funnels, xvi. 34.
Shoe Lamp, xiv. 6.
Still, i. 1—5.
Supporter, xvi. 17.
Iron ring, xvi. 21.
Tymp Plate, xiii, xiv. 4.
Volta’s Eudiometer, xvi. 22.
Water Regulator of a Blast Furnace, xiii, xiv. 2.
Wollafton’s Scale of Chemical Equivalents, xxi. 5, 6.
Woulfe’s Apparatus, v. vi.

CLOUDS.
Cirro Cumulus, i. 4.
Cirro Stratus, i. 2, ii. 1, 2, 4.
Cirrus, i. 1, 3.
Cirro Cumulus, ii. 3.
Cumulo Stratus, i. 6, ii. 4.
Cumulus, v. vi.
Nimbus, i. 5.

CONICS.
Ambigental, i. 1.
Abciffe, i. 2.
Asymptote, i. 2, 3.
Geometry, ix. 4.
Axis.
Cone, i. 4-10.
Conic Sections, ii.—vii.
Harmonic Division of a Line, ii. 1.
Hyperbola, x. xi.
Parabola, xii.

COTTON MANUFACTURE.
Batilo Printing Machine, ii. 1—5.
Calico Printing, i. 1—6.
Carding, iv. 1—4.
Deviling, iii. 1—5.
Drawing Frame, i. 1—4.
Doubling Machine, xiii. 1, 2.
Mule Spinning, xi. 1—5.
Reeling, xii. 1, 2.
Roving Can Frame, vi.
Frame, (double Speeder) vii. viii.
Spinning Frame, Thrust, x. 1—3.
Water, ix. 1—6.
Strutt’s, Miers, Cotton Mills at Belper, xiv.
Twisting Machine, xiii. 3—4.
Winding drawing Cotton into Balls, Machine for, xii.

CUTLERY.
Grinding Mill, Troughs of, i.
Pressing Vice, 3.
Spring Drill, 3.
Tongs for pressing Knife-handles.

CYCLOID.
Fig. 1—8.

See also Analysis, v. 1—8.

DIALLING.
Declinator, i. 1—3.
Dial, Cylindrical, iii. 27, 28.
East, ii. 16.
Equinoctial, i. 4.
Universal, i. 5.
Horizontal, i. 8—12.
Inclined, ii. 23.
Moon, iv. 25, 26.
Polar, ii. 17.
Portable, iii. 29, 30.
South, ii. 15.
Vertical Declining, ii. 21, 22.
North, i. 14.
South, i. 13.
Universal, i. 6.
on a Cross, iii. 31—33.
Mechanical, ii. 24.
on three Planes, ii. 19.
Primary, ii. 20.
Ring, iv. 34—37.
Tide, Miscellaneous, xxi. 10.
Dialling Cylinder, iv. 38—41.
Lines, iv. 42.
Dial constructed by a Globe, iv. 36, 37.
Scales, Dialling, iv. 42.

DOCKS.
East India.
Liverpool.
London.
West-India.

DRAWING.
Claud Lorraine, Engraving from an original Drawing by, x.
Hatching’s specimens of, i.—iii. 3—6.
Head, proportions of, i.—iii. 1, 2, 4, 5.
Landscape, viii.—x.
Outlines of the Human Face, i.—iii. 1, 2, 4—5.
Poullin, G., Engravings from original Drawings by, vii. ix.
Shadows, i.—iii. 3, 6.
Tinted Drawing, x.
Washed Ditto, x.

DRAWING INSTRUMENTS.
Camera Lucida, by Wellafton, i. 6.
Compasses, i. 1—3.
Beam, i. 3.
Compound proportional, i. 8, 9.
Elliptic, Plate Turning, fig. 20.
Hair, i. 6.
Pocket, i. 7.
Triangular, i. 1, 2.
method of adapting a quick and
flow motion to, i. 10, 11.
Delineator, Mifs Edgeworth’s, i. Delineators, 2, 3.
Peacock’s, i. 1.
Elliptograph, by Farcy, ii. 3.
Optigraph, Ramden’s, improved by Jones, i. Delineators, 4.
Oval, Instrument for Drawing, ii. 1, 2.
Protractor, reflecting, by Sir H. Douglas, i. 7.
INDEX OF THE PLATES.

ELECTRICITY.

Battery, Prieiely’s, i.
   Tyler's, i.
   Construction of the side connecting
   Frame, xv. 7.

Brush, xv. 6.

Condensers, ii. 4—9.

Configurations, vi.

Difchargers, iii. 10—20.

Doubler, Cavallo’s, iii. 21—25.

Electricity, Medical, x. 13, 14. xv. 1.

Electrometer, xii, xiii.

Electrophorus, xii, xiv. (xiv.) 1, 2.

Flyers, Electrical, vii. 51.

Inflammable Air Lamp, Volta’s, vii. 55.
   Piolti, vii. 53, 54.

Machine, Electrical
   Beccaria’s, ix. 10.
   Common, ix. 11.
   Cuthbertson’s, i. x. xi. (Numbered x.)
   Hawkbee’s, vii. 1, 2.
   Nairne’s, ix. 12.
   Nollet’s, vii. 3.
   Van Marum’s, ix. 18.
   Dr. Watson’s, vii. 4.
   Wilton’s, vii. 5.

Machines, various, viii.

Thunder-houfe, xv. 2, 3.

Tooth, Apparatus for electrifying, xv. 1.

Torpedo, xv. 4, 5.

ENGINE.

Cutter, Engine for sharpening, by Rehe, vi. 1—6.

Cutting Engine, by Hindley, ii. i—5. iii. 1—5.
   Rehe, iv.

Dividing Engine, by Ramfden, vii—xi.
   for straight Lines, xii.

Screw of Ramfden’s circular dividing Engine, for cutting, x.

Screw of Ramfden’s straight Line dividing Engine, for cutting, xi.

Weighing Engine, by Salmon, i. (Numbered Plate II.)

ENGRAVINGS—Early Britifh.

Alfred’s Jewel, Engraving from
   Anfelm’s Seal, Engraving from
   Fulbourn, William de, Engraved Brass on the Tomb of

FARRIERY.

Horfe Shoes, various

FORTIFICATION.

Angle at the Center, i. & C
   Baflion, i. 1, v. o, p. v. A, B
   Battery, ii. 1, 2, v. No. 3, v. M.

INDEX OF THE PLATES.

MUSIC.

Baßoon, Scale of, xxxii.
Chords used in Thorough Base, Synopsis of, xxx.
Canon in Ogni Modo, xlviij.
Counterpoint, vi.—xx.
Double, xvii.
Expression, Marks of, ii.*
Euclids Scctio Canonis, xlvi.
Fingerings on Keyed Instruments, xxvii.—xxx.
Graves and Marks of Expression, ii.*
Keys, arrangement of a Set of, on Keyed Instruments, i.
Modulation, xx.—xxiv.
Kirnberger's examples of, xxxiii.
RoufTear's xviii.
Sirius.
MUSICAL INSTRUMENTS.

(See also Miscellany.)

Æolian Harp, Miscellany, xxv. 1.
Barbiton, Greek, ii. 1.
Batalina, Guitar with two strings, ix.
Beau, an Indian Musical Instrument, v. 2.
Bow, Violin, xiv. 2.
Bow, Origin of the, viii. 1—5.
Bugle, xii. 5.
Ching, Chinese Instrument. Miscellany, i. 8.
Citharidrria, i. 2.
Crown. Miscellany, xxv. 2.
Fifes, xi. 6, 7.
Flagoelet, English, xi. 8.
Flute, Common English, xi. 1.
German, xi. 2.
Improved, xi. 3.
Flutes, Double, of the Ancients, ix.
Gelaia, ix.
Gong, xi. 9.
Gondoc Rebec, with three strings, ix.
Guitar, Spanish, xv. 3.
Harp, Æolian. Miscellany, xxv. 1.
Bell, x. 4.
of Brie Boromb, x. 1, 2.
Grecian, ii. 1.
Silver Prize, x. 3.
Single, vii.
Ancient Triple, vii.
Modern Triple, vii.
Welsh, vii.
Hautboy, xi. 4, 5.
Horn, Hunting, xii. 1, 2.
French, xii. 4.
Hunting, of Siberia, ix.
Indian Musical Instruments, v. 1, 2.
King, Chinese Instrument, Miscellany, i. 9.
Kit, xiv. 5.
Lutuus, Double, i. 3.
Ancient Metalline, i. 8.
Lute, xv. 4.
Arch, xiii. 1.
Lyre, Ancient, ii. 5, 6. iv. 8. 10.

MUSICAL INSTRUMENTS.

Lyre, Egyptian, iii. 6—10.
Etruscan, with 7 strings, iv. 7.
held by Terpsichore, iv. 3.
Mandola, xiii. 3.
Mandoline, xiii. 2.
Mandore, xv. 2.
Mask of Hercules, ii. 2.
Thais, ii. 3.
Masques, Antique Theatrical, i. 6, 7.
Musicians, Group of, performing an Epithalamium, iii.
1—3.
Pandean Minstrels, representation of, vi.
Psaltery, iv. 4.
Rojak, ix.
Rok, Hunting Horn of Siberia, ix.
Russian Musical Instrument, ix.
Sackbut, or Trombone, xii. 6.
Serpent, xii. 3.
Sordin, or Mute, for a Violin, xiv. 3.
Syrix, Pan playing upon, i. 4.
Sytrum, Egyptian, iv. 9.
Tabour and Pipe, xi. 10. 11.
Teftudo, Abydus, iv. 6.
or Lyre of Amphi, iv. 1, 2.
Tibes Pares, i. 5.
Cupid playing upon, iii. 5.
Timbrel, i. 1.
Trigonom, or Triangular Harp, iv. 5.
Trombone, xii. 6.
Tuba, or long Trumpet of the Jews, iii. 4.
Viol d'Amour, iv. 1.
Viol de Gamba, xiv. 6.
Violin, xiv. 1, 2.
Violoncello, xiv. 4.
Violino Piccola, xiv. 5.

NAVAL ARCHITECTURE.

Bolts, Hill's Machine for drawing, xiv.
Draught of a 74 Gun Ship, i.
East Indianman, xii.
Forecastle, Plan of, vi.
Frame of a 74 Gun Ship, ii. iii.
Frigate of 38 Guns, xi.
Gun Deck, Plan of, v.
Orlop, Plan of, v.
Plans of a 74 Gun Ship, v.—x.
Profile of a 74 Gun Ship, iv.
Quarter-deck, Plan of, vi.
Royal Sovereign Yacht, xiii.
Upper Deck, Plan of, vi.
Whole Moulding, xiv.

NAVIGATION.

Afrolobe, Astronomical Instruments, i. 1.
Backstaff, Astronomical Instruments, i. 2.
Forestaff, Astronomical Instruments, i. 3.
Meridian, i. 1.
Meridional Parts, i. (i. & ii.) 2, 3.
Nocturnal, Astronomical Instruments, i. 6.
Quadrant, Hadley's, ii. (i. & ii.) 1—3.
Sinical, ii. (i. & ii.) 4.
Rhumb Line, ii. (i. & ii.) 5, 6.
Rudder, ii. & iv. 1—4.

5 E
INDEX OF THE PLATES.

NAVIGATION.

Sailing, Great Circle, ii. 26—34.
Current, iii. 3—6.
Mercator's, ii. 24, 25.
Parallel, ii. 20—23.
Plain, ii. & iv. 5—18. ii. 19.
Traverse, iii. 1, 2.
Convoy, NAVAL TACTICS, iii. 1—3.
Tide, i. 4—8.
Trigonometry, (Plate iii.) iii. 1—5.
Variation, ii. (i. & ii.) 7—9.

OIL MILL.

Plan and Elevation, by Smeaton

NAVAL TACTICS.

(See Navigation, Plate iii.)

NOTATION.

Ancient Arithmetical Characters
(See Miscellany, i. 7.)

OPTICS.

Aberration, i. 1.
Altitude, iv. 11.
Angle, i. 2—4.
Burrough's Machine, i. 5.
Burning Lens, Parker's, ii. 1—3.
Camera Obscura, iii. 1—7.
Catoptric Cilium, iv. 1, 2.
Dioptrics, iv. 2—4.
Dispersion of Light, iv. 5—7.
Eyes, v. 2.
Focus, iv. 8.
Virtual, v. 1.
Heliostata, vi. 1.
Hones, Bed of, vi. 2.
Horopter, vi. 3.
Incidence, xv. 1.
Inclination, xv. 1.
Lens, vi. 5—11. vii. 1—12. viii 1—12.
Light, ix. 1—9.
Looking-glass, iv. 9.
Magic Lantern, x. 1—5.
Magnitude, Apparent, x. 4.
Micrometer, x. 5—11.
Herrich's Lamp, xi. 5, 6.
Mafiglyne's, xi. 1.
Troughton's, xi. 2—4.
Microscope, xii. 1—12.
Adams's Compound, xiv. 1—7.
Culpepper's, xiii. 2.
Marshall's, xiii. 1.
B. Martin's, xiv. 5—11.
Solar, xiii. 6—8.
Improved, xvi. 1—7.
Mirror, xv. 2—18.
Mufé Volantes, xv. 18.
Objet Glafs, centering, xv. 19, 20.
Opera Glafs, xv. 21.
Optical Inequality, xv. 22.
Optometer, xvii. 1—8.

OPTICS.

Parhelion, xv. 23, 24.
Pencil of Rays, xvii. 10.
Place, Optic, xvii. 9.
Polemroscope, xvii. 12.
Polyhedron, xvii. 11, 12.
Polyoptrum, xvii. 13.
Rainbow, xvii. 1—9.
Reflection, xvii. 14.
Reflexibility, xvii. 15.
Refraction, vi. 4.
of Light, xviii. 10—24.
Refraigibility of Light, xix. 1—13.
Shadow, iv. 10—13.
Visible, iv. 14—16.
Vilson, iv. 17.

ORGAN.

Church Organ, interior Profile of, ii.
Keys, Pipes, &c. i.
Organ, made by Flight and Robson, iii. iv.

PAINTING.

Apollo Belvidere, i.
Face, Human, diversities of, ii. iii.
African, iii.
American, iii.
Asiatic, iii.
European, iii.

PANORAMA.

Plates i. ii.

PAPER-MILL.

Plates i. ii.

PERSPECTIVE.

Anamorphosis, i. 1—8.
Distance of a Vanishing Line, i. 9.
Line, Horizontal, i. 11.
Perspective, Theory of, i—xii.
Point of a Vanishing Line, i. 10.

PISÉ BUILDINGS.

(See Agriculture, Plate XXXIII.)

PLANETARY MACHINES.

Cometarium, i.
Dial for the Equation of the Sun's Center, ix. 1.
Sun's Declination, ix. 2.
of mean High Tides, ix. 8.
for the Moon's Equation of the Center, ix. 4.
Heliocentric Latitude, ix. 5.
Horizontal Diameter and Parallax, ix. 7.
Parallax, ix. 6.
Reduction of the Ecliptic to the Equator, ix. 3.
Dials, graduated for Sweing Planetary Phenomena, ix.
Equation Mechanism of a Planet's Orbit, by Huygens, iii. 1.

PLANETARY MACHINES.

Cometarium, i.
Dial for the Equation of the Sun's Center, ix. 1.
Sun's Declination, ix. 2.
of mean High Tides, ix. 8.
for the Moon's Equation of the Center, ix. 4.
Heliocentric Latitude, ix. 5.
Horizontal Diameter and Parallax, ix. 7.
Parallax, ix. 6.
Reduction of the Ecliptic to the Equator, ix. 3.
Dials, graduated for Sweing Planetary Phenomena, ix.
Equation Mechanism of a Planet's Orbit, by Huygens, iii. 1.
### PLANETARY MACHINES.

- Equation Mechanism of a Planet’s Orbit, by Priestley, iii. 2.
- Jovialbe, by Janviers, xii. 5.
- Orrery for equated Motions, v.
- Planetarium, Common, x. 1.
- Satellite, by Pearson, xii. 2–4.

### PLATING MANUFACTURE.

- Bramah’s Planing Machine, i. ii.

### PNEUMATICS.

- Æolipile, i. 1.
- Ærolation, i. 2–4. 9–12. ii. 5–8.
- Air Gun, i. 14–23.
- Air Pump, Cuthbertson’s, viii. No. 2. 58–66.
- Anemometer, viii. No. 2. 69.
- Arzometer, viii. No. 2. 70, 71.
- Atmosphere, viii. No. 2. 72.
- Bacchus, viii. No. 2. 73.
- Barometer, ix. xii.
- Caffewell’s, x. 88.
- Chamber, ix. 84.
- Common, ix. 76.
- Des Cartes’, ix. 77.
- Diagonal, ix. 81.
- Hamilton’s, xi. 96, 97.
- Hooke’s, ix. 79.
- Horizontal, ix. 80.
- Huygens’s, ix. 78.
- Keith’s, xi. 91, 92.
- De Luc’s, xi. 94.
- Marine, x. 86, 87.
- Pendulum, ix. 83.
- Rowning’s, x. 89, 90.
- Wheel, ix. 82.
- Machine for enlarging the Scale of, xi. 91.

### PRESS.

- Bellows, xiii. 107–117.
- Condeners, xiv. 1, 2.
- Condening Engine, xiv. 3.
- Gage of a Condenier, xiv. 5–7.
- Pear, xiv. 4.
- Bouguer’s Wind, xv. 12.
- Lind’s ditto, xv. 9.
- Martin’s ditto, xv. 11.
- Freezing, xiv. 4–7.

### PNEUMATICS.

- Freezing Apparatus, xiv. 8.
- Pyrmont Water, Apparatus for making, xv. 1–7.
- Thermometer, Apparatus for adjusting the fixed Points of, xvi. 6–10.
- Amonton’s, xvi. 4.
- Bent, xvi. 2.
- Bernouilli’s, xvi. 3.
- Cavendish’s, xvi. 11–13.
- Drobbe’s, xvi. 1.
- Floretine, xvi. 5.
- Kewley’s, xv. 14.
- Leilie’s, xv. 13.
- Rutherford’s, xvi. 16.
- Six’s, xvi. 14, 15.

### PORTER BREWERY.

- Building and Machinery.

### POTTERY.

- Furnace, &c.

### PRESS.

- Bramah’s Hydrostatic Press

### PRINTING.

- Bacon and Donkin’s Printing Machine, iii.
- Bramah’s Bank-Note Printing Machine, ii.
- Common Printing Presses, iv. 1.
- Composing Stick, iv. 2.
- Stanhope, or Iron Press, i.

### PROJECTION.

- Plates i.–x.

### PROPORTIONAL COMPASSES.

### PYROTECHNY.

### RIGGING.

- (See Ships, Plates ii.–v.)

### SCENOGRAPHY.

### SCULPTURE.

- Apollo Belvidere, iii.
- Cupid of Praxiteles, i.
- Cupid and Psyche, Statue of, i. ii.
- Dirc, ii.
- Durga lying Mahishasura, iv.
- Hercules of Dédalus, i.
- Farnefe, ii.
- Jupiter Olympus, i.
- Laocoon, iii.
- Minerva of the Acropolis, i.
- Dipæmus and Scyllis, i.
- Patera, Etruscan, iv.

5 E 2
INDEX OF THE PLATES.

TRIGONOMETRY.

Cofines, i. 12.
Cotangents, i. 15.
Gunter’s Scale, i. 1.
Secant, i. 14, 16, 17.
Sector, i. 5—7.
Sines, i. 4, 10, 11, 18—22.
Spherical Angle, ii. 2.
    Triangle, ii. 3—8.
Spheres, ii. 9—12.
Tangent, i. 14, ii. 13.
Trigonometry, ii. 14—22.
(For the figures referred to as on TRIGONOMETRY, Plate III. see Navigation, Plate III.)

VERED SINES, i. 13.

TURING.

Lathe, &c.

VOLTAISM.

BATTERY, &c.

WATER PRESSURE ENGINE, by Smeaton.

WATER WHEELS.

Bread Wheel, Improved, i. 7.
    at the Royal Armory Mills, ii. 4.
    with two Shuttles, ii. 3.
Buchanan’s Wheel and Pentrogh, i. 4, 5.
Burns’s Overhot Wheel, ii. 5.
Chain of Buckets, i. 6.
Greasig Machine, i. 8.
Nouaille’s Overhot Wheel, i. 3, 4.
Smeaton’s Bread Wheel, i. 1.
    Pentrogh, i. 2.
    Water, Method of laying on, ii. 9.

WATER WORKS.

Boulton’s Machine for raising Water, i. 2, 3.
Chremnitz Fountain, i. 14.
Greave’s Bucket Machine, i. 13.
Hydraulic Ram, i. 4—6.
Machine for raising Water by the lateral communication of a Stream, i. 10.
    Smeaton’s, for raising Water at London Bridge ii. 1, 2.
    Momentum Pump, i. 1.

WATER WORKS.

Siphon Machine, i. 8.
    Goodwin’s, i. 10.
Spiral Pump, i. 11.
Water Bellows, i. 15.
Whitehurst’s Machine for raising Water, i. 7.
Zurich Machine, i. 11.

WEAVING.

Austin’s Engine Loom, i.
Duff’s Draw Boy, &c. ii.

WINDMILL.

Common Vertical Windmill, ii. 1.
Dutch Windmill, ii. 4.
Hooper’s Horizontal Windmill, i. 1, 2.
Polt Windmill, ii. 3.
Smock Mill, i. 5—5. ii. 2.

WINDING ENGINE.

Smeaton’s Design for a Water Gin for drawing Coals from Pits.

WIRE MILL.

Machinery for Wire-Drawing.

WOOLLEN MANUFACTURE.

Carding Engine, iv.
    Gig Mill, v.
Shearing Machine, iii.
Spinning Jenny, ii.
Stubbing Machine, i.

WORSTED MANUFACTURE.

Breaking Frame, i. 5.
    Combs, i. 1.
Cartwright’s Combing Machine, ii. 1—3.
Gilpin’s Combing Machine, i. 4.
Roving Frame, i. 6.
    Spinning Frame, i. 7.
    Stove, i. 3.

WRITING BY CIPHER.

Characters and Examples, i.—iii.

* *. As only a few of the Plates relating to Natural History are referred to in the articles of the Cyclopedia which they are intended to illustrate, it has been deemed unnecessary to incorporate the subjects of them in the Index. The systematic arrangement and minute analysis of them in the annexed Catalogue will, it is conceived, be found amply sufficient for every purpose of reference and consultatation.

THE END.
DIRECTIONS TO THE BINDER.

In making up the Plates of the Cyclopædia into volumes, the first business of the binder must be to arrange the Plates in their several classes, as Agriculture, Algebra, Analysis, &c., and in the order in which they are numbered. He must, however, observe, that some of the Plates are wrongly numbered: which those are, and to what place in the series they must be transferred, he will easily learn from the Catalogue. In some instances he will find two or three Plates numbered alike; and, in others, Plates on which the number has been omitted: in these cases again, he will readily ascertain, from an inspection of the Catalogue, where, and in what order, they are to be placed. In every case, the Catalogue must be his guide, and to this he must rigidly adhere in the arrangement and disposition of the whole of the engravings.

ERRATUM.

The following Plate has been accidentally omitted, both in the Catalogue and in the Index. The Binder is requested to place it immediately after the other Plate of Architecture numbered XV.

ARCHITECTURE, Plate XV.
Doric Order.

Fig. 1. From the temple of Corinth
2; 3; a Hypothehal Temple at Paestum
4; the Temple of Minerva at Sunium
5. at Syracuse
